This example shows how to price European put options on bonds using the Black model. Consider a European put option on a bond maturing in 10 years. The underlying bond has a clean price of \$122.82, a face value of \$100, and pays 8% semiannual coupons. Also, assume that the annualized volatility of the forward bond yield is 20%. Furthermore, suppose the option expires in 2.25 years and has a strike price of \$115, and that the annualized continuously compounded risk free zero (spot) curve is flat at 5%. For a hypothetical settlement date of March 15, 2004, the following code illustrates the use of Black's model to duplicate the put prices in Example 22.2 of the Hull reference. In particular, it illustrates how to convert a broker's yield volatility to a price volatility suitable for Black's model.

```
% Specify the option information.
Settle      = '15-Mar-2004';
Expiry      = '15-Jun-2006'; % 2.25 years from settlement
Strike      = 115;
YieldSigma  = 0.2;
Convention  = [0; 1];

% Specify the interest-rate environment. Since the
% zero curve is flat, interpolation into the curve always returns
% 0.05. Thus, the following curve is not unique to the solution.
ZeroData    = [datenum('15-Jun-2004') 0.05 -1;
               datenum('15-Dec-2004') 0.05 -1;
               datenum(Expiry)         0.05 -1];

% Specify the bond information.
CleanPrice  = 122.82;
CouponRate  = 0.08;
Maturity    = '15-Mar-2014'; % 10 years from settlement
Face        = 100;
BondData    = [CleanPrice CouponRate datenum(Maturity) Face];
Period      = 2; % semiannual coupons
Basis       = 1; % 30/360 day-count basis

% Convert a broker's yield volatility quote to a price volatility
% required by Black's model. To duplicate Example 22.2 in Hull,
% first compute the periodic (semiannual) yield to maturity from
% the clean bond price.
Yield = bndyield(CleanPrice, CouponRate, Settle, Maturity,...
                Period, Basis);

% Compute the duration of the bond at option expiration. Most
% fixed-income sensitivity analyses use the modified duration
```

```

% statistic to examine the impact of small changes in periodic
% yields on bond prices. However, Hull's example operates in
% continuous time (annualized instantaneous volatilities and
% continuously compounded zero yields for discounting coupons).
% To duplicate Hull's results, use the second output of BNDDURY,
% the Macaulay duration.
[Modified, Macaulay] = bnddury(Yield, CouponRate, Expiry,...
Maturity, Period, Basis);

% Convert the yield-to-maturity from a periodic to a
% continuous yield.
Yield = Period .* log(1 + Yield./Period);

% Convert the yield volatility to a price volatility via
% Hull's Equation 22.6 (page 514).
PriceSigma = Macaulay .* Yield .* YieldSigma;

% Finally, call Black's model.
PutPrices = bkput(Strike, ZeroData, PriceSigma, BondData,...
Settle, Expiry, Period, Basis, [], [], Convention)

PutPrices = 2x1

    1.7838
    2.4071

```

When the strike price is the dirty price (Convention = 0), the call option value is \$1.78. When the strike price is the clean price (Convention = 1), the call option value is \$2.41.

## bndfutimprepo

Implied repo rates for bond future given price

### Syntax

```
ImpRepo = bndfutimprepo(Price,FutSettle,FutPrice,Delivery,ConvFactor,
CouponRate,Maturity)
ImpRepo = bndfutimprepo( ____,Name,Value)
```

### Description

`ImpRepo = bndfutimprepo(Price,FutSettle,FutPrice,Delivery,ConvFactor,CouponRate,Maturity)` computes the implied repo rate for a bond future given the price of a bond, the bond properties, the price of the bond future, and the bond conversion factor. The default behavior is that the coupon reinvestment rate matches the repo rate. However, you can specify a separate reinvestment rate using optional inputs.

`ImpRepo = bndfutimprepo( ____,Name,Value)` specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Repo Rate For a Bond Future

This example shows how to compute the repo rate for a bond future using the following data.

```
bndfutimprepo(129,98,'9/21/2000','12/29/2000',1.3136,.0875,'8/15/2020')
ans = 0.0584
```

### Input Arguments

#### Price — Bond prices

vector

Bond prices, specified as an `numBonds-by-1` vector in decimals.

Data Types: `double`

#### FutPrice — Future prices

vector

Future prices, specified as an `numBonds-by-1` vector.

Data Types: `double` | `cell`

#### FutSettle — Future settlement dates

vector

Future settlement dates, specified as an numBonds-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

### **Delivery — Future delivery dates**

vector

Future delivery dates, specified as an numBonds-by-1 vector.

Data Types: double | cell

### **ConvFactor — Bond conversion factors**

vector

Bond conversion factors, specified as an numBonds-by-1 vector. For more information, see `convfactor`.

Data Types: double

### **CouponRate — Coupon rates**

vector

Coupon rates, specified as an numBonds-by-1 vector of numeric decimals.

Data Types: double

### **Maturity — Maturity dates**

vector

Maturity dates, specified as an numBonds-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `ImpRepo =`

```
bndfutimprepo(Price, FutPrice, FutSettle, Delivery, ConvFactor, CouponRate, Maturity, 'Basis', 5, 'Face', 1000, 'Period', 4)
```

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: `double`

### **EndMonthRule — End-of-month rule flag for generating floorlet dates**

1 (in effect) (default) | scalar of nonnegative integer [0, 1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar with a nonnegative integer [0, 1].

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### **Face — Face value of the bond**

100 (default) | scalar numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar numeric. Face has no impact on key rate duration.

Data Types: `double`

### **FirstCouponDate — Irregular first coupon date**

if you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar date using a serial date number or a date character vector.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Data Types: `double` | `char`

### **IssueDate — Bond issue date**

if you do not specify an IssueDate, the cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar date using a serial date number or a date character vector.

Data Types: `double` | `char`

**LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar date using a serial date number or a date character vector.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Data Types: double | char

**Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a scalar integer. Values for Period are 0, 1, 2, 3, 4, 6, and 12.

Data Types: double

**ReinvestBasis — Day count basis for reinvestment rate**

identical to RepoBasis (default) | integer from 0 to 13

Day count basis for the reinvestment rate, specified as the comma-separated pair consisting of 'ReinvestBasis' and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-208.

Data Types: double

**ReinvestRate — Underlying bond annual coupon**

scalar decimal numeric

Underlying bond annual coupon, specified as the comma-separated pair consisting of 'ReinvestRate' and a scalar decimal numeric.

Data Types: double

**RepoBasis — Day count basis for repo rate**

2 (actual/360) (default) | integer from 0 to 13

Day count basis for repo rate, specified as the comma-separated pair consisting of 'RepoBasis' and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

**StartDate — Forward starting date of payments**

Settle date (default) | serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a scalar date using a serial date number or a date character vector.

Data Types: double

**Output Arguments****ImpRepo — Implied repo rate**

vector

Implied repo rate, or the repo rate that would produce the price input, returned as numBonds-by-1 vector.

## bndfutprice

Price bond future given repo rates

### Syntax

```
[FutPrice,AccrInt] = bndfutprice(RepoRatePrice,FutSettle,Delivery,ConvFactor,
CouponRate,Maturity)
[FutPrice,AccrInt] = bndfutprice( ____,Name,Value)
```

### Description

[FutPrice,AccrInt] = bndfutprice(RepoRatePrice,FutSettle,Delivery,ConvFactor, CouponRate,Maturity) computes the price of a bond futures contract for one or more bonds given a repo rate, and bond properties, including the bond conversion factor. The default behavior is that the coupon reinvestment rate matches the repo rate. However, you can specify a separate reinvestment rate using optional arguments.

[FutPrice,AccrInt] = bndfutprice( \_\_\_\_,Name,Value) specifies options using one or more optional name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Price For a Bond Future

This example shows how to compute the price for a bond future using the following data.

```
bndfutprice(.064, 129, '9/21/2000', '12/29/2000', 1.3136, .0875, '8/15/2020')
ans = 98.1516
```

### Input Arguments

#### RepoRate — Repo rates

vector

Repo rates, specified as an numBonds-by-1 vector in decimals.

Data Types: double

#### Price — Bond prices

vector

Bond prices, specified as an numBonds-by-1 vector in decimals.

Data Types: double

#### FutSettle — Future settlement date

scalar

Future settlement date, specified as scalar date using a serial date number or a date character vectors.

Data Types: `double` | `char`

### **Delivery — Future delivery dates**

vector

Future delivery dates, specified as an `numBonds-by-1` vector.

Data Types: `double` | `cell`

### **ConvFactor — Bond conversion factors**

vector

Bond conversion factors, specified as an `numBonds-by-1` vector. For more information, see `convfactor`.

Data Types: `double`

### **CouponRate — Coupon rates**

vector

Coupon rates, specified as an `numBonds-by-1` vector of numeric decimals.

Data Types: `double`

### **Maturity — Maturity dates**

vector

Maturity dates, specified as an `numBonds-by-1` vector of serial date numbers or a cell array of character vectors.

Data Types: `double` | `cell`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[FutPrice, AccrInt] =`

```
bndfutprice(RepoRate, Price, FutSettle, Delivery, ConvFactor, CouponRate, Maturity,
' Basis', 5, 'Face', 1000, 'Period', 4)
```

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)

- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: `double`

### **EndMonthRule — End-of-month rule flag for generating floorlet dates**

1 (in effect) (default) | scalar of nonnegative integer [0, 1]

End-of-month rule flag, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar with a nonnegative integer [0, 1].

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

if you do not specify an IssueDate, the cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar date using a serial date number or a date character vector.

Data Types: `double` | `char`

### **Face — Face value of the bond**

100 (default) | scalar numeric

Face value of the bond, specified as the comma-separated pair consisting of 'Face' and a scalar numeric. Face has no impact on key rate duration.

Data Types: `double`

### **FirstCouponDate — Irregular first coupon date**

if you do not specify a FirstCouponDate, the cash flow payment dates are determined from other inputs (default) | serial date number | date character vector

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar date using a serial date number or a date character vector.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.

Data Types: `double` | `char`

**LastCouponDate — Irregular last coupon date**

serial date number | date character vector

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar date using a serial date number or a date character vector.

In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date.

Data Types: double | char

**Period — Coupons per year**

2 per year (default) | vector

Coupons per year, specified as the comma-separated pair consisting of 'Period' and a scalar integer. Values for Period are 0, 1, 2, 3, 4, 6, and 12.

Data Types: double

**ReinvestBasis — Day count basis for reinvestment rate**

identical to RepoBasis (default) | integer from 0 to 13

Day count basis for the reinvestment rate, specified as the comma-separated pair consisting of 'ReinvestBasis' and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see "Basis" on page 2-208.

Data Types: double

**ReinvestRate — Underlying bond annual coupon**

scalar decimal numeric

Underlying bond annual coupon, specified as the comma-separated pair consisting of 'ReinvestRate' and a scalar decimal numeric.

Data Types: double

**RepoBasis — Day count basis for repo rate**

2 (actual/360) (default) | integer from 0 to 13

Day count basis for repo rate, specified as the comma-separated pair consisting of 'RepoBasis' and a scalar integer from 0 to 13.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

**StartDate — Forward starting date of payments**

Settle date (default) | serial date number | date character vector

Forward starting date of payments (the date from which a bond cash flow is considered), specified as the comma-separated pair consisting of 'StartDate' and a scalar date using a serial date number or a date character vector.

Data Types: double

**Output Arguments****FutPrice — Quoted futures price, per \$100 notional**

vector

Quoted futures price, per \$100 notional, returned as numBonds-by-1 vector.

**AccrInt — Accrued interest due at delivery date, per \$100 notional**

vector

Accrued interest due at delivery date, per \$100 notional, returned as numBonds-by-1 vector.

## **Introduced in R2009b**

## bootstrap

Bootstrap interest-rate curve from market data

### Class

@IRDataCurve on page A-6

### Syntax

```
Dcurve = IRDataCurve.bootstrap(Type,Settle,InstrumentTypes,Instruments)
```

```
Dcurve = IRDataCurve.bootstrap(Type,Settle,InstrumentTypes,Instruments,'Parameter1',Value1,'Parameter2',Value2,...)
```

### Arguments

Type	Type of interest-rate curve. Type refers to the type of data in the curve that is bootstrapped from the market instruments. Acceptable values are: <code>discount</code> , <code>forward</code> , or <code>zero</code> .  When using the <code>bootstrap</code> method, the choice of the <code>Type</code> parameter can impact the curve construction because it will affect the type of data that will be interpolated on (that is, forward rates, zero rates or discount factors) during the bootstrapping process. So curves that are bootstrapped using different <code>Type</code> parameters undergo different bootstrapping algorithms with different interpolation methods, and they can sometimes produce different results when using the “get” methods (for example, <code>getForwardRates</code> ).
Settle	Scalar or column vector of settlement dates.
InstrumentTypes	N-by-1 cell array (where N is the number of instruments) indicating what kind of instrument is in the <code>Instruments</code> matrix. Acceptable values are <code>deposit</code> , <code>futures</code> , <code>swap</code> , <code>bond</code> , and <code>fra</code> .

Instruments	<p>N-by-3 data matrix for Instruments where the first column is <code>Settle</code> date, the second column is <code>Maturity</code>, and the third column is the market quote (dates must be MATLAB date numbers). The market quote represents the following for each instrument:</p> <ul style="list-style-type: none"> <li>• <code>deposit</code>: rate</li> <li>• <code>futures</code>: price (e.g., 9628.54)</li> <li>• <code>swap</code>: rate</li> <li>• <code>bond</code>: clean price</li> <li>• <code>fra</code>: forward rate</li> </ul> <hr/> <p><b>Note</b> Instruments input for <code>fra</code> and for <code>futures</code> are different. Specifically, the forward rate underlying a <code>fra</code> starts on the start date (column 1 of Instruments) and ends on the end date (column 2 of Instruments). While the forward rate underlying a <code>futures</code> contract starts on the maturity date of the <code>futures</code> contract and ends on a date <math>n</math> months after the <code>futures</code> maturity, where <math>n</math> is the periodicity of the <code>futures</code> contract.</p>
Compounding	<p>(Optional) Scalar that sets the compounding frequency per year for an <code>IRDataCurve</code> object:</p> <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 0 = Simple interest (no compounding) for “zero” and “discount” curve types only, not supported for “forward” curves</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
InterpMethod	<p>(Optional) Values are:</p> <ul style="list-style-type: none"> <li>• 'linear' — Linear interpolation (default).</li> <li>• 'constant' — Piecewise constant interpolation.</li> <li>• 'pchip' — Piecewise cubic Hermite interpolation.</li> <li>• 'spline' — Cubic spline interpolation.</li> </ul>
IRBootstrapOptionsObj	<p>(Optional) An IRBootstrapOptions object.</p>
DiscountCurve	<p>(Optional) RateSpec for a curve used to discount the cash flows.</p>

## Instrument Parameters

For each bond Instrument, you can specify the following additional instrument parameters as parameter/value pairs. For example, InstrumentBasis distinguishes a bond instrument's Basis value from the curve's Basis value. For instruments of type deposit, futures, or swap the Basis and Compounding values must be identical for each instance of the instrument.

InstrumentCouponRate	<p>(Optional) Decimal number indicating the annual percentage rate used to determine the coupons payable on an instrument.</p>
InstrumentPeriod	<p>(Optional) Coupons per year of the instrument. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.</p>

InstrumentBasis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that an instrument's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that an instrument's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** parameter/value pairs, you can specify simple interest for an **Instrument** by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for an **Instrument**, the following default values are used:

- deposit instrument uses InstrumentBasis as 2 (act/360) and InstrumentPeriod is 0 (simple interest).
- futures instrument uses InstrumentBasis as 2 (act/360) and InstrumentPeriod is 4 (quarterly).
- swap instrument uses InstrumentBasis as 2 (act/360) and InstrumentPeriod is 2.
- bond instrument uses InstrumentBasis as 0 (act/act) and InstrumentPeriod is 2.
- FRA instrument uses InstrumentBasis as 2 (act/360) and InstrumentPeriod is 4 (quarterly).

## Description

Dcurve = IRDataCurve.bootstrap(Type, Settle, InstrumentTypes, Instruments, 'Parameter1', Value1, 'Parameter2', Value2, ...) bootstraps an interest-rate curve from market data. The dates of the bootstrapped curve correspond to the maturity dates of the input instruments. You must enter the optional arguments for Basis, Compounding, Interpmethod, IRBootstrapOptionsObj, and DiscountCurve as parameter/value pairs.

## Examples

### Use the bootstrap Method to Create an IRDataCurve Object

In this bootstrapping example, InstrumentTypes, Instruments, and a Settle date are defined:

```
InstrumentTypes = {'Deposit';'Deposit';...
'Futures';'Futures';'Futures';'Futures';'Futures';'Futures';...
'Swap';'Swap';'Swap';'Swap'};

Instruments = [datenum('08/10/2007'),datenum('09/17/2007'),.0532000; ...
datenum('08/10/2007'),datenum('11/17/2007'),.0535866; ...
datenum('08/08/2007'),datenum('19-Dec-2007'),9485; ...
datenum('08/08/2007'),datenum('19-Mar-2008'),9502; ...
datenum('08/08/2007'),datenum('18-Jun-2008'),9509.5; ...
datenum('08/08/2007'),datenum('17-Sep-2008'),9509; ...
datenum('08/08/2007'),datenum('17-Dec-2008'),9505.5; ...
datenum('08/08/2007'),datenum('18-Mar-2009'),9501; ...
datenum('08/08/2007'),datenum('08/08/2014'),.0530; ...
datenum('08/08/2007'),datenum('08/08/2019'),.0551; ...
datenum('08/08/2007'),datenum('08/08/2027'),.0565; ...
datenum('08/08/2007'),datenum('08/08/2037'),.0566];

CurveSettle = datenum('08/10/2007');
```

Use the bootstrap method to create an IRDataCurve object.

```
bootModel = IRDataCurve.bootstrap('Forward', CurveSettle, ...
InstrumentTypes, Instruments,'InterpMethod','pchip');
```

To create the plot for the bootstrapped market data:

```
PlottingDates = (datenum('08/11/2007'):30:CurveSettle+365*25)';
plot(PlottingDates, getParYields(bootModel, PlottingDates),'r')
ylim([0 .06])
datetick
```

### Use the bootstrap Method to Create an IRDataCurve Object That Includes Bonds

In this bootstrapping example, InstrumentTypes, Instruments, and a Settle date are defined:

```
CurveSettle = datenum('8-Mar-2010');
```

```
InstrumentTypes = {'Deposit';'Deposit';'Deposit';'Deposit';...  
                  'Futures';'Futures';'Futures';'Futures';'Swap';'Swap';'Bond';'Bond'};
```

```
Instruments = [datenum('8-Mar-2010'),datenum('8-Apr-2010'),.003; ...  
              datenum('8-Mar-2010'),datenum('8-Jun-2010'),.005; ...  
              datenum('8-Mar-2010'),datenum('8-Sep-2010'),.007; ...  
              datenum('8-Mar-2010'),datenum('8-Mar-2011'),.009; ...  
              datenum('8-Mar-2010'),datenum('18-Jun-2011'),9840; ...  
              datenum('8-Mar-2010'),datenum('17-Sep-2011'),9820; ...  
              datenum('8-Mar-2010'),datenum('17-Dec-2011'),9810; ...  
              datenum('8-Mar-2010'),datenum('18-Mar-2012'),9800; ...  
              datenum('8-Mar-2010'),datenum('8-Mar-2015'),.025; ...  
              datenum('8-Mar-2010'),datenum('8-Mar-2020'),.035; ...  
              datenum('8-Mar-2010'),datenum('8-Mar-2030'),99; ...  
              datenum('8-Mar-2010'),datenum('8-Mar-2040'),101];
```

When bonds are used, InstrumentCouponRate must be specified:

```
InstrumentCouponRate = [zeros(10,1);.045;.05];
```

Note, for parameters that are only applicable to bonds (`InstrumentFirstCouponDate`, `InstrumentLastCouponDate`, `InstrumentIssueDate`, `InstrumentFace`) the entries for non-bond instruments (deposits and futures) are ignored.

Use the `bootstrap` method to create an `IRDataCurve` object.

```
bootModel = IRDataCurve.bootstrap('Forward', CurveSettle, ...
InstrumentTypes, Instruments, 'InterpMethod', 'pchip', ...
'InstrumentCouponRate', InstrumentCouponRate);
```

Create the plot for the bootstrapped market data.

```
PlottingDates = datemnth(CurveSettle, 1:30*12);
plot(PlottingDates, getParYields(bootModel, PlottingDates), 'r')
ylim([0 .06])
datetick
```

### Use `IRBootstrapOptionsObj` with `bootstrap` for Negative Zero Interest-Rates

Use the `IRBootstrapOptionsObj` optional argument with the `bootstrap` method to allow for negative zero rates when solving for the swap zero points.

```
Settle = datenum('15-Mar-2015');
InstrumentTypes = {'Deposit'; 'Deposit'; 'Swap'; 'Swap'; 'Swap'; 'Swap'};
```

```

Instruments = [Settle,datenum('15-Jun-2015'),.001; ...
Settle,datenum('15-Dec-2015'),.0005; ...
Settle,datenum('15-Mar-2016'),-.001; ...
Settle,datenum('15-Mar-2017'),-0.0005; ...
Settle,datenum('15-Mar-2018'),.0017; ...
Settle,datenum('15-Mar-2020'),.0019];

irbo = IRBootstrapOptions('LowerBound',-1);

bootModel = IRDataCurve.bootstrap('zero', Settle, InstrumentTypes,...
    Instruments,'IRBootstrapOptions',irbo);

bootModel.getZeroRates(datemnth(Settle,1:60))

ans = 60x1

    0.0012
    0.0011
    0.0010
    0.0009
    0.0008
    0.0008
    0.0007
    0.0006
    0.0005
   -0.0000
    :

```

Note that optional argument for `LowerBound` is set to `-1` for negative zero rates when solving the swap zero points.

## Introduced in R2008b

## **cdsoptprice**

Price payer and receiver credit default swap options

### **Syntax**

```
[Payer,Receiver] =  
cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,Strike,Spread  
Vol)  
[Payer,Receiver] =  
cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,Strike,Spread  
Vol,Name,Value)
```

### **Description**

[Payer,Receiver] =  
cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,Strike,Spread  
Vol) computes the price of payer and receiver credit default swap options.

[Payer,Receiver] =  
cdsoptprice(ZeroData,ProbData,Settle,OptionMaturity,CDSMaturity,Strike,Spread  
Vol,Name,Value) computes the price of payer and receiver credit default swap options with  
additional options specified by one or more Name, Value pair arguments.

### **Input Arguments**

#### **ZeroData**

M-by-2 vector of dates and zero rates or an IRDataCurve object of zero rates. For more information on an IRDataCurve object, see “Creating an IRDataCurve Object” on page 9-6.

#### **ProbData**

P-by-2 array of dates and default probabilities.

#### **Settle**

Settlement date is a serial date number or date character vector. **Settle** must be earlier than the maturity date.

#### **OptionMaturity**

N-by-1 vector of serial date numbers or date character vectors containing the option maturity dates.

#### **CDSMaturity**

N-by-1 vector of serial date numbers or date character vectors containing the CDS maturity dates.

#### **Strike**

N-by-1 vector of option strikes expressed in basis points.

**SpreadVol**

N-by-1 vector of annualized credit spread volatilities expressed as a positive decimal number.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1, Value1, . . . , NameN, ValueN**.

---

**Note** Any optional input of size N-by-1 is also acceptable as an array of size 1-by-N, or as a single value applicable to all contracts. Single values are internally expanded to an array of size N-by-1.

---

**AdjustedForwardSpread**

N-by-1 vector of adjusted forward spreads (in basis points) to be used when pricing CDS index options.

**Default:** unadjusted forward spread normally used for single-name CDS options

**Basis**

N-by-1 vector of contract day-count basis:

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

**Default:** 2 (actual/360)

**BusDayConvention**

Business day conventions, specified by a character vector or N-by-1 cell array of character vectors of business day conventions. The selection for business day convention determines how non-business days are treated. Non-business days are defined as weekends plus any other date that businesses are not open (e.g. statutory holidays). Values are:

- **actual** — Non-business days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- **follow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day.
- **modifiedfollow** — Cash flows that fall on a non-business day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- **previous** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day.
- **modifiedprevious** — Cash flows that fall on a non-business day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

**Default:** actual

### **Knockout**

N-by-1 vector of Boolean flags. If the credit default swaptions is a knockout, the flag is `True`, otherwise it is `False`.

**Default:** False

### **PayAccruedPremium**

N-by-1 vector of Boolean flags. If accrued premiums are paid upon default, the flag is `True`, otherwise it is `False`.

**Default:** True

### **Period**

N-by-1 vector of the number of premiums per year of the CDS. Allowed values are 1, 2, 3, 4, 6, and 12.

**Default:** 4

### **RecoveryRate**

N-by-1 vector of recovery rates, expressed as a decimal from 0 to 1.

**Default:** 0.4

### **ZeroBasis**

Basis of the zero curve. Choices are identical to `Basis`.

**Default:** 0 (actual/actual)

### **ZeroCompounding**

Compounding frequency of the zero curve. Allowed values are:

- 1 — Annual compounding
- 2 — Semiannual compounding

- 3 — Compounding three times per year
- 4 — Quarterly compounding
- 6 — Bimonthly compounding
- 12 — Monthly compounding
- -1 — Continuous compounding

---

**Note** When `ZeroData` is an `IRDataCurve` object, the arguments `ZeroCompounding` and `ZeroBasis` are implicit in `ZeroData` and are redundant inside this function. In that case, specify these optional arguments when constructing the `IRDataCurve` object before calling this function.

---

**Default:** 2 (Semiannual compounding)

## Output Arguments

### Payer

N-by-1 vector of prices for payer swap options in `Basis` points.

### Receiver

N-by-1 vector of prices for receiver swap options in `Basis` points.

## Examples

### Obtain Payer and Receiver Values for a Credit Default Swap Option

Use `cdsoptprice` to generate Payer and Receiver values for a credit default swap option.

```
Settle = datenum('12-Jun-2012');
OptionMaturity = datenum('20-Sep-2012');
CDSMaturity = datenum('20-Sep-2017');
OptionStrike = 200;
SpreadVolatility = .4;

Zero_Time = [.5 1 2 3 4 5]';
Zero_Rate = [.5 .75 1.5 1.7 1.9 2.2]'/100;
Zero_Dates = daysadd(Settle,360*Zero_Time,1);
ZeroData = [Zero_Dates Zero_Rate];

Market_Time = [1 2 3 5 7 10]';
Market_Rate = [100 120 145 220 245 270]';
Market_Dates = daysadd(Settle,360*Market_Time,1);
MarketData = [Market_Dates Market_Rate];

ProbData = cdsbootstrap(ZeroData, MarketData, Settle);

[Payer,Receiver] = cdsoptprice(ZeroData, ProbData, Settle,...
OptionMaturity, CDSMaturity, OptionStrike, SpreadVolatility)

Payer = 223.5780
Receiver = 22.7460
```

## More About

### Credit Default Swap Option

A credit default swap (CDS) option, or credit default swaption, is a contract that provides the option holder with the right, but not the obligation, to enter into a credit default swap in the future.

CDS options can either be payer swaptions or receiver swaptions. In a payer swaption, the option holder has the right to enter into a CDS in which they are paying premiums and in a receiver swaption, the option holder is receiving premiums.

### Algorithms

The payer and receiver credit default swap options are computed using the Black's model as described in O'Kane [1]:

$$V_{Pay(Knockout)} = RPV01(t, t_E, T)(F\Phi(d_1) - K\Phi(d_2))$$

$$V_{Rec(Knockout)} = RPV01(t, t_E, T)(K\Phi(-d_2) - F\Phi(-d_1))$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \frac{1}{2}\sigma^2(t_E - t)}{\sigma\sqrt{t_E - t}}$$

$$d_2 = d_1 - \sigma\sqrt{t_E - t}$$

$$V_{Pay(Non - Knockout)} = V_{Pay(Knockout)} + FEP$$

$$V_{Pay(Non - Knockout)} = V_{Rec(Knockout)}$$

where

$RPV01$  is the risky present value of a basis point (see `cdsrpv01`).

$\Phi$  is the normal cumulative distribution function.

$\sigma$  is the spread volatility.

$t$  is the valuation date.

$t_E$  is the option expiry date.

$T$  is the CDS maturity date.

$F$  is the forward spread (from option expiry to CDS maturity).

$K$  is the strike spread.

$FEP$  is the front-end protection (from option initiation to option expiry).

## cmosched

Generate principal balance schedule for planned amortization class (PAC) or targeted amortization class (TAC) bond

### Syntax

```
[BalanceSchedule,InitialBalance] = cmosched(Principal,Coupon,OriginalTerm,
TermRemaining,PrepaySpeed)
[BalanceSchedule,InitialBalance] = cmosched( ____,TranchePrincipal)
```

### Description

[BalanceSchedule,InitialBalance] = cmosched(Principal,Coupon,OriginalTerm,TermRemaining,PrepaySpeed) generates a principal balance schedule for planned amortization class (PAC) bonds using two bands of Public Securities Association Prepayment Model (PSA) speeds or targeted amortization class (TAC) bonds using a single PSA speed.

[BalanceSchedule,InitialBalance] = cmosched( \_\_\_\_,TranchePrincipal) adds an optional argument for TranchePrincipal.

### Examples

#### Calculate the Principal Balance Schedule for a CMO PAC Bond

Define the mortgage pool under consideration and generate a principal balance schedule for planned amortization class (PAC) bonds using two bands of PSA speeds.

```
Principal = 128687000;
GrossRate = 0.0648;
OriginalTerm = 360;
TermRemaining = 325;
PrepaySpeed = [300 525];
PacPrincipal = 100250000;
```

```
[BalanceSchedule, InitialBalance] ...
= cmosched(Principal, GrossRate, OriginalTerm, TermRemaining, ...
PrepaySpeed, PacPrincipal)
```

```
BalanceSchedule = 1×325
107 ×
```

```
    9.7996    9.5780    9.3602    9.1461    8.9357    8.7289    8.5257    8.3259    8.1296    7.9
```

```
InitialBalance = 100250000
```

## Input Arguments

### **Principal** — Principal of the underlying mortgage pool

numeric

Principal of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: double

### **Coupon** — Coupon rate of the underlying mortgage pool

decimal

Coupon rate of the underlying mortgage pool, specified as a scalar decimal value.

Data Types: double

### **OriginalTerm** — Original term in months of the underlying mortgage pool

numeric

Original term in months of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: double

### **TermRemaining** — Terms remaining in months of the underlying mortgage pool

numeric

Terms remaining in months of the underlying mortgage pool, specified as a scalar numeric value.

Data Types: double

### **PrepaySpeed** — PSA speed

matrix numeric | scalar numeric

PSA speed is specified as follows:

- For planned amortization class (PAC) bonds, PSA speed is specified as a 1-by-2 matrix, where the first element is the lower band and the second element is the upper band.
- For targeted amortization class (TAC) bonds, the PSA speed is specified as a scalar numeric value

Data Types: double

### **TranchePrincipal** — Principal of the scheduled tranche

numeric

(Optional) Principal of the scheduled tranche, specified as a scalar numeric value. If `TranchePrincipal` is unspecified or empty `[]`, the principal of the scheduled tranche is assumed to be the sum of the payment schedule calculated from the PSA prepayment speeds.

Data Types: double

## Output Arguments

### **BalanceSchedule** — Number of terms remaining

matrix

Number of terms remaining, returned as a matrix of size 1-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. Each column contains the scheduled principal balance for the time period corresponding to the column number.

**InitialBalance — Initial principal balance of the scheduled tranche**

scalar

initial principal balance of the scheduled tranche, returned as a scalar numeric value.

**More About****Planned Amortization Class (PAC) Bond**

PAC bonds are a type of CMO bond and are designed to largely eliminate prepayment risk for investors.

They do this by transferring essentially all prepayment risk to other bonds in the CMO that are called support bonds.

**Targeted Amortization Class (TAC) Bond**

TAC bonds are analogous to PAC bonds, but are structured differently.

TAC bonds offer one-sided protection, shielding investors from high prepayment rates up to a specified PSA and do not protect against low prepayment rates.

**Introduced in R2012a**

## cmoschedcf

Generate cash flows for scheduled collateralized mortgage obligation (CMO) using PAC or TAC model

### Syntax

```
[Balance,Principal,Interest] = cmoschedcf(PrincipalPayments,TranchePrincipals
TrancheCoupons,BalanceSchedule)
```

### Description

[Balance,Principal,Interest] = cmoschedcf(PrincipalPayments,TranchePrincipals TrancheCoupons,BalanceSchedule) generates cash flows for a scheduled CMO, such as the planned amortization class (PAC) or targeted amortization class (TAC), given the underlying mortgage pool payments (or payments from another CMO tranche). The output **Balance**s, **Principal**, and **Interest** from this function can be used as input into **cmoseqcf** to further divide the PAC, TAC, or support dividing a tranche into sequential tranches.

### Examples

#### Calculate Cash Flows for Each PAC Tranche

Define the mortgage pool under consideration for CMO structuring using **mbscfamounts** or **mbspassthrough**. Calculate the underlying mortgage cash flow, define the PAC schedule and CMO tranches, and calculate the cash flows for each tranche.

```
MortgagePrincipal = 1000000; % underlying mortgage
Coupon = 0.12;
Terms = 6; % months

[PrincipalBalance, MonthlyPayments, SchedPrincipalPayments, ...
InterestPayments, Prepayments] = ...
mbspassthrough(MortgagePrincipal, Coupon, Terms, Terms, 0, []);
PrincipalPayments = SchedPrincipalPayments.' + Prepayments.'

PrincipalPayments = 1x6
105 ×

    1.6255    1.6417    1.6582    1.6747    1.6915    1.7084
```

Calculate the PAC schedule for CMO using **cmosched**.

```
PrepaySpeed = [100 300];
[BalanceSchedule, InitialBalance] ...
= cmosched(MortgagePrincipal, Coupon, Terms, Terms, PrepaySpeed, [])

BalanceSchedule = 1x6
105 ×

    8.3617    6.7180    5.0581    3.3828    1.6955    0
```

```
InitialBalance = 9.9886e+05
```

Define CMO tranches.

```
TranchePrincipals = ...
[InitialBalance; MortgagePrincipal-InitialBalance];
TrancheCoupons = [0.12; 0.12];
```

Calculate cash flows for each tranche.

```
[Balance, Principal, Interest] = ...
cmoschedcf(PrincipalPayments, TranchePrincipals, ...
TrancheCoupons, BalanceSchedule)
```

```
Balance = 2×6
105 ×
```

8.3631	6.7213	5.0632	3.3885	1.6970	0

## Input Arguments

### PrincipalPayments — Number of terms remaining for underlying principal payments

numeric matrix

Number of terms remaining for underlying principal payments, specified as a matrix of size 1-by-NUMTERMS, where NUMTERMS is the number of terms remaining. Each column contains the underlying principal payment for the time period corresponding to the row number. Calculate underlying principal payments using `mbscfamounts` or `mbspassthrough`. The underlying principal payments can also be outputs from other CMO cash flow functions.

Data Types: double

### TranchePrincipals — Initial principal for the scheduled and the support tranche

numeric matrix

Initial principal for the scheduled and the support tranche, specified as a matrix of size 2-by-1.

Data Types: double

### TrancheCoupons — Coupons for the schedule tranche and the support tranche

matrix of coupon values

Coupons for the schedule tranche and the support tranche, specified as a matrix of size 2-by-1 of coupon values. The weighted average coupon for the CMO should not exceed the coupon of the underlying mortgage.

Data Types: double

### **BalanceSchedule — Number of terms remaining for targeted balance**

numeric matrix

Number of terms remaining for targeted balance, specified as a matrix of size 1-by-NUMTERMS, where NUMTERMS is the number of terms remaining. Each element represents the targeted balance schedule for the time period corresponding to that column.

Data Types: double

## **Output Arguments**

### **Balance — Number of terms remaining and principal balances**

matrix

Number of terms remaining and principal balances, returned as a matrix of size 2-by-NUMTERMS, where NUMTERMS is the number of terms remaining. The first row is the principal balances of the scheduled tranche, and the second row is the principal balances of the support tranche at the time period corresponding to the column.

### **Principal — Number of terms remaining and principal payments**

matrix

Number of terms remaining and principal payments, returned as a matrix of size 2-by-NUMTERMS, where NUMTERMS is the number of terms remaining. The first row is the principal payments of the scheduled tranche, and the second row is the principal payments of the support tranche at the time period corresponding to the column.

### **Interest — Number of terms remaining and interest payments**

scalar

Number of terms remaining and interest payments, returned as a matrix of size 2-by-NUMTERMS, where NUMTERMS is the number of terms remaining. The first row is the interest payments of the schedule tranche, and the second row is the interest payments of the support tranche at the time period corresponding to the column.

## **More About**

### **Planned Amortization Class (PAC) Tranches**

In a PAC CMO, there is a main tranche, known as the schedule tranche, and a support tranche.

The main purpose of a schedule tranche is to give investors in the PAC tranche a more certain cash flow.

### **Targeted Amortization Class (TAC) Tranches**

TACs are like PACs, but principal payment is specified for only one prepayment rate.

If prepayment rates are higher or lower, then the principal payment to TAC holders are higher or lower accordingly.

### **Schedule and Support Tranche**

The main purpose of a PAC tranche is to give investors in the PAC tranche a more certain cash flow.

The PAC tranche receives priority for receiving payments of principal and interest that gives investors in the PAC tranche a steadier income. If prepayments differ from what was expected, then the support tranche gets the variable portion of the payments. While income to the support tranche is more variable, it is also higher yielding. Estimates of the yield, average life, and lockout periods of the PAC tranche is more certain.

### **Introduced in R2012a**

## cmoseqcf

Generate cash flows for sequential collateralized mortgage obligation (CMO)

### Syntax

```
[Balance,Principal,Interest] = cmoseqcf(PrincipalPayments,TranchePrincipals
TrancheCoupons)
[Balance,Principal,Interest] = cmoseqcf( ____,HasZ)
```

### Description

[Balance,Principal,Interest] = cmoseqcf(PrincipalPayments,TranchePrincipals TrancheCoupons) generates cash flows for a sequential CMO without a Z-bond, given the underlying mortgage pool payments.

[Balance,Principal,Interest] = cmoseqcf( \_\_\_\_,HasZ) generates cash flows for a sequential CMO with a Z-bond, given the underlying mortgage pool payments, by adding an additional optional input for HasZ.

### Examples

#### Calculate Cash Flows for a Sequential Collateralized Mortgage Obligation (CMO)

Define the mortgage pool under consideration for CMO structuring using mbscfamounts or mbspassthrough and calculate the cash flows with an A and B tranche for a sequential CMO.

```
MortgagePrincipal = 1000000;
Coupon = 0.12;
Terms = 6; % months

% Calculate underlying mortgage cash flows
[PrincipalBalance, MonthlyPayments, SchedPrincipalPayments, ...
InterestPayments, Prepayments] = ...
mbspassthrough(MortgagePrincipal, Coupon, Terms, Terms, 0, []);
PrincipalPayments = SchedPrincipalPayments.' + Prepayments.'

PrincipalPayments = 1x6
105 ×

    1.6255    1.6417    1.6582    1.6747    1.6915    1.7084
```

Define CMO tranches, A and B.

```
TranchePrincipals = [500000; 500000];
TrancheCoupons = [0.12; 0.12];
```

Calculate cash flows for each tranche.

```
[Balance, Principal, Interest] = ...
cmoseqcf(PrincipalPayments, TranchePrincipals, TrancheCoupons, false)
```

Balance = 2×6  
10<sup>5</sup> ×

3.3745	1.7328	0.0746	0	0	0
5.0000	5.0000	5.0000	3.3999	1.7084	0.0000

Interest = 2×6  
10<sup>3</sup> ×

5.0000	3.3745	1.7328	0.0746	0	0
5.0000	5.0000	5.0000	5.0000	3.3999	1.7084

## Input Arguments

### PrincipalPayments — Number of terms remaining for underlying principal payments

numeric matrix

Number of terms remaining for underlying principal payments, specified as a matrix of size 1-by-`NUMTERMS`, where `NUMTERMS` is the number of terms remaining. Each column contains the underlying principal payment for the time period corresponding to the row number. Calculate underlying principal payments using `mbscfamounts` or `mbspassthrough`. The underlying principal payments can also be outputs from other CMO cash flow functions.

Data Types: double

### TranchePrincipals — Initial principal for each tranche

numeric matrix

Initial principal for each tranche, specified as a matrix of size `NUMTRANCHES`-by-1, where `NUMTRANCHES` is the number of tranches in the sequential CMO. Each element of the matrix represents the initial principal for each tranche. If the sequential CMO includes a Z-bond (`HasZ` is `true`), the last element of this matrix is the principal of the Z-bond.

Data Types: double

### TrancheCoupons — Coupon for each tranche

matrix of coupon values

Coupon for each tranche, specified as a matrix of size `NUMTRANCHES`-by-1, where `NUMTRANCHES` is the number of tranches in the sequential CMO. Each element of the matrix represents the coupon for each tranche. If the sequential CMO includes a Z-bond (`HasZ` is `true`), the last element of this matrix is the coupon of the Z-bond. The weighted average coupon for the CMO should not exceed the coupon of the underlying mortgage.

Data Types: double

**HasZ — Indicates that the sequential CMO contains a Z-bond**

false (default) | true | false

(Optional) Indicates that the sequential CMO contains a Z-bond, specified as a Boolean (`true` or `false`). A value of `true` indicates that the sequential CMO contains a Z-bond, and the last element of `TranchePrincipals` and `TrancheCoupons` is treated as that of the Z-bond. A value of `false` indicates that there is no Z-bond in the sequential CMO, and the last element of `TranchePrincipals` and `TrancheCoupons` is treated as an ordinary tranche.

Data Types: `logical`**Output Arguments****Balance — Principal balance for time period and tranche**

matrix

Principal balance for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the principal balance at the time period corresponding to the column, and for the tranche corresponding to the row.

**Principal — Principal payments for time period and tranche**

matrix

Principal payments for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the principal payments made at the time period corresponding to the column, and to the tranche corresponding to the row.

**Interest — Interest payments for time period and tranche**

matrix

Interest payments for time period and tranche, returned as a matrix of size `NUMTRANCHES`-by-`NUMTERMS`, where `NUMTRANCHES` is the number of terms remaining and `NUMTRANCHES` is the number of tranches. Each element represents the interest payments made at the time period corresponding to the column, and to the tranche corresponding to the row.

**More About****Sequential Pay CMO**

A sequential pay CMO involves tranches that pay off principal sequentially.

For example, consider the following case, where all principal from the underlying mortgage pool is repaid on tranche A first, then tranche B, then tranche C. Interest is paid on each tranche as long as the principal for the tranche has not been retired.

**CMO Tranche**

Tranche is a term often used to describe a specific class of bonds within an offering wherein each tranche offers varying degrees of risk to the investor.

## Introduced in R2012a

# convfactor

Bond conversion factors

## Syntax

```
CF = convfactor(RefDate,Maturity,CouponRate)
```

```
CF = convfactor( ____,Name,Value)
```

## Description

CF = convfactor(RefDate,Maturity,CouponRate) computes a conversion factor for a bond futures contract.

CF = convfactor( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Conversion Factors For a Bond Futures Contract

This example shows how to calculate CF, given the following RefDate, Maturity, and CouponRate.

```
RefDate = {'1-Dec-2002';
           '1-Mar-2003';
           '1-Jun-2003';
           '1-Sep-2003';
           '1-Dec-2003';
           '1-Sep-2003';
           '1-Dec-2002';
           '1-Jun-2003'};
```

```
Maturity = {'15-Nov-2012';
            '15-Aug-2012';
            '15-Feb-2012';
            '15-Feb-2011';
            '15-Aug-2011';
            '15-Aug-2010';
            '15-Aug-2009';
            '15-Feb-2010'};
```

```
CouponRate = [0.04; 0.04375; 0.04875; 0.05; 0.05; 0.0575; 0.06; 0.065];
```

```
CF = convfactor(RefDate, Maturity, CouponRate)
```

```
CF = 8×1
```

```
0.8539
0.8858
0.9259
0.9418
0.9403
```

```
0.9862  
1.0000  
1.0266
```

### Compute the Conversion Factor For a German Bond

This example shows how to calculate `cf`, given the following `RefDate`, `Maturity`, and `CouponRate` for a German bond.

```
cf = convfactor('3/10/2009', '1/04/2018', .04, .06, 3)  
cf = 0.8659
```

## Input Arguments

### RefDate — Reference dates

serial date number

Reference dates for which conversion factor is computed (usually the first day of delivery months), specified as an N-by-1 vector of serial date numbers.

Data Types: `double`

### Maturity — Maturity date

serial date number

Maturity date, specified as a N-by-1 vector of serial date numbers.

Data Types: `double`

### CouponRate — Annual coupon rates for underlying bond

vector in decimals

Annual coupon rates for underlying bond, specified as an `numBonds`-by-1 vector in decimals.

Data Types: `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `CF = convfactor(RefDate, Maturity, CouponRate, 'Convention', 2)`

### Convention — Conversion factor convention

1 US Treasury bond (30-year) and Treasury note (10-year) futures contract (default) | integer from 1 to 5

Conversion factor convention, specified as the comma-separated pair consisting of `'Convention'` and a N-by-1 vector using the following values:

- 1 = US Treasury bond (30-year) and Treasury note (10-year) futures contract
- 2 = US 2-year and 5-year Treasury note futures contract
- 3 = German Bobl, Bund, Buxl, and Schatz
- 4 = UK gilts
- 5 = Japanese Government Bonds (JGBs)

Data Types: double

### **FirstCouponDate — Irregular first coupon date**

serial date number

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a N-by-1 vector using a serial date numbers.

Data Types: double

### **RefYield — Reference semiannual yield**

0.06 (6%) (default) | vector in decimals

Reference semiannual yield, specified as the comma-separated pair consisting of 'RefYield' and an N-by-1 vector in decimals.

Data Types: double

### **StartDate — Forward starting date of payments**

serial date number

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a N-by-1 vector using serial date numbers.

Data Types: double

## **Output Arguments**

### **CF — Conversion factors against the 6% yield par-bond**

vector

Conversion factors against the 6% yield par-bond, returned as an N-by-1 vector.

## **More About**

### **Conversion Factors**

Conversion factors of US Treasury bonds and other government bonds are based on a bond yielding 6%.

Optionally, you can specify other types of bonds and yields using inputs for RefYield and Convention. For US Treasury bonds, verify the output of convfactor by comparing the output against the quotations provided by the Chicago Board of Trade (<https://www.cmegroup.com/company/cbot.html>).

For German bonds, verify the output of convfactor by comparing the output against the quotations provided by Eurex (<https://www.eurexchange.com>).

For UK Gilts, verify the output of `convfactor` by comparing the output against the quotations provided by Euronext (<https://www.euronext.com>).

For Japanese Government Bonds, verify the output of `convfactor` by comparing the output against the quotations provided by the Tokyo Stock Exchange (<https://www.jpx.co.jp/english/>).

## Introduced in R2009b

# fitFunction

Custom fit interest-rate curve object to bond market data

## Class

@IRFunctionCurve on page A-11

## Syntax

CurveObj = IRFunctionCurve.fitFunction(Type,Settle,FunctionHandle,Instruments,IRFitOptionsObj)

CurveObj = IRFunctionCurve.fitFunction(Type,Settle,FunctionHandle,Instruments,IRFitOptionsObj,Name)

## Arguments

Type	Type of interest-rate curve for a bond: <b>zero</b> , <b>forward</b> , or <b>discount</b> .
Settle	Scalar for the <b>Settle</b> date of the curve.
FunctionHandle	Function handle that defines the interest-rate curve. The function handle takes two numeric vectors (time-to-maturity and a vector of function coefficients) and returns one numeric output (interest rate or discount factor). For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.
Instruments	N-by-4 data matrix for <b>Instruments</b> where the first column is <b>Settle</b> date, the second column is <b>Maturity</b> , the third column is the clean price, and the fourth column is a <b>CouponRate</b> for the bond.
IRFitOptionsObj	Object constructed from <b>IRFitOptions</b> .
Compounding	(Optional) Scalar that sets the compounding frequency per year for the <b>IRFunctionCurve</b> object: <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

<b>Basis</b>	<p>(Optional) Day-count basis of the bond. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
--------------	---

## Instrument Parameters

For each bond `Instrument`, you can specify the following additional instrument parameters as parameter/value pairs. For example, `InstrumentBasis` distinguishes a bond instrument's `Basis` value from the curve's `Basis` value.

<b>InstrumentPeriod</b>	<p>(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.</p>
-------------------------	--

InstrumentBasis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. <b>0</b> = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. <b>1</b> = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** name-value pairs, you can specify simple interest for a bond by specifying the **InstrumentPeriod** value as **0**. If **InstrumentBasis** and **InstrumentPeriod** are not specified for a bond, the following default values are used: **Basis** is **0** (act/act) and **Period** is **2**.

## Description

CurveObj = IRFunctionCurve.fitFunction(Type, Settle, FunctionHandle, Instruments, IRFitOptionsObj, Name, Value) fits a bond to a custom fitting function. You must enter the optional arguments for Basis and Compounding as comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## Examples

```
Settle = repmat(datenum('30-Apr-2008'),[6 1]);
Maturity = [datenum('07-Mar-2009');datenum('07-Mar-2011');...
datenum('07-Mar-2013');datenum('07-Sep-2016');...
datenum('07-Mar-2025');datenum('07-Mar-2036')];
CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
CurveSettle = datenum('30-Apr-2008');
OptOptions = optimoptions('lsqnonlin','display','iter');
functionHandle = @(t,theta) polyval(theta,t);

CustomModel = IRFunctionCurve.fitFunction('Zero', CurveSettle, ...
functionHandle, Instruments, ...
IRFitOptions([.05 .05 .05], 'FitType', 'price', ...
'OptOptions', OptOptions));
```

## fitNelsonSiegel

Fit Nelson-Siegel function to bond market data

---

**Note** `fitNelsonSiegel` for an `IRFunctionCurve` is not recommended. Use `fitNelsonSiegel` with a `parametercurve` object instead. For more information, see `fitNelsonSiegel`.

---

### Class

@IRFunctionCurve on page A-11

### Syntax

`CurveObj = IRFunctionCurve.fitNelsonSiegel(Type,Settle,Instruments)`

`CurveObj = IRFunctionCurve.fitNelsonSiegel(Type,Settle,Instruments,Name,Value)`

### Arguments

Type	Type of interest-rate curve for a bond: zero or forward.
Settle	Scalar for the <code>Settle</code> date of the curve.
Instruments	N-by-4 data matrix for <code>Instruments</code> where the first column is <code>Settle</code> date, the second column is <code>Maturity</code> , the third column is the clean price, and the fourth column is a <code>CouponRate</code> for the bond.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the <code>IRFunctionCurve</code> object: <ul style="list-style-type: none"> <li>-1 = Continuous compounding</li> </ul>

Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
IRFitOptions	<p>(Optional) Object constructed from IRFitOptions. When using IRFitOption, the default FitType is DurationWeightedPrice. Duration weighted price refers to the form of the objective function that needs to be minimized to find the optimal Nelson-Siegel parameters. Specifically, this objective function minimizes using the following three algorithms:</p> <ul style="list-style-type: none"> <li>• The difference between observed and model-predicted yields for each bond, <math>ObsY_i - PredY_i</math></li> <li>• The difference between observed and model-predicted prices for each bond, <math>ObsP_i - PredP_i</math></li> <li>• The difference between observed and model-predicted prices, weighted by the inverse of the duration of each bond <math>(ObsP_i - PredP_i) / D_i</math>. Weighting price by inverse duration converts the pricing errors into yield fitting errors, to a first approximation.</li> </ul>

## Instrument Parameters

For each bond Instrument, you can specify the following additional instrument parameters as name-value pairs. For example, InstrumentBasis distinguishes a bond instrument's Basis value from the curve's Basis value.

InstrumentPeriod	<p>(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.</p>
------------------	--

InstrumentBasis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** name-value pairs, you can specify simple for a bond by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for a bond, the following default values are used: **Basis** is 0 (act/act) and **Period** is 2.

## Description

`CurveObj = IRFunctionCurve.fitNelsonSiegel(Type, Settle, Instruments, Name, Value)` fits a Nelson-Siegel function to market data for a bond. You must enter the optional arguments for `Basis`, `Compounding`, and `IRFitOptions` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

After creating a Nelson-Siegel model, you can view the Nelson-Siegel model parameters using:

```
CurveObj.Parameters
```

where the order of parameters is `[Beta0, Beta1, Beta2, tau1]`.

## Examples

### Use the Nelson-Siegel Function to Fit Bond Market Data

This example shows how to use the Nelson-Siegel function to fit bond market data.

```
Settle = repmat(datenum('30-Apr-2008'), [6 1]);
Maturity = [datenum('07-Mar-2009'); datenum('07-Mar-2011'); ...
    datenum('07-Mar-2013'); datenum('07-Sep-2016'); ...
    datenum('07-Mar-2025'); datenum('07-Mar-2036')];

CleanPrice = [100.1; 100.1; 100.8; 96.6; 103.3; 96.3];
CouponRate = [0.0400; 0.0425; 0.0450; 0.0400; 0.0500; 0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
PlottingPoints = datenum('07-Mar-2009'):180:datenum('07-Mar-2036');
Yield = bndyield(CleanPrice, CouponRate, Settle, Maturity);

NSModel = IRFunctionCurve.fitNelsonSiegel('Zero', datenum('30-Apr-2008'), Instruments);

NSModel.Parameters

ans = 1x4

    4.6617    -1.0227    -0.3484     1.2385

% create the plot
plot(PlottingPoints, getParYields(NSModel, PlottingPoints), 'r')
hold on
scatter(Maturity, Yield, 'black')
datetick('x')
```

## Algorithms

The Nelson-Siegel model proposes that the instantaneous forward curve can be modeled with the following:

$$f = \beta_0 + \beta_1 e^{-\frac{m}{\tau}} + \beta_2 \frac{m}{\tau} e^{-\frac{m}{\tau}}$$

This can be integrated to derive an equation for the zero curve (see [6] for more information on the equations and the derivation):

$$s = \beta_0 + (\beta_1 + \beta_2) \frac{\tau}{m} (1 - e^{-\frac{m}{\tau}}) - \beta_2 e^{-\frac{m}{\tau}}$$

See [1] for more information.

## fitSmoothingSpline

Fit smoothing spline to bond market data

### Class

@IRFunctionCurve on page A-11

### Syntax

```
CurveObj = IRFunctionCurve.fitSmoothingSpline(Type,Settle,Instruments,Lambdafun)
```

```
CurveObj = IRFunctionCurve.fitSmoothingSpline(Type,Settle,Instruments,Lambdafun,Name,Value)
```

### Arguments

**Note** You must have a license for Curve Fitting Toolbox software to use the `fitSmoothingSpline` method.

Type	Type of interest-rate curve for a bond: Forward, Zero, or Discount.
Settle	Scalar for the <code>Settle</code> date of the curve.
Instruments	N-by-4 data matrix for <code>Instruments</code> where the first column is <code>Settle</code> date, the second column is <code>Maturity</code> , the third column is the clean price, and the fourth column is a <code>CouponRate</code> for the bond.
Lambdafun	Penalty function that takes as its input time and returns a penalty value. Use a function handle to support the penalty function. The function handle for the penalty function which takes one numeric input (time-to-maturity) and returns one numeric output (penalty to be applied to the curvature of the spline). For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.  <b>Note</b> The smoothing spline represents the forward curve. The spline is penalized for curvature by specifying a penalty function. This fit may only be done with a <code>FitType</code> of <code>DurationWeightedPrice</code> .
Knots	(Optional) Vector of knot locations (times-to-maturity); by default, <code>knots</code> is set to be a vector comprised of 0 and the time to maturity of all input instruments. The default is for the spline type to be cubic but you can specify any spline type by explicitly specifying the knots. User-defined knots can be specified using the following command, where <code>k</code> is the order: <code>augknt(knots,k)</code> .

Compounding	<p>(Optional) Scalar that sets the compounding frequency per year for the IRFunctionCurve object:</p> <ul style="list-style-type: none"> <li>• -1 = Continuous compounding (default)</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>
Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>

## Instrument Parameters

For each bond Instrument, you can specify the following additional instrument parameters as name-value pairs. For example, InstrumentBasis distinguishes a bond instrument's Basis value from the curve's Basis value.

InstrumentPeriod	<p>(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.</p>
------------------	--

InstrumentBasis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** name-value pairs, you can specify simple interest for a bond by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for a bond, the following default values are used: **Basis** is 0 (act/act) and **Period** is 2.

## Description

`Fcurve = IRFunctionCurve.fitSmoothingSpline(Type, Settle, Instruments, Lambdafun, Name, Value)` fits a smoothing spline to market data for a bond. You must enter the optional arguments for `Basis`, `Compounding`, and `Knots` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## Examples

### Use a Smoothing Spline Function to Fit Market Data For a Bond

This example shows how to use a smoothing spline function to fit market data for a bond.

```
Settle = repmat(datenum('30-Apr-2008'),[6 1]);
Maturity = [datenum('07-Mar-2009');datenum('07-Mar-2011');...
datenum('07-Mar-2013');datenum('07-Sep-2016');...
datenum('07-Mar-2025');datenum('07-Mar-2036')];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];
Instruments = [Settle Maturity CleanPrice CouponRate];
PlottingPoints = datenum('07-Mar-2009'):180:datenum('07-Mar-2036');
Yield = bndyield(CleanPrice,CouponRate,Settle,Maturity);

% use the AUGKNT function to construct the knots for a cubic spline at every 5 years
CustomKnots = augknt(0:5:30,4);
SmoothingModel = IRFunctionCurve.fitSmoothingSpline('Zero',datenum('30-Apr-2008'),...
Instruments,@(t) 1000,'knots', CustomKnots);

% create the plot
plot(PlottingPoints, getParYields(SmoothingModel, PlottingPoints),'b')
hold on
scatter(Maturity,Yield,'black')
datetick('x')
```

### Fitting an IRFunctionCurve Object Using the Smoothing Spline Method With the Penalty Function

Use the `fitSmoothinSpline` method to fit the interest-rate curve and model the `Lambdafun` penalty function. First, load the data.

```
load ukdata20080430
```

Convert the repo rates to be equivalent zero coupon bonds.

```
RepoCouponRate = repmat(0,size(RepoRates));
RepoPrice = bndprice(RepoRates, RepoCouponRate, RepoSettle, RepoMaturity);
```

Aggregate the data.

```
Settle = [RepoSettle;BondSettle];
Maturity = [RepoMaturity;BondMaturity];
CleanPrice = [RepoPrice;BondCleanPrice];
CouponRate = [RepoCouponRate;BondCouponRate];
Instruments = [Settle Maturity CleanPrice CouponRate];
InstrumentPeriod = [repmat(0,6,1);repmat(2,31,1)];
CurveSettle = datenum('30-Apr-2008');
```

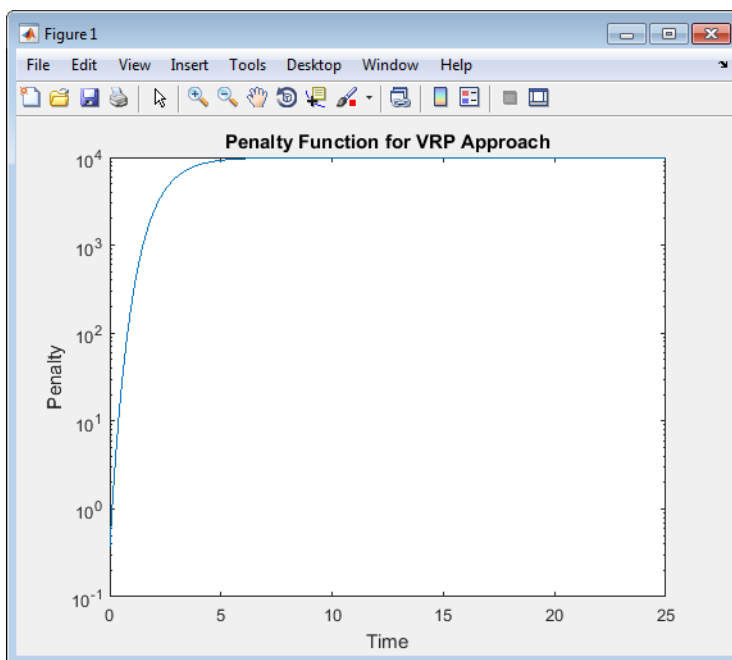

Choose the parameters for the `Lambdafun` input argument.

```
L = 9.2;
S = -1;
mu = 1;
```

Define the Lambdafun penalty function.

```
lambdafun = @(t) exp(L - (L-S)*exp(-t/mu));
t = 0:.1:25;
y = lambdafun(t);
figure
semilogy(t,y);
title('Penalty Function for VRP Approach')
ylabel('Penalty')
xlabel('Time')
```

Use the fitSmoothingSpline method to fit the interest-rate curve and model the Lambdafun penalty function.

```
VRPModel = IRFunctionCurve.fitSmoothingSpline('Forward',CurveSettle,...
Instruments,lambdafun,'Compounding',-1, 'InstrumentPeriod',InstrumentPeriod)
```

```
VRPModel =
```

```
    Type: Forward
    Settle: 733528 (30-Apr-2008)
    Compounding: -1
    Basis: 0 (actual/actual)
```

Plot the smoothing spline interest-rate curve for the forward rates.

```
PlottingDates = CurveSettle+20:30:CurveSettle+365*25;
TimeToMaturity = yearfrac(CurveSettle,PlottingDates);
VRPForwardRates = getForwardRates(VRPModel, PlottingDates);
figure;plot(TimeToMaturity,VRPForwardRates)
title('Smoothing Spline model of UK instantaneous nominal forward curve')
```

## Algorithms

The term structure can be modeled with a spline — specifically, one way to model the term structure is by representing the forward curve with a cubic spline. To ensure that the spline is sufficiently smooth, a penalty is imposed relating to the curvature (second derivative) of the spline:

$$\sum_{i=1}^N \left[ \frac{P_i - \hat{P}_i(f)}{D_i} \right]^2 + \int_0^M \lambda_t(m) [f''(m)]^2 dm$$

where the first term is the difference between the observed price  $P$  and the predicted price,  $\hat{P}$ , (weighted by the bond's duration,  $D$ ) summed over all bonds in our data set and the second term is the penalty term (where  $\lambda$  is a penalty function and  $f$  is the spline).

See [3], [4], [5] below.

There have been different proposals for the specification of the penalty function  $\lambda$ . One approach, advocated by [4], and currently used by the UK Debt Management Office, is a penalty function of the following form:

$$\log(\lambda(m)) = L - (L - S)e^{-\frac{m}{\tau}}$$

## fitSvensson

Fit Svensson function to bond market data

---

**Note** `fitSvensson` for an `IRFunctionCurve` is not recommended. Use `fitSvensson` with a `parametercurve` object instead. For more information, see `fitSvensson`.

---

### Class

@IRFunctionCurve on page A-11

### Syntax

`CurveObj = IRFunctionCurve.fitSvensson(Type, Settle, Instruments)`

`CurveObj = IRFunctionCurve.fitSvensson(Type, Settle, Instruments, Name, Value)`

### Arguments

Type	Type of interest-rate curve for a bond: zero or forward.
Settle	Scalar for the <code>Settle</code> date of the curve.
Instruments	N-by-4 data matrix for <code>Instruments</code> where the first column is <code>Settle</code> date, the second column is <code>Maturity</code> , the third column is the clean price, and the fourth column is a <code>CouponRate</code> for the bond.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the <code>IRFunctionCurve</code> object: <ul style="list-style-type: none"> <li>-1 = Continuous compounding</li> </ul>

Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
IRFitOptions	(Optional) Object constructed from IRFitOptions.

## Instrument Parameters

For each bond Instrument, you can specify the following additional instrument parameters as name-value pairs. For example, InstrumentBasis distinguishes a bond instrument's Basis value from the curve's Basis value.

InstrumentPeriod	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
------------------	---

InstrumentBasis	<p>(Optional) Day-count basis of the bond. A vector of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
InstrumentEndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when <b>Maturity</b> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
InstrumentIssueDate	<p>(Optional) Date when an instrument was issued.</p>
InstrumentFirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment; used when bond has an irregular first coupon period. When <b>FirstCouponDate</b> and <b>LastCouponDate</b> are both specified, <b>FirstCouponDate</b> takes precedence in determining the coupon payment structure. If you do not specify a <b>FirstCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentLastCouponDate	<p>(Optional) Last coupon date of a bond before the maturity date; used when bond has an irregular last coupon period. In the absence of a specified <b>FirstCouponDate</b>, a specified <b>LastCouponDate</b> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <b>LastCouponDate</b>, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify a <b>LastCouponDate</b>, the cash flow payment dates are determined from other inputs.</p>
InstrumentFace	<p>(Optional) Face or par value. Default = 100.</p>

**Note** When using **Instrument** name-value pairs, you can specify simple interest for a bond by specifying the **InstrumentPeriod** value as 0. If **InstrumentBasis** and **InstrumentPeriod** are not specified for a bond, the following default values are used: **Basis** is 0 (act/act) and **Period** is 2.

## Description

`CurveObj = IRFunctionCurve.fitSvensson(Type, Settle, Instruments,Name,Value)` fits the Svensson function to bond market data. You must enter the optional arguments for `Basis`, `Compounding`, and `IRFitOptions` as comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

After creating a Svensson model, you can view the Svensson model parameters using:

```
CurveObj.Parameters
```

where the order of parameters is `[Beta0, Beta1, Beta2, Beta3, tau1, tau2]`.

## Examples

### Use a Svensson Function to Fit Bond Market Data

This example shows how to use a Svensson function to fit bond market data.

```
Settle = datenum('15-Apr-2014');
Maturity = datemnth(Settle,12*[1 2 3 5 7 10 20 30]');

CleanPrice = [100.1 100.1 100.2 99.0 101.8 99.2 101.7 100.2]';
CouponRate = [0.0200 0.0275 0.035 0.042 0.0475 0.0525 0.055 0.052]';
Instruments = [repmat(Settle,size(Maturity)) Maturity CleanPrice CouponRate];
PlottingPoints = datemnth(Settle,1:360);
Yield = bndyield(CleanPrice,CouponRate,Settle,Maturity);

SvenssonModel = IRFunctionCurve.fitSvensson('Zero',Settle,Instruments);

SvenssonModel.Parameters

ans = 1x6

    1.8297    -1.2299    1.6316    12.3891    1.6982    8.9422

% create the plot
plot(PlottingPoints, getParYields(SvenssonModel, PlottingPoints),'g')
hold on
scatter(Maturity,Yield,'black')
datetick('x')
legend({'Svensson Fitted Curve','Yields'},'location','best')
```

## Algorithms

A similar model to the Nelson-Siegel is the Svensson model, which adds two additional parameters to account for greater flexibility in the term structure. This model proposes that the forward rate can be modeled with the following form:

$$f = \beta_0 + \beta_1 e^{-\frac{m}{\tau_1}} + \beta_2 e^{-\frac{m}{\tau_1}} \frac{m}{\tau_1} + \beta_3 e^{-\frac{m}{\tau_2}} \frac{m}{\tau_2}$$

As above, this can be integrated to derive an equation for the zero curve:

$$s = \beta_0 + \beta_1 (1 - e^{-\frac{m}{\tau_1}}) \left(-\frac{\tau_1}{m}\right) + \beta_2 \left( (1 - e^{-\frac{m}{\tau_1}}) \frac{\tau_1}{m} - e^{-\frac{m}{\tau_1}} \right) + \beta_3 \left( (1 - e^{-\frac{m}{\tau_2}}) \frac{\tau_2}{m} - e^{-\frac{m}{\tau_2}} \right)$$

## getDiscountFactors

Get discount factors for input dates for IRDataCurve

### Class

@IRDataCurve on page A-6

### Syntax

```
F = getDiscountFactors(CurveObj,InpDates)
```

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.

### Description

F = getDiscountFactors(CurveObj, InpDates) returns discount factors for the input dates.

### Examples

#### Get Discount Factors For Input Dates for an IRDataCurve

This example shows how to get discount factors for input dates for an IRDataCurve.

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data);
getDiscountFactors(irdc, CurveSettle+30:30:CurveSettle+720)
```

## getForwardRates

Get forward rates for input dates for IRDataCurve

### Class

@IRDataCurve on page A-6

### Syntax

F = getForwardRates(CurveObj, InpDates)

F = getForwardRates(CurveObj, InpDates, Name, Value)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for forward rates. The default <b>Compounding</b> value is <code>CurveObj.Compounding</code> . Acceptable values are: <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 0 = Simple interest (no compounding)</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

<b>Basis</b>	<p>(Optional) Day-count basis values for the forward rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
--------------	--

## Description

`F = getForwardRates(CurveObj, InpDates, Name, Value)` returns forward rates for the input dates. `getForwardRates` returns discrete forward rates for the intervals input into this method. For example, running the following code:

```
getForwardRates(irdc, {Date1, Date2, Date3})
```

gives three forwards rates and the three tenors are: `[Settle, Date1]`, `[Date1, Date2]`, and `[Date2, Date3]`.

You must enter the optional arguments for `Basis` and `Compounding` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

The `getForwardRates` method returns forward rates corresponding to the periodicity of the dates input to `getForwardRates`. For example, where the dates are monthly, monthly forward rates are returned. The first element of the output is the forward rate from the `Settle` to one month, the second element is the forward rate from one month to two months, and so on.

## Examples

### Get Forward Rates For Input Dates for an IRDataCurve

This example shows how to get forward rates for input dates for an `IRDataCurve`.

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
```

```
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data);
getForwardRates(irdc, CurveSettle+30:30:CurveSettle+720)
```

```
ans = 24×1
```

```
0.0174
0.0180
0.0187
0.0193
0.0199
0.0205
0.0212
0.0218
0.0224
0.0230
⋮
```

### Use getForwardRates to Compute the Five Year Forward Rate in Five Years Time

Use `getForwardRates` to compute the forward rate from the `Settle` date to 5 years from March 1, 2017 and then the forward rate for the period from 5 years to 10 years from March 1, 2017.

```
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = daysadd(736755,[360 2*360 3*360 5*360 7*360 10*360 20*360 30*360],1);
irdc = IRDataCurve('Zero',today,Dates,Data);
getForwardRates(irdc,datemnth(irdc.Settle,12*[5 10]))
```

```
ans = 2×1
```

```
0.0364
0.0456
```

The first element (.0312) is the forward rate from the `Settle` to 5 years from March 1, 2017. The second rate (0.0458) is the forward rate for the period from 5 years to 10 years from March 1, 2017, in other words, the 5-year forward rate 5 years from March 1, 2017.

### Compute the Six Month Forward Rates in 1 Month, 2 Months and 3 Months

Use the following data to create an `IRDataCurve` object:

```
Data = [0.1 0.30 0.70 1.05 1.45 1.71 2.12 2.43 2.85 3.57]/100;
Settle = datenum('08-Aug-2016'); % Today's date
Dates = datemnth(Settle,[3 6 9 12*[1 2 3 5 7 10 20]]);
irdc = IRDataCurve('Zero',Settle,Dates,Data)
```

```
irdc =
```

```
    Type: Zero
    Settle: 736550 (08-Aug-2016)
    Compounding: 2
    Basis: 0 (actual/actual)
```

```

InterpMethod: linear
  Dates: [10x1 double]
  Data: [10x1 double]

```

Compute the implied 6 month forward rates in 1 month, 2 months, and 3 months from the Settle date.

```

IntervalMonth = 6; % Interval for 6 month forward rates
FwdMonths = [1 2 3]'; % Starting in 1, 2, and 3 months from Settle
N = length(FwdMonths);
FwdRates_6M = zeros(N,1);

for k = 1:N
    FwdDates = datemnth(irdc.Settle, [FwdMonths(k) FwdMonths(k)+IntervalMonth]);
    f = getForwardRates(irdc,FwdDates);
    FwdRates_6M(k) = f(2);
end

```

```
[FwdMonths FwdRates_6M]
```

```
ans = 3x2
```

```

1.0000    0.0050
2.0000    0.0074
3.0000    0.0101

```

## getForwardRates

Get forward rates for input dates for IRFunctionCurve

### Class

@IRFunctionCurve on page A-11

### Syntax

F = getForwardRates(CurveObj, InpDates)

F = getForwardRates(CurveObj, InpDates, Name, Value)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRFunctionCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the forward rates are: <ul style="list-style-type: none"><li>• -1 = Continuous compounding</li><li>• 1 = Annual compounding</li><li>• 2 = Semiannual compounding (default)</li><li>• 3 = Compounding three times per year</li><li>• 4 = Quarterly compounding</li><li>• 6 = Bimonthly compounding</li><li>• 12 = Monthly compounding</li></ul>

<b>Basis</b>	<p>(Optional) Day-count basis for the forward rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
--------------	---

## Description

$F = \text{getForwardRates}(\text{CurveObj}, \text{InpDates}, \text{Name}, \text{Value})$  returns forward rates for the input dates. You must enter the optional arguments for **Basis** and **Compounding** as comma-separated pairs of **Name,Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

### Compute the Implied 2-Year Forward Rates in 1 Year, 2 Years, 5 Years, and 10 Years

This example shows how to compute the implied 2-year forward rates in 1 year, 2 years, 5 years, and 10 years from the `Settle` date by using the `getForwardRates` method.

Use the following data for an `IRFunctionCurve` object that is created when using the `fitSvensson` method.

```
Settle = datenum('15-Apr-2014');
Maturity = datemnth(Settle,12*[1 2 3 5 7 10 20 30]');

CleanPrice = [100.1 100.1 100.2 99.0 101.8 99.2 101.7 100.2]';
CouponRate = [0.0200 0.0275 0.035 0.042 0.0475 0.0525 0.055 0.052]';
Instruments = [repmat(Settle,size(Maturity)) Maturity CleanPrice CouponRate];

SvenssonModel = IRFunctionCurve.fitSvensson('Zero',Settle,Instruments);
```

Compute the implied 2-year forward rates in 1 year, 2 years, 5 years, and 10 years from the `Settle` date.

```
IntervalMonth = 12.*2;           % Interval months for 2-year forward rates
FwdMonths = 12.*[1 2 5 10]';    % Starting in 1, 2, 5, and 10 years from Settle
N = length(FwdMonths);
FwdRates_2Y = zeros(N,1);

for k = 1:N
    FwdDates = datemnth(SvenssonModel.Settle, [FwdMonths(k) FwdMonths(k)+IntervalMonth]);
    f = getForwardRates(SvenssonModel,FwdDates);
    FwdRates_2Y(k) = f(2);
end
```

```
[FwdMonths FwdRates_2Y]
```

```
ans = 4x2
```

```
12.0000    0.0418
24.0000    0.0504
60.0000    0.0620
120.0000   0.0629
```

## getParYields

Get par yields for input dates for IRDataCurve

### Class

@IRDataCurve on page A-6

### Syntax

F = getParYields(CurveObj, InpDates)

F = getParYields(CurveObj, InpDates, Name, Value)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the par yield rates are: <ul style="list-style-type: none"><li>• -1 = Continuous compounding</li><li>• 1 = Annual compounding</li><li>• 2 = Semiannual compounding (default)</li><li>• 3 = Compounding three times per year</li><li>• 4 = Quarterly compounding</li><li>• 6 = Bimonthly compounding</li><li>• 12 = Monthly compounding</li></ul>

<b>Basis</b>	<p>(Optional) Day-count basis values for the par yield rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
--------------	--

## Description

`F = getParYields(CurveObj, InpDates, Name, Value)` returns par yields for the input dates. You must enter the optional arguments for `Basis` and `Compounding` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## Examples

### Get Par Yields For Input Dates For an IRDataCurve

This example shows how to get par yields for input dates for an `IRDataCurve`.

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle, 12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero', CurveSettle, Dates, Data);
getParYields(irdc, CurveSettle+30:30:CurveSettle+720)
```

```
ans = 24x1
```

# getParYields

Get par yields for input dates for IRFunctionCurve

## Class

@IRFunctionCurve on page A-11

## Syntax

F = getParYields(CurveObj, InpDates)

F = getParYields(CurveObj, InpDates, Name, Value)

## Arguments

CurveObj	Interest-rate curve object that is constructed using IRFunctionCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for par yield rates are: <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

<b>Basis</b>	<p>(Optional) Day-count basis values for par yield rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
--------------	--

## Description

`F = getParYields(CurveObj, InpDates, Name, Value)` returns par yields for the input dates. You must enter the optional arguments for `Basis` and `Compounding` as comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## Examples

### Get Par Yields For Input Dates For an IRFunctionCurve

This example shows how to get par yields for input dates for an `IRFunctionCurve`.

```
irfc = IRFunctionCurve('Forward', today, @(t) polyval([-0.0001 0.003 0.02], t));
getParYields(irfc, today+30:30:today+720)
```

```
ans = 24x1

## getZeroRates

Get zero rates for input dates for IRDataCurve

### Class

@IRDataCurve on page A-6

### Syntax

F = getZeroRates(CurveObj, InpDates)

F = getZeroRates(CurveObj, InpDates, Name, Value)

### Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.
Compounding	(Optional) Scalar that sets the compounding frequency per year for zero rates. The default Compounding value is CurveObj.Compounding. Acceptable values are: <ul style="list-style-type: none"><li>• -1 = Continuous compounding</li><li>• 0 = Simple interest (no compounding)</li><li>• 1 = Annual compounding</li><li>• 2 = Semiannual compounding</li><li>• 3 = Compounding three times per year</li><li>• 4 = Quarterly compounding</li><li>• 6 = Bimonthly compounding</li><li>• 12 = Monthly compounding</li></ul>

<b>Basis</b>	<p>(Optional) Day-count basis values for zero rates:</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>

## IRBootstrapOptions

Construct specific options for bootstrapping interest-rate curve object

### Class

@IRBootstrapOptions on page A-2

### Syntax

```
mybootoptions = IRBootstrapOptions(Name,Value)
```

### Arguments

ConvexityAdjustment	(Optional) Controls the convexity adjustment to interest-rate futures. This can be specified as a function handle that takes one numeric input (time-to-maturity) and returns one numeric output, ConvexityAdjustment. For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.  Alternatively, you can define ConvexityAdjustment as an N-by-1 vector of values, where N is the number of interest-rate futures.  In either case, the ConvexityAdjustment is subtracted from the futures rate.
LowerBound	(Optional) Specifies a lower bound for rates associated with bonds or swaps. LowerBound can be a scalar or N-by-1 vector where N is the number of swaps and bonds. By default, LowerBound is 0.
UpperBound	(Optional) Specifies an upper bound for rates associated with bonds or swaps. UpperBound can be a scalar or N-by-1 vector where N is the number of swaps and bonds. By default, UpperBound is 1. Specify an upper bound that is greater than 1 when bootstrapping a discount curve.

### Description

mybootoptions = IRBootstrapOptions(Name,Value) constructs an IRBootstrapOptionsObj structure. You must enter the optional arguments for ConvexityAdjustment, LowerBound, and UpperBound as comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

The IRBootstrapOptionsObj is used with the bootstrap method.

## Examples

### Create IRBootstrapOptionsObj to Use With the bootstrap Method

Set the ConvexityAdjustment to control interest-rate futures.

```
mybootoptions = IRBootstrapOptions('ConvexityAdjustment', repmat(.005,10,1))
```

```
mybootoptions =
  IRBootstrapOptions with properties:
    ConvexityAdjustment: [10x1 double]
    LowerBound: 0
    UpperBound: 1
```

Use mybootoptions as the optional argument, IRBootstrapOptionsObj, to use with the bootstrap method.

### Create an IRBootstrapOptionsObj to Use With Negative Zero Interest-Rates

Use an IRBootstrapOptionsObj optional argument with the bootstrap method to allow for negative zero rates when solving the swap zero points.

```
Settle = datenum('15-Mar-2015');
InstrumentTypes = {'Deposit'; 'Deposit'; 'Swap'; 'Swap'; 'Swap'; 'Swap'};

Instruments = [Settle, datenum('15-Jun-2015'), .001; ...
Settle, datenum('15-Dec-2015'), .0005; ...
Settle, datenum('15-Mar-2016'), -.001; ...
Settle, datenum('15-Mar-2017'), -0.0005; ...
Settle, datenum('15-Mar-2018'), .0017; ...
Settle, datenum('15-Mar-2020'), .0019];

irbo = IRBootstrapOptions('LowerBound', -1);

bootModel = IRDataCurve.bootstrap('zero', Settle, InstrumentTypes, ...
    Instruments, 'IRBootstrapOptions', irbo);

bootModel.getZeroRates(datemnth(Settle, 1:60))

ans = 60x1

    0.0012
    0.0011
    0.0010
    0.0009
    0.0008
    0.0008
    0.0007
    0.0006
    0.0005
   -0.0000
```

⋮

Note that `IRBootstrapOptions` optional argument for `LowerBound` is set to `-1` for negative zero rates when solving the swap zero points.

# IRDataCurve

Construct interest-rate curve object from dates and data

## Class

@IRDataCurve on page A-6

## Syntax

CurveObj = IRDataCurve(Type, Settle, Dates, Data)

CurveObj = IRDataCurve(Type, Settle, Dates, Data, Name, Value)

## Arguments

Type	Type of interest-rate curve. Acceptable values are forward, zero, or discount.
Settle	Scalar for the Settle date of the curve.
Dates	Dates corresponding to rate data.
Data	Interest-rate data for the curve object.
Compounding	<p>(Optional) Scalar that sets the compounding frequency per year for the IRDataCurve object:</p> <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 0 = Simple interest (no compounding) for “zero” and “discount” curve types only, not supported for “forward” curves</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul> <p><b>Note</b> Simple interest can be specified for an instrument by specifying the Compounding value as 0 and is supported for “zero” and “discount” curve types only (not supported for “forward” curves).</p>

Basis	<p>(Optional) Day-count basis of the interest-rate curve. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
InterpMethod	<p>(Optional) Values are:</p> <ul style="list-style-type: none"> <li>• 'linear' — Linear interpolation (default).</li> <li>• 'constant' — Piecewise constant interpolation.</li> <li>• 'pchip' — Piecewise cubic Hermite interpolation.</li> <li>• 'spline' — Cubic spline interpolation.</li> </ul>

## Description

`CurveObj = IRDataCurve(Type,Settle,Dates,Data,Name,Value)` constructs an interest-rate curve with the specified `Dates` and `Data`. You must enter the optional arguments for `Basis`, `Compounding`, and `InterpMethod` as comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alternatively, an `IRDataCurve` object can be bootstrapped from market data using the `bootstrap` method.

After an `IRDataCurve` curve object is constructed, you can use the following methods to determine the forward rates, zero rates, and discount factors. In addition, you can use the `toRateSpec` method to convert the interest-rate curve object to a `RateSpec` structure.

Method	Description
<code>getForwardRates</code>	Returns forward rates for input dates.
<code>getZeroRates</code>	Returns zero rates for input dates.
<code>getDiscountFactors</code>	Returns discount factors for input dates.

Method	Description
getParYields	Returns par yields for input dates.
toRateSpec	Converts to be a RateSpec object; this structure is identical to the RateSpec produced by the function <code>intenvset</code> .
bootstrap	Bootstraps an interest rate curve from market data.

## Examples

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Zero',CurveSettle,Dates,Data)
```

```
irdc =
```

```

    Type: Zero
    Settle: 736391 (02-Mar-2016)
    Compounding: 2
    Basis: 0 (actual/actual)
    InterpMethod: linear
    Dates: [8x1 double]
    Data: [8x1 double]
```

## Introduced in R2008b

## IRFitOptions

Construct specific options for fitting interest-rate curve object

### Class

@IRFitOptions on page A-9

### Syntax

```
myfitoptions = IRFitOptions(InitialGuess)
myfitoptions = IRFitOptions(InitialGuess,Name,Value)
```

### Arguments

InitialGuess	Initial guess for the parameters of the curve function. Vector of values for the starting point of the optimization.
FitType	(Optional) Price, Yield, or DurationWeightedPrice determines which is minimized in the curve fitting process. The default is DurationWeightedPrice.
UpperBound	(Optional) Lower bound for the parameters of the curve function.
LowerBound	(Optional) Upper bound for the parameters of the curve function.
OptOptions	(Optional) Optimization solver options constructed with optimoptions from the Optimization Toolbox (optimset is also supported).

### Description

`myfitoptions = IRFitOptions(InitialGuess,Name,Value)` constructs the `IRFitOptions` structure with an initial guess or with an initial guess and bounds. You must enter the optional arguments for `FitType`, `UpperBound`, `LowerBound`, and `OptOptions` as comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

---

**Note** `IRFitOptions` constructor must be used with `fitFunction` method when building a custom fitting function.

---

### Examples

```
myfitoptions = IRFitOptions([7 2 1 0], 'FitType', 'yield')
myfitoptions =
    Properties:
        FitType: 'yield'
        InitialGuess: [7 2 1 0]
```

```
UpperBound: []  
LowerBound: []  
OptOptions: []
```

## IRFunctionCurve

Construct interest-rate curve object from function handle or function and fit to market data

### Class

@IRFunctionCurve on page A-11

### Syntax

CurveObj = IRFunctionCurve(Type,Settle,FunctionHandle)

CurveObj = IRFunctionCurve(Type,Settle,FunctionHandle,Name,Value)

### Arguments

Type	Type of interest-rate curve: zero, forward, or discount.
Settle	Scalar for the Settle date of the curve.
Compounding	(Optional) Scalar that sets the compounding frequency per year for the IRFunctionCurve object: <ul style="list-style-type: none"> <li>• -1 = Continuous compounding</li> <li>• 1 = Annual compounding</li> <li>• 2 = Semiannual compounding (default)</li> <li>• 3 = Compounding three times per year</li> <li>• 4 = Quarterly compounding</li> <li>• 6 = Bimonthly compounding</li> <li>• 12 = Monthly compounding</li> </ul>

Basis	<p>(Optional) Day-count basis of the bond. A scalar of integers.</p> <ul style="list-style-type: none"> <li>• 0 = actual/actual (default)</li> <li>• 1 = 30/360 (SIA)</li> <li>• 2 = actual/360</li> <li>• 3 = actual/365</li> <li>• 4 = 30/360 (BMA)</li> <li>• 5 = 30/360 (ISDA)</li> <li>• 6 = 30/360 (European)</li> <li>• 7 = actual/365 (Japanese)</li> <li>• 8 = actual/actual (ICMA)</li> <li>• 9 = actual/360 (ICMA)</li> <li>• 10 = actual/365 (ICMA)</li> <li>• 11 = 30/360E (ICMA)</li> <li>• 12 = actual/365 (ISDA)</li> <li>• 13 = BUS/252</li> </ul> <p>For more information, see “Basis” on page 2-208.</p>
FunctionHandle	<p>Function handle that defines the interest-rate curve. The function handle requires one numeric input (time-to-maturity) and returns one numeric output (interest rate or discount factor). For more information on defining a function handle, see the MATLAB Programming Fundamentals documentation.</p>
Parameters	<p>Fitted parameters for function.</p>

## Description

`CurveObj = IRFunctionCurve(Type,Settle,FunctionHandle,Name,Value)` constructs an interest-rate curve object directly by specifying a function handle. You must enter the optional arguments for **Basis** and **Compounding** as comma-separated pairs of **Name,Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes. You can specify several name and value pair arguments in any order as **Name1,Value1,...,NameN,ValueN**.

After you use the `IRFunctionCurve` constructor to create an `IRFunctionCurve` object, you can fit the bond using the following methods.

Method	Description
<code>getForwardRates</code>	Returns forward rates for input dates.
<code>getZeroRates</code>	Returns zero rates for input dates.
<code>getDiscountFactors</code>	Returns discount factors for input dates.
<code>getParYields</code>	Returns par yields for input dates.
<code>toRateSpec</code>	<p>Converts to be a <code>RateSpec</code> object.</p> <p>This <code>RateSpec</code> structure is identical to the <code>RateSpec</code> produced by the function <code>intenvset</code>.</p>

Alternatively, you can construct an `IRFunctionCurve` object using the following static methods.

Static Method	Description
<code>fitNelsonSiegel</code>	Fits a Nelson-Siegel function to market data.
<code>fitSvensson</code>	Fits a Svensson function to market data.
<code>fitSmoothingSpline</code>	Fits a smoothing spline function to market data.
<code>fitFunction</code>	Fits a custom function to market data.

## Examples

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t))
```

```
irfc =
```

```

      Type: Forward
      Settle: 737406 (12-Dec-2018)
      Compounding: 2
      Basis: 0 (actual/actual)
```

### Introduced in R2008b

# liborduration

Duration of LIBOR-based interest-rate swap

## Syntax

```
[PayFixDuration,GetFixDuration] = liborduration(SwapFixRate,Tenor,Settle)
```

## Description

[PayFixDuration,GetFixDuration] = liborduration(SwapFixRate,Tenor,Settle) computes the duration of LIBOR-based interest-rate swaps.

## Examples

### Compute the Duration of LIBOR-Based Interest-Rate Swaps

This example shows how to compute the duration of LIBOR-based interest-rate swaps using the following data.

```
SwapFixRate = 0.0383;
Tenor = 7;
Settle = datenum('11-Oct-2002');
```

```
[PayFixDuration GetFixDuration] = liborduration(SwapFixRate,...
Tenor, Settle)
```

```
PayFixDuration = -4.7567
```

```
GetFixDuration = 4.7567
```

## Input Arguments

### SwapFixRate — Par swap fixed rate

vector in decimals

Par swap fixed rate (quarterly compounded), specified as an N-by-1 vector in decimals. The Basis should be actual/360.

Data Types: double

### Tenor — Swap tenor in years

vector

Swap tenor in years, specified as a N-by-1 vector. Fractional numbers are rounded upward.

Data Types: double

### Settle — Settlement date

vector

Settlement date, specified as an N-by-1 vector using serial date numbers.

Data Types: `double`

## Output Arguments

**PayFixDuration** — Modified duration, in years, for the pay-fix side of the swap  
vector

Modified duration, in years, for the pay-fix side of the swap, returned as a N-by-1 vector.

**GetFixDuration** — Modified duration, in years, for the receive-fix side of the swap  
vector

Modified duration, in years, for the receive-fix side of the swap, returned as a N-by-1 vector.

# liborfloat2fixed

Compute par fixed-rate of swap given 3-month LIBOR data

## Syntax

```
[FixedSpec, ForwardDates, ForwardRates] = liborfloat2fixed(ThreeMonthRates,
Settle, Tenor)
Price = liborprice(___, StartDate, Interpolation, ConvexAdj, RateParam, InArrears,
Sigma, FixedCompound, FixedBasis)
```

## Description

[FixedSpec, ForwardDates, ForwardRates] = liborfloat2fixed(ThreeMonthRates, Settle, Tenor) computes forward rates, dates, and the swap fixed rate.

---

**Note** The `liborfloat2fixed` function assumes that floating-rate observations occur quarterly on the third Wednesday of a delivery month. The first delivery month is the month of the first third Wednesday after `Settle`. Floating-side payments occur on the third-month anniversaries of observation dates. Fixed payments start on the same date as the first floating payment, and recur on the same date as the first-coupon date (on anniversary months).

---

`Price = liborprice(___, StartDate, Interpolation, ConvexAdj, RateParam, InArrears, Sigma, FixedCompound, FixedBasis)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Par Fixed-Rate of a Swap Given 3-Month LIBOR Data

This example shows how to compute the par fixed-rate of a swap given 3-month LIBOR data. Use the supplied `EDdata.xls` file as input to a `liborfloat2fixed` computation.

```
[EDFutData, textdata] = xlsread('EDdata.xls');
Settle                 = datenum('15-Oct-2002');
Tenor                  = 2;

[FixedSpec, ForwardDates, ForwardRates] = ...
liborfloat2fixed(EDFutData(:,1:3), Settle, Tenor)

FixedSpec = struct with fields:
    Coupon: 0.0222
    Settle: '16-Oct-2002'
    Maturity: '16-Oct-2004'
    Period: 4
    Basis: 1

ForwardDates = 8x1
```

```
731505
731596
731687
731778
731869
731967
732058
732149
```

ForwardRates = 8×1

```

0.0214
0.0248
0.0279
0.0305
```

## Input Arguments

**ThreeMonthRates** — Three-month Eurodollar futures data or forward rate agreement data matrix

Three-month Eurodollar futures data or forward rate agreement data, specified as an N-by-3 matrix in the form of [month year IMMQuote]. A forward rate agreement stipulates that a certain interest rate applies to a certain principal amount for a given future time period. The floating rate is assumed to compound quarterly and to accrue on an actual/360 basis.

Data Types: double

**Settle** — Settlement date of fixed-rate of swap  
scalar numeric

Settlement date of fixed-rate of swap, specified as a scalar numeric using serial date numbers.

Data Types: double

**Tenor** — Life of the swap contract  
scalar integer

Life of the swap contract, specified as a scalar integer.

Data Types: double

**StartDate** — Reference date for valuation of forward swap  
Settle (default) | scalar numeric

(Optional) Reference date for valuation of forward swap, specified as a scalar numeric using serial date numbers. This in effect allows forward swap valuation.

Data Types: double

**Interpolation — Interpolation method to determine applicable forward rate for months when no Eurodollar data is available**

'linear' (1) (default) | scalar integer with value of 0, 1, or 2

(Optional) Interpolation method to determine applicable forward rate for months when no Eurodollar data is available, specified as a scalar numeric with values of:

- 0 is 'nearest'
- 1 is 'linear'
- 2 is 'cubic'

Data Types: double

**ConvexAdj — Indicates whether futures/forward convexity adjustment is required**

0 (off) (default) | scalar logical with a value of 0 or 1

(Optional) Indicates whether futures/forward convexity adjustment is required, specified as a scalar logical. Use ConvexAdj for forward rate adjustments when those rates are taken from Eurodollar futures data.

Data Types: logical

**RateParam — Short-rate model's parameters (Hull-White)**

[0.05 0.015] (default) | vector

(Optional) Short-rate model's parameters (Hull-White), specified a 1-by-2 vector to denote the parameters  $[a \ S]$ , where the short-rate process is:

$$dr = [\theta(t) - ar]dt + Sdz.$$

Data Types: double

**InArrears — Indicates whether the swap is in arrears**

0 (off) (default) | scalar logical with a value of 0 or 1

(Optional) Indicates whether the swap is in arrears, specified as a scalar logical.

Data Types: logical

**Sigma — Overall annual volatility of caplets**

scalar numeric

(Optional) Overall annual volatility of caplets, specified as a scalar numeric.

Data Types: double

**FixedCompound — Compounding or frequency of payment on the fixed side**

4 (quarterly) (default) | scalar numeric with possible values of 1, 2, 4, or 12

(Optional) Compounding or frequency of payment on the fixed side, specified as a scalar numeric with one of the following possible values:

- 1 is annual
- 2 is semiannual

- 4 is quarterly
- 12 is monthly

Data Types: double

**FixedBasis — Basis of the fixed side**

0 (actual/actual ) (default) | scalar numeric

(Optional) Basis of the fixed side, specified as a scalar numeric using one of the supported values:.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

For more information, see “Basis” on page 2-208.

Data Types: double

**Output Arguments****FixedSpec — Structure of the fixed-rate side of the swap**

structure

Structure of the fixed-rate side of the swap, returned as a structure with the following fields:

- **Coupon:** Par-swap rate
- **Settle:** Start date
- **Maturity:** End date
- **Period:** Frequency of payment
- **Basis:** Accrual basis

**ForwardDates — Dates corresponding to ForwardRates**

numeric

Dates corresponding to `ForwardRates`, returned as serial date numbers. All of the dates are third Wednesdays of the month, spread three months apart. The first element is the third Wednesday immediately after `Settle`.

**ForwardRates — Forward rates corresponding to the forward dates**

numeric

Forward rates corresponding to the forward dates, quarterly compounded, and on the actual/360 basis, returned as numeric decimal values.

## liborprice

Price swap given swap rate

### Syntax

```
Price = liborprice(ThreeMonthRates,Settle,Tenor,SwapRate)
Price = liborprice(____,StartDate,Interpolation,ConvexAdj,RateParam,InArrears,
Sigma,FixedCompound,FixedBasis)
```

### Description

`Price = liborprice(ThreeMonthRates,Settle,Tenor,SwapRate)` computes the price per \$100 notional value of a swap given the swap rate. A positive result indicates that fixed side is more valuable than the floating side.

`Price = liborprice(____,StartDate,Interpolation,ConvexAdj,RateParam,InArrears, Sigma,FixedCompound,FixedBasis)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Price Per \$100 Notional Value of a Swap Given the Swap Rate

This example shows that a swap paying the par swap rate has a value of 0.

```
% load the input data
[EDFutData, textdata] = xlsread('EDdata.xls');
Settle = datenum('15-Oct-2002');
Tenor = 2;

% compute the fixed rate from the Eurodollar data
FixedSpec = liborfloat2fixed(EDFutData(:,1:3), Settle, Tenor)

FixedSpec = struct with fields:
    Coupon: 0.0222
    Settle: '16-Oct-2002'
    Maturity: '16-Oct-2004'
    Period: 4
    Basis: 1

% compute the price of a par swap
Price = liborprice(EDFutData(:,1:3), Settle, Tenor, FixedSpec.Coupon)

Price = 2.7756e-15

Price is effectively equal to 0.
```

## Input Arguments

### ThreeMonthRates — Three-month Eurodollar futures data or forward rate agreement data matrix

Three-month Eurodollar futures data or forward rate agreement data, specified as an N-by-3 matrix in the form of [month year IMMQuote]. A forward rate agreement stipulates that a certain interest rate applies to a certain principal amount for a given future time period. The floating rate is assumed to compound quarterly and to accrue on an actual/360 basis.

Data Types: double

### Settle — Settlement date of fixed-rate of swap

scalar numeric

Settlement date of fixed-rate of swap, specified as a scalar numeric using serial date numbers.

Data Types: double

### Tenor — Life of the swap contract

scalar integer

Life of the swap contract, specified as a scalar integer.

Data Types: double

### SwapRate — Swap rate

scalar decimal

Swap rate, specified as a scalar decimal.

Data Types: double

### StartDate — Reference date for valuation of forward swap

Settle (default) | scalar numeric

(Optional) Reference date for valuation of forward swap, specified as a scalar numeric using serial date numbers. This in effect allows forward swap valuation.

Data Types: double

### Interpolation — Interpolation method to determine applicable forward rate for months when no Eurodollar data is available

'linear' (1) (default) | scalar integer with value of 0, 1, or 2

(Optional) Interpolation method to determine applicable forward rate for months when no Eurodollar data is available, specified as a scalar numeric with values of:

- 0 is 'nearest'
- 1 is 'linear'
- 2 is 'cubic'

.

Data Types: double

**ConvexAdj — Indicates whether futures/forward convexity adjustment is required**

0 (off) (default) | scalar logical with a value of 0 or 1

(Optional) Indicates whether futures/forward convexity adjustment is required, specified as a scalar logical. Use ConvexAdj for forward rate adjustments when those rates are taken from Eurodollar futures data.

Data Types: logical

**RateParam — Short-rate model's parameters (Hull-White)**

[0.05 0.015] (default) | vector

(Optional) Short-rate model's parameters (Hull-White), specified a 1-by-2 vector to denote the parameters [a S], where the short-rate process is:

$$dr = [\theta(t) - ar]dt + Sdz.$$

Data Types: double

**InArrears — Indicates whether the swap is in arrears**

0 (off) (default) | scalar logical with a value of 0 or 1

(Optional) Indicates whether the swap is in arrears, specified as a scalar logical.

Data Types: logical

**Sigma — Overall annual volatility of caplets**

scalar numeric

(Optional) Overall annual volatility of caplets, specified as a scalar numeric.

Data Types: double

**FixedCompound — Compounding or frequency of payment on the fixed side**

4 (quarterly) (default) | scalar numeric with possible values of 1, 2, 4, or 12

(Optional) Compounding or frequency of payment on the fixed side, specified as a scalar numeric with one of the following possible values:

- 1 is annual
- 2 is semiannual
- 4 is quarterly
- 12 is monthly

Data Types: double

**FixedBasis — Basis of the fixed side**

0 (actual/actual ) (default) | scalar numeric

(Optional) Basis of the fixed side, specified as a scalar numeric using one of the supported values:.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365

- 4 = 30/360 (BMA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)

For more information, see “Basis” on page 2-208.

Data Types: `double`

## Output Arguments

**Price** — Present value of the difference between floating and fixed-rate sides of the swap per \$100 notional

`numeric`

Present value of the difference between floating and fixed-rate sides of the swap per \$100 notional, returned as a numeric value.

## mbscfamounts

Cash flow and time mapping for mortgage pool

### Syntax

```
[CFlowAmounts, CFlowDates, TFactors, Factors, Payment, Principal, Interest,
Prepayment] = mbscfamounts(Settle, Maturity, IssueDate, GrossRate)
[CFlowAmounts, CFlowDates, TFactors, Factors, Payment, Principal, Interest,
Prepayment] = mbscfamounts( ____, CouponRate, Delay, PrepaySpeed, PrepayMatrix)
```

### Description

[CFlowAmounts, CFlowDates, TFactors, Factors, Payment, Principal, Interest, Prepayment] = mbscfamounts(Settle, Maturity, IssueDate, GrossRate) computes cash flows between Settle and Maturity dates, the corresponding time factors in months from Settle and the mortgage factor (the fraction of loan principal outstanding).

---

**Note** Unlike mbspassthrough, mbscfamounts does not accept an original balance amount as an input. mbscfamounts assumes an original balance of 1.

---

[CFlowAmounts, CFlowDates, TFactors, Factors, Payment, Principal, Interest, Prepayment] = mbscfamounts( \_\_\_\_, CouponRate, Delay, PrepaySpeed, PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Calculate Cash Flow Amounts and Dates, Time Factors, and Mortgage Factors for a Single Mortgage

Given a mortgage with the following characteristics, compute the cash flow amounts and dates, the time factors, and the mortgage factors.

Define the mortgage characteristics.

```
Settle      = datenum('17-April-2002');
Maturity    = datenum('1-Jan-2030');
IssueDate   = datenum('1-Jan-2000');
GrossRate   = 0.08125;
CouponRate  = 0.075;
Delay       = 14;
PrepaySpeed = 100;
```

Use mbscfamounts to evaluate the mortgage.

```
[CFlowAmounts, CFlowDates, TFactors, Factors] = ...
mbscfamounts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)
```

```
CFlowAmounts = 1×334
```

```
-0.0033  0.0118  0.0120  0.0121  0.0120  0.0119  0.0119  0.0118  0.0117  0.0116
```

```
CFlowDates = 1×334
```

```
731323  731337  731368  731398  731429  731460  731490  731521
```

```
TFactors = 1×334
```

```
0  0.9333  1.9333  2.9333  3.9333  4.9333  5.9333  6.9333  7.9333  8.9333
```

```
Factors = 1×334
```

```
1.0000  0.9944  0.9887  0.9828  0.9769  0.9711  0.9653  0.9595  0.9538  0.9480
```

The result is contained in four 334-element row vectors.

### Compute Cash Flow Amounts and Dates, Time Factors, and Mortgage Factors for a Mortgage Portfolio

Given a portfolio of mortgage-backed securities, use `mbscfamounts` to compute the cash flows and other factors from the portfolio.

Define characteristics for a mortgage portfolio.

```
Settle = datenum(['13-Jan-2000'; '17-Apr-2002'; '17-May-2002']);
Maturity = datenum('1-Jan-2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = [0.075; 0.07875; 0.0775];
Delay = 14;
PrepaySpeed = 100;
```

Use `mbscfamounts` to evaluate the mortgage.

```
[CFlowAmounts, CFlowDates, TFactors, Factors] = ...
mbscfamounts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)
```

```
CFlowAmounts = 3×361
```

```
-0.0025  0.0071  0.0072  0.0074  0.0076  0.0077  0.0079  0.0080  0.0082  0.0084
-0.0035  0.0121  0.0123  0.0124  0.0123  0.0122  0.0122  0.0121  0.0120  0.0119
-0.0034  0.0122  0.0123  0.0123  0.0122  0.0121  0.0121  0.0120  0.0119  0.0118
```

```
CFlowDates = 3×361
```

```
730498  730517  730546  730577  730607  730638  730668  730699
731323  731337  731368  731398  731429  731460  731490  731521
```

```

731353      731368      731398      731429      731460      731490      731521      731551

TFactors = 3x361

      0      1.0667      2.0667      3.0667      4.0667      5.0667      6.0667      7.0667      8.0667      9.0667
      0      0.9333      1.9333      2.9333      3.9333      4.9333      5.9333      6.9333      7.9333      8.9333
      0      0.9333      1.9333      2.9333      3.9333      4.9333      5.9333      6.9333      7.9333      8.9333

```

```

Factors = 3x361

      1.0000      0.9992      0.9982      0.9970      0.9957      0.9942      0.9925      0.9907      0.9887      0.9867
      1.0000      0.9944      0.9887      0.9828      0.9769      0.9711      0.9653      0.9595      0.9538      0.9480
      1.0000      0.9942      0.9883      0.9824      0.9766      0.9707      0.9649      0.9592      0.9534      0.9476

```

Each output is a 3-by-361 element matrix padded with NaN's wherever elements are missing.

