
Using a *K*d-tree for large data sets with fewer than 10 dimensions (columns) can be much more efficient than using the exhaustive search method, as `knnsearch` needs to calculate only a subset of the distances. To maximize the efficiency of *K*d-trees, use a `KDTreeSearcher` model.

What Are Search Model Objects?

Basically, model objects are a convenient way of storing information. Related models have the same properties with values and types relevant to a specified search method. In addition to storing information within models, you can perform certain actions on models.

You can efficiently perform a *k*-nearest neighbors search on your search model using `knnsearch`. Or, you can search for all neighbors within a specified radius using your search model and `rangesearch`. In addition, there are a generic `knnsearch` and `rangesearch` functions that search without creating or using a model.

To determine which type of model and search method is best for your data, consider the following:

- Does your data have many columns, say more than 10? The `ExhaustiveSearcher` model may perform better.
- Is your data sparse? Use the `ExhaustiveSearcher` model.
- Do you want to use one of these distance metrics to find the nearest neighbors? Use the `ExhaustiveSearcher` model.
  - `'seuclidean'`

  - `'mahalanobis'`
  - `'cosine'`
  - `'correlation'`
  - `'spearman'`
  - `'hamming'`
  - `'jaccard'`
  - A custom distance function
- Is your data set huge (but with fewer than 10 columns)? Use the `KDTreeSearcher` model.
- Are you searching for the nearest neighbors for a large number of query points? Use the `KDTreeSearcher` model.

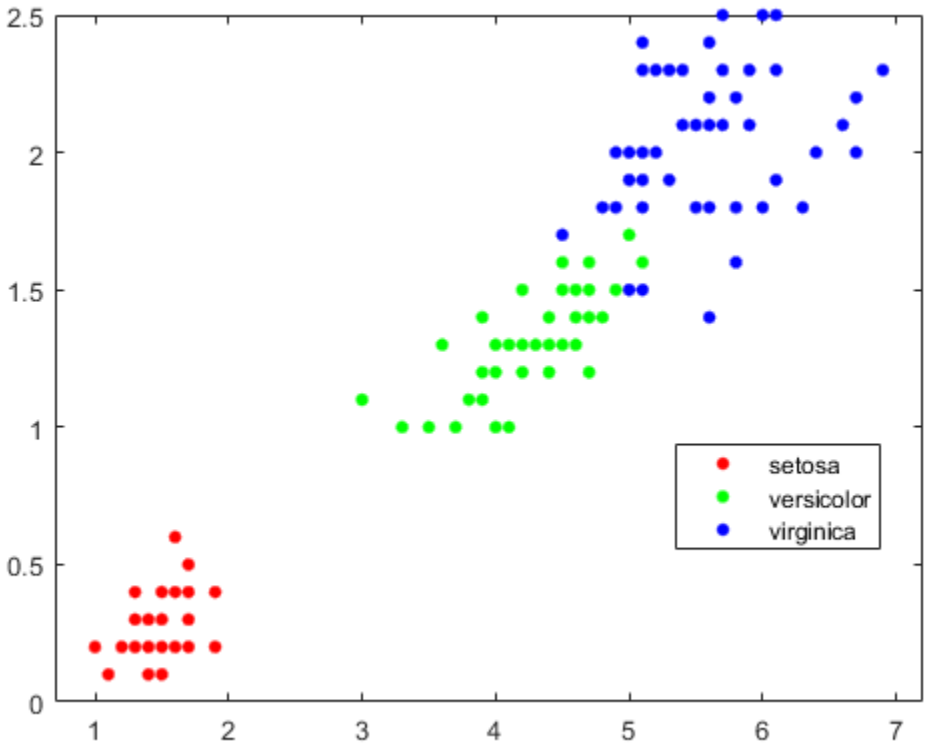
Classify Query Data

This example shows how to classify query data by:

1. Growing a *K*d-tree
2. Conducting a *k* nearest neighbor search using the grown tree.
3. Assigning each query point the class with the highest representation among their respective nearest neighbors.

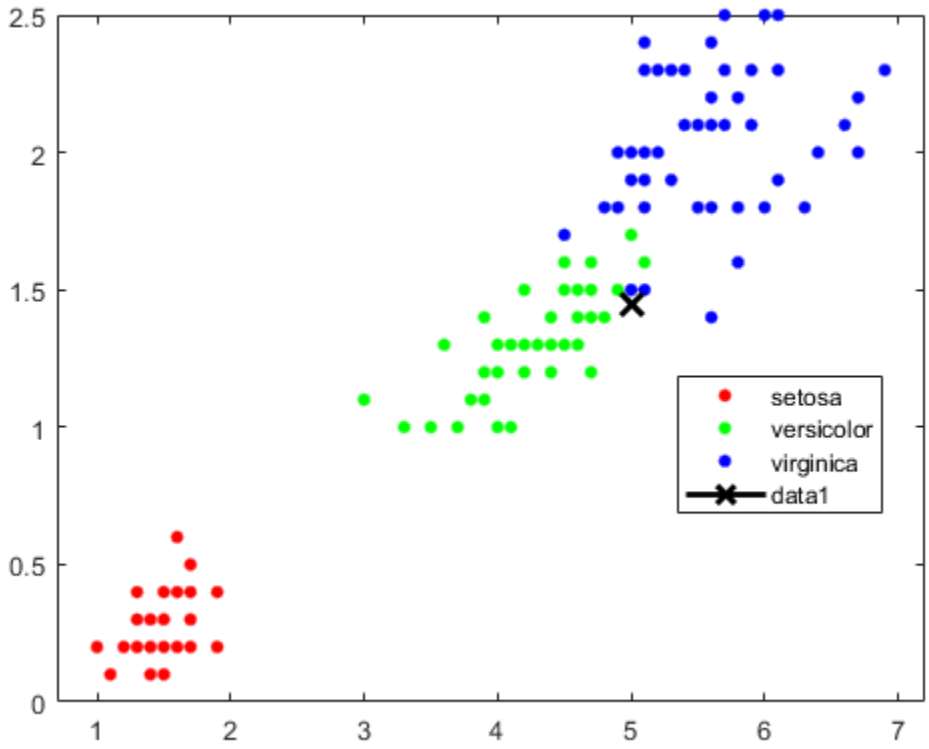
Classify a new point based on the last two columns of the Fisher iris data. Using only the last two columns makes it easier to plot.

```
load fisheriris
x = meas(:,3:4);
gscatter(x(:,1),x(:,2),species)
legend('Location','best')
```



Plot the new point.

```
newpoint = [5 1.45];
line(newpoint(1),newpoint(2),'marker','x','color','k',...
   'markersize',10,'linewidth',2)
```



Prepare a *K*d-tree neighbor searcher model.

```
Mdl = KDTreeSearcher(x)
```

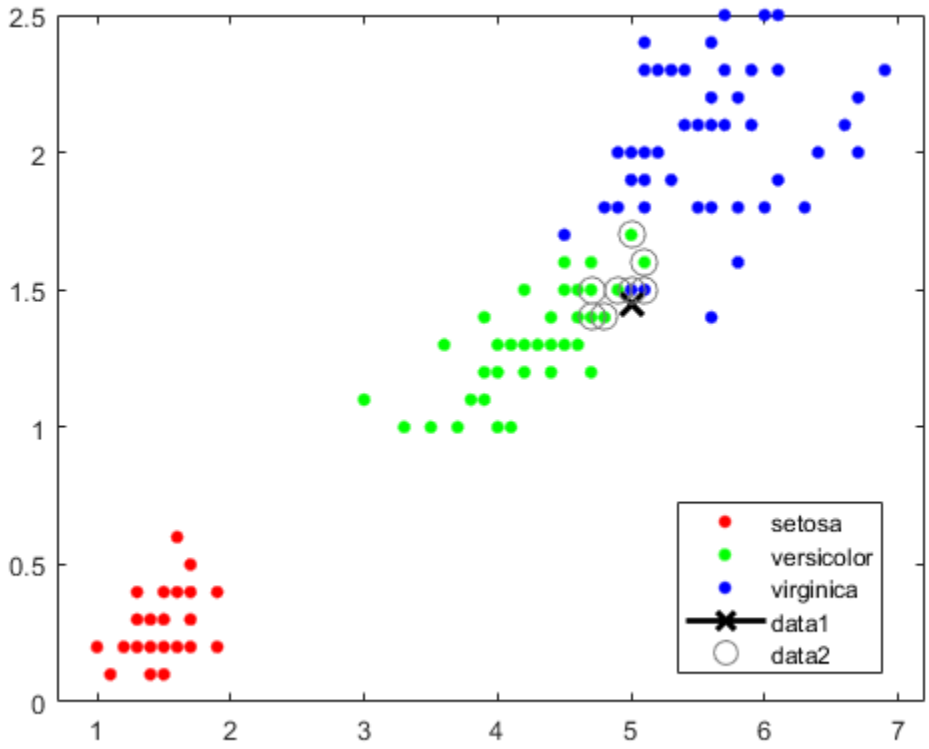
```
Mdl =
  KDTreeSearcher with properties:

       BucketSize: 50
         Distance: 'euclidean'
    DistParameter: []
                X: [150x2 double]
```

`Mdl` is a `KDTreeSearcher` model. By default, the distance metric it uses to search for neighbors is Euclidean distance.

Find the 10 sample points closest to the new point.

```
[n,d] = knnsearch(Mdl,newpoint,'k',10);
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
     'linestyle','none','markersize',10)
```



It appears that `knnsearch` has found only the nearest eight neighbors. In fact, this particular dataset contains duplicate values.

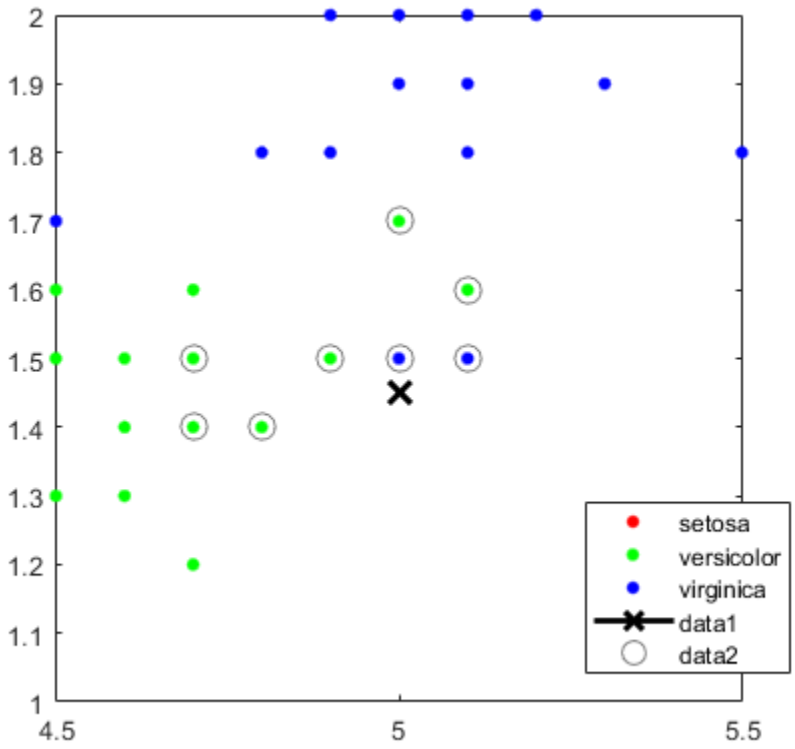
```
x(n,:)
```

```
ans = 10×2

    5.0000    1.5000
    4.9000    1.5000
    4.9000    1.5000
    5.1000    1.5000
    5.1000    1.6000
    4.8000    1.4000
    5.0000    1.7000
    4.7000    1.4000
    4.7000    1.4000
    4.7000    1.5000
```

Make the axes equal so the calculated distances correspond to the apparent distances on the plot axis equal and zoom in to see the neighbors better.

```
xlim([4.5 5.5]);
ylim([1 2]);
axis square
```



Find the species of the 10 neighbors.

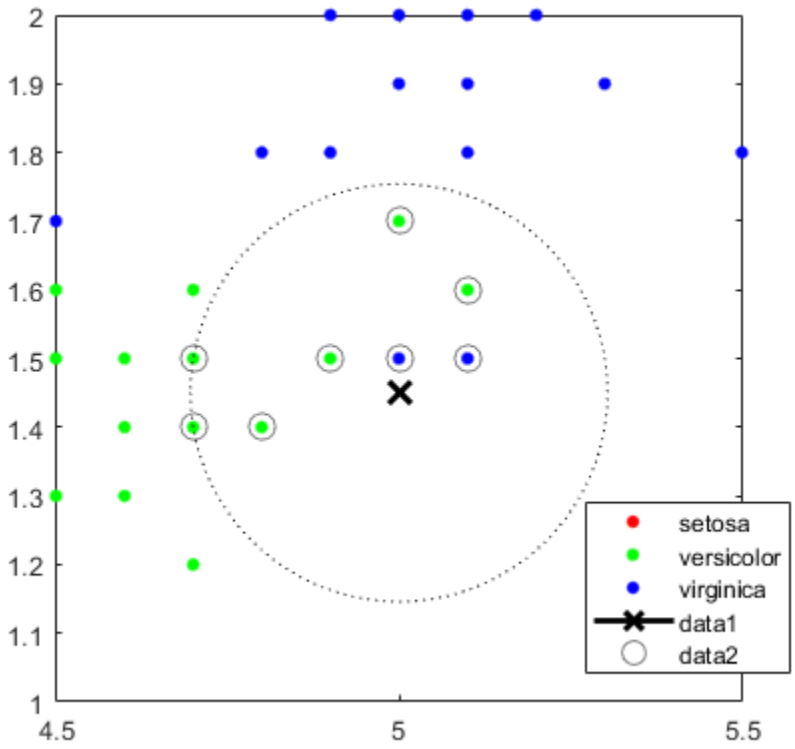
```
tabulate(species(n))
```

```
       Value    Count   Percent
   virginica        2     20.00%
  versicolor        8     80.00%
```

Using a rule based on the majority vote of the 10 nearest neighbors, you can classify this new point as a versicolor.

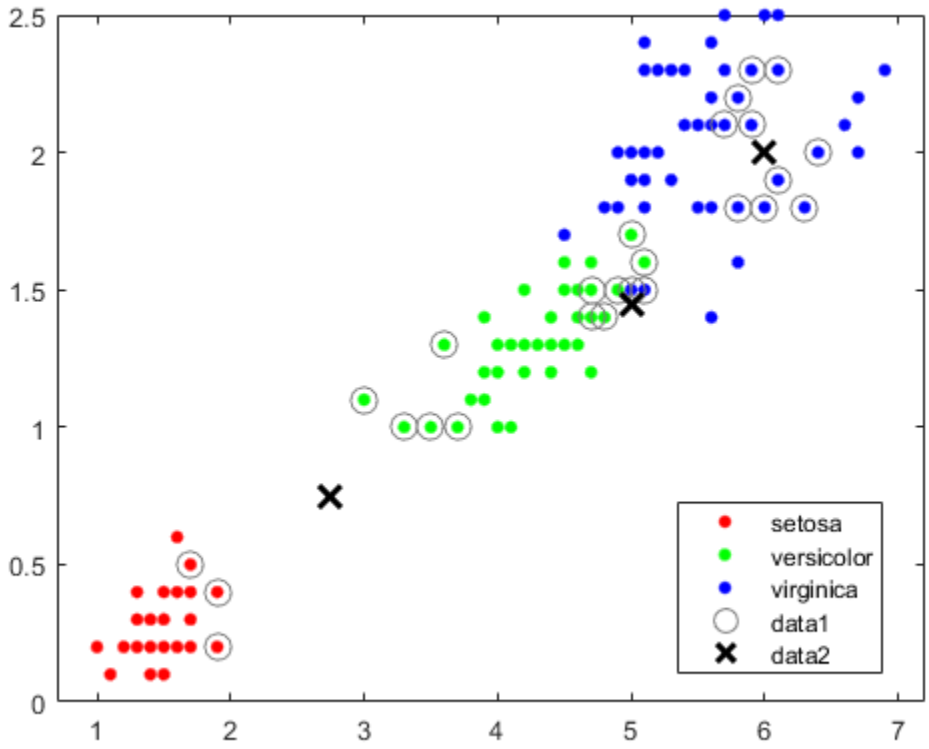
Visually identify the neighbors by drawing a circle around the group of them. Define the center and diameter of a circle, based on the location of the new point.

```
ctr = newpoint - d(end);
diameter = 2*d(end);
% Draw a circle around the 10 nearest neighbors.
h = rectangle('position',[ctr,diameter,diameter],...
    'curvature',[1 1]);
h.LineStyle = ':';
```



Using the same dataset, find the 10 nearest neighbors to three new points.

```
figure
newpoint2 = [5 1.45;6 2;2.75 .75];
gscatter(x(:,1),x(:,2),species)
legend('location','best')
[n2,d2] = knnsearch(Mdl,newpoint2,'k',10);
line(x(n2,1),x(n2,2),'color',[.5 .5 .5],'marker','o',...
   'linestyle','none','markersize',10)
line(newpoint2(:,1),newpoint2(:,2),'marker','x','color','k',...
   'markersize',10,'linewidth',2,'linestyle','none')
```



Find the species of the 10 nearest neighbors for each new point.

```
tabulate(species(n2(1,:)))
```

```
       Value    Count   Percent
   virginica        2     20.00%
  versicolor        8     80.00%
```

```
tabulate(species(n2(2,:)))
```

```
      Value    Count   Percent
  virginica       10    100.00%
```

```
tabulate(species(n2(3,:)))
```

```
       Value    Count   Percent
  versicolor        7     70.00%
      setosa        3     30.00%
```

For more examples using `knnsearch` methods and function, see the individual reference pages.

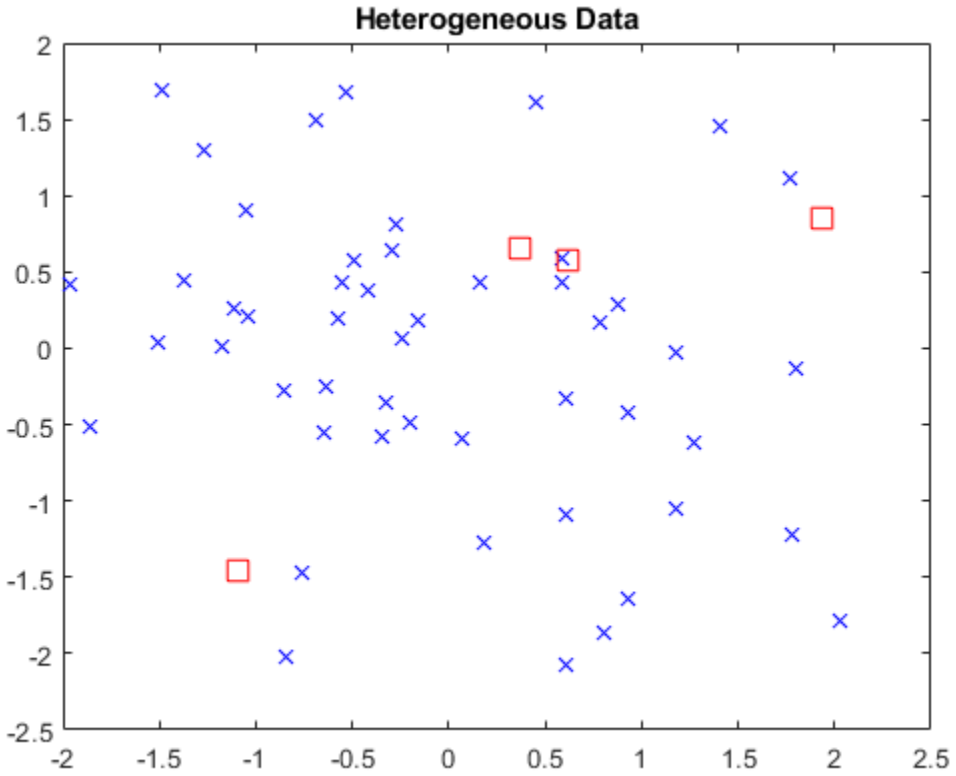
Find Nearest Neighbors Using a Custom Distance Metric

This example shows how to find the indices of the three nearest observations in X to each observation in Y with respect to the chi-square distance. This distance metric is used in correspondence analysis, particularly in ecological applications.

Randomly generate normally distributed data into two matrices. The number of rows can vary, but the number of columns must be equal. This example uses 2-D data for plotting.

```
rng(1) % For reproducibility
X = randn(50,2);
Y = randn(4,2);

h = zeros(3,1);
figure
h(1) = plot(X(:,1),X(:,2),'bx');
hold on
h(2) = plot(Y(:,1),Y(:,2),'rs','MarkerSize',10);
title('Heterogeneous Data')
```



The rows of X and Y correspond to observations, and the columns are, in general, dimensions (for example, predictors).

The chi-square distance between j-dimensional points x and z is

$$\chi(x,z) = \sqrt{\sum_{j=1}^{J} w_j (x_j - z_j)^2},$$

where w_j is the weight associated with dimension j.

Choose weights for each dimension, and specify the chi-square distance function. The distance function must:

- Take as input arguments one row of X, e.g., x, and the matrix Z.
- Compare x to each row of Z.
- Return a vector D of length n_z, where n_z is the number of rows of Z. Each element of D is the distance between the observation corresponding to x and the observations corresponding to each row of Z.

```
w = [0.4; 0.6];
chiSqrDist = @(x,Z)sqrt((bsxfun(@minus,x,Z).^2)*w);
```

This example uses arbitrary weights for illustration.

Find the indices of the three nearest observations in X to each observation in Y.

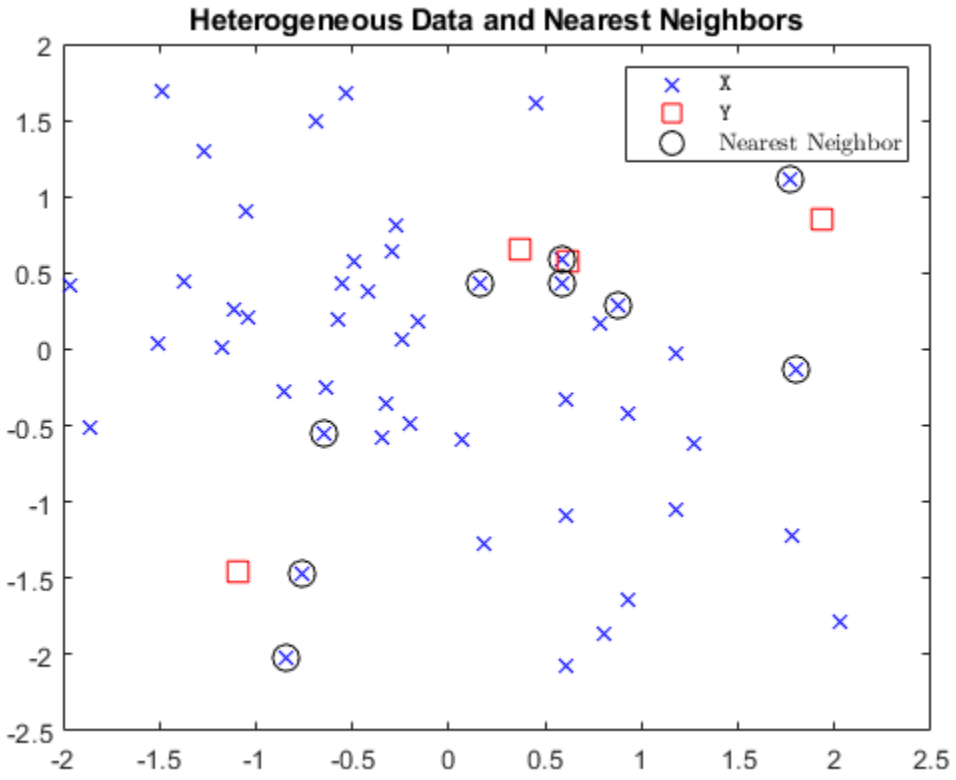
```
k = 3;
[Idx,D] = knnsearch(X,Y,'Distance',chiSqrDist,'k',k);
```

idx and D are 4-by-3 matrices.

- idx(j,1) is the row index of the closest observation in X to observation *j* of Y, and D(j,1) is their distance.
- idx(j,2) is the row index of the next closest observation in X to observation *j* of Y, and D(j,2) is their distance.
- And so on.

Identify the nearest observations in the plot.

```
for j = 1:k
    h(3) = plot(X(Idx(:,j),1),X(Idx(:,j),2),'ko','MarkerSize',10);
end
legend(h,{'\texttt{X}','\texttt{Y}','Nearest Neighbor'},'Interpreter','latex')
title('Heterogeneous Data and Nearest Neighbors')
hold off
```



Several observations of Y share nearest neighbors.

Verify that the chi-square distance metric is equivalent to the Euclidean distance metric, but with an optional scaling parameter.

```
[IdxE,DE] = knnsearch(X,Y,'Distance','seuclidean','k',k, ...
    'Scale',1./(sqrt(w)));
AreDiffIdx = sum(sum(Idx ~= IdxE))
```

```
AreDiffIdx = 0
```

```
AreDiffDist = sum(sum(abs(D - DE) > eps))
```

```
AreDiffDist = 0
```

The indices and distances between the two implementations of three nearest neighbors are practically equivalent.

K-Nearest Neighbor Classification for Supervised Learning

The `ClassificationKNN` classification model lets you:

- “Construct KNN Classifier” on page 18-28
- “Examine Quality of KNN Classifier” on page 18-28
- “Predict Classification Using KNN Classifier” on page 18-29

- “Modify KNN Classifier” on page 18-29

Prepare your data for classification according to the procedure in “Steps in Supervised Learning” on page 18-4. Then, construct the classifier using `fitcknn`.

Construct KNN Classifier

This example shows how to construct a *k*-nearest neighbor classifier for the Fisher iris data.

Load the Fisher iris data.

```
load fisheriris
X = meas;    % Use all data for fitting
Y = species; % Response data
```

Construct the classifier using `fitcknn`.

```
Mdl = fitcknn(X,Y)
```

```
Mdl =
  ClassificationKNN
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
                 Distance: 'euclidean'
             NumNeighbors: 1

  Properties, Methods
```

A default *k*-nearest neighbor classifier uses a single nearest neighbor only. Often, a classifier is more robust with more neighbors than that.

Change the neighborhood size of `Mdl` to 4, meaning that `Mdl` classifies using the four nearest neighbors.

```
Mdl.NumNeighbors = 4;
```

Examine Quality of KNN Classifier

This example shows how to examine the quality of a *k*-nearest neighbor classifier using resubstitution and cross validation.

Construct a KNN classifier for the Fisher iris data as in “Construct KNN Classifier” on page 18-28.

```
load fisheriris
X = meas;
Y = species;
rng(10); % For reproducibility
Mdl = fitcknn(X,Y,'NumNeighbors',4);
```

Examine the resubstitution loss, which, by default, is the fraction of misclassifications from the predictions of `Mdl`. (For nondefault cost, weights, or priors, see `loss`.).

```
rloss = resubLoss(Mdl)
```

```
rloss = 0.0400
```

The classifier predicts incorrectly for 4% of the training data.

Construct a cross-validated classifier from the model.

```
CVMdl = crossval(Mdl);
```

Examine the cross-validation loss, which is the average loss of each cross-validation model when predicting on data that is not used for training.

```
kloss = kfoldLoss(CVMdl)
```

```
kloss = 0.0333
```

The cross-validated classification accuracy resembles the resubstitution accuracy. Therefore, you can expect `Mdl` to misclassify approximately 4% of new data, assuming that the new data has about the same distribution as the training data.

Predict Classification Using KNN Classifier

This example shows how to predict classification for a *k*-nearest neighbor classifier.

Construct a KNN classifier for the Fisher iris data as in “Construct KNN Classifier” on page 18-28.

```
load fisheriris
X = meas;
Y = species;
Mdl = fitcknn(X,Y,'NumNeighbors',4);
```

Predict the classification of an average flower.

```
flwr = mean(X); % an average flower
flwrClass = predict(Mdl,flwr)
```

```
flwrClass = 1x1 cell array
    {'versicolor'}
```

Modify KNN Classifier

This example shows how to modify a *k*-nearest neighbor classifier.

Construct a KNN classifier for the Fisher iris data as in “Construct KNN Classifier” on page 18-28.

```
load fisheriris
X = meas;
Y = species;
Mdl = fitcknn(X,Y,'NumNeighbors',4);
```

Modify the model to use the three nearest neighbors, rather than the default one nearest neighbor.

```
Mdl.NumNeighbors = 3;
```

Compare the resubstitution predictions and cross-validation loss with the new number of neighbors.

```
loss = resubLoss(Mdl)
```

```
loss = 0.0400
```

```
rng(10); % For reproducibility
CVMdl = crossval(Mdl,'KFold',5);
kloss = kfoldLoss(CVMdl)
```

```
kloss = 0.0333
```

In this case, the model with three neighbors has the same cross-validated loss as the model with four neighbors (see “Examine Quality of KNN Classifier” on page 18-28).

Modify the model to use cosine distance instead of the default, and examine the loss. To use cosine distance, you must recreate the model using the exhaustive search method.

```
CMdl = fitcknn(X,Y,'NSMethod','exhaustive','Distance','cosine');
CMdl.NumNeighbors = 3;
closs = resubLoss(CMdl)
```

```
closs = 0.0200
```

The classifier now has lower resubstitution error than before.

Check the quality of a cross-validated version of the new model.

```
CVCMdl = crossval(CMdl);
kcloss = kfoldLoss(CVCMdl)
```

```
kcloss = 0.0200
```

`CVCMdl` has a better cross-validated loss than `CVMdl`. However, in general, improving the resubstitution error does not necessarily produce a model with better test-sample predictions.

Framework for Ensemble Learning

Using various methods, you can meld results from many weak learners into one high-quality ensemble predictor. These methods closely follow the same syntax, so you can try different methods with minor changes in your commands.

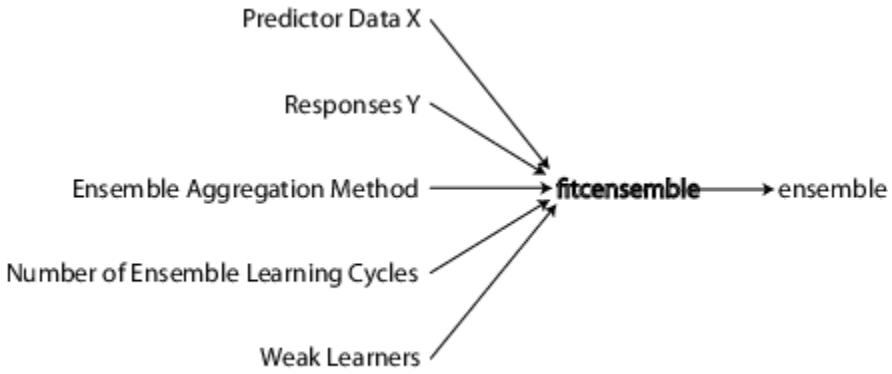
You can create an ensemble for classification by using `fitcensemble` or for regression by using `fitrensemble`.

To train an ensemble for classification using `fitcensemble`, use this syntax.

```
ens = fitcensemble(X,Y,Name,Value)
```

- `X` is the matrix of data. Each row contains one observation, and each column contains one predictor variable.
- `Y` is the vector of responses, with the same number of observations as the rows in `X`.
- `Name,Value` specify additional options using one or more name-value pair arguments. For example, you can specify the ensemble aggregation method with the `'Method'` argument, the number of ensemble learning cycles with the `'NumLearningCycles'` argument, and the type of weak learners with the `'Learners'` argument. For a complete list of name-value pair arguments, see the `fitcensemble` function page.

This figure shows the information you need to create a classification ensemble.



Similarly, you can train an ensemble for regression by using `fitrensemble`, which follows the same syntax as `fitcensemble`. For details on the input arguments and name-value pair arguments, see the `fitrensemble` function page.

For all classification or nonlinear regression problems, follow these steps to create an ensemble:

1. “Prepare the Predictor Data” on page 18-32
2. “Prepare the Response Data” on page 18-32
3. “Choose an Applicable Ensemble Aggregation Method” on page 18-32
4. “Set the Number of Ensemble Members” on page 18-35
5. “Prepare the Weak Learners” on page 18-35
6. “Call fitcensemble or fitrensemble” on page 18-37

Prepare the Predictor Data

All supervised learning methods start with predictor data, usually called X in this documentation. X can be stored in a matrix or a table. Each row of X represents one observation, and each column of X represents one variable or predictor.

Prepare the Response Data

You can use a wide variety of data types for the response data.

- For regression ensembles, Y must be a numeric vector with the same number of elements as the number of rows of X.
- For classification ensembles, Y can be a numeric vector, categorical vector, character array, string array, cell array of character vectors, or logical vector.

  For example, suppose your response data consists of three observations in the following order: `true`, `false`, `true`. You could express Y as:

  - `[1;0;1]` (numeric vector)
  - `categorical({'true','false','true'})` (categorical vector)
  - `[true;false;true]` (logical vector)
  - `['true ';'false';'true ']` (character array, padded with spaces so each row has the same length)
  - `["true","false","true"]` (string array)
  - `{'true','false','true'}` (cell array of character vectors)

  Use whichever data type is most convenient. Because you cannot represent missing values with logical entries, do not use logical entries when you have missing values in Y.

`fitcensemble` and `fitrensemble` ignore missing values in Y when creating an ensemble. This table contains the method of including missing entries.

Data Type	Missing Entry
Numeric vector	`NaN`
Categorical vector	`<undefined>`
Character array	Row of spaces
String array	`<missing>` or `""`
Cell array of character vectors	`''`
Logical vector	(not possible to represent)

Choose an Applicable Ensemble Aggregation Method

To create classification and regression ensembles with `fitcensemble` and `fitrensemble`, respectively, choose appropriate algorithms from this list.

- For classification with two classes:
  - `'AdaBoostM1'`

  - `'LogitBoost'`
  - `'GentleBoost'`
  - `'RobustBoost'` (requires Optimization Toolbox)
  - `'LPBoost'` (requires Optimization Toolbox)
  - `'TotalBoost'` (requires Optimization Toolbox)
  - `'RUSBoost'`
  - `'Subspace'`
  - `'Bag'`
- For classification with three or more classes:
  - `'AdaBoostM2'`
  - `'LPBoost'` (requires Optimization Toolbox)
  - `'TotalBoost'` (requires Optimization Toolbox)
  - `'RUSBoost'`
  - `'Subspace'`
  - `'Bag'`
- For regression:
  - `'LSBoost'`
  - `'Bag'`

For descriptions of the various algorithms, see “Ensemble Algorithms” on page 18-39.

See “Suggestions for Choosing an Appropriate Ensemble Algorithm” on page 18-34.

This table lists characteristics of the various algorithms. In the table titles:

- **Imbalance** — Good for imbalanced data (one class has many more observations than the other)
- **Stop** — Algorithm self-terminates
- **Sparse** — Requires fewer weak learners than other ensemble algorithms

Algorithm	Regression	Binary Classification	Multiclass Classification	Class Imbalance	Stop	Sparse
`Bag`	×	×	×			
`AdaBoostM1`		×				
`AdaBoostM2`			×			
`LogitBoost`		×				
`GentleBoost`		×				
`RobustBoost`		×				
`LPBoost`		×	×		×	×
`TotalBoost`		×	×		×	×
`RUSBoost`		×	×	×		

Algorithm	Regression	Binary Classification	Multiclass Classification	Class Imbalance	Stop	Sparse
LSBoost	×					
Subspace		×	×			

RobustBoost, LPBoost, and TotalBoost require an Optimization Toolbox license. Try TotalBoost before LPBoost, as TotalBoost can be more robust.

Suggestions for Choosing an Appropriate Ensemble Algorithm

- **Regression** — Your choices are LSBoost or Bag. See "General Characteristics of Ensemble Algorithms" on page 18-34 for the main differences between boosting and bagging.
- **Binary Classification** — Try AdaBoostM1 first, with these modifications:

Data Characteristic	Recommended Algorithm
Many predictors	Subspace
Skewed data (many more observations of one class)	RUSBoost
Label noise (some training data has the wrong class)	RobustBoost
Many observations	Avoid LPBoost and TotalBoost

- **Multiclass Classification** — Try AdaBoostM2 first, with these modifications:

Data Characteristic	Recommended Algorithm
Many predictors	Subspace
Skewed data (many more observations of one class)	RUSBoost
Many observations	Avoid LPBoost and TotalBoost

For details of the algorithms, see "Ensemble Algorithms" on page 18-39.

General Characteristics of Ensemble Algorithms

- Boost algorithms generally use very shallow trees. This construction uses relatively little time or memory. However, for effective predictions, boosted trees might need more ensemble members than bagged trees. Therefore it is not always clear which class of algorithms is superior.
- Bag generally constructs deep trees. This construction is both time consuming and memory-intensive. This also leads to relatively slow predictions.
- Bag can estimate the generalization error without additional cross validation. See oobLoss.
- Except for Subspace, all boosting and bagging algorithms are based on decision tree on page 19-2 learners. Subspace can use either discriminant analysis on page 20-2 or *k*-nearest neighbor on page 18-12 learners.