### Calculate Payment, Principal, Interest, and Prepayment for a Single Mortgage

Given a mortgage with the following characteristics, compute payments, principal, interest, and prepayment.

Define the mortgage characteristics.

```

Settle      = datenum('17-April-2002');
Maturity    = datenum('1-Jan-2030');
IssueDate   = datenum('1-Jan-2000');
GrossRate   = 0.08125;
CouponRate  = 0.075;
Delay       = 14;
PrepaySpeed = 100;

```

Use `mbscfamonts` to evaluate the mortgage.

```

[Payment, Principal, Interest, Prepayment] = ...
mbscfamonts(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, PrepaySpeed)

```

```

Payment = 1x334

      -0.0033      0.0118      0.0120      0.0121      0.0120      0.0119      0.0119      0.0118      0.0117      0.0116

```

```

Principal = 1x334

      731323      731337      731368      731398      731429      731460      731490      731521

```

```

Interest = 1x334

      0      0.9333      1.9333      2.9333      3.9333      4.9333      5.9333      6.9333      7.9333      8.9333

```

```

Prepayment = 1x334

```

1.0000 0.9944 0.9887 0.9828 0.9769 0.9711 0.9653 0.9595 0.9538 0.9480

## Input Arguments

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### IssueDate — Issue date

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### GrossRate — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### CouponRate — Net coupon rate

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### Delay — Delay (in days) between payment from homeowner and receipt by bondholder

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

### PrepaySpeed — Speed relative to PSA standard

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**  
matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

## Output Arguments

**CFlowAmounts — Cash flow amounts**  
matrix

Cash flows starting from `Settle` through end of the last month (`Maturity`), returned as a NMBS-by-P matrix.

**CFlowDates — Cash flow dates**  
matrix

Cash flow dates (including at `Settle`), returned as a NMBS-by-P matrix.

**TFactors — Time factors**  
matrix

Time factors (in months from `Settle`), returned as a NMBS-by-P matrix.

**Factors — Mortgage factors (the fraction of the balance still outstanding at the end of each month)**  
matrix

Mortgage factors (the fraction of the balance still outstanding at the end of each month), returned as a NMBS-by-P matrix.

**Payment — Total monthly payment**  
matrix

Total monthly payment, returned as a NMBS-by-P matrix.

**Principal — Principal portion of the payment**  
matrix

Principal portion of the payment, returned as a NMBS-by-P matrix.

**Interest — Interest portion of the payment**  
matrix

Interest portion of the payment, returned as a NMBS-by-P matrix.

**Prepayment — Unscheduled payment of principal**  
matrix

Unscheduled payment of principal, returned as a NMBS-by-P matrix.

## mbsconvp

Convexity of mortgage pool given price

### Syntax

```
Convexity = mbsconvp(Price,Settle,Maturity,IssueDate,GrossRate)
Convexity = mbsconvp( ____,CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

### Description

`Convexity = mbsconvp(Price,Settle,Maturity,IssueDate,GrossRate)` computes mortgage-backed security convexity, given time information, price at settlement, and optionally, a prepayment model.

`Convexity = mbsconvp( ____,CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute a Mortgage-Backed Security Convexity

This example shows how to compute a mortgage-backed security convexity, given a mortgage-backed security with the following characteristics.

```
Price      = 101;
Settle     = '15-Apr-2002';
Maturity   = '1 Jan 2030';
IssueDate  = '1-Jan-2000';
GrossRate  = 0.08125;
CouponRate = 0.075;
Delay      = 14;
Speed      = 100;
```

```
Convexity = mbsconvp(Price, Settle, Maturity, IssueDate, ...
GrossRate, CouponRate, Delay, Speed)
```

```
Convexity = 71.6299
```

### Input Arguments

#### Price — Clean price for every \$100 face value

vector

Clean price for every \$100 face value, specified as an NMBS-by-1 vector.

Data Types: double

**Settle — Settlement dates**

vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**Maturity — Maturity dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**IssueDate — Issue dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**GrossRate — Gross coupon rate (including fees)**

vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**Delay — Delay in days**

0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

## Output Arguments

### **Convexity — Periodic convexity of mortgage pool**

scalar numeric

Periodic convexity of mortgage pool, returned as a scalar numeric.

# mbsconvy

Convexity of mortgage pool given yield

## Syntax

```
Convexity = mbsconvy(Yield,Settle,Maturity,IssueDate,GrossRate)
Convexity = mbsconvy( ____,CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

## Description

`Convexity = mbsconvy(Yield,Settle,Maturity,IssueDate,GrossRate)` computes mortgage-backed security convexity, given time information, semiannual mortgage yield, and optionally, a prepayment model.

`Convexity = mbsconvy( ____,CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Convexity of a Mortgage Pool Given Yield

This example shows how to compute the convexity of mortgage pool given yield for a mortgage-backed security with the following characteristics.

```
Yield      = 0.07125;
Settle     = '15-Apr-2002';
Maturity   = '1 Jan 2030';
IssueDate  = '1-Jan-2000';
GrossRate  = 0.08125;
Speed      = 100;
CouponRate = 0.075;
Delay      = 14;
```

```
Convexity = mbsconvy(Yield, Settle, Maturity, IssueDate, ...
GrossRate, CouponRate, Delay, Speed)
```

```
Convexity = 72.8263
```

## Input Arguments

### Yield — Mortgage yield, compounded monthly

vector

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

**Settle — Settlement dates**

vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | cell

**Maturity — Maturity dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**IssueDate — Issue dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**GrossRate — Gross coupon rate (including fees)**

vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**Delay — Delay in days**

0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the **PrepaySpeed** to [] if you input a customized **PrepayMatrix**.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size  $\max(\text{TermRemaining})$ -by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

## Output Arguments

### **Convexity — Periodic convexity of mortgage pool**

scalar numeric

Periodic convexity of mortgage pool, returned as a scalar numeric.

## mbsdurp

Duration of mortgage pool given price

### Syntax

```
[YearDuration,ModDuration] = mbsdurp(Price,Settle,Maturity,IssueDate,
GrossRate)
[YearDuration,ModDuration] = mbsdurp( ____,CouponRate,Delay,PrepaySpeed,
PrepayMatrix)
```

### Description

[YearDuration,ModDuration] = mbsdurp(Price,Settle,Maturity,IssueDate, GrossRate) computes the mortgage-backed security Macaulay (YearDuration) in years and modified (ModDuration) durations in years, given time information, price at settlement, and optionally, a prepayment model.

[YearDuration,ModDuration] = mbsdurp( \_\_\_\_,CouponRate,Delay,PrepaySpeed, PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Find the Duration of a Mortgage Pool

This example shows how to find the duration of mortgage pool given a mortgage-backed security with the following characteristics.

```
Price = 101;
Settle = datenum('15-Apr-2002');
Maturity = datenum('1 Jan 2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = 0.075;;
Delay = 14;
Speed = 100;
```

```
[YearDuration, ModDuration] = mbsdurp(Price, Settle, Maturity,...
IssueDate, GrossRate, CouponRate, Delay, Speed)
```

```
YearDuration = 6.4380
```

```
ModDuration = 6.2080
```

### Input Arguments

**Price** — Clean price for every \$100 face of issue

vector

Clean price for every \$100 face of issue, specified as an NMBS-by-1 vector.

Data Types: double

### **Settle — Settlement dates**

vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | cell

### **Maturity — Maturity dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

### **IssueDate — Issue dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

### **GrossRate — Gross coupon rate (including fees)**

vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

### **CouponRate — Net coupon rate**

GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

### **Delay — Delay in days**

0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

### **PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

**Output Arguments****YearDuration — Macaulay duration in years**

scalar numeric

Macaulay duration in years, returned as a scalar numeric.

**ModDuration — Modified duration in years**

scalar numeric

Modified duration in years, returned as a scalar numeric.

# mbsdury

Duration of mortgage pool given yield

## Syntax

```
[YearDuration,ModDuration] = mbsdury(Yield,Settle,Maturity,IssueDate,
GrossRate)
[YearDuration,ModDuration] = mbsdury( ____,CouponRate,Delay,PrepaySpeed,
PrepayMatrix)
```

## Description

[YearDuration,ModDuration] = mbsdury(Yield,Settle,Maturity,IssueDate, GrossRate) computes the mortgage-backed security Macaulay (YearDuration) in years and modified (ModDuration) durations in years, given time information, yield to maturity, and optionally, a prepayment model.

[YearDuration,ModDuration] = mbsdury( \_\_\_\_,CouponRate,Delay,PrepaySpeed, PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Find the Duration of a Mortgage Pool Given the Yield

This example shows how to find the duration of mortgage pool given a mortgage-backed security with the following characteristics.

```
Yield = 0.07298413;
Settle = '15-Apr-2002';
Maturity = '1 Jan 2030';
IssueDate = '1-Jan-2000';
GrossRate = 0.08125;
Speed = 100;
CouponRate = 0.075;
Delay = 14;
```

```
[YearDuration, ModDuration] = mbsdury(Yield, Settle, Maturity,...
IssueDate, GrossRate, CouponRate, Delay, Speed)
```

```
YearDuration = 6.4380
```

```
ModDuration = 6.2080
```

## Input Arguments

**Yield** — Mortgage yield, compounded monthly  
vector

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

**Settle — Settlement dates**

vector

Settlement dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | cell

**Maturity — Maturity dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**IssueDate — Issue dates**

vector

Maturity dates, specified as an NMBS-by-1 vector of serial date numbers or a cell array of character vectors.

Data Types: double | cell

**GrossRate — Gross coupon rate (including fees)**

vector

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of numeric decimals.

Data Types: double

**Delay — Delay in days**

0 (no delay) (default) | vector

(Optional) Delay in days, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the **PrepaySpeed** to [] if you input a customized **PrepayMatrix**.

---

Data Types: double

## **PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

## **Output Arguments**

### **YearDuration — Macaulay duration in years**

scalar numeric

Macaulay duration in years, returned as a scalar numeric.

### **ModDuration — Modified duration in years**

scalar numeric

Modified duration in years, returned as a scalar numeric.

## mbsnoprepay

End-of-month mortgage cash flows and balances without prepayment

### Syntax

```
[Balance,Interest,Payment,Principal] = mbsnoprepay(OriginalBalance,GrossRate,Term)
```

### Description

[Balance,Interest,Payment,Principal] = mbsnoprepay(OriginalBalance,GrossRate,Term) computes end-of-month mortgage balance, interest payments, principal payments, and cash flow payments with zero prepayment rate.

mbsnoprepay returns amortizing cash flows and balances over a specified term with no prepayment. When the lengths of pass-throughs are not the same, MATLAB software pads the shorter ones with NaN.

### Examples

#### Compute an Amortization Schedule from Mortgage Pools

Given mortgage pools with the following characteristics, compute an amortization schedule.

```
OriginalBalance = 400000000;
CouponRate = 0.08125;
Term = [357; 355]; % Three- and five-month old mortgage pools.
```

```
[Balance, Interest, Payment, Principal] = mbsnoprepay(OriginalBalance, CouponRate, Term)
```

```
Balance = 357×2

## Input Arguments

### **OriginalBalance** — Original face value in dollars

vector

Original face value in dollars, specified as a table or an NUMOBS-by-1 matrix.

Data Types: double

### **GrossRate** — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an NUMOBS-by-1 vector of decimal values.

Data Types: double

**Term — Term of the mortgage in months**

vector

Term of the mortgage in months, specified as an NUMOBS-by-1 vector.

Data Types: double

**Output Arguments****Balance — End-of-month balances over the life of the pass-through**

vector

End-of-month balances over the life of the pass-through, returned as a Term-by-1 vector.

**Interest — End-of-month interest payments over the life of the pass-through**

vector

End-of-month interest payments over the life of the pass-through, returned as a Term-by-1 vector.

**Payment — End-of-month payments over the life of the pass-through**

vector

End-of-month payments over the life of the pass-through, returned as a Term-by-1 vector.

**Principal — All scheduled end-of-month principal payments over the life of the pass-through**

vector

All scheduled end-of-month principal payments over the life of the pass-through, returned as a Term-by-1 vector.

# mbsoas2price

Price given option-adjusted spread

## Syntax

```
Price = mbsoas2price(ZeroCurve,OAS,Settle,Maturity,IssueDate,GrossRate)
Price = mbsoas2price( ____,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

## Description

Price = mbsoas2price(ZeroCurve,OAS,Settle,Maturity,IssueDate,GrossRate) computes the clean price of a pass-through security for each \$100 face value of outstanding principal.

Price = mbsoas2price( \_\_\_\_,CouponRate,Delay,Interpolation,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Theoretical Price of a Mortgage Pool

Given an option-adjusted spread, a spot curve, and a prepayment assumption, compute theoretical price of a mortgage pool. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002') 0      100 0 2 1;
          datenum('02/20/2003') 0      100 0 2 1;
          datenum('07/31/2004') 0.03   100 2 3 1;
          datenum('08/15/2007') 0.035  100 2 3 1;
          datenum('08/15/2012') 0.04875 100 2 3 1;
          datenum('02/15/2031') 0.05375 100 2 3 1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices = [ 98.97467;
           98.58044;
           100.10534;
           98.18054;
           101.38136;
           99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
105 ×
```

```
    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
OAS           = [26.0502; 28.6348; 31.2222];
Maturity      = datenum('02-Jan-2030');
IssueDate    = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay        = 14;
Interpolation = 1;
PrepaySpeed   = [0 50 100];
```

Calculate the theoretical price from the option-adjusted spread.

```
Price = mbsoas2price(ZeroCurve, OAS, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Interpolation, ...
PrepaySpeed)
```

```
Price = 3×1
```

```
    124.7133
    120.9534
    118.0698
```

## Input Arguments

### ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003') 0.0154 12;
 datenum('1-Jan-2004') 0.0250 12;
```

```
.....
datenum('1-Jan-2020') 0.0675 2];
```

Data Types: double | char | cell

### **OAS — Option-adjusted spreads**

vector

Option-adjusted spreads, in basis points, specified as an NMBS-by-1 vector.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the `PrepaySpeed` to [] if you input a customized `PrepayMatrix`.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

**Output Arguments****Price — Clean price of passthrough per \$100 face of principal outstanding**

vector

Clean price of passthrough per \$100 face of principal outstanding, returned as a NMBS-by-1 vector.

## mbsoas2yield

Yield given option-adjusted spread

### Syntax

```
[MYield,BEMBSYield] = mbsoas2yield(ZeroCurve,OAS,Settle,Maturity,IssueDate,
GrossRate)
[MYield,BEMBSYield] = mbsoas2yield( ____,CouponRate,Delay,Interpolation,
PrepaySpeed,PrepayMatrix)
```

### Description

[MYield,BEMBSYield] = mbsoas2yield(ZeroCurve,OAS,Settle,Maturity,IssueDate, GrossRate) computes the mortgage and bond-equivalent yields of a pass-through security.

[MYield,BEMBSYield] = mbsoas2yield( \_\_\_\_,CouponRate,Delay,Interpolation, PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute the Theoretical Yield to Maturity of a Mortgage Pool

Given an option-adjusted spread, a spot curve, and a prepayment assumption, compute the theoretical yield to maturity of a mortgage pool. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002') 0      100 0 2 1;
          datenum('02/20/2003') 0      100 0 2 1;
          datenum('07/31/2004') 0.03   100 2 3 1;
          datenum('08/15/2007') 0.035   100 2 3 1;
          datenum('08/15/2012') 0.04875 100 2 3 1;
          datenum('02/15/2031') 0.05375 100 2 3 1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices = [ 98.97467;
           98.58044;
           100.10534;
           98.18054;
           101.38136;
           99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
105 ×
```

```
7.3154    0.0000    0.0000
7.3163    0.0000    0.0000
7.3216    0.0000    0.0000
7.3327    0.0000    0.0000
7.3510    0.0000    0.0000
7.4185    0.0000    0.0000
```

Assign the following parameters:

```
OAS          = [26.0502; 28.6348; 31.2222];
Maturity     = datenum('02-Jan-2030');
IssueDate    = datenum('02-Jan-2000');
GrossRate    = 0.08125;
CouponRate   = 0.075;
Delay        = 14;
Interpolation = 1;
PrepaySpeed  = [0 50 100];
```

Compute the mortgage yield and bond equivalent mortgage yield.

```
[MYield BEMBSYield] = mbssoas2yield(ZeroCurve, OAS, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, ...
Interpolation, PrepaySpeed)
```

```
MYield = 3×1
```

```
0.0527
0.0513
0.0499
```

```
BEMBSYield = 3×1
```

```
0.0533
0.0518
0.0504
```

## Input Arguments

### ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).

- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003') 0.0154 12;
 datenum('1-Jan-2004') 0.0250 12;
 .....
 datenum('1-Jan-2020') 0.0675 2];
```

Data Types: double | char | cell

### **OAS — Option-adjusted spreads**

vector

Option-adjusted spreads, in basis points, specified as an NMBS-by-1 vector.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the `PrepaySpeed` to [] if you input a customized `PrepayMatrix`.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

**Output Arguments****MYield — Yield to maturity of the mortgage-backed security**

vector

Yield to maturity of the mortgage-backed security, returned as a NMBS-by-1 vector. This yield is compounded monthly (12 times a year).

**BEMBSYield — Bond equivalent yield of the mortgage-backed security**

vector

Bond equivalent yield of the mortgage-backed security, returned as a NMBS-by-1 vector. This yield is compounded semiannually (two times a year).

# mbspassthrough

Mortgage pool cash flows and balances with prepayment

## Syntax

```
[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough(
OriginalBalance,GrossRate,OriginalTerm)
[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough( ____,
TermRemaining,PrepaySpeed,PrepayMatrix)
```

## Description

[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough(OriginalBalance,GrossRate,OriginalTerm) calculates mortgage pool cash flows and balances with prepayments.

If a standard (PSA) prepayment is specified, "aging" is applied to standard prepayment vector. Aging is the same amount as the age of the pool (OriginalTerm - TermRemaining).

[Balance,Payment,Principal,Interest,Prepayment] = mbspassthrough( \_\_\_\_, TermRemaining,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute the Cash Flow of Principal, Interest, and Prepayment of a Pass-Through Security

This example shows how to compute the cash flows and balances of a 3-month old mortgage pool with original term of 360 months, assuming a prepayment speed of 100.

```
OriginalBalance = 100000;
GrossRate = 0.08125;
OriginalTerm = 360;
TermRemaining = 357;
PrepaySpeed = 100;
```

```
[Balance, Payment, Principal, Interest, Prepayment] =...
mbpassthrough(OriginalBalance, GrossRate, OriginalTerm,...
TermRemaining, PrepaySpeed)

## Input Arguments

### **OriginalBalance** — Original balance value in dollars

vector

Original balance value in dollars (balance at the beginning of each `TermRemaining`), specified as an NMBS-by-1 vector.

Data Types: double

### **GrossRate** — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **OriginalTerm** — Term of the mortgage in months

vector

Term of the mortgage in months, specified as an NMBS-by-1 vector.

Data Types: double

### **TermRemaining** — Number of full months between settlement and maturity

`OriginalTerm` (default) | vector

(Optional) Number of full months between settlement and maturity, specified as an NMBS-by-1 vector. For this argument, "full months" means not including fractional first term (if there is one).

Data Types: double

### **PrepaySpeed** — Speed relative to PSA standard

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

---

Data Types: double

### **PrepayMatrix** — Customized prepayment vector

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)-by-NMBS`. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: `double`

## Output Arguments

### **Balance — Principal balance at end of month**

vector

Principal balance at end of month, returned as a `TermRemaining-by-1` vectors of end-of-month values.

### **Payment — Total monthly payment**

vector

Total monthly payment, returned as a `TermRemaining-by-1` vectors of end-of-month values.

### **Principal — Principal portion of the payment**

vector

Principal portion of the payment, returned as a `TermRemaining-by-1` vectors of end-of-month values.

### **Interest — Interest portion of the payment**

vector

Interest portion of the payment, returned as a `TermRemaining-by-1` vectors of end-of-month values.

### **Prepayment — Unscheduled principal payment**

vector

Unscheduled principal payment, returned as a `TermRemaining-by-1` vectors of end-of-month values.

# mbsprice

Mortgage-backed security price given yield

## Syntax

```
[Price,AccrInt] = mbsprice(Yield,Settle,Maturity,IssueDate,GrossRate)
[Price,AccrInt] = mbsprice( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

## Description

[Price,AccrInt] = mbsprice(Yield,Settle,Maturity,IssueDate,GrossRate) computes a mortgage-backed security price, given time information and mortgage yield at settlement.

[Price,AccrInt] = mbsprice( \_\_\_ CouponRate,Delay,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Determine the Mortgage-Backed Security Price Given the Yield

This example shows how to determine the mortgage-backed security price given a mortgage-backed security with the following characteristics.

```
Yield = 0.0725;
Settle = datenum('15-Apr-2002');
Maturity = datenum('1 Jan 2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;
```

```
[Price AccrInt] = mbsprice(Yield, Settle, Maturity, IssueDate,...
GrossRate, CouponRate, Delay, Speed)
```

```
Price = 101.3147
```

```
AccrInt = 0.2917
```

### Determine the Mortgage-Backed Security Price Using a Customized PrePaytMatrix

This example shows how to determine the mortgage-backed security price, given a mortgage-backed security, and PrePaytMatrix with the following characteristics:

```
Yield = 0.0725;
Settle = datenum('15-Apr-2002');
Maturity = datenum('1 Jan 2030');
```

```
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
PrepayMatrix = 0.005*ones(360,1);

[Price AccrInt] = mbsprice(Yield, Settle, Maturity, IssueDate,...
GrossRate, PrepayMatrix)

## Input Arguments

### Yield — Mortgage yield compounded monthly

vector of decimal values

Mortgage yield compounded monthly, specified as an NMBS-by-1 vector using decimal values.

Data Types: `double`

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: `double` | `char` | `cell`

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

## Output Arguments

### **Price — Clean price for every \$100 face value of the securities**

vector

Clean price for every \$100 face value of the securities, returned as a NMBS-by-1 vector.

### **AccrInt — Accrued interest of the mortgage-backed securities**

vector

Accrued interest of the mortgage-backed securities, returned as a NMBS-by-1 vector.

# mbsprice2oas

Option-adjusted spread given price

## Syntax

```
OAS = mbsprice2oas(ZeroCurve,Price,Settle,Maturity,IssueDate,GrossRate)
OAS = mbsprice2oas( ____,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

## Description

OAS = mbsprice2oas(ZeroCurve,Price,Settle,Maturity,IssueDate,GrossRate) computes the option-adjusted spread in basis points.

OAS = mbsprice2oas( \_\_\_\_,CouponRate,Delay,Interpolation,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Calculate the Option-Adjusted Spread of a 30-Year Fixed-Rate Mortgage

Calculate the option-adjusted spread of a 30-year fixed-rate mortgage with about a 28-year weighted average maturity remaining, given assumptions of 0, 50, and 100 PSA prepayments. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002') 0      100 0 2 1;
          datenum('02/20/2003') 0      100 0 2 1;
          datenum('07/31/2004') 0.03   100 2 3 1;
          datenum('08/15/2007') 0.035  100 2 3 1;
          datenum('08/15/2012') 0.04875 100 2 3 1;
          datenum('02/15/2031') 0.05375 100 2 3 1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices = [ 98.97467;
           98.58044;
           100.10534;
           98.18054;
           101.38136;
           99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
105 ×
```

```
    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
Price          = 95;
Maturity       = datenum('02-Jan-2030');
IssueDate     = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay         = 14;
Interpolation = 1;
PrepaySpeed   = [0; 50; 100];
Interpolation = 1;
```

Compute the option-adjusted spread.

```
OAS = mbsprice2oas(ZeroCurve, Price, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Interpolation, ...
PrepaySpeed)
```

```
OAS = 3×1
```

```
    26.0508
    28.6355
    31.2232
```

## Input Arguments

### ZeroCurve – Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003') 0.0154 12;
 datenum('1-Jan-2004') 0.0250 12;
```

```
.....
datenum('1-Jan-2020') 0.0675 2];
```

Data Types: double | char | cell

**Price — Clean price for every \$100 face value of bond issue**

vector

Clean price for every \$100 face value of bond issue, specified as an NMBS-by-1 vector.

Data Types: double

**Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

**Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the `PrepaySpeed` to [] if you input a customized `PrepayMatrix`.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

**Output Arguments****OAS — Zero volatility OAS**

vector

Zero volatility OAS, in basis point (bp), returned as a NMBS-by-1 vector.

## mbsprice2speed

Implied PSA prepayment speeds given price

### Syntax

```
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsprice2speed(Price, Settle, Maturity,
IssueDate, GrossRate, PrepayMatrix)
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsprice2speed( ____, CouponRate, Delay)
```

### Description

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsprice2speed(Price, Settle, Maturity, IssueDate, GrossRate, PrepayMatrix) computes PSA prepayment speeds implied by pool prices and projected (user-defined) prepayment vectors. The calculated PSA speed produces the same price, modified duration, or modified convexity, depending upon the output requested.

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsprice2speed( \_\_\_\_, CouponRate, Delay) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Compute PSA Prepayment Speeds

This example shows how to compute the equivalent PSA benchmark prepayment speeds for a mortgage pool with the following characteristics and prepayment matrix.

```
Price          = 101;
Settle         = datenum('1-Jan-2000');
Maturity       = datenum('1-Jan-2030');
IssueDate     = datenum('1-Jan-2000');
GrossRate     = 0.08125;
PrepayMatrix  = 0.005*ones(360,1);
CouponRate    = 0.075;
Delay         = 14;
```

```
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = ...
mbsprice2speed(Price, Settle, Maturity, IssueDate, ...
GrossRate, PrepayMatrix, CouponRate, Delay)
```

```
ImpSpdOnPrc = 118.5980
```

```
ImpSpdOnDur = 118.3946
```

```
ImpSpdOnCnv = 109.5115
```

## Input Arguments

### Price — Clean price for every \$100 face value

vector

Clean price for every \$100 face value, specified as an NMBS-by-1 vector.

Data Types: double

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### IssueDate — Issue date

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### GrossRate — Gross coupon rate (including fees)

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### PrepayMatrix — Customized prepayment vector

matrix

Customized prepayment vector, specified as a NaN-padded matrix of size  $\max(\text{TermRemaining})$ -by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use **PrepayMatrix** only when **PrepaySpeed** is unspecified.

---

Data Types: double

### CouponRate — Net coupon rate

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

## Output Arguments

**ImpSpd0nPrc — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price, returned as a NMBS-by-1 vector.

**ImpSpd0nDur — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration, returned as a NMBS-by-1 vector.

**ImpSpd0nCnv — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity, returned as a NMBS-by-1 vector.

# mbswal

Weighted average life of mortgage pool

## Syntax

```
WAL = mbswal(Settle,Maturity,IssueDate,GrossRate)
WAL = mbswal( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

## Description

`WAL = mbswal(Settle,Maturity,IssueDate,GrossRate)` computes the weighted average life, in number of years, of a mortgage pool, as measured from the settlement date.

`WAL = mbswal( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)` specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Determine the Weighted Average Life of a Mortgage Pool

This example shows how to determine the weighted average life of a mortgage pool, given a pass-through security with the following characteristics.

```
Settle = datenum('15-Apr-2002');
Maturity = datenum('1 Jan 2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;
```

```
WAL = mbswal(Settle, Maturity, IssueDate, GrossRate, ...
CouponRate, Delay, Speed)
```

```
WAL = 10.5477
```

## Input Arguments

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. `Settle` must be earlier than `Maturity`.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

## Output Arguments

### **WAL — Weighted Average Life of MBS, in number of years**

vector

Weighted Average Life (WAL) of MBS, in number of years, returned as a NMBS-by-1 vector.

## mbsyield

Mortgage-backed security yields given price

### Syntax

```
[MYield,BEMBSYield] = mbsyield(Price,Settle,Maturity,IssueDate,GrossRate)
[MYield,BEMBSYield] = mbsyield( ___ CouponRate,Delay,PrepaySpeed,PrepayMatrix)
```

### Description

[MYield,BEMBSYield] = mbsyield(Price,Settle,Maturity,IssueDate,GrossRate) computes a mortgage-backed security yield to maturity and the bond equivalent yield, given time information, and price at settlement.

[MYield,BEMBSYield] = mbsyield( \_\_\_ CouponRate,Delay,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Determine a Mortgage-Backed Security Yield Given the Price

This example shows how to determine the mortgage-backed security yield, given a mortgage-backed security with the following characteristics.

```
Price = 102;
Settle = '15-Apr-2002';
Maturity = '1 Jan 2030';
IssueDate = '1-Jan-2000';
GrossRate = 0.08125;
CouponRate = 0.075;
Delay = 14;
Speed = 100;

[MYield, BEMBSYield] = mbsyield(Price, Settle, Maturity, ...
IssueDate, GrossRate, CouponRate, Delay, Speed)

MYield = 0.0715
BEMBSYield = 0.0725
```

#### Determine Multiple Mortgage-Backed Securities Yields Given the Price

This example shows how to determine multiple mortgage-backed securities yields, given a portfolio of mortgage-backed securities with the following characteristics.

```
Price = 102;
Settle = datenum(['13-Feb-2000';'17-Apr-2002';'17-May-2002';...])
```

```

'13-Jan-2000']);
Maturity = datenum('1-Jan-2030');
IssueDate = datenum('1-Jan-2000');
GrossRate = 0.08125;
CouponRate = [0.075; 0.07875; 0.0775; 0.08125];
Delay = 14;
Speed = 100;

[MYield, BEMBSYield] = mbsyield(Price, Settle, Maturity,...
IssueDate, GrossRate, CouponRate, Delay, Speed)

MYield = 4×1

    0.0717
    0.0751
    0.0739
    0.0779

BEMBSYield = 4×1

    0.0728
    0.0763
    0.0750
    0.0791

```

## Input Arguments

### Price — Clean price for every \$100 face value

vector

Clean price for every \$100 face value, specified as an NMBS-by-1 vector.

Data Types: double

### Settle — Settlement date

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### Maturity — Maturity date

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### IssueDate — Issue date

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

**GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

**PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the PrepaySpeed to [] if you input a customized PrepayMatrix.

---

Data Types: double

**PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size  $\max(\text{TermRemaining})$ -by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use PrepayMatrix only when PrepaySpeed is unspecified.

---

Data Types: double

**Output Arguments****MYield — Yield to maturity of the mortgage-backed security**

vector

Yield to maturity of the mortgage-backed security, returned as a NMBS-by-1 vector. This yield is compounded monthly (12 times a year).

**BEMBSYield — Bond equivalent yield of the mortgage-backed security**

vector

Bond equivalent yield of the mortgage-backed security, returned as a NMBS-by-1 vector. This yield is compounded semiannually (two times a year).

## mbsyield2oas

Option-adjusted spread given yield

### Syntax

```
OAS = mbsyield2oas(ZeroCurve,Yield,Settle,Maturity,IssueDate,GrossRate)
OAS = mbsyield2oas( ____,CouponRate,Delay,Interpolation,PrepaySpeed,
PrepayMatrix)
```

### Description

OAS = mbsyield2oas(ZeroCurve,Yield,Settle,Maturity,IssueDate,GrossRate) computes option-adjusted spread in basis points.

OAS = mbsyield2oas( \_\_\_\_,CouponRate,Delay,Interpolation,PrepaySpeed,PrepayMatrix) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Calculate the Option-Adjusted Spread of a 30-Year Fixed-Rate Mortgage Pool

Calculate the option-adjusted spread of a 30-year, fixed-rate mortgage pool with about 28-year weighted average maturity left, given assumptions of 0, 50, and 100 PSA prepayments. First, create the bonds matrix:

```
Bonds = [datenum('11/21/2002') 0      100 0 2 1;
          datenum('02/20/2003') 0      100 0 2 1;
          datenum('07/31/2004') 0.03   100 2 3 1;
          datenum('08/15/2007') 0.035  100 2 3 1;
          datenum('08/15/2012') 0.04875 100 2 3 1;
          datenum('02/15/2031') 0.05375 100 2 3 1];
```

Choose a settlement date.

```
Settle = datenum('20-Aug-2002');
```

Assume the following clean prices for the bonds:

```
Prices = [ 98.97467;
           98.58044;
           100.10534;
           98.18054;
           101.38136;
           99.25411];
```

Use the following formula to compute spot compounding for the bonds:

```
SpotCompounding = 2*ones(size(Prices));
```

Compute the zero curve.

```
[ZeroRatesP, CurveDatesP] = zbtprice(Bonds, Prices, Settle);
ZeroCurve = [CurveDatesP, ZeroRatesP, SpotCompounding]
```

```
ZeroCurve = 6×3
105 ×
```

```
    7.3154    0.0000    0.0000
    7.3163    0.0000    0.0000
    7.3216    0.0000    0.0000
    7.3327    0.0000    0.0000
    7.3510    0.0000    0.0000
    7.4185    0.0000    0.0000
```

Assign the following parameters:

```
Price          = 95;
Maturity       = datenum('02-Jan-2030');
IssueDate     = datenum('02-Jan-2000');
GrossRate     = 0.08125;
CouponRate    = 0.075;
Delay         = 14;
Interpolation = 1;
PrepaySpeed   = [0 50 100];
```

Compute the yield, and from the yield, compute the option-adjusted spread.

```
[mbsyld, beyld] = mbsyield(Price, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, PrepaySpeed);
```

```
OAS = mbsyield2oas(ZeroCurve, mbsyld, Settle, ...
Maturity, IssueDate, GrossRate, CouponRate, Delay, ...
Interpolation, PrepaySpeed)
```

```
OAS = 3×1
```

```
    26.0508
    28.6355
    31.2232
```

## Input Arguments

### ZeroCurve — Zero curve

matrix

Zero curve, specified as a three-column matrix, where:

- Column 1 is serial date numbers.
- Column 2 is spot rates with maturities corresponding to the dates in Column 1, in decimal (for example, 0.075).
- Column 3 is the compounding value of the rates in Column 2. (This is the agency spot rate on the settlement date.) Allowable compounding values are: 1 (annual), 2 (semiannual), 3 (three times per year), 4 (quarterly), 6 (bimonthly), 12 (monthly), and -1 (continuous).

For example:

```
[datenum('1-Jan-2003') 0.0154 12;  
datenum('1-Jan-2004') 0.0250 12;  
.....  
datenum('1-Jan-2020') 0.0675 2];
```

Data Types: double | char | cell

### **Yield — Mortgage yield, compounded monthly**

vector in decimals

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **CouponRate — Net coupon rate**

GrossRate (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

### **Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: double

### **PrepaySpeed — Speed relative to PSA standard**

0 (no prepayment) (default) | vector

(Optional) Speed relative to PSA standard, specified as an NMBS-by-1 vector. The PSA standard is 100.

---

**Note** Set the `PrepaySpeed` to `[]` if you input a customized `PrepayMatrix`.

---

Data Types: double

### **PrepayMatrix — Customized prepayment vector**

matrix

(Optional) Customized prepayment vector, specified as a NaN-padded matrix of size `max(TermRemaining)`-by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use `PrepayMatrix` only when `PrepaySpeed` is unspecified.

---

Data Types: double

## **Output Arguments**

### **OAS — Zero volatility OAS**

vector

Zero volatility OAS, in basis point (bp), returned as a NMBS-by-1 vector.

# mbsyield2speed

Implied PSA prepayment speeds given yield

## Syntax

```
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsyield2speed(Yield, Settle, Maturity,
IssueDate, GrossRate, PrepayMatrix)
[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsyield2speed( ____, CouponRate, Delay)
```

## Description

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsyield2speed(Yield, Settle, Maturity, IssueDate, GrossRate, PrepayMatrix) computes PSA prepayment speeds implied by pool yields and projected (user-defined) prepayment vectors. The calculated PSA speed produces the same yield, modified duration, or modified convexity, depending upon the output requested.

[ImpSpdOnPrc, ImpSpdOnDur, ImpSpdOnCnv] = mbsyield2speed( \_\_\_\_, CouponRate, Delay) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

## Examples

### Compute PSA Prepayment Speeds

Calculate the equivalent PSA benchmark prepayment speeds for a security with these characteristics and prepayment matrix.

```
Yield          = 0.065;
Settle         = datenum('1-Jan-2000');
Maturity       = datenum('1-Jan-2030');
IssueDate      = datenum('1-Jan-2000');
GrossRate     = 0.08125;
PrepayMatrix  = 0.005*ones(360,1);
CouponRate    = 0.075;
Delay         = 14;
```

```
[ImpSpdOnYld, ImpSpdOnDur, ImpSpdOnCnv] = ...
mbsyield2speed(Yield, Settle, Maturity, IssueDate, GrossRate, ...
PrepayMatrix, CouponRate, Delay)
```

```
ImpSpdOnYld = 117.7644
```

```
ImpSpdOnDur = 116.7436
```

```
ImpSpdOnCnv = 108.3309
```

## Input Arguments

### **Yield — Mortgage yield, compounded monthly**

vector in decimals

Mortgage yield, compounded monthly, specified as an NMBS-by-1 vector in decimals.

Data Types: double

### **Settle — Settlement date**

cell array of date character vectors | vector of serial date numbers

Settlement date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors. **Settle** must be earlier than **Maturity**.

Data Types: double | char | cell

### **Maturity — Maturity date**

cell array of date character vectors | vector of serial date numbers

Maturity date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **IssueDate — Issue date**

cell array of date character vectors | vector of serial date numbers

Issue date, specified as an NMBS-by-1 vector using serial date numbers or a cell array of date character vectors.

Data Types: double | char | cell

### **GrossRate — Gross coupon rate (including fees)**

vector of decimal values

Gross coupon rate (including fees), specified as an NMBS-by-1 vector of decimal values.

Data Types: double

### **PrepayMatrix — Customized prepayment vector**

matrix

Customized prepayment vector, specified as a NaN-padded matrix of size  $\max(\text{TermRemaining})$ -by-NMBS. Each column corresponds to each mortgage-backed security, and each row corresponds to each month after settlement.

---

**Note** Use **PrepayMatrix** only when **PrepaySpeed** is unspecified.

---

Data Types: double

### **CouponRate — Net coupon rate**

**GrossRate** (default) | vector of decimal values

(Optional) Net coupon rate, specified as an NMBS-by-1 vector of decimal values.

Data Types: double

**Delay — Delay (in days) between payment from homeowner and receipt by bondholder**

0 (no delay between payment and receipt) (default) | vector

(Optional) Delay (in days) between payment from homeowner and receipt by bondholder, specified as an NMBS-by-1 vector.

Data Types: double

## Output Arguments

**ImpSpd0nPrc — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same price, returned as a NMBS-by-1 vector.

**ImpSpd0nDur — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified duration, returned as a NMBS-by-1 vector.

**ImpSpd0nCnv — Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity**

vector

Equivalent PSA benchmark prepayment speed for the pass-through to carry the same modified convexity, returned as a NMBS-by-1 vector.

## psaspeed2default

Benchmark default

### Syntax

```
[ADRPSA,MDRPSA] = psaspeed2default(DefaultSpeed)
```

### Description

[ADRPSA,MDRPSA] = psaspeed2default(DefaultSpeed) computes the benchmark default on the performing balance of mortgage-backed securities per PSA benchmark speed.

### Examples

#### Compute the Benchmark Default Rates on the Performing Balance of Mortgage-Backed Securities Per PSA Benchmark Speed

This example shows how to compute the benchmark default rates on the performing balance of mortgage-backed securities per PSA benchmark speed, given a mortgage-backed security with annual speed set at the PSA default benchmark.

```
DefaultSpeed = 100;
```

```
[ADRPSA, MDRPSA] = psaspeed2default(DefaultSpeed)
```

```
ADRPSA = 360×1
```

## Input Arguments

### **DefaultSpeed — Annual speed relative to the benchmark**

vector in decimals

Annual speed relative to the benchmark, specified as an NDEF-by-1 vector. The PSA benchmark is 100.

Data Types: double

## Output Arguments

### **ADRPSA — PSA default rate**

vector

PSA default rate, returned as a 360-by-NDEF vector in decimals.

### **MDRPSA — PSA monthly default rate**

vector

PSA monthly default rate, returned as a 360-by-NDEF vector in decimals.

## psaspeed2rate

Single monthly mortality rate given PSA speed

### Syntax

```
[CPRPSA, SMMPSA] = psaspeed2rate(PSASpeed)
```

### Description

[CPRPSA, SMMPSA] = psaspeed2rate(PSASpeed) calculates vectors of PSA prepayments, each containing 360 prepayment elements, to represent the 360 months in a 30-year mortgage pool.

### Examples

#### Compute the Prepayment and Mortality Rates

This example shows how to compute the prepayment and mortality rates, given a mortgage-backed security with annual speed set at the PSA default benchmark.

```
PSASpeed = [100 200];
```

```
[CPRPSA, SMMPSA]= psaspeed2rate(PSASpeed);
```

```
% view the plot of the output  
psaspeed2rate(PSASpeed)
```

## Input Arguments

### PSASpeed — Annual speed relative to the benchmark

vector in decimals

Annual speed relative to the benchmark, specified as any value  $> 0$  using an NSPD-by-1 vector. The PSA benchmark is 100.

Data Types: double

## Output Arguments

### CPRPSA — PSA conditional prepayment rate

vector

PSA conditional prepayment rate, returned as a 360-by-NSPD vector in decimals.

### SMMPSA — PSA single monthly mortality rate

vector

PSA monthly default rate, returned as a 360-by-NSPD vector in decimals.

# stepcpncfamounts

Cash flow amounts and times for bonds and stepped coupons

## Syntax

[CFlows,CDates,CTimes] = stepcpncfamounts(Settle,Maturity,ConvDates, CouponRates)

[CFlows,CDates,CTimes] = stepcpncfamounts( \_\_\_\_,Period,Basis,EndMonthRule,Face)

## Description

[CFlows,CDates,CTimes] = stepcpncfamounts(Settle,Maturity,ConvDates, CouponRates) returns matrices of cash flow amounts, cash flow dates, and time factors for a portfolio of NUMBONDS stepped-coupon bonds.

[CFlows,CDates,CTimes] = stepcpncfamounts( \_\_\_\_,Period,Basis,EndMonthRule,Face) adds additional optional arguments.

## Examples

### Generate Stepped Cash Flows for Three Different Bonds

This example generates stepped cash flows for three different bonds, all paying interest semiannually. The life span of the bonds is about 18–19 years each:

- Bond A has two conversions, but the first one occurs on the settlement date and immediately expires.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with some conversion dates not on the coupon dates. It has the longest maturity. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated here:

The following table illustrates the interest-rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	2.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97))	8.875%	First Conversion (14-Jun-97))	5.0%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	7.5%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-11)	NaN

Define the bond specifications.

```

Settle = datenum('02-Aug-1992');

ConvDates = [datenum('02-Aug-1992'), datenum('15-Jun-2003'),...
             nan;
             datenum('15-Jun-1997'), datenum('15-Jun-2001'),...
             datenum('15-Jun-2005');
             datenum('14-Jun-1997'), datenum('14-Jun-2001'),...
             datenum('14-Jun-2005')];

Maturity = [datenum('15-Jun-2010');
            datenum('15-Jun-2010');
            datenum('15-Jun-2011')];

CouponRates = [0.075 0.08875 0.0925 nan;
               0.075 0.08875 0.0925 0.1;
               0.025 0.05    0.0750 0.1];

Basis = 1;
Period = 2;
EndMonthRule = 1;
Face = 100;

```

Use `stepcpncfamounts` to compute cash flows and timings.

```
[CFlows, CDates, CTimes] = stepcpncfamounts(Settle, Maturity, ConvDates, CouponRates)
```

```
CFlows = 3×39
```

-1.1639	4.4375	4.4375	4.4375	4.4375	4.4375	4.4375	4.4375	4.4375	4.4375	4.4375

CTimes = 3×39
```

0	0.7377	1.7377	2.7377	3.7377	4.7377	5.7377	6.7377	7.7377	8.7377
0	0.7377	1.7377	2.7377	3.7377	4.7377	5.7377	6.7377	7.7377	8.7377
0	0.7377	1.7377	2.7377	3.7377	4.7377	5.7377	6.7377	7.7377	8.7377

Visualize the third bond's cash flows (2.5 - 5 - 7.5 - 10) using the `cfplot` function.

```

cfplot(CDates(3,:),CFlows(3,:));
xlabel('Dates in Serial Number Format')
ylabel('Relative Amounts of Cash Flows')
title('CashFlow of 2.5 - 5 - 7.5 - 10 Stepped Coupon Bond')

```

## Input Arguments

### Settle — Settlement date

serial date number

Settlement date, specified either as a scalar or NSTP-by-1 vector of serial date numbers.

Settle must be earlier than Maturity.

Data Types: double

### Maturity — Maturity date

serial date number

Maturity date, specified as a scalar or an NSTP-by-1 vector of serial date numbers representing the maturity date for each bond.

Data Types: double

### ConvDates — Conversion dates

serial date number

Conversion dates, specified as a NSTP-by-max(NCONV) matrix containing conversion dates after Settle. The size of the matrix is equal to the number of instruments by the maximum number of conversions. Fill unspecified entries with NaN.

Data Types: double

### CouponRates — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NSTP-by-max(NCONV+1) matrix containing coupon rates for each bond in the portfolio in decimal form. The matrix size is equal to the number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between `Settle` and the first conversion date (date in the first column of `ConvDates`). Fill unspecified entries with NaN

`ConvDates` has the same number of rows as `CouponRates` to reflect the same number of bonds. However, `ConvDates` has one less column than `CouponRates`. This situation is illustrated by

```
Settle-----ConvDate1-----ConvDate2-----Maturity
           Rate1           Rate2           Rate3
```

Data Types: double

### Period — Coupons per year

2 per year (default) | vector

(Optional) Coupons per year, specified as an NSTP-by-1 vector. Values for `Period` are 1, 2, 3, 4, 6, and 12.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis of each instrument, specified as an NSTP-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

(Optional) End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month having 30 or fewer days, specified for each bond as a nonnegative integer [0, 1] using a NSTP-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`**Face — Face value**

100 (default) | vector of nonnegative values

(Optional) Face value, specified for each bond as an NSTP-by-1 vector of nonnegative face values.

Data Types: `double`**Output Arguments****CFflows — Cash flow amounts**

vector

Cash flow amounts, returned as a vector where the first entry in each row vector is the (negative) accrued interest due at settlement. If no accrued interest is due, the first column is zero.

**CDates — Cash flow dates**

vector

Cash flow dates, returned as vector in serial date number form. At least two columns are always present: one for settlement and one for maturity.

**CTimes — Time factor**

vector

Time factor for the SIA semiannual price/yield conversion, returned as a vector. The SIA semi-annual price/yield conversion is  $\text{DiscountFactor} = (1 + \text{Yield}/2)^{-\text{TFactor}}$ . Time factors are in units of semiannual coupon periods. For ISMA conventions:  $\text{DiscountFactor} = (1 + \text{Yield})^{-\text{TFactor}}$ . Time factors are in units of annual coupon periods. In computing time factors, use SIA actual/actual conventions for all time factor calculations.

---

**Note** For bonds with fixed coupons, use `cfamounts`. If you use a fixed-coupon bond with `stepcpncfamounts`, MATLAB software generates an error.

---

# stepcpnprice

Price bond with stepped coupons

## Syntax

```
[Price,AccruedInterest] = stepcpnprice(Yield,Settle,Maturity,ConvDates,
CouponRates)
[Price,AccruedInterest] = stepcpnprice( ____,Period,Basis,EndMonthRule,Face)
```

## Description

[Price,AccruedInterest] = stepcpnprice(Yield,Settle,Maturity,ConvDates, CouponRates) computes the price of bonds with stepped coupons given the yield to maturity. The function supports any number of conversion dates.

[Price,AccruedInterest] = stepcpnprice( \_\_\_\_,Period,Basis,EndMonthRule,Face) adds additional optional arguments.

## Examples

### Compute Bond Prices with Stepped Coupons

Compute the price and accrued interest due on a portfolio of stepped-coupon bonds having a yield of 7.221%, given three conversion scenarios:

- Bond A has two conversions, the first one falling on the settle date and immediately expiring.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with one or more conversion dates not on coupon dates. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated below:

The following table illustrates the interest-rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97)	8.875%	First Conversion (14-Jun-97)	8.875%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	9.25%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-10)	NaN

Define the specifications for the bonds.

```
Yield = 0.07221;
Settle = datenum('02-Aug-1992');
```

```

ConvDates = [datenum('02-Aug-1992'), datenum('15-Jun-2003'),...
             nan;
             datenum('15-Jun-1997'), datenum('15-Jun-2001'),...
             datenum('15-Jun-2005');
             datenum('14-Jun-1997'), datenum('14-Jun-2001'),...
             datenum('14-Jun-2005')];
Maturity = datenum('15-Jun-2010');

CouponRates = [0.075 0.08875 0.0925 nan;
               0.075 0.08875 0.0925 0.1;
               0.075 0.08875 0.0925 0.1];

Basis = 1;
Period = 2;
EndMonthRule = 1;
Face = 100;

```

Use `stepcpnprice` to compute the bond prices with stepped coupons.

```

[Price, AccruedInterest] = stepcpnprice(Yield, Settle, Maturity, ConvDates, CouponRates, Period,
Price = 3×1

    117.3874
    113.4387
    114.1759

```

```

AccruedInterest = 3×1

    1.1587
    0.9792
    0.9792

```

## Input Arguments

### Yield — Yield to maturity

numeric

Yield to maturity, specified as a scalar or `NUMBONDS`-by-1 vector of numeric values.

Data Types: `double`

### Settle — Settlement date

serial date number

Settlement date, specified either as a scalar or `NUMBONDS`-by-1 vector of serial date numbers.

`Settle` must be earlier than `Maturity`.

Data Types: `double`

### Maturity — Maturity date

serial date number

Maturity date, specified as a scalar or an `NUMBONDS`-by-1 vector of serial date numbers representing the maturity date for each bond.

Data Types: double

### ConvDates — Conversion dates

serial date number

Conversion dates, specified as a NSTP-by-max(NCONV) matrix containing conversion dates after **Settle**. The size of the matrix is equal to the number of instruments by the maximum number of conversions. Fill unspecified entries with NaN.

Data Types: double

### CouponRates — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NSTP-by-max(NCONV+1) matrix containing coupon rates for each bond in the portfolio in decimal form. The matrix size is equal to the number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between **Settle** and the first conversion date (date in the first column of **ConvDates**). Fill unspecified entries with NaN

**ConvDates** has the same number of rows as **CouponRates** to reflect the same number of bonds. However, **ConvDates** has one less column than **CouponRates**. This situation is illustrated by

```
Settle-----ConvDate1-----ConvDate2-----Maturity
          Rate1           Rate2           Rate3
```

Data Types: double

### Period — Coupons per year

2 per year (default) | vector

(Optional) Coupons per year, specified as an NUMBONDS-by-1 vector. Values for **Period** are 1, 2, 3, 4, 6, and 12.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis of each instrument, specified as an NUMBONDS-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

(Optional) End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified for each bond as a nonnegative integer [0, 1] using a NUMBONDS-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

### **Face — Face value**

100 (default) | vector of nonnegative values

(Optional) Face value, specified for each bond as a NUMBONDS-by-1 vector of nonnegative face values.

Data Types: double

## **Output Arguments**

### **Price — Clean price**

vector

Clean price, returned as a NUMBONDS-by-1 vector.

---

**Note** For bonds with fixed coupons, use `bndprice`. If you use a fixed-coupon bond with `stepcpnprice`, you receive the error: `incorrect number of inputs`.

---

### **AccruedInterest — Accrued interest payable at settlement dates**

vector

accrued interest payable at settlement dates, returned as a NUMBONDS-by-1 vector.

## stepcpnyield

Yield to maturity of bond with stepped coupons

### Syntax

```
Yield = stepcpnyield(Price,Settle,Maturity,ConvDates,CouponRates)
Yield = stepcpnyield( ____,Period,Basis,EndMonthRule,Face)
```

### Description

`Yield = stepcpnyield(Price,Settle,Maturity,ConvDates,CouponRates)` computes the yield to maturity of bonds with stepped coupons given the price. The function supports any number of conversion dates.

`Yield = stepcpnyield( ____,Period,Basis,EndMonthRule,Face)` adds additional optional arguments.

### Examples

#### Compute Yield to Maturity for Bonds with Stepped Coupons

Find the yield to maturity of three stepped-coupon bonds of known price, given three conversion scenarios:

- Bond A has two conversions, the first one falling on the settle date and immediately expiring.
- Bond B has three conversions, with conversion dates exactly on the coupon dates.
- Bond C has three conversions, with one or more conversion dates not on coupon dates. This case illustrates that only cash flows for full periods after conversion dates are affected, as illustrated below.

The following table illustrates the interest-rate characteristics of this bond portfolio.

Bond A Dates	Bond A Rates	Bond B Dates	Bond B Rates	Bond C Dates	Bond C Rates
Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%	Settle (02-Aug-92)	7.5%
First Conversion (02-Aug-92)	8.875%	First Conversion (15-Jun-97)	8.875%	First Conversion (14-Jun-97)	8.875%
Second Conversion (15-Jun-03)	9.25%	Second Conversion (15-Jun-01)	9.25%	Second Conversion (14-Jun-01)	9.25%
Maturity (15-Jun-10)	NaN	Third Conversion (15-Jun-05)	10.0%	Third Conversion (14-Jun-05)	10.0%
		Maturity (15-Jun-10)	NaN	Maturity (15-Jun-10)	NaN

Define the specifications for the bonds.

```
format long
Price = [117.3824; 113.4339; 113.4339];
```

```

Settle = datenum('02-Aug-1992');

ConvDates = [datenum('02-Aug-1992'), datenum('15-Jun-2003'), nan;
datenum('15-Jun-1997'), datenum('15-Jun-2001'), datenum('15-Jun-2005')];
datenum('14-Jun-1997'), datenum('14-Jun-2001'), datenum('14-Jun-2005')]);

Maturity = datenum('15-Jun-2010');

CouponRates = [0.075 0.08875 0.0925 nan;
               0.075 0.08875 0.0925 0.1;
               0.075 0.08875 0.0925 0.1];

Basis = 1;
Period = 2;
EndMonthRule = 1;
Face = 100;

```

Use `stepcpnyield` to compute the yield to maturity for the bonds with stepped coupons.

```
Yield = stepcpnyield(Price, Settle, Maturity, ConvDates, CouponRates, Period, Basis, EndMonthRule)
```

```
Yield = 3×1
```

```

0.072214402049150
0.072214267800360
0.072864799557221

```

## Input Arguments

### Price — Price of bond

numeric

Price of bond, specified as a scalar or `NUMBONDS`-by-1 vector of numeric values.

Data Types: double

### Settle — Settlement date

serial date number

Settlement date, specified either as a scalar or `NUMBONDS`-by-1 vector of serial date numbers.

`Settle` must be earlier than `Maturity`.

Data Types: double

### Maturity — Maturity date

serial date number

Maturity date, specified as a scalar or an `NUMBONDS`-by-1 vector of serial date numbers representing the maturity date for each bond.

Data Types: double

### ConvDates — Conversion dates

serial date number

Conversion dates, specified as a NSTP-by-max(NCONV) matrix containing conversion dates after `Settle`. The size of the matrix is equal to the number of instruments by the maximum number of conversions. Fill unspecified entries with NaN.

Data Types: double

### CouponRates — Bond coupon rate

positive decimal value

Bond coupon rate, specified as an NSTP-by-max(NCONV+1) matrix containing coupon rates for each bond in the portfolio in decimal form. The matrix size is equal to the number of instruments by maximum number of conversions + 1. First column of this matrix contains rates applicable between `Settle` and the first conversion date (date in the first column of `ConvDates`). Fill unspecified entries with NaN

`ConvDates` has the same number of rows as `CouponRates` to reflect the same number of bonds. However, `ConvDates` has one less column than `CouponRates`. This situation is illustrated by

```
Settle-----ConvDate1-----ConvDate2-----Maturity
           Rate1           Rate2           Rate3
```

Data Types: double

### Period — Coupons per year

2 per year (default) | vector

(Optional) Coupons per year, specified as an NUMBONDS-by-1 vector. Values for `Period` are 1, 2, 3, 4, 6, and 12.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Day-count basis of each instrument, specified as an NUMBONDS-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month having 30 or fewer days**

1 (in effect) (default) | nonnegative integer [0, 1]

(Optional) End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, specified for each bond as a nonnegative integer [0, 1] using a NUMBONDS-by-1 vector.

- 0 = Ignore rule, meaning that a payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

**Face — Face value**

100 (default) | vector of nonnegative values

(Optional) Face value, specified for each bond as an NUMBONDS-by-1 vector of nonnegative face values.

Data Types: double

## Output Arguments

**Yield — Yield to maturity**

vector

Yield to maturity, returned as a NUMBONDS-by-1 vector in decimal form.

---

**Note** For bonds with fixed coupons, use `bndyield`. You receive the error incorrect number of inputs if you use a fixed-coupon bond with `stepcpnyield`.

## tfutbyprice

Future prices of Treasury bonds given spot price

### Syntax

```
[QtdFutPrice,AccrInt] = tfutbyprice(SpotCurve,Price,SettleFut,MatFut,
ConvFactor,CouponRate,Maturity)
[QtdFutPrice,AccrInt] = tfutbyprice( ____,Interpolation)
```

### Description

[QtdFutPrice,AccrInt] = tfutbyprice(SpotCurve,Price,SettleFut,MatFut, ConvFactor, CouponRate, Maturity) computes future prices of Treasury notes and bonds given the spot price.

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `tfutbyprice`. For more information, see “Converting an `IRDataCurve` or `IRFunctionCurve` Object” on page 9-33.

[QtdFutPrice,AccrInt] = tfutbyprice( \_\_\_\_, Interpolation) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Determine the Future Prices of Treasury Bonds Given the Spot Price

This example shows how to determine the future price of two Treasury bonds based upon a spot rate curve constructed from data for November 14, 2002.

```
% construct spot curve from Nov 14, data
Bonds = [datenum('02/13/2003'),      0;
         datenum('05/15/2003'),      0;
         datenum('10/31/2004'),    0.02125;
         datenum('11/15/2007'),     0.03;
         datenum('11/15/2012'),     0.04;
         datenum('02/15/2031'),    0.05375];

Yields = [1.20; 1.25; 1.86; 2.99; 4.02; 4.93]/100;

Settle = datenum('11/15/2002');

[ZeroRates, CurveDates] = ...
zbyield(Bonds, Yields, Settle);

SpotCurve = [CurveDates, ZeroRates];

% calculate a particular bond's future quoted price
RefDate    = [datenum('1-Dec-2002'); datenum('1-Mar-2003')];
MatFut     = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
```

```

Maturity = [datenum('15-Aug-2009');datenum('15-Aug-2010')];
CouponRate = [0.06;0.0575];
ConvFactor = convfactor(RefDate, Maturity, CouponRate);
Price = [114.416; 113.171];
Interpolation = 1;

[QtdFutPrice, AccrInt] = tfutbyprice(SpotCurve, Price, Settle, ...
MatFut, ConvFactor, CouponRate, Maturity, Interpolation)

```

QtdFutPrice = 2×1

```

114.0409
113.4029

```

AccrInt = 2×1

```

1.9891
0.4448

```

## Input Arguments

### SpotCurve — Treasury spot curve

matrix

Treasury spot curve, specified as a number of futures using one of the following forms:

- NFUT-by-2 matrix in the form of [SpotDates SpotRates] and these spot rates must be quoted as semiannual compounding (2) when the third column is not supplied.
- NFUT-by-3 matrix in the form of [SpotDates SpotRates Compounding], where allowed Compounding values for the third column are -1, 1, 2 (default), 3, 4, and 12, where -1 is continuous compounding.

Data Types: double

### Price — Prices of Treasury bonds or notes per \$100 notional at settlement date

scalar numeric | vector

Prices of Treasury bonds or notes per \$100 notional at settlement date, specified as a scalar numeric or an NINST-by-1 vector. Use `bndprice` for theoretical value of bond.

Data Types: double

### SettleFut — Settlement date of futures contract

serial date number | date character vector

Settlement date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### MatFut — Maturity dates (or anticipated delivery dates) of futures contract

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

**ConvFactor — Conversion factor**

numeric

Conversion factor, specified using `convfactor`.

Data Types: `double` | `char` | `cell`

**CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: `double`

**Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

**Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

**Output Arguments****QtdFutPrice — Quoted futures price, per \$100 notional**

vector

Quoted futures price, per \$100 notional, returned as a NINST-by-1 vector.

**AccrInt — Accrued Interest due at delivery date, per \$100 notional**

vector

Accrued Interest due at delivery date, per \$100 notional, returned as a NINST-by-1 vector.

## tfutbyyield

Future prices of Treasury bonds given current yield

### Syntax

```
[QtdFutPrice,AccrInt] = tfutbyyield(SpotCurve,Yield,SettleFut,MatFut,
ConvFactor,CouponRate,Maturity)
[QtdFutPrice,AccrInt] = tfutbyyield( ____,Interpolation)
```

### Description

[QtdFutPrice,AccrInt] = tfutbyyield(SpotCurve,Yield,SettleFut,MatFut, ConvFactor,CouponRate,Maturity) computes prices of Treasury bond futures given a spot curve and bond yields at settlement.

In addition, you can use the Financial Instruments Toolbox method `getZeroRates` for an `IRDataCurve` object with a `Dates` property to create a vector of dates and data acceptable for `tfutbyyield`. For more information, see “Converting an `IRDataCurve` or `IRFunctionCurve` Object” on page 9-33.

[QtdFutPrice,AccrInt] = tfutbyyield( \_\_\_\_,Interpolation) specifies options using one or more optional arguments in addition to the input arguments in the previous syntax.

### Examples

#### Determine Future Prices of Treasury Bonds Given the Current Yield

This example shows how to determine the future price of two Treasury bonds based upon a spot rate curve constructed from data for November 14, 2002.

```
% construct spot curve from Nov 14, data
Bonds = [datenum('02/13/2003'),    0;
         datenum('05/15/2003'),    0;
         datenum('10/31/2004'),   0.02125;
         datenum('11/15/2007'),   0.03;
         datenum('11/15/2012'),   0.04;
         datenum('02/15/2031'),   0.05375];

Yields = [1.20; 1.25; 1.86; 2.99; 4.02; 4.93]/100;

Settle = datenum('11/15/2002');

[ZeroRates, CurveDates] = ...
zbyield(Bonds, Yields, Settle);

SpotCurve = [CurveDates, ZeroRates];

% calculate a particular bond's future quoted price
RefDate    = [datenum('1-Dec-2002'); datenum('1-Mar-2003')];
MatFut     = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
```

```

Maturity = [datenum('15-Aug-2009');datenum('15-Aug-2010')];
CouponRate = [0.06;0.0575];
ConvFactor = convfactor(RefDate, Maturity, CouponRate);
Yield = [0.03576; 0.03773];
Interpolation = 1;

[QtdFutPrice, AccrInt] = tfutbyyield(SpotCurve, Yield, Settle, ...
MatFut, ConvFactor, CouponRate, Maturity, Interpolation)

```

QtdFutPrice = 2×1

```

114.0416
113.4034

```

AccrInt = 2×1

```

## Input Arguments

### SpotCurve — Treasury spot curve

matrix

Treasury spot curve, specified as a number of futures using one of the following forms:

- NFUT-by-2 matrix in the form of [SpotDates SpotRates] and these spot rates must be quoted as semiannual compounding (2) when the third column is not supplied.
- NFUT-by-3 matrix in the form of [SpotDates SpotRates Compounding], where allowed Compounding values for the third column are -1, 1, 2 (default), 3, 4, and 12, where -1 is continuous compounding.

Data Types: double

### Yield — Yield to maturities at settlement date

scalar numeric | vector

Yield to maturities at settlement date, specified as a scalar numeric or an NINST-by-1 vector. Use `bndyield` for theoretical value of bond yield.

Data Types: double

### SettleFut — Settlement date of futures contract

serial date number | date character vector

Settlement date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

### MatFut — Maturity dates (or anticipated delivery dates) of futures contract

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

**ConvFactor — Conversion factor**

numeric

Conversion factor, specified using `convfactor`.

Data Types: `double` | `char` | `cell`

**CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: `double`

**Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

**Interpolation — Interpolation method to compute the corresponding spot rates for the bond's cash flow**

1 (linear) (default) | vector

(Optional) Interpolation method to compute the corresponding spot rates for the bond's cash flow, specified as an NMBS-by-1 vector. Available methods are (0) nearest, (1) linear, and (2) cubic spline. For more information on the supported interpolation methods, see `interp1`.

Data Types: `double`

**Output Arguments****QtdFutPrice — Quoted futures price, per \$100 notional**

vector

Quoted futures price, per \$100 notional, returned as a NINST-by-1 vector.

**AccrInt — Accrued Interest due at delivery date, per \$100 notional**

vector

Accrued Interest due at delivery date, per \$100 notional, returned as a NINST-by-1 vector.

## tfutimprepo

Implied repo rates for Treasury bond future given price

### Syntax

```
ImpliedRepo = tfutimprepo(ReinvestData,Price,QtdFutPrice,Settle,MatFut,
ConvFactor,CouponRate,Maturity)
```

### Description

ImpliedRepo = tfutimprepo(ReinvestData,Price,QtdFutPrice,Settle,MatFut,ConvFactor,CouponRate,Maturity) computes the implied repo rate that prevents arbitrage of Treasury bond futures, given the clean price at the settlement and delivery dates.

### Examples

#### Compute the Implied Repo Rates for Treasury Bond Futures Given the Price

This example shows how to compute the implied repo rate given the following set of data.

```
ReinvestData = [0.018 3];
Price = [114.4160; 113.1710];
QtdFutPrice = [114.1201; 113.7090];
Settle = datenum('11/15/2002');
MatFut = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
ConvFactor = [1; 0.9854];
CouponRate = [0.06; 0.0575];
Maturity = [datenum('15-Aug-2009'); datenum('15-Aug-2010')];

ImpliedRepo = tfutimprepo(ReinvestData, Price, QtdFutPrice, ...
Settle, MatFut, ConvFactor, CouponRate, Maturity)

ImpliedRepo = 2×1

    0.0200
    0.0200
```

### Input Arguments

#### ReinvestData — Reinvestment of intervening coupons

matrix

Reinvestment of intervening coupons, specified as a number of futures NFUT-by-2 matrix of rates and bases in the form of [ReinvestRate ReinvestBasis].

ReinvestRate is the simple reinvestment rate, in decimal. Specify ReinvestBasis as 0 = not reinvested, 2 = actual/360, or 3 = actual/365.

Data Types: double

**Price — Current bond price per \$100 notional**

scalar numeric | vector

Current bond price per \$100 notional, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

**QtdFutPrice — Quoted bond futures price per \$100 notional**

scalar numeric | vector

Quoted bond futures price per \$100 notional, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

**Settle — Settlement/valuation date of futures contract**

serial date number | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**MatFut — Maturity dates (or anticipated delivery dates) of futures contract**

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**ConvFactor — Conversion factor**

numeric

Conversion factor, specified using convfactor.

Data Types: double | char | cell

**CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: double

**Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

## Output Arguments

**ImpliedRepo** — **Implied annual repo rate with an actual/360 basis**  
vector in decimals

Implied annual repo rate (in decimals) with an actual/360 basis, returned as a NINST-by-1 vector.

# tfutpricebyrepo

Calculates Treasury bond futures price given the implied repo rates

## Syntax

```
[QtdFutPrice,AccrInt] = tfutpricebyrepo(RepoData,ReinvestData,Price,Settle,
MatFut,ConvFactor,CouponRate,Maturity)
```

## Description

[QtdFutPrice,AccrInt] = tfutpricebyrepo(RepoData,ReinvestData,Price,Settle, MatFut,ConvFactor,CouponRate,Maturity) computes the theoretical futures bond price given the settlement price, the repo/funding rates, and the reinvestment rate.

## Examples

### Compute Treasury Bond Futures Price Given the Implied Repo Rates

This example shows how to compute the quoted futures price and accrued interest due on the target delivery date, given the following data.

```
RepoData      = [0.020  2];
ReinvestData  = [0.018  3];
Price         = [114.416; 113.171];
Settle        = datenum('11/15/2002');
MatFut        = [datenum('15-Dec-2002'); datenum('15-Mar-2003')];
ConvFactor    = [1 ; 0.9854];
CouponRate    = [0.06;0.0575];
Maturity      = [datenum('15-Aug-2009'); datenum('15-Aug-2010')];
```

```
[QtdFutPrice AccrInt] = tfutpricebyrepo(RepoData, ...
ReinvestData, Price, Settle, MatFut, ConvFactor, CouponRate, ...
Maturity)
```

```
QtdFutPrice = 2×1
```

```

## Input Arguments

### RepoData — Simple term repo/funding rates

matrix

Simple term repo/funding rates, specified as a number of futures NFUT-by-2 matrix of rates in decimal and their bases in the form of [RepoRate RepoBasis].

Specify RepoBasis as 2 = actual/360 or 3 = actual/365.

Data Types: double

**ReinvestData — Reinvestment of intervening coupons**

matrix

Reinvestment of intervening coupons, specified as a number of futures NFUT-by-2 matrix of rates and bases in the form of [ReinvestRate ReinvestBasis].

ReinvestRate is the simple reinvestment rate, in decimal. Specify ReinvestBasis as 0 = not reinvested, 2 = actual/360, or 3 = actual/365.

Data Types: double

**Price — Current bond price per \$100 notional**

scalar numeric | vector

Current bond price per \$100 notional, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

**Settle — Settlement/valuation date of futures contract**

serial date number | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**MatFut — Maturity dates (or anticipated delivery dates) of futures contract**

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**ConvFactor — Conversion factor**

numeric

Conversion factor, specified using convfactor.

Data Types: double | char | cell

**CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: double

**Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

## Output Arguments

### **QtdFutPrice** – Quoted futures price, per \$100 notional

vector

Quoted futures price, per \$100 notional, returned as a NINST-by-1 vector.

### **AccrInt** – Accrued Interest due at delivery date, per \$100 notional

vector

Accrued Interest due at delivery date, per \$100 notional, returned as a NINST-by-1 vector.

```
FwdYield = 2×1
```

```
    0.0221
    0.0282
```

### Input Arguments

#### RepoData — Simple term repo/funding rates

matrix

Simple term repo/funding rates, specified as a number of futures NFUT-by-2 matrix of rates in decimal and their bases in the form of [RepoRate RepoBasis].

Specify RepoBasis as 2 = actual/360 or 3 = actual/365.

Data Types: double

**ReinvestData — Reinvestment of intervening coupons**

matrix

Reinvestment of intervening coupons, specified as a number of futures NFUT-by-2 matrix of rates and bases in the form of [ReinvestRate ReinvestBasis].

ReinvestRate is the simple reinvestment rate, in decimal. Specify ReinvestBasis as 0 = not reinvested, 2 = actual/360, or 3 = actual/365.

Data Types: double

**Yield — Yield to maturity of Treasury bonds per \$100 notional at Settle**

scalar numeric | vector

Yield to maturity of Treasury bonds per \$100 notional at Settle, specified as a scalar numeric or an NINST-by-1 vector.

Data Types: double

**Settle — Settlement/valuation date of futures contract**

serial date number | date character vector

Settlement/valuation date of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**MatFut — Maturity dates (or anticipated delivery dates) of futures contract**

serial date number | date character vector

Maturity dates (or anticipated delivery dates) of futures contract, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

**ConvFactor — Conversion factor**

numeric

Conversion factor, specified using convfactor.

Data Types: double | char | cell

**CouponRate — Underlying bond annual coupon**

scalar numeric in decimal | vector in decimals

Underlying bond annual coupon, specified as a scalar numeric decimal or an NINST-by-1 vector of decimals.

Data Types: double

**Maturity — Underlying bond maturity date**

serial date number | date character vector

Underlying bond maturity date, specified as a scalar or an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: double | char | cell

## **Output Arguments**

### **FwdYield — Forward yield to maturity compounded semiannually**

vector in decimals

Forward yield to maturity, in decimals, compounded semiannually, returned as a NINST-by-1 vector.

# toRateSpec

Convert IRDataCurve object to RateSpec

## Class

@IRDataCurve on page A-6

## Syntax

```
F = toratespec(CurveObj, InpDates)
```

## Arguments

CurveObj	Interest-rate curve object that is constructed using IRDataCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.

## Description

F = toratespec(CurveObj, InpDates) returns a RateSpec object that is identical to the RateSpec structure created by the function intenvset.

## Examples

### Convert an IRDataCurve Object to a RateSpec

This example shows how to convert an IRDataCurve object to a RateSpec. First, an IRDataCurve object is created using the function IRDataCurve constructor with Dates and Data, then this object is converted to a RateSpec structure using the toRateSpec method.

```
CurveSettle = datenum('2-Mar-2016');
Data = [2.09 2.47 2.71 3.12 3.43 3.85 4.57 4.58]/100;
Dates = datemnth(CurveSettle,12*[1 2 3 5 7 10 20 30]);
irdc = IRDataCurve('Forward',CurveSettle,Dates,Data);
toRateSpec(irdc, CurveSettle+30:30:CurveSettle+365)
```

```
ans = struct with fields:
    FinObj: 'RateSpec'
    Compounding: 2
    Disc: [12x1 double]
    Rates: [12x1 double]
    EndTimes: [12x1 double]
    StartTimes: [12x1 double]
    EndDates: [12x1 double]
    StartDates: 736391
    ValuationDate: 736391
    Basis: 0
    EndMonthRule: 1
```

# toRateSpec

Convert IRFunctionCurve object to RateSpec

## Class

@IRFunctionCurve on page A-11

## Syntax

`F = toRateSpec(CurveObj, InpDates)`

## Arguments

CurveObj	Interest-rate curve object that is constructed using IRFunctionCurve.
InpDates	Vector of input dates using MATLAB date format. The input dates must be after the settle date.

## Description

`F = toRateSpec(CurveObj, InpDates)` returns a RateSpec object that is identical to the RateSpec structure created by the function `intenvset`.

## Examples

### Convert an IRFunctionCurve Object to a RateSpec

This example shows how to convert an IRFunctionCurve object to a RateSpec. First, an IRFunctionCurve object is created using the function IRFunctionCurve constructor, then a RateSpec structure is created using the toRateSpec method.

```
irfc = IRFunctionCurve('Forward',today,@(t) polyval([-0.0001 0.003 0.02],t));
toRateSpec(irfc, today+30:30:today+365)
```

```
ans = struct with fields:
    FinObj: 'RateSpec'
  Compounding: 2
        Disc: [12x1 double]
        Rates: [12x1 double]
    EndTimes: [12x1 double]
  StartTimes: [12x1 double]
    EndDates: [12x1 double]
  StartDates: 738028
  ValuationDate: 738028
        Basis: 0
  EndMonthRule: 1
```

# zeroprice

Price zero-coupon instruments given yield

## Syntax

```
Price = zeroprice(Yield,Settle,Maturity)
Price = zeroprice( ____,Period,Basis,EndMonthRule)
```

## Description

Price = zeroprice(Yield,Settle,Maturity) prices zero-coupon instruments given a yield. zeroprice calculates the prices for a portfolio of general short and long-term zero-coupon instruments given the yield of reference bonds. In other words, if the zero-coupon computed with this yield is used to discount the reference bond, the value of that reference bond is equal to its price.

Price = zeroprice( \_\_\_\_,Period,Basis,EndMonthRule) adds optional arguments for Period, Basis, and EndMonthRule.

## Examples

### Compute the Price of a Short-Term Zero-Coupon Instrument

This example shows how to compute the price of a short-term zero-coupon instrument.

```
Settle = '24-Jun-1993';
Maturity = '1-Nov-1993';
Period = 2;
Basis = 0;
Yield = 0.04;

Price = zeroprice(Yield, Settle, Maturity, Period, Basis)

Price = 98.6066
```

### Compute the Prices of a Portfolio of Two Zero-Coupon Instruments

This example shows how to compute the prices of a portfolio of two zero-coupon instruments, one short-term, and the other long-term.

```
Settle = '24-Jun-1993';
Maturity = ['01-Nov-1993'; '15-Jan-2024'];
Basis = [0; 1];
Yield = [0.04; 0.1];

Price = zeroprice(Yield, Settle, Maturity, [], Basis)

Price = 2x1
```

98.6066  
5.0697

## Input Arguments

### **Yield — Reference bond yield**

scalar | vector

Reference bond yield, specified as a scalar or a NZERO-by-1 vector.

Data Types: double

### **Settle — Settlement date**

serial date number

Settlement date, specified as a NZERO-by-1 vector of serial date numbers.

Data Types: double

### **Maturity — Maturity date**

serial date number

Maturity date, specified as a NZERO-by-1 vector of serial date numbers.

Data Types: double

### **Period — Number of coupons in one year**

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

(Optional) Number of coupons in one year, specified as a positive integer for the values 1, 2, 4, 6, 12 in a NZERO-by-1 vector.

Data Types: double

### **Basis — Day-count basis of bond**

0 (actual/actual) (default) | vector of positive integers of the set [1 . . . 13]

(Optional) Day-count basis of the bond, specified as a positive integer using a NZERO-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)

- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### EndMonthRule — End-of-month rule flag

1 (in effect) (default) | nonnegative integer with value of 0 or 1

(Optional) End-of-month rule flag, specified as a nonnegative integer with a value of 0 or 1 using a NZERO-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## Output Arguments

### Price — Price for each zero-coupon instrument

vector

Price for each zero-coupon instrument (per \$100 notional), returned as a column vector.

## Algorithms

To compute the price when Period is 1 or 0 for the quasi-coupon periods to redemption, zeroprice uses the formula

$$Price = \frac{RV}{1 + \left(\frac{DSR}{E} \times \frac{Y}{M}\right)}$$

.

*Quasi-coupon periods* are the coupon periods that would exist if the bond were paying interest at a rate other than zero.

When there is more than one quasi-coupon period to the redemption date, zeroprice uses the formula

$$Price = \frac{RV}{\left(1 + \frac{Y}{M}\right)^{Nq} - 1 + \frac{DSC}{E}}$$

.

The elements of the equations are defined as follows.

Variable	Definition
<i>DSC</i>	Number of days from settlement date to next quasi-coupon date as if the security paid periodic interest.
<i>DSR</i>	Number of days from settlement date to the redemption date (call date, put date, and so on).
<i>E</i>	Number of days in quasi-coupon period.
<i>M</i>	Number of quasi-coupon periods per year (standard for the particular security involved).
<i>Nq</i>	Number of quasi-coupon periods between settlement date and redemption date. If this number contains a fractional part, raise it to the next whole number.
<i>Price</i>	Dollar price per \$100 par value.
<i>RV</i>	Redemption value.
<i>Y</i>	Annual yield (decimal) when held to redemption.

## zeroyield

Yield of zero-coupon instruments given price

### Syntax

```
Yield = zeroyield(Price,Settle,Maturity)
Yield = zeroyield( ____,Period,Basis,EndMonthRule)
```

### Description

Yield = zeroyield(Price,Settle,Maturity) computes the yield of zero-coupon instruments given price. zeroyield calculates the bond-equivalent yield for a portfolio of general short and long-term zero-coupon instruments given the price of the instruments. In other words, if the zero-coupon computed with this yield is used to discount the reference bond, the value of that reference bond is equal to its price

Yield = zeroyield( \_\_\_\_,Period,Basis,EndMonthRule) adds optional arguments for Period, Basis, and EndMonthRule.

### Examples

#### Compute the Yield of a Short-Term Zero-Coupon Instrument

This example shows how to compute the yield of a short-term zero-coupon instrument.

```
Settle = '24-Jun-1993';
Maturity = '1-Nov-1993';
Basis = 0;
Price = 95;
```

```
Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.1490
```

#### Compute the Yield of a Short-Term Zero-Coupon Instrument Using a Day-Count Basis of 30/360 (SIA)

This example shows how to compute the yield of a short-term zero-coupon instrument using a day-count basis of 30/360 (SIA).

```
Settle = '24-Jun-1993';
Maturity = '1-Nov-1993';
Basis = 1;
Price = 95;
```

```
Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.1492
```

### Compute the Yield of a Long-Term Zero-Coupon Instrument

This example shows how to compute the yield of a long-term zero-coupon instrument.

```
Settle = '24-Jun-1993';  
Maturity = '15-Jan-2024';  
Basis = 0;  
Price = 9;
```

```
Yield = zeroyield(Price, Settle, Maturity, [], Basis)
```

```
Yield = 0.0804
```

### Input Arguments

#### Price — Reference bond price

scalar | vector

Reference bond price, specified as a scalar or a NZERO-by-1 vector.

Data Types: double

#### Settle — Settlement date

serial date number

Settlement date, specified as a NZERO-by-1 vector of serial date numbers.

Data Types: double

#### Maturity — Maturity date

serial date number

Maturity date, specified as a NZERO-by-1 vector of serial date numbers.

Data Types: double

#### Period — Number of coupons in one year

2 (semiannual) (default) | vector of positive integers from the set [1, 2, 3, 4, 6, 12]

(Optional) Number of coupons in one year, specified as a positive integer for the values 1, 2, 4, 6, 12 in a NZERO-by-1 vector.

Data Types: double

#### Basis — Day-count basis of bond

0 (actual/actual) (default) | vector of positive integers of the set [1 . . . 13]

(Optional) Day-count basis of the bond, specified as a positive integer using a NZERO-by-1 vector.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360

- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

---

**Note** When the Maturity date is fewer than 182 days away and the Basis is actual/365, the zeroyield uses a simple-interest algorithm. If Maturity is more than 182 days away, zeroyield uses present value calculations.

When the Basis is actual/360, the simple interest algorithm gives the money-market yield for short (1-6 months to maturity) Treasury bills.

---

Data Types: double

### **EndMonthRule — End-of-month rule flag**

1 (in effect) (default) | nonnegative integer with value of 0 or 1

(Optional) End-of-month rule flag, specified as a nonnegative integer with a value of 0 or 1 using a NZERO-by-1 vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days.

- 0 = Ignore rule, meaning that a bond coupon payment date is always the same numerical day of the month.
- 1 = Set rule on, meaning that a bond coupon payment date is always the last actual day of the month.

Data Types: double

## **Output Arguments**

### **Yield — Bond-equivalent yield for each zero-coupon instrument**

vector

Bond-equivalent yield for each zero-coupon instrument, returned as a column vector.

## **Algorithms**

To compute the yield when there is zero or one quasi-coupon period to redemption, zeroyield uses the formula

$$\text{Yield} = \left( \frac{RV - P}{P} \right) \times \left( \frac{M \times E}{DSR} \right)$$

*Quasi-coupon periods* are the coupon periods which would exist if the bond was paying interest at a rate other than zero. The first term calculates the yield on invested dollars. The second term converts this yield to a per annum basis.

When there is more than one quasi-coupon period to the redemption date, `zeroyield` uses the formula

$$\text{Yield} = \left( \left( \frac{RV}{P} \right)^{\frac{1}{Nq - 1 + \frac{DSC}{E}}} - 1 \right) \times M$$

The elements of the equations are defined as follows.

Variable	Definition
<i>DSC</i>	Number of days from the settlement date to next quasi-coupon date as if the security paid periodic interest.
<i>DSR</i>	Number of days from the settlement date to redemption date (call date, put date, and so on).
<i>E</i>	Number of days in quasi-coupon period.
<i>M</i>	Number of quasi-coupon periods per year (standard for the particular security involved).
<i>Nq</i>	Number of quasi-coupon periods between the settlement date and redemption date. If this number contains a fractional part, raise it to the next whole number.
<i>P</i>	Dollar price per \$100 par value.
<i>RV</i>	Redemption value.
<i>Yield</i>	Annual yield (decimal) when held to redemption.

# touchbybls

Price one-touch and no-touch binary options using Black-Scholes option pricing model

## Syntax

```
Price = touchybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier,
Payoff)
```

## Description

Price = touchybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff) calculates one-touch and no-touch binary options using the Black-Scholes option pricing model.

## Examples

### Price a One-Touch Option

Compute the price of a one-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = '01-Jan-2018';
Maturity = '01-Jul-2018';
```

Define the RateSpec using intenvset.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the StockSpec using stockspec.

```
DividendType = "Continuous";
DividendYield = Rate - 0.1;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Calculate the price of a one-touch binary option.

```
BarrierSpec = "OT";
Barrier = 100;
Payoff = 15;
```

```
Price = touchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)
```

```
Price = 9.7264
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector | datetime object

Settlement or trade date for the touch option, specified as an NINST-by-1 matrix using serial date numbers, date character vectors, or datetime objects.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the touch option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### BarrierSpec — Barrier option type

character vector with values 'OT' or 'NT'

Barrier option type, specified as an NINST-by-1 cell array of character vectors with the following values:

- 'OT' — One-touch

The one-touch option provides a payoff if the underlying asset ever trades at or beyond the Barrier level. Otherwise, the Payoff is zero.

- 'NT' — No-touch

The no-touch option provides a Payoff if the underlying asset never trades at or beyond the Barrier level. Otherwise, the Payoff is zero.

Data Types: `char` | `cell`

### Barrier — Barrier value

numeric

Barrier value, specified as an NINST-by-1 matrix of numeric values.

Data Types: double

### **Payoff — Payoff value**

numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values.

---

**Note** The payoff value is calculated for the point in time that the **Barrier** value is reached. The payoff is either cash or nothing. If a no-touch option is specified using the **BarrierSpec**, the payoff is at the **Maturity** of the option.

---

Data Types: double

## **Output Arguments**

### **Price — Expected prices for one-touch options**

matrix

Expected prices for one-touch options at time 0, returned as an NINST-by-1 matrix.

## **More About**

### **Touch and No-Touch Options**

The one-touch and no-touch options provide a payoff if the underlying spot either ever or never trades at or beyond the barrier level. Otherwise, the payoff is zero.

Only two outcomes are possible with a one-touch option if a trader holds the contract all the way through expiration:

- The target price (**Barrier**) is reached and the trader collects the full premium.
- The target price (**Barrier**) is not reached and the trader loses the amount originally paid to open the trade.

## touchsensbybls

Calculate price or sensitivities for one-touch and no-touch binary options using Black-Scholes option pricing model

### Syntax

```
PriceSens = touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec,
Barrier, Payoff)
```

```
PriceSens = touchsensbybls( ___, Name, Value)
```

### Description

`PriceSens = touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)` calculates the price and sensitivities for one-touch and no-touch binary options using the Black-Scholes option pricing model.

`PriceSens = touchsensbybls( ___, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Calculate the Price and Sensitivities for a One-Touch Option

Compute the price and sensitivities for a one-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = '01-Jan-2018';
Maturity = '01-Jul-2018';
```

Define the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the `StockSpec` using `stockspec`.

```
DividendType = "Continuous";
DividendYield = Rate - 0.1;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Define the sensitivities.

```
OutSpec = {'price', 'delta', 'gamma'};
```

Calculate the price and sensitivities for a one-touch binary option.

```
BarrierSpec = "OT";
Barrier = 100;
Payoff = 15;
```

```
[Price, Delta, Gamma] = touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, BarrierLevel)

Price = 9.7264
Delta = -0.8939
Gamma = 0.0616
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset. For information on the stock specification, see `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector | datetime object

Settlement or trade date for the touch option, specified as an NINST-by-1 matrix using serial date numbers, date character vectors, or datetime objects.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the touch option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### BarrierSpec — Barrier option type

character vector with values 'OT' or 'NT'

Barrier option type, specified as an NINST-by-1 cell array of character vectors with the following values:

- 'OT' — One-touch. The one-touch option provides a payoff if the underlying spot ever trades at or beyond the `Barrier` level and the payoff is zero otherwise.

- 'NT' — No-touch. The no-touch option provides a Payoff if the underlying spot ever never trades at or beyond the Barrier level and the Payoff is zero otherwise.

Data Types: char | cell

### Barrier — Barrier value

numeric

Barrier value, specified as an NINST-by-1 matrix of numeric values.

Data Types: double

### Payoff — Payoff value

numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values.

---

**Note** The payoff value is calculated for the point in time that the Barrier value is reached. The payoff is either cash or nothing. If a no-touch option is specified using the BarrierSpec, the payoff is at the Maturity of the option.

---

Data Types: double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: Price =  
touchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff,  
'OutSpec', 'Delta')

### OutSpec — Define outputs

{'Price'} (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

OutSpec = {'All'} specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying OutSpec to include each sensitivity.

Example: OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}

Data Types: char | cell

## Output Arguments

### PriceSens — Expected prices or sensitivities for one-touch options

matrix

Expected prices at time 0 or sensitivities (defined using OutSpec) for one-touch options, returned as an NINST-by-1 matrix.

## More About

### Touch and No-Touch Options

The one-touch and no-touch options provide a payoff if the underlying spot either ever or never trades at or beyond the barrier level. Otherwise, the payoff is zero.

Only two outcomes are possible with a one-touch option if a trader holds the contract all the way through expiration:

- The target price (**Barrier**) is reached and the trader collects the full premium.
- The target price (**Barrier**) is not reached and the trader loses the amount originally paid to open the trade.

## dbltouchbybls

Price double one-touch and double no-touch binary options using Black-Scholes option pricing model

### Syntax

```
Price = dbltouchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)
```

### Description

Price = dbltouchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff) calculates double one-touch and double no-touch binary options using Black-Scholes option pricing model.

### Examples

#### Price a Double No-Touch Option

Compute the price of a double no-touch option using the following data:

```
AssetPrice = 105;  
Rate = 0.1;  
Volatility = 0.2;  
Settle = '01-Jan-2018';  
Maturity = '01-Jul-2018';
```

Define the RateSpec using intenvset.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...  
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the StockSpec using stockspect.

```
DividendType = "Continuous";  
DividendYield = Rate - 0.03;  
StockSpec = stockspect(Volatility, AssetPrice, DividendType, DividendYield);
```

Calculate the price of a double no-touch binary option.

```
BarrierSpec = "DNT";  
Barrier = [120 80];  
Payoff = 10;
```

```
Price = dbltouchbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)
```

```
Price = 5.6368
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector | datetime object

Settlement or trade date for the double touch option, specified as an NINST-by-1 matrix using serial date numbers, date character vectors, or datetime objects.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the double touch option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### BarrierSpec — Double barrier option type

cell array of character vectors with values of 'DOT' or 'DNT' | string array with values of "DOT" or "DNT"

Double barrier option type, specified as an NINST-by-1 cell array of character vectors or string array with the following values:

- 'DOT' — Double one-touch. The double one-touch option defines two `Barrier` levels. A double one-touch option provides a `Payoff` if the underlying asset ever touches either the upper or lower `Barrier` levels.
- 'DNT' — Double no-touch. The double no-touch option defines two `Barrier` levels. A double no-touch option provides a `Payoff` if the underlying asset ever never touches either the upper or lower `Barrier` levels.

Data Types: `char` | `cell` | `string`

### Barrier — Double barrier value

numeric

Double barrier value, specified as an NINST-by-2 matrix of numeric values, where the first column is Upper Barrier(1)(UB) and the second column is Lower Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: double

**Payoff – Payoff value**

numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector in which the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

---

**Note** The payoff value is calculated for the point in time that the **Barrier** value is reached. The payoff is either cash or nothing. If you specify a double no-touch option using **BarrierSpec**, the payoff is at the **Maturity** of the option.

---

Data Types: double

**Output Arguments****Price – Expected prices for double one-touch options**

matrix

Expected prices for double one-touch options at time 0, returned as an NINST-by-1 matrix.

**More About****Double One-Touch and Double No-Touch Options**

Double one-touch options and double no-touch options work the same way as one-touch options, except that there are two barriers.

A double one-touch or double no-touch option provides a payoff if the underlying spot either ever or never touches either the upper or lower **Barrier** levels. If neither barrier level is breached prior to expiration, the option expires worthless and the trader loses all the premium paid to the broker for setting up the trade. For example, if the current USD/EUR rate is 1.15, and the trader believes that this rate will change significantly over the next 15 days, the trader can use a double one-touch option with barriers at 1.10 and 1.20. The trader can profit if the rate moves beyond either of the two barriers.

## dbltouchsensbybls

Calculate prices and sensitivities for double one-touch and double no-touch binary options using Black-Scholes option pricing model

### Syntax

```
PriceSens = dbltouchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec,
Barrier, Payoff)
```

```
PriceSens = dbltouchsensbybls( ____, Name, Value)
```

### Description

`PriceSens = dbltouchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Barrier, Payoff)` calculates prices and sensitivities for double one-touch and double no-touch binary options using the Black-Scholes option pricing model.

`PriceSens = dbltouchsensbybls( ____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in the previous syntax.

### Examples

#### Calculate the Price and Sensitivities for a Double No-Touch Option

Compute the price and sensitivities for a double no-touch option using the following data:

```
AssetPrice = 105;
Rate = 0.1;
Volatility = 0.2;
Settle = '01-Jan-2018';
Maturity = '01-Jul-2018';
```

Define the `RateSpec` using `intenvset`.

```
RateSpec = intenvset('ValuationDate', Settle, 'StartDates', Settle, 'EndDates', ...
Maturity, 'Rates', Rate, 'Compounding', -1);
```

Define the `StockSpec` using `stockspec`.

```
DividendType = "Continuous";
DividendYield = Rate - 0.03;
StockSpec = stockspec(Volatility, AssetPrice, DividendType, DividendYield);
```

Define the sensitivities.

```
OutSpec = {'price', 'delta', 'gamma'};
```

Calculate the price and sensitivities for a double no-touch binary option.

```
BarrierSpec = "DNT";
Barrier = [120 80];
Payoff = 10;
```

```
[Price, Delta, Gamma] = dbltouchsensbybls(RateSpec, StockSpec, Settle, Maturity, BarrierSpec, Ba
Price = 5.6368
Delta = -0.2536
Gamma = -0.0275
```

## Input Arguments

### RateSpec — Interest-rate term structure

structure

Interest-rate term structure (annualized and continuously compounded), specified by the `RateSpec` obtained from `intenvset`. For information on the interest-rate specification, see `intenvset`.

Data Types: `struct`

### StockSpec — Stock specification for underlying asset

structure

Stock specification for the underlying asset, specified by the `StockSpec` obtained from `stockspec`.

`stockspec` handles several types of underlying assets. For example, for physical commodities, the price is `StockSpec.Asset`, the volatility is `StockSpec.Sigma`, and the convenience yield is `StockSpec.DividendAmounts`.

Data Types: `struct`

### Settle — Settlement or trade date

serial date number | date character vector | datetime object

Settlement or trade date for the double touch option, specified as an NINST-by-1 matrix using serial date numbers, date character vectors, or datetime objects.

Data Types: `double` | `char` | `datetime`

### Maturity — Maturity date

serial date number | date character vector

Maturity date for the double touch option, specified as an NINST-by-1 vector of serial date numbers or date character vectors.

Data Types: `double` | `char` | `cell`

### BarrierSpec — Double barrier option type

cell array of character vectors with values of 'DOT' or 'DNT' | string array with values of "DOT" or "DNT"

Double barrier option type, specified as an NINST-by-1 cell array of character vectors or string array with the following values:

- 'DOT' — Double one-touch. The double one-touch option defines two `Barrier` levels. A double one-touch option provides a `Payoff` if the underlying asset ever touches either the upper or lower `Barrier` levels.

- 'DNT' — Double no-touch. The double no-touch option defines two `Barrier` levels. A double no-touch option provides a `Payoff` if the underlying asset ever never touches either the upper or lower `Barrier` levels.

Data Types: `char` | `cell` | `string`

### **Barrier — Double barrier value**

numeric

Double barrier value, specified as an NINST-by-2 matrix of numeric values, where the first column is Upper Barrier(1)(UB) and the second column is Lower Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: `double`

### **Payoff — Payoff value**

numeric

Payoff value, specified as an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector in which the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

---

**Note** The payoff value is calculated for the point in time that the `Barrier` value is reached. The payoff is either cash or nothing. If you specify a double no-touch option using `BarrierSpec`, the payoff is at the `Maturity` of the option.

---

Data Types: `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `PriceSens = dbltouchsensbybls(RateSpec, StockSpec, OptSpec, Strike, Settle, Maturity, BarrierSpec, Barrier, 'OutSpec', 'Delta')`

### **OutSpec — Define outputs**

`{'Price'}` (default) | character vector with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All' | string array with values "Price", "Delta", "Gamma", "Vega", "Lambda", "Rho", "Theta", and "All"

Define outputs, specified as the comma-separated pair consisting of 'OutSpec' and an NOUT-by-1 or a 1-by-NOUT cell array of character vectors with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Lambda', 'Rho', 'Theta', and 'All'.

`OutSpec = {'All'}` specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price, in that order. This is the same as specifying `OutSpec` to include each sensitivity.

Example: `OutSpec = {'delta', 'gamma', 'vega', 'lambda', 'rho', 'theta', 'price'}`

Data Types: `char` | `cell`

## Output Arguments

### PriceSens — Expected prices or sensitivities for double one-touch options

matrix

Expected prices at time 0 or sensitivities (defined using OutSpec) for double one-touch options, returned as an NINST-by-1 matrix.

## More About

### Double One-Touch and Double No-Touch Options

Double one-touch options and double no-touch options work the same way as one-touch options, except that there are two barriers.

A double one-touch or double no-touch option provides a payoff if the underlying spot either ever or never touches either the upper or lower `Barrier` levels. If neither barrier level is breached prior to expiration, the option expires worthless and the trader loses all the premium paid to the broker for setting up the trade. For example, if the current USD/EUR rate is 1.15, and the trader believes that this rate will change significantly over the next 15 days, the trader can use a double one-touch option with barriers at 1.10 and 1.20. The trader can profit if the rate moves beyond either of the two barriers.

## fininstrument

Create specified instrument object type

### Syntax

```
Instrument = fininstrument(InstrumentType,Name,Value)
```

### Description

`Instrument = fininstrument(InstrumentType,Name,Value)` creates an instrument object specified by `InstrumentType` and specifies options using one or more name-value pair arguments. The available name-value pair arguments depend on the `InstrumentType` you specify.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Examples

#### Use fininstrument to Create OptionEmbeddedFixedBond Instrument

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object.

```
CallDates = datetime(2025,9,15) + calyears([0 1 2]');
CallStrikes = [101 103 105]';
CallSchedule = timetable(CallDates,CallStrikes);
OptionEmbedFixedBOption = fininstrument("OptionEmbeddedFixedBond", 'Maturity', "15-Sep-2031", 'Coups
```

```
OptionEmbedFixedBOption =
    OptionEmbeddedFixedBond with properties:
```

```

        CouponRate: 0.0300
           Period: 1
            Basis: 0
    EndMonthRule: 1
        Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
            Holidays: NaT
            IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
           StartDate: NaT
           Maturity: 15-Sep-2031
        CallDates: [3x1 datetime]
        PutDates: [0x1 datetime]
    CallSchedule: [3x1 timetable]
    PutSchedule: [0x0 timetable]
```

```

CallExerciseStyle: "bermudan"
PutExerciseStyle: [0x0 string]
Name: "option_embedded_fixedbond"

```

## Input Arguments

### InstrumentType — Type of instrument

character vector | string

Type of instrument, specified as a scalar string or character vector.

Use these options for interest-rate instruments:

- "Deposit" — For more information, see [Deposit](#).
- "FRA" — For more information, see [FRA](#).
- "FixedBond" — For more information, see [FixedBond](#).
- "FixedBondOption" — For more information, see [FixedBondOption](#).
- "FloatBond" — For more information, see [FloatBond](#).
- "FloatBondOption" — For more information, see [FloatBondOption](#).
- "OptionEmbeddedFixedBond" — For more information, see [OptionEmbeddedFixedBond](#).
- "OptionEmbeddedFloatBond" — For more information, see [OptionEmbeddedFloatBond](#).
- "Swap" — For more information, see [Swap](#).
- "Cap" — For more information, see [Cap](#).
- "Floor" — For more information, see [Floor](#).
- "Swaption" — For more information, see [Swaption](#).

Use these options for equity instruments:

- "Vanilla" — For more information, see [Vanilla](#).
- "Lookback" — For more information, see [Lookback](#).
- "Barrier" — For more information, see [Barrier](#).
- "DoubleBarrier" — For more information, see [DoubleBarrier](#).
- "Asian" — For more information, see [Asian](#).
- "Spread" — For more information, see [Spread](#).
- "VarianceSwap" — For more information, see [VarianceSwap](#).
- "Touch" — For more information, see [Touch](#).
- "DoubleTouch" — For more information, see [DoubleTouch](#).
- "Binary" — For more information, see [Binary](#).

Use these options for credit derivative instruments:

- "CDS" — For more information, see [CDS](#).
- "CDSOption" — For more information, see [CDSOption](#).

Data Types: string | char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Instrument = fininstrument("Cap", Name, Value)`

The available name-value pair arguments depend on the value you specify for `InstrumentType`.

### Name-Value Pair Arguments for Interest-Rate Instruments

- `Deposit` — For more information, see “Deposit Name-Value Pair Arguments” on page 11-2485.
- `FRA` — For more information, see “FRA Name-Value Pair Arguments” on page 11-2369.
- `FixedBond` — For more information, see “FixedBond Name-Value Pair Arguments” on page 11-2314.
- `FixedBondOption` — For more information, see “FixedBondOption Name-Value Pair Arguments” on page 11-2327.
- `FloatBond` — For more information, see “FloatBond Name-Value Pair Arguments” on page 11-2337.
- `FloatBondOption` — For more information, see “FloatBondOption Name-Value Pair Arguments” on page 11-2348.
- `OptionEmbeddedFixedBond` — For more information, see “OptionEmbeddedFixedBond Name-Value Pair Arguments” on page 11-2386.
- `OptionEmbeddedFloatBond` — For more information, see “OptionEmbeddedFloatBond Name-Value Pair Arguments” on page 11-2404.
- `Swap` — For more information, see “Swap Name-Value Pair Arguments” on page 11-2427.
- `Cap` — For more information, see “Cap Name-Value Pair Arguments” on page 11-2289.
- `Floor` — For more information, see “Floor Name-Value Pair Arguments” on page 11-2356.
- `Swaption` — For more information, see “Swaption Name-Value Pair Arguments” on page 11-2449.

### Name-Value Pair Arguments for Equity Instruments

- `Vanilla` — For more information, see “Vanilla Name-Value Pair Arguments” on page 11-2464.
- `Lookback` — For more information, see “Lookback Name-Value Pair Arguments” on page 11-2376.
- `Barrier` — For more information, see “Barrier Name-Value Pair Arguments” on page 11-2234.
- `DoubleBarrier` — For more information, see “DoubleBarrier Name-Value Pair Arguments” on page 11-2245.
- `Asian` — For more information, see “Asian Name-Value Pair Arguments” on page 11-2222.
- `Spread` — For more information, see “Spread Name-Value Pair Arguments” on page 11-2418.
- `VarianceSwap` — For more information, see “VarianceSwap Name-Value Pair Arguments” on page 11-2441.
- `Touch` — For more information, see “Touch Name-Value Pair Arguments” on page 11-2260.
- `DoubleTouch` — For more information, see “DoubleTouch Name-Value Pair Arguments” on page 11-2270.
- `Binary` — For more information, see “Binary Name-Value Pair Arguments” on page 11-2280.

**Name-Value Pair Arguments for Credit Derivative Instruments**

- CDS — For more information, see “CDS Name-Value Pair Arguments” on page 11-2301.
- CDSOption — For more information, see “CDSOption Name-Value Pair Arguments” on page 11-2308.

**Output Arguments****Instrument — Instrument**

instrument object

Instrument, returned as an instrument object.

**See Also**

finmodel | finpricer

**Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

**Introduced in R2020a**

## finmodel

Create specified model object type

### Syntax

```
Model = finmodel(ModelType,Name,Value)
```

### Description

`Model = finmodel(ModelType,Name,Value)` creates a `Model` object based on `ModelType` creates a model object specified by `ModelType` and specifies options using one or more name-value pair arguments.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Examples

#### Use finmodel to Create SABR Model

Use `finmodel` to create a SABR model object.

```
SabrModel = finmodel("SABR",'Alpha',0.032,'Beta',0.04, 'Rho', .08, 'Nu', 0043,'Shift',0.002)
```

```
SabrModel =
  SABR with properties:
      Alpha: 0.0320
      Beta: 0.0400
      Rho: 0.0800
      Nu: 43
      Shift: 0.0020
  VolatilityType: "black"
```

### Input Arguments

#### ModelType — Model type

character vector | string

Model type, specified as a scalar string or character vector.

These options are available for interest-rate instruments:

- "Black" — For more information, see `Black`.
- "HullWhite" — For more information, see `HullWhite`.
- "BlackKarasinski" — For more information, see `BlackKarasinski`.
- "Normal" — For more information, see `Normal`.
- "SABR" — For more information, see `SABR`.

These options are available for equity instruments:

- "BlackScholes" — For more information, see `BlackScholes`.
- "Heston" — For more information, see `Heston`.
- "Bates" — For more information, see `Bates`.
- "Merton" — For more information, see `Merton`.
- "Dupire" — For more information, see `Dupire`.

These options are available for credit derivative instruments:

- "CDSBlack" — For more information, see `CDSBlack`.

Data Types: `string` | `char`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Model = finmodel("Black", Name, Value)`

The available name-value pair arguments depend on the value you specify for `ModelType`.

#### **Name-Value Pair Arguments for Interest-Rate Models**

- `Black` — For more information, see “Black Name-Value Pair Arguments” on page 11-2500.
- `HullWhite` — For more information, see “HullWhite Name-Value Pair Arguments” on page 11-2527.
- `BlackKarasinski` — For more information, see “BlackKarasinski Name-Value Pair Arguments” on page 11-2515.
- `Normal` — For more information, see “Normal Name-Value Pair Arguments” on page 11-2537.
- `Sabr` — For more information, see “SABR Name-Value Pair Arguments” on page 11-2547

#### **Name-Value Pair Arguments for Equity Models**

- `BlackScholes` — For more information, see “BlackScholes Name-Value Pair Arguments” on page 11-2509.
- `Heston` — For more information, see “Heston Name-Value Pair Arguments” on page 11-2520.
- `Bates` — For more information, see “Bates Name-Value Pair Arguments” on page 11-2492.
- `Merton` — For more information, see “Merton Name-Value Pair Arguments” on page 11-2531.
- `Dupire` — For more information, see “Dupire Name-Value Pair Arguments” on page 11-2541.

**Name-Value Pair Arguments for Credit Derivative Models**

- CDSBlack — For more information, see “CDSBlack Name-Value Pair Arguments” on page 11-2504.

**Output Arguments****Model — Model**

model object

Model, returned as a model object.

**See Also**

fininstrument | finpricer

**Introduced in R2020a**

# finpricer

Create pricing method

## Syntax

```
Pricer = finpricer(PricerType,Name,Value)
```

## Description

`Pricer = finpricer(PricerType,Name,Value)` creates a `Pricer` object based on `PricerType` creates a pricer object and specifies options using one or more name-value pair arguments. The available name-value pair arguments depend on the `PricerType` you specify.

For more information on the workflow for creating an instrument object, a model object, and a pricer object, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Examples

### Use finpricer to Create ConzeViswanathan Pricer

This example shows the workflow to create a `BlackScholes` model and `ratecurve` object to use with a `ConzeViswanathan` pricing method.

#### Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .358)
```

```
BlackScholesModel =  
    BlackScholes with properties:
```

```
    Volatility: 0.3580  
    Correlation: 1
```

#### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);  
Type = 'zero';  
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];  
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';  
ZeroDates = Settle + ZeroTimes;  
  
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =  
  ratecurve with properties:  
  
      Type: "zero"  
    Compounding: -1  
      Basis: 0  
      Dates: [10x1 datetime]  
      Rates: [10x1 double]  
    Settle: 15-Sep-2020  
    InterpMethod: "linear"  
ShortExtrapMethod: "next"  
LongExtrapMethod: "previous"
```

### Create ConzeViswanathan Pricer Object

Use `finpricer` to create a `ConzeViswanathan` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 950,  
outPricer =  
  ConzeViswanathan with properties:  
  
    DiscountCurve: [1x1 ratecurve]  
      Model: [1x1 finmodel.BlackScholes]  
    SpotPrice: 950  
DividendValue: 2.5000  
DividendType: "continuous"
```

## Input Arguments

### PricerType — Pricer type

character vector | string

Pricer type, specified as a scalar string or character vector.

These options are available for interest-rate instruments:

- "Discount" — For more information, see `Discount`.
- "IRTree" — For more information, see `IRTree`.
- "HullWhite" — For more information, see `HullWhite`.
- "Analytic" — The "Analytic" pricer can be any one of the following types of pricing methods:
  - SABR — For more information, see `SABR`.
  - Normal — For more information, see `Normal`.
  - Black — For more information, see `Black`.

These options are available for equity instruments:

- "Analytic" — The "Analytic" pricer can be any one of the following types of pricing methods:
  - `BlackScholes` — For more information, see `BlackScholes`.

- IkedaKunitomo — For more information, see IkedaKunitomo.
- Heston — For more information, see Heston.
- Levy — For more information, see Levy.
- KemnaVorst — For more information, see KemnaVorst.
- TurnbullWakeman — For more information, see TurnbullWakeman.
- ConzeViswanathan — For more information, see ConzeViswanathan.
- GoldmanSosinGatto — For more information, see GoldmanSosinGatto.
- RollGeskeWhaley — For more information, see RollGeskeWhaley.
- Kirk — For more information, see Kirk.
- BjerksundStensland — For more information, see BjerksundStensland.
- "AssetMonteCarlo" — For more information, see AssetMonteCarlo.
- "FiniteDifference" — For more information, see FiniteDifference.
- "FFT" — For more information, see FFT.
- "NumericalIntegration" — For more information, see NumericalIntegration.
- "VannaVolga" — For more information, see VannaVolga.
- "ReplicatingVarianceSwap" — For more information, see ReplicatingVarianceSwap.

These options are available for credit derivative instruments:

- "Credit" — For more information, see Credit.
- "Analytic" — The "Analytic" pricer can be any one of the following types of pricing methods:
  - CDSBlack — For more information, see CDSBlack.

Data Types: `string` | `char`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `Pricer = finpricer("Black", Name, Value)`

Depending on the `PricerType`, the associated name-value pair arguments are different.

#### **Name-Value Pair Arguments for Interest-Rate Pricers**

- `IRTree` — For more information, see `IRTree`.
- `Black` — For more information, see `Black`.
- `HullWhite` — For more information, see `HullWhite`.
- `Normal` — For more information, see `Normal`.
- `Sabr` — For more information, see `Sabr`.
- `Discount` — For more information, see `Discount`.

#### **Name-Value Pair Arguments for Equity Pricers**

- `Levy` — For more information, see `Levy`.

- `KemnaVorst` — For more information, see `KemnaVorst`.
- `TurnbullWakeman` — For more information, see `TurnbullWakeman`.
- `BlackScholes` — For more information, see `BlackScholes`.
- `IkedaKunitomo` — For more information, see `IkedaKunitomo`.
- `Heston` — For more information, see `Heston`.
- `ConzeViswanathan` — For more information, see `ConzeViswanathan`.
- `GoldmanSosinGatto` — For more information, see `GoldmanSosinGatto`.
- `RollGeskeWhaley` — For more information, see `RollGeskeWhaley`.
- `Kirk` — For more information, see `Kirk`.
- `Bjerk SundStensland` — For more information, see `Bjerk SundStensland`.
- `AssetMonteCarlo` — For more information, see `AssetMonteCarlo`.
- `FiniteDifference` — For more information, see `FiniteDifference`.
- `FFT` — For more information, see `FFT`.
- `NumericalIntegration` — For more information, see `NumericalIntegration`.
- `VannaVolga` — For more information, see `NumericalIntegration`.
- `ReplicatingVarianceSwap` — For more information, see `ReplicatingVarianceSwap`.

#### **Name-Value Pair Arguments for Credit Derivative Pricers**

- `Credit` — For more information, see `Credit`.
- `CDSBlack` — For more information, see `CDSBlack`.

## **Output Arguments**

### **Pricer — Pricer**

`pricer` object

`Pricer`, returned as a `pricer` object.

## **See Also**

`fininstrument` | `finmodel`

# irbootstrap

Bootstrap interest-rate curve from market data

## Syntax

```
outCurve = irbootstrap(BootInstruments,Settle)
outCurve = irbootstrap( ____,Name,Value)
```

## Description

`outCurve = irbootstrap(BootInstruments,Settle)` creates a data structure for storing interest-rate term structure data. The `outCurve` output is a `ratecurve` object.

`outCurve = irbootstrap( ____,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntax. For example, `OutCurve = irbootstrap("zero",BootInstruments,Settle,'Compounding',2,'Basis',5,'InterpMethod','cubic')` bootstraps a zero curve from `BootInstruments`.

## Examples

### Bootstrap ratecurve Object from Market Data

#### Define Deposit and Swap Parameters

```
Settle = datetime(2018,3,21);
DepRates = [.0050769 .0054934 .0061432 .0072388 .0093263]';
DepTimes = [1 2 3 6 12]';
DepDates = datemnth(Settle,DepTimes);
nDeposits = length(DepTimes);

SwapRates = [.0112597 0;.0128489 0;.0138917 0;.0146135 0;.0151175 0;...
             .0155184 0;.0158536 0;.0161435 0];
SwapTimes = (2:9)';
SwapDates = datemnth(Settle,12*SwapTimes);
nSwaps = length(SwapTimes);

nInst = nDeposits + nSwaps;
```

#### Create a Vector of Market Swap Instruments

Use `fininstrument` to create a vector of market Deposit and Swap instrument objects.

```
BootInstruments(nInst,1) = fininstrument.FinInstrument;
for ii=1:length(DepDates)
    BootInstruments(ii) = fininstrument("deposit",'Maturity',DepDates(ii),'Rate',DepRates(ii))
end

for ii=1:length(SwapDates)
    BootInstruments(ii+nDeposits) = fininstrument("swap",'Maturity',SwapDates(ii),'LegRate',[S
end
```

## Create ratecurve Object for Zero-Rate Curve

Use `irbootstrap` to create a `ratecurve` object for the zero-rate curve.

```
ZeroCurve = irbootstrap(BootInstruments,Settle)
```

```
ZeroCurve =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [13x1 datetime]
      Rates: [13x1 double]
      Settle: 21-Mar-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "linear"
      LongExtrapMethod: "linear"
```

## Input Arguments

### BootInstruments — Collection of instruments

array of instrument objects

Collection of instruments, specified as an array of instrument objects.

Data Types: `object`

### Settle — Settlement date

`datetime` | `serial date number` | `date character vector` | `date string`

Settlement date, specified as a scalar `datetime`, `serial date number`, `date character vector`, or `date string`.

Data Types: `double` | `char` | `string` | `datetime`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: OutCurve =
irbootstrap("zero",BootInstruments,Settle,'Compounding',2,'Basis',5,'InterpMethod','cubic')
```

### Type — Type of interest-rate curve

"zero" (default) | string with value "discount", "forward", or "zero" | character vector with value 'discount', 'forward', or 'zero'

Type of interest-rate curve, specified as a scalar string or character vector.

When you use `irbootstrap`, the value you specify for `Type` can impact the curve construction because it affects the type of data that is interpolated on (that is, forward rates, zero rates, or discount factors) during the bootstrapping process.

Data Types: char | string

### **Compounding — Compounding frequency**

Compounding for the ratecurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency, specified as the comma-separated pair consisting of 'Compounding' and a scalar numeric using the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **InterpMethod — Interpolation method**

"linear" (default) | string with value "linear", "cubic", "next", "previous", "pchip", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'cubic', 'next', 'previous', 'pchip', 'v5cubic', 'makima', or 'spline'

Interpolation method, specified as the comma-separated pair consisting of 'InterpMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

### **ShortExtrapMethod — Extrapolation method for data before first data**

"next" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'next', 'previous', 'pchip', 'cubic', 'v5cubic', 'makima', or 'spline'

Extrapolation method for data before first data, specified as the comma-separated pair consisting of 'ShortExtrapMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

**LongExtrapMethod — Extrapolation method for data after last data**

"previous" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'next', 'previous', 'pchip', 'cubic', 'v5cubic', 'makima', or 'spline'

Extrapolation method for data after last data, specified as the comma-separated pair consisting of 'LongExtrapMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: `char` | `string`

## Output Arguments

**outCurve — Rate curve**

ratecurve object

Rate curve, returned as a ratecurve object. The object has the following properties:

- Type
- Settle
- Compounding
- Basis
- Dates
- Rates
- InterpMethod
- ShortExtrapMethod
- LongExtrapMethod

## See Also

`discountfactors` | `forwardrates` | `ratecurve` | `zerorates`

### Introduced in R2020a

# fitNelsonSiegel

Fit Nelson-Siegel model to bond market data

## Syntax

```
outCurve = fitNelsonSiegel(Settle, Instruments, CleanPrice)
```

## Description

`outCurve = fitNelsonSiegel(Settle, Instruments, CleanPrice)` fits a Nelson-Siegel model to bond data.

## Examples

### Fit Nelson-Siegel Model to Bond Market Data

Define the bond data and use `fininstrument` to create `FixedBond` instrument objects.

```
Settle = datetime(2017,9,15);
Maturity = [datetime(2019,9,15);datetime(2021,9,15);...
            datetime(2023,9,15);datetime(2026,9,7);...
            datetime(2035,9,15);datetime(2047,9,15)];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];

nInst = numel(CouponRate);
Bonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    Bonds(ii) = fininstrument("FixedBond", 'Maturity', Maturity(ii), ...
                             'CouponRate', CouponRate(ii));
end
```

Use `fitNelsonSiegel` to create a `parametercurve` object.

```
NSModel = fitNelsonSiegel(Settle, Bonds, CleanPrice)
```

Local minimum possible.

`lsqnonlin` stopped because the final change in the sum of squares relative to its initial value is less than the value of the function tolerance.

```
NSModel =
    parametercurve with properties:

        Type: "zero"
        Settle: 15-Sep-2017
        Compounding: -1
        Basis: 0
        FunctionHandle: @(t)fitF(Params,t)
        Parameters: [1.2465e-05 0.0362 0.0903 16.4263]
```

## Input Arguments

### **Settle – Settlement date**

datetime | serial date number | date character vector | date string

Settlement date, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

### **Instruments – Bond instrument objects**

array

Bond instrument objects, specified as an array of bond instruments objects.

Data Types: object

### **CleanPrice – Observed market prices**

vector

Observed market prices, specified as a vector.

Data Types: double

## Output Arguments

### **outCurve – Fitted Nelson-Siegel model**

parametercurve object

Fitted Nelson-Siegel model, returned as a parametercurve object.

## See Also

discountfactors | forwardrates | zerorates

### **Topics**

“Choose Instruments, Models, and Pricers” on page 1-43

**Introduced in R2020a**

# price

**Package:** `finpricer.analytic`

Compute price for interest-rate, equity, or credit derivative instrument with `Analytic` pricer

## Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

## Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

The `Analytic` pricer supports the following pricer objects:

- `BjerksundStensland`
- `IkedaKunitomo`
- `Black`
- `BlackScholes`
- `CDSBlack`
- `ConzeViswanathan`
- `GoldmanSosinGatto`
- `HullWhite`
- `Heston`
- `KemnaVorst`
- `Kirk`
- `Levy`
- `Normal`
- `RollGeskeWhaley`
- `SABR`
- `TurnbullWakeman`

`[Price,PriceResult] = price( ____,inpSensitivity)` adds an optional argument to specify sensitivities.

## Examples

### Use Bjerksund-Stensland Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a European exercise Spread instrument when you use a `BlackScholes` model and a `BjerksundStensland` pricing method.

### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 5, 'ExerciseDate', datetime(2021, 9, 15), 'OptionType', "put")
SpreadOpt =
    Spread with properties:
        OptionType: "put"
        Strike: 5
        ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2021
        Name: "spread_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [0.2, 0.1])
BlackScholesModel =
    BlackScholes with properties:
        Volatility: [0.2000 0.1000]
        Correlation: [2x2 double]
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 9, 15);
Maturity = datetime(2023, 9, 15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', [100
```

```

outPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
    SpotPrice: [100 105]
    DividendValue: [0.0900 0.1700]
    DividendType: "continuous"

```

## Price Spread Instrument

Use price to compute the price and sensitivities for the Spread instrument.

```
[Price, outPR] = price(outPricer, SpreadOpt, ["all"])
```

```
Price = 7.0596
```

```

outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta		Gamma		Lambda		Vega
7.0596	-0.23249	0.27057	0.0069887	0.0055319	-3.2932	3.8327	41.938

## Input Arguments

### inpPricer – Pricer object

BjerksundStensland object | IkedaKunitomo object | Black object | BlackScholes object | CDSBlack object | ConzeViswanathan object | GoldmanSosinGatto object | HullWhite object | Heston object | KemnaVorst object | Kirk object | Levy object | Normal object | RollGeskeWhaley object | SABR object | TurnbullWakeman object

Pricer object (previously created using `finpricer`), specified as a scalar. The supported pricer objects are:

- BjerksundStensland
- IkedaKunitomo
- Black
- BlackScholes
- CDSBlack
- ConzeViswanathan
- GoldmanSosinGatto
- HullWhite

- Heston
- KemnaVorst
- Kirk
- Levy
- Normal
- RollGeskeWhaley
- SABR
- TurnbullWakeman

Data Types: object

**inpInstrument – Instrument object**

Cap object | Floor object | Swaption object | Vanilla object | Lookback object | Barrier object | DoubleBarrier object | Asian object | Spread object | VarianceSwap object | CDSOption object

Instrument object (previously created using `fininstrument`), specified as a scalar. The supported instrument objects are:

- Cap
- Floor
- Swaption
- Vanilla
- Lookback
- Barrier
- DoubleBarrier
- Asian
- Spread
- VarianceSwap
- CDSOption

Data Types: object

**inpSensitivity – List of sensitivities to compute**

[ ] (default) | string array of character vectors with values dependent on pricer object | cell array of character vectors with values dependent on pricer object

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array.

The supported sensitivities depend on the pricing method.

inpPricer Object	Supported Sensitivities
Bjerk SundStensland	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}
IkedaKunitomo	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}

<b>inpPricer Object</b>	<b>Supported Sensitivities</b>
Black	'price'
BlackScholes	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}
CDSBlack	'price'
ConzeViswanathan	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}
GoldmanSosinGatto	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}
HullWhite	'price'
Heston	'price'
KemnaVorst	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}
Kirk	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}
Levy	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}
Normal	'price'
RollGeskeWhaley	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', 'lambda'}
SABR	'price'
TurnbullWakeman	{'delta', 'gamma', 'vega', 'theta', 'rho', 'price', }

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that all sensitivities for the pricing method are returned. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = ["delta", "gamma", "vega", "lambda", "rho", "theta", "price"]`

Data Types: `cell | string`

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)

- `PriceResult.PricerData` — Structure for pricer data

---

**Note** When pricing a `VarianceSwap`, `PriceResult.FairVariance` is returned.

---

**Note** The `inpPricer` options that do not support sensitivities do not return a `PriceResult`. For example, there is no `PriceResult` returned for when using a `Black`, `CDSBlack`, `HullWhite`, `Normal`, `Heston`, or `SABR` pricing method.

---

**Introduced in R2020a**

# price

**Package:** finpricer

Compute price for equity instrument with VannaVolga pricer

## Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

## Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

[Price,PriceResult] = price( \_\_\_\_,inpSensitivity) adds an optional argument to specify sensitivities.

## Examples

TBD

## Input Arguments

### inpPricer — Pricer object

VannaVolga object

Pricer object, specified as a scalar VannaVolga pricer object. Use finpricer to create the VannaVolga pricer object.

Data Types: object

### inpInstrument — Instrument object

Vanilla object | Barrier object | DoubleBarrier object | Touch object

Instrument object, specified as a scalar Vanilla, Barrier, DoubleBarrier, Touch, or DoubleTouch instrument object. Use fininstrument to create the Vanilla, Barrier, DoubleBarrier, Touch, or DoubleTouchinstrument object.

Data Types: object

### inpSensitivity — List of sensitivities to compute

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", "Rho", "Theta", 'Lambda', and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Lambda', 'Vega', 'Rho', 'Theta', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with supported values.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Delta, Gamma, Vega, Lambda, Rho, Theta, and Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'delta', 'gamma', 'vega', 'rho', 'lambda', 'theta', 'price'}`

The sensitivities supported depend on the `inpInstrument`.

<b>inpInstrument</b>	<b>Supported Sensitivities</b>
Vanilla,	'delta', 'gamma', 'vega', 'rho', 'lambda', 'theta', 'price'
Barrier	'delta', 'gamma', 'vega', 'rho', 'lambda', 'theta', 'price'
DoubleBarrier	'delta', 'gamma', 'vega', 'rho', 'lambda', 'theta', 'price'
Touch	'delta', 'gamma', 'vega', 'rho', 'lambda', 'theta', 'price'
DoubleTouch	'delta', 'gamma', 'vega', 'rho', 'lambda', 'theta', 'price'

Data Types: `string` | `cell`

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data
- `PriceResult.PricerData.Overhedge` — TBD

# price

**Package:** finpricer

Compute price for Vanilla, Barrier, Lookback, Asian, Spread, DoubleBarrier, Touch, DoubleTouch, or Binary instrument with AssetMonteCarlo pricer

## Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

## Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

[Price,PriceResult] = price( \_\_\_\_,inpSensitivity) adds an optional argument to specify sensitivities. Use this syntax with the input argument combination in the previous syntax.

## Examples

### Price Touch Instrument Using Heston Model and Asset Monte Carlo Pricer

This example shows the workflow to price a Touch instrument when you use a Heston model and an AssetMonteCarlo pricing method.

#### Create Touch Instrument Object

Use fininstrument to create a Touch instrument object.

```
TouchOpt = fininstrument("Touch", 'ExerciseDate',datetime(2022,9,15), 'BarrierValue',110, 'PayoffValue',140)
```

```
TouchOpt =
    Touch with properties:
        ExerciseDate: 15-Sep-2022
        BarrierValue: 110
        PayoffValue: 140
        BarrierType: "ot"
        PayoffType: "expiry"
        Name: "touch_option"
```

#### Create Heston Model Object

Use finmodel to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0',0.032, 'ThetaV',0.1, 'Kappa',0.003, 'SigmaV',0.2, 'RhoSV',0.9)
```

```
HestonModel =
    Heston with properties:
```

```
V0: 0.0320
ThetaV: 0.1000
Kappa: 0.0030
SigmaV: 0.2000
RhoSV: 0.9000
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use finpricer to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo","DiscountCurve",myRC,"Model",HestonModel,'SpotPrice',112)
```

```
outPricer =
  HestonMonteCarlo with properties:

    DiscountCurve: [1x1 ratecurve]
    SpotPrice: 112
    SimulationDates: 15-Sep-2022
    NumTrials: 1000
    RandomNumbers: []
    Model: [1x1 finmodel.Heston]
    DividendType: "continuous"
    DividendValue: 0
```

### Price Touch Instrument

Use price to compute the price and sensitivities for the Touch instrument.

```
[Price, outPR] = price(outPricer,TouchOpt,["all"])
```

```
Price = 63.5247
```

```

outPR =
  pricerresult with properties:
    Results: [1x8 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```

ans=1x8 table
  Price      Delta      Gamma      Lambda      Rho      Theta      Vega      VegaLT
  _____  _____  _____  _____  _____  _____  _____  _____
  63.525     -7.2363    1.0541     -12.758     -320.21    3.5527    418.94    8.1498

```

## Input Arguments

### **inpPricer** — Pricer object

AssetMonteCarlo object

Pricer object, specified as a previously created AssetMonteCarlo pricer object. Create the pricer object using `finpricer`.

Data Types: object

### **inpInstrument** — Instrument object

Vanilla object | Barrier object | Lookback object | Asian object | DoubleBarrier object | Spread object | Touch object | DoubleTouch object | Binary object

Instrument object, specified as a previously created instrument object. Create the instrument object using `fininstrument`. The following instrument objects are supported:

- Vanilla
- Lookback
- Barrier
- Asian
- Spread
- DoubleBarrier
- Binary
- Touch
- DoubleTouch

Data Types: object

### **inpSensitivity** — List of sensitivities to compute

[ ] (default) | string array of character vectors with values dependent on pricer object | cell array of character vectors with values dependent on pricer object

(Optional) List of sensitivities to compute, specified as an NOUT-by-1 or 1-by-NOUT cell array of character vectors or string array.

The supported sensitivities depend on the pricing method.

inpInstrument Object	Supported Sensitivities
Vanilla	{'delta','gamma','vega','theta','rho','price','lambda'}
Lookback	{'delta','gamma','vega','theta','rho','price','lambda'}
Barrier	{'delta','gamma','vega','theta','rho','price','lambda'}
Asian	{'delta','gamma','vega','theta','rho','price','lambda'}
Spread	{'delta','gamma','vega','theta','rho','price','lambda'}
DoubleBarrier	{'delta','gamma','vega','theta','rho','price','lambda'}
Binary	{'delta','gamma','vega','theta','rho','price','lambda'}
Touch	{'delta','gamma','vega','theta','rho','price','lambda'}
DoubleTouch	{'delta','gamma','vega','theta','rho','price','lambda'}

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that all sensitivities for the pricing method are returned. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = ["delta","gamma","vega","lambda","rho","theta","price"]`

Data Types: cell | string

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

**Note** The `inpPricer` options that do not support sensitivities do not return a PriceResult. For example, there is no PriceResult returned for when you use a Black, CDSBlack, HullWhite, Normal, or SABR pricing method.

## price

**Package:** finpricer

Compute price for interest-rate instrument with IRTree pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

[Price,PriceResult] = price( \_\_\_\_,inpSensitivity) adds an optional argument to specify sensitivities.

### Examples

#### Use Hull-White Tree Pricer and Hull-White Model to Price FixedBondOption Instrument

This example shows the workflow to price a FixedBondOption instrument when you use a HullWhite model and an IRTree pricing method.

##### Create FixedBond Instrument Object

Use fininstrument to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', 0.025, 'Period',
```

```
BondInst =
    FixedBond with properties:
        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2029
        Name: "fixed_bond_instrument"
```

### Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98, 'B
FixedBOption =
  FixedBondOption with properties:

    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2025
    Strike: 98
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option_instrument"
```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.01, 'Sigma', 0.05)

HullWhiteModel =
  HullWhite with properties:

    Alpha: 0.0100
    Sigma: 0.0500
```

## Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the 'DiscountCurve' name-value pair argument.

```
HWTreepricer = finpricer("irtree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', ZeroDa
```

```
HWTreepricer =
  HWBKTreepricer with properties:

      Tree: [1x1 struct]
   TreeDates: [10x1 datetime]
      Model: [1x1 finmodel.HullWhite]
DiscountCurve: [1x1 ratecurve]
```

HWTreepricer.Tree

```
ans = struct with fields:
   FinObj: 'HWFwdTree'
   tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
   dObs: [1x10 datetime]
   CFlowT: {1x10 cell}
   Probs: {1x9 cell}
   Connect: {1x9 cell}
   FwdTree: {1x10 cell}
```

## Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(HWTreepricer, FixedBOption, ["all"])
```

```
Price = 11.1739
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x4 table]
   PricerData: [1x1 struct]
```

outPR.Results

```
ans=1x4 table
   Price      Vega      Gamma      Delta
   _____  _____  _____  _____
   11.174     243.09     3667.6     -272.19
```

## Input Arguments

### inpPricer — Pricer object

IRTree object

Pricer object, specified as a scalar `IRTree` pricer object. Use `finpricer` to create the `IRTree` pricer object.

Data Types: object

### **inpInstrument – Instrument object**

FixedBond object | OptionEmbeddedFixedBond object | FixedBondOption object | FloatBond object

Instrument object, specified as a previously created instrument object. Create the instrument object using `fininstrument`. The following instrument objects are supported:

- Cap
- Floor
- Swaption
- FixedBond
- OptionEmbeddedFixedBond
- FixedBondOption
- FloatBond
- FloatBondOption
- OptionEmbeddedFloatBond

Data Types: object

### **inpSensitivity – List of sensitivities to compute**

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with possible values of 'Price', 'Delta', 'Gamma', 'Vega', and 'All'.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Delta, Gamma, Vega, and Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

The sensitivities supported depend on the `inpInstrument`.

<b>inpInstrument</b>	<b>Supported Sensitivities</b>
Cap	{'delta', 'gamma', 'vega', 'price'}
Floor	{'delta', 'gamma', 'vega', 'price'}
Swaption	{'delta', 'gamma', 'vega', 'price'}
FixedBond	{'delta', 'gamma', 'vega', 'price'}
OptionEmbeddedFixedBond	{'delta', 'gamma', 'vega', 'price'}
FixedBondOption	{'delta', 'gamma', 'vega', 'price'}
FloatBond	{'delta', 'gamma', 'vega', 'price'}
FloatBondOption	{'delta', 'gamma', 'vega', 'price'}
OptionEmbeddedFloatBond	{'delta', 'gamma', 'vega', 'price'}

---

**Note** Sensitivities are calculated based on yield shifts of 1 basis point, where the `ShiftValue = 1/10000`. All sensitivities are returned as dollar sensitivities. To find the per-dollar sensitivities, divide the sensitivities by their respective instrument price.

---

Example: `inpSensitivity = {'delta','gamma','vega','price'}`

Data Types: `string | cell`

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data that depends on the instrument that is being priced

`FixedBond`, `FloatBond`, `FixedBondOption`, and `OptionEmbeddedFixedBond` have the following shared fields for `PriceResult.PricerData.PriceTree`:

- `FinObj` contains 'HWPriceTree' or 'BKPriceTree' depending whether you use a HullWhite or BlackKarasinski model.
- `tObs` contains the observation times.
- `Connect` contains the connectivity vectors. Each element in the cell array describes how nodes in that level connect to the next. For a given tree level, there are `NumNodes` elements in the vector, and they contain the index of the node at the next level that the middle branch connects to. Subtracting 1 from that value indicates where the up-branch connects to, and adding 1 indicates where the down branch connects to.

The following additional fields for `PriceResult.PricerData.PriceTree` depend on the instrument type:

- `Ptree` contains the clean prices.
- `AITree` contains the accrued interest.
- `Probs` contains the probability arrays. Each element of the cell array contains the up, middle, and down transition probabilities for each node of the level.
- `dObs` contains the date of each level of the tree.
- `CFlowT` is a cell array with as many elements as levels of the tree. Each cell array element contains the time factors (`tObs`) corresponding to its level of the tree and those levels ahead of it.
- `FwdTree` contains the forward spot rate from one node to the next. The forward spot rate is defined as the inverse of the discount factor.
- `ExTree` contains the exercise indicator arrays. Each element of the cell array is an array containing 1's where an option is exercised and 0's where it isn't.

- ProbTree contains the probability of reaching each node from root node.
- ExProbTree contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.
- ExProbsByTreeLevel is an array with each row holding the exercise probability for a given option at each tree observation time.

A FixedBond instrument has these additional fields within PriceResult.PricerData.PriceTree:

- PTree
- AITree
- Probs.

A FloatBond instrument has these additional fields within PriceResult.PricerData.PriceTree:

- dObs
- CFlowT
- Probs
- FwdTree

A FixedBondOption instrument has these additional fields within PriceResult.PricerData.PriceTree:

- PTree
- Probs
- ExTree

A OptionEmbeddedFixedBond instrument has these additional fields within PriceResult.PricerData.PriceTree:

- PTree
- ExTree
- ProbTree
- ExProbTree
- ExProbsByTreeLevel

The following table displays the PriceResult.PricerData.PriceTree fields related to each instrument.

PriceResult.PricerData.PriceTree Fields	FixedBond	FloatBond	FixedBondOption	OptionEmbeddedFixedBond
FinObj	✓	✓	✓	✓
tObs	✓	✓	✓	✓
Connect	✓	✓	✓	✓
PTree	✓	No	✓	✓

PriceResult.PricerData.PriceTree Fields	FixedBond	FloatBond	FixedBondOption	OptionEmbeddedFixedBond
AITree	✓	No	No	No
Probs	✓	✓	✓	No
dObs	No	✓	No	No
CFlowT	No	✓	No	No
FwdTree	No	✓	✓	✓
ExTree	No	No	✓	✓
ProbTree	No	No	No	✓
ExProbTree	No	No	No	✓
ExProbsByTreeLevel	No	No	No	✓

## Introduced in R2020a

# price

**Package:** finpricer

Compute price for credit derivative instrument with Credit pricer

## Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
```

## Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

## Examples

### Use Credit Pricer and Default Probability Curve to Price CDS Instrument

This example shows the workflow to price a CDS instrument when you use a defprobcurve model and a Credit pricing method.

#### Create CDS Instrument Object

Use fininstrument to create a CDS instrument object.

```
CDS = fininstrument("cds", 'Maturity',datetime(2027,9,20), 'ContractSpread', 50, 'Name', "CDS_instrument")
```

```
CDS =
  CDS with properties:
      ContractSpread: 50
      Maturity: 20-Sep-2027
      Period: 4
      Basis: 2
      RecoveryRate: 0.4000
      BusinessDayConvention: "actual"
      Holidays: NaT
      PayAccruedPremium: 1
      Notional: 10000000
      Name: "CDS_instrument"
```

#### Create defprobcurve Object

Create a defprobcurve object using defprobcurve.

```
Settle = datetime(2017, 9, 20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities)
```

```
DefaultProbCurve =
  defprobcurve with properties:

        Settle: 20-Sep-2017
        Basis: 2
        Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates)
```

```
ZeroCurve =
  ratecurve with properties:

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 20-Sep-2017
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create Credit Pricer Object

Use finpricer to create a Credit pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
CDSpricer = finpricer("credit", 'DiscountCurve', ZeroCurve, 'DefaultProbabilityCurve', DefaultProbCurve)
```

```
CDSpricer =
  Credit with properties:

        DiscountCurve: [1x1 ratecurve]
        TimeStep: 10
    DefaultProbabilityCurve: [1x1 defprobcurve]
```

### Price CDS Instrument

Use price to compute the price for the CDS instrument.

```
outPrice = price(CDSpricer, CDS)
```

```
outPrice = 6.9363e+04
```

## Input Arguments

### inpPricer — Pricer object

Credit pricer object

Pricer object, specified as a scalar `Credit` pricer object. Use `finpricer` to create the `Credit` pricer object.

Data Types: `object`

### **inpInstrument — Instrument object**

`CDS` object

Instrument object, specified as a scalar `CDS` instrument object. Use `fininstrument` to create the `CDS` instrument object.

Data Types: `object`

## **Output Arguments**

### **Price — Instrument price**

`numeric`

Instrument price, returned as a `numeric`.

### **PriceResult — Price result**

`PriceResult` object

Price result, returned as a `PriceResult` object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes the `CDS` price and accrued premium
- `PriceResult.PricerData` — Structure that includes the premium leg payment dates, times, and cash flows

## **See Also**

`fininstrument` | `finmodel` | `finpricer`

### **Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

### **Introduced in R2020a**

## price

**Package:** finpricer

Compute price for interest-rate instrument with Discount pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

[Price,PriceResult] = price(inpPricer,inpInstrument) computes the instrument price and related pricing information based on the pricing object inpPricer and the instrument object inpInstrument.

[Price,PriceResult] = price( \_\_\_\_,inpSensitivity) adds an optional argument to specify sensitivities.

### Examples

#### Use Discount Pricer and ratecurve to Price Swap Instrument

This example shows the workflow to price a Swap instrument when using a ratecurve and a Discount pricing method.

##### Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2022,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Jan-2022
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### Create Swap Instrument Object

Use `fininstrument` to create a Swap instrument object.

```
SwapOpt = fininstrument("Swap", 'Maturity', datetime(2027,1,15), 'LegRate', [0.024 0.015], 'LegType',
```

```
SwapOpt =
```

```
Swap with properties:
```

```

        LegRate: [0.0240 0.0150]
        LegType: ["fixed"    "float"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
        LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
        DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [1x2 ratecurve]
        BusinessDayConvention: ["actual" "actual"]
        Holidays: NaT
        EndMonthRule: [1 1]
        StartDate: NaT
        Maturity: 15-Jan-2027
        Name: "swap_instrument"
```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
```

```
Discount with properties:
```

```
DiscountCurve: [1x1 ratecurve]
```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the Swap instrument.

```
[Price, outPR] = price(outPricer, SwapOpt, ["all"])
```

```
Price = -1.3834
```

```
outPR =
```

```
pricerresult with properties:
```

```

        Results: [1x2 table]
        PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
    Price    DV01
    _____  _____
    -1.3834    0.023765
```

## Input Arguments

### inpPricer — Pricer object

Discount pricer object

Pricer object, specified as a scalar Discount pricer object. Use `finpricer` to create the Discountpricer object.

Data Types: object

### inpInstrument — Instrument object

Deposit object | FixedBond object | FloatBond object | FRA object | Swap object

Instrument object, specified as a scalar Deposit, FixedBond, FloatBond, FRA, or Swap instrument object. Use `fininstrument` to create the Deposit, FixedBond, FloatBond, FRA, or Swap instrument object.

Data Types: object

### inpSensitivity — List of sensitivities to compute

[ ] (default) | string array of character vector with values "Price", "DV01", and "All" | cell array of character vectors with values 'Price', 'DV01', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with possible values of 'Price' and 'DV01'.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Price and DV01. This is the same as specifying `inpSensitivity` to include each sensitivity.

The sensitivities supported depend on the `inpInstrument`.

inpInstrument	Supported Sensitivities
Deposit	{'DV01', 'price'}
FixedBond	{'DV01', 'price'}
FloatBond	{'DV01', 'price'}
FRA	{'DV01', 'price'}
Swap	{'DV01', 'price'}

Example: `inpSensitivity = {'DV01', 'price'}`

Data Types: cell | string

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### **PriceResult – Price result**

PriceResult object

Price result, returned as an object. The object has the following fields:

- `PriceResult.Results` – Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` – Structure for pricer data

### **See Also**

`fininstrument` | `finmodel` | `finpricer`

### **Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

### **Introduced in R2020a**

## price

**Package:** finpricer

Compute price for equity instrument with FFT pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ____,inpSensitivity)` adds an optional argument to specify sensitivities.

### Examples

#### Use FFT Pricer and Heston Model to Price Vanilla Instrument

This example shows the workflow to price a Vanilla instrument when you use a Heston model and an FFT pricing method.

##### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'ExerciseSty
```

```
VanillaOpt =
  Vanilla with properties:
```

```
    OptionType: "call"
  ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
        Strike: 105
        Name: "vanilla_option"
```

##### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

```
HestonModel =
  Heston with properties:
```

```

V0: 0.0320
ThetaV: 0.1000
Kappa: 0.0030
SigmaV: 0.2000
RhoSV: 0.9000

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create FFT Pricer Object

Use finpricer to create an FFT pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("fft",'DiscountCurve',myRC,'Model',HestonModel,'SpotPrice',100,'CharacteristicFcn',@characteristicFcnHeston)

```

```

outPricer =
  FFT with properties:
      Model: [1x1 finmodel.Heston]
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 100
      DividendType: "continuous"
      DividendValue: 0
      NumFFT: 8192
      CharacteristicFcnStep: 0.2000
      LogStrikeStep: 0.0038
      CharacteristicFcn: @characteristicFcnHeston
      DampingFactor: 1.5000
      Quadrature: "simpson"
      VolRiskPremium: 0
      LittleTrap: 1

```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
Price = 14.7545
outPR =
    pricerresult with properties:
        Results: [1x7 table]
        PricerData: []

outPR.Results
ans=1x7 table
    Price      Delta      Gamma      Theta      Rho      Vega      VegaLT
    _____  _____  _____  _____  _____  _____  _____
    14.754    0.44868    0.021649   -0.20891   120.45    88.192    1.3248
```

## Input Arguments

### inpPricer — Pricer object

FFT object

Pricer object, specified as a scalar FFT pricer object. Use `finpricer` to create the FFT pricer object.

Data Types: object

### inpInstrument — Instrument object

Vanilla object

Instrument object, specified as a Vanilla instrument object. Use `fininstrument` to create the Vanilla instrument object.

Data Types: object

### inpSensitivity — List of sensitivities to compute

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", "Rho", "Theta", "Vegalt", and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Rho', 'Theta', 'Vegalt', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Rho', 'Theta', 'Vegalt', and 'All'.

---

**Note** For a Vanilla instrument using a Heston model, 'Vegalt' is not supported.

---

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Delta, Gamma, Vega, Rho, Theta, Vegalt, and Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'delta', 'gamma', 'vega', 'rho', 'theta', 'vegalt', 'price'}`

Data Types: string | cell

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

## See Also

`fininstrument` | `finmodel` | `finpricer`

### Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

### Introduced in R2020a

## price

**Package:** finpricer

Compute price for equity instrument with FiniteDifference pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
```

```
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ____,inpSensitivity)` adds an optional argument to specify sensitivities.

### Examples

#### Use Finite Difference Pricer and Black-Scholes Model to Price Barrier Instrument

This example shows the workflow to price a Barrier instrument when you use a BlackScholes model and a FiniteDifference pricing method.

##### Create Barrier Instrument Object

Use `fininstrument` to create a Barrier instrument object.

```
BarrierOpt = fininstrument("Barrier", 'Strike', 105, 'ExerciseDate', datetime(2019,1,1), 'OptionType'
```

```
BarrierOpt =  
  Barrier with properties:  
  
    OptionType: "call"  
        Strike: 105  
    BarrierType: "do"  
BarrierValue: 40  
        Rebate: 0  
ExerciseStyle: "american"  
ExerciseDate: 01-Jan-2019  
        Name: "barrier_option"
```

##### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.30)
```

```

BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.3000
    Correlation: 1

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)

myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 1
    Dates: 01-Jan-2023
    Rates: 0.0350
    Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create FiniteDifference Pricer Object

Use finpricer to create a FiniteDifference pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("FiniteDifference",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice')

outPricer =
  FiniteDifference with properties:

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
    GridProperties: [1x1 struct]
    DividendType: "continuous"
    DividendValue: 0

```

### Price Barrier Instrument

Use price to compute the price and sensitivities for the Barrier instrument.

```

[Price, outPR] = price(outPricer,BarrierOpt,["all"])

Price = 11.3230

outPR =
  pricerresult with properties:

```

```
Results: [1x7 table]
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
11.323	0.54126	0.0132	4.7802	-7.4408	42.766	39.627

## Input Arguments

### inpPricer – Pricer object

FiniteDifference object

Pricer object, specified as a scalar FiniteDifference pricer object. Use `finpricer` to create the FiniteDifference pricer object.

Data Types: object

### inpInstrument – Instrument object

Vanilla object | Barrier object | DoubleBarrier object

Instrument object, specified as a scalar Vanilla, Barrier, or DoubleBarrier instrument object. Use `fininstrument` to create the Vanilla, Barrier or DoubleBarrierinstrument object.

Data Types: object

### inpSensitivity – List of sensitivities to compute

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", "Rho", "Theta", "Lambda", "Vegalt", and "All" | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Lambda', 'Vegalt', 'Vega', 'Rho', 'Theta', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with supported values.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Delta, Gamma, Vega, Vegalt, Lambda, Rho, Theta, and Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

---

**Note** When you price a Barrier instrument using a BlackScholes model, 'Vegalt' is not supported.

---

Example: `inpSensitivity = {'delta', 'gamma', 'vega', 'vegalt', 'rho', 'lambda', 'theta', 'price'}`

The sensitivities supported depend on the `inpInstrument`.

inpInstrument	Supported Sensitivities
Vanilla,	TBD

<b>inpInstrument</b>	<b>Supported Sensitivities</b>
Barrier	TBD
DoubleBarrier	TBD

Data Types: string | cell

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- PriceResult.Results — Table of results that includes sensitivities (if you specify inpSensitivity)
- PriceResult.PricerData — Structure for pricer data

## See Also

fininstrument | finmodel | finpricer

### Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

### Introduced in R2020a

## price

**Package:** finpricer

Compute price for equity instrument with NumericalIntegration pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ____,inpSensitivity)` adds an optional argument to specify sensitivities.

### Examples

#### Use Numerical Integration Pricer and Merton Model to Price Vanilla Instrument

This example shows the workflow to price a Vanilla instrument when you use a Merton model and a NumericalIntegration pricing method.

##### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2020,3,15), 'ExerciseStyle', "european")
```

```
VanillaOpt =
    Vanilla with properties:
```

```
    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Mar-2020
    Strike: 105
    Name: "vanilla_option"
```

##### Create Merton Model Object

Use `finmodel` to create a Merton model object.

```
MertonModel = finmodel("Merton", 'Volatility', 0.45, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)
```

```
MertonModel =
    Merton with properties:
```

```

Volatility: 0.4500
  MeanJ: 0.0200
  JumpVol: 0.0700
  JumpFreq: 0.0900

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
myRC = ratecurve('zero',datetime(2019,9,15),datetime(2020,3,15),0.02)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: 15-Mar-2020
      Rates: 0.0200
      Settle: 15-Sep-2019
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create NumericalIntegration Pricer Object

Use finpricer to create a NumericalIntegration pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("numericalintegration", 'Model', MertonModel, 'DiscountCurve', myRC, 'SpotPrice
```

```

outPricer =
  NumericalIntegration with properties:
      Model: [1x1 finmodel.Merton]
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 100
      DividendType: "continuous"
      DividendValue: 0.0100
      AbsTol: 0.5000
      RelTol: 0.4000
      IntegrationRange: [1.0000e-09 Inf]
      CharacteristicFcn: @characteristicFcnMerton76
      Framework: "lewis2001"
      VolRiskPremium: 0.9000
      LittleTrap: 0

```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 10.7325
```

```

outPR =
  pricerresult with properties:

```

```
Results: [1x6 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x6 table
```

Price	Delta	Gamma	Theta	Rho	Vega
10.732	0.5058	0.012492	-12.969	19.815	27.954

## Input Arguments

### **inpPricer** — Pricer object

NumericalIntegration object

Pricer object, specified as a scalar NumericalIntegration pricer object. Use `finpricer` to create the NumericalIntegration pricer object.

Data Types: object

### **inpInstrument** — Instrument object

Vanilla object

Instrument object, specified as a scalar Vanilla instrument object. Use `fininstrument` to create the Vanilla instrument object.

Data Types: object

### **inpSensitivity** — List of sensitivities to compute

[ ] (default) | string array with values "Price", "Delta", "Gamma", "Vega", "Rho", "Theta", "Vegalt", and 'All' | cell array of character vectors with values 'Price', 'Delta', 'Gamma', 'Vega', 'Rho', 'Theta', 'Vegalt', and 'All'

(Optional) List of sensitivities to compute, specified as a NOUT-by-1 or a 1-by-NOUT cell array of character vectors or string array with possible values of 'Price', 'Delta', 'Gamma', 'Vega', 'Rho', 'Theta', 'Vegalt', and 'All'.

---

**Note** 'Vegalt' is not supported when you price a Vanilla option with a Merton model.

---

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Delta, Gamma, Vega, Rho, Theta, Vegalt, and Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'delta', 'gamma', 'vega', 'rho', 'theta', 'vegalt', 'price'}`

Data Types: string | cell

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as an object. The PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes sensitivities (if you specify `inpSensitivity`)
- `PriceResult.PricerData` — Structure for pricer data

## See Also

`fininstrument` | `finmodel` | `finpricer`

### Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

### Introduced in R2020a

## price

**Package:** finpricer

Compute price for equity instrument with ReplicatingVarianceSwap pricer

### Syntax

```
[Price,PriceResult] = price(inpPricer,inpInstrument)
[Price,PriceResult] = price( ____,inpSensitivity)
```

### Description

`[Price,PriceResult] = price(inpPricer,inpInstrument)` computes the instrument price and related pricing information based on the pricing object `inpPricer` and the instrument object `inpInstrument`.

`[Price,PriceResult] = price( ____,inpSensitivity)` adds an optional argument to specify sensitivities.

### Examples

#### Use Replicating Variance Swap Pricer and ratecurve to Price Variance Swap Instrument

This example shows the workflow to price a VarianceSwap instrument when you use a ratecurve and a ReplicatingVarianceSwap pricing method.

##### Create VarianceSwap Instrument Object

Use `fininstrument` to create a VarianceSwap instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap", 'Maturity', datetime(2021,5,1), 'Notional', 150, 'Sta
```

```
VarianceSwapInst =
    VarianceSwap with properties:
```

```
    Notional: 150
    RealizedVariance: 0.0500
    Strike: 0.1000
    StartDate: 01-May-2020
    Maturity: 01-May-2021
    Name: "variance_swap_instrument"
```

##### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2020, 9, 15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```

Basis = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Basis',Basis)

ZeroCurve =
    ratecurve with properties:

        Type: "zero"
        Compounding: -1
        Basis: 1
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2020
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create ReplicatingVarianceSwap Pricer Object

Use `finpricer` to create a `ReplicatingVarianceSwap` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

Strike = (50:5:135)';
Volatility = [.49;.45;.42;.38;.34;.31;.28;.25;.23;.21;.2;.21;.21;.22;.23;.24;.25;.26];
VolatilitySmile = table(Strike, Volatility);
SpotPrice = 100;
CallPutBoundary = 100;

```

```

outPricer = finpricer("ReplicatingVarianceSwap",'DiscountCurve', ZeroCurve, 'VolatilitySmile', \
'SpotPrice', SpotPrice, 'CallPutBoundary', CallPutBoundary)

```

```

outPricer =
    ReplicatingVarianceSwap with properties:

        DiscountCurve: [1x1 ratecurve]
        InterpMethod: "linear"
        VolatilitySmile: [18x2 table]
        SpotPrice: 100
        CallPutBoundary: 100

```

### Price VarianceSwap Instrument

Use `price` to compute the price and fair variance for the `VarianceSwap` instrument.

```
[Price, outPR] = price(outPricer,VarianceSwapInst,["all"])
```

```
Price = 8.1997
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x2 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x2 table
    Price    FairVariance
```

---

---

8.1997      0.21701

## Input Arguments

### inpPricer — Pricer object

ReplicatingVarianceSwap object

Pricer object, specified as a scalar ReplicatingVarianceSwap pricer object. Use `finpricer` to create the ReplicatingVarianceSwap pricer object.

Data Types: object

### inpInstrument — Instrument object

VarianceSwap object

Instrument object, specified as a VarianceSwap instrument object. Use `fininstrument` to create the VarianceSwap instrument object.

Data Types: object

### inpSensitivity — List of sensitivities to compute

[ ] (default) | string array with values "Price" and 'All' | cell array of character vectors with values 'Price' and 'All'

(Optional) List of sensitivities to compute, specified as an NOUT-by-1 or 1-by-NOUT cell array of character vectors or string array with possible values of 'Price' and 'All'.

`inpSensitivity = {'All'}` or `inpSensitivity = ["All"]` specifies that the output is Price. This is the same as specifying `inpSensitivity` to include each sensitivity.

Example: `inpSensitivity = {'price'}`

Data Types: `string` | `cell`

## Output Arguments

### Price — Instrument price

numeric

Instrument price, returned as a numeric.

### PriceResult — Price result

PriceResult object

Price result, returned as a PriceResult object. The object has the following fields:

- `PriceResult.Results` — Table of results that includes:
  - `Price` — Numeric scalar swap price value
  - `FairVariance` — Numeric fair variance in decimals
- `PriceResult.PricerData.ReplicatingPortfolio` — Table containing pricer data

“Choose Instruments, Models, and Pricers” on page 1-43

### Introduced in R2020b

## pricePortfolio

Compute price and sensitivities for portfolio of instruments

### Syntax

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(inPort)
```

### Description

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(inPort) calculates the price and sensitivities for a portfolio of instruments that is previously created using finportfolio.

### Examples

#### Price Portfolio of Heterogeneous Instruments

Use finportfolio and pricePortfolio to create and price a portfolio containing a FixedBond instrument and an American Vanilla option instrument.

#### Create FixedBond Instrument Object

Use fininstrument to create a FixedBond instrument object.

```
FixB = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.05, 'Name', "fixed_
```

```
FixB =
    FixedBond with properties:
        CouponRate: 0.0500
        Period: 2
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2022
        Name: "fixed_bond"
```

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create Discount Pricer Object for FixedBond Instrument

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
FBPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
FBPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]
```

### Create Vanilla Instrument Object

Use `fininstrument` to create an American Vanilla instrument object.

```
Maturity = datetime(2023,9,15);
AmericanOpt = fininstrument("Vanilla", 'ExerciseDate', Maturity, 'Strike', 120, 'ExerciseStyle', "amer
```

```
AmericanOpt =
  Vanilla with properties:
      OptionType: "call"
  ExerciseStyle: "american"
  ExerciseDate: 15-Sep-2023
      Strike: 120
      Name: "vanilla_option"
```

### Create BlackScholes Model Object for Vanilla Instrument

Use `finmodel` to create a BlackScholes model object.

```
BSModel = finmodel("BlackScholes", 'Volatility', 0.12)
```

```
BSModel =
  BlackScholes with properties:
      Volatility: 0.1200
```

```
Correlation: 1
```

### Create BjerksundStensland Pricer Object for Vanilla Instrument

Use `finpricer` to create an analytic pricer object for the BjerksundStensland pricing method and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
BJSPricer = finpricer("analytic", 'Model', BSMoDel, 'DiscountCurve', myRC, 'SpotPrice', 100, 'DividendValue', 0.0200, 'DividendType', "continuous")
```

```
BJSPricer =
  BjerksundStensland with properties:

    DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
  DividendValue: 0.0200
    DividendType: "continuous"
```

### Add the Instruments to a finportfolio Object

Create a `finportfolio` object using `finportfolio` and add the two instruments with their associated pricers to the portfolio.

```
f1 = finportfolio([AmericanOpt, FixB], [BJSPricer, FBPricer])
```

```
f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FinInstrument]
    Pricers: [2x1 finpricer.FinPricer]
  PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

### Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice, InstPrice, PortSens, InstSens] = pricePortfolio(f1)
```

```
PortPrice = 119.1665
```

```
InstPrice = 2x1
```

```
    3.1912
   115.9753
```

```
PortSens=1x8 table
```

Price	DV01	Delta	Gamma	Lambda	Vega	Theta	Rho
119.17	0.04295	0.23188	0.011522	7.2661	65.454	-0.81408	86.71

```
InstSens=2x8 table
```

Price	DV01	Delta	Gamma	Lambda	Vega	Theta
-------	------	-------	-------	--------	------	-------

vanilla_option	3.1912	NaN	0.23188	0.011522	7.2661	65.454	-0.81408
fixed_bond	115.98	0.04295	NaN	NaN	NaN	NaN	NaN

## Price Portfolio of Bond and Bond Option Instruments

This example shows the workflow to create and price a portfolio of bond and bond option instruments. You can use `finportfolio` and `pricePortfolio` to price `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instruments using an `IRTtree` pricing method.

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 1, 1);
ZeroTimes = calyears(1:4)';
ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
    ratecurve with properties:

        Type: "zero"
        Compounding: 1
        Basis: 0
        Dates: [4x1 datetime]
        Rates: [4x1 double]
        Settle: 01-Jan-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create Bond and Option Instruments

Use `fininstrument` to create a `FixedBond`, `FixedBondOption`, `OptionEmbeddedFixedBond`, and `FloatBond` instrument objects.

```
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
Maturity = datetime(2022,1,1);
Period = 1;
```

```
% Vanilla FixedBond
```

```
VBond = fininstrument("FixedBond", 'Maturity', Maturity, 'CouponRate', 0.0425, 'Period', Period, 'Name'
```

```
VBond =
    FixedBond with properties:

        CouponRate: 0.0425
```

```

        Period: 1
        Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2022
    Name: "vanilla_fixed"

% Stepped coupon bond
SBond = fininstrument("FixedBond", 'Maturity', Maturity, 'CouponRate', CouponRate, 'Period', Period, 'Name', Name)

SBond =
    FixedBond with properties:

        CouponRate: [2x1 timetable]
        Period: 1
        Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2022
    Name: "stepped_coupon_bond"

% FloatBond
Spread = 0;
Reset = 1;
Float = fininstrument("FloatBond", 'Maturity', Maturity, 'Spread', Spread, 'Reset', Reset, 'Name', Name, 'ProjectionCurve', ZeroCurve, 'Name', "floatbond")

Float =
    FloatBond with properties:

        Spread: 0
    ProjectionCurve: [1x1 ratecurve]
        ResetOffset: 0
        Reset: 1
        Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT

```

```

        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        Name: "floatbond"

% Call option
Strike = 100;
ExerciseDates = datetime(2020,1,1);
OptionType = 'call';
Period = 1;
CallOption = fininstrument("FixedBondOption", 'Strike', Strike, 'ExerciseDate', ExerciseDates, ...
    'OptionType', OptionType, 'ExerciseStyle', "american", 'Bond', VBond, 'Name', "fixed_bond_option")

CallOption =
    FixedBondOption with properties:

        OptionType: "call"
        ExerciseStyle: "american"
        ExerciseDate: 01-Jan-2020
        Strike: 100
        Bond: [1x1 fininstrument.FixedBond]
        Name: "fixed_bond_option"

% Option for embedded bond (callable bond)
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates, CRates);
StrikeOE = [100; 100];
ExerciseDatesOE = [datetime(2020,1,1); datetime(2021,1,1)];
CallSchedule = timetable(ExerciseDatesOE, StrikeOE, 'VariableNames', {'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity', Maturity, ...
    'CouponRate', CouponRate, 'Period', Period, ...
    'CallSchedule', CallSchedule, 'Name', "option_embedded_fixedbond")

CallableBond =
    OptionEmbeddedFixedBond with properties:

        CouponRate: [2x1 timetable]
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        CallDates: [2x1 datetime]
        PutDates: [0x1 datetime]
        CallSchedule: [2x1 timetable]
        PutSchedule: [0x0 timetable]
        CallExerciseStyle: "american"
        PutExerciseStyle: [0x0 string]

```

```
Name: "option_embedded_fixedbond"
```

### Create HullWhite Model

Use `finmodel` to create a HullWhite model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("hullwhite", 'alpha', AlphaCurve, 'sigma', VolCurve)

HWModel =
  HullWhite with properties:

    Alpha: 0.1000
    Sigma: 0.0100
```

### Create IRTree Pricer for HullWhite Model

Use `finpricer` to create an IRTree pricer object for a HullWhite model and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
HWTreepricer = finpricer("IRTree", 'Model', HWModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates)

HWTreepricer =
  HWBKTree with properties:

    Tree: [1x1 struct]
    TreeDates: [4x1 datetime]
    Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

### Create finportfolio Object and Add Callable Bond Instrument

Create a `finportfolio` object with the vanilla bond, stepped coupon bond, float bond, and the call option.

```
myportfolio = finportfolio([VBond, SBond, Float, CallOption], HWTreepricer, [1, 2, 2, 1])

myportfolio =
  finportfolio with properties:

    Instruments: [4x1 fininstrument.FinInstrument]
    Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [4x1 double]
    Quantity: [4x1 double]
```

Use `addInstrument` to add the callable bond instrument to the existing portfolio.

```
myportfolio = addInstrument(myportfolio, CallableBond, HWTreepricer, 1)

myportfolio =
  finportfolio with properties:

    Instruments: [5x1 fininstrument.FinInstrument]
```

```

    Pricers: [1x1 finpricer.irtree.HWBKTree]
    PricerIndex: [5x1 double]
    Quantity: [5x1 double]

```

```
myportfolio.PricerIndex
```

```
ans = 5x1
```

```

1
1
1
1
1

```

The `PricerIndex` property has a length equal to the length of instrument objects in the `finportfolio` object and stores the index of which pricer is used for each instrument object. In this case, because there is only one pricer, each instrument must use that pricer.

### Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the bond and option instruments in the portfolio.

```
format bank
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myportfolio)
```

```
PortPrice =
    600.55
```

```
InstPrice = 5x1
```

```

    96.59
    204.14
    200.00
     0.05
    99.77

```

```
PortSens=1x4 table
    Price      Vega      Gamma      Delta
    _____
    600.55     -63.40    5759.65    -1297.48
```

```
InstSens=5x4 table
                Price      Vega      Gamma      Delta
                _____
vanilla_fixed      96.59     -0.00    1603.49    -344.81
stepped_coupon_bond 204.14      0.00    3364.60    -725.96
floatbond          200.00     -0.00     -0.00      0.00
fixed_bond_option   0.05      12.48     24.15     -3.69
```

option_embedded_fixedbond	99.77	-75.88	767.41	-223.03
---------------------------	-------	--------	--------	---------

## Input Arguments

### **inPort – Portfolio object**

finportfolio object

Portfolio object, previously created using finportfolio.

Data Types: object

## Output Arguments

### **PortPrice – Price of portfolio of instruments**

numeric

Price of the portfolio of instruments, returned as a numeric.

### **InstPrice – Instrument prices**

numeric

Instrument prices, returned as a numeric.

### **PortSens – Portfolio sensitivities**

numeric

Portfolio sensitivities, returned as a numeric.

### **InstSens – Instrument sensitivities**

numeric

Instrument sensitivities, returned as a numeric.

“Choose Instruments, Models, and Pricers” on page 1-43

### Introduced in R2020a

# addInstrument

Add instrument to portfolio of instruments

## Syntax

```
outPort = addInstrument(inPort,inInst)
outPort = addInstrument(inPort,inInst,inPricer)
outPort = addInstrument( ____,inQuant)
```

## Description

`outPort = addInstrument(inPort,inInst)` adds the instrument `inInst` to a portfolio `inPort` of instruments previously created using `finportfolio`.

`outPort = addInstrument(inPort,inInst,inPricer)` adds the instrument `inInst` and the associated pricer `inPricer` to a portfolio `inPort` of instruments previously created using `finportfolio`.

`outPort = addInstrument( ____,inQuant)` optionally specifies the number (`inQuant`) of added instruments. Use this syntax with any of the input argument combinations in previous syntaxes.

## Examples

### Add Instruments to Portfolio

Use `finportfolio` to create an empty portfolio and then use `addInstrument` to add instruments to the portfolio.

### Create FixedBond Instrument Objects

Use `fininstrument` to create two `FixedBond` instrument objects.

```
FixB1 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15),'CouponRate',0.045,'Name',"fix
```

```
FixB1 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0450
    Period: 2
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2022
```

```
Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15),'CouponRate',0.035,'Name',"fix
```

```
FixB2 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0350
    Period: 2
    Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2022
    Name: "fixed_bond2"
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
```

```
Type = "zero";
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create Discount Pricer Object for FixedBond Instruments

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
DiscountPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```
DiscountPricer =
```

```
Discount with properties:
```

```
DiscountCurve: [1x1 ratecurve]
```

### Add Instruments to finportfolio Object

Create an empty `finportfolio` object using `finportfolio` and then use `addInstrument` to put the `FixedBond` instruments into the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
    Quantity: 1
```

```
f1 = addInstrument(f1,FixB2)

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

### Set Pricer for Portfolio

Use `setPricer` to set the pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the instruments in the portfolio.

```
f1 = setPricer(f1,DiscountPricer,[1,2])

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [1x1 finpricer.Discount]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)

PortPrice = 224.0834

InstPrice = 2x1

    114.0085
    110.0749

PortSens=1x2 table
    Price    DV01
```

224.08	0.084139
--------	----------

InstSens=2x2 *table*

	Price	DV01
fixed_bond1	114.01	0.04251
fixed_bond2	110.07	0.041629

## Input Arguments

### **inPort** — **finportfolio** object

finportfolio object

finportfolio object, specified as a scalar finportfolio object.

Data Types: object

### **inInst** — **Instrument object to add to portfolio**

scalar instrument object | array of instrument objects

Instrument object to add to portfolio, specified as a scalar instrument object or an array of instrument objects that are previously created using `fininstrument`.

Data Types: object

### **inPricer** — **Pricer object associated with an added instrument object**

scalar pricer object | array of pricer objects

Pricer object associated with an added instrument object, specified as a scalar pricer object or an array of pricer objects that are previously created using `finpricer`.

Data Types: object

### **inQuant** — **Number of added instruments**

1 (default) | positive or negative numeric

Number of instruments, specified as a scalar numeric. Use a positive value for a long position and a negative value for a short position.

Data Types: double

## Output Arguments

### **outPort** — **Updated finportfolio** object

finportfolio object

Updated finportfolio, returned as a finportfolio object.

**Introduced in R2020a**

## removeInstrument

Remove instrument from portfolio of instruments

### Syntax

```
outPort = removeInstrument(inPort,inInst)
```

### Description

`outPort = removeInstrument(inPort,inInst)` removes an instrument object (`inInst`) from a portfolio of instruments (`inPort`) previously created using `finportfolio`.

### Examples

#### Remove Instrument From a Portfolio

Use `addInstrument` to add instruments to an empty portfolio and then remove an instrument from the portfolio using `removeInstrument`.

#### Create FixedBond Instrument Objects

Use `fininstrument` to create two `FixedBond` instrument objects.

```
FixB1 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15), 'CouponRate',0.045, 'Name', "fixed_bond1")
```

```
FixB1 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0450
    Period: 2
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2022
    Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond", 'Maturity',datetime(2022,9,15), 'CouponRate',0.035, 'Name', "fixed_bond2")
```

```
FixB2 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0350
    Period: 2
```

```

        Basis: 0
      EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2022
      Name: "fixed_bond2"

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
    Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object for FixedBond Instruments

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
DiscountPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```

DiscountPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]

```

### Add Instruments to finportfolio Object

Create an empty finportfolio object using finportfolio and then use addInstrument to add the two FixedBond instruments to the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
    Quantity: 1
```

```
f1 = addInstrument(f1,FixB2)

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

### **Remove Instrument from finportfolio Object**

Use `removeInstrument` to remove the first `FixedBond` instrument from the portfolio.

```
f1 = removeInstrument(f1,1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
    Quantity: 1
```

### **Set Pricer for Portfolio**

Use `setPricer` to set the `Discount` pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the single instrument in the portfolio.

```
f1 = setPricer(f1,DiscountPricer)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [1x1 finpricer.Discount]
    PricerIndex: 1
    Quantity: 1

[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)

PortPrice = 110.0749
InstPrice = 110.0749
```

```

PortSens=1x2 table
  Price      DV01
  _____  _____
  110.07     0.041629

```

```

InstSens=1x2 table
              Price      DV01
              _____  _____
  fixed_bond2  110.07     0.041629

```

## Input Arguments

### **inPort** — finportfolio object

finportfolio object

finportfolio object, specified as a scalar finportfolio object.

Data Types: object

### **inInst** — Instrument to remove from finportfolio object

instrument object | index | string for the instrument object 'Name' property

Instrument to remove from finportfolio object, specified as a scalar instrument object, string for the instrument object 'Name' property, or index value for the position of instrument in the finportfolio object.

Data Types: object | double | string

## Output Arguments

### **outPort** — Updated finportfolio object

finportfolio object

Updated finportfolio, returned as a finportfolio object.

## See Also

addInstrument | fininstrument | pricePortfolio | setPricer

### Topics

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

**Introduced in R2020a**

## setPricer

Set pricer for finportfolio object

### Syntax

```
outPort = setPricer(inPort,inPricer,Index)
```

### Description

outPort = setPricer(inPort,inPricer,Index) sets a specified pricer for the previously created finportfolio object.

### Examples

#### Set Pricer for Portfolio Containing Instruments

Use finportfolio to create a portfolio of instruments and then use setPricer to set the pricer for the portfolio.

#### Create FixedBond Instrument Objects

Use fininstrument to create two FixedBond instrument objects.

```
FixB1 = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.045, 'Name', "fixed_bond1")
```

```
FixB1 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0450
    Period: 2
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2022
    Name: "fixed_bond1"
```

```
FixB2 = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.035, 'Name', "fixed_bond2")
```

```
FixB2 =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0350
    Period: 2
```

```

        Basis: 0
      EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2022
      Name: "fixed_bond2"

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
    Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object for FixedBond Instruments

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
DiscountPricer = finpricer("Discount",'DiscountCurve',myRC)
```

```

DiscountPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]

```

### Add Instruments to finportfolio Object

Create a finportfolio object using finportfolio and use addInstrument to put the FixedBond instruments in the portfolio.

```
f1 = finportfolio;
f1 = addInstrument(f1,FixB1)

f1 =
  finportfolio with properties:

    Instruments: [1x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: NaN
    Quantity: 1
```

```
f1 = addInstrument(f1,FixB2)

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [0x1 finpricer.FinPricer]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

### Set Pricer for Portfolio

Use `setPricer` to set the pricer for the portfolio and then use `pricePortfolio` to calculate the price and sensitivities for the instruments in the portfolio.

```
f1 = setPricer(f1,DiscountPricer,[1,2])

f1 =
  finportfolio with properties:

    Instruments: [2x1 fininstrument.FixedBond]
      Pricers: [1x1 finpricer.Discount]
    PricerIndex: [2x1 double]
    Quantity: [2x1 double]
```

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)
```

```
PortPrice = 224.0834
```

```
InstPrice = 2x1
```

```
114.0085
110.0749
```

```
PortSens=1x2 table
```

Price	DV01
224.08	0.084139

```
InstSens=2x2 table
```

Price	DV01
-------	------

```
fixed_bond1    114.01    0.04251
fixed_bond2    110.07    0.041629
```

## Input Arguments

### **inPort – Portfolio**

finportfolio object

Portfolio, specified using a previously created finportfolio object.

Data Types: object

### **inPricer – Pricer object to set for an instrument in a finportfolio object**

object

Pricer object to set for an instrument in a finportfolio object, specified using a previously created pricer object with finpricer.

Data Types: object

### **Index – Index to instruments in finportfolio object**

numeric

Index to instruments in the finportfolio object, specified as a numeric value.

Data Types: double

## Output Arguments

### **outPort – Updated portfolio**

finportfolio object

Updated portfolio, returned as an finportfolio object.

## See Also

addInstrument | finportfolio | pricePortfolio | removeInstrument

### **Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

### **Introduced in R2020a**

## cashflows

**Package:** fininstrument

Computes cash flow for FixedBond, FloatBond, Swap, FRA, or Deposit instrument

### Syntax

```
CF = cashflows(InstrumentObject,Settle)
```

### Description

CF = cashflows(InstrumentObject,Settle) computes cash flow for a Deposit, FRA, Swap, FixedBond, or FloatBond instrument.

### Examples

#### Calculate Cash Flow for FRA Instrument

This example shows the workflow to price a FRA (forward rate agreement) instrument and then use cashflows to determine the cash flow for the FRA instrument.

#### Create FRA Instrument Object

Use fininstrument to create a FRA instrument object.

```
FRAObj = fininstrument("FRA", 'StartDate', datetime(2020,9,15), 'Maturity', datetime(2022,9,15), 'Rate
```

```
FRAObj =  
    FRA with properties:
```

```
        Rate: 0.1750  
        Basis: 2  
    StartDate: 15-Sep-2020  
        Maturity: 15-Sep-2022  
    Principal: 100  
BusinessDayConvention: "actual"  
        Holidays: NaT  
        Name: ""
```

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);  
Type = "zero";  
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];  
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';  
ZeroDates = Settle + ZeroTimes;  
  
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object with the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
outPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]
```

### Price FRA Instrument

Use `price` to compute the price and sensitivities for the FRA instrument.

```
[Price, outPR] = price(outPricer, FRAObj, ["all"])
Price = 34.1757
outPR =
  pricerresult with properties:
      Results: [1x2 table]
      PricerData: []
```

`outPR.Results`

```
ans=1x2 table
  Price      DV01
  _____  _____
  34.176     0.01368
```

Use `cashflows` for the FRA instrument with a `Settle` date of 15-Dec-2021. The specified `Settle` date must be before the instrument `Maturity` date.

```
CF = cashflows(FRAObj, datetime(2021,12,15))
```

```
CF= 1x1 timetable
      Time      CFA
  _____  _____
```

15-Sep-2022 35.486

### Calculate Cash Flow for FixedBond Instrument

This example shows the workflow to price a FixedBond instrument and then use cashflows to calculate the cash flow for the FixedBond instrument.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a FixedBond instrument object.

```
FixB = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.05, 'Period', 4, 'Bas
```

```
FixB =
    FixedBond with properties:
        CouponRate: 0.0500
        Period: 4
        Basis: 7
        EndMonthRule: 1
        Principal: 1000
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "follow"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2022
        Name: "fixed_bond_instrument"
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
  Discount with properties:
    DiscountCurve: [1x1 ratecurve]
```

### Price FixedBond Instrument

Use `price` to compute the price and sensitivities for the `FixedBond` instrument.

```
[Price, outPR] = price(outPricer, FixB, ["all"])
```

```
Price = 1.1600e+03
```

```
outPR =
  pricerresult with properties:
    Results: [1x2 table]
    PricerData: []
```

#### outPR.Results

```
ans=1x2 table
  Price    DV01
  -----  -----
  1160     0.42712
```

Use `cashflows` to calculate the cash flow for the `FixedBond` instrument for any specified `Settle` date before the instrument `Maturity` date.

```
CF = cashflows(FixB, datetime(2021,9,15))
```

```
CF=5x1 timetable
  Time          Var1
  -----  -----
  15-Sep-2021    0
  15-Dec-2021   12.5
  15-Mar-2022   12.5
  15-Jun-2022   12.5
```

15-Sep-2022 1012.5

## Input Arguments

### **InstrumentObject** — Instrument object

Deposit object | FixedBond object | FloatBond object | Swap object | FRA object

Instrument object, specified using a previously created instrument object for one of the following: Deposit, FixedBond, FloatBond, Swap, or FRA.

Data Types: object

### **Settle** — Settlement date for instrument cash flow

datetime | serial date number | date character vector | string array

Settlement date for instrument cash flow, specified as a scalar using a datetime, serial date number, date character vector, or date string.

---

**Note** The Settle date you specify must be before the Maturity date for the Deposit, FixedBond, FloatBond, Swap, or FRA instrument.

---

Data Types: double | char | datetime | string

## Output Arguments

### **CF** — Cash flow

timetable

Cash flow, returned as a timetable.

## See Also

fininstrument | finmodel | finpricer | timetable

“Choose Instruments, Models, and Pricers” on page 1-43

**Introduced in R2020a**

# setCallExercisePolicy

**Package:** fininstrument

Set call exercise policy for `OptionEmbeddedFixedBond` or `OptionEmbeddedFloatBond` instrument

## Syntax

```
UpdatedInstrumentObject = setCallExercisePolicy(InstrumentObject,
exerciseSchedule,exerciseStyle)
```

## Description

`UpdatedInstrumentObject = setCallExercisePolicy(InstrumentObject, exerciseSchedule,exerciseStyle)` sets the call exercise policy for a `OptionEmbeddedFixedBond` or `OptionEmbeddedFloatBond` instrument.

## Examples

### Set Call Exercise Policy for Option Embedded Fixed Bond Instrument

This example shows how to use `setCallExercisePolicy` to maintain consistency between the exercise schedule and exercise style when using a `OptionEmbeddedFixedBond` instrument object.

#### Create `OptionEmbeddedFixedBond` Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object with different exercise styles.

```
Maturity = datetime(2024,1,1);
Strike = [100;100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Period = 1;
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
```

```
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity',Maturity,...
                             'CouponRate',0.025,'Period',Period, ...
                             'CallSchedule',CallSchedule)
```

```
CallableBond =
    OptionEmbeddedFixedBond with properties:
```

```

    CouponRate: 0.0250
    Period: 1
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
```

```

FirstCouponDate: NaT
LastCouponDate: NaT
StartDate: NaT
Maturity: 01-Jan-2024
CallDates: [2x1 datetime]
PutDates: [0x1 datetime]
CallSchedule: [2x1 timetable]
PutSchedule: [0x0 timetable]
CallExerciseStyle: "american"
PutExerciseStyle: [0x0 string]
Name: ""

```

### Set the Exercise Style to Bermudan

Use `setCallExercisePolicy` to define the `CallExerciseStyle` as Bermudan.

```
CallableBond = setCallExercisePolicy(CallableBond, CallSchedule, "Bermudan")
```

```
CallableBond =
OptionEmbeddedFixedBond with properties:
```

```

CouponRate: 0.0250
Period: 1
Basis: 0
EndMonthRule: 1
Principal: 100
DaycountAdjustedCashFlow: 0
BusinessDayConvention: "actual"
Holidays: NaT
IssueDate: NaT
FirstCouponDate: NaT
LastCouponDate: NaT
StartDate: NaT
Maturity: 01-Jan-2024
CallDates: [2x1 datetime]
PutDates: [0x1 datetime]
CallSchedule: [2x1 timetable]
PutSchedule: [0x0 timetable]
CallExerciseStyle: "bermudan"
PutExerciseStyle: [0x0 string]
Name: ""

```

Use `setCallExercisePolicy` to modify `CallSchedule` and continue using a Bermudan exercise style.

```
Strike = [100; 101;102;103];
ExerciseDates = [datetime(2018,1,1);datetime(2020,1,1);datetime(2022,1,1);datetime(2024,1,1)];
```

```
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
```

```
CallableBond = setCallExercisePolicy(CallableBond, CallSchedule)
```

```
CallableBond =
OptionEmbeddedFixedBond with properties:
```

```

CouponRate: 0.0250
Period: 1

```

```

        Basis: 0
      EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
      FirstCouponDate: NaT
      LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2024
      CallDates: [4x1 datetime]
      PutDates: [0x1 datetime]
      CallSchedule: [4x1 timetable]
      PutSchedule: [0x0 timetable]
    CallExerciseStyle: "bermudan"
      PutExerciseStyle: [0x0 string]
      Name: ""

```

## Input Arguments

### InstrumentObject — Instrument object

OptionEmbeddedFixedBond object | OptionEmbeddedFloatBond object

Instrument object, specified as a previously created OptionEmbeddedFixedBond or OptionEmbeddedFloatBond instrument object.

Data Types: object

### exerciseSchedule — Call exercise schedule

timetable

Call exercise schedule, specified as a timetable. The timetable must contain both the exerciseDate value and Strike information.

Data Types: timetable

### exerciseStyle — Call option exercise style

"American" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Call option exercise style, specified as a scalar string or character vector.

Data Types: string | char

## Output Arguments

### UpdatedInstrumentObject — Updated instrument

object

Updated instrument, returned as an object.

## See Also

fininstrument | finmodel | finpricer | timetable

# setPutExercisePolicy

**Package:** fininstrument

Set put exercise policy for `OptionEmbeddedFixedBond` or `OptionEmbeddedFloatBond` instrument

## Syntax

```
UpdatedInstrumentObject = setPutExercisePolicy(InstrumentObject,
exerciseSchedule,exerciseStyle)
```

## Description

`UpdatedInstrumentObject = setPutExercisePolicy(InstrumentObject, exerciseSchedule,exerciseStyle)` sets the put exercise policy for an `OptionEmbeddedFixedBond` or `OptionEmbeddedFloatBond` instrument.

## Examples

### Set Put Exercise Policy for Option Embedded Fixed Bond Instrument

This example shows how to use `setPutExercisePolicy` to maintain consistency between the exercise schedule and exercise style when using a `OptionEmbeddedFixedBond` instrument object.

#### Create `OptionEmbeddedFixedBond` Instrument Object

Use `fininstrument` to create an `OptionEmbeddedFixedBond` instrument object with different exercise styles.

```
Maturity = datetime(2024,1,1);
Strike = [100;100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Period = 1;
PutSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
```

```
PuttableBond = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
    'CouponRate',0.025,'Period',Period, ...
    'PutSchedule',PutSchedule)
```

```
PuttableBond =
    OptionEmbeddedFixedBond with properties:
```

```

        CouponRate: 0.0250
            Period: 1
            Basis: 0
    EndMonthRule: 1
        Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
            Holidays: NaT
            IssueDate: NaT
    FirstCouponDate: NaT
```

```

LastCouponDate: NaT
StartDate: NaT
Maturity: 01-Jan-2024
CallDates: [0x1 datetime]
PutDates: [2x1 datetime]
CallSchedule: [0x0 timetable]
PutSchedule: [2x1 timetable]
CallExerciseStyle: [0x0 string]
PutExerciseStyle: "american"
Name: ""

```

### Set Exercise Style to Bermudan

Use `setPutExercisePolicy` to define `PutExerciseStyle` as Bermudan.

```
PuttableBond = setPutExercisePolicy(PuttableBond, PutSchedule, "Bermudan")
```

```
PuttableBond =
OptionEmbeddedFixedBond with properties:
```

```

CouponRate: 0.0250
Period: 1
Basis: 0
EndMonthRule: 1
Principal: 100
DaycountAdjustedCashFlow: 0
BusinessDayConvention: "actual"
Holidays: NaT
IssueDate: NaT
FirstCouponDate: NaT
LastCouponDate: NaT
StartDate: NaT
Maturity: 01-Jan-2024
CallDates: [0x1 datetime]
PutDates: [2x1 datetime]
CallSchedule: [0x0 timetable]
PutSchedule: [2x1 timetable]
CallExerciseStyle: [0x0 string]
PutExerciseStyle: "bermudan"
Name: ""

```

Use `setPutExercisePolicy` to modify `PutSchedule` and continue using a Bermudan exercise style.

```
Strike = [100; 101;102;103];
ExerciseDates = [datetime(2018,1,1);datetime(2020,1,1);datetime(2022,1,1);datetime(2024,1,1)];
```

```
PutSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
```

```
PuttableBond = setPutExercisePolicy(PuttableBond, PutSchedule)
```

```
PuttableBond =
OptionEmbeddedFixedBond with properties:
```

```

CouponRate: 0.0250
Period: 1
Basis: 0

```

```

        EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2024
    CallDates: [0x1 datetime]
    PutDates: [4x1 datetime]
    CallSchedule: [0x0 timetable]
    PutSchedule: [4x1 timetable]
    CallExerciseStyle: [0x0 string]
    PutExerciseStyle: "bermudan"
    Name: ""

```

## Input Arguments

### **InstrumentObject** — Instrument object

OptionEmbeddedFixedBond object | OptionEmbeddedFloatBond object

Instrument object, specified using a previously created OptionEmbeddedFixedBond or OptionEmbeddedFloatBond instrument object.

Data Types: object

### **exerciseSchedule** — Put exercise schedule

timetable

Put exercise schedule, specified as a timetable. The timetable must contain both the exerciseDate value and Strike information.

Data Types: timetable

### **exerciseStyle** — Put option exercise style

"American" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Put option exercise style, specified as a scalar string or character vector.

Data Types: string | char

## Output Arguments

### **UpdatedInstrumentObject** — Updated instrument

object

Updated instrument, returned as an object.

## See Also

fininstrument | finmodel | finpricer | timetable

# setExercisePolicy

**Package:** fininstrument

Set exercise policy for FixedBondOption, FloatBondOption, or Vanilla instrument

## Syntax

```
UpdatedInstrumentObject = setExercisePolicy(InstrumentObject, exerciseDate,
Strike, exerciseStyle)
```

## Description

UpdatedInstrumentObject = setExercisePolicy(InstrumentObject, exerciseDate, Strike, exerciseStyle) sets the exercise policy for a FixedBondOption, FloatBondOption, or Vanilla instrument.

## Examples

### Set Exercise Policy for Fixed Bond Option Instrument

This example shows how to use setExercisePolicy to maintain consistency between the exercise schedule and exercise style when using a FixedBondOption instrument.

#### Create FixedBond Instrument Object

Use fininstrument to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', .021, 'Period', 1
```

#### Create FixedBondOption Instrument Object

Use fininstrument to create a callable FixedBondOption instrument object with a European exercise.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98, 'B
```

```
FixedBOption =
    FixedBondOption with properties:
```

```
    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2025
    Strike: 98
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option"
```

### Set the Exercise Style to American

Use setExercisePolicy to define ExerciseStyle as American.

```
FixedBOption = setExercisePolicy(FixedBOption,datetime(2025,9,15),98,"American")
```

```
FixedBOption =  
  FixedBondOption with properties:  
    OptionType: "call"  
    ExerciseStyle: "american"  
    ExerciseDate: 15-Sep-2025  
    Strike: 98  
    Bond: [1x1 fininstrument.FixedBond]  
    Name: "fixed_bond_option"
```

## Input Arguments

### **InstrumentObject — Instrument object**

FixedBondOption object | FloatBondOption object | Vanilla object

Instrument object, specified using a previously created FixedBondOption, FloatBondOption, or Vanilla instrument object.

Data Types: object

### **exerciseDate — Exercise date**

datetime

Exercise date, specified as a scalar datetime.

Data Types: datetime

### **Strike — Strike**

numeric

Strike, specified as a scalar numeric.

Data Types: double

### **exerciseStyle — Option exercise style**

"American" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Option exercise style, specified as a scalar string or character vector.

Data Types: string | char

## Output Arguments

### **UpdatedInstrumentObject — Updated instrument object**

object

Updated instrument object, returned as an object.

## See Also

fininstrument | finmodel | finpricer | timetable

## parswaprate

**Package:** fininstrument

Compute par swap rate for Swap instrument

### Syntax

```
outRate = parswaprate(SwapObject,inCurve)
```

### Description

`outRate = parswaprate(SwapObject,inCurve)` computes a par swap rate for a Swap instrument.

### Examples

#### Compute Par Swap Rate for Vanilla Swap Instrument Using ratecurve and Discount Pricer

This example shows the workflow to compute the par swap rate for a vanilla Swap instrument when you use a ratecurve and a Discount pricing method.

##### Create ratecurve Object

Create a ratecurve object using `ratecurve` for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2018,3,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Mar-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

##### Create Swap Instrument Object

Use `fininstrument` to create a vanilla Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2020,9,15), 'LegRate', [0.022 0.019 ], 'LegType', ["
```

```
Swap =
```

```
Swap with properties:
```

```

        LegRate: [0.0220 0.0190]
        LegType: ["float"    "fixed"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
        LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
        DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [1x2 ratecurve]
        BusinessDayConvention: ["actual"    "actual"]
        Holidays: NaT
        EndMonthRule: [1 1]
        StartDate: NaT
        Maturity: 15-Sep-2020
        Name: "swap_instrument"
```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
```

```
Discount with properties:
```

```
DiscountCurve: [1x1 ratecurve]
```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the vanilla Swap instrument.

```
[Price, outPR] = price(outPricer, Swap, ["all"])
```

```
Price = 2.4066
```

```
outPR =
```

```
pricerresult with properties:
```

```

        Results: [1x2 table]
        PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
```

```

    Price      DV01
    _____  _____
    2.4066     -0.012056
```

Compute the par swap rate using `parswaprate`.

```
outRate = parswaprate(Swap,myRC)
```

```
outRate = 0.0287
```

## Input Arguments

### **SwapObject** — Swap object

Swap object

Swap object, specified using a previously created Swap instrument object.

Data Types: object

### **inCurve** — Rate curve

ratecurve object

Rate curve, specified as a previously created ratecurve object.

Data Types: object

## Output Arguments

### **outRate** — Par swap rate

decimal

Par swap rate, returned as a decimal.

## More About

### **Par Swap Rate**

The par swap rate is the rate that renders a swap value equal to zero.

In other words, the par swap rate is the value of the fixed rate that gives the swap a zero present value, or the fixed rate that makes the value of both legs equal (that is, the value of the fixed leg and the value of the floating leg).

# volatilities

**Package:** finpricer.analytic

Compute implied volatilities when using SABR pricer

## Syntax

```
outVolatilities = volatilities(inpPricer,ExerciseDate,ForwardValue,Strike)
```

## Description

`outVolatilities = volatilities(inpPricer,ExerciseDate,ForwardValue,Strike)` computes implied volatilities for a Swaption instrument when you use a SABR pricer.

## Examples

### Compute Implied Volatilities for Swaption Instrument

This example shows the workflow to compute implied volatilities for a Swaption Instrument.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
ValuationDate = datetime(2016,3,5);
ZeroDates = datemnth(ValuationDate,[1 2 3 6 9 12*[1 2 3 4 5 6 7 8 9 10 12]]);
ZeroRates = [-0.33 -0.28 -0.24 -0.12 -0.08 -0.03 0.015 0.028 ...
             0.033 0.042 0.056 0.095 0.194 0.299 0.415 0.525]'/100;
Compounding = 1;
ZeroCurve = ratecurve("zero",ValuationDate,ZeroDates,ZeroRates,'Compounding',Compounding)
```

```
ZeroCurve =
  ratecurve with properties:
      Type: "zero"
      Compounding: 1
      Basis: 0
      Dates: [16x1 datetime]
      Rates: [16x1 double]
      Settle: 05-Mar-2016
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

#### Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
Alpha = 0.0135;
Beta = 0.5;
```

```
Rho = 0.4654;
Nu = 0.4957;
Shift = 0.008;

SABRModel = finmodel("SABR", 'Alpha', Alpha, 'Beta', Beta, 'Rho', Rho, 'Nu', Nu, 'Shift', Shift)

SABRModel =
  SABR with properties:

      Alpha: 0.0135
      Beta: 0.5000
      Rho: 0.4654
      Nu: 0.4957
      Shift: 0.0080
  VolatilityType: "black"
```

### Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
SABRPricer = finpricer("Analytic", 'Model', SABRModel, 'DiscountCurve', ZeroCurve)

SABRPricer =
  SABR with properties:

      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.SABR]
```

### Compute Implied Volatilities

Use `volatilities` to compute the implied volatilities for a Swaption instrument.

```
SwaptionExerciseDate = datetime(2017,3,5);
ForwardValue = 0.0007;
StrikeGrid = [-0.5; -0.25; -0.125; 0; 0.125; 0.25; 0.5; 1.0; 1.5]/100;
MarketStrikes = ForwardValue + StrikeGrid;

outVolatilities = volatilities(SABRPricer, SwaptionExerciseDate, ForwardValue, MarketStrikes)

outVolatilities = 9x1

    0.2132
    0.1500
    0.1409
    0.1474
    0.1609
    0.1752
    0.2004
    0.2372
```

0.2627

## Input Arguments

### **inpPricer – SABR pricer**

SABR pricer object

SABR pricer, specified as a previously created SABR pricer object.

Data Types: object

### **ExerciseDate – Option exercise date**

datetime | serial date number | date character vector | date string

Option exercise date, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

### **ForwardValue – Forward swap rate**

decimal

Forward swap rate, specified as a scalar decimal.

Data Types: object

### **Strike – Strike rate**

decimal

Strike rate, specified as a scalar decimal.

Data Types: double

## Output Arguments

### **outVolatilities – Output volatilities**

numeric

Output volatilities, returned as a numeric.

## See Also

fininstrument | finmodel | finpricer

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

### **Introduced in R2020b**

## fitSvensson

Fit Svensson model to bond market data

### Syntax

```
outCurve = fitSvensson(Settle, Instruments, CleanPrice)
```

### Description

`outCurve = fitSvensson(Settle, Instruments, CleanPrice)` fits a Svensson model to bond data.

### Examples

#### Fit Svensson Model to Bond Market Data

Define the bond data and use `fininstrument` to create `FixedBond` instrument objects.

```
Settle = datetime(2017,9,15);
Maturity = [datetime(2019,9,15);datetime(2021,9,15);...
            datetime(2023,9,15);datetime(2026,9,7);...
            datetime(2035,9,15);datetime(2047,9,15)];

CleanPrice = [100.1;100.1;100.8;96.6;103.3;96.3];
CouponRate = [0.0400;0.0425;0.0450;0.0400;0.0500;0.0425];

nInst = numel(CouponRate);
Bonds(nInst,1) = fininstrument.FinInstrument;
for ii=1:nInst
    Bonds(ii) = fininstrument("FixedBond", 'Maturity',Maturity(ii),...
                             'CouponRate',CouponRate(ii));
end
```

Use `fitSvensson` to create a `parametercurve` object.

```
SvenModel = fitSvensson(Settle,Bonds,CleanPrice)
```

Local minimum possible.

`lsqnonlin` stopped because the final change in the sum of squares relative to its initial value is less than the value of the function tolerance.

```
SvenModel =
    parametercurve with properties:

        Type: "zero"
        Settle: 15-Sep-2017
        Compounding: -1
        Basis: 0
        FunctionHandle: @(t)fitF(Params,t)
        Parameters: [1.6231 -40.5295 42.1660 -4.1690 0.3343 2.9654]
```

## Input Arguments

### **Settle – Settlement date**

datetime | serial date number | date character vector | date string

Settlement date, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

### **Instruments – Bond instrument objects**

array

Bond instrument objects, specified as an array of bond instrument objects.

Data Types: object

### **CleanPrice – Observed market prices**

vector

Observed market prices, specified as a vector.

Data Types: double

## Output Arguments

### **outCurve – Fitted Svensson model**

object

Fitted Svensson model, returned as a parametercurve object.

## discountfactors

Calculate discount factors for a ratecurve object

### Syntax

```
outDF = discountfactors(obj,inpDates)
```

### Description

`outDF = discountfactors(obj,inpDates)` calculates the discount factors for a ratecurve object.

### Examples

#### Calculate Discount Factors for a ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod','pchip');
```

```
myRC =
    ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 2
         Basis: 5
         Dates: [10x1 datetime]
         Rates: [10x1 double]
         Settle: 15-Sep-2019
    InterpMethod: "pchip"
ShortExtrapMethod: "linear"
LongExtrapMethod: "pchip"
```

Compute the discount factors using `discountfactors`.

```
CurveSettle = datetime(2019,9,15);
outRates = discountfactors(myRC,CurveSettle+30:30:CurveSettle+720)
```

```
outRates = 1x24
```

```

    0.9996    0.9992    0.9988    0.9983    0.9979    0.9974    0.9970    0.9965    0.9961    0.9957
```

## Input Arguments

### **obj — ratecurve object**

ratecurve object

ratecurve object, specified using a previously created ratecurve object.

Data Types: object

### **inpDates — Input dates**

datetime | serial date number | date character vector | date string

Input dates, specified as a scalar or an NPOINTS-by-1 vector of datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

## Output Arguments

### **outDF — Discount factors**

numeric

Discount factors, returned as a numeric.

## See Also

forwardrates | irbootstrap | ratecurve | zerorates

### **Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

### **Introduced in R2020a**

## forwardrates

Calculate forward rates for ratecurve object

### Syntax

```
outRates = forwardrates(obj,startDates,endDates)
outRates = forwardrates( ____,inpComp,inpBasis)
```

### Description

`outRates = forwardrates(obj,startDates,endDates)` calculates forward rates for the ratecurve object (`obj`) based on the `startDates` and `endDates`.

`outRates = forwardrates( ____,inpComp,inpBasis)` optionally specifies the input compounding frequency (`inpComp`) and the input day-count basis (`inpBasis`) in addition to any of the input argument combinations in the previous syntax.

### Examples

#### Calculate Forward Rates for ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod','pchip');
```

```
myRC =
    ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 2
         Basis: 5
         Dates: [10x1 datetime]
         Rates: [10x1 double]
        Settle: 15-Sep-2019
    InterpMethod: "pchip"
ShortExtrapMethod: "linear"
LongExtrapMethod: "pchip"
```

Compute the forward rates using `forwardrates`.

```
outRates = forwardrates(myRC,datetime(2019,12,15),datetime(2021,9,15),6,7)
outRates = 0.0062
```

## Input Arguments

### **obj — ratecurve object**

ratecurve object

ratecurve object, specified using a previously created ratecurve object.

Data Types: object

### **startDates — Start dates of interval to discount over**

datetime | serial date number | date character vector | date string

Start dates of the interval to discount over, specified as a scalar or an NPOINTS-by-1 vector of datetimes, serial date numbers, cell array of date character vectors, or string array. **startDates** must be earlier than **endDates**.

Data Types: string | datetime | double | char | cell

### **endDates — Maturity dates ending interval to discount over**

datetime | serial date number | date character vector | date string

Maturity dates ending the interval to discount over, specified as a scalar or an NPOINTS-by-1 vector of datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

### **inpComp — Input compounding frequency**

Compounding for the ratecurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **inpBasis — Input day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)

- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

## **Output Arguments**

### **outRates – Forward rates**

numeric

Forward rates, returned as a numeric.

## **See Also**

[discountfactors](#) | [irbootstrap](#) | [ratecurve](#) | [zerorates](#)

## **Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

**Introduced in R2020a**

## zerorates

Calculate zero rates for ratecurve object

### Syntax

```
outRates = zerorates(obj,inpDates)
outRates = zerorates( ____,inpComp,inpBasis)
```

### Description

`outRates = zerorates(obj,inpDates)` computes zero rates for the ratecurve object (`obj`) based on `inpDates`.

`outRates = zerorates( ____,inpComp,inpBasis)` optionally specifies the input compounding frequency (`inpComp`) and the input day-count basis (`inpBasis`) in addition to any of the input argument combinations in the previous syntax.

### Examples

#### Calculate Zero Rates for ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod','pchip');
```

```
myRC =
    ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 2
         Basis: 5
         Dates: [10x1 datetime]
         Rates: [10x1 double]
         Settle: 15-Sep-2019
    InterpMethod: "pchip"
ShortExtrapMethod: "linear"
LongExtrapMethod: "pchip"
```

Compute the zero rates using `zerorates`.

```
CurveSettle = datetime(2019,9,15);
outRates = zerorates(myRC,CurveSettle+30:30:CurveSettle+720)
```

```
outRates = 1x24
```

0.0049 0.0050 0.0050 0.0051 0.0051 0.0052 0.0052 0.0053 0.0053 0.

## Input Arguments

### **obj** — ratecurve object

ratecurve object

ratecurve object, specified using a previously created ratecurve object.

Data Types: object

### **inpDates** — Input dates

datetime | serial date number | date character vector | date string

Input dates, specified as a scalar or an NPOINTS-by-1 vector of datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

### **inpComp** — Input compounding frequency

Compounding for the ratecurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### **inpBasis** — Input day-count basis

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

## Output Arguments

### **outRates — Zero rates**

numeric

Zero rates, returned as a numeric.

## See Also

## discountfactors

Calculate discount factors for parametercurve object

### Syntax

```
outDF = discountfactors(obj,inpDates)
```

### Description

`outDF = discountfactors(obj,inpDates)` calculates the discount factors for a parametercurve object.

### Examples

#### Calculate Discount Factors for parametercurve Object

Create a parametercurve object using parametercurve.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compounding')
```

```
PCobj =  
parametercurve with properties:
```

```
    Type: "zero"  
    Settle: 15-Sep-2019  
    Compounding: 4  
    Basis: 5  
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)  
    Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the discount factors using `discountfactors`.

```
CurveSettle = datetime(2019,9,15);  
outDF = discountfactors(PCobj,CurveSettle+30:30:CurveSettle+720)
```

```
outDF = 1x24
```

```
    0.9983    0.9967    0.9949    0.9932    0.9914    0.9895    0.9876    0.9857    0.9838    0.9819
```

### Input Arguments

#### **obj** — parametercurve object

parametercurve object

parametercurve object, specified as a previously created parametercurve object.

Data Types: object

**inpDates — Input dates**

datetime | serial date number | date character vector | date string

Input dates, specified as a scalar or an NPOINTS-by-1 vector of a datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

**Output Arguments****outDF — Discount factors**

numeric

Discount factors, returned as a numeric.

**See Also**

fitNelsonSiegel | fitSvensson | forwardrates | ratecurve | zerorates

**Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

## forwardrates

Calculate forward rates for parametercurve object

### Syntax

```
outRates = forwardrates(obj,startDates,endDates)
outRates = forwardrates( ___,inpComp,inpBasis)
```

### Description

`outRates = forwardrates(obj,startDates,endDates)` computes forward rates for the parametercurve object (`obj`) based on `startDates` and `endDates`.

`outRates = forwardrates( ___,inpComp,inpBasis)` specifies options in addition to any of the input argument combinations in the previous syntax.

### Examples

#### Calculate Forward Rates for parametercurve Object

Create a parametercurve object using parametercurve.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compoundi
```

```
PCobj =
    parametercurve with properties:
```

```

        Type: "zero"
        Settle: 15-Sep-2019
    Compounding: 4
        Basis: 5
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
    Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the forward rates using forwardrates.

```
CurveSettle = datetime(2019,9,15);
outRates = forwardrates(PCobj,datetime(2019,12,15),datetime(2020,9,15),6,7)

outRates = 0.0236
```

### Input Arguments

#### **obj** — parametercurve object

parametercurve object

parametercurve object, specified as a previously created parametercurve object.

Data Types: object

**startDates — Start dates of interval to discount over**

datetime | serial date number | date character vector | date string

Start dates of the interval to discount over, specified as a scalar or an NPOINTS-by-1 vector of a datetimes, serial date numbers, cell array of date character vectors, or string array. `startDates` must be earlier than `endDates`.

Data Types: string | datetime | double | char | cell

**endDates — Maturity dates ending the interval to discount over**

serial date number | date character vector | date string | datetime

Maturity dates ending the interval to discount over, specified as a scalar or an NPOINTS-by-1 vector of a datetimes, serial date numbers, cell array of date character vectors, or string array.

Data Types: string | datetime | double | char | cell

**inpComp — Input compounding frequency**

Compounding for the parametercurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**inpBasis — Input day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

## **Output Arguments**

### **outRates — Forward rates**

numeric

Forward rates, returned as a numeric.

## **See Also**

# zerorates

Calculate zero rates for parametercurve object

## Syntax

```
outRates = zerorates(obj,inpDates)
outRates = zerorates( ____,inpComp,inpBasis)
```

## Description

`outRates = zerorates(obj,inpDates)` computes zero rates for the parametercurve object (`obj`) based on `inpDates`.

`outRates = zerorates( ____,inpComp,inpBasis)` specifies options in addition to any of the input argument combinations in the previous syntax.

## Examples

### Calculate Zero Rates for parametercurve Object

Create a parametercurve object using parametercurve.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compoundi
```

```
PCobj =
```

```
parametercurve with properties:
```

```

    Type: "zero"
    Settle: 15-Sep-2019
    Compounding: 4
    Basis: 5
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)
    Parameters: [-1.0000e-04 0.0030 0.0200]
```

Compute the zero rates using zerorates.

```
CurveSettle = datetime(2019,9,15);
outRates = zerorates(PCobj,CurveSettle+30:30:CurveSettle+720)
```

```
outRates = 1×24
```

```
    0.0202    0.0205    0.0207    0.0210    0.0212    0.0215    0.0217    0.0219    0.0222    0.0224
```

## Input Arguments

**obj** — parametercurve object

parametercurve object

parametercurve object, specified as a previously created parametercurve object.

Data Types: object

**inpDates – Input dates**

datetime | serial date number | date character vector | date string

Input dates, specified as a scalar or an NPOINTS-by-1 vector of a datetimes, serial date numbers, cell array of date character vectors, or string array. StartDates must be earlier than EndDates.

Data Types: string | datetime | double | char | cell

**inpComp – Input compounding frequency**

Compounding for the parametercurve object (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

(Optional) Input compounding frequency, specified as a scalar numeric using one of the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

**inpBasis – Input day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

(Optional) Input day-count basis, specified as a scalar integer.

- 0 = actual/actual
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ICMA)
- 9 = actual/360 (ICMA)
- 10 = actual/365 (ICMA)
- 11 = 30/360E (ICMA)
- 12 = actual/365 (ISDA)
- 13 = BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

**Output Arguments****outRates – Zero rates**

numeric

Zero rates, returned as a numeric.

## **See Also**

`discountfactors` | `fitNelsonSiegel` | `fitSvensson` | `forwardrates` | `ratecurve`

## **Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

## **Introduced in R2020a**

# finportfolio

Create a `finportfolio` object

## Description

Create a `finportfolio` object for a collection of instrument objects.

After creating instruments, models, and pricer objects, use `finportfolio` to create a `finportfolio` object for a collection of instruments. For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
finportfolio_obj = finportfolio
finportfolio_obj = finportfolio(inInstruments)
finportfolio_obj = finportfolio(inInstruments,inPricers)
finportfolio_obj = finportfolio( ____,inQuant)
```

### Description

`finportfolio_obj = finportfolio` creates an empty `finportfolio` object.

`finportfolio_obj = finportfolio(inInstruments)` creates a `finportfolio` object containing the instrument objects `inInstruments`.

`finportfolio_obj = finportfolio(inInstruments,inPricers)` creates a `finportfolio` object containing the instrument objects `inInstruments` and the pricer objects `inPricers`.

`finportfolio_obj = finportfolio( ____,inQuant)` optionally sets the `inQuant` property which specifies the number of instruments. Use this syntax with any of the input argument combinations in previous syntaxes to set the properties on page 11-2201 for the `finportfolio` object. For example, `finportfolio_obj =`

```
finportfolio([CapObj,FloorObj,SwaptionObj],
[BlackPricerObj,NormalPricerObj,SabrPricerObj])
```

creates a `finportfolio` object that contains instrument and pricer objects. You can specify multiple name-value pair arguments.

### Input Arguments

#### **inInstruments** — Instrument objects in the portfolio

scalar Instrument object | array of Instrument objects

Instrument objects in the portfolio, specified as a scalar Instrument object or an array of Instrument objects.