For details of the characteristics of individual ensemble members, see "Characteristics of Classification Algorithms" on page 18-7.

Set the Number of Ensemble Members

Choosing the size of an ensemble involves balancing speed and accuracy.

- Larger ensembles take longer to train and to generate predictions.
- Some ensemble algorithms can become overtrained (inaccurate) when too large.

To set an appropriate size, consider starting with several dozen to several hundred members in an ensemble, training the ensemble, and then checking the ensemble quality, as in “Test Ensemble Quality” on page 18-66. If it appears that you need more members, add them using the `resume` method (classification) or the `resume` method (regression). Repeat until adding more members does not improve ensemble quality.

Tip For classification, the `LPBoost` and `TotalBoost` algorithms are self-terminating, meaning you do not have to investigate the appropriate ensemble size. Try setting `NumLearningCycles` to `500`. The algorithms usually terminate with fewer members.

Prepare the Weak Learners

Currently the weak learner types are:

- `'Discriminant'` (recommended for `Subspace` ensemble)
- `'KNN'` (only for `Subspace` ensemble)
- `'Tree'` (for any ensemble except `Subspace`)

There are two ways to set the weak learner type in an ensemble.

- To create an ensemble with default weak learner options, specify the value of the `'Learners'` name-value pair argument as the character vector or string scalar of the weak learner name. For example:

  ```
  ens = fitcensemble(X,Y,'Method','Subspace', ...
     'NumLearningCycles',50,'Learners','KNN');
  % or
  ens = fitrensemble(X,Y,'Method','Bag', ...
     'NumLearningCycles',50,'Learners','Tree');
  ```

- To create an ensemble with nondefault weak learner options, create a nondefault weak learner using the appropriate `template` method.

  For example, if you have missing data, and want to use classification trees with surrogate splits for better accuracy:

  ```
  templ = templateTree('Surrogate','all');
  ens = fitcensemble(X,Y,'Method','AdaBoostM2', ...
     'NumLearningCycles',50,'Learners',templ);
  ```

  To grow trees with leaves containing a number of observations that is at least 10% of the sample size:

  ```
  templ = templateTree('MinLeafSize',size(X,1)/10);
  ens = fitcensemble(X,Y,'Method','AdaBoostM2', ...
     'NumLearningCycles',50,'Learners',templ);
  ```

Alternatively, choose the maximal number of splits per tree:

```
templ = templateTree('MaxNumSplits',4);
ens = fitcensemble(X,Y,'Method','AdaBoostM2', ...
   'NumLearningCycles',50,'Learners',templ);
```

You can also use nondefault weak learners in `fitrensemble`.

While you can give `fitcensemble` and `fitrensemble` a cell array of learner templates, the most common usage is to give just one weak learner template.

For examples using a template, see “Handle Imbalanced Data or Unequal Misclassification Costs in Classification Ensembles” on page 18-84 and “Surrogate Splits” on page 18-91.

Decision trees can handle `NaN` values in `X`. Such values are called “missing”. If you have some missing values in a row of `X`, a decision tree finds optimal splits using nonmissing values only. If an entire row consists of `NaN`, `fitcensemble` and `fitrensemble` ignore that row. If you have data with a large fraction of missing values in `X`, use surrogate decision splits. For examples of surrogate splits, see “Handle Imbalanced Data or Unequal Misclassification Costs in Classification Ensembles” on page 18-84 and “Surrogate Splits” on page 18-91.

Common Settings for Tree Weak Learners

- The depth of a weak learner tree makes a difference for training time, memory usage, and predictive accuracy. You control the depth these parameters:
  - `MaxNumSplits` — The maximal number of branch node splits is `MaxNumSplits` per tree. Set large values of `MaxNumSplits` to get deep trees. The default for bagging is `size(X,1) - 1`. The default for boosting is `1`.
  - `MinLeafSize` — Each leaf has at least `MinLeafSize` observations. Set small values of `MinLeafSize` to get deep trees. The default for classification is `1` and `5` for regression.
  - `MinParentSize` — Each branch node in the tree has at least `MinParentSize` observations. Set small values of `MinParentSize` to get deep trees. The default for classification is `2` and `10` for regression.

  If you supply both `MinParentSize` and `MinLeafSize`, the learner uses the setting that gives larger leaves (shallower trees):

  ```
  MinParent = max(MinParent,2*MinLeaf)
  ```

  If you additionally supply `MaxNumSplits`, then the software splits a tree until one of the three splitting criteria is satisfied.
- `Surrogate` — Grow decision trees with surrogate splits when `Surrogate` is `'on'`. Use surrogate splits when your data has missing values.

  Note Surrogate splits cause slower training and use more memory.
- `PredictorSelection` — `fitcensemble`, `fitrensemble`, and `TreeBagger` grow trees using the standard CART algorithm [11] by default. If the predictor variables are heterogeneous or there are predictors having many levels and other having few levels, then standard CART tends to select predictors having many levels as split predictors. For split-predictor selection that is robust to the number of levels that the predictors have, consider specifying `'curvature'` or `'interaction-curvature'`. These specifications conduct chi-square tests of association between each predictor

and the response or each pair of predictors and the response, respectively. The predictor that yields the minimal *p*-value is the split predictor for a particular node. For more details, see “Choose Split Predictor Selection Technique” on page 19-14.

Note When boosting decision trees, selecting split predictors using the curvature or interaction tests is not recommended.

Call fitcensemble or fitrensemble

The syntaxes for `fitcensemble` and `fitrensemble` are identical. For `fitrensemble`, the syntax is:

```
ens = fitrensemble(X,Y,Name,Value)
```

- `X` is the matrix of data. Each row contains one observation, and each column contains one predictor variable.
- `Y` is the responses, with the same number of observations as rows in `X`.
- `Name,Value` specify additional options using one or more name-value pair arguments. For example, you can specify the ensemble aggregation method with the `'Method'` argument, the number of ensemble learning cycles with the `'NumLearningCycles'` argument, and the type of weak learners with the `'Learners'` argument. For a complete list of name-value pair arguments, see the `fitrensemble` function page.

The result of `fitrensemble` and `fitcensemble` is an ensemble object, suitable for making predictions on new data. For a basic example of creating a regression ensemble, see “Train Regression Ensemble” on page 18-57. For a basic example of creating a classification ensemble, see “Train Classification Ensemble” on page 18-54.

Where to Set Name-Value Pairs

There are several name-value pairs you can pass to `fitcensemble` or `fitrensemble`, and several that apply to the weak learners (`templateDiscriminant`, `templateKNN`, and `templateTree`). To determine which name-value pair argument is appropriate, the ensemble or the weak learner:

- Use template name-value pairs to control the characteristics of the weak learners.
- Use `fitcensemble` or `fitrensemble` name-value pair arguments to control the ensemble as a whole, either for algorithms or for structure.

For example, for an ensemble of boosted classification trees with each tree deeper than the default, set the `templateTree` name-value pair arguments `MinLeafSize` and `MinParentSize` to smaller values than the defaults. Or, `MaxNumSplits` to a larger value than the defaults. The trees are then leafier (deeper).

To name the predictors in a classification ensemble (part of the structure of the ensemble), use the `PredictorNames` name-value pair in `fitcensemble`.

Ensemble Algorithms

In this section...

This topic provides descriptions of ensemble learning algorithms supported by Statistics and Machine Learning Toolbox, including bagging, random space, and various boosting algorithms. You can specify the algorithm by using the `'Method'` name-value pair argument of `fitcensemble`, `fitrensemble`, or `templateEnsemble`. Use `fitcensemble` or `fitrensemble` to create an ensemble of learners for classification or regression, respectively. Use `templateEnsemble` to create an ensemble learner template, and pass the template to `fitcecoc` to specify ensemble binary learners for ECOC multiclass learning.

For bootstrap aggregation (bagging) and random forest, you can use `TreeBagger` as well.

To learn about how to choose an appropriate algorithm, see "Choose an Applicable Ensemble Aggregation Method" on page 18-32.

Note that usage of some algorithms, such as `LPBoost`, `TotalBoost`, and `RobustBoost`, requires Optimization Toolbox.

Bootstrap Aggregation (Bagging) and Random Forest

Statistics and Machine Learning Toolbox offers three objects for bagging and random forest:

- `ClassificationBaggedEnsemble` created by `fitcensemble` for classification
- `RegressionBaggedEnsemble` created by `fitrensemble` for regression
- `TreeBagger` created by `TreeBagger` for classification and regression

For details about the differences between `TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`), see "Comparison of TreeBagger and Bagged Ensembles" on page 18-44.

Bootstrap aggregation (bagging) is a type of ensemble learning. To bag a weak learner such as a decision tree on a data set, generate many bootstrap replicas of the data set and grow decision trees on the replicas. Obtain each bootstrap replica by randomly selecting `N` out of `N` observations with replacement, where `N` is the data set size. In addition, every tree in the ensemble can randomly select predictors for each decision split, a technique called random forest [2] known to improve the accuracy of bagged trees. By default, the number of predictors to select at random for each split is equal to the square root of the number of predictors for classification, and one third of the number of predictors for regression. After training a model, you can find the predicted response of a trained ensemble for new data by using the `predict` function. `predict` takes an average over predictions from individual trees.

By default, the minimum number of observations per leaf for bagged trees is set to `1` for classification and `5` for regression. Trees grown with the default leaf size are usually very deep. These settings are close to optimal for the predictive power of an ensemble. Often you can grow trees with larger leaves without losing predictive power. Doing so reduces training and prediction time, as well as memory usage for the trained ensemble. You can control the minimum number of observations per leaf by using the `'MinLeafSize'` name-value pair argument of `templateTree` or `TreeBagger`. Note that you use the `templateTree` function to specify the options of tree learners when you create a bagged ensemble by using `fitcensemble` or `fitrensemble`.

Several features of bagged decision trees make them a unique algorithm. Drawing `N` out of `N` observations with replacement omits of observations, on average 37%, for each decision tree. These omitted observations are called “out-of-bag” observations. `TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`) have properties and object functions, whose names start with `oob`, that use out-of-bag observations.

- Use the `oobPredict` function to estimate predictive power and feature importance. For each observation, `oobPredict` estimates the out-of-bag prediction by averaging predictions from all trees in the ensemble for which the observation is out of bag.
- Estimate the average out-of-bag error by using `oobError` (for `TreeBagger`) or `oobLoss` (for bagged ensembles). These functions compare the out-of-bag predicted responses against the observed responses for all observations used for training. The out-of-bag average is an unbiased estimator of the true ensemble error.
- Obtain out-of-bag estimates of feature importance by using the `OOBPermutedPredictorDeltaError` property (for `TreeBagger`) or `oobPermutedPredictorImportance` property (for bagged ensembles). The software randomly permutes out-of-bag data across one variable or column at a time and estimates the increase in the out-of-bag error due to this permutation. The larger the increase, the more important the feature. Therefore, you do not need to supply test data for bagged ensembles because you can obtain reliable estimates of predictive power and feature importance in the process of training.

`TreeBagger` also offers the proximity matrix in the `Proximity` property. Every time two observations land on the same leaf of a tree, their proximity increases by 1. For normalization, sum these proximities over all trees in the ensemble and divide by the number of trees. The resulting matrix is symmetric with diagonal elements equal to 1 and off-diagonal elements ranging from 0 to 1. You can use this matrix to find outlier observations and discover clusters in the data through multidimensional scaling.

For examples using bagging, see:

Comparison of TreeBagger and Bagged Ensembles

`TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`) share most functionalities, but not all. Additionally, some functionalities have different names.

`TreeBagger` features not in bagged ensembles

Feature	`TreeBagger` Property	`TreeBagger` Method
Computation of proximity matrix	`Proximity`	`fillprox`, `mdsprox` When you estimate the proximity matrix and outliers of a `TreeBagger` model using `fillprox`, MATLAB must fit an *n*-by-*n* matrix in memory, where *n* is the number of observations. Therefore, if *n* is moderate to large, avoid estimating the proximity matrix and outliers.
Computation of outliers	`OutlierMeasure`	N/A
Out-of-bag estimates of predictor importance using classification margins	`OOBPermutedPredictorDeltaMeanMargin` and `OOBPermutedPredictorCountRaiseMargin`	N/A
Merging two ensembles trained separately	N/A	`append`
Quantile regression	N/A	`quantilePredict`, `quantileError`, `oobQuantilePredict`, `oobQuantileError`
Tall array support for creating ensemble	N/A	For details, see “Tall Arrays” on page 33-6274.

Bagged ensemble features not in `TreeBagger`

Feature	Description
Hyperparameter optimization	Use the `'OptimizeHyperparameters'` name-value pair argument.
Binning numeric predictors to speed up training	Use the `'NumBins'` name-value pair argument.
Code generation for `predict`	After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder™. For details, see “Introduction to Code Generation” on page 32-2.

Different names for `TreeBagger` and bagged ensembles

Feature	`TreeBagger`	Bagged Ensembles
Split criterion contributions for each predictor	`DeltaCriterionDecisionSplit` property	First output of `predictorImportance` (classification) or `predictorImportance` (regression)
Predictor associations	`SurrogateAssociation` property	Second output of `predictorImportance` (classification) or `predictorImportance` (regression)
Out-of-bag estimates of predictor importance	`OOBPermutedPredictorDeltaError` property	Output of `oobPermutedPredictorImportance` (classification) or `oobPermutedPredictorImportance` (regression)
Error (misclassification probability or mean-squared error)	`error` and `oobError` methods	`loss` and `oobLoss` methods (classification) or `loss` and `oobLoss` methods (regression)
Training additional trees and adding them to ensemble	`growTrees` method	`resume` method (classification) or `resume` method (regression)
Mean classification margin per tree	`meanMargin` and `oobMeanMargin` methods	`edge` and `oobEdge` methods (classification)

In addition, two important differences exist when you train a model and predict responses:

- If you pass a misclassification cost matrix to `TreeBagger`, it passes the matrix along to the trees. If you pass a misclassification cost matrix to `fitcensemble`, it uses the matrix to adjust the class prior probabilities. `fitcensemble` then passes the adjusted prior probabilities and the default cost matrix to the trees. The default cost matrix is `ones(K)–eye(K)` for `K` classes.
- Unlike the `loss` and `edge` methods in `ClassificationBaggedEnsemble`, the `TreeBagger` `error` and `meanMargin` methods do not normalize input observation weights of the prior probabilities in the respective class.

Random Subspace

Use random subspace ensembles (`Subspace`) to improve the accuracy of discriminant analysis (`ClassificationDiscriminant`) or *k*-nearest neighbor (`ClassificationKNN`) classifiers. `Subspace` ensembles also have the advantage of using less memory than ensembles with all predictors, and can handle missing values (`NaN`s).

The basic random subspace algorithm uses these parameters.

- *m* is the number of dimensions (variables) to sample in each learner. Set *m* using the `NPredToSample` name-value pair.
- *d* is the number of dimensions in the data, which is the number of columns (predictors) in the data matrix `X`.

- n is the number of learners in the ensemble. Set n using the `NLearn` input.

The basic random subspace algorithm performs the following steps:

1. Choose without replacement a random set of m predictors from the d possible values.
2. Train a weak learner using just the m chosen predictors.
3. Repeat steps 1 and 2 until there are n weak learners.
4. Predict by taking an average of the `score` prediction of the weak learners, and classify the category with the highest average `score`.

You can choose to create a weak learner for every possible set of m predictors from the d dimensions. To do so, set n, the number of learners, to `'AllPredictorCombinations'`. In this case, there are `nchoosek(size(X,2),NPredToSample)` weak learners in the ensemble.

`fitcensemble` downweights predictors after choosing them for a learner, so subsequent learners have a lower chance of using a predictor that was previously used. This weighting tends to make predictors more evenly distributed among learners than in uniform weighting.

For examples using `Subspace`, see “Random Subspace Classification” on page 18-104.

Boosting Algorithms

Adaptive Boosting for Binary Classification

Adaptive boosting named `AdaBoostM1` is a very popular boosting algorithm for binary classification. The algorithm trains learners sequentially. For every learner with index t, `AdaBoostM1` computes the weighted classification error

$$\varepsilon_t = \sum_{n=1}^{N} d_n^{(t)} \mathbb{I}(y_n \neq h_t(x_n)),$$

where

- x_n is a vector of predictor values for observation n.
- y_n is the true class label.
- h_t is the prediction of learner (hypothesis) with index t.
- $\mathbb{I}$ is the indicator function.
- $d_n^{(t)}$ is the weight of observation n at step t.

`AdaBoostM1` then increases weights for observations misclassified by learner t and reduces weights for observations correctly classified by learner t. The next learner $t + 1$ is then trained on the data with updated weights $d_n^{(t+1)}$.

After training finishes, `AdaBoostM1` computes prediction for new data using

$$f(x) = \sum_{t=1}^{T} \alpha_t h_t(x),$$

where

$$\alpha_t = \frac{1}{2}\log\frac{1-\varepsilon_t}{\varepsilon_t}$$

are weights of the weak hypotheses in the ensemble.

Training by `AdaBoostM1` can be viewed as stagewise minimization of the exponential loss

$$\sum_{n=1}^{N} w_n \exp(-y_n f(x_n)),$$

where

- $y_n \in \{-1,+1\}$ is the true class label.
- w_n are observation weights normalized to add up to 1.
- $f(x_n) \in (-\infty,+\infty)$ is the predicted classification score.

The observation weights w_n are the original observation weights you passed to `fitcensemble`.

The second output from the `predict` method of an `AdaBoostM1` classification ensemble is an N-by-2 matrix of classification scores for the two classes and N observations. The second column in this matrix is always equal to minus the first column. The `predict` method returns two scores to be consistent with multiclass models, though this is redundant because the second column is always the negative of the first.

Most often `AdaBoostM1` is used with decision stumps (default) or shallow trees. If boosted stumps give poor performance, try setting the minimal parent node size to one quarter of the training data.

By default, the learning rate for boosting algorithms is `1`. If you set the learning rate to a lower number, the ensemble learns at a slower rate, but can converge to a better solution. `0.1` is a popular choice for the learning rate. Learning at a rate less than `1` is often called “shrinkage”.

For examples using `AdaBoostM1`, see “Conduct Cost-Sensitive Comparison of Two Classification Models” on page 33-898 and “Create an Ensemble Template for ECOC Multiclass Learning” on page 33-6101.

Adaptive Boosting for Multiclass Classification

Adaptive boosting named `AdaBoostM2` is an extension of `AdaBoostM1` for multiple classes. Instead of weighted classification error, `AdaBoostM2` uses weighted pseudo-loss for N observations and K classes

$$\varepsilon_t = \frac{1}{2}\sum_{n=1}^{N}\sum_{k \neq y_n} d_{n,k}^{(t)}(1 - h_t(x_n, y_n) + h_t(x_n, k)),$$

where

- $h_t(x_n,k)$ is the confidence of prediction by learner at step t into class k ranging from 0 (not at all confident) to 1 (highly confident).
- $d_{n,k}^{(t)}$ are observation weights at step t for class k.
- y_n is the true class label taking one of the K values.
- The second sum is over all classes other than the true class y_n.

Interpreting the pseudo-loss is harder than classification error, but the idea is the same. Pseudo-loss can be used as a measure of the classification accuracy from any learner in an ensemble. Pseudo-loss typically exhibits the same behavior as a weighted classification error for `AdaBoostM1`: the first few learners in a boosted ensemble give low pseudo-loss values. After the first few training steps, the ensemble begins to learn at a slower pace, and the pseudo-loss value approaches 0.5 from below.

For an example using `AdaBoostM2`, see “Predict Class Labels Using Classification Ensemble” on page 33-4830.

Gentle Adaptive Boosting

Gentle adaptive boosting (`GentleBoost`, also known as Gentle AdaBoost) combines features of `AdaBoostM1` and `LogitBoost`. Like `AdaBoostM1`, `GentleBoost` minimizes the exponential loss. But its numeric optimization is set up differently. Like `LogitBoost`, every weak learner fits a regression model to response values $y_n \in \{-1,+1\}$.

`fitcensemble` computes and stores the mean-squared error in the `FitInfo` property of the ensemble object. The mean-squared error is

$$\sum_{n=1}^{N} d_n^{(t)} (\tilde{y}_n - h_t(x_n))^2,$$

where

- $d_n^{(t)}$ are observation weights at step t (the weights add up to 1).
- $h_t(x_n)$ are predictions of the regression model h_t fitted to response values y_n.

As the strength of individual learners weakens, the weighted mean-squared error approaches 1.

For examples using `GentleBoost`, see “Speed Up Training ECOC Classifiers Using Binning and Parallel Computing” on page 33-6102 and “Handle Imbalanced Data or Unequal Misclassification Costs in Classification Ensembles” on page 18-84.

Adaptive Logistic Regression

Adaptive logistic regression (`LogitBoost`) is another popular algorithm for binary classification. `LogitBoost` works similarly to `AdaBoostM1`, except it minimizes binomial deviance

$$\sum_{n=1}^{N} w_n \log(1 + \exp(-2 y_n f(x_n))),$$

where

- $y_n \in \{-1,+1\}$ is the true class label.
- w_n are observation weights normalized to add up to 1.
- $f(x_n) \in (-\infty,+\infty)$ is the predicted classification score.

Binomial deviance assigns less weight to badly misclassified observations (observations with large negative values of $y_n f(x_n)$). `LogitBoost` can give better average accuracy than `AdaBoostM1` for data with poorly separable classes.

Learner t in a `LogitBoost` ensemble fits a regression model to response values

$$\tilde{y}_n = \frac{y^*_n - p_t(x_n)}{p_t(x_n)(1 - p_t(x_n))},$$

where

- $y^*_n \in \{0,+1\}$ are relabeled classes (0 instead of –1).
- $p_t(x_n)$ is the current ensemble estimate of the probability for observation x_n to be of class 1.

`fitcensemble` computes and stores the mean-squared error in the `FitInfo` property of the ensemble object. The mean-squared error is

$$\sum_{n=1}^{N} d_n^{(t)} (\tilde{y}_n - h_t(x_n))^2,$$

where

- $d_n^{(t)}$ are observation weights at step t (the weights add up to 1).
- $h_t(x_n)$ are predictions of the regression model h_t fitted to response values $\tilde{y}_n$.

Values y_n can range from –∞ to +∞, so the mean-squared error does not have well-defined bounds.

For examples using `LogitBoost`, see “Train Classification Ensemble” on page 18-54 and “Speed Up Training by Binning Numeric Predictor Values” on page 33-1651.

Linear Programming Boosting

Linear programming boosting (`LPBoost`), like `TotalBoost`, performs multiclass classification by attempting to maximize the minimal margin in the training set. This attempt uses optimization algorithms, namely linear programming for `LPBoost`. So you need an Optimization Toolbox license to use `LPBoost` or `TotalBoost`.

The margin of a classification is the difference between the predicted soft classification score for the true class, and the largest score for the false classes. For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node. For more information, see “More About” on page 33-3921 in `margin`.

Why maximize the minimal margin? For one thing, the generalization error (the error on new data) is the probability of obtaining a negative margin. Schapire and Singer [10] establish this inequality on the probability of obtaining a negative margin:

$$P_{\text{test}}(m \le 0) \le P_{\text{train}}(m \le \theta) + O\left(\frac{1}{\sqrt{N}}\sqrt{\frac{V\log^2(N/V)}{\theta^2} + \log(1/\delta)}\right).$$

Here m is the margin, θ is any positive number, V is the Vapnik-Chervonenkis dimension of the classifier space, N is the size of the training set, and δ is a small positive number. The inequality holds with probability $1–\delta$ over many i.i.d. training and test sets. This inequality says: To obtain a low generalization error, minimize the number of observations below margin θ in the training set.

`LPBoost` iteratively maximizes the minimal margin through a sequence of linear programming problems. Equivalently, by duality, `LPBoost` minimizes the maximal edge, where edge is the weighted

mean margin (see “More About” on page 33-1323). At each iteration, there are more constraints in the problem. So, for large problems, the optimization problem becomes increasingly constrained, and slow to solve.

`LPBoost` typically creates ensembles with many learners having weights that are orders of magnitude smaller than those of other learners. Therefore, to better enable you to remove the unimportant ensemble members, the `compact` method reorders the members of an `LPBoost` ensemble from largest weight to smallest. Therefore, you can easily remove the least important members of the ensemble using the `removeLearners` method.

For an example using `LPBoost`, see “LPBoost and TotalBoost for Small Ensembles” on page 18-96.

Least-Squares Boosting

Least-squares boosting (`LSBoost`) fits regression ensembles. At every step, the ensemble fits a new learner to the difference between the observed response and the aggregated prediction of all learners grown previously. The ensemble fits to minimize mean-squared error.

You can use `LSBoost` with shrinkage by passing in the `LearnRate` parameter. By default this parameter is set to `1`, and the ensemble learns at the maximal speed. If you set `LearnRate` to a value from `0` to `1`, the ensemble fits every new learner to $y_n - \eta f(x_n)$, where

- y_n is the observed response.
- $f(x_n)$ is the aggregated prediction from all weak learners grown so far for observation x_n.
- η is the learning rate.

For examples using `LSBoost`, see “Train Regression Ensemble” on page 18-57, “Optimize a Boosted Regression Ensemble” on page 10-63, and “Ensemble Regularization” on page 18-70.

Robust Boosting

Boosting algorithms such as `AdaBoostM1` and `LogitBoost` increase weights for misclassified observations at every boosting step. These weights can become very large. If this happens, the boosting algorithm sometimes concentrates on a few misclassified observations and neglects the majority of training data. Consequently the average classification accuracy suffers. In this situation, you can try using robust boosting (`RobustBoost`). This algorithm does not assign almost the entire data weight to badly misclassified observations. It can produce better average classification accuracy. You need an Optimization Toolbox license to use `RobustBoost`.

Unlike `AdaBoostM1` and `LogitBoost`, `RobustBoost` does not minimize a specific loss function. Instead, it maximizes the number of observations with the classification margin above a certain threshold.

`RobustBoost` trains based on time evolution. The algorithm starts at $t = 0$. At every step, `RobustBoost` solves an optimization problem to find a positive step in time Δt and a corresponding positive change in the average margin for training data Δm. `RobustBoost` stops training and exits if at least one of these three conditions is true:

- Time t reaches 1.
- `RobustBoost` cannot find a solution to the optimization problem with positive updates Δt and Δm.
- `RobustBoost` grows as many learners as you requested.

Results from `RobustBoost` can be usable for any termination condition. Estimate the classification accuracy by cross validation or by using an independent test set.

To get better classification accuracy from `RobustBoost`, you can adjust three parameters in `fitcensemble`: `RobustErrorGoal`, `RobustMaxMargin`, and `RobustMarginSigma`. Start by varying values for `RobustErrorGoal` from 0 to 1. The maximal allowed value for `RobustErrorGoal` depends on the two other parameters. If you pass a value that is too high, `fitcensemble` produces an error message showing the allowed range for `RobustErrorGoal`.

For an example using `RobustBoost`, see “Tune RobustBoost” on page 18-101.

Random Undersampling Boosting

Random undersampling boosting (`RUSBoost`) is especially effective at classifying imbalanced data, meaning some class in the training data has many fewer members than another. RUS stands for Random Under Sampling. The algorithm takes N, the number of members in the class with the fewest members in the training data, as the basic unit for sampling. Classes with more members are under sampled by taking only N observations of every class. In other words, if there are K classes, then, for each weak learner in the ensemble, `RUSBoost` takes a subset of the data with N observations from each of the K classes. The boosting procedure follows the procedure in “Adaptive Boosting for Multiclass Classification” on page 18-47 for reweighting and constructing the ensemble.

When you construct a `RUSBoost` ensemble, there is an optional name-value pair called `RatioToSmallest`. Give a vector of K values, each value representing the multiple of N to sample for the associated class. For example, if the smallest class has $N = 100$ members, then `RatioToSmallest = [2,3,4]` means each weak learner has 200 members in class 1, 300 in class 2, and 400 in class 3. If `RatioToSmallest` leads to a value that is larger than the number of members in a particular class, then `RUSBoost` samples the members with replacement. Otherwise, `RUSBoost` samples the members without replacement.

For an example using `RUSBoost`, see “Classification with Imbalanced Data” on page 18-79.

Totally Corrective Boosting

Totally corrective boosting (`TotalBoost`), like linear programming boost (`LPBoost`), performs multiclass classification by attempting to maximize the minimal margin in the training set. This attempt uses optimization algorithms, namely quadratic programming for `TotalBoost`. So you need an Optimization Toolbox license to use `LPBoost` or `TotalBoost`.

The margin of a classification is the difference between the predicted soft classification score for the true class, and the largest score for the false classes. For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node. For more information, see “More About” on page 33-3921 in `margin`.

Why maximize the minimal margin? For one thing, the generalization error (the error on new data) is the probability of obtaining a negative margin. Schapire and Singer [10] establish this inequality on the probability of obtaining a negative margin:

$$P_{\text{test}}(m \le 0) \le P_{\text{train}}(m \le \theta) + O\left(\frac{1}{\sqrt{N}}\sqrt{\frac{V\log^2(N/V)}{\theta^2} + \log(1/\delta)}\right).$$

Here m is the margin, θ is any positive number, V is the Vapnik-Chervonenkis dimension of the classifier space, N is the size of the training set, and δ is a small positive number. The inequality holds with probability $1–\delta$ over many i.i.d. training and test sets. This inequality says: To obtain a low generalization error, minimize the number of observations below margin θ in the training set.

`TotalBoost` minimizes a proxy of the Kullback-Leibler divergence between the current weight distribution and the initial weight distribution, subject to the constraint that the edge (the weighted margin) is below a certain value. The proxy is a quadratic expansion of the divergence:

$$D(W, W_0) = \sum_{n=1}^{N} \log\frac{W(n)}{W_0(n)} \approx \sum_{n=1}^{N} \left(1 + \frac{W(n)}{W_0(n)}\right)\Delta + \frac{1}{2W(n)}\Delta^2,$$

where Δ is the difference between $W(n)$, the weights at the current and next iteration, and W_0, the initial weight distribution, which is uniform. This optimization formulation keeps weights from becoming zero. At each iteration, there are more constraints in the problem. So, for large problems, the optimization problem becomes increasingly constrained, and slow to solve.

`TotalBoost` typically creates ensembles with many learners having weights that are orders of magnitude smaller than those of other learners. Therefore, to better enable you to remove the unimportant ensemble members, the `compact` method reorders the members of a `TotalBoost` ensemble from largest weight to smallest. Therefore you can easily remove the least important members of the ensemble using the `removeLearners` method.

For an example using `TotalBoost`, see “LPBoost and TotalBoost for Small Ensembles” on page 18-96.

Train Classification Ensemble

This example shows how to create a classification tree ensemble for the `ionosphere` data set, and use it to predict the classification of a radar return with average measurements.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble. For binary classification problems, `fitcensemble` aggregates 100 classification trees using LogitBoost.

```
Mdl = fitcensemble(X,Y)
```

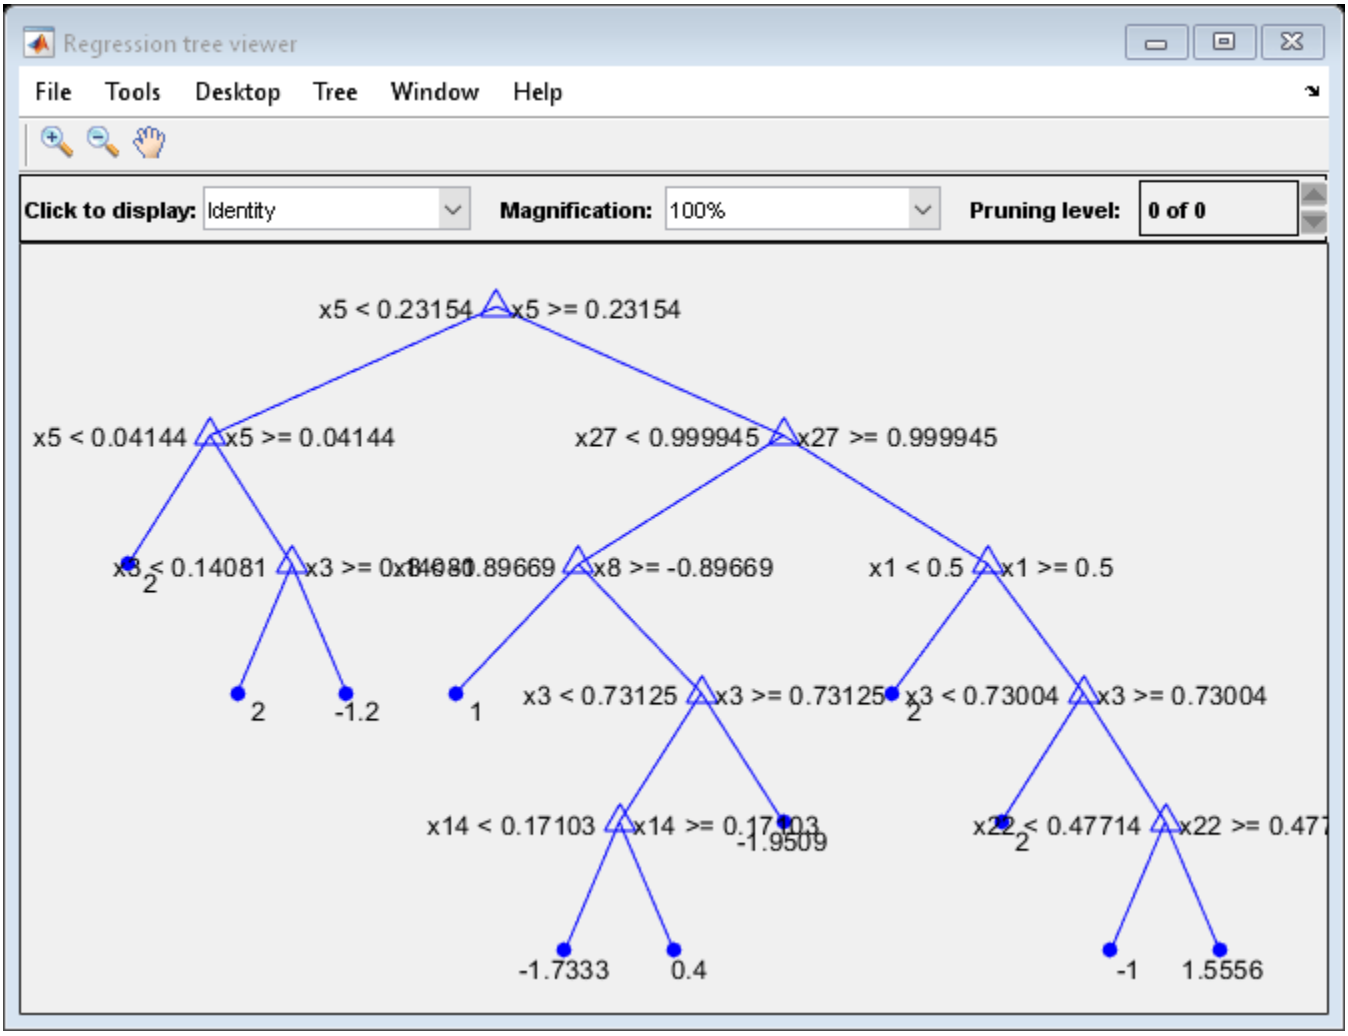
```
Mdl =
  ClassificationEnsemble
             ResponseName: 'Y'
    CategoricalPredictors: []
                ClassNames: {'b'  'g'}
           ScoreTransform: 'none'
          NumObservations: 351
                NumTrained: 100
                    Method: 'LogitBoost'
              LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: [100x1 double]
       FitInfoDescription: {2x1 cell}

  Properties, Methods
```

`Mdl` is a `ClassificationEnsemble` model.

Plot a graph of the first trained classification tree in the ensemble.

```
view(Mdl.Trained{1}.CompactRegressionLearner,'Mode','graph');
```



By default, `fitcensemble` grows shallow trees for boosting algorithms. You can alter the tree depth by passing a tree template object to `fitcensemble`. For more details, see `templateTree`.

Predict the quality of a radar return with average predictor measurements.

```
label = predict(Mdl,mean(X))
```

```
label = 1x1 cell array
    {'g'}
```

Train Regression Ensemble

This example shows how to create a regression ensemble to predict mileage of cars based on their horsepower and weight, trained on the `carsmall` data.

Load the `carsmall` data set.

```
load carsmall
```

Prepare the predictor data.

```
X = [Horsepower Weight];
```

The response data is `MPG`. The only available boosted regression ensemble type is `LSBoost`. For this example, arbitrarily choose an ensemble of 100 trees, and use the default tree options.

Train an ensemble of regression trees.