Data Types: object

### **inPricers — Pricer objects in the portfolio**

scalar Pricer object | array of Pricer objects

Pricer objects in the portfolio, specified as a scalar Pricer object or an array of Pricer objects.

Data Types: object

### **inQuant — Number of instruments**

positive or negative numeric | array of positive or negative numerics

Number of instruments, specified as a scalar numeric or an NINST-by-1 array of numeric values. Use a positive value for long positions and a negative value for short positions.

Data Types: double

## **Properties**

### **Instruments — Instrument objects in the portfolio**

scalar instrument object | array of instrument objects

Instrument objects in the portfolio, returned as a scalar instrument object or an array of instrument objects.

Data Types: struct

### **Pricers — Pricer objects in the portfolio**

scalar pricer object | array of pricer objects

Pricer objects in the portfolio, returned as a scalar pricer object or an array of pricer objects.

Data Types: struct

### **PricerIndex — Mapping of instrument objects to pricer objects in the portfolio**

numeric

This property is read-only.

Mapping of instrument objects to pricer objects in the portfolio, returned as numeric.

PricerIndex has a length equal to the number of instrument objects in the finportfolio object and stores an index of which pricer is used for each instrument object.

Data Types: struct

### **Quantity — Number of instruments**

numeric

Number of instruments, returned as a scalar numeric or numeric array.

Data Types: double

## **Object Functions**

pricePortfolio      Compute price and sensitivities for portfolio of instruments

addInstrument	Add instrument to portfolio of instruments
removeInstrument	Remove instrument from portfolio of instruments
setPricer	Set pricer for finportfolio object

## Examples

### Price Portfolio of Heterogeneous Instruments

Use `finportfolio` and `pricePortfolio` to create and price a portfolio containing a `FixedBond` instrument and an American Vanilla option instrument.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a `FixedBond` instrument object.

```
FixB = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.05, 'Name', "fixed_
```

```
FixB =
    FixedBond with properties:
        CouponRate: 0.0500
        Period: 2
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2022
        Name: "fixed_bond"
```

#### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
```

```

        Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object for FixedBond Instrument

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
FBPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
FBPricer =
    Discount with properties:

        DiscountCurve: [1x1 ratecurve]

```

### Create Vanilla Instrument Object

Use `fininstrument` to create an American Vanilla instrument object.

```
Maturity = datetime(2023,9,15);
AmericanOpt = fininstrument("Vanilla", 'ExerciseDate', Maturity, 'Strike', 120, 'ExerciseStyle', "amer
```

```
AmericanOpt =
    Vanilla with properties:

        OptionType: "call"
        ExerciseStyle: "american"
        ExerciseDate: 15-Sep-2023
        Strike: 120
        Name: "vanilla_option"

```

### Create BlackScholes Model Object for Vanilla Instrument

Use `finmodel` to create a BlackScholes model object.

```
BSModel = finmodel("BlackScholes", 'Volatility', 0.12)
```

```
BSModel =
    BlackScholes with properties:

        Volatility: 0.1200
        Correlation: 1

```

### Create BjerksundStensland Pricer Object for Vanilla Instrument

Use `finpricer` to create an analytic pricer object for the BjerksundStensland pricing method and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
BJSPricer = finpricer("analytic", 'Model', BSModel, 'DiscountCurve', myRC, 'SpotPrice', 100, 'DividendV
```

```
BJSPricer =
    BjerksundStensland with properties:

```

```
DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: 0.0200
      DividendType: "continuous"
```

### Add the Instruments to a finportfolio Object

Create a `finportfolio` object using `finportfolio` and add the two instruments with their associated pricers to the portfolio.

```
f1 = finportfolio([AmericanOpt,FixB],[BJSPricer,FBPricer])
```

```
f1 =
  finportfolio with properties:

  Instruments: [2x1 fininstrument.FinInstrument]
  Pricers: [2x1 finpricer.FinPricer]
  PricerIndex: [2x1 double]
  Quantity: [2x1 double]
```

### Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the instruments in the portfolio.

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(f1)
```

```
PortPrice = 119.1665
```

```
InstPrice = 2x1
```

```
    3.1912
   115.9753
```

```
PortSens=1x8 table
```

Price	DV01	Delta	Gamma	Lambda	Vega	Theta	Rho
119.17	0.04295	0.23188	0.011522	7.2661	65.454	-0.81408	86.71

```
InstSens=2x8 table
```

	Price	DV01	Delta	Gamma	Lambda	Vega	Theta
vanilla_option	3.1912	NaN	0.23188	0.011522	7.2661	65.454	-0.81408
fixed_bond	115.98	0.04295	NaN	NaN	NaN	NaN	NaN

### Price Portfolio of Bond and Bond Option Instruments

This example shows the workflow to create and price a portfolio of bond and bond option instruments. You can use `finportfolio` and `pricePortfolio` to price `FixedBond`,

FixedBondOption, OptionEmbeddedFixedBond, and FloatBond instruments using an IRTree pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018, 1, 1);
ZeroTimes = calyears(1:4)';
ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
    ratecurve with properties:
        Type: "zero"
        Compounding: 1
        Basis: 0
        Dates: [4x1 datetime]
        Rates: [4x1 double]
        Settle: 01-Jan-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create Bond and Option Instruments

Use fininstrument to create a FixedBond, FixedBondOption, OptionEmbeddedFixedBond, and FloatBond instrument objects.

```
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates,CRates);
Maturity = datetime(2022,1,1);
Period = 1;
```

`% Vanilla FixedBond`

```
VBond = fininstrument("FixedBond", 'Maturity',Maturity, 'CouponRate',0.0425, 'Period',Period, 'Name'
```

```
VBond =
    FixedBond with properties:
        CouponRate: 0.0425
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
```

```

        Name: "vanilla_fixed"

% Stepped coupon bond
SBond = fininstrument("FixedBond", 'Maturity', Maturity, 'CouponRate', CouponRate, 'Period', Period, 'Name', Name)

SBond =
    FixedBond with properties:
        CouponRate: [2x1 timetable]
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        Name: "stepped_coupon_bond"

% FloatBond
Spread = 0;
Reset = 1;
Float = fininstrument("FloatBond", 'Maturity', Maturity, 'Spread', Spread, 'Reset', Reset, 'Name', Name, 'ProjectionCurve', ZeroCurve, 'Name', "floatbond")

Float =
    FloatBond with properties:
        Spread: 0
        ProjectionCurve: [1x1 ratecurve]
        ResetOffset: 0
        Reset: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        Name: "floatbond"

% Call option
Strike = 100;
ExerciseDates = datetime(2020,1,1);
OptionType = 'call';
Period = 1;

```

```
CallOption = fininstrument("FixedBondOption", 'Strike', Strike, 'ExerciseDate', ExerciseDates, ...
    'OptionType', OptionType, 'ExerciseStyle', "american", 'Bond', VBond, 'Name', "fixed_bond_option")
```

```
CallOption =
    FixedBondOption with properties:
```

```
    OptionType: "call"
    ExerciseStyle: "american"
    ExerciseDate: 01-Jan-2020
    Strike: 100
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option"
```

```
% Option for embedded bond (callable bond)
```

```
CDates = datetime([2020,1,1 ; 2022,1,1]);
CRates = [.0425; .0750];
CouponRate = timetable(CDates, CRates);
StrikeOE = [100; 100];
ExerciseDatesOE = [datetime(2020,1,1); datetime(2021,1,1)];
CallSchedule = timetable(ExerciseDatesOE, StrikeOE, 'VariableNames', {'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity', Maturity, ...
    'CouponRate', CouponRate, 'Period', Period, ...
    'CallSchedule', CallSchedule, 'Name', "option_embedded_fixedbond")
```

```
CallableBond =
    OptionEmbeddedFixedBond with properties:
```

```
    CouponRate: [2x1 timetable]
    Period: 1
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2022
    CallDates: [2x1 datetime]
    PutDates: [0x1 datetime]
    CallSchedule: [2x1 timetable]
    PutSchedule: [0x0 timetable]
    CallExerciseStyle: "american"
    PutExerciseStyle: [0x0 string]
    Name: "option_embedded_fixedbond"
```

## Create HullWhite Model

Use `finmodel` to create a `HullWhite` model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;
```

```
HWModel = finmodel("hullwhite", 'alpha', AlphaCurve, 'sigma', VolCurve)
```

```

HWModel =
  HullWhite with properties:

    Alpha: 0.1000
    Sigma: 0.0100

```

### Create IRTree Pricer for HullWhite Model

Use `finpricer` to create an `IRTree` pricer object for a `HullWhite` model and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

HWTrePricer = finpricer("IRTree", 'Model', HWModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates)

HWTrePricer =
  HWBKTre with properties:

    Tree: [1x1 struct]
    TreeDates: [4x1 datetime]
    Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]

```

### Create finportfolio Object and Add Callable Bond Instrument

Create a `finportfolio` object with the vanilla bond, stepped coupon bond, float bond, and the call option.

```

myportfolio = finportfolio([VBond, SBond, Float, CallOption], HWTrePricer, [1, 2, 2, 1])

myportfolio =
  finportfolio with properties:

    Instruments: [4x1 fininstrument.FinInstrument]
    Pricers: [1x1 finpricer.irtree.HWBKTre]
    PricerIndex: [4x1 double]
    Quantity: [4x1 double]

```

Use `addInstrument` to add the callable bond instrument to the existing portfolio.

```

myportfolio = addInstrument(myportfolio, CallableBond, HWTrePricer, 1)

myportfolio =
  finportfolio with properties:

    Instruments: [5x1 fininstrument.FinInstrument]
    Pricers: [1x1 finpricer.irtree.HWBKTre]
    PricerIndex: [5x1 double]
    Quantity: [5x1 double]

```

```
myportfolio.PricerIndex
```

```

ans = 5x1

    1
    1
    1

```

```
1
1
```

The `PricerIndex` property has a length equal to the length of instrument objects in the `finportfolio` object and stores the index of which pricer is used for each instrument object. In this case, because there is only one pricer, each instrument must use that pricer.

## Price Portfolio

Use `pricePortfolio` to compute the price and sensitivities for the portfolio and the bond and option instruments in the portfolio.

```
format bank
```

```
[PortPrice,InstPrice,PortSens,InstSens] = pricePortfolio(myportfolio)
```

```
PortPrice =
    600.55
```

```
InstPrice = 5×1
```

```
    96.59
   204.14
   200.00
    0.05
    99.77
```

```
PortSens=1×4 table
```

Price	Vega	Gamma	Delta
600.55	-63.40	5759.65	-1297.48

```
InstSens=5×4 table
```

	Price	Vega	Gamma	Delta
vanilla_fixed	96.59	-0.00	1603.49	-344.81
stepped_coupon_bond	204.14	0.00	3364.60	-725.96
floatbond	200.00	-0.00	-0.00	0.00
fixed_bond_option	0.05	12.48	24.15	-3.69
option_embedded_fixedbond	99.77	-75.88	767.41	-223.03

# ratecurve

Create `ratecurve` object for interest-rate curve from dates and data

## Description

Build a `ratecurve` object using `ratecurve`.

After creating a `ratecurve` object, you can use the associated object functions `forwardrates`, `discountfactors`, and `zerorates`.

---

**Note** If you have the `RateSpec` obtained previously from `intenvset` or `toRateSpec` for an `IRDataCurve` or `toRateSpec` for an `IRFunctionCurve`, refer to “Convert `RateSpec` to a `ratecurve` Object” on page 1-39.

---

To price a `Swap`, `FixedBond`, `FloatBond`, `FRA`, or `Deposit` instrument, you must create a `ratecurve` object and then create `Discount` pricer object.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
ratecurve_obj = ratecurve(Type,Settle,Dates,Rates)
ratecurve_obj = ratecurve( ___,Name,Value)
```

### Description

`ratecurve_obj = ratecurve(Type,Settle,Dates,Rates)` creates a `ratecurve` object.

`ratecurve_obj = ratecurve( ___,Name,Value)` creates a `ratecurve` object using name-value pairs and any of the arguments in the previous syntax. For example, `myRC = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'Interp Method',"pchip','ShortExtrapMethod',"linear','LongExtrapMethod',"cubic")` creates a `ratecurve` object for a zero curve. You can specify multiple name-value pair arguments.

### Input Arguments

#### Type — Type of interest-rate curve

string with value "zero", "forward", or "discount" | character vector with value 'zero', 'forward', or 'discount'

Type of interest-rate curve, specified as a string or character vector for one of the supported types.

Data Types: `char` | `string`

### **Settle — Settlement date**

`datetime` | `serial date number` | `date character vector` | `date string`

Settlement date, specified as a scalar `datetime`, `serial date number`, `date character vector`, or `date string`.

If you use a `date character vector` or `date string`, the format must be recognizable by `datetime` because the `Settle` property is stored as a `datetime`.

Data Types: `double` | `char` | `string` | `datetime`

### **Dates — Dates corresponding to rate data**

`datetime` | `serial date number` | `date character vector` | `date string`

Dates corresponding to the rate data, specified as a scalar `datetime`, `serial date number`, `date character vector`, or `date string`.

If you use a `date character vector` or `date string`, the format must be recognizable by `datetime` because the `Dates` property is stored as a `datetime`.

Data Types: `double` | `char` | `string` | `datetime`

### **Rates — Interest-rate data for the curve**

`numeric`

Interest-rate data for the curve, specified as a scalar `numeric`.

Data Types: `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `myRC =`

```
ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'Interp  
Method',"pchip",'ShortExtrapMethod',"linear",'LongExtrapMethod',"cubic")
```

### **Compounding — Compounding frequency**

-1 (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, or 12.

Compounding frequency, specified as the comma-separated pair consisting of `'Compounding'` and a scalar `numeric` using the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: `double`

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)

- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

#### **InterpMethod — Interpolation method**

"linear" (default) | string with value "linear", "cubic", "next", "previous", "pchip", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'cubic', 'next', 'previous', 'pchip', 'v5cubic', 'makima', or 'spline'

Interpolation method, specified as the comma-separated pair consisting of 'InterpMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

#### **ShortExtrapMethod — Extrapolation method for data before first data**

"next" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'next', 'previous', 'pchip', 'cubic', 'v5cubic', 'makima', or 'spline'

Extrapolation method for data before first data, specified as the comma-separated pair consisting of 'ShortExtrapMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

#### **LongExtrapMethod — Extrapolation method for data after last data**

"previous" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'next', 'previous', 'pchip', 'cubic', 'v5cubic', 'makima', or 'spline'

Extrapolation method for data after last data, specified as the comma-separated pair consisting of 'LongExtrapMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

## Properties

### Type — Type of interest-rate curve

string with value "zero", "forward", or "discount"

Type of interest-rate curve, returned as a string.

Data Types: string

### Compounding — Compounding frequency

-1 (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, or 12.

Compounding frequency, returned as a scalar numeric.

Data Types: double

### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis of the instrument, returned as a scalar integer.

Data Types: double

### Dates — Dates corresponding to rate data

datetime

Dates corresponding to the rate data, returned as a datetime.

Data Types: datetime

### Rates — Rates corresponding to dates data

vector

Rates corresponding to dates data, returned as vector.

Data Types: datetime

### Settle — Settlement date

datetime

Settlement date, returned as a datetime.

Data Types: datetime

### InterpMethod — Interpolation method

"linear" (default) | string with value "linear", "cubic", "next", "previous", "pchip", "v5cubic", "makima", or "spline"

Interpolation method, returned as a scalar string.

Data Types: string

### ShortExtrapMethod — Short extrapolation method

"next" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline"

Short extrapolation method, returned as a scalar string.

Data Types: string

**LongExtrapMethod — Long extrapolation method**

"previous" (default) | string with value "linear", "next", "previous", "pchip", "cubic", "v5cubic", "makima", or "spline"

Log extrapolation method, returned as a scalar string.

Data Types: string

**Object Functions**

forwardrates      Calculate forward rates for ratecurve object  
 discountfactors    Calculate discount factors for a ratecurve object  
 zerorates          Calculate zero rates for ratecurve object  
 irbootstrap        Bootstrap interest-rate curve from market data

**Examples****Create ratecurve Object**

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Compounding',2,'Basis',5,'InterpMethod',"pchip");
```

```
myRC =
    ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 2
        Basis: 5
        Dates: [10x1 datetime]
        Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "pchip"
ShortExtrapMethod: "linear"
LongExtrapMethod: "cubic"
```

# parametercurve

Create parametercurve object for storing interest-rate curve function

## Description

Build a parametercurve object using parametercurve.

After creating a parametercurve object, you can use the associated object functions `discountfactors`, `zerorates`, `forwardrates`, `fitNelsonSiegel`, and `fitSvensson`.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
parametercurve_obj = parametercurve(Type,Settle,FunctionHandle)
parametercurve_obj = parametercurve( ___,Name,Value)
```

### Description

`parametercurve_obj = parametercurve(Type,Settle,FunctionHandle)` creates a parametercurve object.

`parametercurve_obj = parametercurve( ___,Name,Value)` sets properties on page 11-2219 using name-value pairs and any of the arguments in the previous syntax. For example, `parametercurve_obj = parametercurve('zero',datetime(2017,1,30),@(t)polyval([-0.0001 0.003 0.02],t),'Compounding',4,'Basis',5,'Parameters',[-0.0001 0.003 0.02])` creates a parametercurve object for a zero curve. You can specify multiple name-value pair arguments.

### Input Arguments

#### Type — Type of interest-rate curve

string with value "zero", "forward", or "discount" | character vector with value 'zero', 'forward', or 'discount'

Type of interest-rate curve, specified as a scalar string or character vector for one of the supported types.

Data Types: char | string

#### Settle — Settlement date for the curve

datetime | serial date number | date character vector | date string

Settlement date for the curve, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: `double` | `char` | `string` | `datetime`

### **FunctionHandle — Dates corresponding to rate data**

function handle

Dates corresponding to the rate data, specified as a function handle. The function handle requires one numeric input (time to maturity) and returns one numeric output (interest rate or discount factor). For more information on creating a function handle, see “Create Function Handle”.

Data Types: `function_handle`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: parametercurve_obj =  
parametercurve('zero',datetime(2017,1,30),@(t)polyval([-0.0001 0.003  
0.02],t),'Compounding',4,'Basis',5,'Parameters',[-0.0001 0.003 0.02])
```

### **Compounding — Compounding frequency for curve**

-1 (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency for the curve, specified as the comma-separated pair consisting of 'Compounding' and a scalar numeric using the supported values: -1, 0, 1, 2, 3, 4, 6, or 12.

Data Types: `double`

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **Parameters — Curve parameters**

[ ] (default) | numeric

Curve parameters, specified as the comma-separated pair consisting of 'Parameters' and a numeric value.

Data Types: double

## **Properties**

### **Type — Type of interest-rate curve**

string with value "zero", "forward", or "discount"

Instrument type, returned as a string.

Data Types: string

### **Settle — Settlement date**

datetime

Settlement date, returned as a datetime.

Data Types: datetime

### **FunctionHandle — Dates corresponding to rate data**

function handle

Function handle that defines the interest-rate curve, returned as a scalar function handle.

Data Types: function\_handle

### **Compounding — Compounding frequency for curve**

-1 (default) | possible values include: -1, 0, 1, 2, 3, 4, 6, 12.

Compounding frequency for curve, returned as a scalar numeric.

Data Types: double

### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, returned as a scalar integer.

Data Types: double

### **Parameters — Curve parameters**

[ ] (default) | numeric

Curve parameters, returned as a numeric value.

Data Types: double

## Object Functions

discountfactors	Calculate discount factors for parametercurve object
zerorates	Calculate zero rates for parametercurve object
forwardrates	Calculate forward rates for parametercurve object
fitNelsonSiegel	Fit Nelson-Siegel model to bond market data
fitSvensson	Fit Svensson model to bond market data

## Examples

### Create parametercurve Object

Create a parametercurve object using parametercurve.

```
PCobj = parametercurve('zero',datetime(2019,9,15),@(t)polyval([-0.0001 0.003 0.02],t),'Compounding')
```

```
PCobj =
```

```
parametercurve with properties:
```

```
    Type: "zero"  
    Settle: 15-Sep-2019  
    Compounding: 4  
    Basis: 5  
    FunctionHandle: @(t)polyval([-0.0001,0.003,0.02],t)  
    Parameters: [-1.0000e-04 0.0030 0.0200]
```

# Asian

Asian instrument object

## Description

Create and price an Asian instrument object using this workflow:

- 1 Use `fininstrument` to create an Asian instrument object.
- 2 Use `finmodel` to specify a `BlackScholes`, `Heston`, `Bates`, or `Merton` model for the Asian instrument.
- 3 When using a `BlackScholes` model, use `finpricer` to specify a `Levy`, `KemnaVorst`, or `TurnbullWakeman` pricing method for the Asian instrument.

When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for the Asian instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an Asian instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
AsianOpt = fininstrument(InstrumentType, 'Strike', strike_price, '
ExerciseDate', exercise_date)
AsianOpt = fininstrument( ___, Name, Value)
```

### Description

`AsianOpt = fininstrument(InstrumentType, 'Strike', strike_price, 'ExerciseDate', exercise_date)` creates an Asian object by specifying `InstrumentType` and sets the properties on page 11-2223 for the required name-value pair arguments `Strike` and `ExerciseDate`.

The Asian instrument supports arithmetic and geometric average price Asian options. Average price Asian options are also known as fixed-strike Asian options.

`AsianOpt = fininstrument( ___, Name, Value)` sets optional properties on page 11-2223 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `AsianOpt = fininstrument("Asian", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'Option Type', "put", 'ExerciseStyle', "European", 'Name', "asian_option")` creates an Asian put option with an European exercise. You can specify multiple name-value pair arguments.

**Input Arguments****InstrumentType — Instrument type**

string with value "Asian" | character vector with value 'Asian'

Instrument type, specified as a string with the value of "Asian" or a character vector with the value of 'Asian'.

Data Types: string | char

**Asian Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `AsianOpt =`

```
fininstrument("Asian", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'Option
Type', "put", 'ExerciseStyle', "European", 'Name', "asian_option")
```

**Required Asian Name-Value Pair Arguments****Strike — Option strike price value**

nonnegative value

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value.

Data Types: double

**ExerciseDate — Option exercise dates**

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For an Asian European option, there is only one `ExerciseDate` on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**Optional Asian Name-Value Pair Arguments****OptionType — Option type**

"call" (default) | character vector with value 'call' or 'put' | string with value "call" or "put"

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar character vector or string.

Data Types: char | string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

Data Types: string | char

### **AverageType — Average type**

"arithmetic" (default) | string with value "arithmetic" or "geometric" | character vector with value 'arithmetic' or 'geometric'

Average types, specified as the comma-separated pair consisting of 'AverageType' and a scalar string or character vector. Use "arithmetic" for an arithmetic average, or "geometric" for a geometric average.

---

**Note** When you use a RollGeskeWhaley pricer, the AverageType must be "geometric".

---

Data Types: char | string

### **AveragePrice — Average price of underlying asset**

0 (default) | scalar numeric

Average price of the underlying asset, specified as the comma-separated pair consisting of 'AveragePrice' and a scalar numeric.

Data Types: double

### **AverageStartDate — Start date of averaging period**

NaN (default) | datetime | serial date number | date character vector | date string

Start date of averaging period, specified as the comma-separated pair consisting of 'AverageStartDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the AverageStartDate property is stored as a datetime.

Data Types: char | double | datetime | string

### **Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## **Properties**

### **Strike — Option strike price value**

nonnegative value

Option strike price value, returned as a scalar nonnegative value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with the value "call" or "put".

Data Types: string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European"

Option exercise style, returned as a string with the value "European".

Data Types: string

**AverageType — Average type**

"arithmetic" (default) | string with value "arithmetic" or "geometric"

Average types, returned as a scalar string with the value "arithmetic" for arithmetic average or "geometric" for geometric average.

Data Types: string

**AveragePrice — Average price of underlying asset at Settle**

0 (default) | scalar numeric

Average price of underlying asset at Settle, returned as a scalar numeric.

Data Types: double

**AverageStartDate — Start date of averaging period**

NaT (default) | datetime

Start date of averaging period, returned as a scalar datetime.

Data Types: datetime

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Examples****Price Asian Instrument Using a Black-Scholes Model and Turnbull-Wakeman Pricer**

This example shows the workflow to price a fixed-strike Asian instrument when you use a BlackScholes model and a TurnbullWakeman pricing method.

### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 1000, 'OptionType', "put", 'AverageType', "arithmetic", 'AveragePrice', 0, 'AverageStartDate', NaT, 'ExerciseStyle', "european", 'ExerciseDate', 15-Sep-2022, 'Name', "asian_option")
```

```
AsianOpt =
  Asian with properties:
      OptionType: "put"
      Strike: 1000
      AverageType: "arithmetic"
      AveragePrice: 0
      AverageStartDate: NaT
      ExerciseStyle: "european"
      ExerciseDate: 15-Sep-2022
      Name: "asian_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .2)
```

```
BlackScholesModel =
  BlackScholes with properties:
      Volatility: 0.2000
      Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create TurnbullWakeman Pricer Object

Use `finpricer` to create a TurnbullWakeman pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', 1000)
outPricer =
  TurnbullWakeman with properties:

    DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
           SpotPrice: 1000
    DividendValue: 0
    DividendType: "continuous"

```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer, AsianOpt, ["all"])
```

```
Price = 56.7068
```

```

outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
56.707	-0.3155	0.0014381	-5.5637	408.85	-2.9341	-832.53

### Price Asian Instrument for Foreign Exchange Using Black-Scholes Model and Levy Pricer

This example shows the workflow to price an Asian instrument for an arithmetic average currency option when you use a BlackScholes model and a Levy pricing method. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

#### Create Asian Instrument Object

Use fininstrument to create an Asian instrument object.

```

AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 0.65, 'OptionType', "put")
AsianOpt =
  Asian with properties:

    OptionType: "put"
           Strike: 0.6500
    AverageType: "arithmetic"
    AveragePrice: 0
    AverageStartDate: NaT

```

```

ExerciseStyle: "european"
ExerciseDate: 15-Sep-2022
Name: "asian_fx_option"

```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```

Sigma = .12;
BlackScholesModel = finmodel("BlackScholes", 'Volatility', Sigma)

```

```

BlackScholesModel =
  BlackScholes with properties:

```

```

    Volatility: 0.1200
    Correlation: 1

```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)

```

```

myRC =
  ratecurve with properties:

```

```

    Type: "zero"
    Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Levy Pricer Object

Use `finpricer` to create a Levy pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument. When you price currencies using an Asian instrument for an arithmetic average currency option, the `DividendType` must be 'continuous' and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```

ForeignRate = 0.08;
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', .52,

```

```

outPricer =
  Levy with properties:

```

```

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 0.5200
    DividendValue: 0.0800

```

```
DividendType: "continuous"
```

### Price Asian FX Instrument

Use `price` to compute the price and sensitivities for the Asian FX instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 0.1516
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
0.15161	-0.78532	0.37534	-2.6935	0.015668	-0.0038317	-1.3974

### Price Asian Instrument Using a Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a fixed-strike Asian instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

#### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 1000, 'OptionType', "put")
```

```
AsianOpt =
  Asian with properties:
```

```
    OptionType: "put"
      Strike: 1000
  AverageType: "arithmetic"
  AveragePrice: 0
  AverageStartDate: NaT
  ExerciseStyle: "european"
  ExerciseDate: 15-Sep-2022
      Name: "asian_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.2000
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo",'DiscountCurve',myRC,"Model",BlackScholesModel,'SpotPrice')
```

```
outPricer =
  GBMMonteCarlo with properties:

    DiscountCurve: [1x1 ratecurve]
    SpotPrice: 200
    SimulationDates: 15-Sep-2022
    NumTrials: 1000
    RandomNumbers: []
    Model: [1x1 finmodel.BlackScholes]
    DividendType: "continuous"
    DividendValue: 0
```

### Price Asian Instrument

Use `price` to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 682.3365
```

```
outPR =
  pricerresult with properties:
```

```
Results: [1x7 table]
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
682.34	-0.93511	-5.6843e-14	-0.27409	-3129.1	27.433	-1.2121

### Price Asian Instrument Using a Merton Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a fixed-strike Asian instrument when you use a Merton model and an AssetMonteCarlo pricing method.

#### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 1000, 'OptionType', "put")
```

```
AsianOpt =
```

```
Asian with properties:
```

```
OptionType: "put"
Strike: 1000
AverageType: "arithmetic"
AveragePrice: 0
AverageStartDate: NaT
ExerciseStyle: "european"
ExerciseDate: 15-Sep-2022
Name: "asian_option"
```

#### Create Merton Model Object

Use `finmodel` to create a Merton model object.

```
MertonModel = finmodel("Merton", 'Volatility', 0.45, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)
```

```
MertonModel =
```

```
Merton with properties:
```

```
Volatility: 0.4500
MeanJ: 0.0200
JumpVol: 0.0700
JumpFreq: 0.0900
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", MertonModel, 'SpotPrice', 200

```

```

outPricer =
  MertonMonteCarlo with properties:
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 200
      SimulationDates: 15-Sep-2022
      NumTrials: 1000
      RandomNumbers: []
      Model: [1x1 finmodel.Merton]
      DividendType: "continuous"
      DividendValue: 0

```

### Price Asian Instrument

Use `price` to compute the price and sensitivities for the Asian instrument.

```

[Price, outPR] = price(outPricer, AsianOpt, ["all"])

```

```

Price = 683.2017

```

```

outPR =
  pricerresult with properties:

```

```

      Results: [1x7 table]
      PricerData: [1x1 struct]

```

```

outPR.Results

```

```

ans=1x7 table

```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
_____	_____	_____	_____	_____	_____	_____

683.2    -0.9047    -1.9895e-13    -0.26484    -3110.3    25.93    20.227

## More About

### Asian Option

An Asian option is a path-dependent option with a payoff linked to the average value of the underlying asset during the life (or some part of the life) of the option.

Asian options are similar to lookback options in that there are two types of Asian options: fixed (average price option) and floating (average strike option). Fixed Asian options have a specified strike, while floating Asian options have a strike equal to the average value of the underlying asset over the life of the option. For more information, see “Asian Option” on page 3-33.

### Introduced in R2020a

# Barrier

Barrier instrument object

## Description

Create and price a Barrier instrument object using this workflow:

- 1 Use `fininstrument` to create a Barrier instrument object.
- 2 Use `finmodel` to specify a BlackScholes, Heston, Bates, or Merton model for the Barrier instrument.
- 3 When using a BlackScholes model, use `finpricer` to specify a BlackScholes or VannaVolga pricing method for the Barrier instrument.

When using a BlackScholes, Heston, Bates, or Merton model, use `finpricer` to specify an `AssetMonteCarlo` or `FiniteDifference` pricing method for the Barrier instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Barrier instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
BarrierOpt = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date, 'BarrierValue', barrier_value)
BarrierOpt = fininstrument( ___, Name, Value)
```

### Description

`BarrierOpt = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date, 'BarrierValue', barrier_value)` creates a Barrier object by specifying `InstrumentType` and sets the properties on page 11-2236 for the required name-value pair arguments `Strike`, `ExerciseDate`, and `BarrierValue`.

`BarrierOpt = fininstrument( ___, Name, Value)` sets optional properties on page 11-2236 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BarrierOpt = fininstrument("Barrier", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'BarrierValue', 110, 'OptionType', "put", 'ExerciseStyle', "European", 'BarrierType', "D0", 'Name', "barrier_option")` creates a Barrier put option with an European exercise. You can specify multiple name-value pair arguments.

**Input Arguments****InstrumentType — Instrument type**

string with value "Barrier" | character vector with value 'Barrier' | string with value "Barrier"

Instrument type, specified as the string with the value of "Barrier" or a character vector with the value of 'Barrier'.

Data Types: char | string

**Barrier Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: BarrierOpt =  
 fininstrument("Barrier", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'BarrierValue', 110, 'OptionType', "put", 'ExerciseStyle', "European", 'BarrierType', "DO", 'Name', "barrier\_option")

**Required Barrier Name-Value Pair Arguments****Strike — Option strike value**

nonnegative value

Option strike value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one ExerciseDate on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

**BarrierValue — Barrier level**

numeric

Barrier level, specified as the comma-separated pair consisting of 'BarrierLevel' and a scalar numeric value.

Data Types: double

**Optional Barrier Name-Value Pair Arguments****OptionType — Option type**

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

### ExerciseStyle — Option exercise style

"European" (default) | string with value "European" or "American" | character vector with value 'European' or 'American'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

---

**Note** For a Barrier option, the BlackScholes pricer supports only "European" exercise and the FiniteDifference pricer supports an "American" or "European" exercise.

---

Data Types: string | char

### BarrierType — Barrier option type

"UO" (default) | string with value: "UI", "UO", "DI", or "DO" | character vector with value: 'UI', 'UO', 'DI', or 'DO'

Barrier option type, specified as the comma-separated pair consisting of 'BarrierType' and a string or character vector with one of the following values:

- "UI" — Up knock-in

This option becomes effective when the price of the underlying asset passes above the barrier level. If the underlying asset goes above the barrier level during the life of the option, the option holder has the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price.

- "UO" — Up knock-out

This option gives the option holder the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price as long as the underlying asset does not go above the barrier level during the life of the option. This option terminates when the price of the underlying security passes above the barrier level. If the spot price of the underlying asset reaches or exceeds the barrier level with an up-and-out option, the rebate is paid.

- "DI" — Down knock-in

This option becomes effective when the price of the underlying stock passes below the barrier level. If the underlying security goes below the barrier level during the life of the option, the option holder has the right, but not the obligation, to buy or sell (call or put) the underlying security at the strike price. With a down-and-in option, the rebate is paid if the spot price of the underlying does not reach the barrier level during the life of the option. Note that a Barrier instrument using the FiniteDifference pricer does not support American knock-in barrier options.

- "DO" — Down knock-up

This option gives the option holder the right, but not the obligation, to buy or sell (call or put) the underlying asset at the strike price as long as the underlying asset does not go below the barrier level during the life of the option. This option terminates when the price of the underlying security

passes below the barrier level. If the option is worthless when it expires, the option holder receives a rebate amount.

Option	Barrier Type	Payoff If Barrier Crossed	Payoff If Barrier Not Crossed
Call or Put	Down knock-out	Worthless	Standard Call or Put
Call or Put	Down knock-in	Call or Put	Worthless
Call or Put	Up knock-out	Worthless	Standard Call or Put
Call or Put	Up knock-in	Standard Call or Put	Worthless

Data Types: char | string

### Rebate — Rebate value

0 (default) | numeric

Rebate value, specified as the comma-separated pair consisting of 'Rebate' and a scalar numeric.

- For knock-in options, the Rebate is paid at expiry.
- For knock-out options, the Rebate is paid when BarrierValue is reached.

Data Types: double

### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike value

nonnegative value

Option strike value, returned as a scalar nonnegative value.

Data Types: double

### ExerciseDate — Option exercise date

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

### OptionType — Option type

"call" (default) | string with value "call" or "put"

Option type, returned as a string with the value "call" or "put".

Data Types: string

### ExerciseStyle — Option exercise style

"European" (default) | string with value "European" or "American"

Option exercise style, returned as a string with the value of "European" or "American".

Data Types: string

### **BarrierSpec — Barrier option type**

"U0" European (default) | string with value: "UI", "U0", "DI", or "D0"

Barrier option type, returned as a string with a value of "UI", "U0", "DI", or "D0".

Data Types: string

### **BarrierValue — Barrier level**

numeric

Barrier level, returned as a scalar numeric value.

Data Types: double

### **Rebate — Rebate value**

0 (default) | numeric

Rebate value, returned as a scalar numeric.

Data Types: double

### **Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## **Examples**

### **Price Barrier Instrument Using Black-Scholes Model and Finite Difference Pricer**

This example shows the workflow to price an Barrier instrument when you use a BlackScholes model and a FiniteDifference pricing method.

#### **Create Barrier Instrument Object**

Use `fininstrument` to create an Barrier instrument object.

```
BarrierOpt = fininstrument("Barrier", 'Strike', 45, 'ExerciseDate', datetime(2019,1,1), 'OptionType', 'U0')
```

```
BarrierOpt =
```

```
Barrier with properties:
```

```

    OptionType: "call"
    Strike: 45
    BarrierType: "do"
    BarrierValue: 40
    Rebate: 0
    ExerciseStyle: "american"
    ExerciseDate: 01-Jan-2019
    Name: "barrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.30)
```

```
BlackScholesModel =  
  BlackScholes with properties:  
  
    Volatility: 0.3000  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);  
Maturity = datetime(2023,1,1);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)
```

```
myRC =  
  ratecurve with properties:  
  
    Type: "zero"  
    Compounding: -1  
    Basis: 1  
    Dates: 01-Jan-2023  
    Rates: 0.0350  
    Settle: 01-Jan-2018  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create FiniteDifference Pricer Object

Use `finpricer` to create a FiniteDifference pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FiniteDifference", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPri
```

```
outPricer =  
  FiniteDifference with properties:  
  
    DiscountCurve: [1x1 ratecurve]  
    Model: [1x1 finmodel.BlackScholes]  
    SpotPrice: 50  
    GridProperties: [1x1 struct]  
    DividendType: "continuous"  
    DividendValue: 0
```

### Price Barrier Instrument

Use `price` to compute the price and sensitivities for the Barrier instrument.

```
[Price, outPR] = price(outPricer, BarrierOpt, ["all"])
```

```
Price = 8.5014
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
8.5014	0.85673	0.0057199	5.0388	-1.8461	26.238	6.1837

### Price Barrier Instrument Using Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price an Barrier instrument when you use a BlackScholes model and a AssetMonteCarlo pricing method.

#### Create Barrier Instrument Object

Use `fininstrument` to create an Barrier instrument object.

```
BarrierOpt = fininstrument("Barrier", 'Strike', 45, 'ExerciseDate', datetime(2019,1,1), 'OptionType',
```

```
BarrierOpt =
  Barrier with properties:
    OptionType: "call"
    Strike: 45
    BarrierType: "do"
    BarrierValue: 40
    Rebate: 0
    ExerciseStyle: "american"
    ExerciseDate: 01-Jan-2019
    Name: "barrier_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.30)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
    Volatility: 0.3000
    Correlation: 1
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',1)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
    Compounding: -1
      Basis: 1
      Dates: 01-Jan-2023
      Rates: 0.0350
      Settle: 01-Jan-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", BlackScholesModel, 'SpotPrice', 200)
```

```
outPricer =
  GBMMonteCarlo with properties:
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 200
    SimulationDates: 01-Jan-2019
      NumTrials: 1000
    RandomNumbers: []
      Model: [1x1 finmodel.BlackScholes]
    DividendType: "continuous"
    DividendValue: 0
```

### Price Barrier Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 156.6270
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

```
    Price    Delta    Gamma    Lambda    Rho    Theta    Vega
```

```
    _____
```

```
156.63    1.0004    -7.6028e-12    1.2774    43.45    0    0.67904
```

### Price Barrier Instrument Using Heston Model and Asset Monte-Carlo Pricer

This example shows the workflow to price an Barrier instrument when you use a Heston model and an AssetMonteCarlo pricing method.

#### Create Barrier Instrument Object

Use `fininstrument` to create an Barrier instrument object.

```
BarrierOpt = fininstrument("Barrier", 'Strike', 45, 'ExerciseDate', datetime(2019, 1, 1), 'OptionType',
```

```
BarrierOpt =
  Barrier with properties:
    OptionType: "call"
    Strike: 45
    BarrierType: "do"
    BarrierValue: 40
    Rebate: 0
    ExerciseStyle: "american"
    ExerciseDate: 01-Jan-2019
    Name: "barrier_option"
```

#### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

```
HestonModel =
  Heston with properties:
```

```
    V0: 0.0320
    ThetaV: 0.1000
    Kappa: 0.0030
    SigmaV: 0.2000
    RhoSV: 0.9000
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 1, 1);
Maturity = datetime(2023, 1, 1);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)
```

```
myRC =
  ratecurve with properties:
    Type: "zero"
```

```

    Compounding: -1
      Basis: 1
      Dates: 01-Jan-2023
      Rates: 0.0350
      Settle: 01-Jan-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", HestonModel, 'SpotPrice', 200)
```

```

outPricer =
  HestonMonteCarlo with properties:

    DiscountCurve: [1x1 ratecurve]
      SpotPrice: 200
  SimulationDates: 01-Jan-2019
    NumTrials: 1000
  RandomNumbers: []
      Model: [1x1 finmodel.Heston]
  DividendType: "continuous"
  DividendValue: 0

```

### Price Barrier Instrument

Use `price` to compute the price and sensitivities for the Barrier instrument.

```
[Price, outPR] = price(outPricer, BarrierOpt, ["all"])
```

```
Price = 156.9962
```

```

outPR =
  pricerresult with properties:

```

```

    Results: [1x8 table]
  PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x8 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
157	1.0022	-1.08e-12	1.2768	43.45	0	2.7882	0.0013677

## More About

### Barrier Option

A barrier option has not only a strike price but also a barrier level and sometimes a rebate.

The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `BarrierValue`, during the life of the option. If the option cannot be exercised because the barrier level either has or has not been reached, a fixed rebate amount is paid. For more information, see “Barrier Option” on page 3-19.

### Introduced in R2020a

# DoubleBarrier

DoubleBarrier instrument object

## Description

Create and price a DoubleBarrier instrument object using this workflow:

- 1 Use `fininstrument` to create a DoubleBarrier instrument object.
- 2 Use `finmodel` to specify a BlackScholes, Heston, Bates, or Merton model for the DoubleBarrier instrument.
- 3 When using a BlackScholes model, use `finpricer` to specify an IkedaKunitomo or VannaVolga pricing method for the DoubleBarrier instrument.

When using a BlackScholes, Heston, Bates, or Merton model, use `finpricer` to specify a FiniteDifference or an AssetMonteCarlo pricing method for the DoubleBarrier instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a DoubleBarrier instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
DoubleBarrierOpt = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date, 'BarrierValue', barrier_value)
DoubleBarrierOpt = fininstrument( ___, Name, Value)
```

### Description

`DoubleBarrierOpt = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date, 'BarrierValue', barrier_value)` creates a DoubleBarrier object by specifying `InstrumentType` and sets properties on page 11-2247 using the required name-value pair arguments `Strike`, `ExerciseDate`, and `BarrierValue`.

`DoubleBarrierOpt = fininstrument( ___, Name, Value)` sets optional properties on page 11-2247 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'BarrierValue', 110, 'OptionType', "put", 'ExerciseStyle', "European", 'BarrierType', "DKI", 'Name', "doublebarrier_option")` creates a DoubleBarrier put option with a European exercise. You can specify multiple name-value pair arguments.

## Input Arguments

### InstrumentType — Instrument type

string with value "DoubleBarrier" | character vector with value 'DoubleBarrier'

Instrument type, specified as a string with the value of "DoubleBarrier" or a character vector with the value 'DoubleBarrier'.

Data Types: char | string

### DoubleBarrier Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: DoubleBarrierOpt =  
 fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30),  
 'BarrierValue', 110, 'OptionType', "put", 'ExerciseStyle', "European", 'BarrierType',  
 "DKI", 'Name', "doublebarrier\_option")

### Required DoubleBarrier Name-Value Pair Arguments

#### Strike — Option strike value

nonnegative value

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value.

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one ExerciseDate value on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

#### BarrierValue — Double barrier value

numeric

Double barrier value, specified as the comma-separated pair consisting of 'BarrierValue' and an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector where the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: double

### Optional DoubleBarrier Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

### ExerciseStyle — Option exercise style

"European" (default) | string with value "European" or "American" | character vector with value 'European' or 'American'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

---

**Note** For a DoubleBarrier option, the IkedaKunitomo pricer supports only a "European" exercise and the FiniteDifference pricer supports an "American" or "European" exercise.

---

Data Types: string | char

### BarrierType — Double barrier type

"DKO" (default) | string with value of "DKI" or "DKO" | character vector with value of 'DKI' or 'DKO'

Double barrier type, specified as the comma-separated pair consisting of 'BarrierType' and a scalar character vector or string with one of the following values:

- 'DKI' — Double knock-in

The 'DKI' option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.

- 'DKO' — Double knock-out

The 'DKO' option gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

Option	Barrier Type	Payoff If Any Barrier Crossed	Payoff If Barriers Not Crossed
Call/Put	Double Knock-in	Standard Call/Put	Worthless
Call/Put	Double Knock-out	Worthless	Standard Call/Put

Data Types: char | string

### Rebate — Barrier rebate

[0 0] (default) | numeric

Barrier rebate, specified as the comma-separated pair consisting of 'Rebate' and a numeric matrix.

- For knock-in options, the Rebate is paid at expiry.
- For knock-out options, the Rebate is paid if the Upper Barrier(1)(UB) is hit and the second value is paid if the Lower Barrier(2)(LB) is hit.

Data Types: double

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

**Strike — Option strike price value**

nonnegative value

Option strike price value, returned as a scalar nonnegative value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**BarrierValue — Double barrier value**

numeric

Double barrier value, returned as a numeric matrix.

Data Types: double

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with the value "call" or "put".

Data Types: string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" or "American"

Option exercise style, returned as a string with the value of "European" or "American".

Data Types: string

**BarrierType — Double barrier type**

"DK0" (default) | string with value of "DKI" or "DK0"

Double barrier type, returned as a character vector or string.

Data Types: string

**Rebate — Barrier rebate**

[0 0] (default) | numeric

Barrier rebate, returned as a numeric matrix.

Data Types: double

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Double Barrier Instrument Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price an `DoubleBarrier` instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

#### Create `DoubleBarrier` Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 75, 'ExerciseDate', datetime(2019,1,1), 'C
```

```
DoubleBarrierOpt =
    DoubleBarrier with properties:
        OptionType: "call"
        Strike: 75
        BarrierValue: [110 80]
        ExerciseStyle: "american"
        ExerciseDate: 01-Jan-2019
        BarrierType: "dko"
        Rebate: [0 0]
        Name: "doublebarrier_option"
```

#### Create `BlackScholes` Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.30)
```

```
BlackScholesModel =
    BlackScholes with properties:
        Volatility: 0.3000
        Correlation: 1
```

#### Create `ratecurve` Object

Create a flat `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 1
      Dates: 01-Jan-2023
      Rates: 0.0350
      Settle: 01-Jan-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create FiniteDifference Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FiniteDifference", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 100)
```

```

outPricer =
  FiniteDifference with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      GridProperties: [1x1 struct]
      DividendType: "continuous"
      DividendValue: 0

```

### Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer, DoubleBarrierOpt, ["all"])
```

```
Price = 25
```

```

outPR =
  pricerresult with properties:
      Results: [1x7 table]
      PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
   Price   Delta   Gamma   Lambda   Theta   Rho   Vega
   _____
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
25	1	0	4	2.2737e-13	0	0

## Price Double Barrier Instrument Using a Heston Model and Asset Monte Carlo Pricer

This example shows the workflow to price a DoubleBarrier instrument when you use a Heston model and an AssetMonteCarlo pricing method.

### Create DoubleBarrier Instrument Object

Use `fininstrument` to create a DoubleBarrier instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 75, 'ExerciseDate', datetime(2020, 9, 15),
DoubleBarrierOpt =
  DoubleBarrier with properties:
      OptionType: "call"
      Strike: 75
      BarrierValue: [110 80]
      ExerciseStyle: "american"
      ExerciseDate: 15-Sep-2020
      BarrierType: "dko"
      Rebate: [0 0]
      Name: "doublebarrier_option"
```

### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
HestonModel =
  Heston with properties:
      V0: 0.0320
      ThetaV: 0.1000
      Kappa: 0.0030
      SigmaV: 0.2000
      RhoSV: 0.9000
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 9, 15);
Maturity = datetime(2023, 9, 15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
```

```
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", HestonModel, 'SpotPrice', 102)
outPricer =
    HestonMonteCarlo with properties:

        DiscountCurve: [1x1 ratecurve]
        SpotPrice: 102
        SimulationDates: 15-Sep-2020
        NumTrials: 1000
        RandomNumbers: []
        Model: [1x1 finmodel.Heston]
        DividendType: "continuous"
        DividendValue: 0
```

### Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer, DoubleBarrierOpt, ["all"])
```

```
Price = 32.6351
```

```
outPR =
    pricerresult with properties:
```

```
    Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x8 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
32.635	-0.00089196	-0.0025511	-0.0027878	-76.828	1.1334	-0.2616	-0.0029

### Price Double Barrier Instrument Using a Black-Scholes Model and Asset Monte Carlo Pricer

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

#### Create DoubleBarrier Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2020, 8, 15))
```

```
DoubleBarrierOpt =  
  DoubleBarrier with properties:  
  
    OptionType: "call"  
    Strike: 100  
    BarrierValue: [110 80]  
    ExerciseStyle: "american"  
    ExerciseDate: 15-Aug-2020  
    BarrierType: "dko"  
    Rebate: [0 0]  
    Name: "doublebarrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", .3)
```

```
BlackScholesModel =  
  BlackScholes with properties:  
  
    Volatility: 0.3000  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2017,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =  
  ratecurve with properties:  
  
    Type: "zero"  
    Compounding: -1  
    Basis: 12  
    Dates: 15-Sep-2023  
    Rates: 0.0350  
    Settle: 15-Sep-2017  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
ExerciseDate = datetime(2020,08,15);  
Settle = datetime("15-Sep-2017");  
outPricer = finpricer("AssetMonteCarlo", "DiscountCurve", myRC, "Model", BlackScholesModel, 'SpotPrice')
```

## Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 6.9563
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
6.9563	0.23644	-0.11701	3.399	0.14976	-99.727	-8.344

## Price DoubleBarrier Instrument Using Black-Scholes Model and IkedaKunitomo Pricer

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and an `IkedaKunitomo` pricing method.

### Create DoubleBarrier Instrument Object

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2020,8,15))
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:
```

```
    OptionType: "call"
      Strike: 100
  BarrierValue: [110 80]
  ExerciseStyle: "european"
  ExerciseDate: 15-Aug-2020
  BarrierType: "dko"
      Rebate: [0 0]
      Name: "doublebarrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", .3)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```

    Volatility: 0.3000
    Correlation: 1

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2017,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2017
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create IkedaKunitomo Pricer Object

Use finpricer to create an IkedaKunitomo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("Analytic","DiscountCurve",myRC,"Model",BlackScholesModel,'SpotPrice',100,

```

```

outPricer =
    IkedaKunitomo with properties:
        DiscountCurve: [1x1 ratecurve]
        Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
        DividendValue: 0.0290
        DividendType: "continuous"
        Curvature: [0.0300 -0.0300]

```

### Price DoubleBarrier Instrument

Use price to compute the price and sensitivities for the DoubleBarrier instrument.

```

[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])

```

```

Price = 5.6848e-04

```

```

outPR =
    pricerresult with properties:
        Results: [1x7 table]
        PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
0.00056848	-3.7713e-05	-4.2071e-06	-6.6339	-0.031332	0.0008912	-0.00035113

## Price Double Barrier Instrument Using Black-Scholes Model and Vanna Volga Pricer

This example shows the workflow to price a DoubleBarrier instrument when you use a BlackScholes model and a VannaVolga pricing method.

### Create DoubleBarrier Instrument Object

Use `fininstrument` to create a DoubleBarrier instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2020, 8, 15))
```

```
DoubleBarrierOpt =
```

```
DoubleBarrier with properties:
```

```

    OptionType: "call"
        Strike: 100
    BarrierValue: [110 80]
    ExerciseStyle: "european"
    ExerciseDate: 15-Aug-2020
    BarrierType: "dko"
        Rebate: [0 0]
        Name: "doublebarrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", 0.02)
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```

    Volatility: 0.0200
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2019, 9, 15);
Maturity = datetime(2023, 9, 15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
```

```
ratecurve with properties:
```

```

        Type: "zero"
    Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create VannaVolga Pricer Object

Use `finpricer` to create a VannaVolga pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

VolRR = -0.0045;
VolBF = 0.0037;
RateF = 0.0210;
outPricer = finpricer("VannaVolga", "DiscountCurve", myRC, "Model", BlackScholesModel, 'SpotPrice', 100)

```

```

outPricer =
    VannaVolga with properties:

        DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
            SpotPrice: 100
            DividendType: "continuous"
            DividendValue: 0.0210
            VolatilityRR: -0.0045
            VolatilityBF: 0.0037

```

### Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the DoubleBarrier instrument.

```
[Price, outPR] = price(outPricer, DoubleBarrierOpt, ["all"])
```

```
Price = 1.6450
```

```
outPR =
    pricerresult with properties:
```

```

        Results: [1x7 table]
        PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
_____	_____	_____	_____	_____	_____	_____

1.645    0.82818    75.662    50.346    14.697    -1.3145    74.666

## More About

### Double Barrier Option

A double barrier option is similar to the standard single barrier option except that they have two barrier levels: a lower barrier (LB) and an upper barrier (UB).

The payoff for a double barrier option depends on whether the underlying asset remains between the barrier levels during the life of the option. Double barrier options are less expensive than single barrier options as the probability of being knocked out is higher. Because of this, double barrier options allow investors to achieve reduction in the option premiums and match an investor's belief about the future movement of the underlying price process.

There are two types of double barrier options:

- Double knock-in

This option becomes effective when the price of the underlying asset reaches one of the barriers. It gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, if the underlying asset goes above or below the barrier levels during the life of the option.

- Double knock-out

This option gives the option holder the right but not the obligation to buy or sell the underlying security at the strike price, as long as the underlying asset remains between the barrier levels during the life of the option. This option terminates when the price of the underlying asset passes one of the barriers.

The payoff for this type of option depends on whether the underlying asset crosses the predetermined trigger value (barrier level), indicated by `BarrierValue`, during the life of the option. If the option cannot be exercised because the barrier level either has or has not been reached, a fixed rebate amount is paid. For more information, see "Double Barrier Option" on page 3-20.

## Tips

After creating an `DoubleBarrier` instrument object with an `ExerciseStyle` set to "American", you can modify the `ExerciseStyle` property to change it to "European" using dot notation.

```
DoubleBarrier.ExerciseStyle = "European"
```

Because a European option has a scalar `Strike` and `ExerciseDate` value and an American option has a 2-element vector for `Strike` and `ExerciseDate` values, when you change to `ExerciseStyle` from "American" to "European", the `Strike` and `ExerciseDate` values become the last element in the 2-element vector for the `Strike` and `ExerciseDate` values.

# Touch

Touch instrument object

## Description

Create and price a Touch instrument object using this workflow:

- 1 Use `fininstrument` to create a Touch instrument object.
- 2 Use `finmodel` to specify a `BlackScholes`, `Bates`, `Merton`, or `Heston` model for the Touch instrument.
- 3 When using a `BlackScholes` model, use `finpricer` to specify a `BlackScholes` or a `VannaVolga` pricing method for the `Barrier` instrument.

When using a `BlackScholes`, `Heston`, `Bates`, or `Merton` model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for the Touch instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Touch instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
TouchOpt = fininstrument(InstrumentType, 'ExerciseDate', exercise_date, 'BarrierValue', barrier_value, 'PayoffValue', payoff_value)
TouchOpt = fininstrument( ____, Name, Value)
```

### Description

`TouchOpt = fininstrument(InstrumentType, 'ExerciseDate', exercise_date, 'BarrierValue', barrier_value, 'PayoffValue', payoff_value)` creates a Touch instrument object by specifying `InstrumentType` and sets properties on page 11-2261 using the required name-value pair arguments `ExerciseDate`, `BarrierValue`, and `PayoffValue`.

`TouchOpt = fininstrument( ____, Name, Value)` sets optional properties on page 11-2261 using additional name-value pair arguments in addition to the required arguments in the previous syntax.

For example, `TouchOpt = fininstrument("Touch", 'ExerciseDate', datetime(2019,1,30), 'BarrierValue', 110, 'PayoffValue', 130, 'BarrierType', "OT", 'PayoffType', "Expiry", 'Name', "Touch_option")` creates a Touch option with an expiry payoff type. You can specify multiple name-value pair arguments.

## Input Arguments

### InstrumentType — Instrument type

string with value "Touch" | character vector with value 'Touch'

Instrument type, specified as a string with the value of "Touch" or a character vector with the value of 'Touch'.

Data Types: char | string

### Touch Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: TouchOpt =  
fininstrument("Touch",',','ExerciseDate',datetime(2019,1,30),'BarrierValue',110  
, 'PayoffValue',130,'BarrierType',"OT",'PayoffType',"Expiry','Name',"Touch\_opt  
ion")

### Required Touch Name-Value Pair Arguments

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

#### BarrierValue — Barrier level

numeric

Barrier level, specified as the comma-separated pair consisting of 'BarrierValue' and a scalar numeric value.

Data Types: double

#### PayoffValue — Option payoff value

numeric

Option payoff value, specified as the comma-separated pair consisting of 'PayoffValue' and a scalar numeric value.

Data Types: double

### Optional Touch Name-Value Pair Arguments

#### BarrierType — Barrier type

"OT" (default) | string with value "OT" or "NT" | character vector with value 'OT' or 'NT'

Barrier type, specified as the comma-separated pair consisting of 'BarrierType' and a scalar string or character vector with one of the following values:

- 'OT' — One-touch

The one-touch option provides a payoff if the underlying asset ever trades at or beyond the `BarrierValue`. Otherwise, the `PayoffValue` is zero.

- 'NT' — No-touch

The no-touch option provides a payoff if the underlying asset never trades at or beyond the `BarrierValue`. Otherwise, the `PayoffValue` is zero.

Data Types: `char` | `string`

### **PayoffType — Payoff type**

"Hit" (default) | string with value "Hit" or "Expiry" | character vector with value 'Hit' or 'Expiry'

Payoff type, specified as the comma-separated pair consisting of 'PayoffType' and a scalar string or character vector. You can specify "Expiry" only when you specify 'OT' as the `BarrierType`.

---

**Note** When you use a `BlackScholes` pricer, only the "Hit" `PayoffType` is supported.

---

Data Types: `char` | `string`

### **Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: `char` | `string`

## **Properties**

### **ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: `datetime`

### **BarrierValue — Barrier level**

numeric

Barrier level, returned as a scalar numeric value.

Data Types: `double`

### **PayoffValue — Option payoff**

numeric

Option payoff, returned as a numeric value.

Data Types: `double`

### **BarrierType — Barrier type**

"OT" (default) | string with value "OT" or "NT"

Barrier type, returned as a string.

Data Types: string

#### **PayoffType – Payoff type**

"Hit" (default) | string with value "Hit" or "Expiry"

Option type, returned as a string.

Data Types: string

#### **Name – User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## **Examples**

### **Price Touch Instrument Using a Black-Scholes Model and Asset Monte Carlo Pricer**

This example shows the workflow to price a Touch instrument when you use a BlackScholes model and an AssetMonteCarlo pricing method.

#### **Create Touch Instrument Object**

Use `fininstrument` to create a Touch instrument object.

```
TouchOpt = fininstrument("Touch", 'ExerciseDate', datetime(2022,9,15), 'BarrierValue', 100, 'PayoffVa
```

```
TouchOpt =
```

```
Touch with properties:
```

```
ExerciseDate: 15-Sep-2022
BarrierValue: 100
PayoffValue: 110
BarrierType: "ot"
PayoffType: "expiry"
Name: "touch_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .2)
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
Volatility: 0.2000
Correlation: 1
```

#### **Create ratecurve Object**

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", BlackScholesModel, 'SpotPrice', 102)
```

```

outPricer =
  GBMMonteCarlo with properties:
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 102
      SimulationDates: 15-Sep-2022
      NumTrials: 1000
      RandomNumbers: []
      Model: [1x1 finmodel.BlackScholes]
      DividendType: "continuous"
      DividendValue: 0

```

### Price Touch Instrument

Use `price` to compute the price and sensitivities for the Touch instrument.

```
[Price, outPR] = price(outPricer, TouchOpt, ["all"])
```

```
Price = 91.1862
```

```

outPR =
  pricerresult with properties:

```

```

      Results: [1x7 table]
      PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
_____	_____	_____	_____	_____	_____	_____

```
91.186    -2.1825    0.038281    -2.4413    -415.45    2.7374    35.998
```

### Price Touch Instrument Using Heston Model and Asset Monte Carlo Pricer

This example shows the workflow to price a Touch instrument when you use a Heston model and an AssetMonteCarlo pricing method.

#### Create Touch Instrument Object

Use `fininstrument` to create a Touch instrument object.

```
TouchOpt = fininstrument("Touch", 'ExerciseDate', datetime(2022,9,15), 'BarrierValue', 110, 'PayoffValue', 140)
```

```
TouchOpt =
  Touch with properties:

    ExerciseDate: 15-Sep-2022
    BarrierValue: 110
    PayoffValue: 140
    BarrierType: "ot"
    PayoffType: "expiry"
    Name: "touch_option"
```

#### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

```
HestonModel =
  Heston with properties:

    V0: 0.0320
    ThetaV: 0.1000
    Kappa: 0.0030
    SigmaV: 0.2000
    RhoSV: 0.9000
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 12
```

```

        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", HestonModel, 'SpotPrice', 112)
outPricer =
    HestonMonteCarlo with properties:

        DiscountCurve: [1x1 ratecurve]
        SpotPrice: 112
        SimulationDates: 15-Sep-2022
        NumTrials: 1000
        RandomNumbers: []
        Model: [1x1 finmodel.Heston]
        DividendType: "continuous"
        DividendValue: 0

```

### Price Touch Instrument

Use `price` to compute the price and sensitivities for the Touch instrument.

```
[Price, outPR] = price(outPricer, TouchOpt, ["all"])
```

```
Price = 63.5247
```

```

outPR =
    pricerresult with properties:

        Results: [1x8 table]
        PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x8 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
63.525	-7.2363	1.0541	-12.758	-320.21	3.5527	418.94	8.1498

### Price Touch Instrument Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a Touch instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

### Create Touch Instrument Object

Use `fininstrument` to create a Touch instrument object.

```
TouchOpt = fininstrument("Touch", 'ExerciseDate', datetime(2022,9,15), 'BarrierValue', 140, 'PayoffVa
```

```
TouchOpt =  
    Touch with properties:  
  
    ExerciseDate: 15-Sep-2022  
    BarrierValue: 140  
    PayoffValue: 170  
    BarrierType: "ot"  
    PayoffType: "expiry"  
    Name: "touch_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.28)
```

```
BlackScholesModel =  
    BlackScholes with properties:  
  
    Volatility: 0.2800  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =  
    ratecurve with properties:  
  
    Type: "zero"  
    Compounding: -1  
    Basis: 12  
    Dates: 15-Sep-2023  
    Rates: 0.0350  
    Settle: 15-Sep-2018  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create BlackScholes Pricer Object

Use `finpricer` to create a BlackScholes pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', 135,
```

```

outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 135
    DividendValue: 0.0450
    DividendType: "continuous"

```

## Price Touch Instrument

Use price to compute the price and sensitivities for the Touch instrument.

```
[Price, outPR] = price(outPricer,TouchOpt,["all"])
```

```
Price = 136.5553
```

```

outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
136.56	2.2346	0.005457	2.2092	30.812	3.9013	-465.89

## More About

### Touch Option

A touch option (also known as a binary barrier option or American digital) is a path-dependent option in which the existence and payment of the options depend on the movement of the underlying spot through their option life.

The one-touch (no-touch) option provides a payoff if the underlying spot ever (never) trades at or beyond the barrier level and otherwise it is zero. For more information, see “One-Touch and Double One-Touch Options” on page 3-29.

# DoubleTouch

DoubleTouch instrument object

## Description

Create and price a DoubleTouch instrument object using this workflow:

- 1 Use `fininstrument` to create a DoubleTouch instrument object.
- 2 Use `finmodel` to specify a BlackScholes, Bates, Merton, or Heston model for the DoubleTouch instrument.
- 3 When using a BlackScholes model, use `finpricer` to specify a BlackScholes or VannaVolga pricing method for the DoubleTouch instrument.

When using a BlackScholes, Heston, Bates, or Merton model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for the DoubleTouch instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a DoubleTouch instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
DoubleTouchOpt = fininstrument(InstrumentType, 'ExerciseDate', exercise_date, 'BarrierValue', barrier_value, 'PayoffValue', payoff_value)
DoubleTouchOpt = fininstrument( ____, Name, Value)
```

### Description

`DoubleTouchOpt = fininstrument(InstrumentType, 'ExerciseDate', exercise_date, 'BarrierValue', barrier_value, 'PayoffValue', payoff_value)` creates a DoubleTouch object by specifying `InstrumentType` and sets properties on page 11-2271 using the required name-value pair arguments `ExerciseDate`, `BarrierValue`, and `PayoffValue`.

`DoubleTouchOpt = fininstrument( ____, Name, Value)` sets optional properties on page 11-2271 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `DoubleTouchOpt = fininstrument("DoubleTouch", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'BarrierValue', 110, 'PayoffValue', 150, 'BarrierType', "DOT", 'PayoffType', "Expiry", 'Name', "DoubleTouch_option")` creates a DoubleTouch option with a payoff type of `Expiry`. You can specify multiple name-value pair arguments.

## Input Arguments

### InstrumentType — Instrument type

string with value "DoubleTouch" | character vector with value 'DoubleTouch'

Instrument type, specified as a string with the value of "DoubleTouch" or a character vector with the value 'DoubleTouch'.

Data Types: char | string

### DoubleTouch Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: DoubleTouchOpt =  
fininstrument("DoubleTouch", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'BarrierValue', 110, 'OptionType', "put", 'ExerciseStyle', "European", 'BarrierType', "DO", 'Name', "DoubleTouch\_option")

### Required DoubleTouch Name-Value Pair Arguments

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

#### BarrierValue — Option barrier levels

numeric

Option barrier levels, specified as the comma-separated pair consisting of 'BarrierValue' and an NINST-by-2 matrix of numeric values, where the first column is Upper Barrier(1)(UB) and the second column is Lower Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

Data Types: double

#### PayoffValue — Payoff value

numeric

Payoff value, specified as the comma-separated pair consisting of 'PayoffValue' and an NINST-by-1 matrix of numeric values, where each element is a 1-by-2 vector in which the first column is Barrier(1)(UB) and the second column is Barrier(2)(LB). Barrier(1) must be greater than Barrier(2).

---

**Note** The payoff value is calculated for the point in time that the BarrierValue is reached. The payoff is either cash or nothing. If you specify a double no-touch option using BarrierType, the payoff is at the maturity of the option.

---

Data Types: double

### Optional DoubleTouch Name-Value Pair Arguments

#### BarrierType — Double barrier type

"DOT" (default) | string with value "DOT", "DNT", "UNT-LOT", or "UOT-LNT" | character vector with value 'DOT', 'DNT', 'UNT-LOT', or 'UOT-LNT'

Double barrier type, specified as the comma-separated pair consisting of 'BarrierType' and a string or character vector with one of the following values:

- 'DOT' — Double one-touch. The double one-touch option defines two `BarrierValue` values. A double one-touch option provides a `PayoffValue` if the underlying asset ever touches either the upper or lower `BarrierValue` values.
- 'DNT' — Double no-touch. The double no-touch option defines two `BarrierValue` values. A double no-touch option provides a `PayoffValue` if the underlying asset ever never touches either the upper or lower `BarrierValue` values.
- 'UNT-LOT' — Upper `BarrierValue` is No Touch and Lower `BarrierValue` is one Touch.
- 'UOT-LNT' — Upper `BarrierValue` is One Touch and Lower `BarrierValue` is No Touch.

Data Types: char | string

#### PayoffType — Payoff type

"Hit" (default) | string with value "Hit" or "Expiry" | character vector with value 'Hit' or 'Expiry'

Payoff type, specified as the comma-separated pair consisting of 'PayoffType' and a scalar string or character vector. You cannot use specify "Expiry" when using a `BarrierType` of 'DNT'.

---

**Note** When you use a `BlackScholes` pricer, only the "Expiry" `PayoffType` is supported.

---

Data Types: char | string

#### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

#### ExerciseDate — Option exercise date

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

#### BarrierValue — Barrier level

numeric

Barrier level, returned as a numeric matrix.

Data Types: double

### **PayoffValue — Option payoff**

numeric

Option payoff, returned as a numeric matrix.

Data Types: double

### **BarrierType — Double barrier type**

"DOT" (default) | string with value of "DOT", "DNT", "UNT-LOT", or "UOT-LNT"

Double barrier type, returned as a string.

Data Types: string

### **PayoffType — Payoff type**

"Hit" (default) | string with value "Hit" or "Expiry"

Option type, returned as a string.

Data Types: string

### **Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## **Examples**

### **Price Double Touch Instrument Using a Black-Scholes Model and Asset Monte Carlo Pricer**

This example shows the workflow to price a DoubleTouch instrument when you use a BlackScholes model and an AssetMonteCarlo pricing method.

#### **Create DoubleTouch Instrument Object**

Use `fininstrument` to create a DoubleTouch instrument object.

```
DoubleTouchOpt = fininstrument("DoubleTouch", 'ExerciseDate', datetime(2022,9,15), 'BarrierValue', [
```

```
DoubleTouchOpt =  
    DoubleTouch with properties:
```

```
    ExerciseDate: 15-Sep-2022  
    BarrierValue: [110 90]  
    PayoffValue: 50  
    BarrierType: "dot"  
    PayoffType: "expiry"  
    Name: "doubletouch_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .2)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
    Volatility: 0.2000
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate, 'Basis',12)
```

```
myRC =
  ratecurve with properties:
    Type: "zero"
    Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", BlackScholesModel, 'SpotPrice')
```

```
outPricer =
  GBMMonteCarlo with properties:
    DiscountCurve: [1x1 ratecurve]
    SpotPrice: 102
    SimulationDates: 15-Sep-2022
    NumTrials: 1000
    RandomNumbers: []
    Model: [1x1 finmodel.BlackScholes]
    DividendType: "continuous"
    DividendValue: 0
```

### Price DoubleTouch Instrument

Use `price` to compute the price and sensitivities for the `DoubleTouch` instrument.

```
[Price, outPR] = price(outPricer, DoubleTouchOpt, ["all"])
```

```
Price = 43.3860
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
43.386	0.0043916	0.0018346	0.010325	-173.28	1.4722	1.8176

### Price Double Touch Instrument Using a Bates Model and Asset Monte Carlo Pricer

This example shows the workflow to price a DoubleTouch instrument when you use a Bates model and an AssetMonteCarlo pricing method.

#### Create DoubleTouch Instrument Object

Use `fininstrument` to create a DoubleTouch instrument object.

```
DoubleTouchOpt = fininstrument("DoubleTouch", 'ExerciseDate', datetime(2022,9,15), 'BarrierValue', [
```

```
DoubleTouchOpt =
  DoubleTouch with properties:
```

```
    ExerciseDate: 15-Sep-2022
    BarrierValue: [115 95]
    PayoffValue: 40
    BarrierType: "dot"
    PayoffType: "expiry"
    Name: "doubletouch_option"
```

#### Create Bates Model Object

Use `finmodel` to create a Bates model object.

```
BatesModel = finmodel("Bates", 'V0',0.032, 'ThetaV',0.1, 'Kappa',0.003, 'SigmaV',0.2, 'RhoSV',0.9, 'Mea
```

```
BatesModel =
  Bates with properties:
```

```
    V0: 0.0320
    ThetaV: 0.1000
    Kappa: 0.0030
    SigmaV: 0.2000
    RhoSV: 0.9000
    MeanJ: 0.1100
    JumpVol: 0.0230
    JumpFreq: 0.0200
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", BatesModel, 'SpotPrice', 102,
```

```
outPricer =
    BatesMonteCarlo with properties:
        DiscountCurve: [1x1 ratecurve]
        SpotPrice: 102
        SimulationDates: 15-Sep-2022
        NumTrials: 1000
        RandomNumbers: []
        Model: [1x1 finmodel.Bates]
        DividendType: "continuous"
        DividendValue: 0
```

### Price DoubleTouch Instrument

Use `price` to compute the price and sensitivities for the `DoubleTouch` instrument.

```
[Price, outPR] = price(outPricer, DoubleTouchOpt, ["all"])
```

```
Price = 34.7743
```

```
outPR =
    pricerresult with properties:
```

```
    Results: [1x8 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

ans=1x8 table

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
34.774	0	0	0	-139.07	1.2179	0	0

### Price Double Touch Instrument Using a Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a DoubleTouch instrument when you use a BlackScholes model and a BlackScholes pricing method.

#### Create DoubleTouch Instrument Object

Use `fininstrument` to create a DoubleTouch instrument object.

```
DoubleTouchOpt = fininstrument("DoubleTouch", 'ExerciseDate', datetime(2022,9,15), 'BarrierValue', [
```

```
DoubleTouchOpt =
  DoubleTouch with properties:
    ExerciseDate: 15-Sep-2022
    BarrierValue: [115 95]
    PayoffValue: 70
    BarrierType: "unt-lot"
    PayoffType: "expiry"
    Name: "doubletouch_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.28)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
    Volatility: 0.2800
    Correlation: 1
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
  ratecurve with properties:
    Type: "zero"
    Compounding: -1
    Basis: 12
```

```

    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

## Create BlackScholes Pricer Object

Use `finpricer` to create a BlackScholes pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', 100,
outPricer =
    BlackScholes with properties:

        DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 100
    DividendValue: 0.0450
    DividendType: "continuous"

```

## Price DoubleTouch Instrument

Use `price` to compute the price and sensitivities for the DoubleTouch instrument.

```
[Price, outPR] = price(outPricer, DoubleTouchOpt, ["all"])
```

```
Price = 52.6903
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
52.69	-3.4708	-0.0041339	-6.5871	-1.3469	0	-35.883

## More About

### Double Touch Option

Double touch and double no-touch options work the same way as a Touch option, but have two barriers.

Double touch and double no-touch option provides a payoff if the underlying spot ever (never) touches either the upper or lower barriers levels. For more information, see “One-Touch and Double One-Touch Options” on page 3-29.

# Binary

Binary instrument object

## Description

Create and price a Binary instrument object using this workflow:

- 1 Use `fininstrument` to create a Binary instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Binary instrument.
- 3 Use `finpricer` to specify a BlackScholes or AssetMonteCarlo pricing method for the Binary instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Binary instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
BinaryOpt = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date,'PayoffValue',payoff_value)
BinaryOpt = fininstrument(___,Name,Value)
```

### Description

`BinaryOpt = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date,'PayoffValue',payoff_value)` creates a Binary object by specifying `InstrumentType` and sets properties on page 11-2281 using the required name-value pair arguments `Strike`, `ExerciseDate`, and `PayoffValue`.

`BinaryOpt = fininstrument(___,Name,Value)` sets optional properties on page 11-2281 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `BinaryOpt = fininstrument("Binary",'Strike',100,'ExerciseDate',datetime(2019,1,30),'PayoffValue',110,'OptionType',"put",'Name',"binary_option")` creates a Binary put option with a `PayoffValue` of 110. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Binary" | character vector with value 'Binary'

Instrument type, specified as the string with the value of "Binary" or a character vector with the value of 'Binary'.

Data Types: char | string

### Binary Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: BinaryOpt =  
fininstrument("Binary", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'PayoffValue', 110, 'OptionType', "put", 'Name', "binary_option")
```

### Required Binary Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative value

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value.

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Data Types: double | char | string | datetime

#### PayoffValue — Option payoff value

numeric

Option payoff value, specified as the comma-separated pair consisting of 'PayoffValue' and a scalar numeric value.

Data Types: double

### Optional Binary Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

#### ExerciseStyle — Option exercise style

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

Data Types: string | char

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

**Properties****Strike — Option strike price value**

nonnegative value

Option strike price value, returned as a scalar nonnegative value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**PayoffValue — Option payoff value**

numeric

Option payoff value, returned as a numeric value.

Data Types: double

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with the value "call" or "put".

Data Types: string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European"

This property is read-only.

Option exercise style, returned as a string with the value of "European".

Data Types: string

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Examples**

## Price Binary Instrument Using Black-Scholes Model and Asset Monte Carlo Pricer

This example shows the workflow to price a Binary instrument when you use a BlackScholes model and an AssetMonteCarlo pricing method.

### Create Binary Instrument Object

Use `fininstrument` to create a Binary instrument object.

```
BinaryOpt = fininstrument("Binary", 'ExerciseDate', datetime(2022,9,15), 'Strike', 1000, 'PayoffValue
```

```
BinaryOpt =  
  Binary with properties:  
  
      OptionType: "put"  
    ExerciseDate: 15-Sep-2022  
          Strike: 1000  
    PayoffValue: 130  
    ExerciseStyle: "european"  
          Name: "binary_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .2)
```

```
BlackScholesModel =  
  BlackScholes with properties:  
  
      Volatility: 0.2000  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =  
  ratecurve with properties:  
  
      Type: "zero"  
    Compounding: -1  
      Basis: 12  
      Dates: 15-Sep-2023  
      Rates: 0.0350  
      Settle: 15-Sep-2018  
    InterpMethod: "linear"  
ShortExtrapMethod: "next"  
LongExtrapMethod: "previous"
```

## Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", BlackScholesModel, 'SpotPrice')
outPricer =
  GBMMonteCarlo with properties:
    DiscountCurve: [1x1 ratecurve]
    SpotPrice: 102
    SimulationDates: 15-Sep-2022
    NumTrials: 1000
    RandomNumbers: []
    Model: [1x1 finmodel.BlackScholes]
    DividendType: "continuous"
    DividendValue: 0
```

## Price Binary Instrument

Use `price` to compute the price and sensitivities for the Binary instrument.

```
[Price, outPR] = price(outPricer, BinaryOpt, ["all"])
```

```
Price = 113.0166
```

```
outPR =
  pricerresult with properties:
    Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
113.02	0	0	0	-451.98	3.9582	0

## Price Binary Instrument Using Merton Model and Asset Monte Carlo Pricer

This example shows the workflow to price a Binary instrument when you use a Merton model and an `AssetMonteCarlo` pricing method.

### Create Binary Instrument Object

Use `fininstrument` to create a Binary instrument object.

```
BinaryOpt = fininstrument("Binary", 'ExerciseDate', datetime(2022,9,15), 'Strike', 1000, 'PayoffValue')
BinaryOpt =
  Binary with properties:
```

```

OptionType: "put"
ExerciseDate: 15-Sep-2022
Strike: 1000
PayoffValue: 130
ExerciseStyle: "european"
Name: "binary_option"

```

### Create Merton Model Object

Use `finmodel` to create a Merton model object.

```
MertonModel = finmodel("Merton", 'Volatility', 0.45, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)
```

```
MertonModel =
Merton with properties:
```

```

Volatility: 0.4500
MeanJ: 0.0200
JumpVol: 0.0700
JumpFreq: 0.0900

```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```
myRC =
ratecurve with properties:
```

```

Type: "zero"
Compounding: -1
Basis: 12
Dates: 15-Sep-2023
Rates: 0.0350
Settle: 15-Sep-2018
InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an AssetMonteCarlo pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", MertonModel, 'SpotPrice', 102)
```

```
outPricer =
MertonMonteCarlo with properties:
```

```

DiscountCurve: [1x1 ratecurve]
SpotPrice: 102

```

```

SimulationDates: 15-Sep-2022
  NumTrials: 1000
  RandomNumbers: []
    Model: [1x1 finmodel.Merton]
  DividendType: "continuous"
  DividendValue: 0

```

### Price Binary Instrument

Use `price` to compute the price and sensitivities for the Binary instrument.

```
[Price, outPR] = price(outPricer,BinaryOpt,["all"])
```

```
Price = 112.4515
```

```
outPR =
  pricerresult with properties:
```

```

  Results: [1x7 table]
  PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
112.45	0	0	0	-449.72	3.9384	0

### Price Binary Instrument Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a Binary instrument when you use a BlackScholes model and a BlackScholes pricing method.

#### Create Binary Instrument Object

Use `fininstrument` to create a Binary instrument object.

```
BinaryOpt = fininstrument("Binary", 'ExerciseDate', datetime(2022,9,15), 'Strike', 1000, 'PayoffValue
```

```
BinaryOpt =
  Binary with properties:
```

```

  OptionType: "put"
  ExerciseDate: 15-Sep-2022
  Strike: 1000
  PayoffValue: 130
  ExerciseStyle: "european"
  Name: "binary_option"

```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.28)
```

```
BlackScholesModel =  
  BlackScholes with properties:  
  
    Volatility: 0.2800  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =  
  ratecurve with properties:  
  
    Type: "zero"  
    Compounding: -1  
    Basis: 12  
    Dates: 15-Sep-2023  
    Rates: 0.0350  
    Settle: 15-Sep-2018  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create BlackScholes Pricer Object

Use finpricer to create a BlackScholes pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', 800,
```

```
outPricer =  
  BlackScholes with properties:  
  
    DiscountCurve: [1x1 ratecurve]  
    Model: [1x1 finmodel.BlackScholes]  
    SpotPrice: 800  
    DividendValue: 0.0450  
    DividendType: "continuous"
```

### Price Binary Instrument

Use price to compute the price and sensitivities for the Binary instrument.

```
[Price, outPR] = price(outPricer, BinaryOpt, ["all"])
```

```
Price = 87.4005
```

```
outPR =  
  pricerresult with properties:
```

```
Results: [1x7 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
87.4	-0.075973	-3.1264e-05	-0.6954	-23.084	3.2599	-592.61

## More About

### Binary Option

A binary option is where the buyer receives a payout or loses their investment, depending on whether the option expires in the money.

Binary options depend on the outcome of a "yes or no" proposition, hence the name "binary." Binary options have an expiry date and/or time. At the time of expiry, the price of the underlying asset must be on the correct side of the strike price (based on the trade taken) for the trader to make a profit.

A binary option automatically exercises, meaning the gain or loss on the trade is automatically credited or debited to the trader's account when the option expires.

### Introduced in R2020b

# Cap

Cap instrument object

## Description

Create and price a Cap instrument object using this workflow:

- 1 Use `fininstrument` to create a Cap instrument object.
- 2 Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `Black`, or `Normal` model for the Cap instrument.
- 3 Use `finpricer` to specify a `Normal`, `Black`, `HullWhite`, or `IRTree` pricing method for the Cap instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Cap instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
CapOpt = fininstrument(InstrumentType, 'Strike', strike_value, '
Maturity', maturity_date)
CapOpt = fininstrument( ___, Name, Value)
```

### Description

`CapOpt = fininstrument(InstrumentType, 'Strike', strike_value, 'Maturity', maturity_date)` creates a Cap object by specifying `InstrumentType` and sets the properties on page 11-2291 for the required name-value pair arguments `Strike` and `Maturity`.

The Cap instrument supports vanilla and amortizing caps.

`CapOpt = fininstrument( ___, Name, Value)` sets optional properties on page 11-2291 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CapOpt = fininstrument("Cap", 'Strike', 0.65, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Principal', 100, 'ResetOffset', 1, 'Basis', 1, 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve_object, 'Name', "cap_option")` creates a Cap option with a strike of 0.65. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Cap" | character vector with value 'Cap'

Instrument type, specified as a string with the value "Cap" or a character vector with the value 'Cap'.

Data Types: char | string

### Cap Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: CapOpt =

```
fininstrument("Cap", 'Strike', 0.65, 'Maturity', datetime(2019, 1, 30), 'Reset', 4, 'Principal', 100, 'ResetOffset', 1, 'Basis', 1, 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve_object, 'Name', "cap_option")
```

### Required Cap Name-Value Pair Arguments

#### Strike — Cap strike price

nonnegative decimal value

Cap strike price, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative decimal value.

Data Types: double

#### Maturity — Cap maturity date

datetime | serial date number | date character vector | date string

Cap maturity date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Data Types: double | char | string | datetime

### Optional Cap Name-Value Pair Arguments

#### Reset — Reset frequency payments per year

1 (default) | numeric with value of 0, 1, 2, 3, 4, 6, or 12

Reset frequency payments per year, specified as the comma-separated pair consisting of 'Reset' and a scalar numeric.

Data Types: double

#### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer with one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360

- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: `double`

### **Principal — Principal amount or principal value schedule**

100 (default) | `scalar numeric` | `timetable`

Principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a `timetable`, where the first column is dates and the second column is its associated principal value. The date indicates the last day that the principal value is valid.

Data Types: `double` | `timetable`

### **ResetOffset — Lag in rate setting**

0 (default) | `numeric`

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a scalar numeric.

Data Types: `double`

### **DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on the actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar with a value of true or false.

Data Types: `logical`

### **BusinessDayConvention — Business day conventions**

"actual" (default) | `string` | `character vector`

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector for a business day convention. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### Holidays — Holidays used in computing business days

NaN (default) | datetime | cell array of character vectors | date string array | serial date number

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
CapOpt = fininstrument("Cap",'Strike',100,'Maturity',datetime(2025,12,15),'Holidays',H)
```

Data Types: double | cell | datetime | string

### ProjectionCurve — Rate curve used in generating future cash flows

ratecurve.empty (default) | ratecurve object

Rate curve used in projecting the future cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a ratecurve object. This object must be created using ratecurve. Use this optional input if the forward curve is different from the discount curve.

Data Types: object

### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike price value

nonnegative value

Option strike price value, returned as a scalar nonnegative value.

Data Types: double

### Maturity — Cap maturity date

datetime

Cap maturity date, returned as a datetime.

Data Types: `datetime`

**Reset — Reset frequency payments per year**

1 (default) | numeric

Reset frequency payments per year, returned as a scalar numeric.

Data Types: `double`

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, returned as a scalar integer.

Data Types: `double`

**Principal — Principal amount or principal value schedule**

100 (default) | numeric | timetable

Principal amount or principal value schedule, returned as a scalar numeric for a principal amount or a timetable for a principal value schedule.

Data Types: `double` | `timetable`

**ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, returned as a scalar numeric.

Data Types: `double`

**DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on the actual period day count, returned as a logical with a value of true or false.

Data Types: `logical`

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string.

Data Types: `string`

**Holidays — Holidays used in computing business days**

NaN (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: `datetime`

**ProjectionCurve — Rate curve used in generating future cash flows**

`ratecurve.empty` (default) | structure

Rate curve used in projecting the future cash flows, returned as a `ratecurve` object.

Data Types: object

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Vanilla Cap Instrument Using Hull-White Model and Hull-White Pricer

This example shows the workflow to price a vanilla Cap instrument when using a HullWhite model and a HullWhite pricing method.

#### Create Cap Instrument Object

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', 0.02, 'Maturity', datetime(2019, 1, 30), 'Reset', 4, 'Principal', 100)
```

```
CapOpt =
```

```
Cap with properties:
```

```

        Strike: 0.0200
        Maturity: 30-Jan-2019
    ResetOffset: 0
        Reset: 4
        Basis: 8
    Principal: 100
    ProjectionCurve: [0x0 ratecurve]
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        Name: "cap_option"
```

#### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.62, 'Sigma', 0.99)
```

```
HullWhiteModel =
```

```
HullWhite with properties:
```

```

    Alpha: 0.6200
    Sigma: 0.9900
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 9, 15);
Type = 'zero';
```

```

ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

myRC =
    ratecurve with properties:

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create HullWhite Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic", 'Model',HullWhiteModel, 'DiscountCurve',myRC)

outPricer =
    HullWhite with properties:

        DiscountCurve: [1x1 ratecurve]
        Model: [1x1 finmodel.HullWhite]

```

### Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```

Price = price(outPricer,CapOpt)

Price = 2.9366

```

### Price Vanilla Cap Instrument Using Normal Model and Normal Pricer

This example shows the workflow to price a vanilla Cap instrument when you use a `Normal` model and a `Normal` pricing method.

#### Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the cap instrument.

```

Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Cap Instrument Object

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Maturity', datetime(2022,9,15), 'Strike', 0.04, 'ProjectionCurve', myRC)
```

```
CapOpt =
  Cap with properties:
      Strike: 0.0400
      Maturity: 15-Sep-2022
      ResetOffset: 0
      Reset: 1
      Basis: 0
      Principal: 100
      ProjectionCurve: [1x1 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: ""
```

### Create Normal Model Object

Use `finmodel` to create a Normal model object.

```
NormalModel = finmodel("Normal", 'Volatility', 0.01)
```

```
NormalModel =
  Normal with properties:
      Volatility: 0.0100
```

### Create Normal Pricer Object

Use `finpricer` to create a Normal pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', NormalModel)
```

```
outPricer =
  Normal with properties:
```

```
DiscountCurve: [1x1 ratecurve]
Shift: 0
Model: [1x1 finmodel.Normal]
```

### Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
[Price, outPR] = price(outPricer, CapOpt)
```

```
Price = 0.0701
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x1 table]
  PricerData: []
```

### Price Amortizing Cap Instrument Using Black Model and Black Pricer

This example shows the workflow to price an amortizing Cap instrument when you use a Black model and a Black pricing method.

#### Create Cap Instrument Object

Use `fininstrument` to create an amortizing Cap instrument object.

```
CADates = [datetime(2020,9,1) ; datetime(2023,9,1)];
CAPrincipal = [100; 85];
Principal = timetable(CADates,CAPrincipal);
```

```
CapOpt = fininstrument("Cap", 'Maturity',datetime(2023,9,1), 'Strike',0.015, 'Principal',Principal,
```

```
CapOpt =
  Cap with properties:
```

```
    Strike: 0.0150
    Maturity: 01-Sep-2023
    ResetOffset: 0
    Reset: 1
    Basis: 0
    Principal: [2x1 timetable]
    ProjectionCurve: [0x0 ratecurve]
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    Name: "cap_amortizing_option"
```

#### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility',0.2)
```

```
BlackModel =
  Black with properties:

    Volatility: 0.2000
    Shift: 0
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,1);
Type = 'zero';
ZeroTimes = [calyears([1 2 3 4 5 7 10])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates);
```

### Create Black Pricer Object

Use finpricer to create a Black pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)

outPricer =
  Black with properties:

    Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

### Price Cap Instrument

Use price to compute the price for the Cap instrument.

```
Price = price(outPricer,CapOpt)

Price = 0.3897
```

### Price Vanilla Cap Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a vanilla Cap instrument when using a HullWhite model and an IRTree pricing method.

#### Create Cap Instrument Object

Use fininstrument to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', 0.02, 'Maturity', datetime(2020,1,30), 'Reset', 4, 'Principal', ...

CapOpt =
  Cap with properties:

    Strike: 0.0200
    Maturity: 30-Jan-2020
```

```

ResetOffset: 0
Reset: 4
Basis: 8
Principal: 100
ProjectionCurve: [0x0 ratecurve]
DaycountAdjustedCashFlow: 0
BusinessDayConvention: "actual"
Holidays: NaT
Name: "cap_option"

```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.01, 'Sigma', 0.10)
```

```
HullWhiteModel =
HullWhite with properties:
```

```
Alpha: 0.0100
Sigma: 0.1000
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
ratecurve with properties:
```

```

Type: "zero"
Compounding: -1
Basis: 0
Dates: [10x1 datetime]
Rates: [10x1 double]
Settle: 15-Sep-2018
InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"

```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
CFdates = cfdates(Settle, CapOpt.Maturity, CapOpt.Reset, CapOpt.Basis);
outPricer = finpricer("IRTree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', CFdates)
```

```
outPricer =
HWBKTree with properties:
```

```

    Tree: [1x1 struct]
    TreeDates: [6x1 datetime]
    Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]

```

## Price Cap Instrument

Use price to compute the price and sensitivities for the Cap instrument.

```
[Price, outPR] = price(outPricer,CapOpt,["all"])
```

```
Price = 2.7733
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x4 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
2.7733	31.655	-49.227	28.932

## More About

### Cap

A cap is a contract that includes a guarantee that sets the maximum interest rate the holder pays, based on an otherwise floating interest rate.

The payoff for a cap is:  $\max(\text{CurrentRate} - \text{CapRate}, 0)$

For more information, see “Cap” on page 2-11.

# CDS

CDS instrument object

## Description

Create and price a CDS instrument object using this workflow:

- 1 Use `fininstrument` to create a CDS instrument object.
- 2 Use `defprobcurve` to specify a default probability curve for the CDS instrument.
- 3 Use `finpricer` to specify a Credit pricing method for the CDS instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a CDS instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
CDSobj = fininstrument(InstrumentType,'Maturity',maturity_date,'
ContractSpread',contractspread_value)
CDSobj = fininstrument( ____,Name,Value)
```

### Description

`CDSobj = fininstrument(InstrumentType,'Maturity',maturity_date,'ContractSpread',contractspread_value)` creates a CDS object by specifying `InstrumentType` and sets the properties on page 11-2303 for the required name-value pair arguments `Maturity` and `ContractSpread`.

`CDSobj = fininstrument( ____,Name,Value)` sets optional properties on page 11-2303 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CDSobj = fininstrument("CDS",'Maturity',datetime(2019,1,30),'ContractSpread',200,'Period',4,'Basis',5,'BusinessDayConvention','follow','Name',"cds_instrument")` creates a CDS instrument with contract spread of 200. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

character vector with value 'CDS' | string with value "CDS"

Instrument type, specified as a string with the value "CDS" or the character vector with the value 'CDS'.

Data Types: char | string

### CDS Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `CDSobj = fininstrument("CDS", 'Maturity', datetime(2019,1,30), 'ContractSpread', 200, 'Period', 4, 'Basis', 5, 'BusinessDayConvention', "follow", 'Name', "cds_instrument")`

### Required CDS Name-Value Pair Arguments

#### Maturity — Maturity date

datetime | serial date number | character vector | date string

Maturity date, specified as the comma-separated pair consisting of 'Maturity' and a datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Data Types: char | double | string | datetime

#### ContractSpread — Contract spreads expressed in basis points

numeric

Contract spreads expressed in basis points, specified as the comma-separated pair consisting of 'ContractSpread' and a scalar numeric.

Data Types: double

### Optional CDS Name-Value Pair Argument

#### Period — Premium payments per year

1 (default) | numeric with values 1, 2, 3, 4, 6, 12

Premium payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar numeric with values of 1, 2, 3, 4, 6, or 12.

Data Types: double

#### Basis — Day-count basis

0 (actual/actual) (default) | scalar of positive integers of the set [1 . . . 13]

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar positive integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)

- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: `double`

### **BusinessDayConvention — Business day convention for cash flow dates**

`"actual"` (default) | `string` | `character vector`

Business day conventions for cash flow dates, specified as the comma-separated pair consisting of `'BusDayConvention'` and a string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- `"actual"` — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- `"follow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- `"modifiedfollow"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- `"previous"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- `"modifiedprevious"` — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `string`

### **PayAccruedPremium — Flag for accrued premiums**

`true` (default) | `value or true or false`

Flag for accrued premiums, specified as the comma-separated pair consisting of `'PayAccruedPremium'` and a scalar Boolean flag that is `true` if accrued premiums are paid upon default, `false` otherwise.

Data Types: `logical`

### **RecoveryRate — Recovery rate**

`0.4` (default) | `decimal`

Recovery rate, specified as the comma-separated pair consisting of `'RecoveryRate'` and a scalar decimal from 0 to 1.

Data Types: `double`

**Notional — Contract notional value**

100 (default) | positive integer

Contract notional value, specified as the comma-separated pair consisting of 'Notional' and a scalar positive integer.

Data Types: double

**Holidays — Holidays used in computing business days**

NaT (default) | datetime | cell array of character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
CDSobj = fininstrument("CDS",'Maturity',datetime(2025,12,15),'ContractSpread',200,'Holidays',H)
```

Data Types: double | cell | datetime | string

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

**Properties****Maturity — Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

**ContractSpread — Contract spreads expressed in basis points**

numeric

Contract spreads expressed in basis points, returned as a scalar numeric.

Data Types: double

**Period — Premium payments per year**

1 (default) | numeric with values 1, 2, 3, 4, 6 or 12

Premium payments per year, returned as a scalar numeric.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | positive integers of the set [1...13]

Day-count basis, returned as a scalar positive integer.

Data Types: double

**BusinessDayConvention — Business day convention for cash flow dates**

"actual" (default) | string

Business day conventions for cash flow dates, returned as a string.

Data Types: string

**PayAccruedPremium — Flag for accrued premiums**

true (default) | value true or false

Flag for accrued premiums, returned as a scalar Boolean flag.

Data Types: logical

**RecoveryRate — Recovery rate**

0.4 (default) | decimal

Recovery rate, returned as a scalar decimal.

Data Types: double

**Notional — Contract notional value**

100 (default) | positive integer

Contract notional value, returned as a scalar positive integer.

Data Types: double

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Examples****Price CDS Instrument Using Default Probability Curve and Credit Pricer**

This example shows the workflow to price a CDS instrument when you use a defprobcurve model and a Credit pricing method.

**Create CDS Instrument Object**

Use `fininstrument` to create a CDS instrument object.

```
CDS = fininstrument("CDS", 'Maturity', datetime(2021,9,15), 'ContractSpread', 15, 'Notional', 20000, 'P
```

```
CDS =  
    CDS with properties:
```

```

ContractSpread: 15
Maturity: 15-Sep-2021
Period: 4
Basis: 3
RecoveryRate: 0.4000
BusinessDayConvention: "follow"
Holidays: NaT
PayAccruedPremium: 1
Notional: 20000
Name: "CDS_instrument"

```

### Create defprobcurve Object

Create a defprobcurve object using defprobcurve.

```

Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)

```

```

DefaultProbCurve =
  defprobcurve with properties:

      Settle: 20-Sep-2020
      Basis: 5
      Dates: [10x1 datetime]
  DefaultProbabilities: [10x1 double]

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

```

```

myRC =
  ratecurve with properties:

      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2020
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

### Create Credit Pricer Object

Use `finpricer` to create a `Credit` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("credit", 'DefaultProbabilityCurve', DefaultProbCurve, 'DiscountCurve', myRC)
outPricer =
    Credit with properties:
        DiscountCurve: [1x1 ratecurve]
        TimeStep: 10
        DefaultProbabilityCurve: [1x1 defprobcurve]
```

### Price CDS Instrument

Use `price` to compute the price for the CDS instrument.

```
Price = price(outPricer, CDS)
```

```
Price = 52.7426
```

# CDSOption

CDSOption instrument object

## Description

Create and price a CDSOption instrument object using this workflow:

- 1 Use `fininstrument` to create a CDSOption instrument object.
- 2 Use `finmodel` to specify a CDSBlack model for the CDSOption instrument.
- 3 Use `finpricer` to specify a CDSBlack pricing method for the CDSOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods using a CDSOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
CDSOptionObj = fininstrument(InstrumentType, 'ExerciseDate', exercise_date, 'Strike', strike_value, 'CDS', cds_obj)
CDSOptionObj = fininstrument( ___, Name, Value)
```

### Description

`CDSOptionObj = fininstrument(InstrumentType, 'ExerciseDate', exercise_date, 'Strike', strike_value, 'CDS', cds_obj)` creates a CDSOption object by specifying `InstrumentType` and sets the properties on page 11-2309 for the required name-value pair arguments `ExerciseDate`, `Strike`, and `CDS`.

`CDSOptionObj = fininstrument( ___, Name, Value)` sets optional properties on page 11-2309 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `CDSOptionObj = fininstrument("CDSoption", 'ExerciseDate', datetime(2019,1,30), 'Strike', 500, 'CDS', cds_object, 'Name', "cdsoption_instrument")` creates a CDSOption instrument with a strike of 500. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "CDSoption" | character vector with value 'CDSoption'

Instrument type, specified as a string with the value of "CDSoption" or a character vector with the value of 'CDSoption'.

Data Types: char | string

**CDSOption Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: CDSOptionObj =
fininstrument("CDSoption", 'ExerciseDate', datetime(2019,1,30), 'Strike', 500, 'CDS', cds_object, 'Name', "cdsoption_instrument")
```

**Required CDSOption Name-Value Pair Arguments****ExerciseDate — Option exercise date**

`datetime` | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar `datetime`, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a `datetime`.

Data Types: `double` | `char` | `string` | `datetime`

**Strike — Option strike price**

nonnegative numeric

Option strike price, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric.

Data Types: `double`

**CDS — CDS object**

CDS object

CDS object, specified as the comma-separated pair consisting of 'CDS' and a scalar CDS object.

Data Types: `object`

**Optional CDSOption Name-Value Pair Argument****OptionType — Option type**

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: `char` | `string`

**Knockout — Flag indicating if option is knockout type**

false (default) | logical with value true or false

Flag indicating if option is knockout type, specified as the comma-separated pair consisting of 'Knockout' and a scalar logical.

Data Types: `logical`

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: `char` | `string`

## Properties

### **ExerciseDate — Option exercise date**

`datetime`

Option exercise date, returned as a `datetime`.

Data Types: `datetime`

### **Strike — Option strike price**

`nonnegative numeric`

Option strike price, returned as a scalar `nonnegative numeric` value.

Data Types: `double`

### **CDS — CDS object**

`CDS object`

CDS object, returned as a scalar `CDS object`.

Data Types: `object`

### **OptionType — Definition of option**

`"call"` (default) | string with value `"call"` or `"put"`

Definition of option, returned as a string using `"call"` or `"put"`.

Data Types: `string`

### **Knockout — Flag indicating if option is knockout type**

`false` (default) | `logical` with value `true` or `false`

Flag indicating if option is knockout type, returned as a scalar `logical`.

Data Types: `logical`

### **Name — User-defined name for instrument**

`" "` (default) | `string`

User-defined name for the instrument, returned as a `string`.

Data Types: `string`

## Examples

### **Price CDS Option Instrument Using CDS Black Model and CDS Black Pricer**

This example shows the workflow to price a `CDSOption` instrument when you use a `CDSBlack` model and a `CDSBlack` pricing method.

**Create CDS Instrument Object**

Use `fininstrument` to create the underlying CDS instrument object.

```
CDS0pt = fininstrument("CDS", 'Maturity', datetime(2021,9,15), 'ContractSpread', 150, 'Notional', 100,
CDS0pt =
  CDS with properties:
      ContractSpread: 150
      Maturity: 15-Sep-2021
      Period: 4
      Basis: 2
      RecoveryRate: 0.4000
BusinessDayConvention: "actual"
      Holidays: NaT
      PayAccruedPremium: 1
      Notional: 100
      Name: "CDS_option"
```

**Create defprobcurve Object**

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities, 'Basis', 5)

DefaultProbCurve =
  defprobcurve with properties:
      Settle: 20-Sep-2020
      Basis: 5
      Dates: [10x1 datetime]
      DefaultProbabilities: [10x1 double]
```

**Create ratecurve Object**

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])]';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
```

```

        Settle: 15-Sep-2020
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create CDSOption Instrument Object

Use `fininstrument` to create a CDSOption instrument object.

```
CDSOptionInst = fininstrument("CDSOption", 'ExerciseDate', datetime(2021,8,15), 'Strike', 20, 'CDS', CDS)
```

```

CDSOptionInst =
  CDSOption with properties:

    OptionType: "put"
    Strike: 20
    Knockout: 1
    ExerciseDate: 15-Aug-2021
    CDS: [1x1 fininstrument.CDS]
    Name: "CDSOption_option"

```

### Create CDSBlack Model Object

Use `finmodel` to create a CDSBlack model object.

```
CDSBlackModel = finmodel("CDSBlack", 'SpreadVolatility', .2)
```

```

CDSBlackModel =
  CDSBlack with properties:

    SpreadVolatility: 0.2000

```

### Create CDSBlack Pricer Object

Use `finpricer` to create a CDSBlack pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', CDSBlackModel, 'DefaultProbabilityCurve', DefaultProbCurve)
```

```

outPricer =
  CDSBlack with properties:

    Model: [1x1 finmodel.CDSBlack]
    DiscountCurve: [1x1 ratecurve]
    DefaultProbabilityCurve: [1x1 defprobcurve]

```

### Price CDSOption Instrument

Use `price` to compute the price for the CDSOption instrument.

```
Price = price(outPricer, CDSOptionInst)
```

Price = 3.3016e-04

## **More About**

### **Credit Default Swap Option**

A credit default swap (CDS) option, or credit default swaption, is a contract that provides the option holder with the right, but not the obligation, to enter into a credit default swap in the future.

CDS options can be either payer swaptions or receiver swaptions. In a payer swaption, the option holder has the right to enter into a CDS in which they are paying premiums, and in a receiver swaption, the option holder is receiving premiums.

# FixedBond

FixedBond instrument object

## Description

Create and price a FixedBond instrument object using this workflow:

- 1 Use `fininstrument` to create a FixedBond instrument object.
- 2 Use `ratecurve` to specify a curve model for the FixedBond instrument.
- 3 Use `finpricer` to specify a Discount pricing method for the FixedBond instrument.