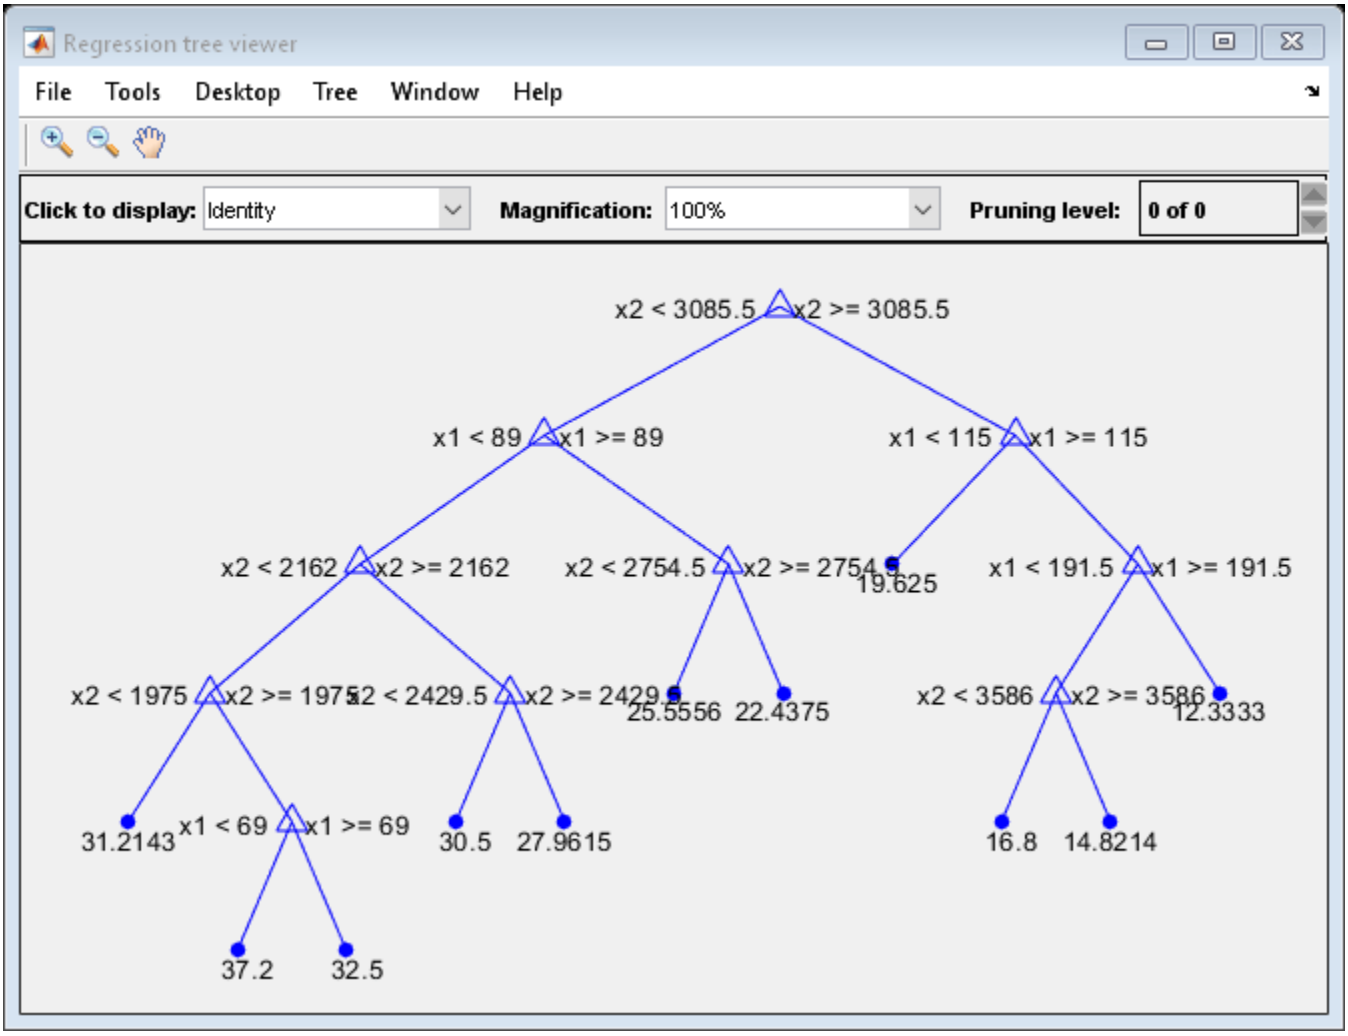
```
Mdl = fitrensemble(X,MPG,'Method','LSBoost','NumLearningCycles',100)
```

```
Mdl =
  RegressionEnsemble
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
          NumObservations: 94
                NumTrained: 100
                    Method: 'LSBoost'
             LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: [100x1 double]
       FitInfoDescription: {2x1 cell}
           Regularization: []

  Properties, Methods
```

Plot a graph of the first trained regression tree in the ensemble.

```
view(Mdl.Trained{1},'Mode','graph');
```



By default, `fitrensemble` grows shallow trees for LSBoost.

Predict the mileage of a car with 150 horsepower weighing 2750 lbs.

```
mileage = predict(Mdl,[150 2750])
```

```
mileage = 23.6713
```

Select Predictors for Random Forests

This example shows how to choose the appropriate split predictor selection technique for your data set when growing a random forest of regression trees. This example also shows how to decide which predictors are most important to include in the training data.

Load and Preprocess Data

Load the `carbig` data set. Consider a model that predicts the fuel economy of a car given its number of cylinders, engine displacement, horsepower, weight, acceleration, model year, and country of origin. Consider `Cylinders`, `Model_Year`, and `Origin` as categorical variables.

```
load carbig
Cylinders = categorical(Cylinders);
Model_Year = categorical(Model_Year);
Origin = categorical(cellstr(Origin));
X = table(Cylinders,Displacement,Horsepower,Weight,Acceleration,Model_Year,Origin);
```

Determine Levels in Predictors

The standard CART algorithm tends to split predictors with many unique values (levels), e.g., continuous variables, over those with fewer levels, e.g., categorical variables. If your data is heterogeneous, or your predictor variables vary greatly in their number of levels, then consider using the curvature or interaction tests for split-predictor selection instead of standard CART.

For each predictor, determine the number of levels in the data. One way to do this is define an anonymous function that:

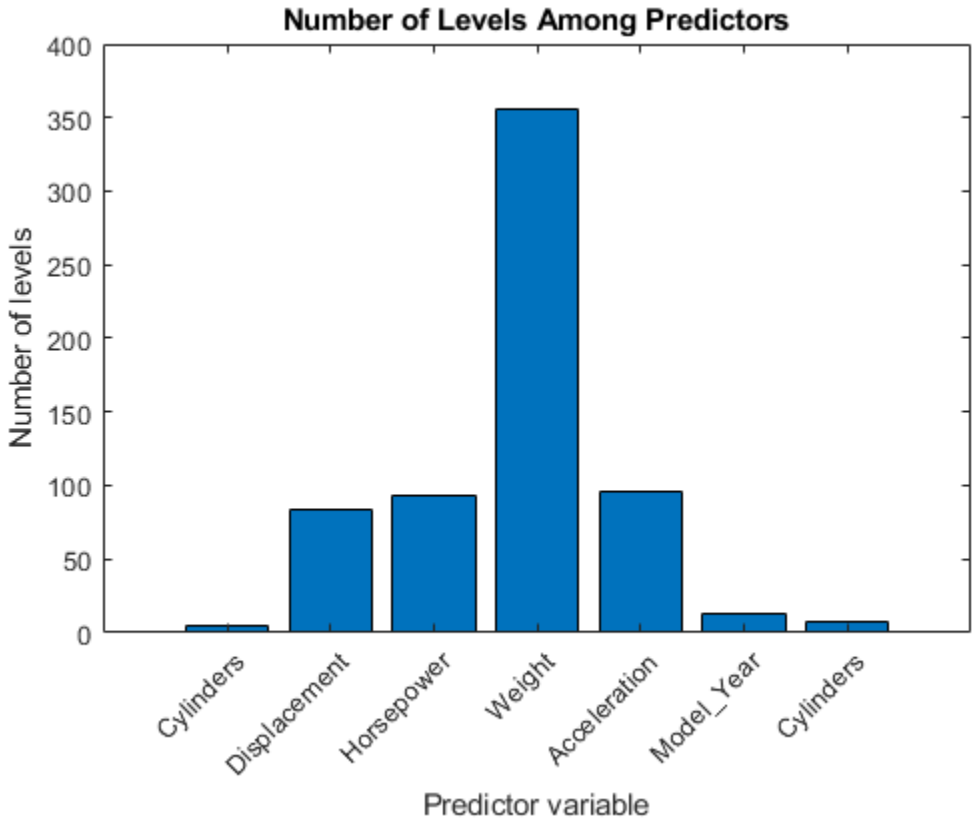
1. Converts all variables to the categorical data type using `categorical`
2. Determines all unique categories while ignoring missing values using `categories`
3. Counts the categories using `numel`

Then, apply the function to each variable using `varfun`.

```
countLevels = @(x)numel(categories(categorical(x)));
numLevels = varfun(countLevels,X,'OutputFormat','uniform');
```

Compare the number of levels among the predictor variables.

```
figure
bar(numLevels)
title('Number of Levels Among Predictors')
xlabel('Predictor variable')
ylabel('Number of levels')
h = gca;
h.XTickLabel = X.Properties.VariableNames(1:end-1);
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```



The continuous variables have many more levels than the categorical variables. Because the number of levels among the predictors varies so much, using standard CART to select split predictors at each node of the trees in a random forest can yield inaccurate predictor importance estimates. In this case, use the curvature test or interaction test. Specify the algorithm by using the `'PredictorSelection'` name-value pair argument. For more details, see “Choose Split Predictor Selection Technique” on page 19-14.

Train Bagged Ensemble of Regression Trees

Train a bagged ensemble of 200 regression trees to estimate predictor importance values. Define a tree learner using these name-value pair arguments:

- `'NumVariablesToSample','all'` — Use all predictor variables at each node to ensure that each tree uses all predictor variables.
- `'PredictorSelection','interaction-curvature'` — Specify usage of the interaction test to select split predictors.
- `'Surrogate','on'` — Specify usage of surrogate splits to increase accuracy because the data set includes missing values.

```
t = templateTree('NumVariablesToSample','all',...
    'PredictorSelection','interaction-curvature','Surrogate','on');
rng(1); % For reproducibility
Mdl = fitrensemble(X,MPG,'Method','Bag','NumLearningCycles',200, ...
    'Learners',t);
```

`Mdl` is a `RegressionBaggedEnsemble` model.

Estimate the model R^2 using out-of-bag predictions.

```
yHat = oobPredict(Mdl);
R2 = corr(Mdl.Y,yHat)^2
```

```
R2 = 0.8744
```

`Mdl` explains 87% of the variability around the mean.

Predictor Importance Estimation

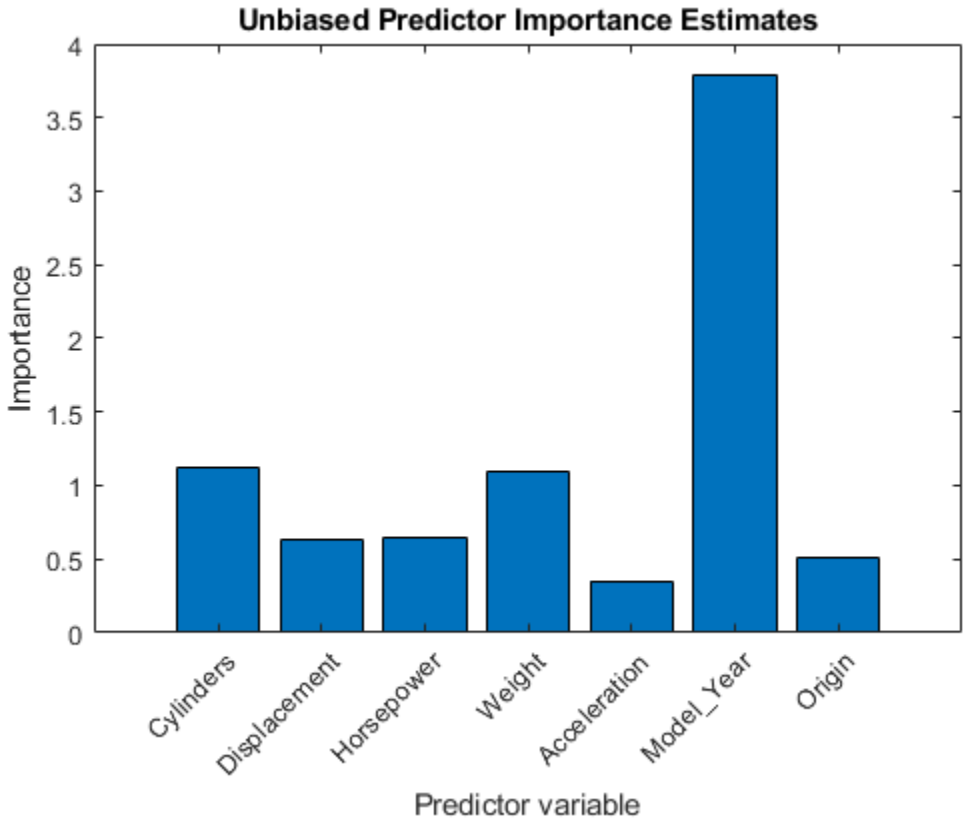
Estimate predictor importance values by permuting out-of-bag observations among the trees.

```
impOOB = oobPermutedPredictorImportance(Mdl);
```

`impOOB` is a 1-by-7 vector of predictor importance estimates corresponding to the predictors in `Mdl.PredictorNames`. The estimates are not biased toward predictors containing many levels.

Compare the predictor importance estimates.

```
figure
bar(impOOB)
title('Unbiased Predictor Importance Estimates')
xlabel('Predictor variable')
ylabel('Importance')
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

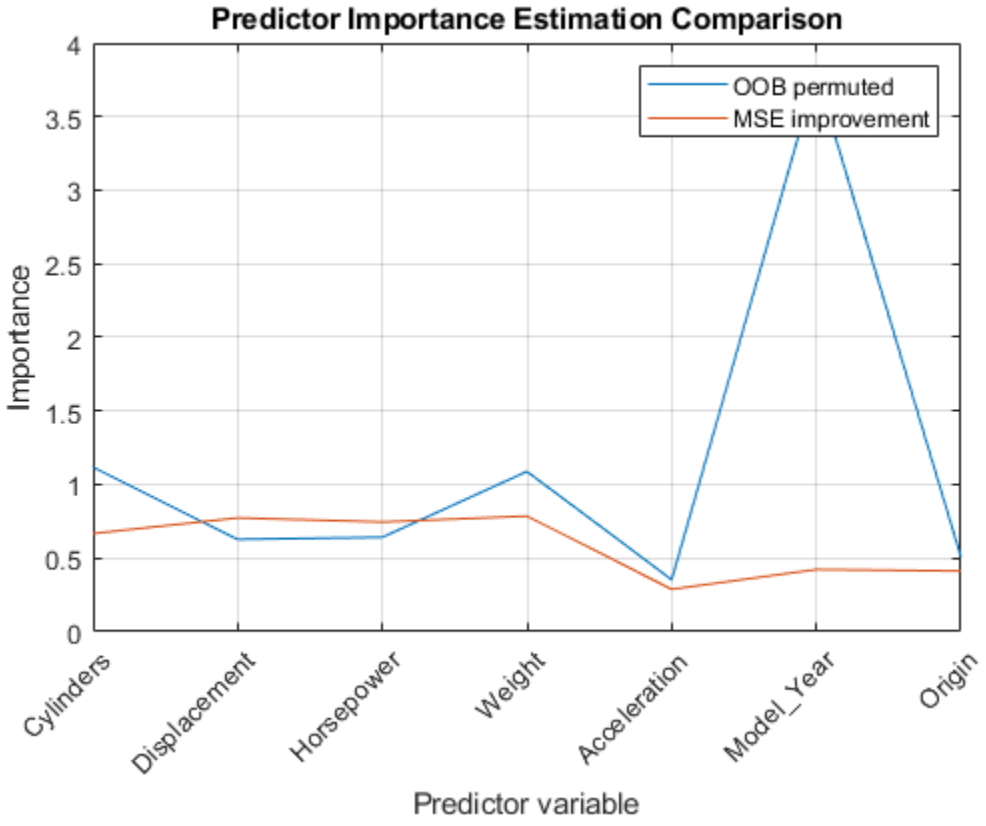


Greater importance estimates indicate more important predictors. The bar graph suggests that `Model_Year` is the most important predictor, followed by `Cylinders` and `Weight`. The `Model_Year` and `Cylinders` variables have only 13 and 5 distinct levels, respectively, whereas the `Weight` variable has over 300 levels.

Compare predictor importance estimates by permuting out-of-bag observations and those estimates obtained by summing gains in the mean squared error due to splits on each predictor. Also, obtain predictor association measures estimated by surrogate splits.

```
[impGain,predAssociation] = predictorImportance(Mdl);

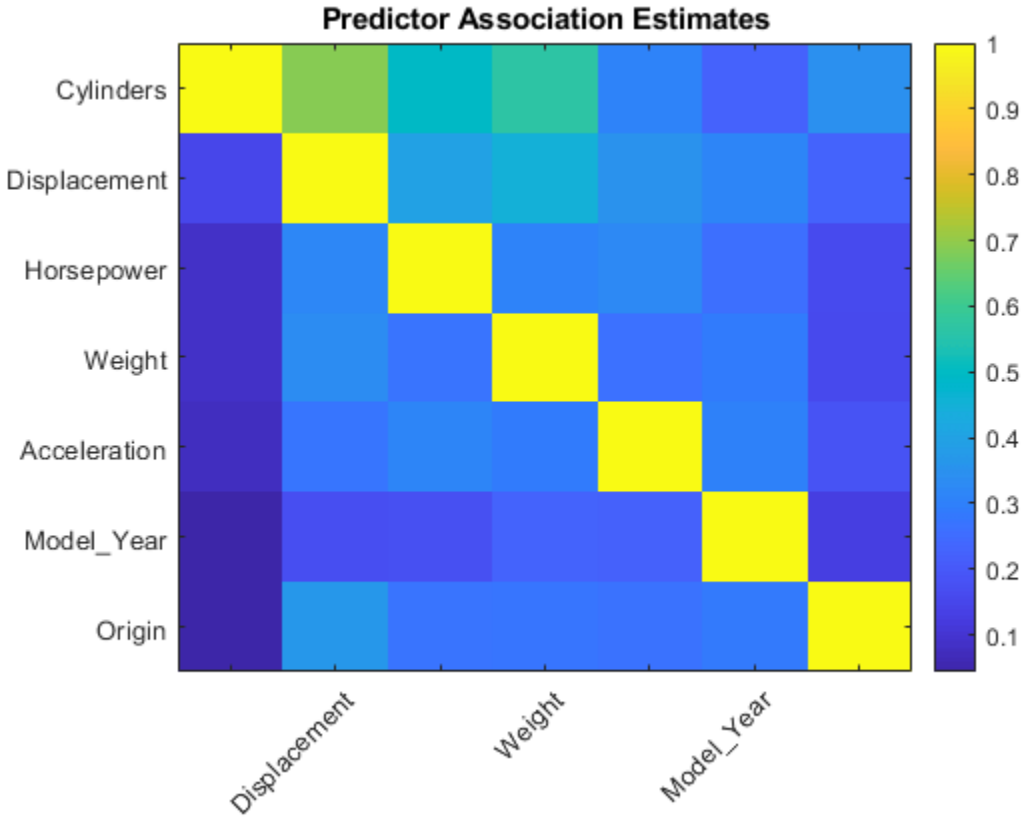
figure
plot(1:numel(Mdl.PredictorNames),[impOOB' impGain'])
title('Predictor Importance Estimation Comparison')
xlabel('Predictor variable')
ylabel('Importance')
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
legend('OOB permuted','MSE improvement')
grid on
```



According to the values of `impGain`, the variables `Displacement`, `Horsepower`, and `Weight` appear to be equally important.

`predAssociation` is a 7-by-7 matrix of predictor association measures. Rows and columns correspond to the predictors in `Mdl.PredictorNames`. The “Predictive Measure of Association” on page 33-5044 is a value that indicates the similarity between decision rules that split observations. The best surrogate decision split yields the maximum predictive measure of association. You can infer the strength of the relationship between pairs of predictors using the elements of `predAssociation`. Larger values indicate more highly correlated pairs of predictors.

```
figure
imagesc(predAssociation)
title('Predictor Association Estimates')
colorbar
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
h.YTickLabel = Mdl.PredictorNames;
```



```
predAssociation(1,2)
```

```
ans = 0.6871
```

The largest association is between `Cylinders` and `Displacement`, but the value is not high enough to indicate a strong relationship between the two predictors.

Grow Random Forest Using Reduced Predictor Set

Because prediction time increases with the number of predictors in random forests, a good practice is to create a model using as few predictors as possible.

Grow a random forest of 200 regression trees using the best two predictors only. The default `'NumVariablesToSample'` value of `templateTree` is one third of the number of predictors for regression, so `fitrensemble` uses the random forest algorithm.

```
t = templateTree('PredictorSelection','interaction-curvature','Surrogate','on', ...
    'Reproducible',true); % For reproducibility of random predictor selections
MdlReduced = fitrensemble(X(:,{'Model_Year' 'Weight'}),MPG,'Method','Bag', ...
    'NumLearningCycles',200,'Learners',t);
```

Compute the R^2 of the reduced model.

```
yHatReduced = oobPredict(MdlReduced);
r2Reduced = corr(Mdl.Y,yHatReduced)^2
```

```
r2Reduced = 0.8653
```

The R^2 for the reduced model is close to the R^2 of the full model. This result suggests that the reduced model is sufficient for prediction.

Test Ensemble Quality

You cannot evaluate the predictive quality of an ensemble based on its performance on training data. Ensembles tend to "overtrain," meaning they produce overly optimistic estimates of their predictive power. This means the result of `resubLoss` for classification (`resubLoss` for regression) usually indicates lower error than you get on new data.

To obtain a better idea of the quality of an ensemble, use one of these methods:

- Evaluate the ensemble on an independent test set (useful when you have a lot of training data).
- Evaluate the ensemble by cross validation (useful when you don't have a lot of training data).
- Evaluate the ensemble on out-of-bag data (useful when you create a bagged ensemble with `fitcensemble` or `fitrensemble`).

This example uses a bagged ensemble so it can use all three methods of evaluating ensemble quality.

Generate an artificial dataset with 20 predictors. Each entry is a random number from 0 to 1. The initial classification is $Y = 1$ if $X_1 + X_2 + X_3 + X_4 + X_5 > 2.5$ and $Y = 0$ otherwise.

```
rng(1,'twister') % For reproducibility
X = rand(2000,20);
Y = sum(X(:,1:5),2) > 2.5;
```

In addition, to add noise to the results, randomly switch 10% of the classifications.

```
idx = randsample(2000,200);
Y(idx) = ~Y(idx);
```

Independent Test Set

Create independent training and test sets of data. Use 70% of the data for a training set by calling `cvpartition` using the `holdout` option.

```
cvpart = cvpartition(Y,'holdout',0.3);
Xtrain = X(training(cvpart),:);
Ytrain = Y(training(cvpart),:);
Xtest = X(test(cvpart),:);
Ytest = Y(test(cvpart),:);
```

Create a bagged classification ensemble of 200 trees from the training data.

```
t = templateTree('Reproducible',true);  % For reproducibility of random predictor selections
bag = fitcensemble(Xtrain,Ytrain,'Method','Bag','NumLearningCycles',200,'Learners',t)
```

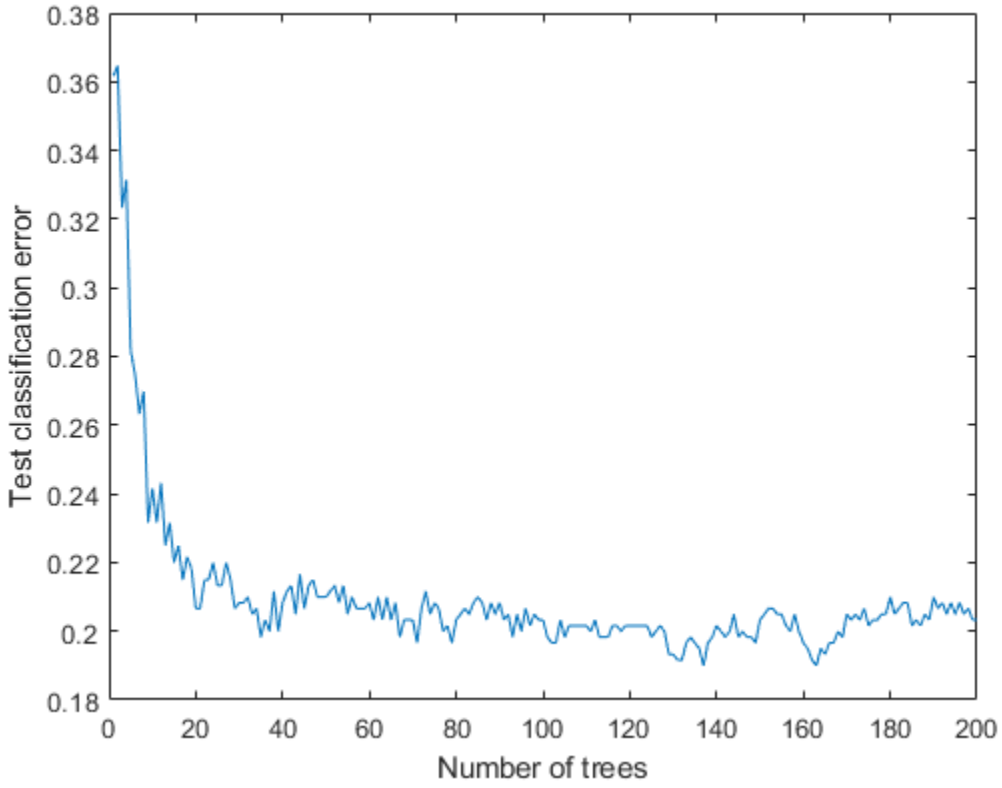
```
bag =
  ClassificationBaggedEnsemble
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: [0 1]
           ScoreTransform: 'none'
          NumObservations: 1400
               NumTrained: 200
                   Method: 'Bag'
             LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: []
```

```
       FitInfoDescription: 'None'
                FResample: 1
                  Replace: 1
          UseObsForLearner: [1400x200 logical]

  Properties, Methods
```

Plot the loss (misclassification) of the test data as a function of the number of trained trees in the ensemble.

```
figure
plot(loss(bag,Xtest,Ytest,'mode','cumulative'))
xlabel('Number of trees')
ylabel('Test classification error')
```



Cross Validation

Generate a five-fold cross-validated bagged ensemble.

```
cv = fitcensemble(X,Y,'Method','Bag','NumLearningCycles',200,'Kfold',5,'Learners',t)
```

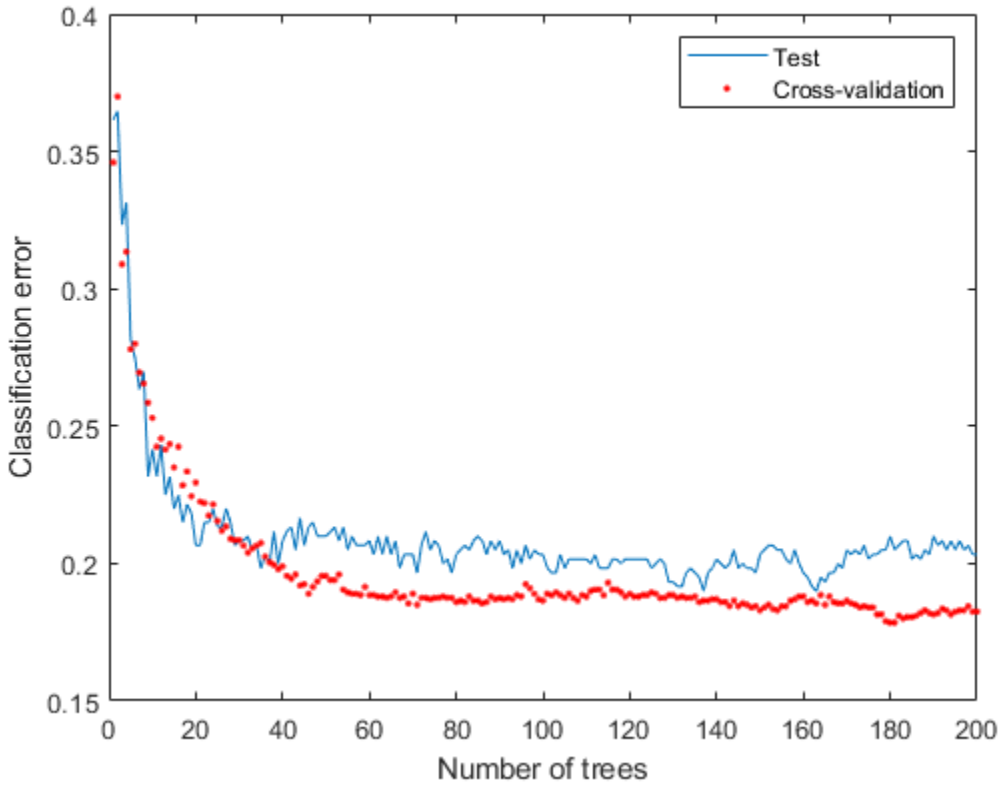
```
cv =
  ClassificationPartitionedEnsemble
    CrossValidatedModel: 'Bag'
         PredictorNames: {1x20 cell}
           ResponseName: 'Y'
```

```
       NumObservations: 2000
                 KFold: 5
             Partition: [1x1 cvpartition]
    NumTrainedPerFold: [200 200 200 200 200]
           ClassNames: [0 1]
       ScoreTransform: 'none'

  Properties, Methods
```

Examine the cross-validation loss as a function of the number of trees in the ensemble.

```
figure
plot(loss(bag,Xtest,Ytest,'mode','cumulative'))
hold on
plot(kfoldLoss(cv,'mode','cumulative'),'r.')
hold off
xlabel('Number of trees')
ylabel('Classification error')
legend('Test','Cross-validation','Location','NE')
```

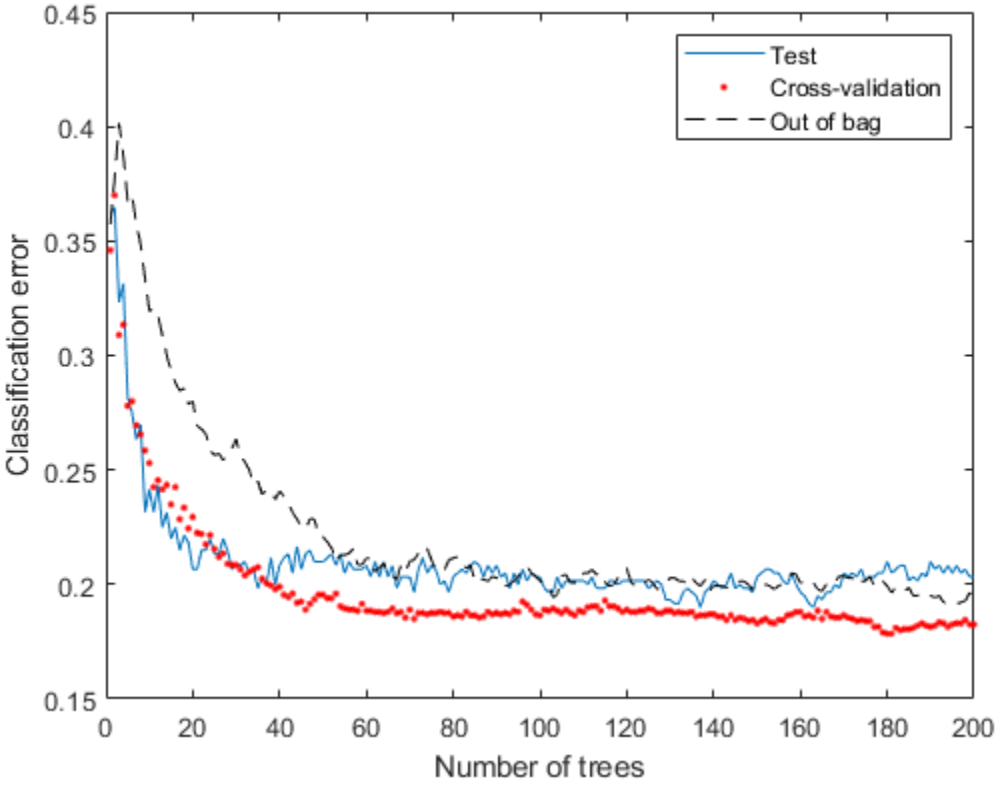


Cross validating gives comparable estimates to those of the independent set.

Out-of-Bag Estimates

Generate the loss curve for out-of-bag estimates, and plot it along with the other curves.

```
figure
plot(loss(bag,Xtest,Ytest,'mode','cumulative'))
hold on
plot(kfoldLoss(cv,'mode','cumulative'),'r.')
plot(oobLoss(bag,'mode','cumulative'),'k--')
hold off
xlabel('Number of trees')
ylabel('Classification error')
legend('Test','Cross-validation','Out of bag','Location','NE')
```



The out-of-bag estimates are again comparable to those of the other methods.

- “Bootstrap Aggregation (Bagging) of Classification Trees Using TreeBagger” on page 18-124

Ensemble Regularization

Regularization is a process of choosing fewer weak learners for an ensemble in a way that does not diminish predictive performance. Currently you can regularize regression ensembles. (You can also regularize a discriminant analysis classifier in a non-ensemble context; see “Regularize Discriminant Analysis Classifier” on page 20-21.)

The `regularize` method finds an optimal set of learner weights α_t that minimize

$$\sum_{n=1}^{N} w_n g\left(\left(\sum_{t=1}^{T} \alpha_t h_t(x_n)\right), y_n\right) + \lambda \sum_{t=1}^{T} |\alpha_t| .$$

Here

- $\lambda \geq 0$ is a parameter you provide, called the lasso parameter.
- h_t is a weak learner in the ensemble trained on N observations with predictors x_n, responses y_n, and weights w_n.
- $g(f,y) = (f - y)^2$ is the squared error.

The ensemble is regularized on the same (x_n,y_n,w_n) data used for training, so

$$\sum_{n=1}^{N} w_n g\left(\left(\sum_{t=1}^{T} \alpha_t h_t(x_n)\right), y_n\right)$$

is the ensemble resubstitution error. The error is measured by mean squared error (MSE).

If you use $\lambda = 0$, `regularize` finds the weak learner weights by minimizing the resubstitution MSE. Ensembles tend to overtrain. In other words, the resubstitution error is typically smaller than the true generalization error. By making the resubstitution error even smaller, you are likely to make the ensemble accuracy worse instead of improving it. On the other hand, positive values of λ push the magnitude of the α_t coefficients to 0. This often improves the generalization error. Of course, if you choose λ too large, all the optimal coefficients are 0, and the ensemble does not have any accuracy. Usually you can find an optimal range for λ in which the accuracy of the regularized ensemble is better or comparable to that of the full ensemble without regularization.

A nice feature of lasso regularization is its ability to drive the optimized coefficients precisely to 0. If a learner's weight α_t is 0, this learner can be excluded from the regularized ensemble. In the end, you get an ensemble with improved accuracy and fewer learners.

Regularize a Regression Ensemble

This example uses data for predicting the insurance risk of a car based on its many attributes.

Load the `imports-85` data into the MATLAB workspace.

```
load imports-85;
```

Look at a description of the data to find the categorical variables and predictor names.

```
Description
```

```
Description = 9x79 char array
    '1985 Auto Imports Database from the UCI repository                          '
    'http://archive.ics.uci.edu/ml/machine-learning-databases/autos/imports-85.names'
    'Variables have been reordered to place variables with numeric values (referred '
    'to as "continuous" on the UCI site) to the left and categorical values to the  '
    'right. Specifically, variables 1:16 are: symboling, normalized-losses,          '
    'wheel-base, length, width, height, curb-weight, engine-size, bore, stroke,      '
    'compression-ratio, horsepower, peak-rpm, city-mpg, highway-mpg, and price.      '
    'Variables 17:26 are: make, fuel-type, aspiration, num-of-doors, body-style,     '
    'drive-wheels, engine-location, engine-type, num-of-cylinders, and fuel-system. '
```

The objective of this process is to predict the "symboling," the first variable in the data, from the other predictors. "symboling" is an integer from `-3` (good insurance risk) to `3` (poor insurance risk). You could use a classification ensemble to predict this risk instead of a regression ensemble. When you have a choice between regression and classification, you should try regression first.