For more detailed information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FixedBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
FixedBondObj = fininstrument(InstrumentType, 'CouponRate', couponrate_value, '
Maturity', maturity_date)
FixedBondObj = fininstrument( ____, Name, Value)
```

### Description

`FixedBondObj = fininstrument(InstrumentType, 'CouponRate', couponrate_value, 'Maturity', maturity_date)` creates a FixedBond object by specifying `InstrumentType` and sets the properties on page 11-2317 for the required name-value pair arguments `CouponRate` and `Maturity`.

The FixedBond instrument supports a vanilla bond, a stepped coupon bond, and an amortizing bond. For more information, see “More About” on page 11-2324.

`FixedBondObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2317 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FixedBondObj = fininstrument("FixedBond", 'CouponRate', 0.034, 'Maturity', datetime(2019,1,30), 'Period', 4, 'Basis', 1, 'Principal', 100, 'FirstCouponDate', datetime(2016,1,30), 'EndMonthRule', true, 'Name', "fixedbond_instrument")` creates a FixedBond option with a coupon rate of 0.34 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "FixedBond" | character vector with value 'FixedBond'

Instrument type, specified as a string with the value of "FixedBond" or a character vector with a value of 'FixedBond'.

Data Types: char | string

### FixedBond Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: FixedBondObj =

```
fininstrument("FixedBond", 'CouponRate', 0.034, 'Maturity', datetime(2019,1,30), 'Period', 4, 'Basis', 1, 'Principal', 100, 'FirstCouponDate', datetime(2016,1,30), 'EndMonthRule', true, 'Name', "fixedbond_instrument")
```

### Required FixedBond Name-Value Pair Arguments

#### CouponRate — FixedBond coupon rate

decimal | timetable

FixedBond coupon rate, specified as the comma-separated pair consisting of 'CouponRate' and a scalar decimal for an annual rate or a timetable where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | timetable

#### Maturity — FixedBond maturity date

datetime | serial date number | date character vector | date string

FixedBond maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Data Types: char | double | string | datetime

### Optional FixedBond Name-Value Pair Arguments

#### Period — Frequency of payments per year

2 (default) | numeric value of 0, 1, 2, 3, 4, 6, or 12

Frequency of payments, specified as the comma-separated pair consisting of 'Period' and a scalar integer. Values for Period are: 1, 2, 3, 4, 6, or 12.

Data Types: double

#### Basis — Day count basis

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360

- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **Principal — Principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a timetable, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

### **DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow is adjusted by day count convention, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar logical with a value of true or false.

Data Types: logical

### **BusinessDayConvention — Business day conventions for cash flow dates**

"actual" (default) | string | character vector

Business day conventions for cash flow dates, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.

- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### Holidays — Holidays used in computing business days

NaT (default) | datetime | cell array of character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FixedBondObj = fininstrument("FixedBond",'CouponRate',0.34,'Maturity',datetime(2025,12,15),'Holidays',H);
```

Data Types: double | cell | datetime | string

### EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days

true (in effect) (default) | value of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar logical value of true or false.

- If you set EndMonthRule to false, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set EndMonthRule to true, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

### IssueDate — Bond issue date

NaT (default) | datetime | serial date number | date character vector | date string

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the IssueDate property is stored as a datetime.

Data Types: double | char | string | datetime

### FirstCouponDate — Irregular first coupon date

NaT (default) | datetime | serial date number | date character vector | date string

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar datetime, serial date number, date character vector, or date string.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify FirstCouponDate, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **LastCouponDate — Irregular last coupon date**

`NaN` (default) | `datetime` | serial date number | date character vector | date string

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **StartDate — Forward starting date of payments**

`NaN` (default) | `datetime` | serial date number | date character vector | date string

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: `char` | `double` | `string` | `datetime`

### **Name — User-defined name for instrument**

`" "` (default) | `string` | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector.

Data Types: `char` | `string`

## **Properties**

### **CouponRate — FixedBond coupon annual rate**

scalar decimal | timetable

`FixedBond` coupon annual rate, returned as a scalar decimal or timetable.

Data Types: `double` | `timetable`

### **Maturity — FixedBond maturity date**

`datetime`

`FixedBond` maturity date, returned as a datetime.

Data Types: `datetime`

**Period — Frequency of payments per year**

2 (default) | integer

Frequency of payments per year, returned as a scalar integer.

Data Types: double

**Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

**Principal — Principal amount or principal value schedules**

100 (default) | scalar numeric | timetable

Principal amount or principal value schedules, returned as a scalar numeric or timetable.

Data Types: double

**DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow adjusts for day count convention, returned as scalar logical with a value of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string

Data Types: string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

true (in effect) (default) | value of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month having 30 or fewer days, returned as a scalar logical.

Data Types: logical

**IssueDate — Bond issue date**

NaT (default) | datetime

Bond issue date, returned as a datetime.

Data Types: datetime

**FirstCouponDate — Irregular first coupon date**

NaT (default) | datetime

Irregular first coupon date, returned as a datetime.

Data Types: datetime

**LastCouponDate — Irregular last coupon date**

NaT (default) | datetime

Irregular last coupon date, returned as a datetime.

Data Types: datetime

**StartDate — Forward starting date of payments**

NaT (default) | datetime

Forward starting date of payments, returned as a datetime.

Data Types: datetime

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Object Functions**

cashflows Computes cash flow for FixedBond, FloatBond, Swap, FRA, or Deposit instrument

**Examples****Price Vanilla Fixed Bond Instrument Using ratecurve and Discount Pricer**

This example shows the workflow to price a vanilla FixedBond instrument when you use a ratecurve and a Discount pricing method.

**Create FixedBond Instrument Object**

Use `fininstrument` to create a FixedBond instrument object.

```
FixB = fininstrument("FixedBond", 'Maturity', datetime(2022,9,15), 'CouponRate', 0.021, 'Period', 2, 'B
```

```
FixB =
```

```
FixedBond with properties:
```

```

        CouponRate: 0.0210
        Period: 2
        Basis: 1
    EndMonthRule: 1
        Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT

```

```

FirstCouponDate: NaT
LastCouponDate: NaT
StartDate: NaT
Maturity: 15-Sep-2022
Name: "fixed_bond_instrument"

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object with the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```

outPricer =
    Discount with properties:
        DiscountCurve: [1x1 ratecurve]

```

### Price FixedBond Instrument

Use price to compute the price and sensitivities for the FixedBond instrument.

```
[Price, outPR] = price(outPricer, FixB, ["all"])
```

```
Price = 104.5679
```

```

outPR =
    pricerresult with properties:
        Results: [1x2 table]
        PricerData: []

```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
104.57	0.040397

## Price Stepped Fixed Bond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a stepped FixedBond instrument when you use a ratecurve and a Discount pricing method.

### Create FixedBond Instrument Object

Use `fininstrument` to create a stepped FixedBond instrument object.

```
Maturity = datetime(2024,1,1);
Period = 1;
CDates = datetime([2020,1,1 ; 2024,1,1]);
CRates = [.025; .03];
CouponRate = timetable(CDates,CRates);
```

```
SBond = fininstrument("FixedBond", 'Maturity',Maturity, 'CouponRate',CouponRate, 'Period',Period)
```

```
SBond =
```

```
FixedBond with properties:
```

```

    CouponRate: [2x1 timetable]
    Period: 1
    Basis: 0
    EndMonthRule: 1
    Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2024
    Name: ""
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
```

```
ratecurve with properties:
```

```

        Type: "zero"
    Compounding: 1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
    Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', ZeroCurve)
```

```

outPricer =
    Discount with properties:
        DiscountCurve: [1x1 ratecurve]

```

### Price FixedBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FixedBond` instrument.

```
[Price, outPR] = price(outPricer, SBond, ["all"])
```

```
Price = 109.6218
```

```

outPR =
    pricerresult with properties:
        Results: [1x2 table]
        PricerData: []

```

```
outPR.Results
```

```

ans=1x2 table
    Price      DV01
    _____
    109.62     0.061108

```

### Price Amortizing Fixed Bond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a amortizing `FixedBond` instrument when you use a `ratecurve` and a `Discount` pricing method.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a amortizing `FixedBond` instrument object.

```

Maturity = datetime(2024,1,1);
Period = 1;
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 85];
Principal = timetable(ADates,APrincipal);
Bondamort = fininstrument("FixedBond", 'Maturity',Maturity, 'CouponRate',0.025, 'Period',Period, 'Pr

Bondamort =
    FixedBond with properties:

        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: [2x1 timetable]
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 01-Jan-2024
    Name: ""

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);

```

### Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',ZeroCurve)
```

```

outPricer =
    Discount with properties:

        DiscountCurve: [1x1 ratecurve]

```

### Price FixedBond Instrument

Use price to compute the price and sensitivities for the vanilla FixedBond instrument.

```
[Price, outPR] = price(outPricer,Bondamort,["all"])
```

```
Price = 107.1273
```

```

outPR =
    pricerresult with properties:

```

```
Results: [1x2 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
107.13	0.054279

## More About

### Fixed-Rate Note

A fixed-rate note is a long-term debt security with a preset interest rate and maturity, by which the interest must be paid.

The principal might or might not be paid at maturity. In Financial Instruments Toolbox, the principal is always paid at maturity. For more information, see “Fixed-Rate Note” on page 2-8.

### Vanilla Bond

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment.

### Stepped Coupon Bond

A step-up bond and a step-down bond are debt securities with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond.

### Bond with an Amortization Schedule

An amortized bond is treated as an asset, with the discount amount being amortized to interest expense over the life of the bond.

# FixedBondOption

FixedBondOption instrument object

## Description

Create and price a FixedBondOption instrument object using this workflow:

- 1 Use `fininstrument` to create a FixedBondOption instrument object.
- 2 Use `finmodel` to specify a HullWhite or BlackKarasinski model for the FixedBondOption instrument.
- 3 Use `finpricer` to specify an IRTree pricing method for the FixedBondOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FixedBondOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
FixedBondOptionObj = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercise_date,'Bond',bond_obj)
FixedBondOptionObj = fininstrument(___,Name,Value)
```

### Description

`FixedBondOptionObj = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercise_date,'Bond',bond_obj)` creates a FixedBondOption object by specifying `InstrumentType` and sets the properties on page 11-2328 for the required name-value pair arguments `Strike`, `ExerciseDate`, and `Bond`.

The FixedBondOption instrument supports a European or American option. For more information, see “More About” on page 11-2334.

`FixedBondOptionObj = fininstrument(___,Name,Value)` sets optional properties on page 11-2328 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FixedBondOptionObj = fininstrument("FixedBondOption",'Strike',100,'ExerciseDate',datetime(2019,1,30),'Bond',bond_obj,'OptionType','put','ExerciseStyle',"American",'Name',"fixed_bond_option")` creates a FixedBondOption instrument with a strike of 100 and an American exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "FixedBondOption" | character vector with value 'FixedBondOption'

Instrument type, specified as a string with the value of "FixedBondOption" or a character vector with the value of 'FixedBondOption'.

Data Types: char | string

### FixedBondOption Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: FixedBondOptionObj =  
`fininstrument("FixedBondOption", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'Bond', bond_obj, 'OptionType', 'put', 'ExerciseStyle', "American", 'Name', "fixed_bond_option")`

### Required FixedBondOption Name-Value Pair Arguments

#### Strike — Option strike value

nonnegative numeric

Option strike value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric.

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string | datetime

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

- For a European option, there is only one ExerciseDate on the option expiry date.
- For a Bermudan option, there is a 1-by-NSTRIKES vector of exercise dates.
- For an American option, the option can be exercised between Settle of the ratecurve and the single listed ExerciseDate.

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

#### Bond — Underlying FixedBond instrument

FixedBond object

Underlying FixedBond instrument, specified as the comma-separated pair consisting of 'BondInstrument' and a FixedBond object.

Data Types: object

### Optional FixedBondOption Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector with a value of "European", "American", or "Bermudan".

Data Types: string | char

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

**Strike — Option strike value**

nonnegative numeric

Option strike value, returned as a scalar nonnegative numeric.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European", "American"

Option exercise style, returned as a string with a value of "European" or "American".

Data Types: string

**Bond — Underlying FixedBond instrument**

FixedBond object

Underlying FixedBond instrument, returned as a FixedBond object.

Data Types: object

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

`setExercisePolicy` Set exercise policy for FixedBondOption, FloatBondOption, or Vanilla instrument

## Examples

### Price a FixedBondOption Instrument Using Hull-White Model and Hull-White Tree Pricer

This example shows the workflow to price a FixedBondOption instrument when you use a HullWhite model and an IRTree pricing method.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', .021, 'Period', 1)
```

```
BondInst =
```

```
FixedBond with properties:
```

```

    CouponRate: 0.0210
    Period: 1
    Basis: 0
    EndMonthRule: 1
    Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    Holidays: NaT
    IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2029
    Name: "bond_instrument"
```

#### Create FixedBondOption Instrument Objects

Use `fininstrument` to create three callable FixedBondOption instrument objects with European, American, and Bermudan exercise.

```
FixedBOptionEuro = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98)
```

```
FixedBOptionEuro =
```

```
FixedBondOption with properties:
```

```

    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2025
    Strike: 98
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option_european"
```

```
FixedBOptionAmerican = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98)
```

```
FixedBOptionAmerican =
  FixedBondOption with properties:

    OptionType: "call"
    ExerciseStyle: "american"
    ExerciseDate: 15-Sep-2025
    Strike: 98
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option_american"
```

```
FixedBOptionBermudan = fininstrument("FixedBondOption", 'ExerciseDate', [datetime(2025,9,15) ; datetime(2025,11,15)], 'Strike', 98)
```

```
FixedBOptionBermudan =
  FixedBondOption with properties:

    OptionType: "call"
    ExerciseStyle: "bermudan"
    ExerciseDate: [15-Sep-2025    15-Nov-2025]
    Strike: [98 1000]
    Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option_bermudan"
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create a HullWhite Model Object

Use finmodel to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.01, 'Sigma', 0.05)
```

```
HullWhiteModel =
  HullWhite with properties:
```

```
Alpha: 0.0100
Sigma: 0.0500
```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object with the 'DiscountCurve' name-value pair argument.

```
HWTrePricer = finpricer("IRTree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', ZeroDa
```

```
HWTrePricer =
  HWBKTre with properties:

      Tree: [1x1 struct]
   TreeDates: [10x1 datetime]
      Model: [1x1 finmodel.HullWhite]
DiscountCurve: [1x1 ratecurve]
```

HWTrePricer.Tree

```
ans = struct with fields:
   FinObj: 'HWFwdTree'
    tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
    dObs: [1x10 datetime]
   CFlowT: {1x10 cell}
    Probs: {1x9 cell}
  Connect: {1x9 cell}
   FwdTree: {1x10 cell}
```

### Price FixedBondOption Instruments

Use `price` to compute the price and sensitivities for the two FixedBondOption instruments.

```
[Price, outPR] = price(HWTrePricer, FixedBOptionEuro, ["all"])
```

```
Price = 10.7571
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x4 table]
  PricerData: [1x1 struct]
```

outPR.Results

```
ans=1x4 table
   Price      Vega      Gamma      Delta
   _____  _____  _____  _____
   10.757    308.87    2207.3    -178.78
```

```
[Price, outPR] = price(HWTrePricer, FixedBOptionAmerican, ["all"])
```

```
Price = 19.2984
```

```

outPR =
  pricerresult with properties:
    Results: [1x4 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```

ans=1x4 table
  Price      Vega      Gamma      Delta
  _____  _____  _____  _____
  19.298     437.32    4977.1    -459.06

```

```
[Price, outPR] = price(HWTreePricer,FixedBOptionBermudan,["all"])
```

```
Price = 11.1241
```

```

outPR =
  pricerresult with properties:
    Results: [1x4 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```

ans=1x4 table
  Price      Vega      Gamma      Delta
  _____  _____  _____  _____
  11.124     322.94    2243.7    -182.44

```

### Price a FixedBondOption Instrument on a Stepped FixedBond Using Hull-White Model and Hull-White Tree Pricer

This example shows the workflow to price a FixedBondOption instrument on a stepped FixedBond instrument when you use a HullWhite model and an IRTree pricing method.

#### Create Stepped FixedBond Instrument Object

Use `fininstrument` to create a stepped FixedBond instrument object as the underlying bond.

```

Maturity = datetime(2027,1,1);
Period = 1;
CDates = datetime([2022,1,1 ; 2027,1,1]);
CRates = [.022; .027];
CouponRate = timetable(CDates,CRates);

```

```
SBond = fininstrument("FixedBond", 'Maturity',Maturity, 'CouponRate',CouponRate, 'Period',Period, 'N
```

```

SBond =
  FixedBond with properties:

```

```

        CouponRate: [2x1 timetable]
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2027
        Name: "stepped_bond_instrument"

```

### Create FixedBondOption Instrument Object

Use `fininstrument` to create a `FixedBondOption` instrument object with European exercise.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2026,1,1), 'Strike', 90, 'Bo
```

```
FixedBOption =
    FixedBondOption with properties:
```

```

        OptionType: "call"
        ExerciseStyle: "european"
        ExerciseDate: 01-Jan-2026
        Strike: 90
        Bond: [1x1 fininstrument.FixedBond]
        Name: "fixed_bond_option_european"

```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```

Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0055 0.0063 0.0071 0.0083 0.0099 0.0131 0.0178 0.0262 0.0343 0.0387]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);

```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```

VolCurve = 0.15;
AlphaCurve = 0.03;

HWModel = finmodel("HullWhite", 'Alpha', AlphaCurve, 'Sigma', VolCurve)

HWModel =
    HullWhite with properties:

        Alpha: 0.0300
        Sigma: 0.1500

```

## Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
HWTreepricer = finpricer("IRTree", 'Model', HWModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates)

HWTreepricer =
    HWBKTree with properties:

        Tree: [1x1 struct]
    TreeDates: [10x1 datetime]
        Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

`HWTreepricer.Tree`

```
ans = struct with fields:
    FinObj: 'HWFwdTree'
    tObs: [0 1 2 3.0027 4.0027 5.0027 6.0027 7.0055 8.0055 9.0055]
    dObs: [1x10 datetime]
    CFlowT: {1x10 cell}
    Probs: {1x9 cell}
    Connect: {1x9 cell}
    FwdTree: {1x10 cell}
```

## Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(HWTreepricer, FixedBOption, "all")
```

```
Price = 12.2717
```

```
outPR =
    pricerresult with properties:
```

```
    Results: [1x4 table]
    PricerData: [1x1 struct]
```

`outPR.Results`

```
ans=1x4 table
    Price      Vega      Gamma      Delta
    _____
    12.272     100.91    1438.4     -130.1
```

## More About

### Bond Option

A bond option gives the holder the right to sell a bond back to the issuer (put) or to redeem a bond from its current owner (call) at a specific price and on a specific date.

The `FixedBondOption` instrument supports two types of put and call options on bonds:

- American option — An option that you exercise any time until its expiration date.
- European option — An option that you exercise only on its expiration date.

For more information, see “Bond Options” on page 2-5.

## Tips

After creating a `FixedBondOption` instrument object, you can use `setExercisePolicy` to change the size of the options. For example, if you have the following instrument:

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2022,9,15), 'Strike', 98, 'B
```

To modify the `FixedBondOption` instrument's size by changing the `ExerciseStyle` from "European" to "American", use `setExercisePolicy`:

```
FixedBOption = setExercisePolicy(FixedBOption, [datetime(2021,1,1) datetime(2022,1,1)], 100, 'Ameri
```

## Introduced in R2020a

# FloatBond

FloatBond instrument object

## Description

Create and price a FloatBond instrument object using this workflow:

- 1 Use `fininstrument` to create a FloatBond instrument object.
- 2 Use `ratecurve` to specify a curve model for the FloatBond instrument.
- 3 Use `finpricer` to specify a Discount pricing method for the FloatBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
FloatBondObj = fininstrument(InstrumentType, 'Spread', spread_value, '
Maturity', maturity_date)
FloatBondObj = fininstrument( ____, Name, Value)
```

### Description

`FloatBondObj = fininstrument(InstrumentType, 'Spread', spread_value, 'Maturity', maturity_date)` creates a FloatBond object by specifying `InstrumentType` and sets the properties on page 11-2341 for the required name-value pair arguments `Spread` and `Maturity`.

The FloatBond instrument supports a vanilla floating rate note and an amortizing floating rate note. For more information, see “Floating-Rate Note” on page 11-2346.

`FloatBondObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2341 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FloatBondObj = fininstrument("FloatBond", 'Spread', 0.6, 'Maturity', datetime(2019,1,30), 'Basis', 1, 'Principal', 100, 'FirstCouponDate', datetime(2016,1,30), 'EndMonthRule', true, 'Name', "float_bond_instrument")` creates a FloatBond instrument with a spread of 0.6 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "FloatBond" | character vector with value 'FloatBond'

Instrument type, specified as a string with the value of "FloatBond" or a character vector with the value of 'FloatBond'.

Data Types: char | string

### FloatBond Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `FloatBondObj = fininstrument("FloatBond", 'Spread', 0.6, 'Maturity', datetime(2019,1,30), 'Basis', 1, 'Principal', 100, 'FirstCouponDate', datetime(2016,1,30), 'EndMonthRule', true, 'Name', "float_bond_instrument")`

### Required FloatBond Name-Value Pair Arguments

#### Spread — Decimal value over the reference rate

nonnegative decimal

Decimal value over the reference rate, specified as the comma-separated pair consisting of 'Spread' and a scalar nonnegative decimal.

Data Types: double

#### Maturity — Maturity date

datetime | serial date number | data character vector | date string

Maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a `datetime`.

Data Types: char | double | string | datetime

### Optional FloatBond Name-Value Pair Arguments

#### Reset — Frequency of payments per year

2 (default) | integer

Frequency of payments per year, specified as the comma-separated pair consisting of 'Reset' and a scalar integer. Values for `Reset` are: 1, 2, 3, 4, 6, or 12.

Data Types: double

#### Basis — Day count basis

[0 0] (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360

- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **Principal — Principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a timetable, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

### **ProjectionCurve — Rate curve for projecting floating cash flows**

ratecurve.empty (default) | ratecurve object

Rate curve for projecting floating cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a ratecurve object. You must create this object using ratecurve.

Data Types: object

### **ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a scalar numeric.

Data Types: double

### **LatestFloatingRate — Latest floating rate**

[] (default) | decimal

Latest floating rate for the FloatBond object, specified as the comma-separated pair consisting of 'LatestFloatingRate' and a scalar decimal.

Data Types: double

### **DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar logical with a value of `true` or `false`.

Data Types: `logical`

### **BusinessDayConvention — Business day conventions**

"actual" (default) | `string` | `character vector`

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar `string` or `character vector`. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `string`

### **Holidays — Holidays used in computing business days**

`NaN` (default) | `datetime` | `cell array of date character vectors` | `date string array` | `serial date numbers`

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using `datetimes`, `serial date numbers`, `cell array of date character vectors`, or `date string array`. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FloatBondObj = fininstrument("floatbond",'Spread',100,'Maturity',datetime(2025,12,15),'Holidays')
```

Data Types: `double` | `cell` | `datetime` | `string`

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

`true` (in effect) (default) | `logical true or false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar logical value of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

**IssueDate — Bond issue date**

NaT (default) | datetime | serial date number | date character vector | date string

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**FirstCouponDate — Irregular first coupon date**

NaT (default) | datetime | serial date number | date character vector | date string

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar datetime, serial date number, date character vector, or date string.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**LastCouponDate — Irregular last coupon date**

NaT (default) | datetime | serial date number | date character vector | date string

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar datetime, serial date number, date character vector, or date string.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**StartDate — Forward starting date of payments**

NaT (default) | datetime | serial date number | character vector | date string

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar datetime, serial date number, character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: char | double | string | datetime

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### **Spread — Number of basis points over the reference rate**

nonnegative numeric

Number of basis points over the reference rate, returned as a scalar nonnegative numeric.

Data Types: double

### **Maturity — Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

### **Reset — Frequency of payment per year**

1 (default) | integer

Coupons per year, returned as a scalar integer.

Data Types: double

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal — Notional principal amount or principal value schedules**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedules, returned as a scalar numeric or timetable.

Data Types: timetable | double

### **ProjectionCurve — Rate curve used in generating future cash flows**

ratecurve.empty (default) | ratecurve object

Rate curve to be used in projecting the future cash flows, returned as a ratecurve object.

Data Types: object

### **ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, returned as a scalar numeric.

Data Types: double

### **LatestFloatingRate — Latest floating rate for FloatBond**

[ ] (default) | decimal

Latest floating rate for `FloatBond`, returned as a scalar decimal.

Data Types: `double`

**DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

`false` (default) | value of `true` or `false`

Flag to adjust cash flows based on actual period day count, returned as scalar logical with a value of `true` or `false`.

Data Types: `logical`

**BusinessDayConvention — Business day conventions**

`"actual"` (default) | string

Business day conventions, returned as a string

Data Types: `string`

**Holidays — Holidays used in computing business days**

`NaT` (default) | `datetime`

Holidays used in computing business days, returned as datetimes.

Data Types: `datetime`

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

`true` (in effect) (default) | logical with value of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical.

Data Types: `logical`

**IssueDate — Bond issue date**

`NaT` (default) | `datetime`

Bond issue date, returned as a `datetime`.

Data Types: `datetime`

**FirstCouponDate — Irregular first coupon date**

`NaT` (default) | `datetime`

Irregular first coupon date, returned as a `datetime`.

Data Types: `datetime`

**LastCouponDate — Irregular last coupon date**

`NaT` (default) | `datetime`

Irregular last coupon date, returned as a `datetime`.

Data Types: `datetime`

**StartDate — Forward starting date of payments**

`NaT` (default) | `datetime`

Forward starting date of payments, returned as a datetime.

Data Types: datetime

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

cashflows Computes cash flow for FixedBond, FloatBond, Swap, FRA, or Deposit instrument

## Examples

### Price Vanilla Float Bond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a vanilla FloatBond instrument when you use a ratecurve and a Discount pricing method.

#### Create FloatBond Instrument Object

Use `fininstrument` to create a vanilla FloatBond instrument object.

```
FloatB = fininstrument("FloatBond", 'Maturity', datetime(2022,9,15), 'Spread', 0.025, 'Reset', 2, 'Basis', 1)
```

```
FloatB =
```

```
FloatBond with properties:
```

```

        Spread: 0.0250
    ProjectionCurve: [0x0 ratecurve]
        ResetOffset: 0
            Reset: 2
            Basis: 1
    EndMonthRule: 0
        Principal: 100
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2022
        Name: "float_bond_instrument"
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
```

```
Type = 'zero';
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
  Discount with properties:
      DiscountCurve: [1x1 ratecurve]
```

### Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FloatBond` instrument.

```
[Price, outPR] = price(outPricer, FloatB, ["all"])
```

```
Price = 109.8322
```

```
outPR =
  pricerresult with properties:
      Results: [1x2 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
  Price      DV01
  _____  _____
  109.83     0.021976
```

## Price Amortizing Float Bond Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price an amortizing FloatBond instrument when you use a ratecurve and a Discount pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

### Create FloatBond Instrument Object

Use fininstrument to create an amortizing FloatdBond instrument object.

```
Maturity = datetime(2024,1,1);
Spread = 0.02;
Reset = 1;
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 80];
Principal = timetable(ADates,APrincipal);
Floatamort = fininstrument("FloatBond","Maturity",Maturity,"Spread",Spread,"Reset",Reset,"Project
```

Floatamort =

FloatBond with properties:

```

        Spread: 0.0200
    ProjectionCurve: [1x1 ratecurve]
        ResetOffset: 0
            Reset: 1
            Basis: 0
        EndMonthRule: 1
        Principal: [2x1 timetable]
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2024
        Name: ""
```

### Create Discount Pricer Object

Use finpricer to create a Discount pricer object and use the ratecurve object with the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount","DiscountCurve",ZeroCurve)
```

outPricer =

Discount with properties:

```
DiscountCurve: [1x1 ratecurve]
```

### Price FloatBond Instrument

Use price to compute the price and sensitivities for the vanilla FloatBond instrument.

```
[Price, outPR] = price(outPricer,Floatamort,["all"])
```

```
Price = 110.1101
```

```
outPR =  
  pricerresult with properties:
```

```
    Results: [1x2 table]  
  PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
110.11	0.028613

## More About

### Floating-Rate Note

A floating-rate note is a security like a bond, but the interest rate of the note is reset periodically, relative to a reference index rate, to reflect fluctuations in market interest rates.

### Introduced in R2020a

# FloatBondOption

FloatBondOption instrument object

## Description

Create and price a FloatBondOption instrument object using this workflow:

- 1 Use `fininstrument` to create an FloatBondOption instrument object.
- 2 Use `finmodel` to specify a HullWhite or BlackKarasinski model for the FloatBondOption instrument.
- 3 Use `finpricer` to specify an IRTree pricing method for the FloatBondOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods FloatBondOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
FloatBondOptionObj = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date, 'Bond', bond_obj)
FloatBondOptionObj = fininstrument( ____, Name, Value)
```

### Description

`FloatBondOptionObj = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date, 'Bond', bond_obj)` creates a FloatBond object by specifying `InstrumentType` and sets properties on page 11-2349 using the required name-value pair arguments `Strike`, `ExerciseDate`, and `Bond`.

`FloatBondOptionObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2349 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `FloatBondOptionObj = fininstrument("floatbondoption", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 3 0), 'Bond', bond_obj, 'OptionType', 'put', 'ExerciseStyle', "american", 'Name', "float_bond_option")` creates a FloatBondOption instrument with a strike of 100 and an American exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

character vector with value 'floatbondoption' | string with value "floatbondoption"

Instrument type, specified as a string with the value "floatbondoption" or a character vector with the value 'floatbondoption'.

Data Types: char | string

### FloatBondOption Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: FloatBondOptionObj =
fininstrument("floatbondoption", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 3
0), 'Bond', bond_obj, 'OptionType', 'put', 'ExerciseStyle', "american", 'Name', "floa
t_bond_option")
```

### Required FloatBondOption Name-Value Pair Arguments

#### Strike — Option strike value

nonnegative value

Option strike value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative value.

Data Types: double

#### ExerciseDate — Option exercise dates

serial date number | date character vector | date string | datetime

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar serial date number, date character vector, date string, or datetime.

- For a European option, there is only one `ExerciseDate` on the option expiry date.
- For a Bermudan option, there is a 1-by-NSTRIKES vector of exercise dates.
- For an American option, the option can be exercised between `ValuationDate` of the stock tree and the single listed `ExerciseDate`.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a `datetime`.

Data Types: double | char | string | datetime

#### Bond — Underlying float bond

FloatBond object

Underlying float bond, specified as the comma-separated pair consisting of 'Bond' and the name of a `FloatBond` object.

Data Types: object

### Optional FloatBondOption Name-Value Pair Arguments

#### OptionType — Definition of option

"call" (default) | character vector with value 'call' or 'put' | string with value "call" or "put"

Definition of option, specified as the comma-separated pair consisting of 'OptionType' and a scalar character vector or a string using 'call' or 'put'.

Data Types: char | string

**ExerciseStyle — Option type**

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Option type, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar character vector or string.

Data Types: string | char

**Name — User-defined name for instrument**

[ ] (default) | character vector | string

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar character vector or string.

Data Types: char | string

**Properties****InstrumentType — Instrument type**

string with value "floatbondoption"

Instrument type, returned as a string with the value "floatbondoption".

Data Types: string

**Strike — Option strike value**

nonnegative value

Option strike value, returned as a scalar nonnegative value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**OptionType — Definition of option**

"call" (default) | string with value "call" or "put"

Definition of option, returned as a string with the value of "call" or "put".

Data Types: string

**ExerciseStyle — Option type**

"European" (default) | string with value "European", "American", or "Bermudan"

Option type, returned as a string with the value of "European", "American", or "Bermudan".

Data Types: string

**Bond — Underlying float bond**

FloatBond object

Underlying float bond, returned as a FloatBond object.

Data Types: object

### Name — User-defined name for instrument

[ ] (default) | character vector | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

`setExercisePolicy` Set exercise policy for `FixedBondOption`, `FloatBondOption`, or `Vanilla` instrument

## Examples

### Price a Float Bond Option Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a `FloatBondOption` instrument when you use a `HullWhite` model and an `IRTree` pricing method.

#### Create FloatBond Instrument Object

Use `fininstrument` to create a `FloatBond` instrument object as the underlying bond.

```
BondInst = fininstrument("FloatBond", 'Maturity', datetime(2030,9,15), 'Spread', 0.021, 'Name', "bond_")
```

```
BondInst =
    FloatBond with properties:
        Spread: 0.0210
        ProjectionCurve: [0x0 ratecurve]
        ResetOffset: 0
        Reset: 2
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 15-Sep-2030
        Name: "bond_instrument"
```

#### Create FloatBondOption Instrument Objects

Use `fininstrument` to create three callable `FloatBondOption` instrument objects with European, American, and Bermudan exercise.

```
FloatBOptionEuro = fininstrument("FloatBondOption", 'ExerciseDate', datetime(2029,9,15), 'Strike', 90)
```

```
FloatBOptionEuro =
    FloatBondOption with properties:
```

```

OptionType: "call"
ExerciseStyle: "european"
ExerciseDate: 15-Sep-2029
Strike: 98
Bond: [1x1 fininstrument.FloatBond]
Name: "float_bond_option_european"

```

```
FloatBOptionAmerican = fininstrument("FloatBondOption", 'ExerciseDate', datetime(2029,9,15), 'Strike')
```

```
FloatBOptionAmerican =
FloatBondOption with properties:
```

```

OptionType: "call"
ExerciseStyle: "american"
ExerciseDate: 15-Sep-2029
Strike: 98
Bond: [1x1 fininstrument.FloatBond]
Name: "float_bond_option_american"

```

```
FloatBOptionBermudan = fininstrument("FloatBondOption", 'ExerciseDate', [datetime(2025,9,15) ; date
```

```
FloatBOptionBermudan =
FloatBondOption with properties:
```

```

OptionType: "call"
ExerciseStyle: "bermudan"
ExerciseDate: [15-Sep-2025    15-Sep-2029]
Strike: [98 100]
Bond: [1x1 fininstrument.FloatBond]
Name: "float_bond_option_bermudan"

```

## Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2024,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
ratecurve with properties:
```

```

Type: "zero"
Compounding: -1
Basis: 0
Dates: [10x1 datetime]
Rates: [10x1 double]
Settle: 15-Sep-2024
InterpMethod: "linear"
ShortExtrapMethod: "next"

```

```
LongExtrapMethod: "previous"
```

### Create a HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.01, 'Sigma', 0.05)
```

```
HullWhiteModel =  
  HullWhite with properties:
```

```
  Alpha: 0.0100  
  Sigma: 0.0500
```

### Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
CFdates = cfdates(Settle, BondInst.Maturity, BondInst.Reset, BondInst.Basis);  
HWTrePricer = finpricer("IRTree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', CFdates)
```

```
HWTrePricer =  
  HWBKTree with properties:  
  
    Tree: [1x1 struct]  
  TreeDates: [12x1 datetime]  
    Model: [1x1 finmodel.HullWhite]  
  DiscountCurve: [1x1 ratecurve]
```

```
HWTrePricer.Tree
```

```
ans = struct with fields:  
  FinObj: 'HWFwdTree'  
    tObs: [0 0.4959 1 1.4959 2 2.4959 3 3.4986 4.0027 4.4986 5.0027 5.4986]  
    dObs: [1x12 datetime]  
  CFlowT: {1x12 cell}  
  Probs: {1x11 cell}  
  Connect: {1x11 cell}  
  FwdTree: {1x12 cell}
```

### Price FixedBondOption Instruments

Use `price` to compute the price and sensitivities for the two `FixedBondOption` instruments.

```
[Price, outPR] = price(HWTrePricer, FloatBOptionEuro, ["all"])
```

```
Price = 3.8040
```

```
outPR =  
  pricerresult with properties:
```

```
  Results: [1x4 table]  
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
3.804	-2.6645e-11	110.75	-20.465

```
[Price, outPR] = price(HWTreePricer,FloatBOptionAmerican,["all"])
```

```
Price = 14.1700
```

```
outPR =
```

```
  pricerresult with properties:
```

```
    Results: [1x4 table]
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
14.17	0	160.87	-38.981

```
[Price, outPR] = price(HWTreePricer,FloatBOptionBermudan,["all"])
```

```
Price = 12.0676
```

```
outPR =
```

```
  pricerresult with properties:
```

```
    Results: [1x4 table]
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
12.068	-2.8422e-10	161.55	-39.402

## More About

### Floating-Rate Note Option

A floating-rate note option gives the option holder the right to sell the option back to the issuer (put) or to redeem an option (call) at a specific price and on a specific date.

Financial Instruments Toolbox supports three types of put and call options on bonds:

- American option — An option that you exercise any time until its expiration date
- European option — An option that you exercise only on its expiration date
- Bermuda option — A Bermuda option resembles a hybrid of American and European options; you can only exercise it on predetermined dates, usually monthly

For more information, see “Bond Options” on page 2-5.

## Tips

After creating a `FloatBondOption` instrument object, you can use `setExercisePolicy` to change the size of the options. For example, consider the following instrument:

```
FloatBOption = fininstrument("FloatBondOption", 'ExerciseDate', datetime(2029,9,15), 'Strike', 98, 'B
```

To modify the size of the `FloatBondOption` instrument by changing the `ExerciseStyle` from "European" to "American", use `setExercisePolicy`:

```
FloatBOption = setExercisePolicy(FloatBOption, [datetime(2021,1,1) datetime(2022,1,1)], 100, 'Ameri
```

### Introduced in R2020a

# Floor

Floor instrument object

## Description

Create and price a Floor instrument object using this workflow:

- 1 Use `fininstrument` to create a Floor instrument object.
- 2 Use `finmodel` to specify a HullWhite, BlackKarasinski, Black, or Normal model for the Floor instrument.
- 3 Use `finpricer` to specify a Normal, Black, HullWhite, or IRTree pricing method for the Floor instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Floor instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
FloorOpt = fininstrument(InstrumentType, 'Strike', strike_value, '
Maturity', maturity_date)
FloorOpt = fininstrument( ___, Name, Value)
```

### Description

`FloorOpt = fininstrument(InstrumentType, 'Strike', strike_value, 'Maturity', maturity_date)` creates a Floor object by specifying `InstrumentType` and sets the properties on page 11-2358 for the required name-value pair arguments `Strike` and `Maturity`.

The Floor instrument supports vanilla and amortizing floors.

`FloorOpt = fininstrument( ___, Name, Value)` sets optional properties on page 11-2358 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FloorOpt = fininstrument("floor", 'Strike', 100, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Principal', 100, 'ResetOffset', 1, 'Basis', 4, 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve_object, 'Name', "floor_option")` creates a Floor instrument with a strike of 100 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Floor" | character vector with value 'Floor'

Instrument type, specified as a string with the value of "Floor" or a character vector with the value of 'Floor'.

Data Types: char | string

### Floor Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: FloorOpt =  
fininstrument("floor", 'Strike', 100, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Principal', 100, 'ResetOffset', 1, 'Basis', 4, 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve\_object, 'Name', "floor\_option")

### Required Floor Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative decimal

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative decimal value.

Data Types: double

#### Maturity — Cap maturity date

datetime | serial date number | date character vector | date string

Cap maturity date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Data Types: double | char | string | datetime

### Optional Floor Name-Value Pair Arguments

#### Reset — Reset frequency payments per year

1 (default) | numeric with value of 0, 1, 2, 3, 4, 6, or 12

Reset frequency payments per year, specified as the comma-separated pair consisting of 'Reset' and a scalar numeric.

Data Types: double

#### Basis — Day-count basis

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of 'Basis' and a scalar integer with one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360

- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **Principal — Principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a timetable, where the first column is dates and the second column is its associated principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

### **ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a scalar numeric.

Data Types: double

### **DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar with a value of true or false.

Data Types: logical

### **BusinessDayConvention — Business day conventions**

"actual" (default) | string | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector for a business day convention. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### Holidays — Holidays used in computing business days

NaN (default) | datetime | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FloorOpt = fininstrument("floor",'Strike',100,'Maturity',datetime(2025,12,15),'Holidays',H)
```

Data Types: double | cell | datetime | string

### ProjectionCurve — Rate curve used in generating future cash flows

ratecurve.empty (default) | ratecurve object

Rate curve used in projecting the future cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a ratecurve object. This object is created using ratecurve. Use this optional input if the forward curve is different from the discount curve.

Data Types: object

### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike price value

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric value.

Data Types: double

### Maturity — Floor maturity date

datetime

Floor maturity date, returned as a datetime.

Data Types: datetime

**Reset — Reset frequency payments per year**

1 (default) | numeric

Reset frequency payments per year, returned as a scalar numeric.

Data Types: double

**Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, returned as a scalar integer.

Data Types: double

**Principal — Principal amount or principal value schedule**

100 (default) | numeric | timetable

Principal amount or principal value schedule, returned as a scalar numeric for principal amount or a timetable for a principal value schedule.

Data Types: double | timetable

**ResetOffset — Lag in rate setting**

0 (default) | numeric

Lag in rate setting, returned as a scalar numeric.

Data Types: double

**DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, returned as a logical with a value of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string.

Data Types: string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**ProjectionCurve — Rate curve used in generating future cash flows**

ratecurve.empty (default) | structure

Rate curve used in projecting the future cash flows, returned as a ratecurve object.

Data Types: object

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Vanilla Floor Instrument Using Black Model and Black Pricer

This example shows the workflow to price a vanilla Floor instrument when you use a Black model and a Black pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the floor instrument.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

#### Create Floor Instrument Object

Use fininstrument to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor", 'Maturity', datetime(2022,9,15), 'Strike', 0.03, 'ProjectionCurve', ,
```

```
FloorOpt =
```

```
Floor with properties:
```

```

    Strike: 0.0300
    Maturity: 15-Sep-2022
    ResetOffset: 0
    Reset: 1
```

```

        Basis: 0
        Principal: 100
        ProjectionCurve: [1x1 ratecurve]
DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        Name: ""

```

### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.2)
```

```
BlackModel =
  Black with properties:
    Volatility: 0.2000
    Shift: 0

```

### Create Black Pricer Object

Use `finpricer` to create a Black pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackModel)

outPricer =
  Black with properties:
    Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]

```

### Price Floor Instrument

Use `price` to compute the price for the Floor instrument.

```
[Price, outPR] = price(outPricer, FloorOpt)
```

```
Price = 8.0878
```

```
outPR =
  pricerresult with properties:
    Results: [1x1 table]
    PricerData: []

```

### Price Vanilla Floor Instrument Using Hull-White Model and Hull-White Pricer

This example shows the workflow to price a vanilla Floor instrument when you use a HullWhite model and a HullWhite pricing method.

### Create Floor Instrument Object

Use `fininstrument` to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor", 'Strike', 0.039, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Princi
```

```
FloorOpt =
  Floor with properties:
      Strike: 0.0390
      Maturity: 30-Jan-2019
      ResetOffset: 0
      Reset: 4
      Basis: 12
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "floor_option"
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.032, 'Sigma', 0.04)
```

```
HullWhiteModel =
  HullWhite with properties:
```

```
    Alpha: 0.0320
    Sigma: 0.0400
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### Create HullWhite Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', HullWhiteModel, 'DiscountCurve', myRC)
```

```
outPricer =
    HullWhite with properties:

        DiscountCurve: [1x1 ratecurve]
        Model: [1x1 finmodel.HullWhite]
```

### Price Floor Instrument

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer, FloorOpt)
```

```
Price = 1.2676
```

### Price Amortizing Floor Instrument Using Black Model and Black Pricer

This example shows the workflow to price an amortizing `Floor` instrument when you use a `Black` model and a `Black` pricing method.

#### Create Floor Instrument Object

Use `fininstrument` to create an amortizing `Floor` instrument object.

```
CADates = datetime([2020,9,1 ; 2023,9,1]);
CAPrincipal = [100; 85];
Principal = timetable(CADates, CAPrincipal);
```

```
FloorOpt = fininstrument("Floor", 'Maturity', datetime(2023,9,1), 'Strike', 0.015, 'Principal', Principi
```

```
FloorOpt =
    Floor with properties:

        Strike: 0.0150
        Maturity: 01-Sep-2023
        ResetOffset: 0
        Reset: 1
        Basis: 0
        Principal: [2x1 timetable]
        ProjectionCurve: [0x0 ratecurve]
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        Name: "floor_amortizing_option"
```

### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.2)
```

```
BlackModel =  
  Black with properties:  
  
    Volatility: 0.2000  
      Shift: 0
```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,1);  
Type = 'zero';  
ZeroTimes = [calyears([1 2 3 4 5 7 10])]';  
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168]';  
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates);
```

### Create Black Pricer Object

Use `finpricer` to create a Black pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)
```

```
outPricer =  
  Black with properties:  
  
      Model: [1x1 finmodel.Black]  
DiscountCurve: [1x1 ratecurve]
```

### Price Floor Instrument

Use `price` to compute the price for the Floor instrument.

```
Price = price(outPricer, FloorOpt)
```

```
Price = 3.0030
```

### Price Vanilla Floor Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a vanilla Floor instrument when using a HullWhite model and an IRTree pricing method.

#### Create Floor Instrument Object

Use `fininstrument` to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor", 'Strike', 0.03, 'Maturity', datetime(2020,1,30), 'Reset', 4, 'Princip
```

```
FloorOpt =
  Floor with properties:

      Strike: 0.0300
      Maturity: 30-Jan-2020
      ResetOffset: 0
      Reset: 4
      Basis: 8
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "floor_option"
```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.01, 'Sigma', 0.10)

HullWhiteModel =
  HullWhite with properties:

      Alpha: 0.0100
      Sigma: 0.1000
```

### Create ratecurve Object

Create a `ratecurve` object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)

myRC =
  ratecurve with properties:

      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```

CFdates = cfdates(Settle, FloorOpt.Maturity, FloorOpt.Reset, FloorOpt.Basis);
outPricer = finpricer("IRTree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', CFdates')

outPricer =
  HWBKTree with properties:

      Tree: [1x1 struct]
  TreeDates: [6x1 datetime]
      Model: [1x1 finmodel.HullWhite]
  DiscountCurve: [1x1 ratecurve]

```

## Price Floor Instrument

Use price to compute the price and sensitivities for the Floor instrument.

```
[Price, outPR] = price(outPricer, FloorOpt, ["all"])
```

```
Price = 5.7821
```

```
outPR =
  pricerresult with properties:
```

```

    Results: [1x4 table]
  PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
5.7821	31.821	141.45	-110.54

## More About

### Floor

A floor is a contract that includes a guarantee setting the minimum interest rate received by the holder, based on an otherwise floating interest rate.

The payoff for a floor is:  $\max(\text{FloorRate} - \text{CurrentRate}, 0)$

# FRA

FRA instrument object

## Description

Create and price a FRA (forward rate agreement) instrument object using this workflow:

- 1 Use `fininstrument` to create a FRA instrument object.
- 2 Use `ratecurve` to specify an interest-rate model for the FRA instrument.
- 3 Use `finpricer` to specify a `Discount` pricing method for the FRA instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a FRA instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
FRAObj = fininstrument(InstrumentType, 'StartDate', start_date, '
Maturity', maturity_date, 'Rate', rate_value)
FRAObj = fininstrument( ___, Name, Value)
```

### Description

`FRAObj = fininstrument(InstrumentType, 'StartDate', start_date, 'Maturity', maturity_date, 'Rate', rate_value)` creates a FRA object by specifying `InstrumentType` and sets the properties on page 11-2371 for the required name-value pair arguments `StartDate`, `Maturity`, and `Rate`. For more information on a FRA instrument, see “More About” on page 11-2373.

`FRAObj = fininstrument( ___, Name, Value)` sets optional properties on page 11-2371 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FRAObj = fininstrument("FRA", 'StartDate', datetime(2016,1,30), 'Maturity', datetime(2019,1,30), 'Rate', 0.025, 'Principal', 100, 'Basis', 1, 'BusinessDayConvention', "follow", 'Name', "FRA_instrument")` creates a FRA instrument with a principal of 100 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "FRA" | character vector with value 'FRA'

Instrument type, specified as a string with the value of "FRA" or a character vector with the value of 'FRA'.

Data Types: char | string

### **FRA Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `FRAObj = fininstrument("FRA", 'StartDate', datetime(2016,1,30), 'Maturity', datetime(2019,1,30), 'Rate', 0.025, 'Principal', 100, 'Basis', 1, 'BusinessDayConvention', "follow", 'Name', "FRA_instrument")`

### **Required FRA Name-Value Pair Arguments**

#### **StartDate — FRA start date**

datetime | serial date number | date character vector | date string

FRA start date, specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: char | double | string | datetime

#### **Maturity — FRA maturity date**

datetime | serial date number | date character vector | date string

FRA maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Data Types: char | double | string | datetime

#### **Rate — FRA coupon rate**

decimal

FRA coupon rate, specified as the comma-separated pair consisting of `'Rate'` and a scalar decimal.

Data Types: double

### **Optional FRA Name-Value Pair Arguments**

#### **Basis — Day-count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and scalar value from one of the following:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365

- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **Principal — Principal amount**

100 (default) | numeric

Principal amount, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric.

Data Types: double

### **BusinessDayConvention — Business day convention**

"actual" (default) | string | character vector

Business day convention, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### **Holidays — Holidays used in computing business days**

NaN (default) | datetime | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
FRAObj = fininstrument("FRA",'StartDate',datetime(2016,1,30),'Maturity',datetime(2025,12,15),'Ra
```

Data Types: double | cell | datetime | string

### **Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## **Properties**

### **StartDate — FRA start date**

datetime

FRA start date, returned as a datetime.

Data Types: datetime

### **Maturity — FRA maturity date**

datetime

FRA maturity date, returned as a datetime.

Data Types: datetime

### **Rate — FRA coupon rate**

decimal

FRA coupon rate, returned as a scalar decimal.

Data Types: double

### **Basis — Day count basis**

[0 0] (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal — Principal amount**

100 (default) | numeric

Principal amount, returned as a scalar numeric value.

Data Types: cell | double

### **BusinessDayConvention — Business day convention**

"actual" (default) | string

Business day convention, returned as a string.

Data Types: string

### Holidays — Holidays used in computing business days

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

cashflows Computes cash flow for FixedBond, FloatBond, Swap, FRA, or Deposit instrument

## Examples

### Price FRA Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a FRA (forward rate agreement) instrument when you use a ratecurve and a Discount pricing method.

#### Create FRA Instrument Object

Use `fininstrument` to create a FRA instrument object.

```
FRAObj = fininstrument("FRA", 'StartDate', datetime(2020,9,15), 'Maturity', datetime(2022,9,15), 'Rate
```

```
FRAObj =  
    FRA with properties:
```

```
        Rate: 0.0175  
        Basis: 2  
    StartDate: 15-Sep-2020  
        Maturity: 15-Sep-2022  
    Principal: 100  
BusinessDayConvention: "actual"  
        Holidays: NaT  
        Name: ""
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Type = 'zero';  
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];  
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';  
ZeroDates = Settle + ZeroTimes;  
  
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create Discount Pricer Object

Use `finpricer` to create a `Discount` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("Discount", 'DiscountCurve', myRC)

outPricer =
    Discount with properties:
        DiscountCurve: [1x1 ratecurve]

```

### Price FRA Instrument

Use `price` to compute the price and sensitivities for the FRA instrument.

```

[Price, outPR] = price(outPricer, FRAObj, ["all"])

Price = 3.4176

outPR =
    pricerresult with properties:
        Results: [1x2 table]
        PricerData: []

```

`outPR.Results`

```

ans=1x2 table
    Price      DV01
    _____
    3.4176     0.001368

```

## More About

### FRA Instrument

A FRA (forward rate agreement) instrument is an over-the-counter contract between parties that determines the rate of interest to be paid on an agreed upon date in the future.

The FRA determines the rates to be used along with the termination date and notional value. FRAs are cash-settled with the payment based on the net difference between the interest rate of the contract and the floating rate in the market, called the reference rate. The notional amount is not exchanged, but is rather a cash amount based on the rate differentials and the notional value of the contract.

# Lookback

Lookback instrument

## Description

Create and price a Lookback instrument object using this workflow:

- 1 Use `fininstrument` to create a Lookback instrument object.
- 2 Use `finmodel` to specify a BlackScholes, Heston, Bates, or Merton model for the Lookback instrument.
- 3 When using a BlackScholes model, use `finpricer` to specify a ConzeViswanathan or GoldmanSosinGatto pricing method for the Lookback instrument.

When using a BlackScholes, Heston, Bates, or Merton model, use `finpricer` to specify an `AssetMonteCarlo` pricing method for the Lookback instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Lookback instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
LookbackObj = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date)
LookbackObj = fininstrument( ____, Name, Value)
```

### Description

`LookbackObj = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date)` creates a Lookback object by specifying `InstrumentType` and sets the properties on page 11-2377 for the required name-value pair arguments `Strike` and `ExerciseDate`.

The Lookback instrument supports fixed and floating strike lookback options. For more information on a Lookback instrument, see “More About” on page 11-2383.

`LookbackObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2377 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `LookbackObj = fininstrument("Lookback", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'OptionType', "put", 'ExerciseStyle', "European", 'Name', "lookback_option")` creates a Lookback put option with an European exercise. You can specify multiple name-value pair arguments.

**Input Arguments****InstrumentType — Instrument type**

string with value "Lookback" | character vector with value 'Lookback'

Instrument type, specified as a string with the value of "Lookback" or a character vector with the value of 'Lookback'.

Data Types: char | string

**Lookback Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `LookbackObj =`

```
fininstrument("Lookback", 'Strike', 100, 'ExerciseDate', datetime(2019, 1, 30), 'OptionType', "put", 'ExerciseStyle', "European", 'Name', "lookback_option")
```

**Required Lookback Name-Value Pair Arguments****Strike — Option strike price value**

nonnegative numeric | NaN

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric value for a fixed strike Lookback option or a NaN for a floating strike Lookback option.

---

**Note** Use the `ConzeViswanathan` pricer for a fixed strike Lookback option and use the `GoldmanSosinGatto` pricer for a floating strike Lookback option.

---

Data Types: double

**ExerciseDate — Option exercise date**

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one `ExerciseDate` on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**Optional Lookback Name-Value Pair Arguments****OptionType — Option type**

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

### **ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

Data Types: string | char

### **AssetMinMax — Maximum or minimum underlying asset price**

NaN where SpotPrice of the underlying asset is used (default) | scalar numeric

Maximum or minimum underlying asset price, specified as the comma-separated pair consisting of 'AssetMinMax' and a scalar numeric.

Data Types: double

### **Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## **Properties**

### **Strike — Option strike price value**

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric.

Data Types: double

### **ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

### **OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

### **ExerciseStyle — Option exercise style**

"European" (default) | string with value "European"

Option exercise style, returned as a string with a value of "European".

Data Types: string

### **AssetMinMax — Maximum or minimum underlying asset price**

NaN where SpotPrice of the underlying asset is used (default) | scalar numeric

Maximum or minimum underlying asset price, returned as a scalar numeric.

Data Types: double

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Lookback Instrument Using a Black-Scholes Model and Conze-Viswanathan Pricer

This example shows the workflow to price a LookBack instrument when you use a BlackScholes model and a ConzeViswanathan pricing method.

#### Create Lookback Instrument Object

Use `fininstrument` to create a Lookback instrument object.

```
LookbackOpt = fininstrument("Lookback", 'Strike', 105, 'ExerciseDate', datetime(2022,9,15), 'OptionType', 'put')
```

```
LookbackOpt =
```

```
Lookback with properties:
```

```
    OptionType: "put"
        Strike: 105
    AssetMinMax: NaN
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
        Name: "lookback_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.2)
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
    Volatility: 0.2000
    Correlation: 1
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create ConzeViswanathan Pricer Object

Use `finpricer` to create a `ConzeViswanathan` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic","Model",BlackScholesModel,"DiscountCurve",myRC,"SpotPrice",100,
outPricer =
  ConzeViswanathan with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: 0.2500
      DividendType: "continuous"

```

### Price Lookback Instrument

Use `price` to compute the price and sensitivities for the Lookback instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 57.8786
```

```
outPR =
  pricerresult with properties:
```

```

    Results: [1x7 table]
  PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
57.879	-0.33404	0	-0.57714	32.587	-5.1863	-350.41

## Price Lookback Instrument Using a Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a LookBack instrument when you use a BlackScholes model and an AssetMonteCarlo pricing method.

### Create Lookback Instrument Object

Use `fininstrument` to create a Lookback instrument object.

```
LookbackOpt = fininstrument("Lookback", 'Strike', 105, 'ExerciseDate', datetime(2022, 9, 15), 'OptionType', 'put')
```

```
LookbackOpt =
  Lookback with properties:
      OptionType: "put"
      Strike: 105
      AssetMinMax: NaN
      ExerciseStyle: "european"
      ExerciseDate: 15-Sep-2022
      Name: "lookback_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:
      Volatility: 0.2000
      Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 9, 15);
Maturity = datetime(2023, 9, 15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", BlackScholesModel, 'SpotPrice')
outPricer =
    GBMMonteCarlo with properties:
        DiscountCurve: [1x1 ratecurve]
        SpotPrice: 200
        SimulationDates: 15-Sep-2022
        NumTrials: 1000
        RandomNumbers: []
        Model: [1x1 finmodel.BlackScholes]
        DividendType: "continuous"
        DividendValue: 0
```

### Price Lookback Instrument

Use `price` to compute the price and sensitivities for the Lookback instrument.

```
[Price, outPR] = price(outPricer, LookbackOpt, ["all"])
```

```
Price = 1.8553
```

```
outPR =
    pricerresult with properties:
        Results: [1x7 table]
        PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
1.8553	-0.040442	0.00062792	-4.3596	-39.426	-0.71345	42.311

### Price Lookback Instrument Using a Bates Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a LookBack instrument when you use a Bates model and an `AssetMonteCarlo` pricing method.

#### Create Lookback Instrument Object

Use `fininstrument` to create a Lookback instrument object.

```
LookbackOpt = fininstrument("Lookback", 'Strike', 105, 'ExerciseDate', datetime(2022,9,15), 'OptionType', 'Call')
```

```
LookbackOpt =
    Lookback with properties:
```

```

    OptionType: "put"
      Strike: 105
    AssetMinMax: NaN
  ExerciseStyle: "european"
  ExerciseDate: 15-Sep-2022
    Name: "lookback_option"

```

### Create Bates Model Object

Use `finmodel` to create a Bates model object.

```
BatesModel = finmodel("Bates", 'V0',0.032, 'ThetaV',0.1, 'Kappa',0.003, 'SigmaV',0.2, 'RhoSV',0.9, 'Me
```

```
BatesModel =
  Bates with properties:
```

```

    V0: 0.0320
  ThetaV: 0.1000
    Kappa: 0.0030
  SigmaV: 0.2000
  RhoSV: 0.9000
    MeanJ: 0.1100
  JumpVol: 0.0230
  JumpFreq: 0.0200

```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate, 'Basis',12)

```

```
myRC =
  ratecurve with properties:
```

```

    Type: "zero"
  Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2018
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", BatesModel, 'SpotPrice', 100,
```

```
outPricer =
  BatesMonteCarlo with properties:
```

```

DiscountCurve: [1x1 ratecurve]
  SpotPrice: 100
SimulationDates: 15-Sep-2022
  NumTrials: 1000
  RandomNumbers: []
  Model: [1x1 finmodel.Bates]
DividendType: "continuous"
DividendValue: 0

```

## Price Lookback Instrument

Use price to compute the price and sensitivities for the Lookback instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 7.3592
```

```
outPR =
  pricerresult with properties:
```

```

  Results: [1x8 table]
  PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x8 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
7.3592	-0.83923	-3.5527e-15	-11.404	-29.431	-0.030786	31.941	0.71394

## More About

### Lookback Option

A lookback option is a path-dependent option based on the maximum or minimum value the underlying asset achieves during the entire life of the option.

Financial Instruments Toolbox software supports two types of lookback options: fixed and floating. Fixed lookback options have a specified strike price, while floating lookback options have a strike price determined by the asset path. For more information, see “Lookback Option” on page 3-38.

**Introduced in R2020a**

# OptionEmbeddedFixedBond

OptionEmbeddedFixedBond instrument object

## Description

Create and price a OptionEmbeddedFixedBond instrument object using this workflow:

- 1 Use `fininstrument` to create an OptionEmbeddedFixedBond instrument object.
- 2 use `finmodel` to specify a HullWhite or BlackKarasinski model for the OptionEmbeddedFixedBond instrument.
- 3 Use `finpricer` to specify an IRTree pricing method for the OptionEmbeddedFixedBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an OptionEmbeddedFixedBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
OptionEmbeddedFixedBondObj = fininstrument(InstrumentType, '
CouponRate', couponrate_value, 'Maturity', maturity_date, '
CallSchedule', call_schedule_value)
OptionEmbeddedFixedBondObj = fininstrument(InstrumentType, '
CouponRate', couponrate_value, 'Maturity', maturity_date, '
PutSchedule', put_schedule_value)
OptionEmbeddedFixedBondObj = fininstrument( ____, Name, Value)
```

### Description

`OptionEmbeddedFixedBondObj = fininstrument(InstrumentType, 'CouponRate', couponrate_value, 'Maturity', maturity_date, 'CallSchedule', call_schedule_value)` creates a OptionEmbeddedFixedBond object by specifying `InstrumentType` and sets the properties on page 11-2391 for the required name-value pair arguments `CouponRate`, `Maturity`, and `CallSchedule`.

The OptionEmbeddedFixedBond instrument supports a vanilla bond with embedded option, stepped coupon bond with embedded option, and an amortizing bond with embedded option. For more information, see “More About” on page 11-2401.

```
OptionEmbeddedFixedBondObj = fininstrument(InstrumentType, '
CouponRate', couponrate_value, 'Maturity', maturity_date, '
PutSchedule', put_schedule_value)
```

creates a OptionEmbeddedFixedBond object by

specifying `InstrumentType` and sets the properties on page 11-2391 for the required name-value pair arguments `CouponRate`, `Maturity`, and `PutSchedule`.

`OptionEmbeddedFixedBondObj = fininstrument(____,Name,Value)` sets optional properties on page 11-2391 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond", 'CouponRate',0.034, 'Maturity',datetime(2019,1,30), 'Period',2, 'Basis',1, 'Principal',100, 'CallSchedule',schedule, 'CallExerciseStyle',"American", 'Name',"optionembeddedfixedbond_instrument")` creates an `OptionEmbeddedFixedBond` instrument with an American exercise and a call schedule. You can specify multiple name-value pair arguments.

## Input Arguments

### InstrumentType — Instrument type

string with value "OptionEmbeddedFixedBond" | character vector with value 'OptionEmbeddedFixedBond'

Instrument type, specified as a string with the value of "OptionEmbeddedFixedBond" or a character vector with the value of 'OptionEmbeddedFixedBond'.

Data Types: char | string

### OptionEmbeddedFixedBond Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond", 'CouponRate',0.034, 'Maturity',datetime(2019,1,30), 'Period',2, 'Basis',1, 'Principal',100, 'CallSchedule',schedule, 'CallExerciseStyle',"American", 'Name',"optionembeddedfixedbond_instrument")`

### Required OptionEmbeddedFixedBond Name-Value Pair Arguments

#### CouponRate — Coupon rate for OptionEmbeddedFixedBond

scalar decimal | timetable

Coupon rate for `OptionEmbeddedFixedBond`, specified as the comma-separated pair consisting of 'CouponRate' as a scalar decimal for an annual rate or a timetable where the first column is dates and the second column is associated rates. The date indicates the last day that the coupon rate is valid.

Data Types: double | timetable

#### Maturity — Maturity date for OptionEmbeddedFixedBond

datetime | serial date number | date character vector | date string

Maturity date for `OptionEmbeddedFixedBond`, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a datetime.

Data Types: char | double | string | datetime

**CallSchedule — Call schedule**

timetable

Call schedule, specified as the comma-separated pair consisting of 'CallSchedule' and a timetable of call dates and strikes.

If you use a date character vector or date string for the dates in this timetable, the format must be recognizable by `datetime` because the `CallSchedule` property is stored as a `datetime`.

---

**Note** The `OptionEmbeddedFixedBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

---

Data Types: timetable

**PutSchedule — Call schedule**

timetable

Put schedule, specified as the comma-separated pair consisting of 'PutSchedule' and a timetable of call dates and strikes.

If you use a date character vector or date string for dates in this timetable, the format must be recognizable by `datetime` because the `PutSchedule` property is stored as a `datetime`.

---

**Note** The `OptionEmbeddedFixedBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

---

Data Types: timetable

**Optional OptionEmbeddedFixedBond Name-Value Pair Arguments****Period — Frequency of payments per year**

2 (default) | integer

Frequency of payments per year, specified as the comma-separated pair consisting of 'Period' and a scalar integer. Values for `Period` are: 1, 2, 3, 4, 6, and 12.

Data Types: double

**CallExerciseStyle — Call option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Call option exercise style, specified as the comma-separated pair consisting of 'CallExerciseStyle' and a scalar string or character vector.

Data Types: string | char

**PutExerciseStyle — Put option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Put option exercise style, specified as the comma-separated pair consisting of 'PutExerciseStyle' and a scalar string or character vector.

Data Types: string | char

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **Principal — Notional principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a `timetable`, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

### **DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow adjusts for day count convention, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar logical with a value of true or false.

Data Types: logical

### **BusinessDayConvention — Business day conventions**

"actual" (default) | string | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: char | string

### Holidays — Holidays used in computing business days

NaT (default) | datetime | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond",'CouponRate',0.34,'Maturity',
'CallSchedule',schedule,'CallExerciseStyle',"american",'Holidays',H)
```

Data Types: double | cell | datetime | string

### EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days

true (in effect) (default) | value of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar logical value of true or false.

- If you set EndMonthRule to false, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set EndMonthRule to true, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: logical

### IssueDate — Bond issue date

NaT (default) | datetime | serial date number | date character vector | date string

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **FirstCouponDate — Irregular first coupon date**

`NaN` (default) | `datetime` | serial date number | date character vector | date string

Irregular first coupon date, specified as the comma-separated pair consisting of `'FirstCouponDate'` and a scalar datetime, serial date number, date character vector, or date string.

When `FirstCouponDate` and `LastCouponDate` are both specified, `FirstCouponDate` takes precedence in determining the coupon payment structure. If you do not specify `FirstCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `FirstCouponDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **LastCouponDate — Irregular last coupon date**

`NaN` (default) | `datetime` | serial date number | date character vector | date string

Irregular last coupon date, specified as the comma-separated pair consisting of `'LastCouponDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you specify `LastCouponDate` but not `FirstCouponDate`, `LastCouponDate` determines the coupon structure of the bond. The coupon structure of a bond is truncated at `LastCouponDate`, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify `LastCouponDate`, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `LastCouponDate` property is stored as a datetime.

Data Types: `double` | `char` | `string` | `datetime`

### **StartDate — Forward starting date of payments**

`NaN` (default) | `datetime` | serial date number | date character vector | date string

Forward starting date of payments, specified as the comma-separated pair consisting of `'StartDate'` and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: `char` | `double` | `string` | `datetime`

### **Name — User-defined name for instrument**

`" "` (default) | `string` | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector.

Data Types: `char` | `string`

## Properties

### **CouponRate – Coupon annual rate**

scalar decimal | timetable

Coupon annual rate, returned as a scalar decimal or timetable.

Data Types: double | timetable

### **Maturity – Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

### **CallSchedule – Call schedule**

timetable

Call schedule, returned as a timetable.

Data Types: cell | datetime

### **PutSchedule – Call schedule**

timetable

Put schedule, returned as a timetable.

Data Types: cell | datetime

### **Period – Coupons per year**

2 (default) | integer

Coupons per year, returned as a scalar integer.

Data Types: double

### **Basis – Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal – Notional principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, returned as a scalar numeric or timetable.

Data Types: timetable | double

### **DaycountAdjustedCashFlow – Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow adjusted for day count convention, returned as scalar logical with a value of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string

Data Types: string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

true (in effect) (default) | value of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical.

Data Types: logical

**IssueDate — Bond issue date**

NaT (default) | datetime

Bond issue date, returned as a datetime.

Data Types: datetime

**FirstCouponDate — Irregular first coupon date**

NaT (default) | datetime

Irregular first coupon date, returned as a datetime.

Data Types: datetime

**LastCouponDate — Irregular last coupon date**

NaT (default) | datetime

Irregular last coupon date, returned as a datetime.

Data Types: datetime

**StartDate — Forward starting date of payments**

NaT (default) | datetime

Forward starting date of payments, returned as a datetime.

Data Types: datetime

**CallExerciseStyle — Call option exercise style**

"European" (default) | string with value "European", "American", or "Bermuda"

This property is read-only.

Call option exercise style, returned as a string with a value of "European", "American", or "Bermuda".

Data Types: string

### PutExerciseStyle — Put option exercise style

"European" (default) | string with value "European", "American", or "Bermuda"

This property is read-only.

Put option exercise style, returned as a string with a value of "European", "American", or "Bermuda".

Data Types: string

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

setCallExercisePolicy Set call exercise policy for OptionEmbeddedFixedBond or OptionEmbeddedFloatBond instrument

setPutExercisePolicy Set put exercise policy for OptionEmbeddedFixedBond or OptionEmbeddedFloatBond instrument

## Examples

### Price Option Embedded Fixed Bond Instruments Using Hull-White Model and IRTree Pricer

This example shows the workflow to price American, European, and Bermudan exercise styles for three callable OptionEmbeddedFixedBond instruments when you use a HullWhite model and an IRTree pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

#### Create OptionEmbeddedFixedBond Instrument Objects

Use fininstrument to create three OptionEmbeddedFixedBond instrument objects with the different exercise styles.

```
Maturity = datetime(2024,1,1);

% Option embedded bond (Bermudan callable bond)
Strike = [100; 100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Period = 1;
```

```

CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

CallableBondBermudan = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
    'CouponRate',0.025,'Period',Period, ...
    'CallSchedule',CallSchedule,'CallExerciseStyle',"bermudan")

CallableBondBermudan =
    OptionEmbeddedFixedBond with properties:

        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2024
        CallDates: [2x1 datetime]
        PutDates: [0x1 datetime]
        CallSchedule: [2x1 timetable]
        PutSchedule: [0x0 timetable]
    CallExerciseStyle: "bermudan"
        PutExerciseStyle: [0x0 string]
        Name: ""

% Option embedded bond (American callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

CallableBondAmerican = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
    'CouponRate',0.025,'Period',Period, ...
    'CallSchedule',CallSchedule,'CallExerciseStyle',"american")

CallableBondAmerican =
    OptionEmbeddedFixedBond with properties:

        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2024
        CallDates: 01-Jan-2024
        PutDates: [0x1 datetime]

```

```

        CallSchedule: [1x1 timetable]
        PutSchedule: [0x0 timetable]
    CallExerciseStyle: "american"
    PutExerciseStyle: [0x0 string]
    Name: ""

% Option embedded bond (European callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Period = 1;

CallableBondEuropean = fininstrument("OptionEmbeddedFixedBond",'Maturity',Maturity,...
    'CouponRate',0.025,'Period',Period, ...
    'CallSchedule',CallSchedule)

CallableBondEuropean =
    OptionEmbeddedFixedBond with properties:

        CouponRate: 0.0250
        Period: 1
        Basis: 0
    EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2024
    CallDates: 01-Jan-2024
        PutDates: [0x1 datetime]
    CallSchedule: [1x1 timetable]
    PutSchedule: [0x0 timetable]
    CallExerciseStyle: "european"
    PutExerciseStyle: [0x0 string]
    Name: ""

```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```

VolCurve = 0.01;
AlphaCurve = 0.1;

```

```

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);

```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

HWTrePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates);

```

```

HWTrePricer =
    HWBKTree with properties:

```

```

Tree: [1x1 struct]
TreeDates: [10x1 datetime]
Model: [1x1 finmodel.HullWhite]
DiscountCurve: [1x1 ratecurve]

```

### Price OptionEmbeddedFixedBond Instruments

Use `price` to compute the price and sensitivities for the three `OptionEmbeddedFixedBond` instruments.

```
[Price, outPR] = price(HWTreePricer,CallableBondBermudan,["all"])
```

```
Price = 103.2729
```

```
outPR =
  pricerresult with properties:
```

```

Results: [1x4 table]
PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x4 table
   Price      Vega      Gamma      Delta
   _____  _____  _____  _____
   103.27    -148.28    1375.9    -290.33
```

```
[Price, outPR] = price(HWTreePricer,CallableBondAmerican,["all"])
```

```
Price = 100
```

```
outPR =
  pricerresult with properties:
```

```

Results: [1x4 table]
PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x4 table
   Price      Vega      Gamma      Delta
   _____  _____  _____  _____
   100         0         0         0
```

```
[Price, outPR] = price(HWTreePricer,CallableBondEuropean,["all"])
```

```
Price = 107.7023
```

```
outPR =
  pricerresult with properties:
```

```
Results: [1x4 table]
```

```
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
107.7	0	4086.4	-602.56

### Price OptionEmbeddedFixedBond Instrument and Obtain Exercise Probabilities Using Black-Karasinski Model and IRTree Pricer

This example shows the workflow to price a callable OptionEmbeddedFixedBond instrument and obtain the exercise probabilities when you use a BlackKarasinski model and an IRTree pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018, 1, 1);
ZeroTimes = calyears(1:4)';
ZeroRates = [0.035; 0.042147; 0.047345; 0.052707];
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding)
```

```
ZeroCurve =
```

```
ratecurve with properties:
```

```

    Type: "zero"
  Compounding: 1
    Basis: 0
    Dates: [4x1 datetime]
    Rates: [4x1 double]
    Settle: 01-Jan-2018
  InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

#### Create OptionEmbeddedFixedBond Instrument Object

Use fininstrument to create an OptionEmbeddedFixedBond instrument object with an American exercise style.

```
CouponRate = 0.0425;
Strike = [95; 98];
ExerciseDates = [datetime(2021,1,1); datetime(2022,1,1)];
Maturity = datetime(2022,1,1);
Period = 1;
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
CallableBond = fininstrument("OptionEmbeddedFixedBond", 'Maturity',Maturity,...
```

```

        'CouponRate', CouponRate, 'Period', Period, ...
        'CallSchedule', CallSchedule, ...
        'CallExerciseStyle', "American", ...
        'Name', "MyCallableBond")

CallableBond =
    OptionEmbeddedFixedBond with properties:

        CouponRate: 0.0425
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
        DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
        StartDate: NaT
        Maturity: 01-Jan-2022
        CallDates: [2x1 datetime]
        PutDates: [0x1 datetime]
        CallSchedule: [2x1 timetable]
        PutSchedule: [0x0 timetable]
        CallExerciseStyle: "american"
        PutExerciseStyle: [0x0 string]
        Name: "MyCallableBond"

```

### Create BlackKarasinski Model Object

Use `finmodel` to create a BlackKarasinski model object.

```

VolCurve = 0.01;
AlphaCurve = 0.1;
BKModel = finmodel("BlackKarasinski", 'alpha', AlphaCurve, 'sigma', VolCurve)

```

```

BKModel =
    BlackKarasinski with properties:

```

```

    Alpha: 0.1000
    Sigma: 0.0100

```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

BKTreePricer = finpricer("IRTree", 'Model', BKModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates)

```

```

BKTreePricer =
    HWBKTree with properties:

        Tree: [1x1 struct]
        TreeDates: [4x1 datetime]
        Model: [1x1 finmodel.BlackKarasinski]

```

```
DiscountCurve: [1x1 ratecurve]
```

### Price OptionEmbeddedFixedBond Instrument

Use price to compute the price and sensitivities for the OptionEmbeddedFixedBond instrument.

```
[Price, PriceResults]= price(BKTreePricer, CallableBond)
```

```
Price = 92.5235
```

```
PriceResults =  
  pricerresult with properties:
```

```
    Results: [1x1 table]  
  PricerData: [1x1 struct]
```

Examine the output `PriceResults.PricerData.PriceTree.ExTree`, which contains the exercise indicator arrays. In the cell array, a 1 indicates an exercised option and a 0 indicates an unexercised option.

```
PriceResults.PricerData.PriceTree.ExTree{5}
```

```
ans = 1x7
```

```
    1    1    1    1    1    1    1
```

No options are exercised.

```
PriceResults.PricerData.PriceTree.ExTree{4}
```

```
ans = 1x7
```

```
    0    0    0    0    0    0    0
```

The instrument is exercised at all nodes.

```
PriceResults.PricerData.PriceTree.ExTree{3}
```

```
ans = 1x5
```

```
    0    0    0    0    0
```

No options are exercised.

```
PriceResults.PricerData.PriceTree.ExTree{2}
```

```
ans = 1x3
```

```
    0    0    0
```

No options are exercised.

View the probability of reaching each node from the root node using `PriceResults.PricerData.PriceTree.ProbTree`.

```
PriceResults.PricerData.PriceTree.ProbTree{2}
```

```
ans = 1×3
```

```
0.1667 0.6667 0.1667
```

```
PriceResults.PricerData.PriceTree.ProbTree{3}
```

```
ans = 1×5
```

```
0.0203 0.2206 0.5183 0.2206 0.0203
```

```
PriceResults.PricerData.PriceTree.ProbTree{4}
```

```
ans = 1×7
```

```
0.0018 0.0395 0.2370 0.4433 0.2370 0.0395 0.0018
```

```
PriceResults.PricerData.PriceTree.ProbTree{5}
```

```
ans = 1×7
```

```
0.0018 0.0395 0.2370 0.4433 0.2370 0.0395 0.0018
```

View the exercise probabilities using `PriceResults.PricerData.PriceTree.ExProbTree`. `PriceResults.PricerData.PriceTree.ExProbTree` contains the exercise probabilities. Each element in the cell array is an array containing 0's where there is no exercise, or the probability of reaching that node where exercise happens.

```
PriceResults.PricerData.PriceTree.ExProbTree{5}
```

```
ans = 1×7
```

```
0.0018 0.0395 0.2370 0.4433 0.2370 0.0395 0.0018
```

```
PriceResults.PricerData.PriceTree.ExProbTree{4}
```

```
ans = 1×7
```

```
0 0 0 0 0 0 0
```

```
PriceResults.PricerData.PriceTree.ExProbTree{3}
```

```
ans = 1×5
```

```
0 0 0 0 0
```

```
PriceResults.PricerData.PriceTree.ExProbTree{2}
```

```
ans = 1×3
```

```
0 0 0
```

View the exercise probabilities at each tree level using `PriceResults.PricerData.PriceTree.ExProbsByTreeLevel`. `PriceResults.PricerData.PriceTree.ExProbsByTreeLevel` is an array in which each row holds the exercise probability for a given option at each tree observation time.

```
PriceResults.PricerData.PriceTree.ExProbsByTreeLevel
```

```
ans = 1x5
```

```
    0    0    0    0    1.0000
```

## More About

### Vanilla Bond with Embedded Option

A vanilla coupon bond is a security representing an obligation to repay a borrowed amount at a designated time and to make periodic interest payments until that time.

The issuer of a bond makes the periodic interest payments until the bond matures. At maturity, the issuer pays to the holder of the bond the principal amount owed (face value) and the last interest payment. A vanilla bond with an embedded option is where an option contract has an underlying asset of a vanilla bond.

### Stepped Coupon Bond with Callable and Puttable Features

A step-up bond and step-down bond is a debt security with a predetermined coupon structure over time.

With these instruments, coupons increase (step up) or decrease (step down) at specific times during the life of the bond. Stepped coupon bonds can have options features (call and puts).

### Amortizing Callable and Puttable Bond

An amortizing callable bond or amortizing puttable bond work under a scheduled `Principal`.

An amortizing callable bond gives the issuer the right to call back the bond, but instead of paying the `Principal` amount at maturity, it repays part of the principal along with the coupon payments. An amortizing puttable bond, repays part of the principal along with the coupon payments and gives the bondholder the right to sell the bond back to the issuer.

## Tips

After creating an `OptionEmbeddedFixedBond` object, you can modify the `CallSchedule` and `CallExerciseStyle` using `setCallExercisePolicy`. Or, you can modify the `PutSchedule` and `PutExerciseStyle` values using `setPutExercisePolicy`.

# OptionEmbeddedFloatBond

OptionEmbeddedFloatBond instrument object

## Description

Create and price a OptionEmbeddedFloatBond instrument object using this workflow:

- 1 Use `fininstrument` to create an OptionEmbeddedFloatBond instrument object.
- 2 Use `finmodel` to specify a HullWhite or BlackKarasinski model for the OptionEmbeddedFloatBond instrument.
- 3 Use `finpricer` to specify an IRTree pricing method for the OptionEmbeddedFloatBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for an OptionEmbeddedFloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
OptionEmbeddedFloatBondObj = fininstrument(InstrumentType, '
Spread', spread_value, 'Maturity', maturity_date, '
CallSchedule', call_schedule_value)
OptionEmbeddedFloatBondObj = fininstrument(InstrumentType, '
Spread', spread_value, 'Maturity', maturity_date, '
PutSchedule', put_schedule_value)
OptionEmbeddedFloatBondObj = fininstrument( ____, Name, Value)
```

### Description

`OptionEmbeddedFloatBondObj = fininstrument(InstrumentType, 'Spread', spread_value, 'Maturity', maturity_date, 'CallSchedule', call_schedule_value)` creates a OptionEmbeddedFloatBond object by specifying `InstrumentType` and the required name-value pair arguments `Spread`, `Maturity`, and `CallSchedule` sets the properties on page 11-2409 using required name-value pair arguments.

OptionEmbeddedFloatBond supports vanilla bonds with embedded options, stepped coupon bonds with embedded options and amortizing bonds with embedded options.

```
OptionEmbeddedFloatBondObj = fininstrument(InstrumentType, '
Spread', spread_value, 'Maturity', maturity_date, '
PutSchedule', put_schedule_value)
```

creates a OptionEmbeddedFloatBond object by

specifying `InstrumentType` and the required name-value pair arguments `Spread`, `Maturity`, and `PutSchedule` sets the properties on page 11-2409 using required name-value pair arguments.

`OptionEmbeddedFloatBondObj = fininstrument( ____,Name,Value)` sets optional properties on page 11-2409 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `OptionEmbeddedFloatBondObj = fininstrument("OptionEmbeddedFloatBond", 'Spread',0.01, 'Maturity',datetime(2019,1,30), 'Period',4, 'Basis',5, 'Principal',1000, 'FirstCouponDate',datetime(2016,1,30), 'EndMonthRule',1, 'CallSchedule',schedule, 'CallExerciseStyle',"american", 'ProjectionCurve',ratecurve_obj, 'Name',"optionembeddedfloatbond")`. You can specify multiple name-value pairs.

## Input Arguments

### InstrumentType — Instrument type

string with value "OptionEmbeddedFloatBond" | character vector with value 'OptionEmbeddedFloatBond'

Instrument type, specified as a string with the value of "OptionEmbeddedFloatBond" or a character vector with a value of 'OptionEmbeddedFloatBond'.

Data Types: char | string

### OptionEmbeddedFloatBond Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1, . . . ,NameN,ValueN`.

Example: `OptionEmbeddedFloatBondObj = fininstrument("OptionEmbeddedFloatBond", 'Spread',0.01, 'Maturity',datetime(2019,1,30), 'Period',4, 'Basis',5, 'Principal',1000, 'FirstCouponDate',datetime(2016,1,30), 'EndMonthRule',1, 'CallSchedule',schedule, 'CallExerciseStyle',"american", 'ProjectionCurve',ratecurve_obj, 'Name',"optionembeddedfloatbond")`

### Required OptionEmbeddedFloatBond Name-Value Pair Arguments

#### Spread — Number of basis points over the reference rate

nonnegative numeric

Number of basis points over the reference rate, specified as the comma-separated pair consisting of 'Spread' and a scalar nonnegative numeric.

Data Types: double

#### Maturity — Maturity date

serial date number | character vector | datetime | date string

Maturity date, specified as the comma-separated pair consisting of 'Maturity' and a serial date number, date character vector, date string, or datetime.

Data Types: char | double | string | datetime

#### CallSchedule — Call schedule

timetable

Call schedule, specified as the comma-separated pair consisting of 'CallSchedule' and a timetable of call dates and strikes.

If you use a date character vector or date string for the dates in this timetable, the format must be recognizable by `datetime` because the `CallSchedule` property is stored as a `datetime`.

---

**Note** The `OptionEmbeddedFloatBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

---

Data Types: `timetable`

### **PutSchedule — Call schedule**

`timetable`

Put schedule, specified as the comma-separated pair consisting of 'PutSchedule' and a timetable of call dates and strikes.

If you use a date character vector or date string for dates in this timetable, the format must be recognizable by `datetime` because the `PutSchedule` property is stored as a `datetime`.

---

**Note** The `OptionEmbeddedFloatBond` instrument supports either `CallSchedule` and `CallExerciseStyle` or `PutSchedule` and `PutExerciseStyle`, but not both.

---

Data Types: `timetable`

### **Optional OptionEmbeddedFloatBond Name-Value Pair Arguments**

#### **Reset — Frequency of payments per year**

2 (default) | integer

Frequency of payments per year, specified as the comma-separated pair consisting of 'Reset' and a scalar integer. Values for `Reset` are: 1, 2, 3, 4, 6, and 12.

Data Types: `double`

#### **CallExerciseStyle — Call option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Call option exercise style, specified as the comma-separated pair consisting of 'CallExerciseStyle' and a scalar string or character vector.

Data Types: `string` | `char`

#### **PutExerciseStyle — Put option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Put option exercise style, specified as the comma-separated pair consisting of 'PutExerciseStyle' and a scalar string or character vector.

Data Types: `string` | `char`

**Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of 'Basis' and scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

**Principal — Notional principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric or timetable.

Principal accepts a timetable, where the first column is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: double | timetable

**DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow adjusts for day count convention, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a scalar logical with a value of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string | character vector

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a scalar string or character vector. The selection for business day

convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `string`

### **Holidays — Holidays used in computing business days**

`NaT` (default) | `datetime` | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
OptionEmbeddedFixedBondObj = fininstrument("OptionEmbeddedFixedBond", 'CouponRate', 0.34, 'Maturity', 'CallSchedule', schedule, 'CallExerciseStyle', "american", 'Holidays', H)
```

Data Types: `double` | `cell` | `datetime` | `string`

### **EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

`true` (in effect) (default) | value of `true` or `false`

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a scalar logical value of `true` or `false`.

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### **IssueDate — Bond issue date**

`NaT` (default) | `datetime` | serial date number | date character vector | date string

Bond issue date, specified as the comma-separated pair consisting of 'IssueDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `IssueDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**FirstCouponDate — Irregular first coupon date**

NaT (default) | datetime | serial date number | date character vector | date string

Irregular first coupon date, specified as the comma-separated pair consisting of 'FirstCouponDate' and a scalar datetime, serial date number, date character vector, or date string.

When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure. If you do not specify FirstCouponDate, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by datetime because the FirstCouponDate property is stored as a datetime.

Data Types: double | char | string | datetime

**LastCouponDate — Irregular last coupon date**

NaT (default) | datetime | serial date number | date character vector | date string

Irregular last coupon date, specified as the comma-separated pair consisting of 'LastCouponDate' and a scalar datetime, serial date number, date character vector, or date string.

If you specify LastCouponDate but not FirstCouponDate, LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at LastCouponDate, regardless of where it falls, and is followed only by the bond's maturity cash flow date. If you do not specify LastCouponDate, the cash flow payment dates are determined from other inputs.

If you use a date character vector or date string, the format must be recognizable by datetime because the LastCouponDate property is stored as a datetime.

Data Types: double | char | string | datetime

**StartDate — Forward starting date of payments**

NaT (default) | datetime | serial date number | date character vector | date string

Forward starting date of payments, specified as the comma-separated pair consisting of 'StartDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the StartDate property is stored as a datetime.

Data Types: char | double | string | datetime

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### **InstrumentType — Instrument type**

string with value "OptionEmbeddedFloatBond"

Instrument type, returned as a string with the value of "OptionEmbeddedFloatBond".

Data Types: string

### **Spread — Number of basis points over the reference rate**

nonnegative numeric

Number of basis points over the reference rate, returned as a scalar nonnegative numeric.

Data Types: double

### **Maturity — Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

### **CallSchedule — Call schedule**

timetable

Call schedule, returned as a timetable.

Data Types: cell | datetime

### **PutSchedule — Call schedule**

timetable

Put schedule, returned as a timetable.

Data Types: cell | datetime

### **Reset — Frequency of payments per year**

2 (default) | integer

Frequency of payments per year, returned as a scalar integer.

Data Types: double

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal — Notional principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, returned as a scalar numeric or timetable.

Data Types: timetable | double

**DaycountAdjustedCashFlow — Flag indicating whether cash flow adjusts for day count convention**

false (default) | value of true or false

Flag indicating whether cash flow adjusted for day count convention, returned as scalar logical with a value of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string

Business day conventions, returned as a string

Data Types: string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

true (in effect) (default) | value of true or false

End-of-month rule flag for generating dates when Maturity is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical.

Data Types: logical

**IssueDate — Bond issue date**

NaT (default) | datetime

Bond issue date, returned as a datetime.

Data Types: datetime

**FirstCouponDate — Irregular first coupon date**

NaT (default) | datetime

Irregular first coupon date, returned as a datetime.

Data Types: datetime

**LastCouponDate — Irregular last coupon date**

NaT (default) | datetime

Irregular last coupon date, returned as a datetime.

Data Types: datetime

**StartDate — Forward starting date of payments**

NaT (default) | datetime

Forward starting date of payments, returned as a datetime.

Data Types: datetime

**CallExerciseStyle – Call option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan"

This property is read-only.

Call option exercise style, returned as a string with a value of "European", "American", or "Bermudan".

Data Types: string

**PutExerciseStyle – Put option exercise style**

"European" (default) | string with value "European", "American", or "Bermudan"

This property is read-only.

Put option exercise style, returned as a string with a value of "European", "American", or "Bermudan".

Data Types: string

**Name – User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Object Functions**

setCallExercisePolicy Set call exercise policy for OptionEmbeddedFixedBond or OptionEmbeddedFloatBond instrument  
 setPutExercisePolicy Set put exercise policy for OptionEmbeddedFixedBond or OptionEmbeddedFloatBond instrument

**Examples****Price Option Embedded Float Bond Instruments Using Hull-White Model and IRTree Pricer**

This example shows the workflow to price American, European, and Bermudan exercise styles for three callable OptionEmbeddedFloatBond instruments when you use a HullWhite model and an IRTree pricing method.

**Create ratecurve Object**

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

## Create OptionEmbeddedFloatBond Instrument Objects

Use `fininstrument` to create three `OptionEmbeddedFloatBond` instrument objects with different exercise styles.

```
Maturity = datetime(2024,1,1);

% Option embedded float bond (Bermudan callable bond)
Strike = [100; 100];
ExerciseDates = [datetime(2020,1,1); datetime(2024,1,1)];
Reset = 1;
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});

CallableBondBermudan = fininstrument("OptionEmbeddedFloatBond",'Maturity',Maturity,...
    'Spread',0.025,'Reset',Reset, ...
    'CallSchedule',CallSchedule,'CallExerciseStyle', "bermudan")

CallableBondBermudan =
    OptionEmbeddedFloatBond with properties:

        Spread: 0.0250
    ProjectionCurve: [0x0 ratecurve]
        ResetOffset: 0
            Reset: 1
            Basis: 0
        EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
        BusinessDayConvention: "actual"
            Holidays: NaT
            IssueDate: NaT
        FirstCouponDate: NaT
        LastCouponDate: NaT
            StartDate: NaT
        Maturity: 01-Jan-2024
        CallDates: [2x1 datetime]
        PutDates: [0x1 datetime]
        CallSchedule: [2x1 timetable]
        PutSchedule: [0x0 timetable]
    CallExerciseStyle: "bermudan"
        PutExerciseStyle: [0x0 string]
            Name: ""

% Option embedded float bond (American callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Reset = 1;

CallableBondAmerican = fininstrument("OptionEmbeddedFloatBond",'Maturity',Maturity,...
    'Spread',0.025,'Reset',Reset, ...
    'CallSchedule',CallSchedule,'CallExerciseStyle',"american")

CallableBondAmerican =
    OptionEmbeddedFloatBond with properties:

        Spread: 0.0250
```

```

        ProjectionCurve: [0x0 ratecurve]
          ResetOffset: 0
            Reset: 1
              Basis: 0
                EndMonthRule: 1
                  Principal: 100
                    DaycountAdjustedCashFlow: 0
                      BusinessDayConvention: "actual"
                        Holidays: NaT
                          IssueDate: NaT
                            FirstCouponDate: NaT
                              LastCouponDate: NaT
                                StartDate: NaT
                                  Maturity: 01-Jan-2024
                                    CallDates: 01-Jan-2024
                                      PutDates: [0x1 datetime]
                                        CallSchedule: [1x1 timetable]
                                          PutSchedule: [0x0 timetable]
                                            CallExerciseStyle: "american"
                                              PutExerciseStyle: [0x0 string]
                                                Name: ""

% Option embedded float bond (European callable bond)
Strike = 100;
ExerciseDates = datetime(2024,1,1);
CallSchedule = timetable(ExerciseDates,Strike,'VariableNames',{'Strike Schedule'});
Reset = 1;

CallableBondEuropean = fininstrument("OptionEmbeddedFloatBond",'Maturity',Maturity,...
                                     'Spread',0.025,'Reset',Reset, ...
                                     'CallSchedule',CallSchedule)

CallableBondEuropean =
  OptionEmbeddedFloatBond with properties:

        Spread: 0.0250
        ProjectionCurve: [0x0 ratecurve]
          ResetOffset: 0
            Reset: 1
              Basis: 0
                EndMonthRule: 1
                  Principal: 100
                    DaycountAdjustedCashFlow: 0
                      BusinessDayConvention: "actual"
                        Holidays: NaT
                          IssueDate: NaT
                            FirstCouponDate: NaT
                              LastCouponDate: NaT
                                StartDate: NaT
                                  Maturity: 01-Jan-2024
                                    CallDates: 01-Jan-2024
                                      PutDates: [0x1 datetime]
                                        CallSchedule: [1x1 timetable]
                                          PutSchedule: [0x0 timetable]
                                            CallExerciseStyle: "european"
                                              PutExerciseStyle: [0x0 string]

```

```
Name: ""
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite", 'alpha', AlphaCurve, 'sigma', VolCurve);
```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
HWTrePricer = finpricer("IRTree", 'Model', HWModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates);
```

```
HWTrePricer =
  HWBKTre with properties:
    Tree: [1x1 struct]
    TreeDates: [10x1 datetime]
    Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

### Price OptionEmbeddedFixedBond Instruments

Use `price` to compute the price and sensitivities for the three OptionEmbeddedFixedBond instruments.

```
[Price, outPR] = price(HWTrePricer, CallableBondBermudan, ["all"])
```

```
Price = 104.9598
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
104.96	0	19.597	-7.3926

```
[Price, outPR] = price(HWTrePricer, CallableBondAmerican, ["all"])
```

```
Price = 100
```

```
outPR =
  pricerresult with properties:
```

```
Results: [1x4 table]
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
  Price      Vega      Gamma      Delta
  _____  _____  _____  _____
      100         0         0         0
```

```
[Price, outPR] = price(HWTreePricer,CallableBondEuropean,["all"])
```

```
Price = 114.5571
```

```
outPR =
  pricerresult with properties:
```

```
Results: [1x4 table]
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
  Price      Vega      Gamma      Delta
  _____  _____  _____  _____
  114.56    -2.8422e-10  262.58    -50.006
```

## More About

### Floating-Rate Note with Embedded Options

A floating-rate note with an embedded option enables floating-rate notes to have early redemption features.

A floating-rate note with an embedded option gives investors or issuers the option to retire the outstanding principal prior to maturity. An embedded call option gives the right to retire the note prior to the maturity date (callable floater), and an embedded put option gives the right to sell the note back at a specific price (puttable floater).

For more information, see “Floating-Rate Note with Embedded Options” on page 2-10.

## Tips

After creating an `OptionEmbeddedFixedBond` object, you can modify the `CallSchedule` and `CallExerciseStyle` using `setCallExercisePolicy`. Or, you can modify the `PutSchedule` and `PutExerciseStyle` values using `setPutExercisePolicy`.

## **See Also**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

**Introduced in R2020a**

# Spread

Spread instrument object

## Description

Create and price a Spread instrument object using this workflow:

- 1 Use `fininstrument` to create a Spread instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Spread instrument.
- 3 Use `finpricer` to specify a Kirk, BjerksundStensland, or AssetMonteCarlo pricing method for the Spread instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Spread instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
SpreadObj = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date)
SpreadObj = fininstrument( ____, Name, Value)
```

### Description

`SpreadObj = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date)` creates a Spread object by specifying `InstrumentType` and sets the properties on page 11-2419 for the required name-value pair arguments `Strike` and `ExerciseDate`.

`SpreadObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2419 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SpreadObj = fininstrument("Spread", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'OptionType', "put", 'ExerciseStyle', "American", 'Name', "spread_instrument")` creates a Spread put option with an American exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Spread" | character vector with value 'Spread'

Instrument type, specified as a string with the value of "Spread" or a character vector with a value of 'Spread'.

Data Types: char | string

### Spread Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `SpreadObj = fininstrument("Spread", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'OptionType', "put", 'ExerciseStyle', "American", 'Name', "spread_instrument")`

### Required Spread Name-Value Pair Arguments

#### Strike — Option strike price value

nonnegative numeric

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric value.

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one `ExerciseDate` on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Data Types: double | char | string | datetime

### Optional Spread Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

#### ExerciseStyle — Option exercise style

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

Data Types: string | char

#### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: `char` | `string`

## Properties

### Strike — Option strike price value

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric value.

Data Types: `double`

### ExerciseDate — Option exercise date

datetime

Option exercise date, returned as a datetime.

Data Types: `datetime`

### OptionType — Option type

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: `string`

### ExerciseStyle — Option exercise style

"European" (default) | string with value "European"

Option exercise style, returned as a string with a value of "European".

Data Types: `string`

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: `string`

## Examples

### Price Spread Instrument with European Option Using Black-Scholes Model and Bjerksund-Stensland Pricer

This example shows the workflow to price a Spread instrument with a European option when using a BlackScholes model and a BjerksundStensland pricing method.

#### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 105, 'ExerciseDate', datetime(2021,9,15), 'OptionType', '');
```

```
SpreadOpt =  
  Spread with properties:  
  
    OptionType: "put"  
    Strike: 105  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2021  
    Name: "spread_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [0.2,0.1])
```

```
BlackScholesModel =  
  BlackScholes with properties:  
  
    Volatility: [0.2000 0.1000]  
    Correlation: [2x2 double]
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =  
  ratecurve with properties:  
  
    Type: "zero"  
    Compounding: -1  
    Basis: 12  
    Dates: 15-Sep-2023  
    Rates: 0.0350  
    Settle: 15-Sep-2018  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', [103
```

```
outPricer =  
  BjerksundStensland with properties:  
  
    DiscountCurve: [1x1 ratecurve]  
    Model: [1x1 finmodel.BlackScholes]  
    SpotPrice: [103 105]
```

```
DividendValue: [0.0250 0.0280]
DividendType: "continuous"
```

### Price Spread Instrument

Use price to compute the price and sensitivities for the Spread instrument.

```
[Price, outPR] = price(outPricer,SpreadOpt,["all"])
```

```
Price = 95.9884
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta		Gamma		Lambda		Vega
95.988	-0.8916	0.90457	0.0021316	0.00048175	-0.95673	0.97064	13.582

### Price Spread Instrument for a Commodity Using Black-Scholes Model and Analytic Pricers

This example shows the workflow to price a commodity Spread instrument when you use a BlackScholes model and Kirk and BjerksundStensland analytic pricing methods.

#### Understanding Crack Spread Options

In the petroleum industry, refiners are concerned about the difference between their input costs (crude oil) and output prices (refined products — gasoline, heating oil, diesel fuel, and so on). The differential between these two underlying commodities is referred to as a *crack spread*. It represents the profit margin between crude oil and the refined products.

A *spread option* is an option on the spread where the holder has the right, but not the obligation, to enter into a spot or forward spread contract. Crack spread options are often used to protect against declines in the crack spread or to monetize volatility or price expectations on the spread.

#### Define the Commodity

Assume that current gasoline prices are strong, and you want to model a crack spread option strategy to protect the gasoline margin. A crack spread option strategy is used to maintain profits for the following season. The WTI crude oil futures are at \$93.20 per barrel and RBOB gasoline futures contract are at \$2.85 per gallon.

```
Strike = 20;
Rate = 0.05;
```

```
Settle = datetime(2020,1,1);
Maturity = datemnth(Settle,3);
```

```

% Price and volatility of RBOB gasoline
PriceGallon1 = 2.85;           % Dollars per gallon
Price1 = PriceGallon1 * 42;    % Dollars per barrel
Vol1 = 0.29;

% Price and volatility of WTI crude oil
Price2 = 93.20;               % Dollars per barrel
Vol2 = 0.36;

% Correlation between the prices of the commodities
Corr = 0.42;

```

### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```

SpreadOpt = fininstrument("Spread", 'ExerciseDate', Maturity, 'Strike', Strike, 'ExerciseStyle', 'D')
SpreadOpt =
    Spread with properties:
        OptionType: "call"
        Strike: 20
        ExerciseStyle: "european"
        ExerciseDate: 01-Apr-2020
        Name: "spread_instrument"

```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```

BlackScholesModel = finmodel("BlackScholes", 'Volatility', [Vol1,Vol2], 'Correlation', [1 Corr; 0]);

```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

ZeroCurve = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1);

```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

BJSPricer = finpricer("Analytic", 'Model', BlackScholesModel, 'SpotPrice', [Price1 , Price2], 'DiscountCurve', ZeroCurve);

```

### Create Kirk Pricer Object

Use `finpricer` to create a Kirk pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

KirkPricer = finpricer("Analytic", 'Model', BlackScholesModel, 'SpotPrice', [Price1 , Price2], 'DiscountCurve', ZeroCurve);

```

### Price Spread Instrument Using BjerksundStensland and Kirk Analytic Pricing Methods

Use `price` to compute the price and sensitivities for the commodity Spread instrument.

```
[PriceKirk, outPR_Kirk] = price(KirkPricer, SpreadOpt, "all");
[PriceBJS, outPR_BJS] = price(BJSPricer, SpreadOpt, "all");
```

```
[outPR_Kirk.Results; outPR_BJS.Results]
```

```
ans=2x7 table
```

Price	Delta		Gamma		Lambda		Vega	
11.19	0.67224	-0.60665	0.019081	0.021662	7.1907	-6.4891	11.299	9.886
11.2	0.67371	-0.60816	0.018992	0.021572	7.2003	-6.4997	11.198	9.987

### Price Spread Instrument with American Option Using Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price a Spread instrument with an American option when using a BlackScholes model and an AssetMonteCarlo pricing method.

#### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 100, 'ExerciseDate', datetime(2021,9,15), 'OptionType', 'put');
```

```
SpreadOpt =
```

```
Spread with properties:
```

```
    OptionType: "put"
      Strike: 100
ExerciseStyle: "american"
ExerciseDate: 15-Sep-2021
        Name: "spread_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
Corr = 0.42;
```

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", [0.3,0.1], "Correlation", [1 Corr; Corr 1]);
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
    Volatility: [0.3000 0.1000]
    Correlation: [2x2 double]
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
```

```
Maturity = datetime(2023,9,15);
```

```
Rate = 0.035;
```

```
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", "DiscountCurve", myRC, "Model", BlackScholesModel, 'SpotPrice')
```

```

outPricer =
  GBMMonteCarlo with properties:
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: [100 95]
      SimulationDates: 15-Sep-2021
      NumTrials: 1000
      RandomNumbers: []
      Model: [1x1 finmodel.BlackScholes]
      DividendType: ["continuous" "continuous"]
      DividendValue: [0 0.0100]

```

### Price Spread Instrument

Use `price` to compute the price and sensitivities for the Spread instrument.

```
[Price, outPR] = price(outPricer, SpreadOpt, ["all"])
```

```
Price = 95
```

```

outPR =
  pricerresult with properties:
      Results: [1x7 table]
      PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
_____	_____	_____	_____	_____	_____	_____

---

95      -1      1      0      3.1492e-14      -1.0526      1      0      0      0      0

## More About

### Spread Option

A spread option is written on the difference of two underlying assets.

For example, a European call on the difference of two assets  $X1$  and  $X2$  has the following pay off at maturity:

$$\max(X1 - X2 - K, 0)$$

$K$  is the strike price.

For more information, see “Spread Option” on page 3-29.