Prepare the data for ensemble fitting.

```
Y = X(:,1);
X(:,1) = [];
VarNames = {'normalized-losses' 'wheel-base' 'length' 'width' 'height' ...
  'curb-weight' 'engine-size' 'bore' 'stroke' 'compression-ratio' ...
  'horsepower' 'peak-rpm' 'city-mpg' 'highway-mpg' 'price' 'make' ...
  'fuel-type' 'aspiration' 'num-of-doors' 'body-style' 'drive-wheels' ...
  'engine-location' 'engine-type' 'num-of-cylinders' 'fuel-system'};
catidx = 16:25; % indices of categorical predictors
```

Create a regression ensemble from the data using 300 trees.

```
ls = fitrensemble(X,Y,'Method','LSBoost','NumLearningCycles',300, ...
    'LearnRate',0.1,'PredictorNames',VarNames, ...
    'ResponseName','Symboling','CategoricalPredictors',catidx)
```

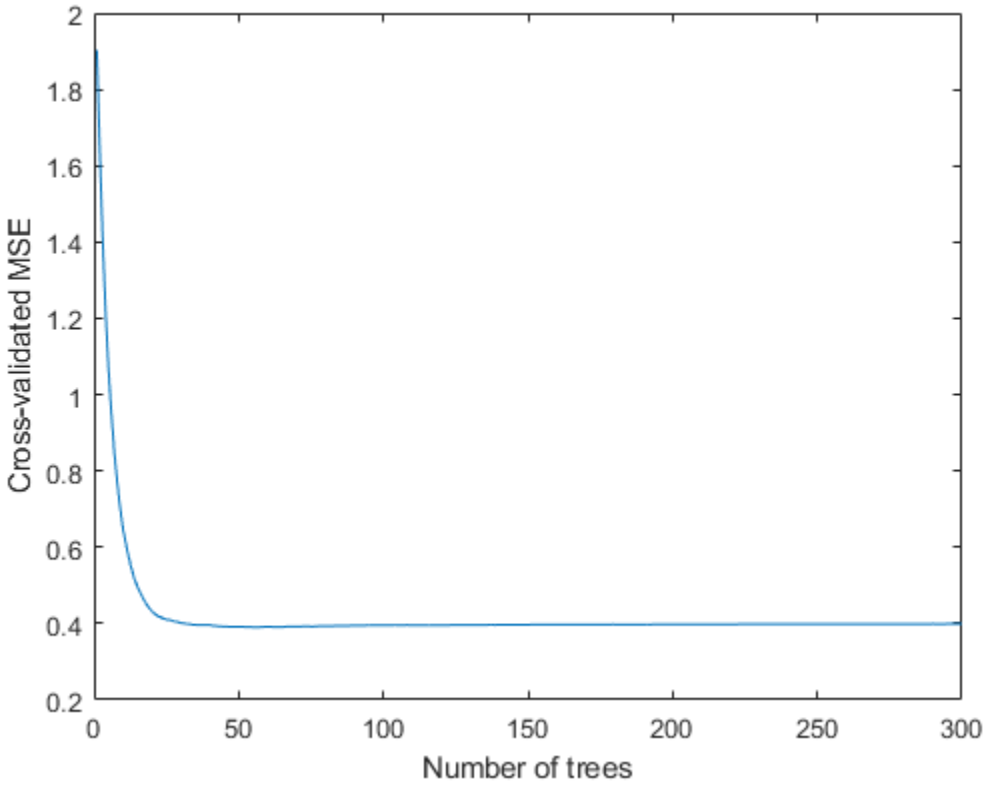
```
ls =
  RegressionEnsemble
            PredictorNames: {1x25 cell}
              ResponseName: 'Symboling'
    CategoricalPredictors: [16 17 18 19 20 21 22 23 24 25]
        ResponseTransform: 'none'
          NumObservations: 205
                NumTrained: 300
                    Method: 'LSBoost'
             LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: [300x1 double]
       FitInfoDescription: {2x1 cell}
           Regularization: []

  Properties, Methods
```

The final line, `Regularization`, is empty ([]). To regularize the ensemble, you have to use the `regularize` method.

```
cv = crossval(ls,'KFold',5);
figure;
```

```
plot(kfoldLoss(cv,'Mode','Cumulative'));
xlabel('Number of trees');
ylabel('Cross-validated MSE');
ylim([0.2,2])
```



It appears you might obtain satisfactory performance from a smaller ensemble, perhaps one containing from 50 to 100 trees.

Call the `regularize` method to try to find trees that you can remove from the ensemble. By default, `regularize` examines 10 values of the lasso (`Lambda`) parameter spaced exponentially.

```
ls = regularize(ls)
```

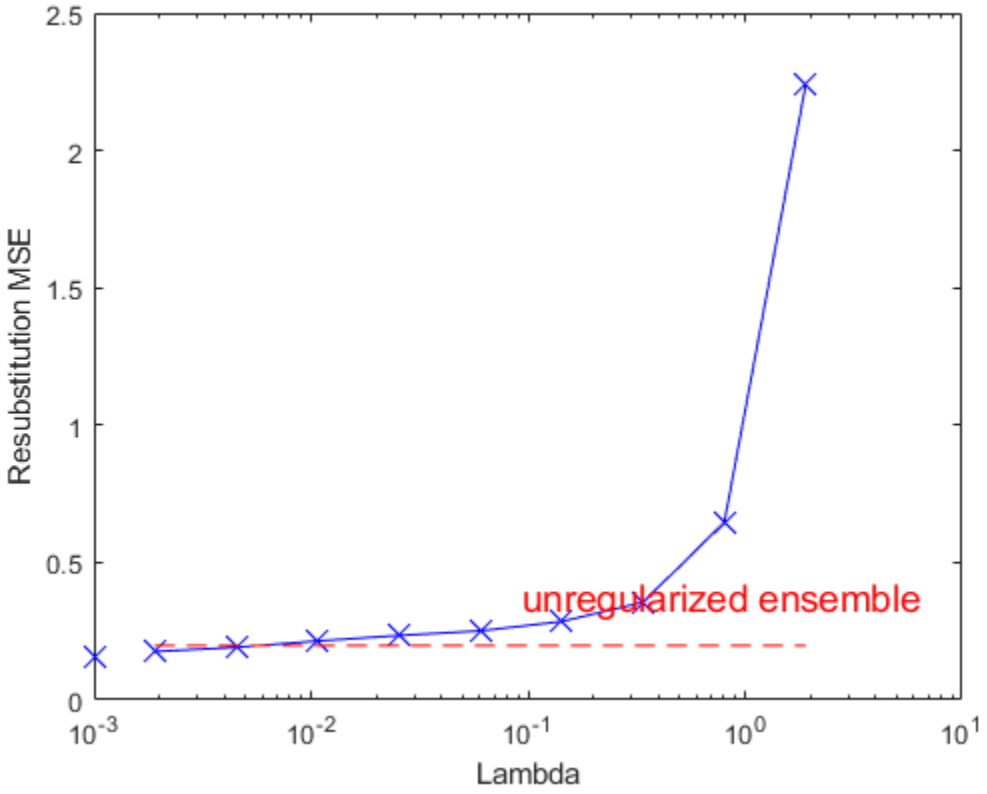
```
ls =
  RegressionEnsemble
            PredictorNames: {1x25 cell}
              ResponseName: 'Symboling'
    CategoricalPredictors: [16 17 18 19 20 21 22 23 24 25]
        ResponseTransform: 'none'
          NumObservations: 205
               NumTrained: 300
                   Method: 'LSBoost'
             LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: [300x1 double]
       FitInfoDescription: {2x1 cell}
           Regularization: [1x1 struct]
```

```
  Properties, Methods
```

The `Regularization` property is no longer empty.

Plot the resubstitution mean-squared error (MSE) and number of learners with nonzero weights against the lasso parameter. Separately plot the value at `Lambda = 0`. Use a logarithmic scale because the values of `Lambda` are exponentially spaced.

```
figure;
semilogx(ls.Regularization.Lambda,ls.Regularization.ResubstitutionMSE, ...
    'bx-','Markersize',10);
line([1e-3 1e-3],[ls.Regularization.ResubstitutionMSE(1) ...
     ls.Regularization.ResubstitutionMSE(1)],...
    'Marker','x','Markersize',10,'Color','b');
r0 = resubLoss(ls);
line([ls.Regularization.Lambda(2) ls.Regularization.Lambda(end)],...
     [r0 r0],'Color','r','LineStyle','--');
xlabel('Lambda');
ylabel('Resubstitution MSE');
annotation('textbox',[0.5 0.22 0.5 0.05],'String','unregularized ensemble', ...
    'Color','r','FontSize',14,'LineStyle','none');
```



```
figure;
loglog(ls.Regularization.Lambda,sum(ls.Regularization.TrainedWeights>0,1));
line([1e-3 1e-3],...
```

```
    [sum(ls.Regularization.TrainedWeights(:,1)>0) ...
    sum(ls.Regularization.TrainedWeights(:,1)>0)],...
    'marker','x','markersize',10,'color','b');
line([ls.Regularization.Lambda(2) ls.Regularization.Lambda(end)],...
    [ls.NTrained ls.NTrained],...
    'color','r','LineStyle','--');

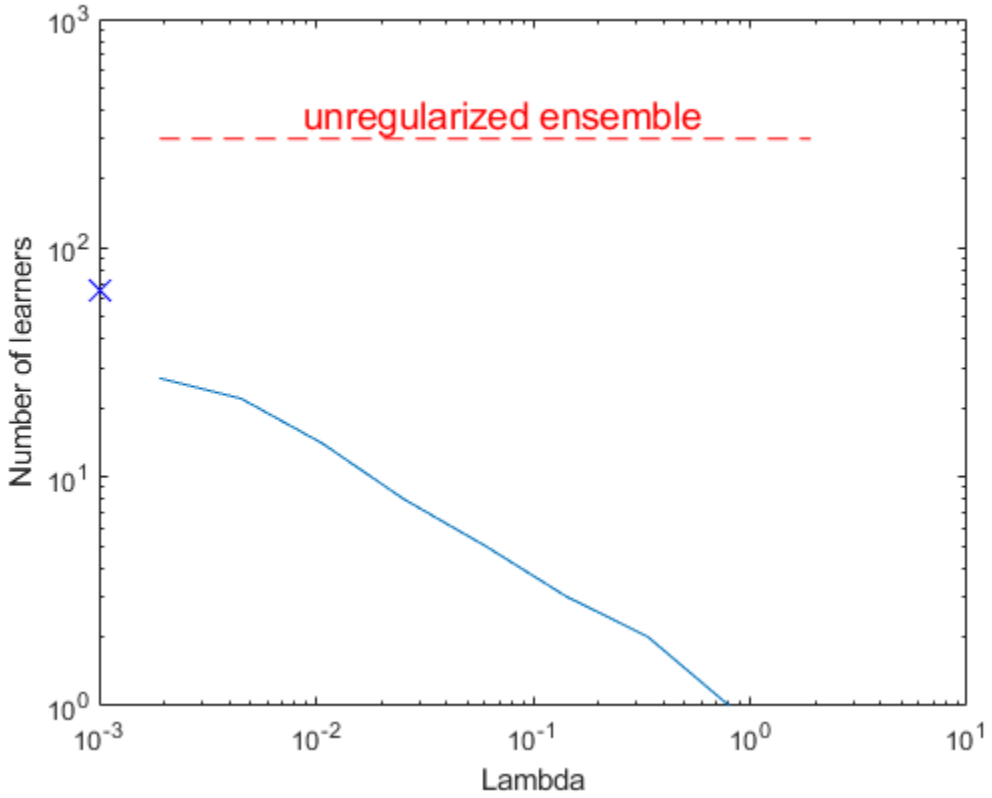
annotation('textbox',[0.3 0.8 0.5 0.05],'String','unregularized ensemble',...
    'color','r','FontSize',14,'LineStyle','none');
```



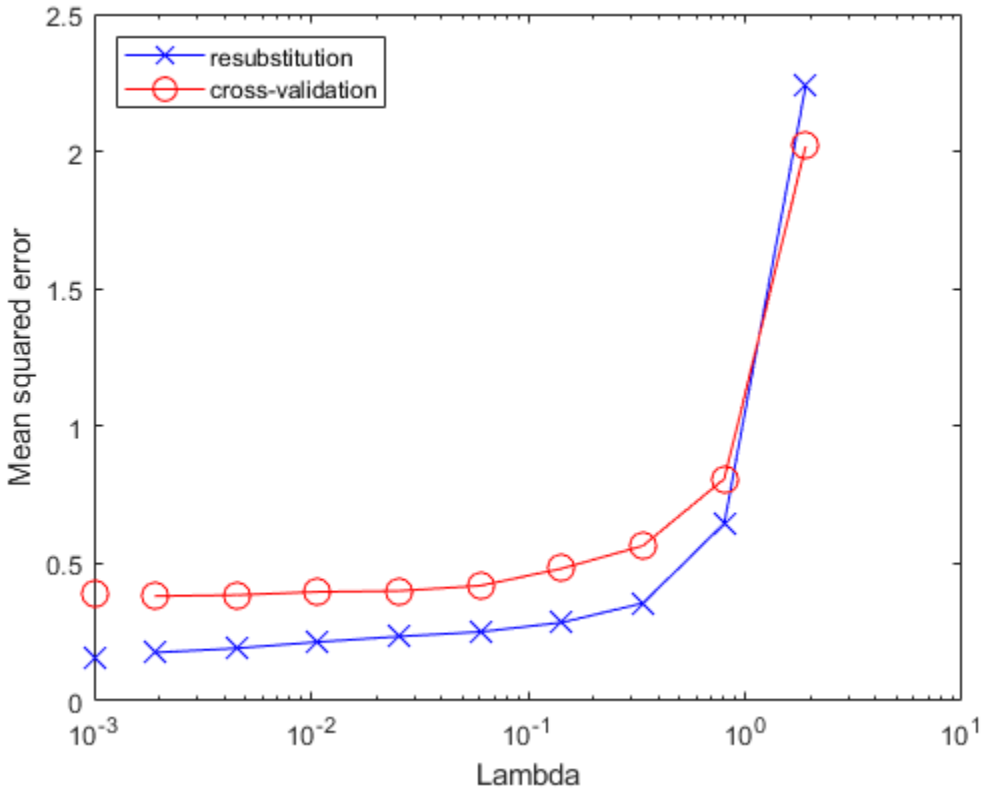
The resubstitution MSE values are likely to be overly optimistic. To obtain more reliable estimates of the error associated with various values of `Lambda`, cross validate the ensemble using `cvshrink`. Plot the resulting cross-validation loss (MSE) and number of learners against `Lambda`.

```
rng(0,'Twister') % for reproducibility
[mse,nlearn] = cvshrink(ls,'Lambda',ls.Regularization.Lambda,'KFold',5);
```

```
Warning: Some folds do not have any trained weak learners.
```

```
figure;
semilogx(ls.Regularization.Lambda,ls.Regularization.ResubstitutionMSE, ...
    'bx-','Markersize',10);
hold on;
semilogx(ls.Regularization.Lambda,mse,'ro-','Markersize',10);
hold off;
xlabel('Lambda');
```

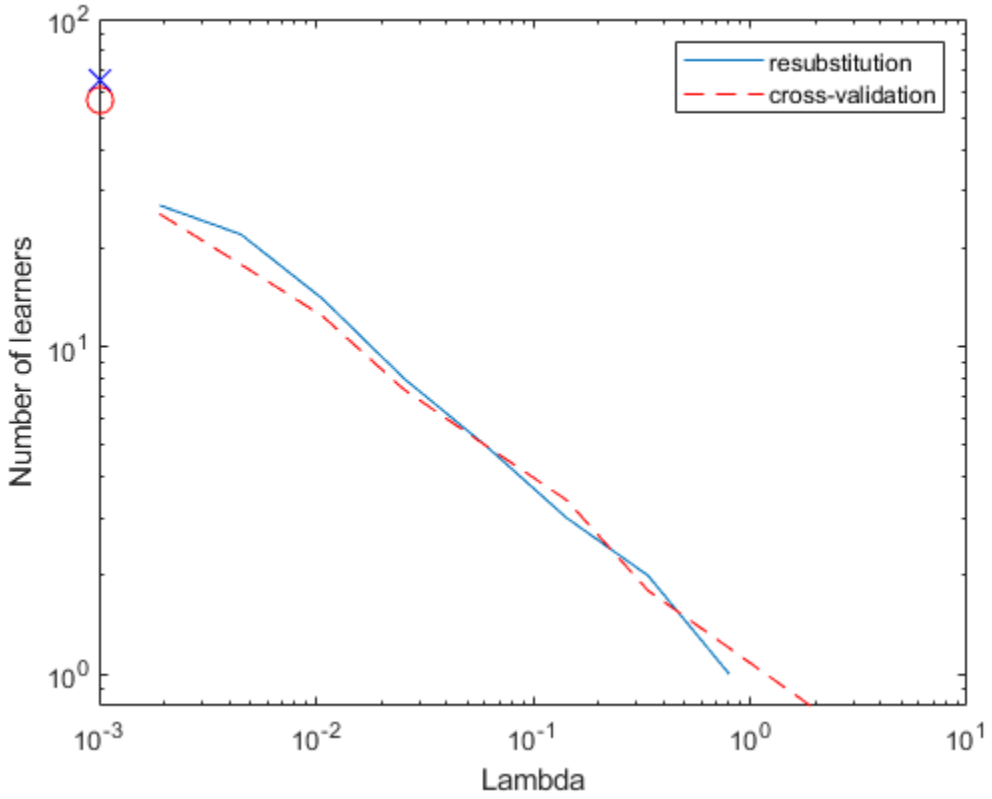
```
ylabel('Mean squared error');
legend('resubstitution','cross-validation','Location','NW');
line([1e-3 1e-3],[ls.Regularization.ResubstitutionMSE(1) ...
     ls.Regularization.ResubstitutionMSE(1)],...
    'Marker','x','Markersize',10,'Color','b','HandleVisibility','off');
line([1e-3 1e-3],[mse(1) mse(1)],'Marker','o',...
    'Markersize',10,'Color','r','LineStyle','--','HandleVisibility','off');
```



```
figure;
loglog(ls.Regularization.Lambda,sum(ls.Regularization.TrainedWeights>0,1));
hold;
```

```
Current plot held
```

```
loglog(ls.Regularization.Lambda,nlearn,'r--');
hold off;
xlabel('Lambda');
ylabel('Number of learners');
legend('resubstitution','cross-validation','Location','NE');
line([1e-3 1e-3],...
    [sum(ls.Regularization.TrainedWeights(:,1)>0) ...
    sum(ls.Regularization.TrainedWeights(:,1)>0)],...
    'Marker','x','Markersize',10,'Color','b','HandleVisibility','off');
line([1e-3 1e-3],[nlearn(1) nlearn(1)],'marker','o',...
    'Markersize',10,'Color','r','LineStyle','--','HandleVisibility','off');
```



Examining the cross-validated error shows that the cross-validation MSE is almost flat for `Lambda` up to a bit over `1e-2`.

Examine `ls.Regularization.Lambda` to find the highest value that gives MSE in the flat region (up to a bit over `1e-2`).

```
jj = 1:length(ls.Regularization.Lambda);
[jj;ls.Regularization.Lambda]
```

```
ans = 2×10

    1.0000    2.0000    3.0000    4.0000    5.0000    6.0000    7.0000    8.0000    9.0000   10.0
         0    0.0019    0.0045    0.0107    0.0254    0.0602    0.1428    0.3387    0.8033    1.9
```

Element `5` of `ls.Regularization.Lambda` has value `0.0254`, the largest in the flat range.