### Introduced in R2020a

# Swap

Swap instrument object

## Description

Create and price a Swap instrument object using this workflow:

- 1 Use `fininstrument` to create a Swap instrument object.
- 2 Use `ratecurve` to specify a curve model for the Swap instrument or use `finmodel` to specify a HullWhite or BlackKarasinski model.
- 3 Use `finpricer` to specify a Discount pricing method when using a `ratecurve` object or an IRTree pricing method when using a HullWhite or BlackKarasinski model for the Swap instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Swap instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
SwapInstrument = fininstrument(InstrumentType, 'Maturity', maturity_date, '
LegRate', leg_rate)
SwapInstrument = fininstrument( ____, Name, Value)
```

### Description

`SwapInstrument = fininstrument(InstrumentType, 'Maturity', maturity_date, 'LegRate', leg_rate)` creates a Swap object by specifying `InstrumentType` and sets the properties on page 11-2431 for the required name-value pair arguments `Maturity` and `LegRate`.

The Swap instrument supports vanilla swaps, amortizing swaps and forward swaps. You can use the Swap instrument for a single currency swap but not a cross-currency swap. For more information on a Swap instrument, see “More About” on page 11-2439.

`SwapInstrument = fininstrument( ____, Name, Value)` sets optional properties on page 11-2431 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SwapInstrument = fininstrument("Swap", 'Maturity', datetime(2019,1,30), 'LegRate', [0.06 0.12], 'LegType', ["fixed", "fixed"], 'Basis', 1, 'Notional', 100, 'StartDate', datetime(2016,1,30), 'DaycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCurve', ratecurve, 'Name', "swap_instrument")` creates a Swap option with a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

## Input Arguments

### InstrumentType — Instrument type

string with value "Swap" | character vector with value 'Swap'

Instrument type, specified as a string with the value of "Swap" or a character vector with the value of 'Swap'.

Data Types: char | string

### Swap Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: SwapInstrument =  
 fininstrument("Swap", 'Maturity', datetime(2019,1,30), 'LegRate', [0.06  
 0.12], 'LegType',  
 ["fixed", "fixed"], 'Basis', 1, 'Notional', 100, 'StartDate', datetime(2016,1,30), 'D  
 aycountAdjustedCashFlow', true, 'BusinessDayConvention', "follow", 'ProjectionCur  
 ve', ratecurve, 'Name', "swap\_instrument")

### Required Swap Name-Value Pair Arguments

#### Maturity — Swap maturity date

datetime | serial date number | date character vector | date string

Swap maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Data Types: char | double | string | datetime

#### LegRate — Leg rate in decimal values

matrix

Leg rate in decimal values, specified as the comma-separated pair consisting of 'LegRate' and a NINST-by-2 matrix. Each row can be defined as one of the following:

- [CouponRate Spread] (fixed-float)
- [Spread CouponRate] (float-fixed)
- [CouponRate CouponRate] (fixed-fixed)
- [Spread Spread] (float-float)

CouponRate is the decimal annual rate. Spread is the number of basis points in decimals over the reference rate. The first column represents the receiving leg, while the second column represents the paying leg.

Data Types: double

### Optional Swap Name-Value Pair Arguments

#### LegType — Leg type

["fixed", "float"] for each instrument (default) | cell array of character vectors with values {'fixed', 'fixed'}, {'fixed', 'float'}, {'float', 'fixed'}, or {'float', 'float'} |

string array with values ["fixed", "fixed"], ["fixed", "float"], ["float", "fixed"], or ["float", "float"]

Leg type, specified as the comma-separated pair consisting of 'LegType' and a cell array of character vectors or a string array with the supported values. The LegType defines the interpretation of the values entered in LegRate.

---

**Note** When you specify a Swap instrument as the underlying asset for a Swaption instrument while using a Normal, SABR, Black, or HullWhite pricer, the Swap LegType must be ["fixed", "float"] or ["float", "fixed"]. You must also set the ExerciseStyle name-value pair argument of the associated Swaption instrument to 'European'.

---

Data Types: cell | string

### ProjectionCurve — Rate curve for projecting floating cash flows

ratecurve.empty (default) | ratecurve object

Rate curve for projecting floating cash flows, specified as the comma-separated pair consisting of 'ProjectionCurve' and a ratecurve object. You must create this object using ratecurve. Use this optional input if the forward curve is different from the discount curve.

Data Types: object

### Reset — Frequency of payments per year

[2 2] (default) | numeric value of 0, 1, 2, 3, 4, 6, or 12 | vector

Frequency of payments per year, specified as the comma-separated pair consisting of 'Reset' and scalar or NINST-by-2 if Reset is different for each leg) with one of the following values: 0, 1, 2, 3, 4, 6, or 12.

Data Types: double

### Basis — Day-count basis representing the basis for each leg

[0 0] (actual/actual) (default) | integer from 0 to 13

Day-count basis representing the basis for each leg, specified as the comma-separated pair consisting of 'Basis' and a NINST-by-1 array (or NINST-by-2 if Basis is different for each leg).

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)

- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: double

### **Notional — Notional principal amount or principal value schedule**

100 (default) | scalar numeric | timetable

Notional principal amount or principal value schedule, specified as the comma-separated pair consisting of 'Notional' and a scalar numeric or timetable. Use a scalar for a vanilla Swap instrument and a timetable for an amortizing Swap instrument.

Notional accepts a scalar for a principal amount (or a NINST-by-2 matrix if Notional is different for each leg) or a timetable for principal value schedules. For schedules, the first column of the timetable is dates and the second column is the associated notional principal value. The date indicates the last day that the principal value is valid.

Data Types: timetable | double

### **LatestFloatingRate — Latest floating rate for float legs**

if not specified, then ratecurve must contain this information (default) | scalar numeric | vector

Latest floating rate for float legs, specified as the comma-separated pair consisting of 'LatestFloatingRate' and a scalar numeric value.

LatestFloatingRate is a NINST-by-1 matrix (or NINST-by-2 matrix if LatestFloatingRate is different for each leg).

Data Types: double

### **ResetOffset — Lag in rate setting**

[0 0] (default) | vector

Lag in rate setting, specified as the comma-separated pair consisting of 'ResetOffset' and a NINST-by-2 vector.

Data Types: double

### **DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, specified as the comma-separated pair consisting of 'DaycountAdjustedCashFlow' and a NINST-by-1 (or NINST-by-2 if AdjustCashFlowsBasis is different for each leg) of logicals with values of true or false.

Data Types: logical

### **BusinessDayConvention — Business day conventions**

"actual" (default) | string | string array | character vector | cell array of character vectors

Business day conventions, specified as the comma-separated pair consisting of 'BusinessDayConvention' and string (or string array if BusinessDayConvention is different for each leg) or a character vector (or NINST-by-2 cell array of character vectors if

`BusinessDayConvention` is different for each leg). The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on non-business days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `cell` | `string`

### Holidays — Holidays used in computing business days

`NaN` (default) | `datetime` | cell array of date character vectors | date string array | serial date numbers

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using `datetimes`, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));
Swap = fininstrument("Swap",'Maturity',datetime(2025,12,15),'LegRate',[0.06 20],'Holidays',H)
```

Data Types: `double` | `cell` | `datetime` | `string`

### EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days

[`true true`] (in effect) (default) | logical with value of `true` or `false`

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, specified as the comma-separated pair consisting of 'EndMonthRule' and a logical value of `true` or `false` using a `NINST-by-1` (or `NINST-by-2` if `EndMonthRule` is different for each leg).

- If you set `EndMonthRule` to `false`, the software ignores the rule, meaning that a payment date is always the same numerical day of the month.
- If you set `EndMonthRule` to `true`, the software sets the rule on, meaning that a payment date is always the last actual day of the month.

Data Types: `logical`

### StartDate — Date swap starts

Settle date (default) | `datetime` | serial date number | date character vector | date string

Date swap starts, specified as the comma-separated pair consisting of 'StartDate' and a scalar `datetime`, serial date number, date character vector, or date string.

Use `StartDate` to price a forward swap, that is, a swap that starts at a future date.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `StartDate` property is stored as a datetime.

Data Types: `char` | `double` | `string` | `datetime`

### **Name — User-defined name for instrument**

`" "` (default) | `string` | `character vector`

User-defined name for the instrument, specified as the comma-separated pair consisting of `'Name'` and a scalar string or character vector.

Data Types: `char` | `string`

## **Properties**

### **Maturity — Maturity date**

`datetime`

Maturity date, returned as a datetime.

Data Types: `datetime`

### **LegRate — Leg rate**

`matrix`

Leg rate, returned as a NINST-by-2 matrix of decimal values, with each row defined as one of the following:

- `[CouponRate Spread]` (fixed-float)
- `[Spread CouponRate]` (float-fixed)
- `[CouponRate CouponRate]` (fixed-fixed)
- `[Spread Spread]` (float-float)

Data Types: `double`

### **LegType — Leg type**

`["fixed", "float"]` for each instrument (default) | `string array` with values `["fixed", "fixed"]`, `["fixed", "float"]`, `["float", "fixed"]`, or `["float", "float"]`

Leg type, returned as a string array with the values `["fixed", "fixed"]`, `["fixed", "float"]`, `["float", "fixed"]`, or `["float", "float"]`.

Data Types: `string`

### **ProjectionCurve — Rate curve used in generating future cash flows**

`ratecurve.empty` (default) | `ratecurve object`

Rate curve used in projecting the future cash flows, returned as a `ratecurve` object.

Data Types: `object`

### **Reset — Reset frequency per year for each swap**

`[2 2]` (default) | `vector`

Reset frequency per year for each swap, returned as an NINST-by-2 vector.

Data Types: double

**Basis — Day count basis**

[0 0] (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as an NINST-by-2 vector.

Data Types: double

**ResetOffset — Lag in rate setting**

[0 0] (default) | vector

Lag in rate setting, returned as an NINST-by-2 vector.

Data Types: double

**Notional — Notional principal amount or principal value schedules**

100 (default) | scalar numeric | timetable

Notional principal amount, returned as a scalar numeric or timetable.

Data Types: cell | double

**LatestFloatingRate — Rate for the next floating payment**

if not specified, then `ratecurve` must contain this information (default) | scalar numeric

Rate for the next floating payment, set at the last reset date, returned as a scalar numeric value.

Data Types: double

**DaycountAdjustedCashFlow — Flag to adjust cash flows based on actual period day count**

false (default) | value of true or false

Flag to adjust cash flows based on actual period day count, returned as an NINST-by-1 matrix (or an NINST-by-2 matrix if `AdjustCashFlowsBasis` is different for each leg) of logicals with values of true or false.

Data Types: logical

**BusinessDayConvention — Business day conventions**

"actual" (default) | string | string array

Business day conventions, returned as a string or a NINST-by-2 string array if `BusinessDayConvention` is different for each leg.

Data Types: char | cell | string

**Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

**EndMonthRule — End-of-month rule flag for generating dates when Maturity is end-of-month date for month with 30 or fewer days**

[true true] (in effect) (default) | logical with value of true or false

End-of-month rule flag for generating dates when `Maturity` is an end-of-month date for a month with 30 or fewer days, returned as a scalar logical.

Data Types: `logical`

### **StartDate — Date swap starts**

Settle date (default) | `datetime`

Date swap starts, returned as a `datetime`.

Data Types: `datetime`

### **Name — User-defined name for instrument**

" " (default) | `string`

User-defined name for the instrument, returned as a `string`.

Data Types: `string`

## **Object Functions**

`cashflows`      Computes cash flow for `FixedBond`, `FloatBond`, `Swap`, `FRA`, or `Deposit` instrument

`parswaprate`    Compute par swap rate for `Swap` instrument

## **Examples**

### **Price Vanilla Swap Instrument Using ratecurve and Discount Pricer**

This example shows the workflow to price a vanilla `Swap` instrument when you use a `ratecurve` and a `Discount` pricing method.

#### **Create ratecurve Object**

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the `Swap` instrument.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create Swap Instrument Object

Use `fininstrument` to create a vanilla Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2024,9,15), 'LegRate', [0.022 0.019 ], 'LegType', ["float", "fixed"], 'Notional', 100)

Swap =
    Swap with properties:
        LegRate: [0.0220 0.0190]
        LegType: ["float"    "fixed"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
        LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
        DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [1x2 ratecurve]
        BusinessDayConvention: ["actual"    "actual"]
        Holidays: NaT
        EndMonthRule: [1 1]
        StartDate: NaT
        Maturity: 15-Sep-2024
        Name: "swap_instrument"
```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)

outPricer =
    Discount with properties:
        DiscountCurve: [1x1 ratecurve]
```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the vanilla Swap instrument.

```
[Price, outPR] = price(outPricer, Swap, ["all"])
```

```
Price = 7.2279
```

```
outPR =
    pricerresult with properties:
        Results: [1x2 table]
        PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
_____	_____

```
7.2279    -0.02212
```

## Price Amortizing Swap Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price an amortizing Swap instrument when you use a ratecurve and a Discount pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2019,1,1);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 01-Jan-2019
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create Swap Instrument Object

Use fininstrument to create an amortizing Swap instrument object.

```
Maturity = datetime(2024,1,1);
ADates = datetime([2020,1,1 ; 2024,1,1]);
APrincipal = [100; 85];
Notional = timetable(ADates,APrincipal);
Swap = fininstrument("Swap",'Maturity',Maturity,'LegRate',[0.035,0.01],'Reset',[1 1],'Notional',Notional);
```

```
Swap =
    Swap with properties:
        LegRate: [0.0350 0.0100]
        LegType: ["fixed" "float"]
        Reset: [1 1]
        Basis: [0 0]
        Notional: [2x1 timetable]
        LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
```

```

DaycountAdjustedCashFlow: [0 0]
  ProjectionCurve: [0x0 ratecurve]
  BusinessDayConvention: ["actual" "actual"]
  Holidays: NaT
  EndMonthRule: [1 1]
  StartDate: NaT
  Maturity: 01-Jan-2024
  Name: "swap_instrument"

```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```

outPricer =
  Discount with properties:

    DiscountCurve: [1x1 ratecurve]

```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the amortizing Swap instrument.

```
[Price, outPR] = price(outPricer, Swap,["all"])
```

```
Price = 5.7183
```

```

outPR =
  pricerresult with properties:

```

```

    Results: [1x2 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
5.7183	0.022979

### Price Vanilla Swap Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a vanilla Swap instrument when you use a HullWhite model and an IRTree pricing method.

#### Create ratecurve Object

Create a `ratecurve` object using `ratecurve` for the underlying interest-rate curve for the Swap instrument.

```

Settle = datetime(2020,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Jan-2020
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create Swap Instrument Object

Use `fininstrument` to create a vanilla Swap instrument object.

```
LegType = ["float","fixed"]
```

```

LegType = 1x2 string
    "float"    "fixed"

```

```
Swap = fininstrument("Swap","Maturity",datetime(2030,9,15),'LegRate',[0.022 0.019],'LegType',LegType)
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite","Alpha",0.032,'Sigma',0.04)
```

```

HullWhiteModel =
    HullWhite with properties:

```

```

    Alpha: 0.0320
    Sigma: 0.0400

```

### Compute Swap Instrument Cash Flow Dates

Use `cfdates` to compute the cash flows.

```
CFdates = cfdates(Settle, Swap.Maturity, Swap.Reset(1), Swap.Basis(1))
```

```

CFdates = 1x22 datetime
Columns 1 through 5

```

```

    15-Mar-2020    15-Sep-2020    15-Mar-2021    15-Sep-2021    15-Mar-2022

```

```

Columns 6 through 10

```

```

    15-Sep-2022    15-Mar-2023    15-Sep-2023    15-Mar-2024    15-Sep-2024
Columns 11 through 15
    15-Mar-2025    15-Sep-2025    15-Mar-2026    15-Sep-2026    15-Mar-2027
Columns 16 through 20
    15-Sep-2027    15-Mar-2028    15-Sep-2028    15-Mar-2029    15-Sep-2029
Columns 21 through 22
    15-Mar-2030    15-Sep-2030

```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
HWTreepricer = finpricer("IRTree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', CFdates)
```

```
HWTreepricer =
  HWBKTree with properties:
      Tree: [1x1 struct]
    TreeDates: [22x1 datetime]
      Model: [1x1 finmodel.HullWhite]
DiscountCurve: [1x1 ratecurve]
```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the vanilla Swap instrument.

```
[Price, outPR] = price(HWTreepricer, Swap, "all")
```

```
Price = 24.3727
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x4 table]
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
_____	_____	_____	_____

24.373    8.5265e-10    -8790.5    820.67

## More About

### Swap

A swap is contract between two parties obligating the parties to exchange future cash flows.

A vanilla swap is composed of a floating-rate leg and a fixed-rate leg.

### Swap with Amortization

A swap with an amortization schedule repays part of the principal (face value) along with the coupon payments.

A swap with an amortization schedule is used to manage interest-rate risk and serve as a cash flow management tool. For this particular type of swap, the notional amount decreases over time. This means that interest payments decrease not only on the floating leg but also on the fixed leg. Use the `Notional` name-value pair argument to support an amortization schedule.

### Forward Swap

In a forward interest-rate swap, a fixed interest-rate loan is exchanged for a floating interest-rate loan at a future specified date.

The `StartDate` name-value pair argument supports the future date for the forward swap.

# VarianceSwap

VarianceSwap instrument object

## Description

Create and price a `VarianceSwap` instrument object using this workflow:

- 1 Use `fininstrument` to create a `VarianceSwap` instrument object.
- 2 Use `ratecurve` to specify a curve model or use `finmodel` to specify a Heston model.
- 3 When using a curve model, use `finpricer` to specify a `ReplicatingVarianceSwap` pricing method for the `VarianceSwap` instrument.

When using a Heston model, use `finpricer` to specify a Heston pricing method for the `VarianceSwap` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `VarianceSwap` instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
VarianceSwapInstrument = fininstrument(InstrumentType, '
Maturity', maturity_date, 'Notional', notional_value)
VarianceSwapInstrument = fininstrument( ___, Name, Value)
```

### Description

`VarianceSwapInstrument = fininstrument(InstrumentType, 'Maturity', maturity_date, 'Notional', notional_value)` creates a `VarianceSwap` object by specifying `InstrumentType` and sets properties on page 11-2442 using the required name-value pair arguments `Maturity` and `Notional`.

The `VarianceSwap` instrument supports the `ReplicatingVarianceSwap` and Heston pricing methods. For more information on the `VarianceSwap` instrument, see “More About” on page 11-2446.

`VarianceSwapInstrument = fininstrument( ___, Name, Value)` sets optional properties on page 11-2431 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `VarianceSwapInstrument = fininstrument("VarianceSwap", 'Maturity', datetime(2019,1,30), 'Notional', 100, 'StartDate', datetime(2016,1,30), 'RealizedVariance', 0.02, 'Strike', 110, 'Name', "varianceswap_instrument")` creates a `VarianceSwap` option with a maturity date of January 30, 2019. You can specify multiple name-value pair arguments.

**Input Arguments****InstrumentType — Instrument type**

string with value "VarianceSwap" | character vector with value 'VarianceSwap'

Instrument type, specified as a string with the value of "VarianceSwap" or a character vector with the value of 'VarianceSwap'.

Data Types: char | string

**VarianceSwap Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `VarianceSwapInstrument = fininstrument("VarianceSwap", 'Maturity', datetime(2019,1,30), 'Notional', 100, 'StartDate', datetime(2016,1,30), 'RealizedVariance', 0.02, 'Strike', 110, 'Name', "varianceswap_instrument")`

**Required VarianceSwap Name-Value Pair Arguments****Maturity — Variance swap maturity date**

datetime | serial date number | date character vector | date string

Variance swap maturity date, specified as the comma-separated pair consisting of 'Maturity' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the Maturity property is stored as a datetime.

Data Types: char | double | string | datetime

**Notional — Notional amount**

numeric

Notional amount, specified as the comma-separated pair consisting of 'Notional' and a scalar numeric.

Data Types: double

**Optional VarianceSwap Name-Value Pair Arguments****StartDate — Start date**

Settle date of the ratecurve (default) | datetime | serial date number | date character vector | date string

Start date, specified as the comma-separated pair consisting of 'StartDate' and a scalar datetime, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

**RealizedVariance — Realized variance**

0 (default) | decimal

Realized variance, specified as the comma-separated pair consisting of 'RealizedVariance' and a scalar decimal.

Data Types: double

**Strike – Strike variance**

fair variance computed by pricer (default) | decimal

Strike variance, specified as the comma-separated pair consisting of 'Strike' and a scalar decimal.

Data Types: double

**Name – User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

**Properties****Maturity – Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

**Notional – Notional amount**

numeric

Notional amount, returned as a scalar numeric.

Data Types: double

**StartDate – Start date**

Settle date of the ratecurve (default) | datetime

Start date, returned as a datetime.

Data Types: double | char | string | datetime

**RealizedVariance – Realized variance**

0 (default) | decimal

Realized variance, returned as a scalar decimal.

Data Types: double

**Strike – Strike variance**

fair variance computed by pricer (default) | decimal

Strike variance, returned as a scalar decimal.

Data Types: double

**Name – User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

### Examples

#### Price Variance Swap Instrument Using Heston Model and Heston Pricer

This example shows the workflow to price a VarianceSwap instrument when you use a Heston model and a Heston pricing method.

##### Create VarianceSwap Instrument Object

Use `fininstrument` to create a VarianceSwap instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap", 'Maturity', datetime(2020,9,15), 'Notional', 100, 'S
```

```
VarianceSwapInst =
  VarianceSwap with properties:
      Notional: 100
  RealizedVariance: 0.0200
      Strike: 0.0500
  StartDate: 15-Jun-2020
  Maturity: 15-Sep-2020
      Name: "variance_swap_instrument"
```

##### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.06, 'ThetaV', 0.1, 'Kappa', 0.9, 'SigmaV', 0.7, 'RhoSV', -.3)
```

```
HestonModel =
  Heston with properties:
      V0: 0.0600
  ThetaV: 0.1000
  Kappa: 0.9000
  SigmaV: 0.7000
  RhoSV: -0.3000
```

##### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2020, 1, 1);
ZeroTimes = calmonths(3);
ZeroRates = 0.05;
ZeroDates = Settle + ZeroTimes;
Basis = 1;
ZeroCurve = ratecurve("zero", Settle, ZeroDates, ZeroRates, 'Basis', Basis)
```

```
ZeroCurve =
  ratecurve with properties:

      Type: "zero"
      Compounding: -1
      Basis: 1
      Dates: 01-Apr-2020
      Rates: 0.0500
      Settle: 01-Jan-2020
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Heston Pricer Object

Use `finpricer` to create a Heston pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Analytic", 'DiscountCurve', ZeroCurve, 'Model', HestonModel)

outPricer =
  Heston with properties:

      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.Heston]
```

### Price VarianceSwap Instrument

Use `price` to compute the price and fair variance for the `VarianceSwap` instrument.

```
[Price, outPR] = price(outPricer, VarianceSwapInst, ["all"])
```

```
Price = 10.8321
```

```
outPR =
  pricerresult with properties:

      Results: [1x2 table]
      PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
   Price   FairVariance
   _____
  10.832   0.07039
```

### Price Variance Swap Instrument Using ratecurve and Replicating Variance Swap Pricer

This example shows the workflow to price a `VarianceSwap` instrument when you use a `ratecurve` object and a `ReplicatingVarianceSwap` pricing method.

### Create VarianceSwap Instrument Object

Use `fininstrument` to create a `VarianceSwap` instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap", 'Maturity', datetime(2021,5,1), 'Notional', 150, 'St
```

```
VarianceSwapInst =
  VarianceSwap with properties:

      Notional: 150
  RealizedVariance: 0.0500
      Strike: 0.1000
  StartDate: 01-May-2020
  Maturity: 01-May-2021
      Name: "variance_swap_instrument"
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2020, 9, 15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Basis = 1;
ZeroCurve = ratecurve("zero", Settle, ZeroDates, ZeroRates, 'Basis', Basis)
```

```
ZeroCurve =
  ratecurve with properties:

      Type: "zero"
  Compounding: -1
      Basis: 1
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2020
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create ReplicatingVarianceSwap Pricer Object

Use `finpricer` to create a `ReplicatingVarianceSwap` pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
Strike = (50:5:135)';
Volatility = [.49;.45;.42;.38;.34;.31;.28;.25;.23;.21;.2;.21;.21;.22;.23;.24;.25;.26];
VolatilitySmile = table(Strike, Volatility);
SpotPrice = 100;
CallPutBoundary = 100;
```

```
outPricer = finpricer("ReplicatingVarianceSwap", 'DiscountCurve', ZeroCurve, 'VolatilitySmile', \
  'SpotPrice', SpotPrice, 'CallPutBoundary', CallPutBoundary)
```

```
outPricer =
  ReplicatingVarianceSwap with properties:
```

```

DiscountCurve: [1x1 ratecurve]
InterpMethod: "linear"
VolatilitySmile: [18x2 table]
SpotPrice: 100
CallPutBoundary: 100

```

### Price VarianceSwap Instrument

Use price to compute the price and fair variance for the VarianceSwap instrument.

```
[Price, outPR] = price(outPricer,VarianceSwapInst,["all"])
```

```
Price = 8.1997
```

```
outPR =
  pricerresult with properties:
```

```

Results: [1x2 table]
PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x2 table
   Price   FairVariance
   _____  _____
   8.1997   0.21701
```

## More About

### VarianceSwap

A variance swap is a forward contract on the realized variance over time.

At expiration, the payoff of a variance swap is  $(\sigma_R^2 - K_{\text{var}}) \times N$

Here:

$\sigma_R^2$  is the realized variance of the underlying asset (for example a stock or equity index) over the life of the contract.

$K_{\text{var}}$  is the strike (contractual) variance that is set at the beginning of the contract to make the starting value equal to zero.

$N$  is the notional amount.

# Swaption

Swaption instrument object

## Description

Create and price a `Swaption` instrument object using this workflow:

- 1 Use `fininstrument` to create a `Swaption` instrument object.
- 2 Use `finmodel` to specify a `HullWhite`, `BlackKarasinski`, `Black`, `Normal`, or `SABR` model for the `Swaption` instrument.
- 3 Use `finpricer` to specify a `Normal`, `SABR`, `Black`, `HullWhite`, or `IRTtree` pricing method for the `Swaption` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
SwaptionInstrument = fininstrument(InstrumentType,'Strike',strike_value,'
ExerciseDate',exercice_date)
SwaptionInstrument = fininstrument( ____,Name,Value)
```

### Description

`SwaptionInstrument = fininstrument(InstrumentType,'Strike',strike_value,'ExerciseDate',exercice_date)` creates a `Swaption` object by specifying `InstrumentType` and sets the properties on page 11-2450 for the required name-value pair arguments `Strike` and `ExerciseDate`. For more information on a `Swaption` instrument, see “More About” on page 11-2461.

`SwaptionInstrument = fininstrument( ____,Name,Value)` sets optional properties on page 11-2450 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SwaptionInstrument = fininstrument("Swaption",'Strike',0.67,'ExerciseDate',datetime(2019,1,30),'Swap','Swap_obj','OptionType',"put",'ExerciseStyle',"European",'Name',"swaption_instrument")` creates a `Swaption` put instrument with a strike of 0.67 and an European exercise. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Swaption" | character vector with value 'Swaption'

Instrument type, specified as a string with the value of "Swaption" or a character vector with the value of 'Swaption'.

Data Types: char | string

### Swaption Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `SwaptionInstrument = fininstrument("Swaption", 'Strike', .67, 'ExerciseDate', datetime(2019,1,30), 'Swap', Swap_obj, 'OptionType', "put", 'ExerciseStyle', "European", 'Name', "swaption_instrument")`

### Required Swaption Name-Value Pair Arguments

#### Strike — Option strike value

nonnegative decimal

Option strike value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative decimal value.

Data Types: double

#### ExerciseDate — Option exercise date

datetime | serial date number | date character vector | date string

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one ExerciseDate on the option expiry date.

---

If you use a date character vector or date string, the format must be recognizable by datetime because the ExerciseDate property is stored as a datetime.

Data Types: double | char | string | datetime

#### Swap — Underlying Swap object

Swap object

Underlying Swap object, specified as the comma-separated pair consisting of 'Swap' and a scalar Swap object.

Data Types: object

### Optional Swaption Name-Value Pair Arguments

#### OptionType — Option type

"call" (default) | string with values "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

Data Types: char | string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European" | character vector with value 'European'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

---

**Note** When you specify a Swap instrument as the underlying asset for a Swaption instrument and use a Normal, SABR, Black, or HullWhite pricer, the Swap instrument LegType must be ["fixed", "float"] or ["float", "fixed"] and the Swaption instrument ExerciseStyle must be "European".

---

Data Types: string | char

**Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

**Properties****Strike — Option strike value**

nonnegative decimal

Option strike value, returned as a scalar nonnegative decimal value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**Swap — Underlying Swap object**

Swap object

Swap object, returned as a scalar Swap object.

Data Types: object

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

**ExerciseStyle — Option exercise style**

"European" (default) | string with value "European"

Option exercise style, returned as a string with a value of "European".

Data Types: string

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Examples

### Price Swaption Instrument Using SABR Model and SABR Pricer

This example shows the workflow to price a Swaption instrument when you use a SABR model and a SABR pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

#### Create Swap Instrument Object

Use `fininstrument` to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2027,3,15), 'LegRate', [0 0], 'LegType', ...
    ["float", "fixed"], 'Notional', 100, 'StartDate', datetime(2022,3,15), 'Name', "swap_instrument")
```

```
Swap =
    Swap with properties:
        LegRate: [0 0]
        LegType: ["float" "fixed"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
```

```

    LatestFloatingRate: [NaN NaN]
      ResetOffset: [0 0]
DaycountAdjustedCashFlow: [0 0]
    ProjectionCurve: [0x0 ratecurve]
    BusinessDayConvention: ["actual" "actual"]
      Holidays: NaT
    EndMonthRule: [1 1]
      StartDate: 15-Mar-2022
      Maturity: 15-Mar-2027
      Name: "swap_instrument"

```

### Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("Swaption", 'Strike', 0.02, 'ExerciseDate', datetime(2022, 3, 15), 'Swap', Swap
```

```
Swaption =
  Swaption with properties:
```

```

    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Mar-2022
    Strike: 0.0200
      Swap: [1x1 fininstrument.Swap]
      Name: "swaption_option"

```

### Create SABR Model Object

Use `finmodel` to create a `SABR` model object.

```
SabrModel = finmodel("SABR", 'Alpha', 0.032, 'Beta', 0.04, 'Rho', .08, 'Nu', 0.49, 'Shift', 0.002)
```

```
SabrModel =
  SABR with properties:
```

```

    Alpha: 0.0320
    Beta: 0.0400
    Rho: 0.0800
    Nu: 0.4900
    Shift: 0.0020
    VolatilityType: "black"

```

### Create SABR Pricer Object

Use `finpricer` to create a `SABR` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', SabrModel, 'DiscountCurve', myRC)
```

```
outPricer =
  SABR with properties:
```

```

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.SABR]

```

## Price Swaption Instrument

Use price to compute the price for the Swaption instrument.

```
Price = price(outPricer,Swaption)
```

```
Price = 10.8558
```

## Price Swaption Instrument Using Black Model and Black Pricer

This example shows the workflow to price a Swaption instrument when you use a Black model and a Black pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
```

```
Type = 'zero';
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
    InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"

```

### Create Swap Instrument Object

Use fininstrument to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2027,3,15), 'LegRate', [0 0], 'LegType', ...
    ["float", "fixed"], 'Notional', 100, 'StartDate', datetime(2022,3,15), 'Name', "swap_instrument")
```

```
Swap =
```

```
Swap with properties:
```

```

        LegRate: [0 0]
        LegType: ["float"    "fixed"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
DaycountAdjustedCashFlow: [0 0]

```

```
        ProjectionCurve: [0x0 ratecurve]
    BusinessDayConvention: ["actual" "actual"]
        Holidays: NaT
    EndMonthRule: [1 1]
    StartDate: 15-Mar-2022
    Maturity: 15-Mar-2027
    Name: "swap_instrument"
```

### Create Swaption Instrument Object

Use `fininstrument` to create a `Swaption` instrument object.

```
Swaption = fininstrument("Swaption", 'Strike', 0.02, 'ExerciseDate', datetime(2022, 3, 15), 'Swap', Swap)
```

```
Swaption =
    Swaption with properties:

        OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Mar-2022
        Strike: 0.0200
        Swap: [1x1 fininstrument.Swap]
    Name: "swaption_option"
```

### Create Black Model Object

Use `finmodel` to create a `Black` model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.032, 'Shift', 0.002)
```

```
BlackModel =
    Black with properties:

        Volatility: 0.0320
        Shift: 0.0020
```

### Create Black Pricer Object

Use `finpricer` to create a `Black` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)
```

```
outPricer =
    Black with properties:

        Model: [1x1 finmodel.Black]
    DiscountCurve: [1x1 ratecurve]
```

### Price Swaption Instrument

Use `price` to compute the price for the `Swaption` instrument.

```
Price = price(outPricer, Swaption)
```

```
Price = 3.3116
```

### Price Swaption Instrument Using Hull-White Model and IRTree Pricer

This example shows the workflow to price a Swaption instrument when you use a HullWhite model and an IRTree pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

#### Create Swap Instrument Object

Use fininstrument to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2027,3,15), 'LegRate', [0 0], 'LegType', ...
    ["float", "fixed"], 'Notional', 100, 'StartDate', datetime(2022,3,15), 'Name', "swap_instrument")
```

```
Swap =
    Swap with properties:
        LegRate: [0 0]
        LegType: ["float" "fixed"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
        LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
        DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [0x0 ratecurve]
        BusinessDayConvention: ["actual" "actual"]
        Holidays: NaT
        EndMonthRule: [1 1]
        StartDate: 15-Mar-2022
        Maturity: 15-Mar-2027
```

```
Name: "swap_instrument"
```

### Create Swaption Instrument Object

Use `fininstrument` to create a Swaption instrument object.

```
Swaption = fininstrument("Swaption", 'Strike', 0.02, 'ExerciseDate', datetime(2022, 3, 15), 'Swap', Swap)
```

```
Swaption =
  Swaption with properties:
      OptionType: "call"
  ExerciseStyle: "european"
  ExerciseDate: 15-Mar-2022
      Strike: 0.0200
      Swap: [1x1 fininstrument.Swap]
      Name: "swaption_option"
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.032, 'Sigma', 0.04)
```

```
HullWhiteModel =
  HullWhite with properties:
      Alpha: 0.0320
      Sigma: 0.0400
```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("IRTree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', ZeroDates)
```

```
outPricer =
  HWBKTree with properties:
      Tree: [1x1 struct]
  TreeDates: [10x1 datetime]
      Model: [1x1 finmodel.HullWhite]
  DiscountCurve: [1x1 ratecurve]
```

### Price Swaption Instrument

Use `price` to compute the price and sensitivities for the Swaption instrument.

```
[Price, outPR] = price(outPricer, Swaption, ["all"])
```

```
Price = 14.6581
```

```
outPR =
  pricerresult with properties:
```

```
Results: [1x4 table]
PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
   Price      Vega      Gamma      Delta
   _____  _____  _____  _____
   14.658    321.44    -2261.6    142.2
```

### Calibrate Shifted SABR Model Parameters for Swaption Instrument

This example shows how to calibrate the shifted SABR model parameters for a Swaption instrument when you use a SABR pricing method.

#### Load Market Data

```
% Zero curve
ValuationDate = datetime("5-Mar-2016", 'Locale', 'en_US');
ZeroDates = datemnth(ValuationDate,[1 2 3 6 9 12*[1 2 3 4 5 6 7 8 9 10 12]]);
ZeroRates = [-0.33 -0.28 -0.24 -0.12 -0.08 -0.03 0.015 0.028 ...
             0.033 0.042 0.056 0.095 0.194 0.299 0.415 0.525]'/100;
Compounding = 1;
ZeroCurve = ratecurve("zero",ValuationDate,ZeroDates,ZeroRates,'Compounding',Compounding)

ZeroCurve =
    ratecurve with properties:

        Type: "zero"
    Compounding: 1
        Basis: 0
        Dates: [16x1 datetime]
        Rates: [16x1 double]
        Settle: 05-Mar-2016
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

```
% Define the swaptions
SwaptionSettle = datetime("5-Mar-2016", 'Locale', 'en_US');
SwaptionExerciseDate = datetime("5-Mar-2017", 'Locale', 'en_US');
SwaptionStrikes = (-0.6:0.01:1.6)'/100; % Include negative strikes
SwapMaturity = datetime("5-Mar-2022", 'Locale', 'en_US'); % Maturity of underlying swap
OptSpec = 'call';
```

#### Compute Forward Swap Rate by Creating Swap Instrument

Use `fininstrument` to create a Swap instrument object.

```
LegRate = [0 0];
Swap = fininstrument("Swap", 'Maturity', SwapMaturity, 'LegRate', LegRate, "LegType",["fixed" "f
    "ProjectionCurve", ZeroCurve, "StartDate", SwaptionExerciseDate)
```

```
Swap =
  Swap with properties:
      LegRate: [0 0]
      LegType: ["fixed" "float"]
      Reset: [2 2]
      Basis: [0 0]
      Notional: 100
      LatestFloatingRate: [NaN NaN]
      ResetOffset: [0 0]
      DaycountAdjustedCashFlow: [0 0]
      ProjectionCurve: [1x2 ratecurve]
      BusinessDayConvention: ["actual" "actual"]
      Holidays: NaT
      EndMonthRule: [1 1]
      StartDate: 05-Mar-2017
      Maturity: 05-Mar-2022
      Name: ""
```

```
ForwardValue = parswaprate(Swap,ZeroCurve)
```

```
ForwardValue = 7.3271e-04
```

### Load the Market Implied Volatility Data

The market swaption volatilities are quoted in terms of shifted Black volatilities with a 0.8 percent shift.

```
StrikeGrid = [-0.5; -0.25; -0.125; 0; 0.125; 0.25; 0.5; 1.0; 1.5]/100;
MarketStrikes = ForwardValue + StrikeGrid;
Shift = 0.008; % 0.8 percent shift
MarketShiftedBlackVolatilities = [21.1; 15.3; 14.0; 14.6; 16.0; 17.7; 19.8; 23.9; 26.2]/100;
ATMShiftedBlackVolatility = MarketShiftedBlackVolatilities(StrikeGrid==0);
```

### Calibrate Shifted SABR Model Parameters

The Beta parameter is predetermined at 0.5. Use volatilities to compute the implied volatility.

```
Beta = 0.5;
```

```
% Calibrate Alpha, Rho, and Nu
objFun = @(X) MarketShiftedBlackVolatilities - volatilities(finpricer("Analytic", 'Model', ...
    finmodel("SABR", 'Alpha', X(1), 'Beta', Beta, 'Rho', X(2), 'Nu', X(3), 'Shift', Shift), ...
    'DiscountCurve', ZeroCurve), SwaptionExerciseDate, ForwardValue, MarketStrikes);
```

```
X = lsqnonlin(objFun, [0.5 0 0.5], [0 -1 0], [Inf 1 Inf]);
```

Local minimum possible.

lsqnonlin stopped because the final change in the sum of squares relative to its initial value is less than the value of the function tolerance.

```
Alpha = X(1);
Rho = X(2);
Nu = X(3);
```

## Create SABR Model Using the Calibrated Parameters

Use `finmodel` to create a SABR model object.

```
SABRModel = finmodel("SABR", 'Alpha',Alpha, 'Beta',Beta, 'Rho',Rho, 'Nu',Nu, 'Shift',Shift)
```

```
SABRModel =
  SABR with properties:
      Alpha: 0.0135
      Beta: 0.5000
      Rho: 0.4654
      Nu: 0.4957
      Shift: 0.0080
  VolatilityType: "black"
```

## Create SABR Pricer Using Calibrated SABR Model and Compute Volatilities

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
SABRPricer = finpricer("Analytic", 'Model', SABRModel, 'DiscountCurve', ZeroCurve)
```

```
SABRPricer =
  SABR with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.SABR]
```

```
SABRShiftedBlackVolatilities = volatilities(SABRPricer, SwaptionExerciseDate, ForwardValue, Swap
```

```
SABRShiftedBlackVolatilities = 221x1
```

```
0.2978
0.2911
0.2848
0.2787
0.2729
0.2673
0.2620
0.2568
0.2518
0.2470
:
```

```
figure;
plot(MarketStrikes, MarketShiftedBlackVolatilities, 'o', ...
     SwapStrikes, SABRShiftedBlackVolatilities);
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)], 'LineStyle', '--');
ylim([0.13 0.31])
xlabel('Strike');
legend('Market quotes','Shifted SABR', 'location', 'southeast');
title(['Shifted Black Volatility (' ,num2str(Shift*100), ' percent shift)']);
```

### Price Swaption Instruments Using Calibrated SABR Model and SABR Pricer

```

% Create swaption instruments
NumInst = length(SwaptionStrikes);
Swaptions(NumInst, 1) = fininstrument("Swaption", ...
  'Strike', SwaptionStrikes(1), 'ExerciseDate', SwaptionExerciseDate(1), 'Swap', Swap);
for k = 1:NumInst
    Swaptions(k) = fininstrument("Swaption", 'Strike', SwaptionStrikes(k), ...
      'ExerciseDate', SwaptionExerciseDate, 'Swap', Swap, 'OptionType', OptSpec);
end
Swaptions

Swaptions=221x1 object
  16x1 Swaption array with properties:

    OptionType
    ExerciseStyle
    ExerciseDate
    Strike
    Swap
    Name
    :

% Price swaptions using the SABR pricer
SwaptionPrices = price(SABRPricer,Swaptions);

figure;

```

```

plot(SwaptionStrikes, SwaptionPrices, 'r');
h = gca;
line([0,0],[min(h.YLim),max(h.YLim)],'LineStyle','--');
xlabel('Strike');
title('Swaption Price');

```

## More About

### Call Swaption

A call swaption or payer swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option pays the fixed rate and receives the floating rate.

### Put Swaption

A put swaption or receiver swaption allows the option buyer to enter into an interest-rate swap in which the buyer of the option receives the fixed rate and pays the floating rate.

# Vanilla

Vanilla instrument object

## Description

Create and price a Vanilla instrument object using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a BlackScholes, Heston, Bates, Merton, or Dupire model for the Vanilla instrument.
- 3 When using a BlackScholes model, use `finpricer` to specify a FiniteDifference, , , BlackScholes, BjerksundStensland, RollGeskeWhaley, VannaVolga, or AssetMonteCarlo pricing method for the Vanilla instrument.

When using a Heston, Bates, or Merton model, use `finpricer` to specify a FiniteDifference, NumericalIntegration, FFT, or AssetMonteCarlo pricing method for the Vanilla instrument.

When using a Dupire model, use `finpricer` to specify a FiniteDifference pricing method for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
VanillaObj = fininstrument(InstrumentType, 'Strike', strike_value, '
ExerciseDate', exercise_date)
VanillaObj = fininstrument( ___, Name, Value)
```

### Description

`VanillaObj = fininstrument(InstrumentType, 'Strike', strike_value, 'ExerciseDate', exercise_date)` creates a Vanilla object by specifying `InstrumentType` and sets the properties on page 11-2465 for the required name-value pair arguments `Strike` and `ExerciseDate`. For more information on a Vanilla instrument, see “More About” on page 11-2482.

`VanillaObj = fininstrument( ___, Name, Value)` sets optional properties on page 11-2465 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `VanillaObj = fininstrument("Vanilla", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'OptionType', "put", 'ExerciseStyle', "American", 'Name', "vanilla_instrument")` creates a Vanilla put option with an American exercise. You can specify multiple name-value pair arguments.

**Input Arguments****InstrumentType — Instrument type**

string with value "Vanilla" | character vector with value 'Vanilla'

Instrument type, specified as a string with the value of "Vanilla" or a character vector with the value of 'Vanilla'.

Data Types: char | string

**Vanilla Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

Example: `VanillaObj =`

```
fininstrument("Vanilla", 'Strike', 100, 'ExerciseDate', datetime(2019,1,30), 'OptionType', "put", 'ExerciseStyle', "American", 'Name', "vanilla_instrument")
```

**Required Vanilla Name-Value Pair Arguments****Strike — Option strike price value**

nonnegative numeric | vector

Option strike price value, specified as the comma-separated pair consisting of 'Strike' and a scalar nonnegative numeric value.

---

**Note** When using a "Bermudan" `ExerciseStyle` with a `FiniteDifference` pricer, the `Strike` is a vector.

---

Data Types: double

**ExerciseDate — Option exercise date**datetime | serial date number | date character vector | date string | vector when `ExerciseStyle` is "Bermudan"

Option exercise date, specified as the comma-separated pair consisting of 'ExerciseDate' and a scalar datetime, serial date number, date character vector, or date string.

---

**Note** For a European option, there is only one `ExerciseDate` on the option expiry date.

---

When using a "Bermudan" `ExerciseStyle` with a `FiniteDifference` pricer, the `ExerciseDate` is a vector.

---

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ExerciseDate` property is stored as a datetime.

Data Types: double | char | string | datetime

**Optional Vanilla Name-Value Pair Arguments****OptionType — Option type**

"call" (default) | string with value "call" or "put" | character vector with value 'call' or 'put'

Option type, specified as the comma-separated pair consisting of 'OptionType' and a scalar string or character vector.

---

**Note** When you use a RollGeskeWhaley pricer with a Vanilla option, OptionType must be 'call'.

---

Data Types: char | string

### ExerciseStyle — Option exercise style

"European" (default) | string with value "European", "American", or "Bermudan" | character vector with value 'European', 'American', or 'Bermudan'

Option exercise style, specified as the comma-separated pair consisting of 'ExerciseStyle' and a scalar string or character vector.

---

### Note

- When you use a BlackScholes pricer with a Vanilla option, the 'American' option type is not supported.
- When you use a RollGeskeWhaley or a BjerksundStensland pricer with a Vanilla option, you must specify an 'American' option.
- When you use a NumericalIntegration pricer with a Bates, Merton, or Heston model for a Vanilla option, the ExerciseStyle must be 'European'.
- When you use a FFT pricer with a Bates, Merton, or Heston model for a Vanilla option, the ExerciseStyle must be 'European'.
- When you use an AssetMonteCarlo pricer with a BlackScholes, Bates, Merton, or Heston model for a Vanilla option, the ExerciseStyle can be 'American', 'European', or 'Bermudan'.
- When you use a FiniteDifference pricer with a BlackScholes, Dupire, Bates, Merton, or Heston model for a Vanilla option, the ExerciseStyle can be 'American', 'European', or 'Bermudan'.

For more information on ExerciseStyle, see “Supported Exercise Styles” on page 1-48.

---

Data Types: string | char

### Name — User-defined name for instrument

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## Properties

### Strike — Option strike price value

nonnegative numeric

Option strike price value, returned as a scalar nonnegative numeric value.

Data Types: double

**ExerciseDate — Option exercise date**

datetime

Option exercise date, returned as a datetime.

Data Types: datetime

**OptionType — Option type**

"call" (default) | string with value "call" or "put"

Option type, returned as a string with a value of "call" or "put".

Data Types: string

**ExerciseStyle — Option type**

"European" (default) | string with value "European", "American", or "Bermudan"

Option exercise style, returned as a string with a value of "European", "American", or "Bermudan".

Data Types: string

**Name — User-defined name for instrument**

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

**Object Functions**

`setExercisePolicy` Set exercise policy for `FixedBondOption`, `FloatBondOption`, or `Vanilla` instrument

**Examples****Price Vanilla Instrument Using Black-Scholes Model and Black-Scholes Pricer**

This example shows the workflow to price a `Vanilla` instrument when you use a `BlackScholes` model and a `BlackScholes` pricing method.

**Create Vanilla Instrument Object**

Use `fininstrument` to create a `Vanilla` instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2018,5,1), 'Strike', 29, 'OptionType',
```

```
VanillaOpt =  
    Vanilla with properties:
```

```
        OptionType: "put"  
        ExerciseStyle: "european"  
        ExerciseDate: 01-May-2018  
        Strike: 29  
        Name: "vanilla_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.2500
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
Rate = 0.05;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)
```

```
myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 1
    Dates: 01-Jan-2019
    Rates: 0.0500
    Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create BlackScholes Pricer Object

Use `finpricer` to create a BlackScholes pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', 30, 'I
```

```
outPricer =
  BlackScholes with properties:

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 30
    DividendValue: 0.0450
    DividendType: "continuous"
```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 1.2046
```

```

outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```

ans=1x7 table
  Price      Delta      Gamma      Lambda      Vega      Rho      Theta
  -----  -
  1.2046    -0.36943    0.086269   -9.3396     6.4702    -4.0959   -2.3107

```

### Price American Option for Vanilla Instrument Using Black-Scholes Model and Roll-Geske-Whaley Pricer

This example shows the workflow to price an American option for a Vanilla instrument when you use a BlackScholes model and a RollGeskeWhaley pricing method.

#### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'Strike', 105, 'ExerciseDate', datetime(2022, 9, 15), 'OptionType
```

```

VanillaOpt =
  Vanilla with properties:

    OptionType: "call"
    ExerciseStyle: "american"
    ExerciseDate: 15-Sep-2022
    Strike: 105
    Name: "vanilla_option"

```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", 0.2)
```

```

BlackScholesModel =
  BlackScholes with properties:

```

```

  Volatility: 0.2000
  Correlation: 1

```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018, 9, 15);
Maturity = datetime(2023, 9, 15);

```

```
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create RollGeskeWhaley Pricer Object

Use `finpricer` to create a `RollGeskeWhaley` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  RollGeskeWhaley with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: [1x1 timetable]
      DividendType: "cash"
```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 19.9066
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
      PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
19.907	0.66568	0.0090971	3.344	72.804	-3.4537	186.68

## Price a Vanilla Instrument for Foreign Exchange Using Black-Scholes Model and Black-Scholes Pricer

This example shows the workflow to price a Vanilla instrument for foreign exchange (FX) when you use a BlackScholes model and a BlackScholes pricing method. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', .50, 'OptionType')

VanillaOpt =
    Vanilla with properties:

        OptionType: "put"
        ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
        Strike: 0.5000
        Name: "vanilla_fx_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes", "Volatility", Sigma)

BlackScholesModel =
    BlackScholes with properties:

        Volatility: 0.1200
        Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)

myRC =
    ratecurve with properties:

        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument. When pricing currencies using a Vanilla instrument, the `DividendType` must be `'continuous'` and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```
ForeignRate = 0.08;
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', .52,
outPricer =
    BlackScholes with properties:
        DiscountCurve: [1x1 ratecurve]
        Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 0.5200
        DividendValue: 0.0800
        DividendType: "continuous"
```

### Price Vanilla FX Instrument

Use `price` to compute the price and sensitivities for the Vanilla FX instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
Price = 0.0738
outPR =
    pricerresult with properties:
        Results: [1x7 table]
        PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
0.073778	-0.49349	2.0818	-4.7899	0.27021	-1.3216	-0.013019

### Price American Option for Vanilla Instrument Using Black-Scholes Model and Asset Monte-Carlo Pricer

This example shows the workflow to price an American option for a Vanilla instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

#### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```

VanillaOpt = fininstrument("Vanilla", 'Strike', 105, 'ExerciseDate', datetime(2022, 9, 15), 'OptionType', 'call')
VanillaOpt =
    Vanilla with properties:
        OptionType: "call"
        ExerciseStyle: "american"
        ExerciseDate: 15-Sep-2022
        Strike: 105
        Name: "vanilla_option"

```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```

BlackScholesModel = finmodel("BlackScholes", "Volatility", 0.2)
BlackScholesModel =
    BlackScholes with properties:
        Volatility: 0.2000
        Correlation: 1

```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018, 9, 15);
Maturity = datetime(2023, 9, 15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2018
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", BlackScholesModel, 'SpotPrice', 105)
outPricer =
    GBMMonteCarlo with properties:
        DiscountCurve: [1x1 ratecurve]

```

```

    SpotPrice: 150
SimulationDates: 15-Sep-2022
    NumTrials: 1000
    RandomNumbers: []
        Model: [1x1 finmodel.BlackScholes]
    DividendType: "continuous"
    DividendValue: 0

```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 61.2010
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x7 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
61.201	0.93074	0.0027813	2.2812	313.95	-3.7909	41.626

### Price American Option for Vanilla Instrument Using Heston Model and Asset Monte-Carlo Pricer

This example shows the workflow to price an American option for a Vanilla instrument when you use a Heston model and an `AssetMonteCarlo` pricing method.

#### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'Strike', 105, 'ExerciseDate', datetime(2022,9,15), 'OptionType
```

```
VanillaOpt =
    Vanilla with properties:
```

```

    OptionType: "call"
    ExerciseStyle: "american"
    ExerciseDate: 15-Sep-2022
    Strike: 105
    Name: "vanilla_option"

```

#### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.07, 'Kappa', 0.003, 'SigmaV', 0.02, 'RhoSV', 0.0)

HestonModel =
  Heston with properties:

      V0: 0.0320
    ThetaV: 0.0700
      Kappa: 0.0030
    SigmaV: 0.0200
    RhoSV: 0.0900
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)

myRC =
  ratecurve with properties:

      Type: "zero"
    Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use finpricer to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", HestonModel, 'SpotPrice', 150)

outPricer =
  HestonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 150
    SimulationDates: 15-Sep-2022
      NumTrials: 1000
    RandomNumbers: []
      Model: [1x1 finmodel.Heston]
    DividendType: "continuous"
    DividendValue: 0
```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 60.5637
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x8 table]
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x8 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
60.564	0.94774	0.0011954	2.3473	326.36	-3.7126	35.272	0.31155

### Price Bermudan Option for Vanilla Instrument Using Black-Scholes Model and Finite Difference Pricer

This example shows the workflow to price a Bermudan option for a Vanilla instrument when you use a BlackScholes model and a FiniteDifference pricing method.

#### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'Strike', [110,120], 'ExerciseDate', [datetime(2022,9,15) ; da
```

```
VanillaOpt =
  Vanilla with properties:
```

```
    OptionType: "call"
  ExerciseStyle: "bermudan"
    ExerciseDate: [15-Sep-2022    15-Sep-2023]
        Strike: [110 120]
        Name: "vanilla_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", 0.2)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
    Volatility: 0.2000
    Correlation: 1
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create FiniteDifference Pricer Object

Use `finpricer` to create a `FiniteDifference` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("FiniteDifference", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 100)

```

```

outPricer =
  FiniteDifference with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      GridProperties: [1x1 struct]
      DividendType: "continuous"
      DividendValue: 0

```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```

[Price, outPR] = price(outPricer, VanillaOpt, ["all"])

```

```

Price = 17.3930

```

```

outPR =
  pricerresult with properties:

```

```

      Results: [1x7 table]
      PricerData: [1x1 struct]

```

```

outPR.Results

```

```

ans=1x7 table

```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
_____	_____	_____	_____	_____	_____	_____

17.393    0.58203    0.008905    3.3463    -3.1757    203.94    87.324

## Price Vanilla Instrument Using Heston Model and Multiple Different Pricers

This example shows the workflow to price a Vanilla instrument when you use a Heston model and various pricing methods.

### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
Settle = datetime(2017,6,29);
Maturity = datemnth(Settle,6);
Strike = 80;
VanillaOpt = fininstrument('Vanilla','ExerciseDate',Maturity,'Strike',Strike,'Name',"vanilla_opt");
```

```
VanillaOpt =
  Vanilla with properties:

      OptionType: "call"
  ExerciseStyle: "european"
  ExerciseDate: 29-Dec-2017
        Strike: 80
          Name: "vanilla_option"
```

### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
V0 = 0.04;
ThetaV = 0.05;
Kappa = 1.0;
SigmaV = 0.2;
RhoSV = -0.7;

HestonModel = finmodel("Heston",'V0',V0,'ThetaV',ThetaV,'Kappa',Kappa,'SigmaV',SigmaV,'RhoSV',RhoSV);
```

```
HestonModel =
  Heston with properties:

      V0: 0.0400
  ThetaV: 0.0500
    Kappa: 1
  SigmaV: 0.2000
  RhoSV: -0.7000
```

### Create ratecurve object

Create a ratecurve object using `ratecurve`.

```
Rate = 0.03;
ZeroCurve = ratecurve('zero',Settle,Maturity,Rate);
```

### Create NumericalIntegration, FFT, and FiniteDifference Pricer Objects

Use `finpricer` to create a `NumericalIntegration`, `FFT`, and `FiniteDifference` pricer objects and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
SpotPrice = 80;
Strike = 80;
DividendYield = 0.02;
```

```
NIPricer = finpricer("NumericalIntegration", 'Model', HestonModel, 'SpotPrice', SpotPrice, 'DiscountCurve', ratecurve);
```

```
NIPricer =
    NumericalIntegration with properties:

        Model: [1x1 finmodel.Heston]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 80
    DividendType: "continuous"
    DividendValue: 0.0200
        AbsTol: 1.0000e-10
        RelTol: 1.0000e-10
    IntegrationRange: [1.0000e-09 Inf]
    CharacteristicFcn: @characteristicFcnHeston
        Framework: "heston1993"
    VolRiskPremium: 0
        LittleTrap: 1
```

```
FFTPricer = finpricer("FFT", 'Model', HestonModel, ...
    'SpotPrice', SpotPrice, 'DiscountCurve', ZeroCurve, ...
    'DividendValue', DividendYield, 'NumFFT', 8192)
```

```
FFTPricer =
    FFT with properties:
```

```
        Model: [1x1 finmodel.Heston]
    DiscountCurve: [1x1 ratecurve]
        SpotPrice: 80
    DividendType: "continuous"
    DividendValue: 0.0200
        NumFFT: 8192
    CharacteristicFcnStep: 0.0100
        LogStrikeStep: 0.0767
    CharacteristicFcn: @characteristicFcnHeston
        DampingFactor: 1.5000
        Quadrature: "simpson"
    VolRiskPremium: 0
        LittleTrap: 1
```

```
FDPricer = finpricer("FiniteDifference", 'Model', HestonModel, 'SpotPrice', SpotPrice, 'DiscountCurve', ratecurve);
```

```
FDPricer =
    FiniteDifference with properties:

        DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.Heston]
        SpotPrice: 80
    GridProperties: [1x1 struct]
```

```
DividendType: "continuous"
DividendValue: 0.0200
```

### Price Vanilla Instrument

Use the following sensitivities when pricing the Vanilla instrument.

```
InpSensitivity = ["delta", "gamma", "theta", "rho", "vega", "vegalt"];
```

Use price to compute the price and sensitivities for the Vanilla instrument that uses the NumericalIntegration pricer.

```
[PriceNI, outPR_NI] = price(NIPricer, VanillaOpt, InpSensitivity)
```

```
PriceNI = 4.7007
```

```
outPR_NI =
  pricerresult with properties:
```

```
    Results: [1x7 table]
    PricerData: []
```

Use price to compute the price and sensitivities for the Vanilla instrument that uses the FFT pricer.

```
[PriceFFT, outPR_FFT] = price(FFTPricer, VanillaOpt, InpSensitivity)
```

```
PriceFFT = 4.7007
```

```
outPR_FFT =
  pricerresult with properties:
```

```
    Results: [1x7 table]
    PricerData: []
```

Use price to compute the price and sensitivities for the Vanilla instrument that uses the FiniteDifference pricer.

```
[PriceFD, outPR_FD] = price(FDPricer, VanillaOpt, InpSensitivity)
```

```
PriceFD = 4.7003
```

```
outPR_FD =
  pricerresult with properties:
```

```
    Results: [1x7 table]
    PricerData: [1x1 struct]
```

Aggregate the price results.

```
[outPR_NI.Results; outPR_FFT.Results; outPR_FD.Results]
```

```
ans=3x7 table
```

Price	Delta	Gamma	Theta	Rho	Vega	VegaLT
_____	_____	_____	_____	_____	_____	_____

4.7007	0.57747	0.03392	-4.8474	20.805	17.028	5.2394
4.7007	0.57747	0.03392	-4.8474	20.805	17.028	5.2394
4.7003	0.57722	0.035254	-4.8483	20.801	17.046	5.2422

### Compute Option Price Surfaces

Use the price function for the NumericalIntegration pricer and the price function for the FFT pricer to compute the prices for a range of Vanilla instruments.

```

Maturities = datemnth(Settle,(3:3:24)');
NumMaturities = length(Maturities);
Strikes = (20:10:160)';
NumStrikes = length(Strikes);

[Maturities_Full,Strikes_Full] = meshgrid(Maturities,Strikes);

NumInst = numel(Strikes_Full);
VanillaOptions(NumInst, 1) = fininstrument("vanilla",...
    "ExerciseDate", Maturities_Full(1), "Strike", Strikes_Full(1));
for instidx=1:NumInst
    VanillaOptions(instidx) = fininstrument("vanilla",...
        "ExerciseDate", Maturities_Full(instidx), "Strike", Strikes_Full(instidx));
end

Prices_NI = price(NIPricer, VanillaOptions);
Prices_FFT = price(FFTPricer, VanillaOptions);

figure;
surf(Maturities_Full,Strikes_Full,reshape(Prices_NI,[NumStrikes,NumMaturities]));
title('Price (Numerical Integration)');
view(-112,34);
xlabel('Maturity')
ylabel('Strike')

```

```
figure;  
surf(Maturities_Full, Strikes_Full, reshape(Prices_FFT, [NumStrikes, NumMaturities]));  
title('Price (FFT)');  
view(-112, 34);  
xlabel('Maturity');  
ylabel('Strike');
```

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(St - K, 0)$
- For a put:  $\max(K - St, 0)$

where:

$St$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see "Vanilla Option" on page 3-26.

## Tips

After creating a `Vanilla` instrument object, you can use `setExercisePolicy` to change the size of the options. For example, if you have the following instrument:

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2021,5,1), 'Strike', 29, 'OptionType', 'P')
```

To modify the `Vanilla` instrument's size by changing the `ExerciseStyle` from "European" to "American", use `setExercisePolicy`:

```
VanillaOpt = setExercisePolicy(VanillaOpt, [datetime(2021,1,1) datetime(2022,1,1)], 100, 'American', 'P')
```

### Introduced in R2020a

# Deposit

Deposit instrument object

## Description

Create and price a `Deposit` instrument object using this workflow:

- 1 Use `fininstrument` to create a `Deposit` instrument object.
- 2 Use `ratecurve` to specify an interest-rate model for the `Deposit` instrument.
- 3 Use `finpricer` to specify a `Discount` pricing method for the `Deposit` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available models and pricing methods for a `Deposit` instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
DepositObj = fininstrument(InstrumentType, 'Maturity', maturity_date, '
Rate', rate_value)
DepositObj = fininstrument( ____, Name, Value)
```

### Description

`DepositObj = fininstrument(InstrumentType, 'Maturity', maturity_date, 'Rate', rate_value)` creates a `Deposit` object by specifying `InstrumentType` and sets the properties on page 11-2487 for the required name-value pair arguments `Maturity` and `Rate`.

`DepositObj = fininstrument( ____, Name, Value)` sets optional properties on page 11-2487 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `DepositObj = fininstrument("Deposit", 'Maturity', datetime(2019,1,30), 'Rate', 0.027, 'Period', 2, 'Basis', 1, 'Principal', 100, 'BusinessDayConvention', "follow", 'Name', "deposit_instrument")` creates a `Deposit` instrument with an interest rate of .027 and a maturity of January 30, 2019. You can specify multiple name-value pair arguments.

### Input Arguments

#### InstrumentType — Instrument type

string with value "Deposit" | character vector with value 'Deposit'

Instrument type, specified as a string with the value of "Deposit" or a character vector with the value of 'Deposit'.

Data Types: char | string

### Deposit Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: DepositObj =
fininstrument("Deposit", 'Maturity', datetime(2019,1,30), 'Rate', 0.027, 'Period',
2, 'Basis', 1, 'Principal', 100, 'BusinessDayConvention', "follow", 'Name', "deposit_
instrument")
```

### Required Deposit Name-Value Pair Arguments

#### Maturity — Maturity date

`datetime` | serial date number | date character vector | date string

Maturity date, specified as the comma-separated pair consisting of `'Maturity'` and a `datetime`, serial date number, date character vector, or date string.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Maturity` property is stored as a `datetime`.

Data Types: `char` | `double` | `string` | `datetime`

#### Rate — Deposit interest rate

decimal

Deposit interest rate, specified as the comma-separated pair consisting of `'Rate'` and a scalar decimal.

Data Types: `double`

### Optional Deposit Name-Value Pair Arguments

#### Period — Frequency of payments per year

1 (default) | numeric value of 0, 1, 2, 3, 4, 6, or 12

Frequency of payments per year, specified as the comma-separated pair consisting of `'Period'` and scalar integer. Values for `Period` are: 0, 1, 2, 3, 4, 6, or 12.

Data Types: `double`

#### Basis — Day count basis

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer using one of the following values:

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)

- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: `double`

### **Principal — Principal amount**

100 (default) | `numeric`

Principal amount, specified as the comma-separated pair consisting of 'Principal' and a scalar numeric.

Data Types: `double`

### **BusinessDayConvention — Business day convention**

"actual" (default) | `string` | `character vector`

Business day convention, specified as the comma-separated pair consisting of 'BusinessDayConvention' and a string or character vector. The selection for business day convention determines how nonbusiness days are treated. Nonbusiness days are defined as weekends plus any other date that businesses are not open (for example, statutory holidays). Values are:

- "actual" — Nonbusiness days are effectively ignored. Cash flows that fall on nonbusiness days are assumed to be distributed on the actual date.
- "follow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day.
- "modifiedfollow" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the following business day. However if the following business day is in a different month, the previous business day is adopted instead.
- "previous" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day.
- "modifiedprevious" — Cash flows that fall on a nonbusiness day are assumed to be distributed on the previous business day. However if the previous business day is in a different month, the following business day is adopted instead.

Data Types: `char` | `string`

### **Holidays — Holidays used in computing business days**

NaT (default) | `datetime` | `cell array of character vectors` | `date string array` | `serial date numbers`

Holidays used in computing business days, specified as the comma-separated pair consisting of 'Holidays' and dates using datetimes, serial date numbers, cell array of date character vectors, or date string array. For example:

```
H = holidays(datetime('today'),datetime(2025,12,15));  
DepositObj = fininstrument("deposit",'Maturity',datetime(2025,12,15),'Rate',0.027,'Holidays',H)
```

Data Types: double | cell | datetime | string

### **Name — User-defined name for instrument**

" " (default) | string | character vector

User-defined name for the instrument, specified as the comma-separated pair consisting of 'Name' and a scalar string or character vector.

Data Types: char | string

## **Properties**

### **Maturity — Maturity date**

datetime

Maturity date, returned as a datetime.

Data Types: datetime

### **Rate — Deposit interest rate**

decimal

Deposit interest rate, returned as a scalar decimal.

Data Types: double

### **Period — Frequency of payments per year**

1 (default) | integer

Frequency of payments per year, returned as a scalar integer.

Data Types: double

### **Basis — Day count basis**

0 (actual/actual) (default) | integer from 0 to 13

Day count basis, returned as a scalar integer.

Data Types: double

### **Principal — Principal amount**

100 (default) | numeric

Principal amount, returned as a scalar numeric.

Data Types: double

### **BusinessDayConvention — Business day convention**

"actual" (default) | string

Business day convention, returned as a string.

Data Types: string

### **Holidays — Holidays used in computing business days**

NaT (default) | datetime

Holidays used in computing business days, returned as datetimes.

Data Types: datetime

### Name — User-defined name for instrument

" " (default) | string

User-defined name for the instrument, returned as a string.

Data Types: string

## Object Functions

cashflows Computes cash flow for FixedBond, FloatBond, Swap, FRA, or Deposit instrument

## Examples

### Price Deposit Instrument Using ratecurve and Discount Pricer

This example shows the workflow to price a Deposit instrument when using a ratecurve and a Discount pricing method.

#### Create Deposit Instrument Object

Use `fininstrument` to create a Deposit instrument object.

```
DepositObj = fininstrument("Deposit", 'Maturity', datetime(2019,3,15), 'Rate', 0.0195, 'Period', 2, 'Ba
```

```
DepositObj =
```

```
Deposit with properties:
```

```

        Rate: 0.0195
        Period: 2
        Basis: 1
        Maturity: 15-Mar-2019
        Principal: 100
        BusinessDayConvention: "actual"
        Holidays: NaT
        Name: "deposit_instrument"

```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
```

```
Type = 'zero';
```

```
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
```

```
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
```

```
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```
    Type: "zero"
```

```

    Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"

```

## Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve',myRC)
```

```

outPricer =
  Discount with properties:
    DiscountCurve: [1x1 ratecurve]

```

## Price Deposit Instrument

Use `price` to compute the price and sensitivities for the Deposit instrument.

```
[Price, outPR] = price(outPricer, DepositObj,["all"])
```

```
Price = 0.9725
```

```

outPR =
  pricerresult with properties:
    Results: [1x2 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
0.97249	4.8225e-05

## More About

### Deposit Instrument

A deposit instrument is an over-the-counter contract between banks for interbank lending.

### Functions

`finmodel` | `finpricer`

**Topics**

“Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22

“Choose Instruments, Models, and Pricers” on page 1-43

**Introduced in R2020a**

## Bates

Create Bates model object for Vanilla, Asian, Barrier, DoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument

## Description

Create and price a Vanilla, Asian, Barrier, DoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument object with a Bates model using this workflow:

- 1 Use `fininstrument` to create a Vanilla, Barrier, Lookback, Asian, DoubleBarrier, Binary, Touch, or DoubleTouch instrument object.
- 2 Use `finmodel` to specify a Bates model object for the Vanilla, Asian, Barrier, DoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument.
- 3 Use `finpricer` to specify a FiniteDifference, NumericalIntegration, or FFT pricing method for the Vanilla instrument.

Use `finpricer` to specify an AssetMonteCarlo pricing method for the Vanilla, Asian, Barrier, DoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla, Asian, Barrier, DoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
BatesObj = finmodel(ModelType, 'V0', V0_value, 'ThetaV', thetav_value, 'Kappa', kappa_value, 'SigmaV', sigmav_value, 'RhoSV', rhosv_value, 'MeanJ', meanj_value, 'JumpVol', jumpvol_value, 'JumpFreq', jumpfreq_value)
```

### Description

`BatesObj = finmodel(ModelType, 'V0', V0_value, 'ThetaV', thetav_value, 'Kappa', kappa_value, 'SigmaV', sigmav_value, 'RhoSV', rhosv_value, 'MeanJ', meanj_value, 'JumpVol', jumpvol_value, 'JumpFreq', jumpfreq_value)` creates an Bates object by specifying `ModelType` and the required name-value pair arguments `V0`, `ThetaV`, `Kappa`, `SigmaV`, `RhoSV`, `MeanJ`, `JumpVol`, and `JumpFreq`. The required name-value pair arguments set properties on page 11-2493. For example, `BatesObj = finmodel("Bates", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9, 'MeanJ', 0.11, 'JumpVol', .023, 'JumpFreq', 0.02)` creates a Bates model object.

## Input Arguments

### ModelType — Model type

string with value "Bates" | character vector with value 'Bates'

Model type, specified as a string with the value of "Bates" or a character vector with the value of 'Bates'.

Data Types: char | string

### Bates Name-Value Pair Arguments

Specify required comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: Bates =

```
finmodel("Bates", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9, 'MeanJ', 0.11, 'JumpVol', .023, 'JumpFreq', 0.02)
```

### V0 — Initial variance of underlying asset

numeric

Initial variance of the underlying asset, specified as the comma-separated pair consisting of 'V0' and a scalar numeric value.

Data Types: double

### ThetaV — Long-term variance of underlying asset

numeric

Long-term variance of the underlying asset, specified as the comma-separated pair consisting of 'ThetaV' and a scalar numeric value.

Data Types: double

### Kappa — Mean revision speed for the variance of underlying asset

numeric

Mean revision speed for the underlying asset, specified as the comma-separated pair consisting of 'Kappa' and a scalar numeric value.

Data Types: double

### SigmaV — Volatility of the variance of underlying asset

numeric

Volatility of the variance of the underlying asset, specified as the comma-separated pair consisting of 'SigmaV' and a scalar numeric value.

Data Types: double

### RhoSV — Correlation between Weiner processes for underlying asset and its variance

numeric

Correlation between the Weiner processes for the underlying asset and its variance, specified as the comma-separated pair consisting of 'RhoSV' and a scalar numeric value.

Data Types: double

### **MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as the comma-separated pair consisting of 'MeanJ' and a scalar decimal value where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

### **JumpVol — Standard deviation of $\log(1+J)$**

decimal

Standard deviation of  $\log(1+J)$ , where  $J$  is the random percentage jump size, specified as the comma-separated pair consisting of 'JumpVol' and a scalar decimal value.

Data Types: double

### **JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of the Poisson jump process, specified as the comma-separated pair consisting of 'JumpFreq' and a scalar numeric value.

Data Types: double

## **Properties**

### **V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

### **ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

### **Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, returned as a scalar numeric value.

Data Types: double

### **SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

**RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, returned as a scalar numeric value.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), returned as a scalar decimal value.

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$ , where  $J$  is the random percentage jump size, returned as a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of the Poisson jump process, returned as a scalar numeric value.

Data Types: double

**Examples****Use a Bates Model and Numerical Integration Pricer to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Bates model and a NumericalIntegration pricing method.

**Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType
```

```
VanillaOpt =
```

```
Vanilla with properties:
```

```
    OptionType: "put"  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2022  
    Strike: 105  
    Name: "vanilla_option"
```

**Create Bates Model Object**

Use `finmodel` to create a Bates model object.

```
BatesModel = finmodel("Bates", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9, 'Me
```

```
BatesModel =
  Bates with properties:
```

```

    V0: 0.0320
  ThetaV: 0.1000
    Kappa: 0.0030
  SigmaV: 0.2000
  RhoSV: 0.9000
  MeanJ: 0.1100
  JumpVol: 0.0230
  JumpFreq: 0.0200
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
```

```

          Type: "zero"
  Compounding: -1
          Basis: 12
          Dates: 15-Sep-2023
          Rates: 0.0350
          Settle: 15-Sep-2018
  InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

### Create NumericalIntegration Pricer Object

Use `finpricer` to create a `NumericalIntegration` pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("numericalintegration", 'DiscountCurve', myRC, 'Model', BatesModel, 'SpotPrice')
```

```
outPricer =
  NumericalIntegration with properties:
```

```

          Model: [1x1 finmodel.Bates]
  DiscountCurve: [1x1 ratecurve]
          SpotPrice: 100
  DividendType: "continuous"
  DividendValue: 0
          AbsTol: 1.0000e-10
          RelTol: 1.0000e-10
  IntegrationRange: [1.0000e-09 Inf]
  CharacteristicFcn: @characteristicFcnBates
          Framework: "heston1993"
  VolRiskPremium: 0
```

```
LittleTrap: 1
```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 6.4007
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x7 table]
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Theta	Rho	Vega	VegaLT
6.4007	-0.53541	0.02006	1.106	-239.77	94.257	1.3059

### Use Bates Model and Asset Monte-Carlo Pricer to Price Asian Instrument

This example shows the workflow to price a fixed-strike Asian instrument when you use a Bates model and an `AssetMonteCarlo` pricing method.

#### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 100, 'OptionType', "put")
```

```
AsianOpt =
  Asian with properties:
```

```
    OptionType: "put"
      Strike: 100
  AverageType: "arithmetic"
  AveragePrice: 0
  AverageStartDate: NaT
  ExerciseStyle: "european"
  ExerciseDate: 15-Sep-2022
      Name: "asian_option"
```

#### Create Bates Model Object

Use `finmodel` to create a Bates model object.

```
BatesModel = finmodel("Bates", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.02, 'RhoSV', 0.9, 'M
```

```

BatesModel =
  Bates with properties:
      V0: 0.0320
      ThetaV: 0.1000
      Kappa: 0.0030
      SigmaV: 0.0200
      RhoSV: 0.9000
      MeanJ: 0.1100
      JumpVol: 0.0230
      JumpFreq: 0.0200

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
myRC =
  ratecurve with properties:

```

```

      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use finpricer to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("AssetMonteCarlo","DiscountCurve",myRC,"Model",BatesModel,'SpotPrice',80,'

```

```

outPricer =
  BatesMonteCarlo with properties:
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 80
      SimulationDates: 15-Sep-2022
      NumTrials: 1000
      RandomNumbers: []
      Model: [1x1 finmodel.Bates]
      DividendType: "continuous"
      DividendValue: 0

```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 14.5689
```

```
outPR =
```

```
  pricerresult with properties:
```

```
    Results: [1x8 table]
```

```
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x8 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
14.569	-0.7137	0.0137	-3.919	-172.1	0.77965	26.779	0.2576

# Black

Create Black model object for Cap, Floor, or Swaption instrument

## Description

Create and price a Cap, Floor, or Swaption instrument object with a Black model using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, or Swaption instrument object.
- 2 Use `finmodel` to specify a Black model object for the Cap, Floor, or Swaption instrument.
- 3 Use `finpricer` to specify a Black pricing method for the Cap, Floor, or Swaption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Cap, Floor, or Swaption instrument when using a Black model, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
BlackModelObj = finmodel(ModelType,'Volatility',volatility_value)
BlackModelObj = finmodel( ___,Name,Value)
```

### Description

`BlackModelObj = finmodel(ModelType,'Volatility',volatility_value)` creates a Black model object by specifying `ModelType` and sets the properties on page 11-2500 for the required name-value pair argument `Volatility`. For more information on a Black model, see “More About” on page 11-2502 and “Algorithms” on page 11-2502.

`BlackModelObj = finmodel( ___,Name,Value)` sets optional properties on page 11-2500 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BlackModelObj = finmodel("Black",'Volatility',0.032,'Shift',0.002)` creates a Black model object. You can specify multiple name-value pair arguments.

### Input Arguments

#### ModelType — Model type

string with value "Black" | character vector with value 'Black'

Model type, specified as a string with the value of "Black" or a character vector with the value of 'Black'.

Data Types: char | string

### Black Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `BlackModelObj = finmodel("Black", 'Volatility', 0.032, 'Shift', 0.002)`

### Required Black Name-Value Pair Arguments

#### **Volatility — Volatility value for the underlying asset**

nonnegative numeric

Volatility value for the underlying asset, specified as the comma-separated pair consisting of `'Volatility'` and a scalar nonnegative numeric.

Data Types: `double`

### Optional Black Name-Value Pair Argument

#### **Shift — Shift in decimals for shifted Black model**

0 (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, specified as the comma-separated pair consisting of `'Shift'` and a scalar rate shift in positive decimals. Set this parameter to a positive rate shift in decimals to add a positive shift to the forward rate and strike, which effectively sets a negative lower bound for the forward rate. For example, a `Shift` value of `0.01` is equal to a 1% shift.

Data Types: `double`

## Properties

#### **Volatility — Volatility value**

nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: `double`

#### **Shift — Shift in decimals for shifted Black model**

0 (no shift) (default) | positive decimal

Shift in decimals for the shifted Black model, returned as a scalar rate shift in a positive decimal.

Data Types: `double`

## Examples

### **Use Black Model and Black Pricer to Price Cap Instrument**

This example shows the workflow to price a Cap instrument when you use a Black model and a Black pricing method.

#### **Create Cap Instrument Object**

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', .001, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Principal', ...
```

```
CapOpt =
  Cap with properties:
      Strike: 1.0000e-03
      Maturity: 30-Jan-2019
      ResetOffset: 0
      Reset: 4
      Basis: 8
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "cap_option"
```

### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.032, 'Shift', 0.002)
```

```
BlackModel =
  Black with properties:
      Volatility: 0.0320
      Shift: 0.0020
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Black Pricer Object

Use `finpricer` to create a Black pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)

outPricer =
    Black with properties:
        Model: [1x1 finmodel.Black]
        DiscountCurve: [1x1 ratecurve]
```

### Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
Price = price(outPricer, CapOpt)

Price = 0.1575
```

## More About

### Shifted Black Model

The shifted Black model is the same as the Black model, except that it models the movements of ( $F + \text{Shift}$ ) as the underlying asset, instead of  $F$  (which is the forward rate in the case of caplets).

This model allows negative rates, with a fixed negative lower bound defined by the amount of shift; that is, the zero lower bound of the Black model is shifted.

## Algorithms

### Black Model

$$dF = \sigma_{Black} F dw$$

$$call = e^{-vT} [FN(d_1) - KN(d_2)]$$

$$put = e^{-vT} [KN(-d_2) - FN(-d_1)]$$

$$d_1 = \frac{\ln\left(\frac{F}{K}\right) + \left(\frac{\sigma_B^2}{2}\right)T}{\sigma_B \sqrt{T}}, \quad d_2 = d_1 - \sigma_B \sqrt{T}$$

$$\sigma_B = \sigma_{Black}$$

Here,  $F$  is the forward value and  $K$  is the strike.

**Shifted Black Model**

$$dF = \sigma_{\text{Shifted\_Black}}(F + \text{Shift})dw$$

$$\text{call} = e^{-\nu T}[(F + \text{Shift})N(d_{s1}) - (K + \text{Shift})N(d_{s2})]$$

$$\text{put} = e^{-\nu T}[(K + \text{Shift})N(-d_{s2}) - (F + \text{Shift})N(-d_{s1})]$$

$$d_{s1} = \frac{\ln\left(\frac{F + \text{Shift}}{K + \text{Shift}}\right) + \left(\frac{\sigma_{sB}^2}{2}\right)T}{\sigma_{sB}\sqrt{T}}, \quad d_{s2} = d_{s1} - \sigma_{sB}\sqrt{T}$$

$$\sigma_{sB} = \sigma_{\text{Shifted\_Black}}$$

Here,  $F + \text{Shift}$  is the forward value and  $K + \text{Shift}$  is the strike for the shifted version.

# CDSBlack

Create CDSBlack model object for CDSOption instrument

## Description

Create and price a CDSOption instrument object with a CDSBlack model using this workflow:

- 1 Use `fininstrument` to create a CDSOption instrument object.
- 2 Use `finmodel` to specify a CDSBlack model object for the CDSOption instrument.
- 3 Use `finpricer` to specify a CDSBlack pricing method for the CDSOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a CDSOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
CDSBlackModelObj = finmodel(ModelType, 'SpreadVolatility', spreadvolatility_value)
```

### Description

`CDSBlackModelObj = finmodel(ModelType, 'SpreadVolatility', spreadvolatility_value)` creates a CDSBlack model object by specifying `ModelType` and the required name-value pair argument `SpreadVolatility` to set the properties on page 11-2505 using name-value pair arguments. For example, `CDSBlackModelObj = finmodel("CDSBlack", 'SpreadVolatility', 0.052)` creates a CDSBlack model object.

### Input Arguments

#### ModelType — Model type

string with value "CDSBlack" | character vector with value 'CDSBlack'

Model type, specified as a string with the value of "CDSBlack" or a character vector with the value of 'CDSBlack'.

Data Types: char | string

#### CDSBlack Name-Value Pair Arguments

Specify required comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `CDSBlackModelObj = finmodel("CDSBlack", 'SpreadVolatility', 0.052)`

**SpreadVolatility — Spread volatility value**

nonnegative numeric

Spread volatility value, specified as the comma-separated pair consisting of 'SpreadVolatility' and a scalar nonnegative numeric.

Data Types: double

**Properties****SpreadVolatility — Spread volatility value**

nonnegative numeric

Spread volatility value, returned as a scalar nonnegative numeric.

Data Types: double

**Examples****Use CDS Black Model and CDS Black Pricer to Price CDS Option Instrument**

This example shows the workflow to price a CDSOption instrument when you use a CDSBlack model and a CDSBlack pricing method.

**Create CDS Instrument Object**

Use `fininstrument` to create a CDS instrument object as the underlying instrument.

```
CDS = fininstrument("CDS", 'Maturity', datetime(2021,9,15), 'ContractSpread', 150, 'Notional', 100, 'Name', 'CDS')
```

```
CDS =
```

```
  CDS with properties:
```

```
      ContractSpread: 150
      Maturity: 15-Sep-2021
      Period: 4
      Basis: 2
      RecoveryRate: 0.4000
      BusinessDayConvention: "actual"
      Holidays: NaT
      PayAccruedPremium: 1
      Notional: 100
      Name: "CDS_instrument"
```

**Create defprobcurve Object**

Create a `defprobcurve` object using `defprobcurve`.

```
Settle = datetime(2020,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities, 'Basis', 5)
```

```
DefaultProbCurve =
```

```
  defprobcurve with properties:
```

```

        Settle: 20-Sep-2020
        Basis: 5
        Dates: [10x1 datetime]
DefaultProbabilities: [10x1 double]

```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```

Settle = datetime(2020,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)

```

```

myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2020
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"

```

### Create CDSOption Instrument Object

Use `fininstrument` to create a CDSOption instrument object.

```

CDSOptionInst = fininstrument("CDSOption", 'ExerciseDate', datetime(2021,8,15), 'Strike', 20, 'CDS', C

```

```

CDSOptionInst =
    CDSOption with properties:
        OptionType: "put"
        Strike: 20
        Knockout: 0
        ExerciseDate: 15-Aug-2021
        CDS: [1x1 fininstrument.CDS]
        Name: "CDSoption_option"

```

### Create CDSBlack Model Object

Use `finmodel` to create a CDSBlack model object.

```

CDSBlackModel = finmodel("CDSBlack", 'SpreadVolatility', .2)

```

```

CDSBlackModel =
    CDSBlack with properties:
        SpreadVolatility: 0.2000

```

## Create CDSBlack Pricer Object

Use `finpricer` to create a CDSBlack pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', CDSBlackModel, 'DefaultProbabilityCurve', DefaultProbCurve)
outPricer =
    CDSBlack with properties:
        Model: [1x1 finmodel.CDSBlack]
        DiscountCurve: [1x1 ratecurve]
        DefaultProbabilityCurve: [1x1 defprobcurve]
```

## Price CDSOption Instrument

Use `price` to compute the price for the CDSOption instrument.

```
Price = price(outPricer, CDSOptionInst)
```

```
Price = 3.3016e-04
```

## Introduced in R2020a

## BlackScholes

Create BlackScholes model object for an Asian, Barrier, DoubleBarrier, Lookback, Spread, Vanilla, Touch, DoubleTouch, or Binary instrument

### Description

Create and price a Vanilla, Lookback, Barrier, DoubleBarrier Asian, Spread, Touch, DoubleTouch, or Binary instrument object with a BlackScholes model using this workflow:

- 1 Use `fininstrument` to create a Vanilla, Lookback, Barrier, Asian, Spread, DoubleBarrier, Binary, Touch, or DoubleTouch instrument object.
- 2 Use `finmodel` to specify the BlackScholes model object for a Vanilla, Lookback, Barrier, DoubleBarrier, Asian, Spread, Touch, DoubleTouch, or Binary instrument.
- 3 Use `finpricer` to specify a supported pricing method. For more information on the available pricing methods for the Vanilla, Lookback, Barrier, DoubleBarrier, Asian, Spread, Touch, DoubleTouch, or Binary instrument when using a BlackScholes model, see “Choose Instruments, Models, and Pricers” on page 1-43.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla, Lookback, Barrier, DoubleBarrier, Asian, Spread, Touch, DoubleTouch, or Binary instrument when using a BlackScholes model, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Creation

#### Syntax

```
BlackScholesModelObj = finmodel(ModelType, 'Volatility', volatility_value)
BlackScholesModelObj = finmodel( ___, Name, Value)
```

#### Description

`BlackScholesModelObj = finmodel(ModelType, 'Volatility', volatility_value)` creates a BlackScholes model object by specifying `ModelType` and sets the properties on page 11-2509 for the required name-value pair argument `Volatility`.

`BlackScholesModelObj = finmodel( ___, Name, Value)` sets optional properties on page 11-2509 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BlackScholesModelObj = finmodel("BlackScholes", 'Volatility', 0.032)` creates a BlackScholes model object. You can specify multiple name-value pair arguments.

#### Input Arguments

##### ModelType — Model type

string with value "BlackScholes" | character vector with value 'BlackScholes'

Model type, specified as a string with the value of "BlackScholes" or a character vector with the value of 'BlackScholes'.

Data Types: char | string

### BlackScholes Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `BlackScholesModelObj = finmodel("BlackScholes", 'Volatility', 0.032)`

### Required BlackScholes Name-Value Pair Arguments

#### Volatility — Volatility value

nonnegative numeric

Volatility value, specified as the comma-separated pair consisting of 'Volatility' and a scalar nonnegative numeric.

Data Types: double

### Optional BlackScholes Name-Value Pair Arguments

#### Corr — Correlation between underlying asset prices

numeric

Correlation between the underlying asset prices, specified as the comma-separated pair consisting of 'Corr' and a scalar numeric.

Data Types: double

## Properties

#### Volatility — Volatility value

nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: double

#### Corr — Correlation between underlying asset prices

numeric

Correlation between underlying asset prices, returned as a scalar numeric.

Data Types: double

## Examples

### Use Black-Scholes Model and Turnbull-Wakeman Pricer to Price Asian Instrument

This example shows the workflow to price an Asian instrument when you use a BlackScholes model and a TurnbullWakeman pricing method.

### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType', "put")
```

```
AsianOpt =  
Asian with properties:  
  
    OptionType: "put"  
        Strike: 105  
    AverageType: "arithmetic"  
    AveragePrice: 0  
    AverageStartDate: NaT  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2022  
        Name: "asian_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.28)
```

```
BlackScholesModel =  
BlackScholes with properties:  
  
    Volatility: 0.2800  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =  
ratecurve with properties:  
  
    Type: "zero"  
    Compounding: -1  
    Basis: 12  
    Dates: 15-Sep-2023  
    Rates: 0.0350  
    Settle: 15-Sep-2018  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create TurnbullWakeman Pricer Object

Use `finpricer` to create a TurnbullWakeman pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 100,
outPricer =
  TurnbullWakeman with properties:

    DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
           SpotPrice: 100
    DividendValue: 0
    DividendType: "continuous"

```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer, AsianOpt, ["all"])
```

```
Price = 11.2249
```

```
outPR =
  pricerresult with properties:
```

```

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
11.225	-0.38072	0.01087	-3.3917	44.242	-0.5256	-116.88

### Use Black-Scholes Model and Asset Monte-Carlo Pricer to Price DoubleBarrier Instrument

This example shows the workflow to price a DoubleBarrier instrument when you use a BlackScholes model and an AssetMonteCarlo pricing method.

#### Create DoubleBarrier Instrument Object

Use fininstrument to create a DoubleBarrier instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2020, 8, 15))
```

```
DoubleBarrierOpt =
  DoubleBarrier with properties:
```

```

    OptionType: "call"
           Strike: 100
    BarrierValue: [110 80]
    ExerciseStyle: "american"
    ExerciseDate: 15-Aug-2020
    BarrierType: "dko"
           Rebate: [0 0]

```

```
Name: "doublebarrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", .3)
```

```
BlackScholesModel =  
  BlackScholes with properties:
```

```
    Volatility: 0.3000  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2017,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =  
  ratecurve with properties:
```

```
    Type: "zero"  
    Compounding: -1  
    Basis: 12  
    Dates: 15-Sep-2023  
    Rates: 0.0350  
    Settle: 15-Sep-2017  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an AssetMonteCarlo pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
ExerciseDate = datetime(2020,08,15);  
Settle = datetime(2017,9,15);  
outPricer = finpricer("AssetMonteCarlo", "DiscountCurve", myRC, "Model", BlackScholesModel, 'SpotPrice')
```

### Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the DoubleBarrier instrument.

```
[Price, outPR] = price(outPricer, DoubleBarrierOpt, ["all"])
```

```
Price = 6.9563
```

```
outPR =  
  pricerresult with properties:
```

```

## BlackKarasinski

Create BlackKarasinski model object for a Cap, FloorSwaption, Swap, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument

### Description

Create and price a Cap, Floor, Swaption, Swap, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object with a BlackKarasinski model using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, Swaption, Swap, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
- 2 Use `finmodel` to specify a BlackKarasinski model object for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument.
- 3 Use `finpricer` to specify a IRTree pricing method for the Cap, Floor, Swaption, SwapFixedBond, FloatBond, FixedBondOption or OptionEmbeddedFixedBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Cap, FloorSwaption, Swap, FixedBond, FloatBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Creation

#### Syntax

```
BlackKarasinskiModelObj = finmodel(ModelType, 'Alpha', alpha_value, 'Sigma', sigma_value)
```

#### Description

`BlackKarasinskiModelObj = finmodel(ModelType, 'Alpha', alpha_value, 'Sigma', sigma_value)` creates a BlackKarasinski model object by specifying `ModelType` and the required name-value pair arguments `Alpha` and `Sigma` to set properties on page 11-2515 using required name-value pair arguments. For example, `BlackKarasinskiModelObj = finmodel("BlackKarasinski", 'Alpha', 0.052, 'Sigma', 0.34)` creates a BlackKarasinski model object.

## Input Arguments

### ModelType — Model type

string with value "BlackKarasinski" | character vector with value 'BlackKarasinski'

Model type, specified as a string with the value of "BlackKarasinski" or a character vector with the value of 'BlackKarasinski'.

Data Types: char | string

### BlackKarasinski Name-Value Pair Arguments

Specify required comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: BlackKarasinskiModelObj =  
finmodel("BlackKarasinski", 'Alpha', 0.052, 'Sigma', 0.34)

### Alpha — Mean reversion speed

numeric | timetable

Mean reversion speed, specified as the comma-separated pair consisting of 'Alpha' and a scalar numeric value or timetable.

Alpha accepts a timetable, where the first column is dates and the second column is the associated Alpha value.

Data Types: double | timetable

### Sigma — Volatility

numeric | timetable

Volatility, specified as the comma-separated pair consisting of 'Sigma' and a scalar numeric value or timetable.

Sigma accepts a timetable, where the first column is dates and the second column is the associated Sigma value.

Data Types: double | timetable

## Properties

### Alpha — Mean reversion speed

numeric

Mean reversion speed, returned as a scalar numeric value or timetable.

Data Types: double | timetable

### Sigma — Volatility

numeric

Volatility, returned as a scalar numeric value or timetable.

Data Types: double | timetable

## Examples

### Use Black-Karasinski Model and Black-Karasinski Tree Pricer to Price FixedBondOption Instrument

This example shows the workflow to price a FixedBondOption instrument when you use a BlackKarasinski model and an IRTree pricing method.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', .024, 'Principal', 100)
```

```
BondInst =
  FixedBond with properties:
      CouponRate: 0.0240
      Period: 1
      Basis: 1
      EndMonthRule: 1
      Principal: 100
  DaycountAdjustedCashFlow: 0
  BusinessDayConvention: "actual"
      Holidays: NaT
      IssueDate: NaT
  FirstCouponDate: NaT
  LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2029
      Name: "fixed_bond"
```

#### Create FixedBondOption Instrument Object

Use `fininstrument` to create a FixedBondOption instrument object.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 800, 'Bond', BondInst)
```

```
FixedBOption =
  FixedBondOption with properties:
      OptionType: "put"
  ExerciseStyle: "american"
  ExerciseDate: 15-Sep-2025
      Strike: 800
      Bond: [1x1 fininstrument.FixedBond]
      Name: "fixed_bond_option"
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
```

```
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates, 'Basis',5)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
  Compounding: -1
      Basis: 5
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2019
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create BlackKarasinski Model Object

Use `finmodel` to create a BlackKarasinski model object.

```
BlackKarasinskiModel = finmodel("BlackKarasinski", 'Alpha',0.02, 'Sigma',0.34)
```

```
BlackKarasinskiModel =
  BlackKarasinski with properties:
      Alpha: 0.0200
      Sigma: 0.3400
```

### Create IRTree Pricer Object

Use `finpricer` to create an IRTree pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
BKTreePricer = finpricer("IRTree", 'Model',BlackKarasinskiModel, 'DiscountCurve',myRC, 'TreeDates', ...)
```

```
BKTreePricer =
  HWBKTree with properties:
      Tree: [1x1 struct]
      TreeDates: [10x1 datetime]
      Model: [1x1 finmodel.BlackKarasinski]
      DiscountCurve: [1x1 ratecurve]
```

```
BKTreePricer.Tree
```

```
ans = struct with fields:
  FinObj: 'BKFwdTree'
  tObs: [0 1 2 3 4 5 6 7 8 9]
  dObs: [1x10 datetime]
  CFlowT: {1x10 cell}
  Probs: {1x9 cell}
  Connect: {1x9 cell}
  FwdTree: {1x10 cell}
```

### Price FixedBondOption Instrument

Use price to compute the price and sensitivities for the FixedBondOption instrument.

```
[Price, outPR] = price(BKTreePricer,FixedBOption,["all"])
```

```
Price = 705.2729
```

```
outPR =  
  pricerresult with properties:
```

```
    Results: [1x4 table]  
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
```

Price	Vega	Gamma	Delta
705.27	-1.1369e-09	-8084.8	844.75

# Heston

Create Heston model object for Vanilla, Asian, Barrier, DoubleBarrier, Lookback, VarianceSwap, Touch, DoubleTouch, or Binary instrument

## Description

Create and price a Vanilla, Asian, Barrier, DoubleBarrier, Lookback, VarianceSwap, Touch, DoubleTouch, or Binary instrument object with a Heston model using this workflow:

- 1 Use `fininstrument` to create a Vanilla, Barrier, Lookback, Asian, DoubleBarrier, VarianceSwap, Binary, Touch, or DoubleTouch instrument object.
- 2 Use `finmodel` to specify a Heston model object for the Vanilla, Asian, Barrier, DoubleBarrier, Lookback, VarianceSwap, Touch, DoubleTouch, or Binary instrument.
- 3 Use `finpricer` to specify a FiniteDifference, NumericalIntegration, or FFT pricing method for the Vanilla instrument.

Use `finpricer` to specify an AssetMonteCarlo pricing method for the Vanilla, Asian, BarrierDoubleBarrier, Lookback, VarianceSwap, Touch, DoubleTouch, or Binary instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla, AsianBarrier, DoubleBarrier, Lookback, VarianceSwap, Touch, DoubleTouch, or Binary instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
HestonModelObj = finmodel(ModelType, 'V0'v0_value, 'ThetaV', thetav_value, 'Kappa', kappa_value, 'SigmaV', sigmav_value, 'RhoSV', rhosv_value)
```

### Description

`HestonModelObj = finmodel(ModelType, 'V0'v0_value, 'ThetaV', thetav_value, 'Kappa', kappa_value, 'SigmaV', sigmav_value, 'RhoSV', rhosv_value)` creates a Black model object by specifying `ModelType` and the required name-value pair arguments `V0`, `ThetaV`, `Kappa`, `SigmaV`, and `RhoSV` to set properties on page 11-2521 using required name-value pair arguments. For example, `HestonModelObj = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)` creates a Heston model object.

### Input Arguments

#### **ModelType** — Model type

string with value "Heston" | character vector with value 'Heston'

Model type, specified as a string with the value of "Heston" or a character vector with the value of 'Heston'.

Data Types: char | string

### **Heston Name-Value Pair Arguments**

Specify required comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: HestonModelObj =

```
finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

### **V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, specified as the comma-separated pair consisting of 'V0' and a scalar numeric value.

Data Types: double

### **ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, specified as the comma-separated pair consisting of 'ThetaV' and a scalar numeric value.

Data Types: double

### **Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, specified as the comma-separated pair consisting of 'Kappa' and a scalar numeric value.

Data Types: double

### **SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, specified as the comma-separated pair consisting of 'SigmaV' and a scalar numeric value.

Data Types: double

### **RhoSV — Correlation between Wiener processes for underlying asset and its variance**

numeric

Correlation between the Wiener processes for the underlying asset and its variance, specified as the comma-separated pair consisting of 'RhoSV' and a scalar numeric value.

Data Types: double

## Properties

### **V0 — Initial variance of underlying asset**

numeric

Initial variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

### **ThetaV — Long-term variance of underlying asset**

numeric

Long-term variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

### **Kappa — Mean revision speed for the variance of underlying asset**

numeric

Mean revision speed for the underlying asset, returned as a scalar numeric value.

Data Types: double

### **SigmaV — Volatility of the variance of underlying asset**

numeric

Volatility of the variance of the underlying asset, returned as a scalar numeric value.

Data Types: double

### **RhoSV — Correlation between Weiner processes for underlying asset and its variance**

numeric

Correlation between the Weiner processes for the underlying asset and its variance, returned as a scalar numeric value.

Data Types: double

## Examples

### **Use Heston Model and FFT Pricer to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Heston model and an FFT pricing method.

#### **Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'ExerciseSty
```

```
VanillaOpt =
```

```
  Vanilla with properties:
```

```
    OptionType: "call"
    ExerciseStyle: "european"
```

```

ExerciseDate: 15-Sep-2022
Strike: 105
Name: "vanilla_option"

```

### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

```
HestonModel =
Heston with properties:
```

```

V0: 0.0320
ThetaV: 0.1000
Kappa: 0.0030
SigmaV: 0.2000
RhoSV: 0.9000

```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)

```

```
myRC =
ratecurve with properties:
```

```

Type: "zero"
Compounding: -1
Basis: 12
Dates: 15-Sep-2023
Rates: 0.0350
Settle: 15-Sep-2018
InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"

```

### Create FFT Pricer Object

Use `finpricer` to create an FFT pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FFT", 'DiscountCurve', myRC, 'Model', HestonModel, 'SpotPrice', 100, 'Characteri
```

```
outPricer =
FFT with properties:
```

```

Model: [1x1 finmodel.Heston]
DiscountCurve: [1x1 ratecurve]
SpotPrice: 100
DividendType: "continuous"
DividendValue: 0

```

```

        NumFFT: 8192
    CharacteristicFcnStep: 0.2000
        LogStrikeStep: 0.0038
    CharacteristicFcn: @characteristicFcnHeston
        DampingFactor: 1.5000
        Quadrature: "simpson"
    VolRiskPremium: 0
        LittleTrap: 1

```

## Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 14.7545
```

```
outPR =
    pricerresult with properties:
```

```

        Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Theta	Rho	Vega	VegaLT
14.754	0.44868	0.021649	-0.20891	120.45	88.192	1.3248

## Use Heston Model and Asset Monte-Carlo Pricer to Price Lookback Instrument

This example shows the workflow to price a LookBack instrument when you use a Heston model and an AssetMonteCarlo pricing method.

### Create Lookback Instrument Object

Use fininstrument to create a Lookback instrument object.

```
LookbackOpt = fininstrument("Lookback", 'Strike', 105, 'ExerciseDate', datetime(2022, 9, 15), 'OptionType', 'put')
```

```

LookbackOpt =
    Lookback with properties:

        OptionType: "put"
        Strike: 105
        AssetMinMax: NaN
        ExerciseStyle: "american"
        ExerciseDate: 15-Sep-2022
        Name: "lookback_option"

```

### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.08, 'RhoSV', 0.9)

HestonModel =
  Heston with properties:

      V0: 0.0320
    ThetaV: 0.1000
      Kappa: 0.0030
    SigmaV: 0.0800
    RhoSV: 0.9000
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)

myRC =
  ratecurve with properties:

      Type: "zero"
    Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
    InterpMethod: "linear"
  ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", HestonModel, 'SpotPrice', 90,

outPricer =
  HestonMonteCarlo with properties:

      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 90
    SimulationDates: 15-Sep-2022
      NumTrials: 1000
    RandomNumbers: []
      Model: [1x1 finmodel.Heston]
    DividendType: "continuous"
    DividendValue: 0
```

## Price Lookback Instrument

Use `price` to compute the price and sensitivities for the `Lookback` instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 21.9733
```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x8 table]
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x8 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
21.973	-0.7701	0	-3.1542	-215.94	0.28812	99.825	1.447

## HullWhite

Create HullWhite model object for Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument

## Description

Create and price a Cap, Floor, Swaption, Swap, FloatBond, FloatBondOption, FixedBond, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object with a HullWhite model using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
- 2 Use `finmodel` to specify a HullWhite model object for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument.
- 3 Use `finpricer` to specify a HullWhite pricing method for a Cap, Floor, or Swaption and use an IRTree pricing method for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, FixedBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
HullWhiteModelObj = finmodel(ModelType, 'Alpha'alpha_value, 'Sigma', sigma_value)
```

### Description

`HullWhiteModelObj = finmodel(ModelType, 'Alpha'alpha_value, 'Sigma', sigma_value)` creates a HullWhite model object by specifying `ModelType` and the required name-value pair arguments `Alpha` and `Sigma` to set properties on page 11-2527 using name-value pair arguments. For example, `HullWhiteModelObj = finmodel("HullWhite", 'Alpha', 0.052, 'Sigma', 0.34)` creates a HullWhite model object.

## Input Arguments

### ModelType — Model type

string with value "HullWhite" | character vector with value 'HullWhite'

Model type, specified as a string with the value of "HullWhite" or a character vector with the value of 'HullWhite'.

Data Types: char | string

### HullWhite Name-Value Pair Arguments

Specify required comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: HullWhiteModelObj = finmodel("HullWhite", 'Alpha', 0.052, 'Sigma', 0.34)

### Alpha — Mean reversion speed

numeric

Mean reversion speed, specified as the comma-separated pair consisting of 'Alpha' and a scalar numeric or timetable.

Alpha accepts a timetable, where the first column is dates and the second column is the associated Alpha value.

Data Types: double | timetable

### Sigma — Volatility

numeric | timetable

Volatility, specified as the comma-separated pair consisting of 'Sigma' and a scalar numeric or timetable.

Sigma accepts a timetable, where the first column is dates and the second column is the associated Sigma value.

Data Types: double | timetable

## Properties

### Alpha — Mean reversion speed

numeric

Mean reversion speed, returned as a scalar numeric or timetable.

Data Types: double | timetable

### Sigma — Volatility

numeric | timetable

Volatility, returned as a scalar numeric value or timetable.

Data Types: double | timetable

## Examples

### Use Hull-White Model and Hull-White Pricer to Price Floor Instrument

This example shows the workflow to price a Floor instrument when you use a HullWhite model and a HullWhite pricing method.

#### Create Floor Instrument Object

Use `fininstrument` to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor", 'Strike', 0.045, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Princi
```

```
FloorOpt =
  Floor with properties:
      Strike: 0.0450
      Maturity: 30-Jan-2019
      ResetOffset: 0
      Reset: 4
      Basis: 1
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "floor_option"
```

#### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.032, 'Sigma', 0.04)
```

```
HullWhiteModel =
  HullWhite with properties:
```

```
    Alpha: 0.0320
    Sigma: 0.0400
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)

myRC =
  ratecurve with properties:
```

```
        Type: "zero"  
    Compounding: -1  
        Basis: 0  
        Dates: [10x1 datetime]  
        Rates: [10x1 double]  
    Settle: 15-Sep-2018  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

## Create HullWhite Pricer Object

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', HullWhiteModel, 'DiscountCurve', myRC)  
  
outPricer =  
    HullWhite with properties:  
  
        DiscountCurve: [1x1 ratecurve]  
        Model: [1x1 finmodel.HullWhite]
```

## Price Floor Instrument

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer, FloorOpt)  
  
Price = 1.4917
```

## See Also

## Merton

Create Merton model object for Vanilla, Asian, Barrier, DoubleBarrier, Lookback, OneTouch, DoubleTouch, or Binary instrument

### Description

Create and price a Vanilla, Asian, Barrier, DoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument object with a Merton model using this workflow:

- 1 Use `fininstrument` to create a Vanilla, Barrier, Lookback, Asian, DoubleBarrier, Binary, Touch, or DoubleTouch instrument object.
- 2 Use `finmodel` to specify a Merton model object for the Vanilla, Asian, Barrier, DoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument.
- 3 Use `finpricer` to specify a FiniteDifference, NumericalIntegration, or FFT pricing method for the Vanilla instrument.

Use `finpricer` to specify an AssetMonteCarlo pricing method for the Vanilla, Asian, BarrierDoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla, Asian, Barrier, DoubleBarrier, Lookback, Touch, DoubleTouch, or Binary instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
MertonModelObj = finmodel(ModelType,'Volatility',volatility_value,'MeanJ',meanj_value,'JumpVol',jumpvol_value,'JumpFreq',jumpfreq_value)
```

### Description

`MertonModelObj = finmodel(ModelType,'Volatility',volatility_value,'MeanJ',meanj_value,'JumpVol',jumpvol_value,'JumpFreq',jumpfreq_value)` creates a Merton model object by specifying `ModelType` and the required name-value pair arguments `MeanJ`, `JumpVol`, and `JumpFreq` to set properties on page 11-2531 using name-value pair arguments. For example, `MertonModelObj = finmodel("Merton",'Volatility',0.03,'MeanJ',0.22,'JumpVol',0.007,'JumpFreq',0.009)` creates a Merton model object.

### Input Arguments

#### **ModelType** — Model type

string with value "Merton" | character vector with value 'Merton'

Model type, specified as a string with the value of "Merton" or a character vector with the value of 'Merton'.

Data Types: char | string

### **Merton Name-Value Pair Arguments**

Specify required comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `MertonModelObj = finmodel("Merton", 'Volatility', 0.03, 'MeanJ', 0.22, 'JumpVol', 0.007, 'JumpFreq', 0.009)`

### **Volatility — Volatility value for the underlying asset**

nonnegative numeric

Volatility value for the underlying asset, specified as the comma-separated pair consisting of 'Volatility' and a scalar nonnegative numeric.

Data Types: double

### **MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), specified as the comma-separated pair consisting of 'MeanJ' and a scalar decimal value, where  $\log(1+J)$  is normally distributed with mean  $(\log(1+\text{MeanJ})-0.5*\text{JumpVol}^2)$  and the standard deviation  $\text{JumpVol}$ .

Data Types: double

### **JumpVol — Standard deviation of $\log(1+J)$**

decimal

Standard deviation of  $\log(1+J)$ , where  $J$  is the random percentage jump size, specified as the comma-separated pair consisting of 'JumpVol' and a scalar decimal value.

Data Types: double

### **JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of the Poisson jump process, specified as the comma-separated pair consisting of 'JumpFreq' and a scalar numeric value.

Data Types: double

## **Properties**

### **Volatility — Volatility value**

nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: double

**MeanJ — Mean of the random percentage jump size**

decimal

Mean of the random percentage jump size ( $J$ ), returned as a scalar decimal value.

Data Types: double

**JumpVol — Standard deviation of  $\log(1+J)$** 

decimal

Standard deviation of  $\log(1+J)$ , where  $J$  is the random percentage jump size, returned as a scalar decimal value.

Data Types: double

**JumpFreq — Annual frequency of Poisson jump process**

numeric

Annual frequency of the Poisson jump process, returned as a scalar numeric value.

Data Types: double

**Examples****Use Merton Model and Numerical Integration Pricer to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Merton model and a NumericalIntegration pricing method.

**Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType
```

```
VanillaOpt =
```

```
Vanilla with properties:
```

```
    OptionType: "put"  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2022  
    Strike: 105  
    Name: "vanilla_option"
```

**Create Merton Model Object**

Use `finmodel` to create a Merton model object.

```
MertonModel = finmodel("Merton", 'Volatility', 0.45, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)
```

```
MertonModel =
```

```
Merton with properties:
```

```
    Volatility: 0.4500  
    MeanJ: 0.0200  
    JumpVol: 0.0700
```

```
JumpFreq: 0.0900
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

      Type: "zero"
  Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
  InterpMethod: "linear"
ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create NumericalIntegration Pricer Object

Use finpricer to create a NumericalIntegration pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("numericalintegration",'DiscountCurve',myRC,'Model',MertonModel,'SpotPrice
```

```
outPricer =
  NumericalIntegration with properties:

      Model: [1x1 finmodel.Merton]
  DiscountCurve: [1x1 ratecurve]
      SpotPrice: 100
  DividendType: "continuous"
  DividendValue: 0.4500
      AbsTol: 0.5000
      RelTol: 0.0400
  IntegrationRange: [1.0000e-09 Inf]
  CharacteristicFcn: @characteristicFcnMerton76
      Framework: "lewis2001"
  VolRiskPremium: 0.0900
      LittleTrap: 0
```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 75.1139
```

```
outPR =
  pricerresult with properties:
```

```
Results: [1x6 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x6 table
```

Price	Delta	Gamma	Theta	Rho	Vega
75.114	-0.15305	0.00025732	-3.9836	-361.67	4.6317

### Use Merton Model and Asset Monte-Carlo Pricer to Price Binary Instrument

This example shows the workflow to price a Binary instrument when you use a Merton model and an AssetMonteCarlo pricing method.

#### Create Binary Instrument Object

Use `fininstrument` to create an Binary instrument object.

```
BinaryOpt = fininstrument("Binary", 'ExerciseDate', datetime(2022,9,15), 'Strike', 100, 'PayoffValue'
```

```
BinaryOpt =
```

```
Binary with properties:
```

```
OptionType: "put"
ExerciseDate: 15-Sep-2022
Strike: 100
PayoffValue: 130
ExerciseStyle: "european"
Name: "binary_option"
```

#### Create Merton Model Object

Use `finmodel` to create a Merton model object.

```
MertonModel = finmodel("Merton", 'Volatility', 0.25, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)
```

```
MertonModel =
```

```
Merton with properties:
```

```
Volatility: 0.2500
MeanJ: 0.0200
JumpVol: 0.0700
JumpFreq: 0.0900
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
```

```
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
  Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
  InterpMethod: "linear"
  ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", MertonModel, 'SpotPrice', 102)
```

```
outPricer =
  MertonMonteCarlo with properties:
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 102
  SimulationDates: 15-Sep-2022
      NumTrials: 1000
  RandomNumbers: []
      Model: [1x1 finmodel.Merton]
  DividendType: "continuous"
  DividendValue: 0
```

### Price Binary Instrument

Use `price` to compute the price and sensitivities for the Binary instrument.

```
[Price, outPR] = price(outPricer, BinaryOpt, ["all"])
```

```
Price = 53.2308
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
  PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
_____	_____	_____	_____	_____	_____	_____

53.231   -0.831   0.54314   -1.5924   -212.88   1.8643   0

# Normal

Create `Normal` model object for `Cap`, `Floor`, or `Swaption` instrument

## Description

Create and price a `Cap`, `Floor`, or `Swaption` instrument object with a `Normal` model using this workflow:

- 1 Use `fininstrument` to create a `Cap`, `Floor`, or `Swaption` instrument object.
- 2 Use `finmodel` to specify a `Normal` model object for the `Cap`, `Floor`, or `Swaption` instrument.
- 3 Use `finpricer` to specify a `Normal` pricing method for the `Cap`, `Floor`, or `Swaption` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Cap`, `Floor`, or `Swaption` instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
NormalModelObj = finmodel(ModelType, 'Volatility', volatility_value)
```

### Description

`NormalModelObj = finmodel(ModelType, 'Volatility', volatility_value)` creates a `Normal` model object by specifying `ModelType` and the required name-value pair argument `Volatility` to set properties on page 11-2538 using name-value pair arguments. For example, `NormalModelObj = finmodel("Normal", 'Volatility', 0.063)` creates a `Normal` model object.

### Input Arguments

#### ModelType — Model type

string with value "Normal" | character vector with value 'Normal'

Model type, specified as a string with the value of "Normal" or a character vector with the value of 'Normal'.

Data Types: char | string

#### Normal Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: NormalModelObj = finmodel("Normal",'Volatility',0.063)
```

### **Volatility – Volatility value**

nonnegative numeric

Volatility value, specified as the comma-separated pair consisting of 'Volatility' and a scalar nonnegative numeric.

Data Types: double

## **Properties**

### **Volatility – Volatility value**

nonnegative numeric

Volatility value, returned as a scalar nonnegative numeric.

Data Types: double

## **Examples**

### **Use Normal Model and Normal Pricer to Price Cap Instrument**

This example shows the workflow to price a Cap instrument when you use a Normal model and a Normal pricing method.

#### **Create Cap Instrument Object**

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', 0.51, 'Maturity', datetime(2019,6,25), 'Reset', 4, 'Principal', ...)
```

```
CapOpt =  
    Cap with properties:
```

```

        Strike: 0.5100
        Maturity: 25-Jun-2019
    ResetOffset: 0
        Reset: 4
        Basis: 8
    Principal: 100
    ProjectionCurve: [0x0 ratecurve]
DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        Name: "cap_option"
```

#### **Create Normal Model Object**

Use `finmodel` to create a Normal model object.

```
NormalModel = finmodel("normal", 'Volatility', 0.063)
```

```
NormalModel =  
    Normal with properties:
```

```
Volatility: 0.0630
```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create Normal Pricer Object

Use finpricer to create a Normal pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',NormalModel,'DiscountCurve',myRC)
```

```
outPricer =
    Normal with properties:

        DiscountCurve: [1x1 ratecurve]
        Shift: 0
        Model: [1x1 finmodel.Normal]
```

### Price Cap Instrument

Use price to compute the price for the Cap instrument.

```
Price = price(outPricer,CapOpt)
```

```
Price = 9.3325e-30
```

# Dupire

Create Dupire model object for local volatility for Vanilla instrument

## Description

Create and price a Vanilla instrument object with a Dupire model using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Dupire model object for the Vanilla instrument.
- 3 Use `finpricer` to specify a FiniteDifference pricing method for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
DupireObj = finmodel(ModelType,'ImpliedVolData',impliedvoldata_value)
```

### Description

`DupireObj = finmodel(ModelType,'ImpliedVolData',impliedvoldata_value)` creates a Dupire model object by specifying `ModelType` and the required name-value pair argument `ImpliedVolData` to set properties on page 11-2542 using name-value pair arguments. For example, `DupireObj = finmodel("Dupire",'ImpliedVolData',voldata_table)` creates a Dupire model object.

### Input Arguments

#### ModelType — Model type

string with value "Dupire" | character vector with value 'Dupire'

Model type, specified as the string with the value "Dupire" or the character vector with the value 'Dupire'.

Data Types: char | string

#### Dupire Name-Value Pair Arguments

Specify required comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `DupireObj = finmodel("Dupire",'ImpliedVolData',voldata_table)`

**ImpliedVolData — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities**

table

Table of maturity dates, strike or exercise prices, and their corresponding implied volatilities, specified as the comma-separated pair consisting of 'ImpliedVolData' and an NVOL-by-3 table.

Data Types: table

**Properties****ImpliedVolData — Table of maturity dates, strike or exercise prices, and corresponding implied volatilities**

table

Table of maturity dates, strike or exercise prices, and corresponding implied volatilities, returned as an NVOL-by-3 table.

Data Types: table

**Examples****Use Dupire Model and Finite Difference Pricer to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Dupire model and a FiniteDifference pricing method.

**Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2020,1,1), 'Strike', 105, 'ExerciseStyle', 'american');
```

```
VanillaOpt =
  Vanilla with properties:
      OptionType: "call"
  ExerciseStyle: "american"
  ExerciseDate: 01-Jan-2020
      Strike: 105
      Name: "vanilla_option"
```

**Create Dupire Model Object**

Define the implied volatility surface data.

```
AssetPrice = 590;
Maturity = ["06-Mar-2018" "05-Jun-2018" "12-Sep-2018" "10-Dec-2018" "01-Jan-2019" ...
"02-Jul-2019" "01-Jan-2020" "01-Jan-2021" "01-Jan-2022" "01-Jan-2023"];
Maturity = repmat(Maturity,10,1);
Maturity = Maturity(:);

ExercisePrice = AssetPrice.*[0.85 0.90 0.95 1.00 1.05 1.10 1.15 1.20 1.30 1.40];
ExercisePrice = repmat(ExercisePrice,1,10)';
```

```

ImpliedVol = [...
    0.190; 0.168; 0.133; 0.113; 0.102; 0.097; 0.120; 0.142; 0.169; 0.200; ...
    0.177; 0.155; 0.138; 0.125; 0.109; 0.103; 0.100; 0.114; 0.130; 0.150; ...
    0.172; 0.157; 0.144; 0.133; 0.118; 0.104; 0.100; 0.101; 0.108; 0.124; ...
    0.171; 0.159; 0.149; 0.137; 0.127; 0.113; 0.106; 0.103; 0.100; 0.110; ...
    0.171; 0.159; 0.150; 0.138; 0.128; 0.115; 0.107; 0.103; 0.099; 0.108; ...
    0.169; 0.160; 0.151; 0.142; 0.133; 0.124; 0.119; 0.113; 0.107; 0.102; ...
    0.169; 0.161; 0.153; 0.145; 0.137; 0.130; 0.126; 0.119; 0.115; 0.111; ...
    0.168; 0.161; 0.155; 0.149; 0.143; 0.137; 0.133; 0.128; 0.124; 0.123; ...
    0.168; 0.162; 0.157; 0.152; 0.148; 0.143; 0.139; 0.135; 0.130; 0.128; ...
    0.168; 0.164; 0.159; 0.154; 0.151; 0.147; 0.144; 0.140; 0.136; 0.132];

```

```
ImpliedVolData = table(Maturity, ExercisePrice, ImpliedVol);
```

Use `finmodel` to create a Dupire model object.

```
DupireModel = finmodel("Dupire", 'ImpliedVolData', ImpliedVolData)
```

```
DupireModel =
```

```
  Dupire with properties:
```

```
    ImpliedVolData: [100x3 table]
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,1,1);
Maturity = datetime(2020,9,1);
Rate = 0.06;
myRC = ratecurve('zero', Settle, Maturity, Rate)

```

```
myRC =
```

```
  ratecurve with properties:
```

```

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: 01-Sep-2020
        Rates: 0.0600
        Settle: 01-Jan-2018
    InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"

```

### Create FiniteDifference Pricer Object

Use `finpricer` to create a FiniteDifference pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FiniteDifference", 'Model', DupireModel, 'DiscountCurve', myRC, 'SpotPrice', 100)
```

```
outPricer =
```

```
  FiniteDifference with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
```

```

        Model: [1x1 finmodel.Dupire]
        SpotPrice: 100
    GridProperties: [1x1 struct]
        DividendType: "continuous"
        DividendValue: 0.0262

```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 15.5930
```

```
outPR =
    pricerresult with properties:
```

```

        Results: [1x7 table]
        PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
15.593	0.55004	0.0091484	3.5275	-3.3431	78.792	49.33

## More About

### Local Volatility Model

A local volatility model treats volatility as a function both of the current asset level and of time.

The local volatility can be estimated by using the Dupire formula [2]:

$$\sigma_{loc}^2(K, \tau) = \frac{\sigma_{imp}^2 + 2\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial\tau} + 2(\tau - d)K\tau\sigma_{imp}\frac{\partial\sigma_{imp}}{\partial K}}{\left(1 + Kd_1\sqrt{\tau}\frac{\partial\sigma_{imp}}{\partial K}\right)^2 + K^2\tau\sigma_{imp}\left(\frac{\partial^2\sigma_{imp}}{\partial K^2} - d_1\sqrt{\tau}\left(\frac{\partial\sigma_{imp}}{\partial K}\right)^2\right)}$$

$$d_1 = \frac{\ln(S_0/K) + ((\tau - d) + \sigma_{imp}^2/2)\tau}{\sigma_{imp}\sqrt{\tau}}$$

# SABR

Create SABR model object for Swaption instrument

## Description

Create and price a Swaption instrument object with a SABR model using this workflow:

- 1 Use `fininstrument` to create a Swaption instrument object.
- 2 Use `finmodel` to specify a SABR model object for the Swaption instrument.
- 3 Use `finpricer` to specify a SABR pricing method for the Swaption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
SabrModelObj = finmodel(ModelType,'Alpha',alpha_value,'Beta',beta_value,'
Rho',rho_value,'Nu',nu_value)
SabrModelObj = finmodel(___,Name,Value)
```

### Description

`SabrModelObj = finmodel(ModelType,'Alpha',alpha_value,'Beta',beta_value,'Rho',rho_value,'Nu',nu_value)` creates a SABR model object by specifying `ModelType` and sets the properties on page 11-2548 for the required name-value pair arguments `Alpha`, `Beta`, `Rho`, and `Nu`.

`SabrModelObj = finmodel(___,Name,Value)` sets optional properties on page 11-2548 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `SabrModelObj = finmodel("SABR",'Alpha',0.22,'Beta',0.007,'Rho',0.009,'Nu',0.03,'Shift',0.002,'VolatilityType','black')` creates a SABR model object. You can specify multiple name-value pair arguments.

### Input Arguments

#### ModelType — Model type

string with value "SABR" | character vector with value 'SABR'

Model type, specified as a string with the value of "SABR" or a character vector with the value of 'SABR'.

Data Types: char | string

### SABR Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: SabrModelObj =
finmodel("SABR", 'Alpha', 0.22, 'Beta', 0.007, 'Rho', 0.009, 'Nu', 0.03, 'Shift', 0.002
, 'VolatilityType', "black")
```

### Required SABR Name-Value Pair Arguments

#### Alpha — Current SABR volatility

scalar numeric

Current SABR volatility, specified as the comma-separated pair consisting of 'Alpha' and a scalar numeric.

Data Types: double

#### Beta — SABR constant elasticity of variance (CEV) exponent

scalar numeric

SABR constant elasticity of variance (CEV) exponent, specified as the comma-separated pair consisting of 'Beta' and a scalar numeric.

---

**Note** Set the Beta parameter to 0 to allow a negative ForwardValue and Strike.

---

Data Types: double

#### Rho — Correlation between forward value and volatility

scalar numeric

Correlation between the forward value and volatility, specified as the comma-separated pair consisting of 'Rho' and a scalar numeric.

Data Types: double

#### Nu — Volatility of volatility

scalar numeric

Volatility of volatility, specified as the comma-separated pair consisting of 'Nu' and a scalar numeric.

Data Types: double

### Optional SABR Name-Value Pair Arguments

#### Shift — Shift in decimals for shifted SABR model

0 (no shift) (default) | scalar positive decimal

Shift in decimals for the shifted SABR model (to be used with the shifted Black model), specified as the comma-separated pair consisting of 'Shift' and a scalar positive decimal value. For example, a Shift value of 0.01 is equal to a 1% positive shift.

---

**Note** If you set VolatilityType to 'normal', the Shift value must be 0.

---

Data Types: double

**VolatilityType — Model used by the implied volatility sigma**

"black" (default) | string with value "black" or "normal" | character vector with value 'black' or 'normal'

Model used by the implied volatility sigma, specified as the comma-separated pair consisting of 'VolatilityType' and a scalar string or character vector.

---

**Note** The value of VolatilityType affects the interpretation of the implied volatility ("sigma").

- If you set VolatilityType to 'black' (default), "sigma" can be either implied Black (no shift) or implied shifted Black volatility.
  - If you set VolatilityType to 'normal', "sigma" is the implied Normal (Bachelier) volatility and you must also set Shift to zero.
- 

Data Types: char | string

**Properties****Alpha — Current SABR volatility**

scalar numeric

Current SABR volatility, returned as a scalar numeric.

Data Types: double

**Beta — SABR constant elasticity of variance (CEV) exponent**

scalar numeric

SABR constant elasticity of variance (CEV) exponent, returned as a scalar numeric.

Data Types: double

**Rho — Correlation between forward value and volatility**

scalar numeric

Correlation between forward value and volatility, returned as a scalar numeric.

Data Types: double

**Nu — Volatility of volatility**

scalar numeric

Volatility of volatility, returned as a scalar numeric.

Data Types: double

**Shift — Shift in decimals for shifted SABR model**

0 (no shift) (default) | scalar positive decimal

Shift in decimals for the shifted SABR model (to be used with the Shifted Black model), returned as a scalar positive decimal value.

Data Types: double

### VolatilityType — Model used by the implied volatility sigma

"black" (default) | string with value "black" or "normal"

Model used by the implied volatility sigma, returned as a string with a value of "black" or "normal".

Data Types: string

## Examples

### Use SABR Model and SABR Pricer to Price Swaption Instrument

This example shows the workflow to price a Swaption instrument when you use a SABR model and a SABR pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307];
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
```

```
ratecurve with properties:
```

```

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2018
    InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

#### Create Swap Instrument Object

Use fininstrument to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2023,1,30), 'LegRate', [0.018 0.24], 'LegType', ["fi
```

```
Swap =
```

```
Swap with properties:
```

```

    LegRate: [0.0180 0.2400]
    LegType: ["fixed"    "float"]
        Reset: [2 2]
        Basis: [5 5]
```

```

        Notional: 1000
    LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [1 1]
        ProjectionCurve: [1x2 ratecurve]
    BusinessDayConvention: ["follow" "follow"]
        Holidays: NaT
    EndMonthRule: [1 1]
        StartDate: 30-Mar-2020
        Maturity: 30-Jan-2023
        Name: "swap_instrument"

```

### Create Swaption Instrument Object

Use `fininstrument` to create a Swaption instrument object.

```
Swaption = fininstrument("swaption", 'Strike', 0.25, 'ExerciseDate', datetime(2021, 7, 30), 'Swap', Swap)
```

```
Swaption =
    Swaption with properties:

        OptionType: "put"
    ExerciseStyle: "european"
    ExerciseDate: 30-Jul-2021
        Strike: 0.2500
        Swap: [1x1 fininstrument.Swap]
        Name: "swaption_instrument"

```

### Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
SabrModel = finmodel("SABR", 'Alpha', 0.032, 'Beta', 0.04, 'Rho', .08, 'Nu', 0.49, 'Shift', 0.002)
```

```
SabrModel =
    SABR with properties:

        Alpha: 0.0320
        Beta: 0.0400
        Rho: 0.0800
        Nu: 0.4900
        Shift: 0.0020
    VolatilityType: "black"

```

### Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', SabrModel, 'DiscountCurve', myRC)
```

```
outPricer =
    SABR with properties:

        DiscountCurve: [1x1 ratecurve]

```

---

Model: [1x1 finmodel.SABR]

### **Price Swaption Instrument**

Use price to compute the price for the Swaption instrument.

```
Price = price(outPricer,Swaption)
```

```
Price = 55.8596
```

## AssetMonteCarlo

Create `AssetMonteCarlo` pricer object for equity instruments using `BlackScholes`, `Merton`, `Heston`, or `Bates` model

### Description

Create and price a `Vanilla`, `Barrier`, `Lookback`, `Asian`, `Spread`, `DoubleBarrier`, `Touch`, `DoubleTouch`, `Binary` instrument object with a `BlackScholes`, `Merton`, `Heston`, or `Bates` model and a `AssetMonteCarlo` pricing method using this workflow:

- 1 Use `fininstrument` to create a `Vanilla`, `Barrier`, `Lookback`, `Asian`, `Spread`, `DoubleBarrier`, `Binary`, `Touch`, or `DoubleTouch` instrument object.
- 2 Use `finmodel` to specify a `BlackScholes` model for the `Vanilla`, `Barrier`, `Lookback`, `Asian`, `Spread`, `DoubleBarrier`, `Touch`, `DoubleTouch`, or `Binary` instrument.  
  
Use `finmodel` to specify a `Merton`, `Bates`, or `Heston` model for the `Vanilla`, `Barrier`, `Lookback`, `Asian`, `DoubleBarrier`, `Touch`, `DoubleTouch`, or `Binary` instrument.
- 3 Use `finpricer` to specify a `AssetMonteCarlo` pricer object for the `Vanilla`, `Barrier`, `Lookback`, `Asian`, `Spread`, `DoubleBarrier`, `Touch`, `DoubleTouch`, or `Binary` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for `Vanilla`, `Barrier`, `Lookback`, `Asian`, `Spread`, `DoubleBarrier`, `Touch`, `DoubleTouch`, or `Binary` instruments, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Creation

#### Syntax

```
AssetMonteCarloPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotprice_value, 'SimulationDates', simulation_dates, )
AssetMonteCarloPricerObj = finpricer( ___, Name, Value)
```

#### Description

`AssetMonteCarloPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotprice_value, 'SimulationDates', simulation_dates, )` creates a `AssetMonteCarlo` pricer object by specifying `PricerType` and sets the properties on page 11-2555 using the required name-value pair arguments `Model`, `DiscountCurve`, `SpotPrice`, and `SimulationDates`.

`AssetMonteCarloPricerObj = finpricer( ___, Name, Value)` sets optional properties on page 11-2555 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `AssetMonteCarloPricerObj =`

`finpricer("assetmontecarlo", 'Model', BSModel, 'DiscountCurve', ratecurve_obj, 'SpotPrice', 1000, 'SimulationDates', [datetime(2018,1,30); datetime(2019,1,30)], 'NumTrails', 500, 'DividendType', 'continuous', 'DividendValue', 0.3)` creates an AssetMonteCarlo pricer object using a BlackScholes model. You can specify multiple name-value pair arguments.

## Input Arguments

### PricerType — Pricer type

string with value "AssetMonteCarlo" | character vector with value 'AssetMonteCarlo'

Pricer type, specified as a string with the value "AssetMonteCarlo" or a character vector with the value 'AssetMonteCarlo'.

Data Types: char | string

### AssetMonteCarlo Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `AssetMonteCarloPricerObj = finpricer("assetmontecarlo", 'Model', BSModel, 'DiscountCurve', ratecurve_obj, 'SpotPrice', 1000, 'SimulationDates', [datetime(2018,1,30); datetime(2019,1,30)], 'NumTrails', 500, 'DividendType', 'continuous', 'DividendValue', 0.3)`

### Required AssetMonteCarlo Name-Value Pair Arguments

#### Model — Model object

BlackScholes object | Merton object | Bates object | Heston object

Model object, specified as the comma-separated pair consisting of 'Model' and a scalar character vector or string containing the name of a previously created BlackScholes, Merton, Bates, or Heston model object. Create the model object using `finmodel`.

Data Types: object

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

**SimulationDates — Simulation dates**

[ ] (default) | serial date number | date character vector | datetime | vector

Simulation dates, specified as the comma-separated pair consisting of 'SimulationDates' and a scalar serial date number, date character vector, or datetime or a vector of serial date numbers, cell array of character vectors, string array, or datetime array.

Data Types: double | char | string | cell | datetime

**Optional AssetMonteCarlo Name-Value Pair Arguments****NumTrials — Simulation trials**

1000 (default) | scalar

Simulation trials, specified as the comma-separated pair consisting of 'NumTrials' and a scalar number of independent sample paths.

Data Types: double

**RandomNumbers — Dependent random variates**

[ ] (default) | structure

Dependent random variates, specified as the comma-separated pair consisting of 'RandomNumbers' and an NSimulationDates-by-NBrownians-by-NTrials 3D time series array. The 3D time series array has the following fields:

- **Z** — NSimulationDates-by-NBrownians-by-NTrials 3D time series array of dependent random variates used to generate the Brownian motion vector (that is, Wiener processes) that drive the simulation.
- **N** — NSimulationDates-by-NBrownians-by-NTrials 3D time series array of dependent random variates used as the number of jumps.
- **SizeJ** — NSimulationDates-by-NBrownians-by-NTrials 3D time series array of dependent random variates used as the jump sizes.

---

**Note** BlackScholes and Heston models only require Z field.

---

Data Types: struct

**DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. DividendType must be either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

**DividendValue — Dividend yield or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend yield for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend yield or a timetable for a dividend schedule.

---

**Note** Specify a scalar if DividendType is "continuous" and a timetable if DividendType is "cash".

---

Data Types: double | timetable

## Properties

### **Model** — Model object

object

Model object, returned as an object.

Data Types: object

### **DiscountCurve** — ratecurve object for discounting cash flows

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **SpotPrice** — Current price of underlying asset

nonnegative numeric

Current price of underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **SimulationDates** — Simulation dates

datetime

Simulation dates, returned as a datetime array.

Data Types: datetime

### **NumTrials** — Simulation trials

1000 (default) | scalar

Simulation trials, returned as a scalar number of independent sample paths.

Data Types: double

### **RandomNumbers** — Dependent random variates

[ ] (default) | structure

Dependent random variates, returned as an NSimulationDates-by-NBrownians-by-NTrials 3D time series array.

Data Types: struct

**EarlyExerciseFunction — Calculation for early exercise premium**`@longstaffschwartz_cubic` (default) | function handle

Calculation for the early exercise premium, returned as a scalar function handle. The default `@longstaffschwartz_cubic` uses the Longstaff-Schwartz least squares method.

Data Types: `function_handle`

**DividendType — Dividend type**`"continuous"` (default) | string with value "cash" or "continuous"

This property is read-only.

Dividend type, returned as a string. `DividendType` is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: `string`

**DividendValue — Dividend yield or dividend schedule for underlying stock**`0` (default) | scalar nonnegative numeric | timetable

Dividend yield or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

**Object Functions**

`price` Compute price for Vanilla, Barrier, Lookback, Asian, Spread, DoubleBarrier, Touch, DoubleTouch, or Binary instrument with `AssetMonteCarlo` pricer

**Examples****Use Asset Monte-Carlo Pricer and Black-Scholes Model to Price Double Barrier Instrument**

This example shows the workflow to price a `DoubleBarrier` instrument when you use a `BlackScholes` model and an `AssetMonteCarlo` pricing method.

**Create DoubleBarrier Instrument Object**

Use `fininstrument` to create a `DoubleBarrier` instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2020, 8, 15))
```

```
DoubleBarrierOpt =  
    DoubleBarrier with properties:
```

```
    OptionType: "call"  
    Strike: 100  
    BarrierValue: [110 80]  
    ExerciseStyle: "american"  
    ExerciseDate: 15-Aug-2020  
    BarrierType: "dko"  
    Rebate: [0 0]  
    Name: "doublebarrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", 0.3)

BlackScholesModel =
    BlackScholes with properties:

        Volatility: 0.3000
        Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2017,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)

myRC =
    ratecurve with properties:

        Type: "zero"
        Compounding: -1
        Basis: 12
        Dates: 15-Sep-2023
        Rates: 0.0350
        Settle: 15-Sep-2017
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an AssetMonteCarlo pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
ExerciseDate = datetime(2020,08,15);
Settle = datetime(2017,9,15);
outPricer = finpricer("AssetMonteCarlo", "DiscountCurve", myRC, "Model", BlackScholesModel, 'SpotPrice')
```

### Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the DoubleBarrier instrument.

```
[Price, outPR] = price(outPricer, DoubleBarrierOpt, "all")

Price = 6.9563

outPR =
    pricerresult with properties:

        Results: [1x7 table]
        PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega
6.9563	0.23644	-0.11701	3.399	0.14976	-99.727	-8.344

### Use Asset Monte-Carlo Pricer and Heston Model to Price Asian Instrument

This example shows the workflow to price a fixed-strike Asian instrument when you use a Heston model and an AssetMonteCarlo pricing method.

#### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 100, 'OptionType', "put")
```

```
AsianOpt =
```

```
Asian with properties:
```

```

    OptionType: "put"
    Strike: 100
    AverageType: "arithmetic"
    AveragePrice: 0
    AverageStartDate: NaT
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
    Name: "asian_option"
```

#### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.02, 'RhoSV', 0.9)
```

```
HestonModel =
```

```
Heston with properties:
```

```

    V0: 0.0320
    ThetaV: 0.1000
    Kappa: 0.0030
    SigmaV: 0.0200
    RhoSV: 0.9000
```

#### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create AssetMonteCarlo Pricer Object

Use `finpricer` to create an `AssetMonteCarlo` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("AssetMonteCarlo", 'DiscountCurve', myRC, "Model", HestonModel, 'SpotPrice', 80,
outPricer =
  HestonMonteCarlo with properties:
      DiscountCurve: [1x1 ratecurve]
      SpotPrice: 80
      SimulationDates: [1x48 datetime]
      NumTrials: 1000
      RandomNumbers: []
      Model: [1x1 finmodel.Heston]
      DividendType: "continuous"
      DividendValue: 0

```

### Price Asian Instrument

Use `price` to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer, AsianOpt, "all")
```

```
Price = 14.7999
```

```
outPR =
  pricerresult with properties:
```

```

      Results: [1x8 table]
      PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x8 table
```

Price	Delta	Gamma	Lambda	Rho	Theta	Vega	VegaLT
-------	-------	-------	--------	-----	-------	------	--------

14.8      -0.71073      0.023453      -3.8418      -173.12      0.61794      27.992      0.15319

# IkedaKunitomo

Create IkedaKunitomo pricer object for DoubleBarrier instrument using BlackScholes model

## Description

Create and price a DoubleBarrier instrument object with a BlackScholes model and a IkedaKunitomo pricing method using this workflow:

- 1 Use `fininstrument` to create a DoubleBarrier instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the DoubleBarrier instrument.
- 3 Use `finpricer` to specify a IkedaKunitomo pricer object for the DoubleBarrier instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a DoubleBarrier instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
IkedaKunitomoPricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
IkedaKunitomoPricerObj = finpricer( ___,Name,Value)
```

### Description

`IkedaKunitomoPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a IkedaKunitomo pricer object by specifying `PricerType` and sets properties on page 11-2563 using the required name-value pair arguments `Model`, `DividendType`, and `SpotPrice`.

`IkedaKunitomoPricerObj = finpricer( ___,Name,Value)` sets optional properties on page 11-2563 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `IkedaKunitomoPricerObj = finpricer("Analytic",'Model','BSModel','DiscountCurve',ratecurve_obj,'SpotPrice',100,'DividendValue',0.025,'PricingMethod','IkedaKunitomo')` creates a IkedaKunitomo pricer object. You can specify multiple name-value pair arguments.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value "Analytic" or a character vector with the value 'Analytic'.

Data Types: char | string

### **IkedaKunitomo Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `IkedaKunitomoPricerObj = finpricer("Analytic", 'Model', 'BSModel', 'DiscountCurve', ratecurve_obj, 'SpotPrice', 100, 'DividendValue', 0.025, 'PricingMethod', "IkedaKunitomo")`

### **Required IkedaKunitomo Name-Value Pair Arguments**

#### **Model — IkedaKunitomo model object**

object

Model object, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created `BlackScholes` model object using `finmodel`.

Data Types: object

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for `DiscountCurve`.

---

Data Types: object

#### **SpotPrice — Current price of underlying asset**

scalar nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric value.

Data Types: double

### **Optional IkedaKunitomo Name-Value Pair Arguments**

#### **DividendValue — Dividend yield**

0 (default) | scalar nonnegative numeric

Dividend yield, specified as the comma-separated pair consisting of `'DividendValue'` and a scalar nonnegative numeric value.

Data Types: double

#### **DividendType — Dividend type**

"continuous" (default) | string with value "continuous" | character vector with value 'continuous'

Dividend type, specified as the comma-separated pair consisting of `'DividendType'` and string or character vector.

Data Types: char | string

### **Curvature — Curvature levels of the upper and lower barriers**

[0 0] (default) | vector

Curvature levels of the upper and lower barriers, specified as the comma-separated pair consisting of 'Curvature' and a vector where the first level is the upper barrier curvature (d1) and second level is the lower barrier curvature (d2). The possible curvature levels are as follows:

- $d1 = d2 = 0$  corresponds to two flat boundaries.
- $d1 < 0 < d2$  corresponds to an exponentially growing lower boundary and an exponentially decaying upper boundary.
- $d1 > 0 > d2$  corresponds to a convex downward lower boundary and a convex upward upper boundary.

Data Types: char | string

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "IkedaKunitomo" | character vector with value 'IkedaKunitomo'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a character vector or string.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: string | char

## **Properties**

### **Model — Model**

model object

Model, returned as a model object.

Data Types: object

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric value.

Data Types: double

**DividendValue – Dividend yield**

0 (default) | scalar nonnegative numeric

Dividend yield, returned as a scalar nonnegative numeric.

Data Types: double

**DividendType – Dividend type**

"continuous" (default) | string with value "continuous"

This property is read-only.

Dividend type, returned as a string.

Data Types: string

**Curvature – Curvature levels of the upper and lower barriers**

[0 0] (default) | vector

Curvature levels of the upper and lower barriers, returned as a vector where the first level is the upper barrier curvature (d1) and second level is the lower barrier curvature (d2).

Data Types: char | string

**PricingMethod – Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "IkedaKunitomo"

Analytic pricing method, returned as a string.

Data Types: string

**Object Functions**

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

**Examples****Use Ikeda-Kunitomo Pricer and Black-Scholes Model to Price Double Barrier Instrument**

This example shows the workflow to price a DoubleBarrier instrument when you use a BlackScholes model and an IkedaKunitomo pricing method.

**Create DoubleBarrier Instrument Object**

Use `fininstrument` to create a DoubleBarrier instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2020, 8, 15))
```

```
DoubleBarrierOpt =  
    DoubleBarrier with properties:
```

```
    OptionType: "call"  
    Strike: 100  
    BarrierValue: [110 80]  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Aug-2020  
    BarrierType: "dko"
```

```

Rebate: [0 0]
Name: "doublebarrier_option"

```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", .3)
```

```

BlackScholesModel =
  BlackScholes with properties:

    Volatility: 0.3000
    Correlation: 1

```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2017,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2017
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create IkedaKunitomo Pricer Object

Use `finpricer` to create an IkedaKunitomo pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Analytic", "DiscountCurve", myRC, "Model", BlackScholesModel, 'SpotPrice', 100,
```

```

outPricer =
  IkedaKunitomo with properties:

    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
    DividendValue: 0.0290
    DividendType: "continuous"
    Curvature: [0.0300 -0.0300]

```

## Price DoubleBarrier Instrument

Use `price` to compute the price and sensitivities for the `DoubleBarrier` instrument.

```
[Price, outPR] = price(outPricer,DoubleBarrierOpt,["all"])
```

```
Price = 5.6848e-04
```

```
outPR =  
  pricerresult with properties:
```

```
    Results: [1x7 table]  
  PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
0.00056848	-3.7713e-05	-4.2071e-06	-6.6339	-0.031332	0.0008912	-0.00035113

# VannaVolga

Create VannaVolga pricer object for Vanilla, Barrier, DoubleBarrier, Touch, or DoubleTouch instrument using BlackScholes model

## Description

Create and price a Vanilla, Barrier, DoubleBarrier, Touch, or DoubleTouch instrument object with a BlackScholes model and a VannaVolga pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla, Barrier, DoubleBarrier, Touch, or DoubleTouch instrument object.
- 2 Use `finmodel` to specify the BlackScholes model for the Vanilla, Barrier, DoubleBarrier, Touch, or DoubleTouch instrument.
- 3 Use `finpricer` to specify the VannaVolga pricer object for the Vanilla, Barrier, DoubleBarrier, Touch, or DoubleTouch instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Vanilla, Barrier, DoubleBarrier, Touch, or DoubleTouch instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
VannaVolgaPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spot_price, 'VolatilityRR', volatilityrr_value, 'VolatilityBF', volatilitybf_value)
```

### Description

`VannaVolgaPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spot_price, 'VolatilityRR', volatilityrr_value, 'VolatilityBF', volatilitybf_value)` creates a VannaVolga pricer object by specifying `PricerType` and sets properties on page 11-2569 using the required name-value pair arguments `DiscountCurve`, `Model`, `SpotPrice`, `VolatilityRR`, and `VolatilityBF`. For example, `VannaVolgaPricerObj = finpricer("VannaVolga", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', Spot, 'VolatilityRR', VolRR, 'VolatilityBF', VolBF, 'DividendValue', RateF)` creates a VannaVolga pricer object.

`VannaVolgaPricerObj = finpricer( ___, Name, Value)` sets optional properties on page 11-2569 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `VannaVolgaPricerObj = finpricer("VannaVolga", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPri`

ce',Spot,'VolatilityRR',VolRR,'VolatilityBF',VolBF,'DividendValue',RateF) creates a VannaVolga pricer object. You can specify multiple name-value pair arguments.

### Input Arguments

#### PricerType — Pricer type

string with value "VannaVolga" | character vector with value 'VannaVolga'

Pricer type, specified as a string with the value "VannaVolga" or a character vector with the value 'VannaVolga'.

Data Types: char | string

#### Required VannaVolga Name-Value Pair Arguments

Specify required comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: VannaVolgaPricerObj =

```
finpricer("VannaVolga", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', Spot, 'VolatilityRR', VolRR, 'VolatilityBF', VolBF, 'DividendValue', RateF)
```

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Data Types: object

#### Model — Model object

BlackScholes model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

#### SpotPrice — Current price of underlying asset

numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar numeric.

Data Types: double

#### VolatilityRR — 25-delta risk reversal (RR) volatility

numeric

25-delta risk reversal (RR) volatility, specified as the comma-separated pair consisting of 'VolatilityRR' and a scalar numeric.

Data Types: double

#### VolatilityBF — 25-delta butterfly (BF) volatility

numeric

25-delta butterfly (BF) volatility, specified as the comma-separated pair consisting of 'VolatilityBF' and a scalar numeric.

Data Types: double

### Optional VannaVolga Name-Value Pair Arguments

#### DividendType — Dividend type

"continuous" (default) | string with value of "continuous" | character vector with value of 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector for a continuous dividend yield.

Data Types: char | string

#### DividendValue — Continuous dividend yield

0 (default) | scalar numeric

Continuous dividend yield, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric.

---

**Note** When pricing currency (FX) options, specify the optional input argument 'DividendValue' as the continuously compounded risk-free interest rate in the foreign country.

---

Data Types: double

## Properties

#### DiscountCurve — ratecurve object for discounting cash flows

object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

#### Model — Model

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

#### SpotPrice — Current price of underlying asset

numeric

Current price of the underlying asset, returned as a scalar numeric.

Data Types: double

#### VolatilityRR — 25-delta risk reversal (RR) volatility

numeric

25-delta risk reversal (RR) volatility, returned as a scalar numeric.

Data Types: double

**VolatilityBF — 25-delta butterfly (BF) volatility**

numeric

25-delta butterfly (BF) volatility, returned as a scalar numeric.

Data Types: double

**DividendType — Dividend type**

"continuous" (default) | string with value of "continuous"

This property is read-only.

Dividend type, returned as a string.

Data Types: string

**DividendValue — Continuous dividend yield**

0 (default) | scalar numeric

Continuous dividend yield, returned as a scalar numeric.

Data Types: double

**Object Functions**

price Compute price for equity instrument with VannaVolga pricer

**Examples****Use Vanna Volga Pricer and Black-Scholes Model to Price Double Barrier Instrument**

This example shows the workflow to price a DoubleBarrier instrument when you use a BlackScholes model and a VannaVolga pricing method.

**Create DoubleBarrier Instrument Object**Use `fininstrument` to create a DoubleBarrier instrument object.

```
DoubleBarrierOpt = fininstrument("DoubleBarrier", 'Strike', 100, 'ExerciseDate', datetime(2020, 8, 15))
```

```
DoubleBarrierOpt =  
    DoubleBarrier with properties:
```

```
    OptionType: "call"  
    Strike: 100  
    BarrierValue: [110 80]  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Aug-2020  
    BarrierType: "dko"  
    Rebate: [0 0]  
    Name: "doublebarrier_option"
```

**Create BlackScholes Model Object**Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", "Volatility", 0.02)
```

```
BlackScholesModel =
  BlackScholes with properties:
```

```
    Volatility: 0.0200
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2019,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
  ratecurve with properties:
    Type: "zero"
    Compounding: -1
    Basis: 12
    Dates: 15-Sep-2023
    Rates: 0.0350
    Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create VannaVolga Pricer Object

Use finpricer to create a VannaVolga pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
VolRR = -0.0045;
VolBF = 0.0037;
RateF = 0.0210;
outPricer = finpricer("VannaVolga", "DiscountCurve", myRC, "Model", BlackScholesModel, 'SpotPrice', 100)
```

```
outPricer =
  VannaVolga with properties:
    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
    DividendType: "continuous"
    DividendValue: 0.0210
    VolatilityRR: -0.0045
    VolatilityBF: 0.0037
```

### Price DoubleBarrier Instrument

Use price to compute the price and sensitivities for the DoubleBarrier instrument.

```
[Price, outPR] = price(outPricer, DoubleBarrierOpt, ["all"])
```

```
Price = 1.6450
outPR =
  pricerresult with properties:
    Results: [1x7 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
1.645	0.82818	75.662	50.346	14.697	-1.3145	74.666

## More About

### Vanna-Volga Method

The Vanna Volga method is an empirical procedure based on adding an analytically derived correction to the Black-Scholes price of the instrument.

The Vanna-Volga method consists of adjusting the Black-Scholes theoretical value (BSTV) by the cost of a portfolio which hedges three main risks associated to the volatility of the option: the Vega, the Vanna and the Volga.

The general formulation of the Vanna-Volga method suggests that the Vega, Vanna, and Volga values can be replicated by the weighted sum of at-the-money (ATM), risk-reversal (RR), and butterfly (BF) strategies.

$$X_i = \omega_{ATM}ATM_i + \omega_{RR}RR_i + \omega_{BF}BF_i \quad (i = vega, vanna, volga)$$

Here, the weights are obtained by solving the system  $x = A\omega$

$$A = \begin{matrix} ATM_{vega} & RR_{vega} & BF_{vega} \\ ATM_{vanna} & RR_{vanna} & BF_{vanna} \\ ATM_{volga} & RR_{volga} & BF_{volga} \end{matrix}, \quad \omega = \begin{matrix} \omega_{ATM} \\ \omega_{RR} \\ \omega_{BF} \end{matrix}, \quad X = \begin{matrix} X_{vega} \\ X_{vanna} \\ X_{volga} \end{matrix}$$

Given this replication, the Vanna-Volga method adjusts the Black-Scholes price of the option by the smile cost of the above weighted sum:

$$\begin{aligned} X^{VV} &= X^{BS} + \omega_{ATM}(ATM^{mkt} - ATM^{BS}) + \omega_{RR}(RR^{mkt} - RR^{BS}) + \omega_{BF}(BF^{mkt} - BF^{BS}) \\ &= X^{BS} + \chi^T(A^T I) \\ &= X^{BS} + X_{vega}\Omega_{vega} + X_{vanna}\Omega_{vanna} + X_{volga}\Omega_{volga} \end{aligned}$$

$$\text{where } I = \begin{matrix} ATM^{mkt} - ATM^{BS} \\ RR^{mkt} - RR^{BS} \\ BF^{mkt} - BF^{BS} \end{matrix}, \quad \Omega_{vega} = \begin{matrix} \Omega_{vega} \\ \Omega_{vanna} \\ \Omega_{volga} \end{matrix} = (A^T I)$$

The resulting correction or overhedge turns out to be too large. So, the option value is modified as follows:

$$X^{VV} = X^{BS} + X_{vega}\Omega_{vega} + X_{vanna}\Omega_{vanna} + X_{volga}\Omega_{volga}$$

$$\text{where, } \rho_{vega} = \frac{1}{2} + \frac{1}{2}\rho, \text{ and } \rho_{volga} = \frac{1}{2} + \frac{1}{2}\rho.$$

$\rho$  is the risk-neutral probability of not hitting the barrier.

## Introduced in R2020b

## Heston

Create Heston pricer object for VarianceSwap instrument using Heston model

### Description

Create and price a VarianceSwap instrument object with a Heston model and a Heston pricing method using this workflow:

- 1 Use `fininstrument` to create a VarianceSwap instrument object.
- 2 Use `finmodel` to specify the Heston model for the VarianceSwap instrument.
- 3 Use `finpricer` to specify the Heston pricer object for the VarianceSwap instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a VarianceSwap instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Creation

#### Syntax

```
HestonPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

#### Description

`HestonPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a Heston pricer object by specifying `PricerType` and sets properties on page 11-2575 using the required name-value pair arguments `DiscountCurve` and `Model`. For example, `HestonPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', HWMModel)` creates a Heston pricer object.

#### Input Arguments

##### **PricerType** – Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value "Analytic" or a character vector with the value 'Analytic'.

Data Types: char | string

##### **Heston Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: HestonPricerObj =
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', HWModel)
```

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** The software uses the Basis value of the specified ratecurve object to calculate both the discounting and accrual for the VarianceSwap instrument object.

---

Data Types: object

### **Model — Model object**

Heston model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of the previously created Heston model object using finmodel.

Data Types: object

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **Model — Model**

Heston model object

Model, returned as a Heston model object.

Data Types: object

## **Object Functions**

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Heston Pricer and Heston Model to Price Variance Swap Instrument**

This example shows the workflow to price a VarianceSwap instrument when you use a Heston model and a Heston pricing method.

#### **Create VarianceSwap Instrument Object**

Use fininstrument to create a VarianceSwap instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap", 'Maturity', datetime(2020,9,15), 'Notional', 100, 'S
```

```
VarianceSwapInst =  
  VarianceSwap with properties:  
      Notional: 100  
  RealizedVariance: 0.0200  
      Strike: 0.1000  
  StartDate: 15-Jun-2020  
  Maturity: 15-Sep-2020  
      Name: "variance_swap_instrument"
```

### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.06, 'ThetaV', 0.1, 'Kappa', 0.9, 'SigmaV', 0.7, 'RhoSV', -.3)
```

```
HestonModel =  
  Heston with properties:
```

```
      V0: 0.0600  
  ThetaV: 0.1000  
      Kappa: 0.9000  
  SigmaV: 0.7000  
  RhoSV: -0.3000
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2020, 1, 1);  
ZeroTimes = calmonths(3);  
ZeroRates = 0.05;  
ZeroDates = Settle + ZeroTimes;  
Basis = 1;  
ZeroCurve = ratecurve("zero", Settle, ZeroDates, ZeroRates, 'Basis', Basis)
```

```
ZeroCurve =  
  ratecurve with properties:
```

```
      Type: "zero"  
  Compounding: -1  
      Basis: 1  
      Dates: 01-Apr-2020  
      Rates: 0.0500  
      Settle: 01-Jan-2020  
  InterpMethod: "linear"  
  ShortExtrapMethod: "next"  
  LongExtrapMethod: "previous"
```

### Create Heston Pricer Object

Use `finpricer` to create a Heston pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("Analytic", 'DiscountCurve', ZeroCurve, 'Model', HestonModel)
outPricer =
  Heston with properties:
    DiscountCurve: [1x1 ratecurve]
    Model: [1x1 finmodel.Heston]

```

### Price VarianceSwap Instrument

Use price to compute the price and fair variance for the VarianceSwap instrument.

```
[Price, outPR] = price(outPricer, VarianceSwapInst, ["all"])
```

```
Price = 6.0054
```

```

outPR =
  pricerresult with properties:
    Results: [1x2 table]
    PricerData: []

```

```
outPR.Results
```

```

ans=1x2 table
  Price      FairVariance
  _____  _____
  6.0054     0.07039

```

### Algorithms

Variance swaps can be priced with the calibrated Heston model by using the following closed-form expression for the fair variance:

$$K_{\text{var}} = \frac{1 - e^{-kT}}{kT} (n_0 - \theta) + \theta$$

Here:

- $\nu_0$  is the initial variance of the underlying asset at  $t=0$   $\nu_0 > 0$ .
- $\theta$  is the long-term variance level  $\theta > 0$ .
- $k$  is the mean reversion speed for the variance ( $k > 0$ ).

Once the fair variance is computed, the actual price paid in the market at time  $t$  for the variance swap with a start date at time 0 is computed as follows:

$$\text{VarianceSwap}(t) = \text{Notional} \times \text{Disc}(t, T) \times \left[ \frac{t}{T} \text{RealizedVariance}(0, t) + \frac{T-t}{T} \text{FairVariance}(t, T) - \text{StrikeVariance} \right]$$

Here:

- $t$  is the time from the start date of the variance swap to the settle date.
- $T$  is the time from the start date to the maturity date of the variance swap.
- $Disc(t,T)$  is the discount factor from settle to the maturity date.
- $RealizedVariance(0,t)$  is the realized variance from start date to the settle date, in basis points.
- $FairVariance(t,T)$  is the fair variance for the remaining life of the contract as of the settle date, in basis points.
- $StrikeVariance$  is the strike variance predetermined at inception (start date), in basis points.

# ReplicatingVarianceSwap

Create ReplicatingVarianceSwap pricer object for VarianceSwap instrument using ratecurve object

## Description

Create and price a VarianceSwap instrument object with a ratecurve object and a ReplicatingVarianceSwap pricing method using this workflow:

- 1 Use fininstrument to create a VarianceSwap instrument object.
- 2 Use ratecurve to specify a curve model for the VarianceSwap instrument.
- 3 Use finpricer to specify a ReplicatingVarianceSwap pricer object for the VarianceSwap instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a VarianceSwap instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
ReplicatingVarianceSwapPricerObj = finpricer(PricerType, '
DiscountCurve', ratecurve_obj, 'VolatilitySmile', volatilitysmile_value, '
SpotPrce', spotprice_value)
ReplicatingVarianceSwapPricerObj = finpricer( ___, Name, Value)
```

### Description

ReplicatingVarianceSwapPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve\_obj, 'VolatilitySmile', volatilitysmile\_value, 'SpotPrce', spotprice\_value) creates an ReplicatingVarianceSwap pricer object by specifying PricerType and sets properties on page 11-2581 using the required name-value pair arguments DiscountCurve, VolatilitySmile, and SpotPrice.

ReplicatingVarianceSwapPricerObj = finpricer( \_\_\_, Name, Value) sets optional properties on page 11-2581 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, ReplicatingVarianceSwapPricerObj = finpricer("ReplicatingVarianceSwap", 'DiscountCurve', ratecurve\_obj, 'VolatilitySmile', smiletable, 'SpotPrice', 1000, 'CallPutBoundary', "forwardprice", 'InterpMethod', "cubic") creates a ReplicatingVarianceSwap pricer object. You can specify multiple name-value pair arguments.

## Input Arguments

### **PricerType — Pricer type**

string with value "ReplicatingVarianceSwap" | character vector with value 'ReplicatingVarianceSwap'

Pricer type, specified as a string with the value "ReplicatingVarianceSwap" or a character vector with the value 'ReplicatingVarianceSwap'.

Data Types: char | string

### **ReplicatingVarianceSwap Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: ReplicatingVarianceSwapPricerObj =  
finpricer("ReplicatingVarianceSwap", 'DiscountCurve', ratecurve\_obj, 'VolatilitySmile', smiletable, 'SpotPrice', 1000, 'CallPutBoundary', "forwardprice", 'InterpMethod', "cubic")

### **Required ReplicatingVarianceSwap Name-Value Pair Arguments**

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a ratecurve object.

---

## Note

- Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.
  - The software uses the Basis value of the specified ratecurve object to calculate both the discounting and accrual for the VarianceSwap instrument object.
- 

Data Types: object

#### **VolatilitySmile — Volatility smile table**

table | matrix

Volatility smile table, specified as the comma-separated pair consisting of 'VolatilitySmile' and a table with the columns "Strike" and "Volatility" or a NumVols-by-2 matrix where the first column is the strikes and the second column is the volatilities in decimals.

Data Types: table | double

#### **SpotPrice — Spot price of underlying asset**

nonnegative numeric

Spot price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

---

**Note** SpotPrice must be covered by the range of strikes in VolatilitySmile.

---

Data Types: double

### Optional ReplicatingVarianceSwap Name-Value Pair Arguments

#### CallPutBoundary — Boundary strike for call and put options

"spotprice" (default) | scalar numeric | character vector with value 'spotprice' or 'forwardprice' | string with value "spotprice" or "forwardprice"

Boundary strike for call and put options, specified as the comma-separated pair consisting of 'CallPutBoundary' and a scalar numeric or one of the following character vectors or strings:

- "spotprice" — The call and put option boundary strike is the spot price.
- "forwardprice" — The call and put option boundary strike is the forward price.

---

**Note** CallPutBoundary must be covered by the range of strikes in VolatilitySmile.

---

Data Types: double | char | string

#### InterpMethod — Interpolation method for SmileTable

"linear" (default) | string with value "linear", "cubic", "next", "previous", "pchip", "v5cubic", "makima", or "spline" | character vector with value 'linear', 'cubic', 'next', 'previous', 'pchip', 'v5cubic', 'makima', or 'spline'

Interpolation method for SmileTable, specified as the comma-separated pair consisting of 'InterpMethod' and a scalar string or character vector using a supported value. For more information on interpolation methods, see `interp1`.

Data Types: char | string

## Properties

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object.

---

**Note** The software uses the Basis value of the specified ratecurve object to calculate both the discounting and accrual for the VarianceSwap instrument object.

---

Data Types: object

### VolatilitySmile — Volatility smile table

table | matrix

Volatility smile table, returned as a table with the columns "Strike" and "Volatility" or a NumVols-by-2 matrix where the first column is the strikes and the second column is the volatilities in decimals.

Data Types: table | double

### SpotPrice — Strike price of underlying asset

nonnegative numeric

Strike price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### CallPutBoundary — Boundary strike for call and put options

"spotprice" (default) | scalar numeric | string with value "spotprice" or "forwardprice"

Boundary strike for call and put options, returned as a numeric or as a string with the value "spotprice" or "forwardprice".

Data Types: double | char | string

### InterpMethod — Interpolation method

"linear" (default) | string with value "linear", "cubic", "next", "previous", "pchip", "v5cubic", "makima", or "spline"

Interpolation method, returned as a scalar string.

Data Types: string

## Object Functions

price Compute price for equity instrument with ReplicatingVarianceSwap pricer

## Examples

### Use Replicating Variance Swap Pricer and ratecurve to Price Variance Swap Instrument

This example shows the workflow to price a VarianceSwap instrument when you use a ratecurve and a ReplicatingVarianceSwap pricing method.

#### Create VarianceSwap Instrument Object

Use `fininstrument` to create a VarianceSwap instrument object.

```
VarianceSwapInst = fininstrument("VarianceSwap", 'Maturity', datetime(2021,5,1), 'Notional', 150, 'St
```

```
VarianceSwapInst =
  VarianceSwap with properties:

    Notional: 150
    RealizedVariance: 0.0500
    Strike: 0.1000
    StartDate: 01-May-2020
    Maturity: 01-May-2021
    Name: "variance_swap_instrument"
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2020, 9, 15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Basis = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates,'Basis',Basis)
```

```
ZeroCurve =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 1
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2020
        InterpMethod: "linear"
        ShortExtrapMethod: "next"
        LongExtrapMethod: "previous"
```

### Create ReplicatingVarianceSwap Pricer Object

Use finpricer to create a ReplicatingVarianceSwap pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
Strike = (50:5:135)';
Volatility = [.49;.45;.42;.38;.34;.31;.28;.25;.23;.21;.2;.21;.21;.22;.23;.24;.25;.26];
VolatilitySmile = table(Strike, Volatility);
SpotPrice = 100;
CallPutBoundary = 100;
```

```
outPricer = finpricer("ReplicatingVarianceSwap",'DiscountCurve', ZeroCurve, 'VolatilitySmile', 'SpotPrice', SpotPrice, 'CallPutBoundary', CallPutBoundary)
```

```
outPricer =
    ReplicatingVarianceSwap with properties:
```

```
    DiscountCurve: [1x1 ratecurve]
    InterpMethod: "linear"
    VolatilitySmile: [18x2 table]
    SpotPrice: 100
    CallPutBoundary: 100
```

### Price VarianceSwap Instrument

Use price to compute the price and fair variance for the VarianceSwap instrument.

```
[Price, outPR] = price(outPricer,VarianceSwapInst,["all"])
```

```
Price = 8.1997
```

```
outPR =
    pricerresult with properties:
```

```
Results: [1x2 table]
PricerData: [1x1 struct]
```

outPR.Results

```
ans=1x2 table
    Price    FairVariance
    _____
    8.1997    0.21701
```

outPR.PricerData.ReplicatingPortfolio

```
ans=19x6 table
    CallPut    Strike    Volatility    Weight    Value    Contribution
    _____
    "put"      50        0.49        0.0064038    0.39164    0.002508
    "put"      55        0.45        0.0052877    0.49353    0.0026097
    "put"      60        0.42        0.0044402    0.67329    0.0029895
    "put"      65        0.38        0.0037814    0.80343    0.0030381
    "put"      70        0.34        0.0032592    0.9419     0.0030698
    "put"      75        0.31        0.0028382    1.223     0.0034711
    "put"      80        0.28        0.0024938    1.58      0.0039403
    "put"      85        0.25        0.0022086    2.0456    0.0045177
    "put"      90        0.23        0.0019696    2.9221    0.0057554
    "put"      95        0.21        0.0017675    4.1406    0.0073183
    "put"      100       0.2        0.00082405   6.1408    0.0050603
    "call"     100       0.2        0.00077087   6.4715    0.0049887
    "call"     105       0.21       0.0014465    4.7094    0.0068119
    "call"     110       0.21       0.0013178    3.1644    0.0041701
    "call"     115       0.22       0.0012056    2.307     0.0027814
    "call"     120       0.23       0.0011072    1.7127    0.0018962
    :
```

## More About

### Replicating Variance Swap

A replicating variance swap uses a portfolio of options.

The variance swap replication is accomplished using a portfolio of options with different strikes.

### Algorithms

The fair value of the future variance  $K_{var}$  is approximated in terms of the following portfolio of options  $\Pi_{CP}$ :

$$K_{var} = \frac{2}{T} \left\{ rT - \left( \frac{S_0}{S^*} e^{rT} - 1 \right) - \log \frac{S^*}{S_0} + e^{rT} \Pi_{CP} \right\}$$

$$\Pi_{CP} = \sum_i w(K_{ip}) P(S, K_{ip}) + \sum_i w(K_{ic}) C(S, K_{ic})$$

Here:

- Call option strikes — The call option strike are  $K_0 < K_{1c} < K_{2c} < K_{3c} \dots < K_{nc}$ .
- Put option strikes — The put option strikes are  $K_{mp} < \dots < K_{3p} < K_{2p} < K_{1p} < K_0 = S_*$ .
- $K_{var}$  — is the fair value of future variance
- $\Pi_{CP}$  — is the portfolio of call and put options
- $S_0$  — is the current asset price
- $S_*$  — is the boundary between the call and put option strikes (for example, the spot price  $S_0$  or forward price  $S_0 e^{rT}$ )
- $P(K)$  — is the current put option price with strike  $K$
- $C(K)$  — is the current call option price with strike  $K$

If the options portfolio  $\Pi_{CP}$  has an infinite number of options with continuously varying strikes, it has the following payoff function at maturity:

$$f(S_T) = \frac{2}{T} \left[ \frac{S_T - S_*}{S_*} - \log \frac{S_T}{S_*} \right]$$

Since it is not possible to construct such a portfolio with an infinite number of options and continuously varying strikes, the appropriate weights  $w(K_{ip})$  and  $w(K_{ic})$  for a portfolio with a finite number of options and discretely varying strikes can be computed by approximating the continuous payoff function  $f(S_T)$  in a piecewise linear fashion. Starting with the strike at  $K_0$ , the first call option weight can be computed as the slope of the first piecewise linear function:

$$w_c(K_0) = \frac{f(K_{1c}) - f(K_0)}{K_{1c} - K_0}$$

The next call option weight with the strike  $K_{1c}$  is computed as the slope of the next piece-wise linear function minus the previous weight:

$$w_c(K_{1c}) = \frac{f(K_{2c}) - f(K_{1c})}{K_{2c} - K_{1c}} - w_c(K_0)$$

This procedure is continued for the remaining call option strikes:

$$w_c(K_{n,c}) = \frac{f(K_{n+1,c}) - f(K_{nc})}{K_{n+1,c} - K_{n,c}} - \sum_{i=0}^{n-1} w_c(K_{i,c})$$

To compute the put option weights, a similar procedure can be used in the opposite direction (starting from  $K_0$ ):

$$w_p(K_{m,p}) = \frac{f(K_{m+1,p}) - f(K_{mp})}{K_{m,p} - K_{m+1,p}} - \sum_{i=0}^{m-1} w_p(K_{i,p})$$

Once the fair variance is computed, the actual price paid in the market at time  $t$  for the variance swap with a StartDate at time 0 is computed as follows:

$$\text{VarianceSwap}(t) = \text{Notional} \times \text{Disc}(t, T) \times \left[ \frac{t}{T} \text{RealizedVariance}(0, t) + \frac{T-t}{T} \text{FairVariance}(t, T) - \text{StrikeVariance} \right]$$

Here:

- $t$  is the time from the start date of the variance swap to the settle date.
- $T$  is the time from the start date to the maturity date of the variance swap.
- $Disc(t,T)$  is the discount factor from settle to the maturity date.
- $RealizedVariance(0,t)$  is the realized variance from start date to the settle date, in basis points.
- $FairVariance(t,T)$  is the fair variance for the remaining life of the contract as of the settle date, in basis points.
- $StrikeVariance$  is the strike variance predetermined at inception (start date), in basis points.

# BjersundStensland

Create BjersundStensland pricer object for Vanilla or Spread instrument using BlackScholes model

## Description

Create and price a Vanilla or Spread instrument object with a BlackScholes model and a BjersundStensland pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla or Spread instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Vanilla or Spread instrument.
- 3 Use `finpricer` to specify a BjersundStensland pricer object for the Vanilla instrument (American exercise) or Spread instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Vanilla or Spread instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
BjersundStenslandPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotprice_value)
BjersundStenslandPricerObj = finpricer( ___, Name, Value)
```

### Description

`BjersundStenslandPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotprice_value)` creates a BjersundStensland pricer object by specifying `PricerType` and sets the properties on page 11-2589 for the required name-value pair arguments `Model`, `DividendType`, and `SpotPrice`.

`BjersundStenslandPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2589 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `BjersundStenslandPricerObj = finpricer("Analytic", 'Model', 'BSModel', 'DiscountCurve', ratecurve_obj, 'SpotPrice', [100;105], 'DividendValue', [2.5,2.8], 'PricingMethod', "BjersundStensland")` creates a BjersundStensland pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### **BjerksundStensland Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `BjerksundStenslandPricerObj = finpricer("Analytic", 'Model', 'BSModel', 'DiscountCurve', ratecurve_obj, 'SpotPrice', [100;105], 'DividendValue', [2.5,2.8], 'PricingMethod', "BjerksundStensland")`

### **Required BjerksundStensland Name-Value Pair Arguments**

#### **Model — Model object**

object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of the previously created BlackScholes model object using `finmodel`.

Data Types: object

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **SpotPrice — Current price of underlying asset**

scalar nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar or vector of nonnegative numeric values. Use a vector for SpotPrice when pricing a Spread instrument.

Data Types: double

### **Optional BjerksundStensland Name-Value Pair Arguments**

#### **DividendValue — Dividend yield**

[0,0] (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield, specified as the comma-separated pair consisting of 'DividendValue' and a scalar or vector of nonnegative numeric values. Use a 1-by-2 vector of nonnegative values for DividendValue when pricing a Spread instrument.

Data Types: double

**DividendType — Dividend type**

"continuous" (default) | string with value "continuous" | character vector with value 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and string or character vector.

Data Types: char | string

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "Bjerk SundStensland" | character vector with value 'Bjerk SundStensland'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a character vector or string.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: string | char

**Properties****Model — Model**

model object

Model, returned as a model object.

Data Types: object

**DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, returned as a scalar or vector of nonnegative numeric values.

Data Types: double

**DividendValue — Dividend yield**

scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield, returned as a scalar or vector of nonnegative numeric.

Data Types: double

**DividendType — Dividend type**

"continuous" (default) | string with value "continuous"

This property is read-only.

Dividend type, returned as a string.

Data Types: string

### PricingMethod — Analytic pricing method

default pricer associated with BlackScholes model (default) | string with value "BjerkSundStensland"

Analytic pricing method, returned as a string.

Data Types: string

## Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use BjerkSund-Stensland Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a European exercise Spread instrument when you use a BlackScholes model and a BjerkSundStensland pricing method.

#### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 5, 'ExerciseDate', datetime(2021, 9, 15), 'OptionType', "put")
```

```
SpreadOpt =
```

```
Spread with properties:
```

```
    OptionType: "put"
    Strike: 5
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2021
    Name: "spread_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [0.2, 0.1])
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
    Volatility: [0.2000 0.1000]
    Correlation: [2x2 double]
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create BjerksundStensland Pricer Object

Use `finpricer` to create a BjerksundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',[100

```

```

outPricer =
  BjerksundStensland with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: [100 105]
      DividendValue: [0.0900 0.1700]
      DividendType: "continuous"

```

### Price Spread Instrument

Use `price` to compute the price and sensitivities for the Spread instrument.

```

[Price, outPR] = price(outPricer,SpreadOpt,["all"])

```

```

Price = 7.0596

```

```

outPR =
  pricerresult with properties:

```

```

      Results: [1x7 table]
      PricerData: []

```

```

outPR.Results

```

```

ans=1x7 table

```

Price	Delta	Gamma	Lambda	Vega
-------	-------	-------	--------	------

```
7.0596 -0.23249 0.27057 0.0069887 0.0055319 -3.2932 3.8327 41.938
```

### Use Bjerksund-Stensland Pricer and Black-Scholes Model to Price an American Exercise Vanilla Instrument

This example shows the workflow to price an American exercise Vanilla instrument when you use a BlackScholes model and a BjerksundStensland pricing method.

#### Create Vanilla Instrument Object

Use `fininstrument` to create an American exercise Vanilla instrument object.

```
VanillaObj = fininstrument("Vanilla", 'Strike', 120, 'ExerciseDate', datetime(2019,1,30), 'OptionType'
```

```
VanillaObj =
  Vanilla with properties:

      OptionType: "put"
      ExerciseStyle: "american"
      ExerciseDate: 30-Jan-2019
      Strike: 120
      Name: "vanilla_instrument"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .2)
```

```
BlackScholesModel =
  BlackScholes with properties:

      Volatility: 0.2000
      Correlation: 1
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =
  ratecurve with properties:

      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
```

```
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

## Create Bjerk SundStensland Pricer Object

Use `finpricer` to create a Bjerk SundStensland pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', 120,
outPricer =
    Bjerk SundStensland with properties:

        DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
        SpotPrice: 120
    DividendValue: 0.0500
    DividendType: "continuous"
```

## Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaObj, ["all"])
```

```
Price = 6.1080
```

```
outPR =
    pricerresult with properties:

        Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
6.108	-0.48471	0.026611	-9.5227	28.781	-8.3418	-24.115

## Black

Create Black pricer object for Cap, Floor, or Swaption instrument using Black model

### Description

Create and price a Cap, Floor, or Swaption instrument object with a Black model and a Black pricing method using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, or Swaption instrument object.
- 2 Use `finmodel` to specify a Black model for the Cap, Floor, or Swaption instrument.
- 3 Use `finpricer` to specify a Black pricer object for the Cap, Floor, or Swaption instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a Cap, Floor, or Swaption instrument with the Black pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Cap, Floor, or Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
BlackPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

### Description

`BlackPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a Black pricer object by specifying `PricerType` and the required name-value pair arguments for `DiscountCurve` and `Model` to set properties on page 11-2595 using name-value pairs. For example, `BlackPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BlackModel)` creates a Black pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### Black Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: BlackPricerObj =
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BlackModel)
```

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

Data Types: object

### Model — Model

Black model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created Black model object using `finmodel`.

Data Types: object

## Properties

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object

Data Types: object

### Model — Model

Black model object

Model, returned as a Black model object.

Data Types: object

## Object Functions

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use Black Pricer and Black Model to Price Cap Instrument

This example shows the workflow to price a Cap instrument when you use a Black model and a Black pricing method.

#### Create Cap Instrument Object

Use `fininstrument` to create a Cap instrument object.

```

CapOpt = fininstrument("Cap", 'Strike', .02, 'Maturity', datetime(2021,12,30), 'Reset', 4, 'Principal', ...
CapOpt =
  Cap with properties:
      Strike: 0.0200
      Maturity: 30-Dec-2021
      ResetOffset: 0
      Reset: 4
      Basis: 12
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "cap_option"

```

### Create Black Model Object

Use `finmodel` to create a Black model object.

```
BlackModel = finmodel("Black", 'Volatility', 0.09, 'Shift', 0.002)
```

```

BlackModel =
  Black with properties:
      Volatility: 0.0900
      Shift: 0.0020

```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```

Settle = datetime(2020,9,14);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 14-Sep-2020
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

## Create Black Pricer Object

Use `finpricer` to create a Black pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', BlackModel, 'DiscountCurve', myRC)

outPricer =
    Black with properties:
        Model: [1x1 finmodel.Black]
        DiscountCurve: [1x1 ratecurve]
```

## Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
Price = price(outPricer, CapOpt)

Price = 4.6412e-29
```

## See Also

## Introduced in R2020a

## BlackScholes

Create BlackScholes pricer object for Vanilla, Barrier, Touch, DoubleTouch, or Binary instrument using BlackScholes model

### Description

Create and price a Vanilla, Barrier, Touch, DoubleTouch, or Binary instrument object with a BlackScholes model and a BlackScholes pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla, Barrier, DoubleTouch, Binary or , Touch instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Vanilla, Barrier, Touch, DoubleTouch, or Binary instrument.
- 3 Use `finpricer` to specify a BlackScholes pricer object for the Vanilla, Barrier, Touch, DoubleTouch, or Binary instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Vanilla, Lookback, Barrier, Asian, Spread, Touch, DoubleTouch, or Binary instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Creation

#### Syntax

```
BlackScholesPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, '
Model', model, 'SpotPrice', spotprice_value, )
BlackScholesPricerObj = finpricer( ____, Name, Value)
```

#### Description

`BlackScholesPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value, )` creates a BlackScholes pricer object by specifying `PricerType` and sets properties on page 11-2600 using the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`BlackScholesPricerObj = finpricer( ____, Name, Value)` sets optional properties on page 11-2600 using additional name-value pair arguments in addition to the required arguments in the previous syntax. For example, `BlackScholesPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100)` creates a BlackScholes pricer object. You can specify multiple name-value pair arguments.

## Input Arguments

### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value "Analytic" or a character vector with the value 'Analytic'.

Data Types: char | string

### BlackScholes Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: BlackScholesPricerObj =  
finpricer("Analytic", 'DiscountCurve', ratecurve\_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100)

### Required BlackScholes Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### Model — Model object

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional BlackScholes Name-Value Pair Arguments

#### DividendType — Stock dividend type

"continuous" (default) | string with value "continuous" | character vector with value 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string.

---

**Note** When you price currencies using a Vanilla instrument, DividendType must be "continuous" and DividendValue is the annualized risk-free interest rate in the foreign country.

---

Data Types: char | string

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend amount or dividend schedule for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

---

**Note** When you price currencies using a Vanilla instrument, the DividendType must be "continuous" and DividendValue is the annualized risk-free interest rate in the foreign country.

---

Data Types: double | timetable

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **DividendType — Stock dividend type**

"continuous" (default) | string with value "continuous"

This property is read-only.

Stock dividend type, returned as a string.

Data Types: string

**DividendValue – Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Data Types: double | timetable

**Object Functions**

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

**Examples****Price Vanilla Instrument Using Black-Scholes Model and Black-Scholes Pricer**

This example shows the workflow to price a Vanilla instrument when you use a BlackScholes model and a BlackScholes pricing method.

**Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2018,5,1), 'Strike', 29, 'OptionType', 'put')
```

```
VanillaOpt =
  Vanilla with properties:
      OptionType: "put"
  ExerciseStyle: "european"
  ExerciseDate: 01-May-2018
      Strike: 29
      Name: "vanilla_option"
```

**Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.25)
```

```
BlackScholesModel =
  BlackScholes with properties:
      Volatility: 0.2500
  Correlation: 1
```

**Create ratecurve Object**

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2019,1,1);
Rate = 0.05;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 1
      Dates: 01-Jan-2019
      Rates: 0.0500
      Settle: 01-Jan-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create BlackScholes Pricer Object

Use `finpricer` to create a `BlackScholes` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', 30, 'D', 0.0450)
```

```

outPricer =
  BlackScholes with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 30
      DividendValue: 0.0450
      DividendType: "continuous"

```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the `Vanilla` instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 1.2046
```

```

outPR =
  pricerresult with properties:

```

```

      Results: [1x7 table]
      PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
1.2046	-0.36943	0.086269	-9.3396	6.4702	-4.0959	-2.3107

## Use Black-Scholes Pricer and Black-Scholes Model to Price Vanilla Instrument for Foreign Exchange

This example shows the workflow to price a Vanilla instrument for foreign exchange (FX) when you use a BlackScholes model and a BlackScholes pricing method. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per year. The annualized continuously compounded foreign risk-free rate is 8% per year.

### Create Vanilla Instrument Object

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', .50, 'OptionType')
VanillaOpt =
    Vanilla with properties:
        OptionType: "put"
        ExerciseStyle: "european"
        ExerciseDate: 15-Sep-2022
        Strike: 0.5000
        Name: "vanilla_fx_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes", 'Volatility', Sigma)
BlackScholesModel =
    BlackScholes with properties:
        Volatility: 0.1200
        Correlation: 1
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
```

```

        Settle: 15-Sep-2018
        InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create BlackScholes Pricer Object

Use `finpricer` to create a BlackScholes pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument. When you price currencies using a Vanilla instrument, `DividendType` must be 'continuous' and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```

ForeignRate = 0.08;
outPricer = finpricer("analytic", 'DiscountCurve', myRC, 'Model', BlackScholesModel, 'SpotPrice', .52,
outPricer =
    BlackScholes with properties:

        DiscountCurve: [1x1 ratecurve]
            Model: [1x1 finmodel.BlackScholes]
            SpotPrice: 0.5200
        DividendValue: 0.0800
        DividendType: "continuous"

```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla FX instrument.

```

[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
Price = 0.1123
outPR =
    pricerresult with properties:

        Results: [1x7 table]
        PricerData: []

```

outPR.Results

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
0.11229	-0.59114	1.5562	-3.7706	0.20212	-1.6799	-0.023676

# ConzeViswanathan

Create ConzeViswanathan pricer object for Lookback instrument using BlackScholes model

## Description

Create and price a Lookback instrument object with a BlackScholes model and a ConzeViswanathan pricing method using this workflow:

- 1 Use `fininstrument` to create a Lookback instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Lookback instrument.
- 3 Use `finpricer` to specify a ConzeViswanathan pricer object for the Lookback instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Lookback instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
ConzeViswanathanPricerObj = finpricer(PricerType, '
DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)
ConzeViswanathanPricerObj = finpricer( ___, Name, Value)
```

### Description

`ConzeViswanathanPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a ConzeViswanathan pricer object by specifying `PricerType` and sets the properties on page 11-2608 for the required name-value pair argument `Model`, `DiscountCurve`, and `SpotPrice`.

`ConzeViswanathanPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2608 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `ConzeViswanathanPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "ConzeViswanathan")` creates a ConzeViswanathan pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### ConzeViswanathan Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: `ConzeViswanathanPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "ConzeViswanathan")`

### Required ConzeViswanathan Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional ConzeViswanathan Name-Value Pair Arguments

#### DividendType — Stock dividend type

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and character vector or string. DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

**DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend amount for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

---

**Note** Specify a scalar if DividendType is "continuous" and a timetable if DividendType is "cash".

---

Data Types: double | timetable

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "ConzeViswanathan" | character vector with value 'ConzeViswanathan'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

**Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. DividendType is "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend amounts or dividend schedule for underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "ConzeViswanathan"

Analytic pricing method, returned as a string.

Data Types: string

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Conze-Viswanathan Pricer and Black-Scholes Model to Price Lookback Instrument**

This example shows the workflow to price a fixed strike Lookback instrument when you use a BlackScholes model and a ConzeViswanathan pricing method.

#### **Create Lookback Instrument Object**

Use `fininstrument` to create a fixed strike Lookback instrument object.

```
LookbackOpt = fininstrument("Lookback", 'Strike', 90, 'ExerciseDate', datetime(2021,9,15), 'OptionType', 'put')
```

```
LookbackOpt =
  Lookback with properties:
    OptionType: "put"
    Strike: 90
    AssetMinMax: NaN
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2021
    Name: "lookback_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .358)
```

```
BlackScholesModel =
  BlackScholes with properties:
    Volatility: 0.3580
```

```
Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create ConzeViswanathan Pricer Object

Use finpricer to create a ConzeViswanathan pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',95,'I
```

```
outPricer =
  ConzeViswanathan with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 95
      DividendValue: 0.0250
      DividendType: "continuous"
```

### Price Lookback Instrument

Use price to compute the price and sensitivities for the Lookback instrument.

```
[Price, outPR] = price(outPricer,LookbackOpt,["all"])
```

```
Price = 29.6209
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
      PricerData: []
```

```
outPR.Results
```

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
29.621	-0.49834	0.0085048	-1.5983	78.578	-3.4045	-163.55

## Credit

Create `Credit` pricer object for CDS instrument using `defprobcurve`

## Description

Create and price a CDS instrument object with a `defprobcurve` and a `Credit` pricing method using this workflow:

- 1 Create a default probability curve object using `defprobcurve`.
- 2 Use `finpricer` to specify a `Credit` pricer object for the CDS instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a CDS instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
CreditPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', defprobcurve_object)
```

### Description

`CreditPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', defprobcurve_object)` creates a `Credit` pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `DefaultProbabilityCurve` to set properties on page 11-2613 using name-value pairs. For example, `CreditPricerObj = finpricer("Credit", 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', defprobcurve_obj)` creates a `Credit` pricer object.

### Input Arguments

#### **PricerType** – Pricer type

string with value "Credit" | character vector with value 'Credit'

Pricer type, specified as a string with the value of "Credit" or a character vector with the value of 'Credit'.

Data Types: char | string

#### **Credit Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: CreditPricerObj =
finpricer("Credit", 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', de
fprobcurve_obj)
```

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object

Data Types: object

### **DefaultProbabilityCurve — Default probability curve**

defprobcurve object

Default probability curve, specified as the comma-separated pair consisting of 'DefaultProbabilityCurve' and the name of a previously created defprobcurve object.

Data Types: object

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object

Data Types: object

### **DefaultProbabilityCurve — Default probability curve**

defprobcurve object

Default probability curve, returned as a defprobcurve object.

Data Types: object

## **Object Functions**

price Compute price for credit derivative instrument with Credit pricer

## **Examples**

### **Use Credit Pricer and Default Probability Curve to Price CDS Instrument**

This example shows the workflow to price a CDS instrument when you use a defprobcurve model and a Credit pricing method.

#### **Create CDS Instrument Object**

Use `fininstrument` to create a CDS instrument object.

```
CDS = fininstrument("cds", 'Maturity', datetime(2027,9,20), 'ContractSpread', 50, 'Name', "CDS_instrum
```

```
CDS =
    CDS with properties:
```

```

        ContractSpread: 50
          Maturity: 20-Sep-2027
            Period: 4
              Basis: 2
                RecoveryRate: 0.4000
BusinessDayConvention: "actual"
          Holidays: NaT
    PayAccruedPremium: 1
      Notional: 10000000
        Name: "CDS_instrument"

```

### Create defprobcurve Object

Create a defprobcurve object using defprobcurve.

```

Settle = datetime(2017, 9, 20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)

```

```

DefaultProbCurve =
  defprobcurve with properties:

          Settle: 20-Sep-2017
            Basis: 2
              Dates: [10x1 datetime]
DefaultProbabilities: [10x1 double]

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero", Settle, ZeroDates, ZeroRates)

```

```

ZeroCurve =
  ratecurve with properties:

          Type: "zero"
    Compounding: -1
            Basis: 0
              Dates: [10x1 datetime]
              Rates: [10x1 double]
            Settle: 20-Sep-2017
    InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"

```

### Create Credit Pricer Object

Use finpricer to create a Credit pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
CDSpricer = finpricer("credit", 'DiscountCurve', ZeroCurve, 'DefaultProbabilityCurve', DefaultProbCu
CDSpricer =
  Credit with properties:
      DiscountCurve: [1x1 ratecurve]
      TimeStep: 10
      DefaultProbabilityCurve: [1x1 defprobcurve]
```

### Price CDS Instrument

Use price to compute the price for the CDS instrument.

```
outPrice = price(CDSpricer, CDS)
```

```
outPrice = 6.9363e+04
```

## CDSBlack

Create CDSBlack pricer object for CDSOption instrument using CDSBlack model

### Description

Create and price a CDSOption instrument object with a CDSBlack model and a CDSBlack pricing method using this workflow:

- 1 Use `fininstrument` to create the CDSOption instrument object.
- 2 Use `finmodel` to specify the CDSBlack model for the CDSOption instrument.
- 3 Use `finpricer` to specify the CDSBlack pricer object for the CDSOption instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a CDSOption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Creation

#### Syntax

```
CDSBlackPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'DefaultProbabilityCurve',defaultprobabilitycurve_obj)
```

#### Description

`CDSBlackPricerObj = finpricer(PricerType,'DiscountCurve',ratecurve_obj,'Model',model,'DefaultProbabilityCurve',defaultprobabilitycurve_obj)` creates a CDSBlack pricer object by specifying `PricerType` and the required name-value pair arguments for `DiscountCurve`, `Model`, and `DefaultProbabilityCurve` to set properties on page 11-2617 using name-value pairs. For example, `CDSBlackPricerObj = finpricer("Analytic",'Model',CDSBlack,'DiscountCurve',ratecurve_obj,'DefaultProbabilityCurve',defaultprobabilitycurve_obj)` creates a CDSBlack pricer object.

#### Input Arguments

##### **PricerType** — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or the character vector with a value of 'Analytic'.

Data Types: char | string

**CDSBlack Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: CDSBlackPricerObj =
finpricer("Analytic", 'Model', CDSBlack, 'DiscountCurve', ratecurve_obj, 'DefaultProbabilityCurve', defaultprobabilitycurve_obj)
```

**Required CDSBlack Name-Value Pair Arguments****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

Data Types: object

**Model — Model**

CDSBlack model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of a previously created CDSBlack model object using `finmodel`.

Data Types: object

**DefaultProbabilityCurve — Default probability curve**

defprobcurve object

Default probability curve, specified as the comma-separated pair consisting of 'DefaultProbabilityCurve' and a name of a previously created defprobcurve.

Data Types: object

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

**Model — Model**

CDSBlack model object

Model, returned as a CDSBlack model object.

Data Types: object

**DefaultProbabilityCurve — Default probability curve**

object

Default probability curve, returned as a defprobcurve object.

Data Types: object

## Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use CDS Black Pricer and CDS Black Model to Price CDS Option Instrument

This example shows the workflow to price a CDSOption instrument when you use a CDSBlack model and a CDSBlack pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2017,9,20);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero", Settle, ZeroDates ,ZeroRates)
```

ZeroCurve =

ratecurve with properties:

```

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 20-Sep-2017
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

#### Create defprobcurve Object

Create a defprobcurve object using defprobcurve.

```
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)
```

DefaultProbCurve =

defprobcurve with properties:

```

    Settle: 20-Sep-2017
    Basis: 2
    Dates: [10x1 datetime]
    DefaultProbabilities: [10x1 double]
```

#### Create CDS Instrument Object

Use fininstrument to create an underlying CDS instrument object.

```
ContractSpreadBP = 0; % Contractual spread is determined on ExerciseDate
CDS = fininstrument("CDS", 'Maturity', datetime(2027,9,20), 'ContractSpread', ContractSpreadBP)
```

```
CDS =
  CDS with properties:
      ContractSpread: 0
      Maturity: 20-Sep-2027
      Period: 4
      Basis: 2
      RecoveryRate: 0.4000
  BusinessDayConvention: "actual"
      Holidays: NaT
  PayAccruedPremium: 1
      Notional: 10000000
      Name: ""
```

### Create CDSOption Instrument Object

Use `fininstrument` to create a `CDSOption` instrument object.

```
ExerciseDate = datetime(2017, 12, 20);
Strike = 50;
CDSOption = fininstrument("CDSOption", 'Strike', Strike, 'ExerciseDate', ExerciseDate, 'OptionType', "put")
```

```
CDSOption =
  CDSOption with properties:
      OptionType: "put"
      Strike: 50
      Knockout: 0
  ExerciseDate: 20-Dec-2017
      CDS: [1x1 fininstrument.CDS]
      Name: ""
```

### Create CDSBlack Model Object

Use `finmodel` to create a `CDSBlack` model object.

```
SpreadVolatility = 0.3;
CDSOptionModel = finmodel("CDSBlack", 'SpreadVolatility', SpreadVolatility)
```

```
CDSOptionModel =
  CDSBlack with properties:
      SpreadVolatility: 0.3000
```

### Create CDSBlack Pricer Object

Use `finpricer` to create a `CDSBlack` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
CDSOptionpricer = finpricer("analytic", 'Model', CDSOptionModel, 'DiscountCurve', ZeroCurve, 'Default')
```

```
CDSOptionpricer =
  CDSBlack with properties:
```

```
Model: [1x1 finmodel.CDSBlack]
DiscountCurve: [1x1 ratecurve]
DefaultProbabilityCurve: [1x1 defprobcurve]
```

### Price CDSOption Instrument

Use `price` to compute the price for the CDSOption instrument.

```
outPrice = price(CDSOptionpricer,CDSOption)
```

```
outPrice = 6.5054
```

# NumericalIntegration

Create NumericalIntegration pricer object for Vanilla instrument using Heston, Bates, or Merton model

## Description

Create and price a Vanilla instrument object with a Heston, Bates, or Merton model and a NumericalIntegration pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Heston, Bates, or Merton model for the Vanilla instrument.
- 3 Use `finpricer` to specify a NumericalIntegration pricer object for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
NumericalIntegrationPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
NumericalIntegrationPricerObj = finpricer( ___,Name,Value)
```

### Description

`NumericalIntegrationPricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a NumericalIntegration pricer object by specifying `PricerType` and sets the properties on page 11-2624 for the required name-value pair arguments `Model`, `DiscountCurve`, and `SpotPrice`.

`NumericalIntegrationPricerObj = finpricer( ___,Name,Value)` sets optional properties on page 11-2624 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `NumericalIntegrationPricerObj = finpricer("NumericalIntegration",'Model',NIModel,'DiscountCurve',ratecurve_obj,'SpotPrice',1000,'DividendValue',100,'VolRiskPremium',0.9)` creates a NumericalIntegration pricer object. You can specify multiple name-value pair arguments.

### Input Arguments

#### PricerType — Pricer type

string with value "NumericalIntegration" | character vector with value 'NumericalIntegration'

Pricer type, specified as a string with the value of "NumericalIntegration" or a character vector with the value of 'NumericalIntegration'.

Data Types: char | string

#### **NumericalIntegration Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: NumericalIntegrationPricerObj =  
 finpricer("NumericalIntegration", 'Model', NIModel, 'DiscountCurve', ratecurve\_obj, 'SpotPrice', 1000, 'DividendValue', 100, 'VolRiskPremium', 0.9)

#### **Required NumericalIntegration Name-Value Pair Arguments**

##### **Model — Model**

model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created Merton, Bates, or Heston model object using finmodel.

Data Types: object

##### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

##### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

#### **Optional NumericalIntegration Name-Value Pair Arguments**

##### **DividendValue — Dividend yield**

0 (default) | scalar numeric

Dividend yield, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric.

Data Types: double

**VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

**LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with values true or false

Flag indicating Little Heston Trap formulation by Albrecher et al., specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- `true` — Use the Albrecher et al. formulation.

For more information on the `LittleTrap`, see [1] and also the Little Trap formulation is defined by  $C_j$  and  $D_j$ , see “Heston Stochastic Volatility Model” on page 11-2627 and “Bates Stochastic Volatility Jump Diffusion Model” on page 11-2629.

- `false` — Use the original Heston formation.

---

**Note** `LittleTrap` is supported only for Heston and Bates models.

---

Data Types: logical

**AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, specified as the comma-separated pair consisting of 'AbsTol' and a scalar numeric value.

Data Types: double

**RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, specified as the comma-separated pair consisting of 'RelTol' and a scalar numeric value.

Data Types: double

**IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over  $[0 \text{ Inf}]$ , specified as the comma-separated pair consisting of 'IntegrationRange' and a 1-by-2 vector representing  $[\text{LowerLimit UpperLimit}]$ .

Data Types: double

**Framework — Framework for computing option prices and sensitivities using numerical integration of models**

"heston1993" (default) | string with values "heston1993" or "lewis2001" | character vector with values 'heston1993' or 'lewis2001'

Framework for computing option prices and sensitivities using the numerical integration of models, specified as the comma-separated pair consisting of 'Framework' and a scalar string or character vector with the following values:

- "heston1993" or 'heston1993' — Method used in Heston (1993)
- "lewis2001" or 'lewis2001' — Method used in Lewis (2001)

Data Types: char | string

## Properties

### **Model — Model**

model object

Model, returned as a model object.

Data Types: object

### **DiscountCurve — ratecurve object for discounting cash flows**

object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **DividendValue — Dividend yield**

0 (default) | scalar numeric

Dividend yield, returned as a scalar numeric.

Data Types: double

### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, returned as a scalar numeric value.

Data Types: double

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with value true or false

Flag indicating Little Heston Trap formulation by Albrecher et al., returned as a logical.

Data Types: logical

### **AbsTol — Absolute error tolerance for numerical integration**

1e-10 (default) | numeric

Absolute error tolerance for numerical integration, returned as a scalar numeric value.

Data Types: double

### **RelTol — Relative error tolerance for numerical integration**

1e-6 (default) | numeric

Relative error tolerance for numerical integration, returned as a scalar numeric value.

Data Types: double

### **IntegrationRange — Numerical integration range used to approximate continuous integral over [0 Inf]**

[1e-9 Inf] (default) | vector

Numerical integration range used to approximate the continuous integral over [0 Inf], returned as a 1-by-2 vector representing [LowerLimit UpperLimit].

Data Types: double

### **Framework — Framework for computing option prices and sensitivities using numerical integration of models**

"heston1993" (default) | string with value "heston1993" or "lewis2001"

Framework for computing option prices and sensitivities using the numerical integration of models, returned as a scalar string.

Data Types: string

## **Object Functions**

price Compute price for equity instrument with NumericalIntegration pricer

## **Examples**

### **Use Numerical Integration Pricer and Merton Model to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Merton model and a NumericalIntegration pricing method.

#### **Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2020,3,15), 'ExerciseStyle', "european")
```

```
VanillaOpt =
```

```
Vanilla with properties:
```

```
    OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Mar-2020
    Strike: 105
    Name: "vanilla_option"
```

#### **Create Merton Model Object**

Use `finmodel` to create a Merton model object.

```
MertonModel = finmodel("Merton", 'Volatility', 0.45, 'MeanJ', 0.02, 'JumpVol', 0.07, 'JumpFreq', 0.09)

MertonModel =
  Merton with properties:

    Volatility: 0.4500
    MeanJ: 0.0200
    JumpVol: 0.0700
    JumpFreq: 0.0900
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
myRC = ratecurve('zero', datetime(2019,9,15), datetime(2020,3,15), 0.02)

myRC =
  ratecurve with properties:

    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: 15-Mar-2020
    Rates: 0.0200
    Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create NumericalIntegration Pricer Object

Use finpricer to create a NumericalIntegration pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("numericalintegration", 'Model', MertonModel, 'DiscountCurve', myRC, 'SpotPrice')

outPricer =
  NumericalIntegration with properties:

    Model: [1x1 finmodel.Merton]
    DiscountCurve: [1x1 ratecurve]
    SpotPrice: 100
    DividendType: "continuous"
    DividendValue: 0.0100
    AbsTol: 0.5000
    RelTol: 0.4000
    IntegrationRange: [1.0000e-09 Inf]
    CharacteristicFcn: @characteristicFcnMerton76
    Framework: "lewis2001"
    VolRiskPremium: 0.9000
    LittleTrap: 0
```

### Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
Price = 10.7325
outPR =
  pricerresult with properties:
      Results: [1x6 table]
      PricerData: []

outPR.Results
ans=1x6 table
   Price      Delta      Gamma      Theta      Rho      Vega
   -----      -----      -----      -----      -----      -----
   10.732    0.5058    0.012492   -12.969    19.815    27.954
```

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

Here:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (square root of variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is

$$dS_t = (r - q)S_t dt + \sqrt{v_t}S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^\nu$$

$$E[dW_t dW_t^\nu] = \rho dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

The characteristic function  $f_{Heston_j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - \rho\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}} \right)$$

$$g_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{b_j - \rho\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - \rho\sigma_v i\phi)^2 - \sigma_v^2(2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - \rho\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  for the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates 1996) is an extension of the Heston model where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) are also added to model sudden asset price movements.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t$$

$$E[dW_t dW_t^y] = \rho dt$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{ -\frac{\left[ \ln(1+J) - \left( \ln(1 + \mu_J) - \frac{\delta^2}{2} \right) \right]^2}{2\delta^2} \right\}$$

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

$\mu_j$  is the mean of  $J$  for ( $\mu_j > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

The characteristic function  $f_{Bates_j(\phi)}$  for  $j = 1$  (asset price mean measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t) \exp(\lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1 \right] - \lambda_p \tau \mu_j i\phi)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity for ( $\tau = T - t$ ).

$i$  is the unit imaginary number for ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  for the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j \tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j \tau}}{1 - \varepsilon_j e^{-d_j \tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Merton Jump Diffusion Model

The Merton jump diffusion model (Merton 1976) is an extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{-\frac{\left[\ln(1+J) - \left(\ln(1 + \mu_J) - \frac{\delta^2}{2}\right)\right]^2}{2\delta^2}\right\}$$

$\mu_J$  is the mean of  $J$  for ( $\mu_J > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

$\sigma$  is the volatility of the asset price for ( $\sigma > 0$ ).

The characteristic function  $f_{Merton76,j}(\phi)$  for  $j = 1$  (asset prices measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Merton76,j} = f_{BS_j} \exp\left(\lambda_p \tau (1 + \mu_j)^{m_j} + \frac{1}{2} \left[ (1 + \mu_j)^i \phi e^{\delta^2 \left(m_j i \phi + \frac{(i\phi)^2}{2}\right)} - 1 \right] - \lambda_p \tau \mu_j i \phi\right)$$

where for  $j = 1, 2$ :

$$f_{BS_1}(\phi) = \frac{f_{BS_2}(\phi - i)}{f_{BS_2}(-i)}$$

$$f_{BS_2}(\phi) = \exp\left(i\phi \left[\ln S_t + \left(r - q - \frac{\sigma^2}{2}\right)\tau\right] - \frac{\phi^2 \sigma^2}{2} \tau\right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

Here:

$\phi$  is the characteristic function variable

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

### Numerical Integration Method Under Heston (1993) Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Heston (1993) framework is based on the following expressions

$$Call(K) = S_t e^{-q\tau} P_1 - K e^{-r\tau} P_2$$

$$Put(K) = Call(K) + K e^{-r\tau} - S_t e^{-q\tau}$$

$$P_j = \frac{1}{2} + \frac{1}{\pi} \int_0^{\infty} \text{Re} \left[ \frac{e^{-i\phi \ln(K)} f_j(\phi)}{i\phi} \right] d\phi$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T - t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$f_j(\phi)$  is the characteristic function for  $P_j$  ( $j = 1, 2$ ).

$P_1$  is the probability of  $S_t > K$  under the asset price measure for the model.

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Where  $j = 1, 2$  so that  $f_1(\phi)$  and  $f_2(\phi)$  are the characteristic functions for probabilities  $P_1$  and  $P_2$ , respectively.

Choose this framework by specifying the default value "Heston1993" for the Framework name-value pair argument.

### Numerical Integration Method Under Lewis Framework

Numerical integration is used to evaluate the continuous integral for the inverse Fourier transform.

The numerical integration method under the Lewis (2001) framework is based on the following expressions:

$$Call(k) = S_t e^{-q\tau} - \frac{\sqrt{K} e^{-\tau t}}{\pi} \int_0^{\infty} \operatorname{Re} \left[ K^{-iu} f_2 \left( \phi = \left( u - \frac{i}{2} \right) \frac{1}{u^2 + \frac{1}{4}} \right) \right] du$$

$$Put(K) = Call(K) = K e^{-\tau t} - S_t e^{-q\tau}$$

Here

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$K$  is the strike.

$\tau$  is time to maturity ( $\tau = T-t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$ .

$i$  is a unit imaginary number ( $i^2 = -1$ ).

$\phi$  is the characteristic function variable.

$u$  is the characteristic function variable for integration, where  $\phi = \left( u - \frac{i}{2} \right)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

Choose this framework by specifying the value "Lewis2001" for the Framework name-value pair argument.

**Introduced in R2020a**

# Discount

Create `Discount` pricer object for `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` using `ratecurve` object

## Description

Create and price a `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` instrument object with a `ratecurve` and a `Discount` pricing method using this workflow:

- 1 Create an interest-rate curve object using `ratecurve`.
- 2 Use `finpricer` to specify a `Discount` pricer object for the `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a `Swap` or `FloatBond` instrument with the `Discount` pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a `Deposit`, `FRA`, `Swap`, `FixedBond`, or `FloatBond` instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
DiscountPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_object)
```

### Description

`DiscountPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_object)` creates a `Discount` pricer object by specifying `PricerType` and the required name-value pair argument `DiscountCurve` to set properties on page 11-2636 using name-value pairs. For example, `DiscountPricerObj = finpricer("Discount", 'DiscountCurve', ratecurve_obj)` creates a `Discount` pricer object.

### Input Arguments

#### **PricerType** — Pricer type

string with value "Discount" | character vector with value 'Discount'

Pricer type, specified as a string with the value of "Discount" or a character vector with the value of 'Discount'.

Data Types: char | string

**Discount Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: DiscountPricerObj =
finpricer("Discount", 'DiscountCurve', ratecurve_obj)
```

**DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object

Data Types: object

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

**Object Functions**

price Compute price for interest-rate instrument with Discount pricer

**Examples****Use Discount Pricer and ratecurve to Price Swap Instrument**

This example shows the workflow to price a Swap instrument when using a ratecurve and a Discount pricing method.

**Create ratecurve Object**

Create a ratecurve object using ratecurve for the underlying interest-rate curve for the Swap instrument.

```
Settle = datetime(2022,1,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
    ratecurve with properties:
        Type: "zero"
        Compounding: -1
```

```

        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Jan-2022
    InterpMethod: "linear"
ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create Swap Instrument Object

Use `fininstrument` to create a Swap instrument object.

```
SwapOpt = fininstrument("Swap", 'Maturity', datetime(2027,1,15), 'LegRate', [0.024 0.015], 'LegType',
```

```
SwapOpt =
```

```
    Swap with properties:
```

```

        LegRate: [0.0240 0.0150]
        LegType: ["fixed"    "float"]
        Reset: [2 2]
        Basis: [0 0]
        Notional: 100
    LatestFloatingRate: [NaN NaN]
        ResetOffset: [0 0]
    DaycountAdjustedCashFlow: [0 0]
        ProjectionCurve: [1x2 ratecurve]
    BusinessDayConvention: ["actual"    "actual"]
        Holidays: NaT
    EndMonthRule: [1 1]
        StartDate: NaT
        Maturity: 15-Jan-2027
        Name: "swap_instrument"

```

### Create Discount Pricer Object

Use `finpricer` to create a Discount pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("Discount", 'DiscountCurve', myRC)
```

```
outPricer =
```

```
    Discount with properties:
```

```

    DiscountCurve: [1x1 ratecurve]

```

### Price Swap Instrument

Use `price` to compute the price and sensitivities for the Swap instrument.

```
[Price, outPR] = price(outPricer, SwapOpt, ["all"])
```

```
Price = -1.3834
```

```
outPR =
```

```
    pricerresult with properties:
```

```
Results: [1x2 table]
PricerData: []
```

```
outPR.Results
```

```
ans=1x2 table
```

Price	DV01
-1.3834	0.023765

### Introduced in R2020a

# FFT

Create FFT pricer object for Vanilla instrument using Merton, Heston, or Bates model

## Description

Create and price a Vanilla instrument object with a Heston, Bates, or Merton model and an FFT pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a Heston, Bates, or Merton model for the Vanilla instrument.
- 3 Use `finpricer` to specify an FFT pricer object for the Vanilla instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
FFTPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj)
FFTPricerObj = finpricer( ___, Name, Value)
```

### Description

`FFTPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj)` creates an FFT pricer object by specifying `PricerType` and sets the properties on page 11-2642 for the required name-value pair arguments `Model` and `DiscountCurve`.

`FFTPricerObj = finpricer( ___, Name, Value)` sets optional properties on page 11-2642 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FFTPricerObj = finpricer("FFT", 'Model', FFTModel, 'DiscountCurve', ratecurve_obj, 'SpotPrice', 1000, 'DividendValue', 0.01, 'VolRiskPremium', 0.9)` creates an FFT pricer object. You can specify multiple name-value pair arguments.

### Input Arguments

#### **PricerType** — Pricer type

string with value "FFT" | character vector with value 'FFT'

Pricer type, specified as a string with the value of "FFT" or a character vector with the value of 'FFT'.

Data Types: char | string

### FFT Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

```
Example: FFTPricerObj = finpricer("FFT", 'Model', FFTModel,  
'DiscountCurve', ratecurve_obj, 'SpotPrice', 1000, 'DividendValue', 0.01, 'VolRiskP  
remium', 0.9)
```

### Required FFT Name-Value Pair Arguments

#### **Model — Model**

model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of the previously created Merton, Bates, or Heston model object using `finmodel`.

Data Types: object

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the ratecurve object.

---

**Note** Specify a flat ratecurve object for `DiscountCurve`. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at `Maturity` and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional FFT Name-Value Pair Arguments

#### **DividendValue — Dividend yield**

0 (default) | scalar nonnegative numeric

Dividend yield, specified as the comma-separated pair consisting of 'DividendValue' and a scalar nonnegative numeric in decimals.

Data Types: double

#### **VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, specified as the comma-separated pair consisting of 'VolRiskPremium' and a scalar numeric value.

Data Types: double

### **LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with value true or false

Flag indicating Little Heston Trap formulation by Albrecher et al., specified as the comma-separated pair consisting of 'LittleTrap' and a logical:

- true — Use the Albrecher et al. formulation.

For more information on the LittleTrap, see [1] and also the Little Trap formulation is defined by  $C_j$  and  $D_j$  in “Heston Stochastic Volatility Model” on page 11-2645 and “Bates Stochastic Volatility Jump Diffusion Model” on page 11-2647.

- false — Use the original Heston formation.

---

**Note** LittleTrap is supported only for Heston and Bates models.

---

Data Types: logical

### **NumFFT — Number of grid points in characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, specified as the comma-separated pair consisting of 'NumFFT' and a scalar numeric value.

Data Types: double

### **CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, specified as the comma-separated pair consisting of 'CharacteristicFcnStep' and a scalar numeric value.

Data Types: double

### **LogStrikeStep — Log-strike grid spacing**

$2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, specified as the comma-separated pair consisting of 'LogStrikeStep' and a scalar numeric value.

---

**Note** If  $(\text{LogStrikeStep} \times \text{CharacteristicFcnStep})$  is  $2\pi/\text{NumFFT}$ , FFT is used. Otherwise, FRFT is used.

---

Data Types: double

### **DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for the Carr-Madan formulation, specified as the comma-separated pair consisting of 'DampingFactor' and a scalar numeric value.

Data Types: double

**Quadrature — Type of quadrature**

"simpson" (default) | string with value "simpson" or "trapezoidal" | character vector with value 'simpson' or 'trapezoidal'

Type of quadrature, specified as the comma-separated pair consisting of 'Quadrature' and a scalar string or character vector.

Data Types: char | string

**Properties****Model — Model**

model object

Model, returned as a model object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendValue — Dividend yield**

0 (default) | scalar nonnegative numeric

Dividend yield, returned as a scalar nonnegative numeric in decimals.

Data Types: double

**VolRiskPremium — Volatility risk premium**

0 (default) | numeric

Volatility risk premium, returned as a scalar numeric value.

Data Types: double

**LittleTrap — Flag indicating Little Heston Trap formulation**

true (default) | logical with value true or false

Flag indicating Little Heston Trap formulation by Albrecher et al., returned as a logical.

Data Types: logical

**NumFFT — Number of grid points in the characteristic function variable**

4096 (default) | numeric

Number of grid points in the characteristic function variable and in each column of the log-strike grid, returned as a scalar numeric value.

Data Types: double

**CharacteristicFcnStep — Characteristic function variable grid spacing**

0.01 (default) | numeric

Characteristic function variable grid spacing, returned as a scalar numeric value.

Data Types: double

**LogStrikeStep — Log-strike grid spacing** $2\pi/\text{NumFFT}/\text{CharacteristicFcnStep}$  (default) | numeric

Log-strike grid spacing, returned as a scalar numeric value.

Data Types: double

**DampingFactor — Damping factor for Carr-Madan formulation**

1.5 (default) | numeric

Damping factor for the Carr-Madan formulation, returned as a scalar numeric value.

Data Types: double

**Quadrature — Type of quadrature**

"simpson" (default) | string with value "simpson" or "trapezoidal"

Type of quadrature, returned as a string.

Data Types: string

**Object Functions**

price Compute price for equity instrument with FFT pricer

**Examples****Use FFT Pricer and Heston Model to Price Vanilla Instrument**

This example shows the workflow to price a Vanilla instrument when you use a Heston model and an FFT pricing method.

**Create Vanilla Instrument Object**Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'ExerciseSty
```

```
VanillaOpt =
```

```
  Vanilla with properties:
```

```
    OptionType: "call"
  ExerciseStyle: "european"
  ExerciseDate: 15-Sep-2022
        Strike: 105
        Name: "vanilla_option"
```

### Create Heston Model Object

Use `finmodel` to create a Heston model object.

```
HestonModel = finmodel("Heston", 'V0', 0.032, 'ThetaV', 0.1, 'Kappa', 0.003, 'SigmaV', 0.2, 'RhoSV', 0.9)
```

```
HestonModel =  
  Heston with properties:
```

```
      V0: 0.0320  
    ThetaV: 0.1000  
      Kappa: 0.0030  
    SigmaV: 0.2000  
    RhoSV: 0.9000
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);  
Maturity = datetime(2023,9,15);  
Rate = 0.035;  
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```
myRC =  
  ratecurve with properties:
```

```
      Type: "zero"  
    Compounding: -1  
      Basis: 12  
      Dates: 15-Sep-2023  
      Rates: 0.0350  
      Settle: 15-Sep-2018  
    InterpMethod: "linear"  
    ShortExtrapMethod: "next"  
    LongExtrapMethod: "previous"
```

### Create FFT Pricer Object

Use `finpricer` to create an FFT pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("fft", 'DiscountCurve', myRC, 'Model', HestonModel, 'SpotPrice', 100, 'CharacteristicFcn', @characteristicFcnHeston)
```

```
outPricer =  
  FFT with properties:
```

```
      Model: [1x1 finmodel.Heston]  
    DiscountCurve: [1x1 ratecurve]  
      SpotPrice: 100  
    DividendType: "continuous"  
    DividendValue: 0  
      NumFFT: 8192  
    CharacteristicFcnStep: 0.2000  
      LogStrikeStep: 0.0038  
    CharacteristicFcn: @characteristicFcnHeston  
      DampingFactor: 1.5000
```

```

    Quadrature: "simpson"
    VolRiskPremium: 0
    LittleTrap: 1

```

## Price Vanilla Instrument

Use price to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 14.7545
```

```
outPR =
  pricerresult with properties:
```

```

    Results: [1x7 table]
    PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Theta	Rho	Vega	VegaLT
14.754	0.44868	0.021649	-0.20891	120.45	88.192	1.3248

## More About

### Vanilla Option

A vanilla option is a category of options that includes only the most standard components.

A vanilla option has an expiration date and straightforward strike price. American-style options and European-style options are both categorized as vanilla options.

The payoff for a vanilla option is as follows:

- For a call:  $\max(S_t - K, 0)$
- For a put:  $\max(K - S_t, 0)$

Here:

$S_t$  is the price of the underlying asset at time  $t$ .

$K$  is the strike price.

For more information, see “Vanilla Option” on page 3-26.

### Heston Stochastic Volatility Model

The Heston model is an extension of the Black-Scholes model, where the volatility (the square root of the variance) is no longer assumed to be constant, and the variance now follows a stochastic (CIR) process. This process allows modeling the implied volatility smiles observed in the market.

The stochastic differential equation is

$$dS_t = (r - q)S_t dt + \sqrt{v_t}S_t dW_t$$

$$dv_t = \kappa(\theta - v_t)dt + \sigma_v \sqrt{v_t} dW_t^v$$

$$E[dW_t dW_t^v] = \rho dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$v_0$  is the initial variance of the asset price at  $t = 0$  for ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for the variance for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of the variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

The characteristic function  $f_{Heston_j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Heston_j}(\phi) = \exp(C_j + D_j v_0 + i\phi \ln S_t)$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j\tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j\tau}}{1 - g_j e^{d_j\tau}} \right)$$

$$g_j = \frac{b_j - p\sigma_v i\phi + d_j}{b_j - p\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - p\sigma_v i\phi)^2 - \sigma_v^2(2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - p\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  in the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Bates Stochastic Volatility Jump Diffusion Model

The Bates model (Bates 1996) is an extension of the Heston model where, in addition to stochastic volatility, the jump diffusion parameters similar to Merton (1976) are also added to model sudden asset price movements.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_J) S_t dt + \sqrt{v_t} S_t dW_t + JS_t dP_t$$

$$dv_t = \kappa(\theta - v_t) dt + \sigma_v \sqrt{v_t} dW_t$$

$$E[dW_t dW_t^v] = \rho dt$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$v_t$  is the asset price variance at time  $t$ .

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{ -\frac{\left[ \ln(1+J) - \left( \ln(1 + \mu_J) - \frac{\delta^2}{2} \right) \right]^2}{2\delta^2} \right\}$$

Here:

$v_0$  is the initial variance of the asset price at  $t = 0$  ( $v_0 > 0$ ).

$\theta$  is the long-term variance level for ( $\theta > 0$ ).

$\kappa$  is the mean reversion speed for ( $\kappa > 0$ ).

$\sigma_v$  is the volatility of variance for ( $\sigma_v > 0$ ).

$\rho$  is the correlation between the Weiner processes  $W_t$  and  $W_t^v$  for ( $-1 \leq \rho \leq 1$ ).

$\mu_j$  is the mean of  $J$  for ( $\mu_j > -1$ ).

$\delta$  is the standard deviation of  $\ln(1+J)$  for ( $\delta \geq 0$ ).

$\lambda_p$  is the annual frequency (intensity) of Poisson process  $P_t$  for ( $\lambda_p \geq 0$ ).

The characteristic function  $f_{Bates_j(\phi)}$  for  $j = 1$  (asset price mean measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Bates(\phi)} = \exp(C_j + D_j v_0 + i\phi \ln S_t) \exp(\lambda_p \tau (1 + \mu_j)^{m_j + \frac{1}{2}} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 (m_j i\phi + \frac{(i\phi)^2}{2})} - 1 \right] - \lambda_p \tau \mu_j i\phi)$$

$$m_j = \begin{cases} m_1 = \frac{1}{2} \\ m_2 = -\frac{1}{2} \end{cases}$$

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - \rho\sigma_v i\phi + d_j)\tau - 2\ln\left(\frac{1 - g_j e^{d_j \tau}}{1 - g_j}\right) \right]$$

$$D_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{\sigma_v^2} \left( \frac{1 - e^{d_j \tau}}{1 - g_j e^{d_j \tau}} \right)$$

$$g_j = \frac{b_j - \rho\sigma_v i\phi + d_j}{b_j - \rho\sigma_v i\phi - d_j}$$

$$d_j = \sqrt{(b_j - \rho\sigma_v i\phi)^2 - \sigma_v^2 (2u_j i\phi - \phi^2)}$$

where for  $j = 1, 2$ :

$$u_1 = \frac{1}{2}, u_2 = -\frac{1}{2}, b_1 = \kappa + \lambda_{VolRisk} - \rho\sigma_v, b_2 = \kappa + \lambda_{VolRisk}$$

Here:

$\phi$  is the characteristic function variable.

$\lambda_{VolRisk}$  is the volatility risk premium.

$\tau$  is the time to maturity for ( $\tau = T - t$ ).

$i$  is the unit imaginary number for ( $i^2 = -1$ ).

The definitions for  $C_j$  and  $D_j$  in the Little Heston Trap by Albrecher et al. (2007) are

$$C_j = (r - q)i\phi\tau + \frac{\kappa\theta}{\sigma_v^2} \left[ (b_j - p\sigma_v i\phi - d_j)\tau - 2\ln\left(\frac{1 - \varepsilon_j e^{-d_j\tau}}{1 - \varepsilon_j}\right) \right]$$

$$D_j = \frac{b_j - p\sigma_v i\phi - d_j}{\sigma_v^2} \left( \frac{1 - e^{-d_j\tau}}{1 - \varepsilon_j e^{-d_j\tau}} \right)$$

$$\varepsilon_j = \frac{b_j - p\sigma_v i\phi - d_j}{b_j - p\sigma_v i\phi + d_j}$$

### Merton Jump Diffusion Model

The Merton jump diffusion model (Merton 1976) is an extension of the Black-Scholes model, where sudden asset price movements (both up and down) are modeled by adding the jump diffusion parameters with the Poisson process.

The stochastic differential equation is

$$dS_t = (r - q - \lambda_p \mu_j) S_t dt + \sigma S_t dW_t + JS_t dP_t$$

$$\text{prob}(dP_t = 1) = \lambda_p dt$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$W_t$  is the Weiner process.

$J$  is the random percentage jump size conditional on the jump occurring, where  $\ln(1+J)$  is normally distributed with mean  $\ln(1 + \mu_J) - \frac{\delta^2}{2}$  and the standard deviation  $\delta$ , and  $(1+J)$  has a lognormal distribution:

$$\frac{1}{(1+J)\delta\sqrt{2\pi}} \exp\left\{ -\frac{\left[ \ln(1+J) - \left( \ln(1 + \mu_J) - \frac{\delta^2}{2} \right) \right]^2}{2\delta^2} \right\}$$

Here:

$\mu_J$  is the mean of  $J$  for  $(\mu_J > -1)$ .

$\delta$  is the standard deviation of  $\ln(1+J)$  for  $(\delta \geq 0)$ .

$\lambda_p$  is the annual frequency (intensity) of the Poisson process  $P_t$  for  $(\lambda_p \geq 0)$ .

$\sigma$  is the volatility of the asset price for  $(\sigma > 0)$ .

The characteristic function  $f_{Merton76,j}(\phi)$  for  $j = 1$  (asset price measure) and  $j = 2$  (risk-neutral measure) is

$$f_{Merton76j} = f_{BSj} \exp \left( \lambda_p \tau (1 + \mu_j)^{mj} + \frac{1}{2} \left[ (1 + \mu_j)^{i\phi} e^{\delta^2 \left( m_j i \phi + \frac{(i\phi)^2}{2} \right)} - 1 \right] - \lambda_p \tau \mu_j i \phi \right)$$

where for  $j = 1, 2$ :

$$f_{BS1}(\phi) = \frac{f_{BS2}(\phi - i)}{f_{BS2}(-i)}$$

$$f_{BS2}(\phi) = \exp \left( i\phi \left[ \ln S_t + \left( r - q - \frac{\sigma^2}{2} \right) \tau \right] - \frac{\phi^2 \sigma^2 \tau}{2} \right)$$

$$m_1 = \frac{1}{2}, m_2 = -\frac{1}{2}$$

Here:

$\phi$  is the characteristic function variable.

$\tau$  is the time to maturity ( $\tau = T - t$ ).

$i$  is the unit imaginary number ( $i^2 = -1$ ).

### Carr-Madan Formulation

The Carr-Madan (1999) formulation is a popular modified implementation of Heston (1993) framework.

Rather than computing the probabilities  $P_1$  and  $P_2$  as intermediate steps, Carr and Madan developed an alternative expression so that taking its inverse Fourier transform gives the option price itself directly.

$$Call(k) = \frac{e^{-\alpha k}}{\pi} \int_0^{\infty} \text{Re} \left[ e^{-iuk} \psi(u) \right] du$$

$$\psi(u) = \frac{e^{-r\tau} f_2(\phi = (u - (\alpha + 1)i))}{\alpha^2 + \alpha - u^2 + iu(2\alpha + 1)}$$

$$Put(K) = Call(K) + Ke^{-r\tau} - S_t e^{-q\tau}$$

Here:

$r$  is the continuous risk-free rate.

$q$  is the continuous dividend yield.

$S_t$  is the asset price at time  $t$ .

$\tau$  is time to maturity ( $\tau = T - t$ ).

$Call(K)$  is the call price at strike  $K$ .

$Put(K)$  is the put price at strike  $K$

$i$  is a unit imaginary number ( $i^2 = -1$ )

$\phi$  is the characteristic function variable.

$\alpha$  is the damping factor.

$u$  is the characteristic function variable for integration, where  $\phi = (u - (\alpha+1)i)$ .

$f_2(\phi)$  is the characteristic function for  $P_2$ .

$P_2$  is the probability of  $S_t > K$  under the risk-neutral measure for the model.

To apply FFT or FRFT to this formulation, the characteristic function variable for integration  $u$  is discretized into NumFFT( $N$ ) points with the step size CharacteristicFcnStep ( $\Delta u$ ), and the log-strike  $k$  is discretized into  $N$  points with the step size LogStrikeStep( $\Delta k$ ).

The discretized characteristic function variable for integration  $u_j$  (for  $j = 1, 2, 3, \dots, N$ ) has a minimum value of 0 and a maximum value of  $(N-1) (\Delta u)$ , and it approximates the continuous integration range from 0 to infinity.

The discretized log-strike grid  $k_n$  (for  $n = 1, 2, 3, N$ ) is approximately centered around  $\ln(S_t)$ , with a minimum value of

$$\ln(S_t) - \frac{N}{2}\Delta k$$

and a maximum value of

$$\ln(S_t) + \left(\frac{N}{2} - 1\right)\Delta k$$

Where the minimum allowable strike is

$$S_t \exp\left(-\frac{N}{2}\Delta k\right)$$

and the maximum allowable strike is

$$S_t \exp\left[\left(\frac{N}{2} - 1\right)\Delta k\right]$$

As a result of the discretization, the expression for the call option becomes

$$Call(k_n) = \Delta u \frac{e^{-\alpha k_n}}{\pi} \sum_{j=1}^N \operatorname{Re} \left[ e^{-i\Delta k \Delta u (j-1)(n-1)} e^{iu_j \left[ \frac{N\Delta k}{2} - \ln(S_t) \right]} \psi(u_j) \right] w_j$$

Here:

$\Delta u$  is the step size of the discretized characteristic function variable for integration.

$\Delta k$  is the step size of the discretized log strike.

$N$  is the number of FFT or FRFT points.

$w_j$  is the weights for quadrature used for approximating the integral.

FFT is used to evaluate the above expression if  $\Delta k$  and  $\Delta u$  are subject to the following constraint:

$$\Delta k \Delta u = \left(\frac{2\pi}{N}\right)$$

Otherwise, the functions use the FRFT method described in Chourdakis (2005).

# GoldmanSosinGatto

Create GoldmanSosinGatto pricer object for Lookback instrument using BlackScholes model

## Description

Create and price a Lookback instrument object with a BlackScholes model and a GoldmanSosinGatto pricing method using this workflow:

- 1 Use `fininstrument` to create a Lookback instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Lookback instrument.
- 3 Use `finpricer` to specify a GoldmanSosinGatto pricer object for the Lookback instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Lookback instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
GoldmanSosinGattoPricerObj = finpricer(PricerType, '
DiscountCurve,ratecurve_obj, 'Model,model, 'SpotPrice',spotprice_value)
GoldmanSosinGattoPricerObj = finpricer( ___,Name,Value)
```

### Description

`GoldmanSosinGattoPricerObj = finpricer(PricerType, 'DiscountCurve,ratecurve_obj, 'Model,model, 'SpotPrice',spotprice_value)` creates a GoldmanSosinGatto pricer object by specifying `PricerType` and sets the properties on page 11-2655 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`GoldmanSosinGattoPricerObj = finpricer( ___,Name,Value)` to set optional properties on page 11-2655 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `GoldmanSosinGattoPricerObj = finpricer("Analytic", 'DiscountCurve',ratecurve_obj, 'Model',BSModel, 'SpotPrice',1000, 'DividendType',"continuous", 'DividendValue',500, 'PricingMethod',"GoldmanSosinGatto")` creates a GoldmanSosinGatto pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### **GoldmanSosinGatto Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

```
Example: GoldmanSosinGattoPricerObj =  
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice'  
, 1000, 'DividendType', "continuous", 'DividendValue', 500, 'PricingMethod', "Goldm  
anSosinGatto")
```

### **Required GoldmanSosinGatto Name-Value Pair Arguments**

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **Model — Model**

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### **Optional GoldmanSosinGatto Name-Value Pair Arguments**

#### **DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. `DividendType` must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

**DividendValue – Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend amount for underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

---

**Note** Specify a scalar if DividendType is "continuous" and a timetable if DividendType is "cash".

---

Data Types: double | timetable

**PricingMethod – Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "GoldmanSosinGatto" | character vector with value 'GoldmanSosinGatto'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a character vector or string.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

**Properties****DiscountCurve – ratecurve object for discounting cash flows**

object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**Model – Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

**SpotPrice – Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendType – Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. DividendType is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend amount or a timetable for a dividend schedule.

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "GoldmanSosinGatto"

Analytic pricing method, returned as a string.

Data Types: string

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Goldman-Sosin-Gatto Pricer and Black-Scholes Model to Price Lookback Instrument**

This example shows the workflow to price a floating-strike Lookback instrument when you use a BlackScholes model and a GoldmanSosinGatto pricing method.

#### **Create Lookback Instrument Object**

Use `fininstrument` to create a floating-strike Lookback instrument object where the `Strike` argument is specified as `NaN`.

```
LookbackOpt = fininstrument("lookback", 'Strike', NaN, 'ExerciseDate', datetime(2021,9,15), 'OptionType', 'put')
```

```
LookbackOpt =  
  Lookback with properties:  
  
    OptionType: "put"  
      Strike: NaN  
    AssetMinMax: NaN  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2021  
      Name: "lookback_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', .358)
```

```
BlackScholesModel =  
  BlackScholes with properties:
```

```

Volatility: 0.3580
Correlation: 1

```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```

Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)

```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create GoldmanSosinGatto Pricer Object

Use finpricer to create a GoldmanSosinGatto pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,

```

```

outPricer =
  GoldmanSosinGatto with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: 0.0250
      DividendType: "continuous"

```

### Price Lookback Instrument

Use price to compute the price and sensitivities for the floating-strike Lookback instrument.

```

[Price, outPR] = price(outPricer,LookbackOpt,["all"])

```

```

Price = 53.3720

```

```

outPR =
  pricerresult with properties:

```

```

      Results: [1x7 table]
      PricerData: []

```

```

outPR.Results

```

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
53.372	0.53372	-1.4211e-06	1	181.36	-8.7793	-213.01

# HullWhite

Create HullWhite pricer object for Cap, Floor, or Swaption instrument using HullWhite model

## Description

Create and price a Cap, Floor, or Swaption instrument object with a HullWhite model and a HullWhite pricing method using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, or Swaption instrument object.
- 2 Use `finmodel` to specify the HullWhite model for the Cap, Floor, or Swaption instrument.
- 3 Use `finpricer` to specify the HullWhite pricer object for the Cap, Floor, or Swaption instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a Cap, Floor, or Swaption instrument with the HullWhite pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Cap, Floor, or Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
HullWhitePricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

### Description

`HullWhitePricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a HullWhite pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `Model` to set properties on page 11-2660 using name-value pairs. For example, `HullWhitePricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', HWMModel)` creates a HullWhite pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### **HullWhite Name-Value Pair Arguments**

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `HullWhitePricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', HWModel)`

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Data Types: object

### **Model — Model**

HullWhite model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of the previously created HullWhite model object using `finmodel`.

Data Types: object

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **Model — Model**

HullWhite model object

Model, returned as a HullWhite model object.

Data Types: object

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Hull-White Pricer and Hull-White Model to Price a Floor Instrument**

This example shows the workflow to price a Floor instrument when you use a HullWhite model and a HullWhite pricing method.

### Create Floor Instrument Object

Use `fininstrument` to create a Floor instrument object.

```
FloorOpt = fininstrument("Floor", 'Strike', 0.02, 'Maturity', datetime(2019,1,30), 'Reset', 4, 'Princip
```

```
FloorOpt =
  Floor with properties:
      Strike: 0.0200
      Maturity: 30-Jan-2019
      ResetOffset: 0
      Reset: 4
      Basis: 8
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "floor_option"
```

### Create HullWhite Model Object

Use `finmodel` to create a HullWhite model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.032, 'Sigma', 0.04)
```

```
HullWhiteModel =
  HullWhite with properties:
```

```
    Alpha: 0.0320
    Sigma: 0.0400
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = "zero";
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
```

```
    Type: "zero"
    Compounding: -1
    Basis: 0
    Dates: [10x1 datetime]
    Rates: [10x1 double]
    Settle: 15-Sep-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
```

```
LongExtrapMethod: "previous"
```

### **Create HullWhite Pricer Object**

Use `finpricer` to create a `HullWhite` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', HullWhiteModel, 'DiscountCurve', myRC)
```

```
outPricer =
```

```
  HullWhite with properties:
```

```
    DiscountCurve: [1x1 ratecurve]  
         Model: [1x1 finmodel.HullWhite]
```

### **Price Floor Instrument**

Use `price` to compute the price for the `Floor` instrument.

```
Price = price(outPricer, FloorOpt)
```

```
Price = 0.5809
```

## **See Also**

# IRTree

Create IRTree pricer object for Cap, Floor, Swap, Swaption, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument

## Description

Create and price a Cap, Floor, Swap, Swaption, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object with a HullWhite or BlackKarasinski model and an IRTree pricing method using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, Swaption, Swap, FloatBond, FixedBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument object.
- 2 Use `finmodel` to specify a HullWhite or BlackKarasinski model for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument.
- 3 Use `finpricer` to specify an IRTree pricer object for a BK or HW trinomial tree model for the Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FixedBondOption, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Cap, Floor, Swaption, Swap, FixedBond, FloatBond, FloatBondOption, OptionEmbeddedFixedBond, or OptionEmbeddedFloatBond instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
IRTreePricerObj = finpricer(PricerType, 'Model', model_type, 'DiscountCurve', ratecurve_obj, 'TreeDates', tree_dates)
```

### Description

`IRTreePricerObj = finpricer(PricerType, 'Model', model_type, 'DiscountCurve', ratecurve_obj, 'TreeDates', tree_dates)` creates a IRTree pricer object by specifying `PricerType` and the required name-value pair arguments for `Model`, `DiscountCurve`, and `TreeDates` to set properties on page 11-2664 using name-value pair arguments. For example, `IRTreePricerObj = finpricer("IRTree", 'Model', HullWhite, 'DiscountCurve', ratecure_obj, 'TreeDates', ['jan-30-2018'; 'jan-30-2019'])` creates an IRTree pricer object.

## Input Arguments

### PricerType — Pricer type

string with value "IRTree" | character vector with value 'IRTree'

Pricer type, specified as a string with the value of "IRTree" or a character vector with the value of 'IRTree'.

Data Types: char | string

### IRTree Name-Value Pair Arguments

Specify required comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `IRTreePricerObj = finpricer("IRTree", 'Model', HullWhite, 'DiscountCurve', ratecurve_obj, 'TreeDates', ['jan-30-2018'; 'jan-30-2019'])`

### Model — Model type

string with value of "HullWhite" or "BlackKarasinski" | character vector with value of 'HullWhite' or 'BlackKarasinski'

Model type, specified as the comma-separated pair consisting of 'Model' and a character vector or string.

---

**Note** When you use a "HullWhite" model, the IRTree pricer uses the HW2000 algorithm [1].

---

Data Types: char | string

### DiscountCurve — ratecurve object for creating IRTree and discounting cash flows

ratecurve object

This property is read-only.

ratecurve object for creating IRTree and discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a ratecurve object.

Data Types: object

### TreeDates — Dates marking the cash flow dates of the tree

vector

Dates marking the cash flow dates of the tree, specified as the comma-separated pair consisting of 'TreeDates' and an NLEVELS-by-1 vector of dates. Cash flows with these dates will fall on tree nodes. The TreeDates argument determines the number of levels, or depth, of the tree. List dates in increasing order.

Data Types: double | cell | datetime

## Properties

### Tree — HW or BK trinomial tree

struct for HW or BK tree

HW or BK trinomial tree, returned as a struct with the following properties:

- `tObs` contains the time factor of each level of the tree.
- `dObs` contains the date of each level of the tree.
- `Probs` contains a cell array of 3-by-N numeric arrays with the up, mid, down probabilities of each node of the tree except for the last level. The cells in the cell array are ordered from root node. The arrays are 3-by-N with the first row corresponding to an up move, the mid row to a mid-move, and so on. Each column of the array represents a node starting from the top node of a given level.
- `CFlowT` is a cell array with as many elements as levels of the tree. Each cell array element contains the time factors (`tObs`) corresponding to its level of the tree and those levels ahead of it.
- `Connect` contains a cell array with connectivity information for each node of the tree. The arrangement is similar to `Probs`, with the exception that it has only one row in each cell. The number represents the node in the next level to which the middle branch connects to. The top branch connects to the value above (minus one) and the lower branch connects to the value below (plus one).
- `FwdTree` contains the forward spot rate from one node to the next. The forward spot rate is defined as the inverse of the discount factor.

Data Types: `struct`

### **TreeDates — Tree dates**

`datetime`

Tree dates, returned as a scalar `datetime` or `datetime` array.

Data Types: `datetime`

### **Model — Model type**

string with value of "HullWhite" or "BlackKarasinski"

Model type, returned as a string.

Data Types: `string`

### **DiscountCurve — ratecurve object for creating IRTree and discounting cash flows**

`ratecurve` object

This property is read-only.

`ratecurve` object for creating the `IRTree` object and discounting cash flows, returned as a `ratecurve` object.

Data Types: `object`

## **Object Functions**

`price` Compute price for interest-rate instrument with `IRTree` pricer

## **Examples**

## Use Hull-White Tree Pricer and Hull-White Model to Price FixedBondOption Instrument

This example shows the workflow to price a FixedBondOption instrument when you use a HullWhite model and an IRTree pricing method.

### Create FixedBond Instrument Object

Use `fininstrument` to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', 0.025, 'Period',
```

```

BondInst =
    FixedBond with properties:
        CouponRate: 0.0250
        Period: 1
        Basis: 0
        EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
        Holidays: NaT
        IssueDate: NaT
    FirstCouponDate: NaT
    LastCouponDate: NaT
    StartDate: NaT
    Maturity: 15-Sep-2029
    Name: "fixed_bond_instrument"

```

### Create FixedBondOption Instrument Object

Use `fininstrument` to create a FixedBondOption instrument object.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 98, 'B
```

```

FixedBOption =
    FixedBondOption with properties:
        OptionType: "call"
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2025
    Strike: 98
        Bond: [1x1 fininstrument.FixedBond]
    Name: "fixed_bond_option_instrument"

```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```

Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)

```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2019
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```
HullWhiteModel = finmodel("HullWhite", 'Alpha', 0.01, 'Sigma', 0.05)
```

```
HullWhiteModel =
  HullWhite with properties:
```

```
    Alpha: 0.0100
    Sigma: 0.0500
```

### Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object with the `'DiscountCurve'` name-value pair argument.

```
HWTrePricer = finpricer("irtree", 'Model', HullWhiteModel, 'DiscountCurve', myRC, 'TreeDates', ZeroDa
```

```
HWTrePricer =
  HWBKTree with properties:
```

```
    Tree: [1x1 struct]
    TreeDates: [10x1 datetime]
    Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]
```

```
HWTrePricer.Tree
```

```
ans = struct with fields:
    FinObj: 'HWFwdTree'
    tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
    dObs: [1x10 datetime]
    CFlowT: {1x10 cell}
    Probs: {1x9 cell}
    Connect: {1x9 cell}
    FwdTree: {1x10 cell}
```

### Price FixedBondOption Instrument

Use `price` to compute the price and sensitivities for the `FixedBondOption` instrument.

```
[Price, outPR] = price(HWTrePricer, FixedBOption, ["all"])
```

```
Price = 11.1739
outPR =
  pricerresult with properties:
      Results: [1x4 table]
      PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
   Price      Vega      Gamma      Delta
   _____  _____  _____  _____
   11.174    243.09    3667.6    -272.19
```

### Use Black-Karasinski Tree Pricer and Black-Karasinski Model to Price FixedBondOption Instrument

This example shows the workflow to price a FixedBondOption instrument when you use a BlackKarasinski model and an IRTree pricing method.

#### Create FixedBond Instrument Object

Use `fininstrument` to create a FixedBond instrument object as the underlying bond.

```
BondInst = fininstrument("FixedBond", 'Maturity', datetime(2029,9,15), 'CouponRate', 0.025, 'Period', 1, 'DaycountAdjustedCashFlow', 0, 'BusinessDayConvention', 'actual', 'Holidays', NaT, 'IssueDate', NaT, 'FirstCouponDate', NaT, 'LastCouponDate', NaT, 'StartDate', NaT, 'Maturity', 15-Sep-2029, 'Name', 'fixed_bond_instrument')
```

```
BondInst =
  FixedBond with properties:
      CouponRate: 0.0250
      Period: 1
      Basis: 0
      EndMonthRule: 1
      Principal: 100
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      IssueDate: NaT
      FirstCouponDate: NaT
      LastCouponDate: NaT
      StartDate: NaT
      Maturity: 15-Sep-2029
      Name: "fixed_bond_instrument"
```

#### Create FixedBondOption Instrument Object

Use `fininstrument` to create a FixedBondOption instrument object.

```
FixedBOption = fininstrument("FixedBondOption", 'ExerciseDate', datetime(2025,9,15), 'Strike', 100, 'DaycountAdjustedCashFlow', 0, 'BusinessDayConvention', 'actual', 'Holidays', NaT, 'IssueDate', NaT, 'FirstCouponDate', NaT, 'LastCouponDate', NaT, 'StartDate', NaT, 'Maturity', 15-Sep-2029, 'Name', 'fixed_bond_option_instrument')
```

```
FixedBOption =
  FixedBondOption with properties:
```

```

OptionType: "call"
ExerciseStyle: "european"
ExerciseDate: 15-Sep-2025
Strike: 100
Bond: [1x1 fininstrument.FixedBond]
Name: "fixed_bond_option"

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2019,9,15);
Type = 'zero';
ZeroTimes = [calyears([1:10])]';
ZeroRates = [0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307 0.0310]';
ZeroDates = Settle + ZeroTimes;

```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```

myRC =
    ratecurve with properties:

        Type: "zero"
    Compounding: -1
        Basis: 0
        Dates: [10x1 datetime]
        Rates: [10x1 double]
        Settle: 15-Sep-2019
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"

```

### Create BlackKarasinski Model Object

Use finmodel to create a BlackKarasinski model object.

```
BlackKarasinskiModel = finmodel("BlackKarasinski", 'Alpha',0.02, 'Sigma',0.34)
```

```

BlackKarasinskiModel =
    BlackKarasinski with properties:

        Alpha: 0.0200
        Sigma: 0.3400

```

### Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
BKTreePricer = finpricer("IRTree", 'Model',BlackKarasinskiModel, 'DiscountCurve',myRC, 'TreeDates', ...)
```

```

BKTreePricer =
    HWBKTree with properties:

        Tree: [1x1 struct]

```

```

    TreeDates: [10x1 datetime]
    Model: [1x1 finmodel.BlackKarasinski]
    DiscountCurve: [1x1 ratecurve]

```

### BKTreePricer.Tree

```

ans = struct with fields:
    FinObj: 'BKFwdTree'
    tObs: [0 1 1.9973 2.9945 3.9918 4.9918 5.9891 6.9863 7.9836 8.9836]
    dObs: [1x10 datetime]
    CFlowT: {1x10 cell}
    Probs: {1x9 cell}
    Connect: {1x9 cell}
    FwdTree: {1x10 cell}

```

### Price FixedBondOption Instrument

Use price to compute the price and sensitivities for the FixedBondOption instrument.

```
[Price, outPR] = price(BKTreePricer,FixedBOption,["all"])
```

```
Price = 0.5814
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x4 table]
    PricerData: [1x1 struct]

```

### outPR.Results

```
ans=1x4 table
    Price      Vega      Gamma      Delta
    -----
    0.58143    2.793    45.702    -15.842
```

### Use Hull-White Tree Pricer and Hull-White Model to Price Vanilla FixedBond Instrument

This example shows the workflow to price a vanilla FixedBond instrument when you use a HullWhite model and an IRTree pricing method.

#### Create FixedBond Instrument Object

Use fininstrument to create a FixedBond instrument object.

```

Maturity = datetime(2024,1,1);
Period = 1;
VBond = fininstrument("FixedBond", 'Maturity', Maturity, 'CouponRate', 0.025, 'Period', Period)

```

```

VBond =
    FixedBond with properties:

```

```

        CouponRate: 0.0250
          Period: 1
            Basis: 0
      EndMonthRule: 1
        Principal: 100
DaycountAdjustedCashFlow: 0
  BusinessDayConvention: "actual"
    Holidays: NaT
      IssueDate: NaT
FirstCouponDate: NaT
LastCouponDate: NaT
      StartDate: NaT
        Maturity: 01-Jan-2024
          Name: ""

```

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```

Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);

```

### Create HullWhite Model Object

Use finmodel to create a HullWhite model object.

```

VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite",'alpha',AlphaCurve,'sigma',VolCurve);

```

### Create IRTree Pricer Object

Use finpricer to create an IRTree pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```

HWTrePricer = finpricer("IRTree",'Model',HWModel,'DiscountCurve',ZeroCurve,'TreeDates',ZeroDates);

```

```

HWTrePricer =
  HWBKTree with properties:

    Tree: [1x1 struct]
  TreeDates: [10x1 datetime]
    Model: [1x1 finmodel.HullWhite]
DiscountCurve: [1x1 ratecurve]

```

### Price FixedBond Instrument

Use price to compute the price and sensitivities for the vanilla FixedBond instrument.

```

[Price, outPR] = price(HWTrePricer, VBond,["all"])

Price = 107.7023

```

```
outPR =
  pricerresult with properties:
```

```
    Results: [1x4 table]
    PricerData: [1x1 struct]
```

```
outPR.Results
```

```
ans=1x4 table
    Price      Vega      Gamma      Delta
    -----
    107.7      0      4086.4     -602.56
```

### Use Hull-White Tree Pricer and Hull-White Model to Price Vanilla FloatBond Instrument

This example shows the workflow to price a vanilla FloatBond instrument when you use a HullWhite model and an IRTree pricing method.

#### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,1,1);
ZeroTimes = calyears(1:10)';
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
Compounding = 1;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates, "Compounding",Compounding);
```

#### Create FloatBond Instrument Object

Use fininstrument to create a vanilla FloatBond instrument object.

```
Spread = 0.03;
Reset = 1;
Maturity = datetime(2024,1,1);
Period = 1;
Float = fininstrument("FloatBond", 'Maturity',Maturity, 'Spread',Spread, 'Reset',Reset, 'ProjectionC
```

```
Float =
  FloatBond with properties:
        Spread: 0.0300
    ProjectionCurve: [1x1 ratecurve]
        ResetOffset: 0
            Reset: 1
            Basis: 0
        EndMonthRule: 1
        Principal: 100
    DaycountAdjustedCashFlow: 0
    BusinessDayConvention: "actual"
    LatestFloatingRate: NaN
        Holidays: NaT
        IssueDate: NaT
```

```

FirstCouponDate: NaT
LastCouponDate: NaT
StartDate: NaT
Maturity: 01-Jan-2024
Name: ""

```

### Create HullWhite Model Object

Use `finmodel` to create a `HullWhite` model object.

```

VolCurve = 0.01;
AlphaCurve = 0.1;

HWModel = finmodel("HullWhite", 'alpha', AlphaCurve, 'sigma', VolCurve);

```

### Create IRTree Pricer Object

Use `finpricer` to create an `IRTree` pricer object and use the `ratecurve` object for the `'DiscountCurve'` name-value pair argument.

```

HWTreepricer = finpricer("IRTree", 'Model', HWModel, 'DiscountCurve', ZeroCurve, 'TreeDates', ZeroDates);

HWTreepricer =
    HWBKTree with properties:

        Tree: [1x1 struct]
    TreeDates: [10x1 datetime]
        Model: [1x1 finmodel.HullWhite]
    DiscountCurve: [1x1 ratecurve]

```

### Price FloatBond Instrument

Use `price` to compute the price and sensitivities for the vanilla `FloatBond` instrument.

```
[Price, outPR] = price(HWTreepricer, Float, ["all"]);
```

```
Price = 117.4686
```

```
outPR =
    pricerresult with properties:
```

```

    Results: [1x4 table]
    PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x4 table
```

```

    Price    Vega    Gamma    Delta
    _____

```

117.47    0    315.09    -60.007

# KemnaVorst

Create KemnaVorst pricer object for Asian instrument using BlackScholes model

## Description

Create and price a Asian instrument object with a BlackScholes model and a KemnaVorst pricing method using this workflow:

- 1 Use `fininstrument` to create an Asian instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Asian instrument.
- 3 Use `finpricer` to specify a KemnaVorst pricer object for the Asian instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an Asian instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
KemnaVorstPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, '
Model', model, 'SpotPrice', spotprice_value)
KemnaVorstPricerObj = finpricer( ___, Name, Value)
```

### Description

`KemnaVorstPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a KemnaVorst pricer object by specifying `PricerType` and sets the properties on page 11-2677 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`KemnaVorstPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2677 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `KemnaVorstPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "KemnaVorst")` creates a KemnaVorst pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### **KemnaVorst Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1`, `Value1`, . . . , `NameN`, `ValueN`.

Example: `KemnaVorstPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "KemnaVorst")`

### **Required KemnaVorst Name-Value Pair Arguments**

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of `'DiscountCurve'` and the name of the previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for `DiscountCurve`. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at `Maturity` and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **Model — Model**

BlackScholes model object

Model, specified as the comma-separated pair consisting of `'Model'` and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of `'SpotPrice'` and a scalar nonnegative numeric.

Data Types: double

### **Optional KemnaVorst Name-Value Pair Arguments**

#### **DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of `'DividendType'` and a string or character vector. `DividendType` must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

**DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar numeric | timetable

Dividend amount for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend amount or a timetable for a dividend schedule.

---

**Note** DividendValue must be a scalar for a "continuous" DividendType or a timetable for "cash" DividendType.

---

Data Types: double | timetable

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "KemnaVorst" | character vector with value 'KemnaVorst'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

**Properties****DiscountCurve — ratecurve object for discounting cash flows**

object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

**Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendType — Stock dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. `DividendType` is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: `string`

### **DividendValue — Dividend amount or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend amount or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

### **PricingMethod — Analytic pricing method**

default pricer associated with `BlackScholes` model (default) | string with value "KemnaVorst"

Analytic pricing method, returned as a string.

Data Types: `string`

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Kemna-Vorst Pricer and Black-Scholes Model to Price Asian Instrument**

This example shows the workflow to price an Asian instrument when you use a `BlackScholes` model and a `KemnaVorst` pricing method.

#### **Create Asian Instrument Object**

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType', "put")
```

```
AsianOpt =
```

```
Asian with properties:
```

```

    OptionType: "put"
        Strike: 105
    AverageType: "geometric"
    AveragePrice: 0
    AverageStartDate: NaT
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
        Name: "asian_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.32)
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
Volatility: 0.3200
Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:

      Type: "zero"
  Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
  InterpMethod: "linear"
ShortExtrapMethod: "next"
LongExtrapMethod: "previous"
```

### Create KemnaVorst Pricer Object

Use finpricer to create a KemnaVorst pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  KemnaVorst with properties:

  DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
  SpotPrice: 100
  DividendValue: 0.0500
  DividendType: "continuous"
```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 18.1186
```

```
outPR =
  pricerresult with properties:

      Results: [1x7 table]
  PricerData: []
```

outPR.Results

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Rho	Theta
18.119	-0.44689	0.0087391	-3.025	64.582	-251.23	-1.5738

# Kirk

Create Kirk pricer object for Spread instrument using BlackScholes model

## Description

Create and price a Spread instrument object with a BlackScholes model and a Kirk pricing method using this workflow:

- 1 Use `fininstrument` to create a Spread instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Spread instrument.
- 3 Use `finpricer` to specify a Kirk pricer object for the Spread instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Spread instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
KirkPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, '
Model', model, 'SpotPrice', spotprice_value)
KirkPricerObj = finpricer( ___, Name, Value)
```

### Description

`KirkPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a Kirk pricer object by specifying `PricerType` and sets the properties on page 11-2683 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`KirkPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2683 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `KirkPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', [100;105], 'DividendValue', [2.5,2.8], 'PricingMethod', "Kirk")` creates a Kirk pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### **Kirk Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `KirkPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', [100;105], 'DividendValue', [2.5,2.8], 'PricingMethod', "Kirk")`

### **Required Kirk Name-Value Pair Arguments**

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for `DiscountCurve`. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at `Maturity` and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### **Model — Model**

BlackScholes model object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### **SpotPrice — Current price of underlying asset**

scalar nonnegative numeric | cell array of nonnegative numerics

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar or cell array of nonnegative numerics.

Data Types: double

### **Optional Kirk Name-Value Pair Arguments**

#### **DividendType — Dividend type**

"continuous" (default) | string with value "continuous" | character vector with value 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector for a continuous dividend yield.

Data Types: char | string

#### **DividendValue — Dividend yield for underlying asset**

[0, 0] (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield for the underlying asset, specified as the comma-separated pair consisting of 'DividendValue' and a scalar or a vector of nonnegative numerics. Use a vector of nonnegative values for DividendValue when pricing a Spread instrument.

Data Types: double

#### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "Kirk" | character vector with value 'Kirk'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

## **Properties**

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

#### **Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

#### **SpotPrice — Current price of underlying asset**

required input (default) | scalar nonnegative numeric | vector of nonnegative numerics

Current price of the underlying asset, returned as a scalar or vector of nonnegative numeric values.

Data Types: double

#### **DividendType — Dividend type**

"continuous" (default) | string with value "continuous"

This property is read-only.

Dividend type, returned as a string.

Data Types: string

#### **DividendValue — Dividend yield for underlying stock**

[0, 0] (default) | scalar nonnegative numeric | vector of nonnegative numerics

Dividend yield for the underlying stock, returned as a scalar or vector of nonnegative numerics.

Data Types: double

### PricingMethod — Analytic pricing method

default pricer associated with BlackScholes model (default) | string with value "Kirk"

Analytic pricing method, returned as a string.

Data Types: string

## Object Functions

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use Kirk Pricer and Black-Scholes Model to Price Spread Instrument

This example shows the workflow to price a Spread instrument when you use a BlackScholes model and a Kirk pricing method.

#### Create Spread Instrument Object

Use `fininstrument` to create a Spread instrument object.

```
SpreadOpt = fininstrument("Spread", 'Strike', 5, 'ExerciseDate', datetime(2021,9,15), 'OptionType', "p
```

```
SpreadOpt =
```

```
Spread with properties:
```

```
    OptionType: "put"
    Strike: 5
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2021
    Name: "spread_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', [0.2 , 0.1])
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
    Volatility: [0.2000 0.1000]
    Correlation: [2x2 double]
```

#### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 12)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create Kirk Pricer Object

Use `finpricer` to create a Kirk pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```

outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', [103
outPricer =
  Kirk with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: [103 105]
      DividendValue: [0.0250 0.0280]
      DividendType: "continuous"

```

### Price Spread Instrument

Use `price` to compute the price and sensitivities for the Spread instrument.

```

[Price, outPR] = price(outPricer, SpreadOpt, ["all"])
Price = 17.8614
outPR =
  pricerresult with properties:
      Results: [1x7 table]
      PricerData: []

```

outPR.Results

ans=1x7 table

Price	Delta		Gamma		Lambda		Vega
17.861	-0.44663	0.58229	0.0093493	0.008195	-2.5756	3.3578	59.518

# Levy

Create Levy pricer object for Asian instrument using BlackScholes model

## Description

Create and price a Asian instrument object with a BlackScholes model and a Levy pricing method using this workflow:

- 1 Use `fininstrument` to create an Asian instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Asian instrument.
- 3 Use `finpricer` to specify a Levy pricer object for the Asian instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an Asian instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
LevyPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, '
Model', model, 'SpotPrice', spotprice_value)
LevyPricerObj = finpricer( ___, Name, Value)
```

### Description

`LevyPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a Levy pricer object by specifying `PricerType` and sets the properties on page 11-2689 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`LevyPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2689 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `LevyPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "Levy")` creates a Levy pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### Levy Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: LevyPricerObj =
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice',
1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', "Levy"
)
```

### Required Levy Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for `DiscountCurve`. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at `Maturity` and assumes that the value is constant for the life of the equity option.

---

Data Types: object

#### Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional Levy Name-Value Pair Arguments

#### DividendType — Dividend type

"continuous" (default) | string with value of "continuous" | character vector with value of 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector for a continuous dividend yield.

Data Types: char | string

#### DividendValue — Dividend yield or dividend schedule for underlying stock

0 (default) | scalar numeric | timetable

Dividend yield for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend yield or a timetable for a dividend schedule.

---

**Note** Specify a scalar if DividendType is "continuous" and a timetable if DividendType is "cash".

---

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "Levy" | character vector with value 'Levy'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a character vector or string.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **DividendType — Dividend type**

"continuous" (default) | string with value of "continuous"

This property is read-only.

Dividend type, returned as a string.

Data Types: string

### **DividendValue — Dividend yield or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend yield or dividend schedule for the underlying stock, returned as a scalar numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: `double` | `timetable`

### **PricingMethod — Analytic pricing method**

default pricer associated with `BlackScholes` model (default) | string with value "Levy"

Analytic pricing method, returned as a string.

Data Types: `string`

## **Object Functions**

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use Levy Pricer and Black-Scholes Model to Price Asian Instrument**

This example shows the workflow to price an Asian instrument when you use a `BlackScholes` model and a Levy pricing method.

#### **Create Asian Instrument Object**

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType', "p
```

```
AsianOpt =
```

```
Asian with properties:
```

```
    OptionType: "put"  
        Strike: 105  
    AverageType: "arithmetic"  
    AveragePrice: 0  
    AverageStartDate: NaT  
    ExerciseStyle: "european"  
    ExerciseDate: 15-Sep-2022  
        Name: "asian_option"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a `BlackScholes` model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.32)
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
    Volatility: 0.3200  
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Levy Pricer Object

Use finpricer to create a Levy pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  Levy with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: 0
      DividendType: "continuous"
```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 13.0014
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
      PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
      Price      Delta      Gamma      Lambda      Vega      Theta      Rho
```

---

```
13.001    -0.3749    0.0094403    -2.8836    44.586    -0.71607    -121.97
```

### Use Levy Pricer and Black-Scholes Model to Price Asian Instrument for Foreign Exchange

This example shows the workflow to price an Asian instrument for an arithmetic average currency option when you use a BlackScholes model and a Levy pricing method. Assume that the current exchange rate is \$0.52 and has a volatility of 12% per annum. The annualized continuously compounded foreign risk-free rate is 8% per annum.

#### Create Asian Instrument Object

Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', .50, 'OptionType', "put")
```

```
AsianOpt =
  Asian with properties:
      OptionType: "put"
      Strike: 0.5000
      AverageType: "arithmetic"
      AveragePrice: 0
      AverageStartDate: NaT
      ExerciseStyle: "european"
      ExerciseDate: 15-Sep-2022
      Name: "asian_fx_option"
```

#### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
Sigma = .12;
BlackScholesModel = finmodel("BlackScholes", 'Volatility', Sigma)
```

```
BlackScholesModel =
  BlackScholes with properties:
      Volatility: 0.1200
      Correlation: 1
```

#### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;

myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```

myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"

```

### Create Levy Pricer Object

Use `finpricer` to create a Levy pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument. When you price currencies using a Asian instrument for an arithmetic average currency option, `DividendType` must be "continuous" and `DividendValue` is the annualized risk-free interest rate in the foreign country.

```

ForeignRate = 0.08;
outPricer = finpricer("analytic", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPrice', .52,
outPricer =
  Levy with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 0.5200
      DividendValue: 0.0800
      DividendType: "continuous"

```

### Price Asian FX Instrument

Use `price` to compute the price and sensitivities for the Asian FX instrument.

```
[Price, outPR] = price(outPricer, AsianOpt, ["all"])
```

```
Price = 0.0535
```

```
outPR =
  pricerresult with properties:
```

```

      Results: [1x7 table]
      PricerData: []

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
-------	-------	-------	--------	------	-------	-----

0.053516   -0.62792   3.8371   -6.1014   0.15613   -0.010917   -0.82694

## Normal

Create Normal pricer object for Cap, Floor, or Swaption instrument using Normal model

### Description

Create and price a Cap, Floor, or Swaption instrument object with a Normal model and a Normal pricing method using this workflow:

- 1 Use `fininstrument` to create a Cap, Floor, or Swaption instrument object.
- 2 Use `finmodel` to specify a Normal model for the Cap, Floor, or Swaption instrument.
- 3 Use `finpricer` to specify a Normal pricer object for the Cap, Floor, or Swaption instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a Cap, Floor, or Swaption instrument with the HullWhite pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Cap, Floor, or Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
NormalPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

### Description

`NormalPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a Normal pricer object by specifying `PricerType` and the required name-value pair arguments `DiscountCurve` and `Model` to set properties on page 11-2696 using name-value pair arguments. For example, `NormalPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', NormModel)` creates a Normal pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### Normal Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: NormalPricerObj =  
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', NormModel)
```

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Data Types: object

### Model — Model

Normal model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created Normal model object using `finmodel`.

Data Types: object

## Properties

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### Model — Model

Normal model object

Model, returned as a Normal model object.

Data Types: object

## Object Functions

`price` Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## Examples

### Use Normal Pricer and Normal Model to Price Cap Instrument

This example shows the workflow to price a Cap instrument when you use a Normal model and a Normal pricing method.

#### Create Cap Instrument Object

Use `fininstrument` to create a Cap instrument object.

```
CapOpt = fininstrument("Cap", 'Strike', 0.02, 'Maturity', datetime(2019, 6, 25), 'Reset', 4, 'Principal', ...
```

```
CapOpt =
  Cap with properties:
      Strike: 0.0200
      Maturity: 25-Jun-2019
      ResetOffset: 0
      Reset: 4
      Basis: 8
      Principal: 100
      ProjectionCurve: [0x0 ratecurve]
      DaycountAdjustedCashFlow: 0
      BusinessDayConvention: "actual"
      Holidays: NaT
      Name: "cap_option"
```

### Create Normal Model Object

Use `finmodel` to create a Normal model object.

```
NormalModel = finmodel("Normal", 'Volatility', 0.063)
```

```
NormalModel =
  Normal with properties:
```

```
    Volatility: 0.0630
```

### Create ratecurve Object

Create a ratecurve object using `ratecurve`.

```
Settle = datetime(2018, 9, 15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero', Settle, ZeroDates, ZeroRates)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create Normal Pricer Object

Use `finpricer` to create a `Normal` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', NormalModel, 'DiscountCurve', myRC)

outPricer =
  Normal with properties:
    DiscountCurve: [1x1 ratecurve]
    Shift: 0
    Model: [1x1 finmodel.Normal]
```

### Price Cap Instrument

Use `price` to compute the price for the Cap instrument.

```
Price = price(outPricer, CapOpt)
```

```
Price = 0.4828
```

# RollGeskeWhaley

Create RollGeskeWhaley pricer object for American exercise Vanilla instrument using BlackScholes model

## Description

Create and price a Vanilla instrument object with a BlackScholes model and a RollGeskeWhaley pricing method using this workflow:

- 1 Use `fininstrument` to create a Vanilla instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Vanilla instrument.
- 3 Use `finpricer` to specify a RollGeskeWhaley pricer object for the Vanilla instrument (American exercise).

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Vanilla instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
RollGeskeWhaleyPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotrate_value, 'DividendType', dividendtype, 'DividendValue', dividendvalue)
RollGeskeWhaleyPricerObj = finpricer( ____, Name, Value)
```

### Description

`RollGeskeWhaleyPricerObj = finpricer(PricerType, 'Model', model, 'DiscountCurve', ratecurve_obj, 'SpotPrice', spotrate_value, 'DividendType', dividendtype, 'DividendValue', dividendvalue)` creates a RollGeskeWhaley pricer object by specifying `PricerType` and sets the properties on page 11-2701 for the required name-value pair arguments `Model`, `DiscountCurve`, and `SpotPrice`.

`RollGeskeWhaleyPricerObj = finpricer( ____, Name, Value)` to set optional properties on page 11-2701 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `RollGeskeWhaleyPricerObj = finpricer("Analytic", 'Model', BSMModel, 'DiscountCurve', ratecurve_obj, 'SpotPrice', 1000, 'DividendValue', timetable(datetime(2021,6,15),2.5), 'DividendType', "cash", 'PricingMethod', "RollGeskeWhaley")` creates a RollGeskeWhaley pricer object. You can specify multiple name-value pair arguments.

**Input Arguments****PricerType — Pricer type**

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

**RollGeskeWhaley Name-Value Pair Arguments**

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: RollGeskeWhaleyPricerObj =  
 finpricer("Analytic", 'Model', BSMModel, 'DiscountCurve', ratecurve\_obj, 'SpotPrice', 1000, 'DividendValue', timetable(datetime(2021,6,15), 2.5), 'DividendType', "cash", 'PricingMethod', "RollGeskeWhaley")

**Required RollGeskeWhaley Name-Value Pair Arguments****Model — Model**

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using finmodel.

Data Types: object

**DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

**DividendValue — Cash dividend for underlying stock**

timetable

Cash dividend for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a timetable.

Data Types: timetable

### Optional RollGeskeWhaley Name-Value Pair Arguments

#### **DividendType — Stock dividend type**

"cash" (default) | string with value "cash" | character vector with value 'cash'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a string or character vector.

Data Types: char | string

#### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "RollGeskeWhaley" | character vector with value 'RollGeskeWhaley'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

## Properties

#### **Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

#### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object

Data Types: object

#### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

#### **DividendValue — Cash dividend for underlying stock**

timetable

Cash dividend for the underlying stock, returned as a timetable.

Data Types: timetable

#### **DividendType — Stock dividend type**

"cash" (default) | string with value "cash"

Stock dividend type, returned as a string.

Data Types: char | string

### **PricingMethod – Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "RollGeskeWhaley"

Analytic pricing method, returned as a string.

Data Types: string

## **Object Functions**

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

## **Examples**

### **Use a Roll-Geske-Whaley Pricer and Black-Scholes Model to Price Vanilla Instrument**

This example shows the workflow to price an American exercise Vanilla instrument when you use a BlackScholes model and a RollGeskeWhaley pricing method.

#### **Create Vanilla Instrument Object**

Use `fininstrument` to create a Vanilla instrument object.

```
VanillaOpt = fininstrument("Vanilla", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'ExerciseStyle', 'american')
```

```
VanillaOpt =  
  Vanilla with properties:
```

```
    OptionType: "call"  
    ExerciseStyle: "american"  
    ExerciseDate: 15-Sep-2022  
    Strike: 105  
    Name: "vanilla_american_instrument"
```

#### **Create BlackScholes Model Object**

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.07)
```

```
BlackScholesModel =  
  BlackScholes with properties:
```

```
    Volatility: 0.0700  
    Correlation: 1
```

#### **Create ratecurve Object**

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,9,15);
myRC = ratecurve("zero",Settle,datetime(2023,9,15),.05,'Basis',12);
```

### Create RollGeskeWhaley Pricer Object

Use `finpricer` to create a `RollGeskeWhaley` pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  RollGeskeWhaley with properties:

    DiscountCurve: [1x1 ratecurve]
           Model: [1x1 finmodel.BlackScholes]
    SpotPrice: 100
    DividendValue: [1x1 timetable]
    DividendType: "cash"
```

### Price Vanilla Instrument

Use `price` to compute the price and sensitivities for the Vanilla instrument.

```
[Price, outPR] = price(outPricer, VanillaOpt, ["all"])
```

```
Price = 14.9582
```

```
outPR =
  pricerresult with properties:

    Results: [1x7 table]
    PricerData: []
```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
14.958	0.87494	0.01471	5.8493	41.184	-3.9873	290.2

## SABR

Create SABR pricer object for Swaption instrument using SABR model

### Description

Create and price a Swaption instrument object with a SABR model and a SABR pricing method using this workflow:

- 1 Use `fininstrument` to create a Swaption instrument object.
- 2 Use `finmodel` to specify a SABR model for the Swaption instrument.
- 3 Use `finpricer` to specify a SABR pricer object for the Swaption instrument.

---

**Note** If you do not specify `ProjectionCurve` when you create a Swaption instrument with the SABR pricer, the `ProjectionCurve` value defaults to the `DiscountCurve` value.

---

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for a Swaption instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
SABRPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)
```

### Description

`SABRPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model)` creates a SABR pricer object by specifying `PricerType` and the required name-value pair argument `Model` to set properties on page 11-2705 using name-value pairs. For example, `SABRPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', SABRModel)` creates a SABR pricer object.

### Input Arguments

#### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### SABR Name-Value Pair Arguments

Specify required comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

```
Example: SABRPricerObj =
finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', SABRModel)
```

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Data Types: object

### Model — Model

SABR model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created SABR model object using `finmodel`.

Data Types: object

## Properties

### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object

Data Types: object

### Model — Model object

SABR model object

Model, returned as a SABR model object.

Data Types: object

## Object Functions

price            Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer  
volatilities    Compute implied volatilities when using SABR pricer

## Examples

### Use SABR Pricer and SABR Model to Price Swaption Instrument

This example shows the workflow to price a Swaption instrument when you use a SABR model and a SABR pricing method.

### Create ratecurve Object

Create a ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Type = 'zero';
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
```

```
myRC = ratecurve('zero',Settle,ZeroDates,ZeroRates)
```

```
myRC =
  ratecurve with properties:

      Type: "zero"
  Compounding: -1
      Basis: 0
      Dates: [10x1 datetime]
      Rates: [10x1 double]
      Settle: 15-Sep-2018
  InterpMethod: "linear"
ShortExtrapMethod: "next"
  LongExtrapMethod: "previous"
```

### Create Swap Instrument Object

Use fininstrument to create the underlying Swap instrument object.

```
Swap = fininstrument("Swap", 'Maturity', datetime(2023,1,30), 'LegRate', [0.018 0.24], 'LegType', ["fi
```

```
Swap =
  Swap with properties:

      LegRate: [0.0180 0.2400]
      LegType: ["fixed" "float"]
      Reset: [2 2]
      Basis: [1 1]
      Notional: 100
  LatestFloatingRate: [NaN NaN]
      ResetOffset: [0 0]
  DaycountAdjustedCashFlow: [0 0]
      ProjectionCurve: [1x2 ratecurve]
  BusinessDayConvention: ["actual" "actual"]
      Holidays: NaT
      EndMonthRule: [1 1]
      StartDate: 30-Mar-2020
      Maturity: 30-Jan-2023
      Name: "swap_instrument"
```

### Create Swaption Instrument Object

Use fininstrument to create a Swaption instrument object.

```
Swaption = fininstrument("Swaption", 'Strike', 0.275, 'ExerciseDate', datetime(2021,7,30), 'Swap', Swap
```

```
Swaption =
  Swaption with properties:
```

```

OptionType: "put"
ExerciseStyle: "european"
ExerciseDate: 30-Jul-2021
Strike: 0.2750
Swap: [1x1 fininstrument.Swap]
Name: "swaption_instrument"

```

### Create SABR Model Object

Use `finmodel` to create a SABR model object.

```
SABRModel = finmodel("SABR", 'Alpha', 0.032, 'Beta', 0.04, 'Rho', .08, 'Nu', 0.49, 'Shift', 0.002)
```

```

SABRModel =
  SABR with properties:

      Alpha: 0.0320
      Beta: 0.0400
      Rho: 0.0800
      Nu: 0.4900
      Shift: 0.0020
  VolatilityType: "black"

```

### Create SABR Pricer Object

Use `finpricer` to create a SABR pricer object and use the `ratecurve` object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic", 'Model', SABRModel, 'DiscountCurve', myRC)
```

```

outPricer =
  SABR with properties:

      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.SABR]

```

### Price Swaption Instrument

Use `price` to compute the price for the Swaption instrument.

```
Price = price(outPricer, Swaption)
```

```
Price = 10.3771
```

# FiniteDifference

Create `FiniteDifference` pricer object for `Barrier`, `DoubleBarrier`, or `Vanilla` instrument using a `BlackScholes`, `Heston`, `Merton`, or `Bates` model

## Description

Create and price a `Vanilla`, `Barrier`, or `DoubleBarrier` instrument object with a `BlackScholes`, `Heston`, `Bates`, `Merton`, or `Dupire` model and a `FiniteDifference` pricing method using this workflow:

- 1 Use `fininstrument` to create the `Barrier`, `DoubleBarrier`, or `Vanilla` instrument object.
- 2 Use `finmodel` to specify the `BlackScholes` model for a `Barrier` or `DoubleBarrier` instrument or a `Heston`, `Bates`, `Dupire`, or `Merton` model for the `Vanilla` instrument.
- 3 Use `finpricer` to specify the `FiniteDifference` pricer object for the `Barrier`, `DoubleBarrier`, or `Vanilla` instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available pricing methods for a `Vanilla`, `Barrier`, or `DoubleBarrier` instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

## Creation

### Syntax

```
FiniteDifferencePricerObj = finpricer(PricerType,'Model',model,'
DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)
FiniteDifferencePricerObj = finpricer(___,Name,Value)
```

### Description

`FiniteDifferencePricerObj = finpricer(PricerType,'Model',model,'DiscountCurve',ratecurve_obj,'SpotPrice',spotprice_value)` creates a `FiniteDifference` pricer object by specifying `PricerType` and sets the properties on page 11-2712 for the required name-value pair arguments `Model`, `DiscountCurve`, and `SpotPrice`.

`FiniteDifferencePricerObj = finpricer(___,Name,Value)` sets optional properties on page 11-2712 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `FiniteDifferencePricerObj = finpricer("FiniteDifference",'Model',BSModel,'DiscountCurve',ratecurve_obj,'SpotPrice',100,'DividendValue',.025,'DividendType',"cash")` creates a `FiniteDifference` pricer object. You can specify multiple name-value pair arguments.

### Input Arguments

#### PricerType — Pricer type

string with value "FiniteDifference" | character vector with value 'FiniteDifference'

Pricer type, specified as a string with the value of "FiniteDifference" or the character vector with a value of 'FiniteDifference'.

Data Types: char | string

#### FiniteDifference Name-Value Pair Arguments

Specify required and optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: `FiniteDifferencePricerObj = finpricer("FiniteDifference", 'Model', BSMModel, 'DiscountCurve', ratecurve_obj, 'SpotPrice', 100, 'DividendValue', .025, 'DividendType', "cash")`

#### Required FiniteDifference Name-Value Pair Arguments

##### Model — Model object

object

Model object, specified as the comma-separated pair consisting of 'Model' and the name of the previously created Merton, Bates, or Heston model object using `finmodel`.

Data Types: object

##### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of the ratecurve object.

---

**Note** Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

---

Data Types: object

##### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

#### Optional FiniteDifference Name-Value Pair Arguments

##### DividendValue — Dividend yield or dividend schedule

0 (default) | scalar | timetable

Dividend yield or dividend schedule, specified as the comma-separated pair consisting of 'DividendValue' and a scalar for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

**DividendType — Dividend type**

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. DividendType must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

---

**Note** When you use a Barrier instrument, you must set DividendType to "cash".

---

Data Types: char | string

**SpotGridSize — Size of spot grid for finite difference grid**

400 (default) | scalar numeric

Size of the spot grid for the finite difference grid, specified as the comma-separated pair consisting of 'SpotGridSize' and a scalar numeric.

Data Types: double

**SpotPriceMax — Maximum price for price grid boundary**

if unspecified, SpotPrice values are calculated using asset distributions at maturity (default) | positive scalar

Maximum price for the price grid boundary, specified as the comma-separated pair consisting of 'SpotPriceMax' and a positive scalar.

Data Types: single | double

**VarianceGridSize — Number of nodes of variance grid for finite difference grid**

200 (default) | scalar numeric

Number of nodes of the variance grid for the finite difference grid, specified as the comma-separated pair consisting of 'VarianceGridSize' and a scalar numeric.

---

**Note** VarianceGridSize is supported only when you use a Heston or Bates model.

---

Data Types: double

**VarianceMax — Maximum variance for variance grid boundary**

1.0 (default) | scalar numeric

Maximum variance for the variance grid boundary, specified as the comma-separated pair consisting of 'VarianceMax' as a scalar numeric.

---

**Note** VarianceMax is supported only when you use a Heston or Bates model.

---

Data Types: double

**TimeGridSize — Number of nodes of time grid for finite difference grid**

100 (default) | positive numeric scalar

Number of nodes of the time grid for the finite difference grid, specified as the comma-separated pair consisting of 'TimeGridSize' and a positive numeric scalar.

Data Types: double

**InterpMethod — Method of interpolation for estimating the implied volatility surface from ImpliedVolData**

'linear' (default) | string with value "linear", "makima", "spline", or "tpaps" | character vector with value 'linear', 'makima', 'spline', or 'tpaps'

Method of interpolation for estimating the implied volatility surface from ImpliedVolData for use only with a Dupire model, specified as the comma-separated pair consisting of 'InterpMethod' and a string or character vector with one of the following values:

- 'linear' — Linear interpolation
- 'makima' — Modified Akima cubic Hermite interpolation
- 'spline' — Cubic spline interpolation
- 'tpaps' — Thin-plate smoothing spline interpolation

---

**Note** The 'tpaps' method uses the thin-plate smoothing spline functionality from Curve Fitting Toolbox.

The 'makima' and 'spline' methods work only for gridded data. For scattered data, use the 'linear' or 'tpaps' methods.

---

For more information on gridded or scattered data and details on interpolation methods, see “Gridded and Scattered Sample Data” and “Interpolating Gridded Data”.

Data Types: char | string

## Properties

**Model — Model**

object

Model, returned as a model object.

Data Types: object

**DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

This property is read-only.

ratecurve object for discounting cash flows, returned as the ratecurve object.

Data Types: object

**SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

**DividendValue — Dividend yield or dividend schedule**

0 (default) | scalar | timetable

Dividend yield or dividend schedule, returned as a scalar for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

**DividendType — Dividend type**

"continuous" (default) | string with value "cash" or "continuous"

This property is read-only.

Dividend type, returned as a string. The `DividendType` is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

**GridProperties — Grid properties**

400 (default) | scalar numeric

Grid properties, returned as a struct.

For a Dupire model, `GridProperties` contains the following fields:

- `SpotGridSize` — Size of the spot grid for the finite difference grid, returned as a scalar numeric.
- `SpotPriceMax` — Maximum price for price grid boundary, returned as a positive scalar.
- `TimeGridSize` — Number of nodes of the time grid for the finite difference grid, returned as a positive numeric scalar.
- `InterpMethod` — Method of interpolation for estimating the implied volatility surface, returned as a string.

For a Heston or Bates model, `GridProperties` contains the following fields:

- `VarianceGridSize` — Size of the variance grid for the finite difference grid, returned as a scalar numeric.
- `VarianceMax` — Maximum variance for the variance grid boundary, returned as a scalar numeric.

Data Types: struct

**Object Functions**

`price` Compute price for equity instrument with `FiniteDifference` pricer

**Examples****Use Finite Difference Pricer and Black-Scholes Model to Price Barrier Instrument**

This example shows the workflow to price a Barrier instrument when you use a `BlackScholes` model and a `FiniteDifference` pricing method.

**Create Barrier Instrument Object**

Use `fininstrument` to create a Barrier instrument object.

```
BarrierOpt = fininstrument("Barrier", 'Strike', 105, 'ExerciseDate', datetime(2019,1,1), 'OptionType', 'call')
BarrierOpt =
  Barrier with properties:
    OptionType: "call"
    Strike: 105
    BarrierType: "do"
    BarrierValue: 40
    Rebate: 0
    ExerciseStyle: "american"
    ExerciseDate: 01-Jan-2019
    Name: "barrier_option"
```

### Create BlackScholes Model Object

Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.30)
BlackScholesModel =
  BlackScholes with properties:
    Volatility: 0.3000
    Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using `ratecurve`.

```
Settle = datetime(2018,1,1);
Maturity = datetime(2023,1,1);
Rate = 0.035;
myRC = ratecurve('zero', Settle, Maturity, Rate, 'Basis', 1)
myRC =
  ratecurve with properties:
    Type: "zero"
    Compounding: -1
    Basis: 1
    Dates: 01-Jan-2023
    Rates: 0.0350
    Settle: 01-Jan-2018
    InterpMethod: "linear"
    ShortExtrapMethod: "next"
    LongExtrapMethod: "previous"
```

### Create FiniteDifference Pricer Object

Use `finpricer` to create a FiniteDifference pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("FiniteDifference", 'Model', BlackScholesModel, 'DiscountCurve', myRC, 'SpotPricer')
outPricer =
  FiniteDifference with properties:
```

```

DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
GridProperties: [1x1 struct]
      DividendType: "continuous"
      DividendValue: 0

```

## Price Barrier Instrument

Use `price` to compute the price and sensitivities for the `Barrier` instrument.

```
[Price, outPR] = price(outPricer,BarrierOpt,["all"])
```

```
Price = 11.3230
```

```
outPR =
  pricerresult with properties:
```

```

      Results: [1x7 table]
      PricerData: [1x1 struct]

```

```
outPR.Results
```

```
ans=1x7 table
```

Price	Delta	Gamma	Lambda	Theta	Rho	Vega
11.323	0.54126	0.0132	4.7802	-7.4408	42.766	39.627

## See Also

### Functions

`fininstrument` | `finmodel` | `timetable`

## TurnbullWakeman

Create TurnbullWakeman pricer object for Asian instrument using BlackScholes model

### Description

Create and price a Asian instrument object with a BlackScholes model and a TurnbullWakeman pricing method using this workflow:

- 1 Use `fininstrument` to create an Asian instrument object.
- 2 Use `finmodel` to specify a BlackScholes model for the Asian instrument.
- 3 Use `finpricer` to specify a TurnbullWakeman pricer object for the Asian instrument.

For more information on this workflow, see “Get Started with Workflows Using Object-Based Framework for Pricing Financial Instruments” on page 1-22.

For more information on the available instruments, models, and pricing methods for an Asian instrument, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Creation

#### Syntax

```
TurnbullWakemanPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)
TurnbullWakemanPricerObj = finpricer( ___, Name, Value)
```

#### Description

`TurnbullWakemanPricerObj = finpricer(PricerType, 'DiscountCurve', ratecurve_obj, 'Model', model, 'SpotPrice', spotprice_value)` creates a TurnbullWakeman pricer object by specifying `PricerType` and sets the properties on page 11-2718 for the required name-value pair arguments `DiscountCurve`, `Model`, and `SpotPrice`.

`TurnbullWakemanPricerObj = finpricer( ___, Name, Value)` to set optional properties on page 11-2718 using additional name-value pairs in addition to the required arguments in the previous syntax. For example, `TurnbullWakemanPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100)` creates a TurnbullWakeman pricer object.

#### Input Arguments

##### PricerType — Pricer type

string with value "Analytic" | character vector with value 'Analytic'

Pricer type, specified as a string with the value of "Analytic" or a character vector with the value of 'Analytic'.

Data Types: char | string

### TurnbullWakeman Name-Value Pair Arguments

Specify required and optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `TurnbullWakemanPricerObj = finpricer("Analytic", 'DiscountCurve', ratecurve_obj, 'Model', BSMModel, 'SpotPrice', 1000, 'DividendType', "continuous", 'DividendValue', 100, 'PricingMethod', 'TurnbullWakeman')`

### Required TurnbullWakeman Name-Value Pair Arguments

#### DiscountCurve — ratecurve object for discounting cash flows

ratecurve object

ratecurve object for discounting cash flows, specified as the comma-separated pair consisting of 'DiscountCurve' and the name of a previously created ratecurve object.

Specify a flat ratecurve object for DiscountCurve. If you use a nonflat ratecurve object, the software uses the rate in the ratecurve object at Maturity and assumes that the value is constant for the life of the equity option.

Data Types: object

#### Model — Model

BlackScholes model object

Model, specified as the comma-separated pair consisting of 'Model' and the name of a previously created BlackScholes model object using `finmodel`.

Data Types: object

#### SpotPrice — Current price of underlying asset

nonnegative numeric

Current price of the underlying asset, specified as the comma-separated pair consisting of 'SpotPrice' and a scalar nonnegative numeric.

Data Types: double

### Optional TurnbullWakeman Name-Value Pair Arguments

#### DividendType — Stock dividend type

"continuous" (default) | string with value "cash" or "continuous" | character vector with value 'cash' or 'continuous'

Stock dividend type, specified as the comma-separated pair consisting of 'DividendType' and a character vector or string. `DividendType` must be "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: char | string

#### DividendValue — Dividend yield or dividend schedule for underlying stock

0 (default) | scalar numeric | timetable

Dividend yield for the underlying stock, specified as the comma-separated pair consisting of 'DividendValue' and a scalar numeric for a dividend yield or a timetable for a dividend schedule.

---

**Note** DividendValue must be a scalar for a "continuous" DividendType or a timetable for a "cash" DividendType.

---

Data Types: double | timetable

### **PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "TurnbullWakeman" | character vector with value 'TurnbullWakeman'

Analytic pricing method, specified as the comma-separated pair consisting of 'PricingMethod' and a string or character vector.

---

**Note** The default pricing method for a BlackScholes model is a BlackScholes pricer.

---

Data Types: double

## **Properties**

### **DiscountCurve — ratecurve object for discounting cash flows**

ratecurve object

ratecurve object for discounting cash flows, returned as a ratecurve object.

Data Types: object

### **Model — Model**

BlackScholes model object

Model, returned as a BlackScholes model object.

Data Types: object

### **SpotPrice — Current price of underlying asset**

nonnegative numeric

Current price of the underlying asset, returned as a scalar nonnegative numeric.

Data Types: double

### **DividendType — Stock dividend type**

'continuous' (default) | string with value "cash" or "continuous"

This property is read-only.

Stock dividend type, returned as a string. DividendType is either "cash" for actual dollar dividends or "continuous" for a continuous dividend yield.

Data Types: string

**DividendValue — Dividend yield or dividend schedule for underlying stock**

0 (default) | scalar nonnegative numeric | timetable

Dividend yield or dividend schedule for the underlying stock, returned as a scalar nonnegative numeric for a dividend yield or a timetable for a dividend schedule.

Data Types: double | timetable

**PricingMethod — Analytic pricing method**

default pricer associated with BlackScholes model (default) | string with value "TurnbullWakeman"

Analytic pricing method, returned as a string.

Data Types: string

**Object Functions**

price Compute price for interest-rate, equity, or credit derivative instrument with Analytic pricer

**Examples****Use Turnbull-Wakeman Pricer and Black-Scholes Model to Price Asian Instrument**

This example shows the workflow to price an Asian instrument when you use a BlackScholes model and a TurnbullWakeman pricing method.

**Create Asian Instrument Object**Use `fininstrument` to create an Asian instrument object.

```
AsianOpt = fininstrument("Asian", 'ExerciseDate', datetime(2022,9,15), 'Strike', 105, 'OptionType', "put")
```

```
AsianOpt =
```

```
Asian with properties:
```

```

    OptionType: "put"
        Strike: 105
    AverageType: "arithmetic"
    AveragePrice: 0
    AverageStartDate: NaT
    ExerciseStyle: "european"
    ExerciseDate: 15-Sep-2022
        Name: "asian_option"
```

**Create BlackScholes Model Object**Use `finmodel` to create a BlackScholes model object.

```
BlackScholesModel = finmodel("BlackScholes", 'Volatility', 0.35)
```

```
BlackScholesModel =
```

```
BlackScholes with properties:
```

```
Volatility: 0.3500
```

```
Correlation: 1
```

### Create ratecurve Object

Create a flat ratecurve object using ratecurve.

```
Settle = datetime(2018,9,15);
Maturity = datetime(2023,9,15);
Rate = 0.035;
myRC = ratecurve('zero',Settle,Maturity,Rate,'Basis',12)
```

```
myRC =
  ratecurve with properties:
      Type: "zero"
      Compounding: -1
      Basis: 12
      Dates: 15-Sep-2023
      Rates: 0.0350
      Settle: 15-Sep-2018
      InterpMethod: "linear"
      ShortExtrapMethod: "next"
      LongExtrapMethod: "previous"
```

### Create TurnbullWakeman Pricer Object

Use finpricer to create a TurnbullWakeman pricer object and use the ratecurve object for the 'DiscountCurve' name-value pair argument.

```
outPricer = finpricer("analytic",'Model',BlackScholesModel,'DiscountCurve',myRC,'SpotPrice',100,
```

```
outPricer =
  TurnbullWakeman with properties:
      DiscountCurve: [1x1 ratecurve]
      Model: [1x1 finmodel.BlackScholes]
      SpotPrice: 100
      DividendValue: 0
      DividendType: "continuous"
```

### Price Asian Instrument

Use price to compute the price and sensitivities for the Asian instrument.

```
[Price, outPR] = price(outPricer,AsianOpt,["all"])
```

```
Price = 14.3431
```

```
outPR =
  pricerresult with properties:
```

```
      Results: [1x7 table]
      PricerData: []
```

```
outPR.Results
```

ans=1x7 table

Price	Delta	Gamma	Lambda	Vega	Theta	Rho
14.343	-0.37004	0.0085706	-2.5799	44.864	-0.86257	-125.73

## defprobcurve

Create defprobcurve object for credit instrument

### Description

Create a defprobcurve object for a credit instrument.

After creating a defprobcurve object, you can use the associated functions `survprobs`, `hazardrates`, and `defprobstrip`.

To price a CDS instrument, you must create a defprobcurve object and then create a `Credit` pricer object.

For more information on the available instruments, models, and pricing methods, see “Choose Instruments, Models, and Pricers” on page 1-43.

### Creation

#### Syntax

```
DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)
DefaultProbCurve = defprobcurve( ____, Name, Value)
```

#### Description

`DefaultProbCurve = defprobcurve(Settle, ProbDates, DefaultProbabilities)` creates a defprobcurve object.

`DefaultProbCurve = defprobcurve( ____, Name, Value)` sets properties on page 11-2723 using name-value pairs and any of the arguments in the previous syntax. For example, `DefaultProbCurve = defprobcurve(datetime(2017,1,30), [datetime(2018,1,30); datetime(2019,1,30)], [0.005 0.007], 'Basis', 2)` creates a default probability curve object. You can specify multiple name-value pair arguments.

#### Input Arguments

##### Settle — Settle date for curve

serial date number | date character vector | date string | datetime

Settle date for curve, specified as a scalar serial date number, date character vector, date string, or datetime.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `Settle` property is stored as a datetime.

Data Types: `char` | `string` | `double` | `datetime`

##### ProbDates — Dates corresponding to DefaultProbabilities

serial date number | cell array of date character vectors | date string | datetime

Dates corresponding to `DefaultProbabilities`, specified as an `NPOINTS`-by-1 vector of serial date numbers, cell array of date character vectors, string array, or datetime array.

If you use a date character vector or date string, the format must be recognizable by `datetime` because the `ProbDates` property is stored as a datetime.

Data Types: `string` | `datetime` | `double` | `char` | `cell`

### **DefaultProbabilities — Default probability data for the curve** vector

Default probability data for the curve, specified as a numeric vector.

Data Types: `double`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `defprobcurve = defprobcurve(datetime(2017,1,30), [datetime(2018,1,30);datetime(2019,1,30)], [0.005 0.007], 'Basis', 2)`

### **Basis — Day-count basis**

2 (actual/360) (default) | integer from 0 to 13

Day-count basis, specified as the comma-separated pair consisting of `'Basis'` and a scalar integer.

- 0 — actual/actual
- 1 — 30/360 (SIA)
- 2 — actual/360
- 3 — actual/365
- 4 — 30/360 (PSA)
- 5 — 30/360 (ISDA)
- 6 — 30/360 (European)
- 7 — actual/365 (Japanese)
- 8 — actual/actual (ICMA)
- 9 — actual/360 (ICMA)
- 10 — actual/365 (ICMA)
- 11 — 30/360E (ICMA)
- 12 — actual/365 (ISDA)
- 13 — BUS/252

For more information, see “Basis” on page 2-208.

Data Types: `double`

## **Properties**

### **Settle — Settlement date**

`datetime`

Settlement date, returned as a datetime.

Data Types: datetime

### **Basis — Day-count basis**

2 (actual/360) (default) | integer from 0 to 13

This property is read-only.

Day-count basis of the instrument, returned as a scalar integer.

Data Types: double

### **Dates — Dates corresponding to rate data**

datetime

Dates corresponding to the rate data, returned as a datetime.

Data Types: datetime

### **DefaultProbabilities — Default probabilities for the curve**

vector

Default probabilities for the curve, returned as a vector.

Data Types: double

## **Object Functions**

survprobs      Compute survival probability based on default probability curve  
hazardrates    Compute hazard rates based on default probability curve  
defprobstrip   Bootstrap defprobcurve object from market CDS instruments

## **Examples**

### **Create defprobcurve Object**

Create a defprobcurve object using defprobcurve.

```
Settle = datetime(2017,9,20);  
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];  
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';  
ProbDates = Settle + DefProbTimes;
```

```
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',2)
```

```
DefaultProbCurve =  
  defprobcurve with properties:
```

```
      Settle: 20-Sep-2017  
      Basis: 2  
      Dates: [10x1 datetime]  
  DefaultProbabilities: [10x1 double]
```

### Introduced in R2020a

## survprobs

Compute survival probability based on default probability curve

### Syntax

```
outSurvProbs = survprobs(obj,inDates)
```

### Description

`outSurvProbs = survprobs(obj,inDates)` computes the survival probability based on the default probability curve object.

### Examples

#### Calculate Survival Probability Based on Default Probability Curve

Create a `defprobcurve` object using `defprobcurve` and then use `survprobs` to calculate the survival probability.

```
Settle = datetime(2017,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
DefProbDates = Settle + DefProbTimes;

DefaultProbCurve = defprobcurve(Settle,DefProbDates,DefaultProbabilities,'Basis',5)

DefaultProbCurve =
    defprobcurve with properties:

        Settle: 20-Sep-2017
        Basis: 5
        Dates: [10x1 datetime]
        DefaultProbabilities: [10x1 double]

SurvProbTimes = [calmonths([6 12 18])];
SurvProbDates = Settle + SurvProbTimes;
outSurvProb = survprobs(DefaultProbCurve, SurvProbDates)

outSurvProb = 3x1

    0.9950
    0.9930
    0.9915
```

### Input Arguments

**obj** — `defprobcurve` object  
`defprobcurve` object

defprobcurve object, specified as a previously created defprobcurve object.

Data Types: object

**inDates — Survival probability dates**

datetime | serial date number | date character vector | date string

Survival probability dates, specified as a scalar datetime, serial date number, date character vector, or date string.

Data Types: double | char | string | datetime

## Output Arguments

**outSurvProbs — Survival probability**

numeric

Survival probability, returned as a numeric.

## See Also

defprobstrip | hazardrates

## hazardrates

Compute hazard rates based on default probability curve

### Syntax

```
OutRates = hazardrates(obj)
```

### Description

OutRates = hazardrates(obj) computes hazard rates based on a defprobcurve object.

### Examples

#### Calculate Hazard Rates Based on Default Probability Curve

Create a defprobcurve object using defprobcurve and then use hazardrates to calculate the hazard rates.

```
Settle = datetime(2017,9,20);
DefProbTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
DefaultProbabilities = [0.005 0.007 0.01 0.015 0.026 0.04 0.077 0.093 0.15 0.20]';
ProbDates = Settle + DefProbTimes;
```

```
DefaultProbCurve = defprobcurve(Settle,ProbDates,DefaultProbabilities,'Basis',5)
```

```
DefaultProbCurve =
    defprobcurve with properties:
        Settle: 20-Sep-2017
        Basis: 5
        Dates: [10x1 datetime]
        DefaultProbabilities: [10x1 double]
```

```
hazardrates(DefaultProbCurve)
```

```
ans = 10x1
    0.0100
    0.0040
    0.0030
    0.0051
    0.0112
    0.0145
    0.0197
    0.0058
    0.0065
    0.0061
```

## Input Arguments

### **obj — defprobcurve object**

defprobcurve object

defprobcurve object, specified as a previously created defprobcurve object.

Data Types: object

## Output Arguments

### **OutRates — Hazard rates**

numeric

Hazard rates, returned as a numeric.

## See Also

defprobstrip | survprobs

## Topics

“Bootstrapping a Default Probability Curve from Credit Default Swaps” on page 8-41

## defprobstrip

Bootstrap defprobcurve object from market CDS instruments

### Syntax

```
OutCurve = defprobstrip(ZeroCurve,MarketInstruments,MarketQuotes)
OutCurve = defprobstrip( ____,Name,Value)
```

### Description

OutCurve = defprobstrip(ZeroCurve,MarketInstruments,MarketQuotes) bootstraps a defprobcurve object from market CDS instruments.

OutCurve = defprobstrip( \_\_\_\_,Name,Value) specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntax.

### Examples

#### Bootstrap Default Probability Curve from Market CDS Instruments

This example shows how to use defprobstrip to bootstrap a defprobcurve object based on market CDS instruments.

#### Create ratecurve Object for Zero-Rate Curve

Create a ratecurve object using ratecurve.

```
Settle = datetime(2017,9,15);
ZeroTimes = [calmonths(6) calyears([1 2 3 4 5 7 10 20 30])];
ZeroRates = [0.0052 0.0055 0.0061 0.0073 0.0094 0.0119 0.0168 0.0222 0.0293 0.0307]';
ZeroDates = Settle + ZeroTimes;
ZeroCurve = ratecurve("zero",Settle,ZeroDates,ZeroRates);
```

#### Market CDS Spreads and Vector of Market CDS Instruments

Define the market CDS spreads and use fininstrument to create a vector of market CDS instrument objects.

```
SpreadTimes = [1 2 3 4 5 7 10 20 30]';
Spread = [140 175 210 265 310 360 410 460 490]';
MarketDates = datemnth(Settle,12*SpreadTimes);

NumMarketInst = length(MarketDates);
ContractSpreadBP = zeros(NumMarketInst,1);

MarketCDSInstruments(NumMarketInst,1) = fininstrument("cds", ...
    'ContractSpread', ContractSpreadBP(end), 'Maturity', MarketDates(end));
for k = 1:NumMarketInst
    MarketCDSInstruments(k,1) = fininstrument("cds", ...
        'ContractSpread', ContractSpreadBP(k), 'Maturity', MarketDates(k));
end
```

Use `defprobstrip` to create a `defprobcurve` object.

```
DefaultProbCurve = defprobstrip(ZeroCurve,MarketCDSInstruments, Spread)
```

```
DefaultProbCurve =
  defprobcurve with properties:
      Settle: 15-Sep-2017
      Basis: 2
      Dates: [9x1 datetime]
      DefaultProbabilities: [9x1 double]
```

## Input Arguments

### ZeroCurve — Zero-rate curve

ratecurve object

Zero-rate curve, specified by a previously created ratecurve.

Data Types: object

### MarketInstruments — Market CDS instruments

vector

Market CDS instruments, specified as an NINST-by-1 vector.

Data Types: double

### MarketQuotes — Market spread

vector

Market quotes, specified as an NINST-by-1 vector.

Data Types: double

### Name-Value Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `DefaultProbCurve = defprobstrip(ZeroCurve, MarketInstruments, MarketQuotes, 'QuoteType', "upfront")`

### QuoteType — Market quote type

"fairspread" (default) | string with value of "fairspread" or "upfront" | character vector with value of 'fairspread' or 'upfront'

Frequency of payments per year, specified as the comma-separated pair consisting of 'QuoteType' and a scalar character vector or string.

- "fairspread" — CDS break-even spread for zero upfront price
- "upfront" — CDS upfront price for a given contractual spread

Data Types: char | string

## Output Arguments

### **OutCurve — Default probability curve**

defprobcurve object

Default probability curve, returned as a defprobcurve object with the following properties:

- `Settle`
- `Basis`
- `Dates`
- `DefaultProbabilities`

### **See Also**

# **Derivatives Pricing Options**

## Pricing Options Structure

### In this section...

“Introduction” on page B-2

“Default Structure” on page B-2

“Customizing the Structure” on page B-3

### Introduction

The MATLAB Options structure provides additional input to most pricing functions. The Options structure

- Tells pricing functions how to use the interest-rate tree to calculate instrument prices.
- Determines what additional information the Command Window displays along with instrument prices.
- Tells pricing functions which method to use in pricing barrier options.

The pricing options structure is primarily used in the pricing of interest-rate-based financial derivatives. However, the `BarrierMethod` field in the structure allows you to use it in pricing equity barrier options as well.

You provide pricing options in an optional `Options` argument passed to a pricing function. (See, for example, `bondbyhjm`, `bdtprice`, `barrierbycrr`, `barrierbyeqp`, or `barrierbyitt`.)

### Default Structure

If you do not specify the `Options` argument in the call to a pricing function, the function uses a default structure. To observe the default structure, use `derivset` without any arguments.

```
Options = derivset
```

```
Options =
```

```
    Diagnostics: 'off'  
    Warnings:   'on'  
    ConstRate:  'on'  
    BarrierMethod: 'unenhanced'
```

The `Options` structure has four fields: `Diagnostics` on page B-2, `Warnings` on page B-2, `ConstRate` on page B-3, and `BarrierMethod` on page B-3.

### Diagnostics Field

`Diagnostics` indicates whether additional information is displayed if the tree is modified. The default value for this option is 'off'. If `Diagnostics` is set to 'on' and `ConstRate` is set to 'off', the pricing functions display information such as the number of nodes in the last level of the tree generated for pricing purposes.

### Warnings Field

`Warnings` indicates whether to display warning messages when the input tree is not adequate for accurately pricing the instruments. The default value for this option is 'on'. If both `ConstRate` and

Warnings are 'on', a warning is displayed if any of the instruments in the input portfolio have a cash flow date between tree dates. If `ConstRate` is 'off', and `Warnings` is 'on', a warning is displayed if the tree is modified to match the cash flow dates on the instruments in the portfolio.

### ConstRate Field

`ConstRate` indicates whether the interest rates should be assumed constant between tree dates. By default this option is 'on', which is not an arbitrage-free assumption. So the pricing functions return an approximate price for instruments featuring cash flows between tree dates. Instruments featuring cash flows only on tree nodes are not affected by this option and return exact (arbitrage-free) prices. When `ConstRate` is 'off', the pricing function finds the cash flow dates for all instruments in the portfolio. If these cash flows do not align exactly with the tree dates, a new tree is generated and used for pricing. This new tree features the same volatility and initial rate specifications of the input tree but contains tree nodes for each date in which at least one instrument in the portfolio has a cash flow. Keep in mind that the number of nodes in a tree grows exponentially with the number of tree dates. So, setting `ConstRate` 'off' dramatically increases the memory and processor demands on the computer.

### BarrierMethod Field

When using binomial trees to price barrier options, this may require many tree steps to achieve an accurate result when tree nodes do not align with the barrier level. With the `BarrierMethod` field, the toolbox provides an enhancement method that improves the accuracy of the results without having to use large trees.

The `BarrierMethod` field can be set to 'unenhanced' (default) or 'interp'. If you specify 'unenhanced', no correction calculation is used. Otherwise, if you specify 'interp', the toolbox provides an enhanced valuation by interpolating between nodes on barrier boundaries.

You specify the barrier method in the last input argument, `Options`, of the functions `barrierbycrr`, `barrierbyeqp`, `barrierbyitt`, `crrprice`, `eqpprice`, `ittprice`, `crrsens`, `eqpsens`, or `ittsens`. `Options` is a structure that you create with the function `derivset`. Using `derivset`, you specify whether to use the enhanced or the unenhanced method.

For more information about this algorithm, see Derman, E., I. Kani, D. Ergener and I. Bardhan, "Enhanced Numerical Methods for Options with Barriers," *Financial Analysts Journal*, (Nov. - Dec. 1995), pp. 65-74.

## Customizing the Structure

Customize the `Options` structure by passing property name/property value pairs to the `derivset` function.

As an example, consider an `Options` structure with `ConstRate` 'off' and `Diagnostics` 'on'.

```
Options = derivset('ConstRate', 'off', 'Diagnostics', 'on')
```

```
Options =
```

```
    Diagnostics: 'on'
      Warnings: 'on'
     ConstRate: 'off'
BarrierMethod: 'unenhanced'
```

To obtain the value of a specific property from the `Options` structure, use `derivget`.

```
CR = derivget(Options, 'ConstRate')
```

```
CR =  
Off
```

---

**Note** Use `derivset` and `derivget` to construct the Options structure. These functions are guaranteed to remain unchanged, while the implementation of the structure itself may be modified in the future.

---

Now observe the effects of setting `ConstRate` 'off'. Obtain the tree dates from the HJM tree.

```
TreeDates = [HJMTree.TimeSpec.ValuationDate;...  
HJMTree.TimeSpec.Maturity]
```

```
TreeDates =
```

```
    730486  
    730852  
    731217  
    731582  
    731947
```

```
datedisp(TreeDates)
```

```
01-Jan-2000  
01-Jan-2001  
01-Jan-2002  
01-Jan-2003  
01-Jan-2004
```

All instruments in `HJMInstSet` settle on January 1, 2000, and all have cash flows once a year, except for the second bond, which features a period of 2. This bond has cash flows twice a year, with every other cash flow consequently falling between tree dates. You can extract this bond from the portfolio to compare how its price differs by setting `ConstRate` to 'on' and 'off'.

```
BondPort = instselect(HJMInstSet, 'Index', 2);
```

```
instdisp(BondPort)
```

```
Index Type CouponRate Settle      Maturity      Period Basis...  
1      Bond 0.04          01-Jan-2000 01-Jan-2004  2      NaN...
```

First price the bond with `ConstRate` 'on' (default).

```
format long  
[BondPrice, BondPriceTree] = hjmprice(HJMTree, BondPort)  
Warning: Not all cash flows are aligned with the tree. Result will  
be approximated.
```

```
BondPrice =
```

```
    97.52801411736377
```

```
BondPriceTree =
```

```
FinObj: 'HJMPriceTree'  
PBush: {1x5 cell}  
AIBush: {[0] [1x1x2 double] ... [1x4x2 double] [1x8 double]}  
tobs: [0 1 2 3 4]
```

Now recalculate the price of the bond setting `ConstRate` 'off'.

```
OptionsNoCR = derivset('ConstR', 'off')

OptionsNoCR =

Diagnostics: 'off'
  Warnings: 'on'
  ConstRate: 'off'

[BondPriceNoCR, BondPriceTreeNoCR] = hjmprice(HJMTree,...
BondPort, OptionsNoCR)
Warning: Not all cash flows are aligned with the tree. Rebuilding
tree.

BondPriceNoCR =

    97.53342361674437

BondPriceTreeNoCR =

FinObj: 'HJMPriceTree'
PBush: {1x9 cell}
AIBush: {1x9 cell}
  tObs: [0 0.5000 1 1.5000 2 2.5000 3 3.5000 4]
```

As indicated in the last warning, because the cash flows of the bond did not align with the tree dates, a new tree was generated for pricing the bond. This pricing method returns more accurate results since it guarantees that the process is arbitrage-free. It also takes longer to calculate and requires more memory. The `tObs` field of the price tree structure indicates the increased memory usage. `BondPriceTree.tObs` has only five elements, while `BondPriceTreeNoCR.tObs` has nine. While this may not seem like a large difference, it has a dramatic effect on the number of states in the last node.

```
size(BondPriceTree.PBush{end})

ans =

    1 8

size(BondPriceTreeNoCR.PBush{end})

ans =

    1 128
```

The differences become more obvious by examining the price trees with `treeviewer`.

```
treeviewer(BondPriceTree, BondPort)
```

`treeviewer(BondPriceTreeNoCR, BondPort)`

`All = [Delta ./ Price, Gamma ./ Price, Vega ./ Price, Price]`

## Glossary

### **basis**

Day count basis determines how interest accrues over time for various instruments and the amount transferred on interest payment dates. The calculation of accrued interest for dates between payments also uses day count basis. Day count basis is a fraction of Number of interest accrual days / Days in the relevant coupon period. Supported day count conventions and basis values are:

<b>Basis Value</b>	<b>Day Count Convention</b>
0	actual/actual (default) — Number of days in both a period and a year is the actual number of days. Also, another common actual/actual basis is basis 12.
1	30/360 SIA — Year fraction is calculated based on a 360 day year with 30-day months, after applying the following rules: If the first date and the second date are the last day of February, the second date is changed to the 30th. If the first date falls on the 31st or is the last day of February, it is changed to the 30th. If after the preceding test, the first day is the 30th and the second day is the 31st, then the second day is changed to the 30th.
2	actual/360 — Number of days in a period is equal to the actual number of days, however the number of days in a year is 360.
3	actual/365 — Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year).

Basis Value	Day Count Convention
4	30/360 PSA — Number of days in every month is set to 30 (including February). If the start date of the period is either the 31st of a month or the last day of February, the start date is set to the 30th, while if the start date is the 30th of a month and the end date is the 31st, the end date is set to the 30th. The number of days in a year is 360.
5	30/360 ISDA — Number of days in every month is set to 30, except for February where it is the actual number of days. If the start date of the period is the 31st of a month, the start date is set to the 30th while if the start date is the 30th of a month and the end date is the 31st, the end date is set to the 30th. The number of days in a year is 360.
6	30E /360 — Number of days in every month is set to 30 except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360.
7	actual/365 Japanese — Number of days in a period is equal to the actual number of days, except for leap days (29th February) which are ignored. The number of days in a year is 365 (even in a leap year).
8	actual/actual ICMA — Number of days in both a period and a year is the actual number of days and the compounding frequency is annual.

<b>Basis Value</b>	<b>Day Count Convention</b>
9	actual/360 ICMA — Number of days in a period is equal to the actual number of days, however the number of days in a year is 360 and the compounding frequency is annual.
10	actual/365 ICMA — Number of days in a period is equal to the actual number of days, however the number of days in a year is 365 (even in a leap year) and the compounding frequency is annual.
11	30/360 ICMA — Number of days in every month is set to 30, except for February where it is equal to the actual number of days. If the start date or the end date of the period is the 31st of a month, that date is set to the 30th. The number of days in a year is 360 and the compounding frequency is annual.
12	actual/365 ISDA — The day count fraction is calculated using the following formula: $(\text{Actual number of days in period that fall in a leap year} / 366) + (\text{Actual number of days in period that fall in a normal year} / 365)$ . Basis 12 is also referred to as actual/actual ISDA.
13	bus/252 — The number of days in a period is equal to the actual number of business days. The number of business days in a year is 252.