Reduce the ensemble size using the `shrink` method. `shrink` returns a compact ensemble with no training data. The generalization error for the new compact ensemble was already estimated by cross validation in `mse(5)`.

```
cmp = shrink(ls,'weightcolumn',5)
```

```
cmp =
  CompactRegressionEnsemble
            PredictorNames: {1x25 cell}
              ResponseName: 'Symboling'
    CategoricalPredictors: [16 17 18 19 20 21 22 23 24 25]
```

```
        ResponseTransform: 'none'
                NumTrained: 8

  Properties, Methods
```

The number of trees in the new ensemble has notably reduced from the 300 in `ls`.

Compare the sizes of the ensembles.

```
sz(1) = whos('cmp'); sz(2) = whos('ls');
[sz(1).bytes sz(2).bytes]
```

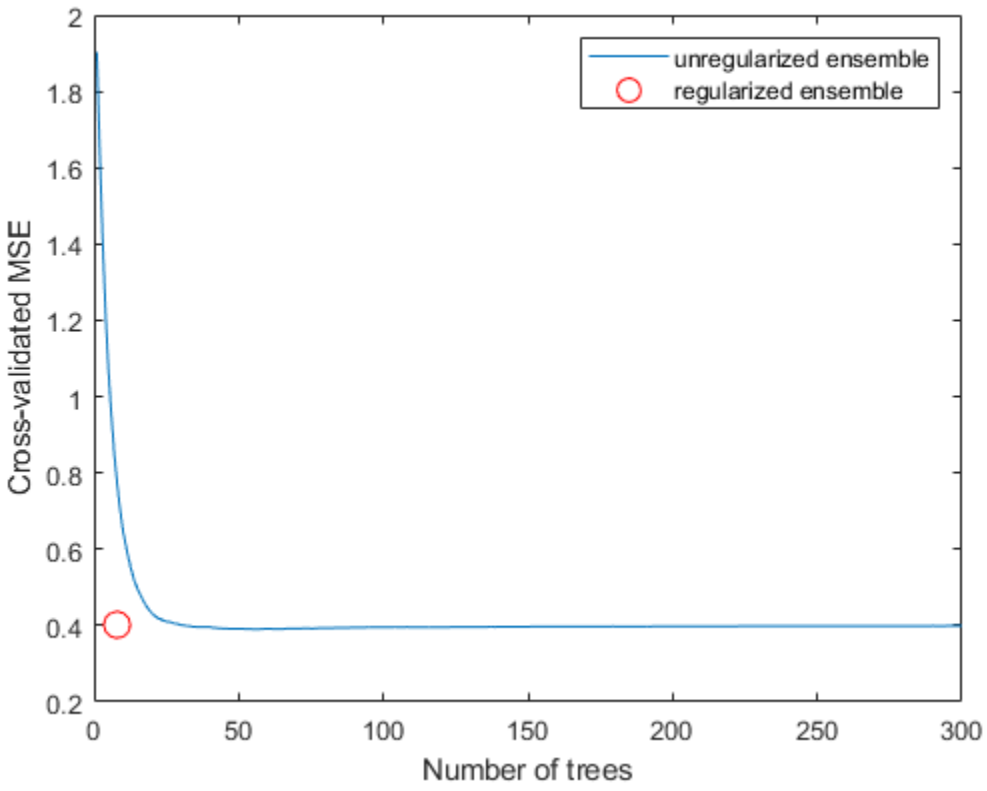
```
ans = 1×2

       91209     3226892
```

The size of the reduced ensemble is a fraction of the size of the original. Note that your ensemble sizes can vary depending on your operating system.

Compare the MSE of the reduced ensemble to that of the original ensemble.

```
figure;
plot(kfoldLoss(cv,'mode','cumulative'));
hold on
plot(cmp.NTrained,mse(5),'ro','MarkerSize',10);
xlabel('Number of trees');
ylabel('Cross-validated MSE');
legend('unregularized ensemble','regularized ensemble',...
    'Location','NE');
hold off
```



The reduced ensemble gives low loss while using many fewer trees.

Classification with Imbalanced Data

This example shows how to perform classification when one class has many more observations than another. You use the `RUSBoost` algorithm first, because it is designed to handle this case. Another way to handle imbalanced data is to use the name-value pair arguments `'Prior'` or `'Cost'`. For details, see “Handle Imbalanced Data or Unequal Misclassification Costs in Classification Ensembles” on page 18-84.

This example uses the "Cover type" data from the UCI machine learning archive, described in https://archive.ics.uci.edu/ml/datasets/Covertype. The data classifies types of forest (ground cover), based on predictors such as elevation, soil type, and distance to water. The data has over 500,000 observations and over 50 predictors, so training and using a classifier is time consuming.

Blackard and Dean [1] describe a neural net classification of this data. They quote a 70.6% classification accuracy. `RUSBoost` obtains over 81% classification accuracy.

Obtain the data

Import the data into your workspace. Extract the last data column into a variable named `Y`.

```
gunzip('https://archive.ics.uci.edu/ml/machine-learning-databases/covtype/covtype.data.gz')
load covtype.data
Y = covtype(:,end);
covtype(:,end) = [];
```

Examine the response data

```
tabulate(Y)
```

```
  Value    Count   Percent
      1   211840     36.46%
      2   283301     48.76%
      3    35754      6.15%
      4     2747      0.47%
      5     9493      1.63%
      6    17367      2.99%
      7    20510      3.53%
```

There are hundreds of thousands of data points. Those of class 4 are less than 0.5% of the total. This imbalance indicates that `RUSBoost` is an appropriate algorithm.

Partition the data for quality assessment

Use half the data to fit a classifier, and half to examine the quality of the resulting classifier.

```
rng(10,'twister')         % For reproducibility
part = cvpartition(Y,'Holdout',0.5);
istrain = training(part); % Data for fitting
istest = test(part);      % Data for quality assessment
tabulate(Y(istrain))
```

```
  Value    Count   Percent
      1   105919     36.46%
      2   141651     48.76%
      3    17877      6.15%
      4     1374      0.47%
      5     4747      1.63%
```

```
      6     8684      2.99%
      7    10254      3.53%
```

Create the ensemble

Use deep trees for higher ensemble accuracy. To do so, set the trees to have maximal number of decision splits of `N`, where `N` is the number of observations in the training sample. Set `LearnRate` to `0.1` in order to achieve higher accuracy as well. The data is large, and, with deep trees, creating the ensemble is time consuming.

```
N = sum(istrain);         % Number of observations in the training sample
t = templateTree('MaxNumSplits',N);
tic
rusTree = fitcensemble(covtype(istrain,:),Y(istrain),'Method','RUSBoost', ...
    'NumLearningCycles',1000,'Learners',t,'LearnRate',0.1,'nprint',100);
```

```
Training RUSBoost...
Grown weak learners: 100
Grown weak learners: 200
Grown weak learners: 300
Grown weak learners: 400
Grown weak learners: 500
Grown weak learners: 600
Grown weak learners: 700
Grown weak learners: 800
Grown weak learners: 900
Grown weak learners: 1000
```

```
toc
```

```
Elapsed time is 242.836734 seconds.
```

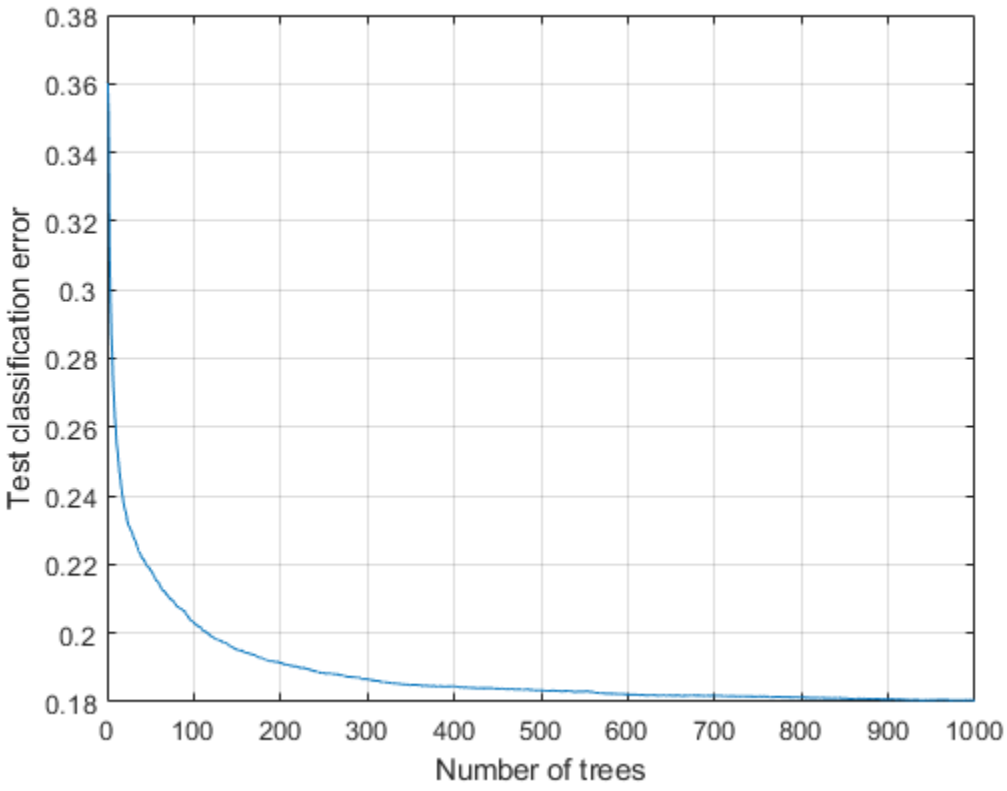
Inspect the classification error

Plot the classification error against the number of members in the ensemble.

```
figure;
tic
plot(loss(rusTree,covtype(istest,:),Y(istest),'mode','cumulative'));
toc
```

```
Elapsed time is 164.470086 seconds.
```

```
grid on;
xlabel('Number of trees');
ylabel('Test classification error');
```



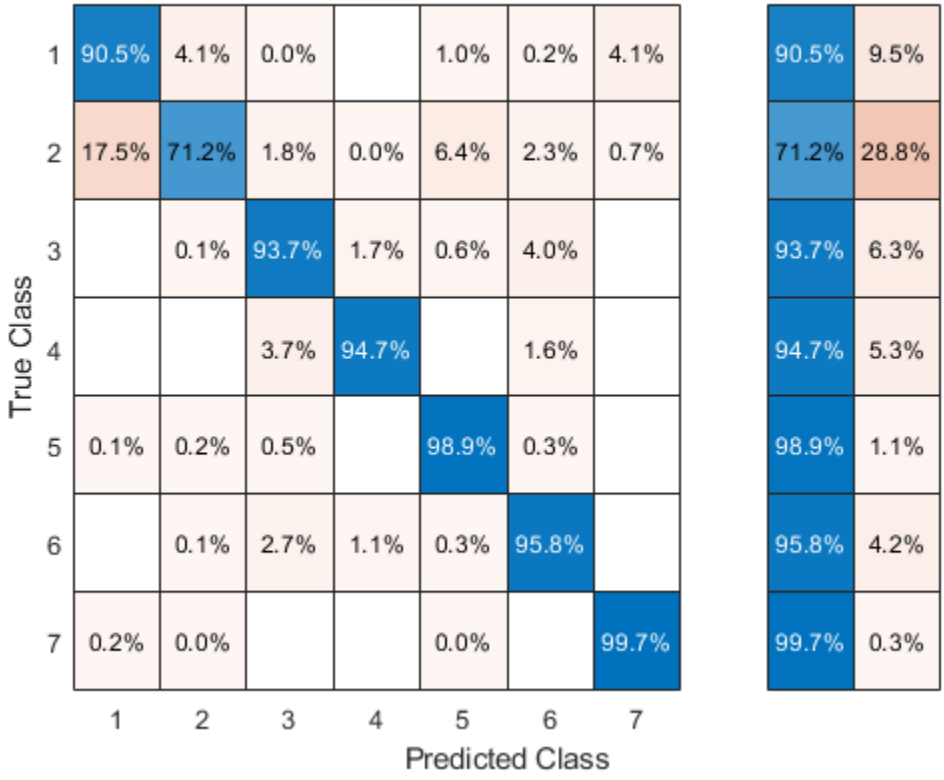
The ensemble achieves a classification error of under 20% using 116 or more trees. For 500 or more trees, the classification error decreases at a slower rate.

Examine the confusion matrix for each class as a percentage of the true class.

```
tic
Yfit = predict(rusTree,covtype(istest,:));
toc
```

```
Elapsed time is 132.353489 seconds.
```

```
confusionchart(Y(istest),Yfit,'Normalization','row-normalized','RowSummary','row-normalized')
```



All classes except class 2 have over 90% classification accuracy. But class 2 makes up close to half the data, so the overall accuracy is not that high.

Compact the ensemble

The ensemble is large. Remove the data using the `compact` method.

```
cmpctRus = compact(rusTree);

sz(1) = whos('rusTree');
sz(2) = whos('cmpctRus');
[sz(1).bytes sz(2).bytes]
```

```
ans = 1×2
10^9 ×

    1.6579    0.9423
```

The compacted ensemble is about half the size of the original.

Remove half the trees from `cmpctRus`. This action is likely to have minimal effect on the predictive performance, based on the observation that 500 out of 1000 trees give nearly optimal accuracy.

```
cmpctRus = removeLearners(cmpctRus,[500:1000]);

sz(3) = whos('cmpctRus');
sz(3).bytes
```

```
ans = 452868660
```

The reduced compact ensemble takes about a quarter of the memory of the full ensemble. Its overall loss rate is under 19%:

```
L = loss(cmpctRus,covtype(istest,:),Y(istest))
```

```
L = 0.1833
```

The predictive accuracy on new data might differ, because the ensemble accuracy might be biased. The bias arises because the same data used for assessing the ensemble was used for reducing the ensemble size. To obtain an unbiased estimate of requisite ensemble size, you should use cross validation. However, that procedure is time consuming.

Handle Imbalanced Data or Unequal Misclassification Costs in Classification Ensembles

In many applications, you might prefer to treat classes in your data asymmetrically. For example, the data might have many more observations of one class than any other. Or misclassifying observations of one class has more severe consequences than misclassifying observations of another class. In such situations, you can either use the RUSBoost algorithm (specify `'Method'` as `'RUSBoost'`) or use the name-value pair argument `'Prior'` or `'Cost'` of `fitcensemble`.

If some classes are underrepresented or overrepresented in your training set, use either the `'Prior'` name-value pair argument or the RUSBoost algorithm. For example, suppose you obtain your training data by simulation. Because simulating class `A` is more expensive than simulating class `B`, you choose to generate fewer observations of class `A` and more observations of class `B`. The expectation, however, is that class `A` and class `B` are mixed in a different proportion in real (nonsimulated) situations. In this case, use `'Prior'` to set prior probabilities for class `A` and `B` approximately to the values you expect to observe in a real situation. The `fitcensemble` function normalizes prior probabilities to make them add up to `1`. Multiplying all prior probabilities by the same positive factor does not affect the result of classification. Another way to handle imbalanced data is to use the `RUSBoost` algorithm (`'Method','RUSBoost'`). You do not need to adjust the prior probabilities when using this algorithm. For details, see “Random Undersampling Boosting” on page 18-51 and “Classification with Imbalanced Data” on page 18-79.

If classes are adequately represented in the training data but you want to treat them asymmetrically, use the `'Cost'` name-value pair argument. Suppose you want to classify benign and malignant tumors in cancer patients. Failure to identify a malignant tumor (false negative) has far more severe consequences than misidentifying benign as malignant (false positive). You should assign high cost to misidentifying malignant as benign and low cost to misidentifying benign as malignant.

You must pass misclassification costs as a square matrix with nonnegative elements. Element `C(i,j)` of this matrix is the cost of classifying an observation into class `j` if the true class is `i`. The diagonal elements `C(i,i)` of the cost matrix must be `0`. For the previous example, you can choose malignant tumor to be class 1 and benign tumor to be class 2. Then you can set the cost matrix to

$$\begin{bmatrix} 0 & c \\ 1 & 0 \end{bmatrix}$$

where $c > 1$ is the cost of misidentifying a malignant tumor as benign. Costs are relative—multiplying all costs by the same positive factor does not affect the result of classification.

If you have only two classes, `fitcensemble` adjusts their prior probabilities using $\tilde{P}_i = C_{ij}P_i$ for class $i = 1,2$ and $j \neq i$. P_i are prior probabilities either passed into `fitcensemble` or computed from class frequencies in the training data, and $\tilde{P}_i$ are adjusted prior probabilities. Then `fitcensemble` uses the default cost matrix

$$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

and these adjusted probabilities for training its weak learners. Manipulating the cost matrix is thus equivalent to manipulating the prior probabilities.

If you have three or more classes, `fitcensemble` also converts input costs into adjusted prior probabilities. This conversion is more complex. First, `fitcensemble` attempts to solve a matrix

equation described in Zhou and Liu [1]. If it fails to find a solution, `fitcensemble` applies the "average cost" adjustment described in Breiman et al. [2]. For more information, see Zadrozny, Langford, and Abe [3].

Train Ensemble With Unequal Classification Costs

This example shows how to train an ensemble of classification trees with unequal classification costs. This example uses data on patients with hepatitis to see if they live or die as a result of the disease. The data set is described at UCI Machine Learning Data Repository.

Read the hepatitis data set from the UCI repository as a character array. Then convert the result to a cell array of character vectors using `textscan`. Specify a cell array of character vectors containing the variable names.

```
options = weboptions('ContentType','text');
hepatitis = textscan(webread(['http://archive.ics.uci.edu/ml/' ...
    'machine-learning-databases/hepatitis/hepatitis.data'],options),...
    '%f%f%f%f%f%f%f%f%f%f%f%f%f%f%f%f%f%f%f%f','Delimiter',',',...
    'EndOfLine','\n','TreatAsEmpty','?');
size(hepatitis)
```

```
ans = 1×2

     1    20
```

```
VarNames = {'dieOrLive' 'age' 'sex' 'steroid' 'antivirals' 'fatigue' ...
    'malaise' 'anorexia' 'liverBig' 'liverFirm' 'spleen' ...
    'spiders' 'ascites' 'varices' 'bilirubin' 'alkPhosphate' 'sgot' ...
    'albumin' 'protime' 'histology'};
```

`hepatitis` is a 1-by-20 cell array of character vectors. The cells correspond to the response (`liveOrDie`) and 19 heterogeneous predictors.

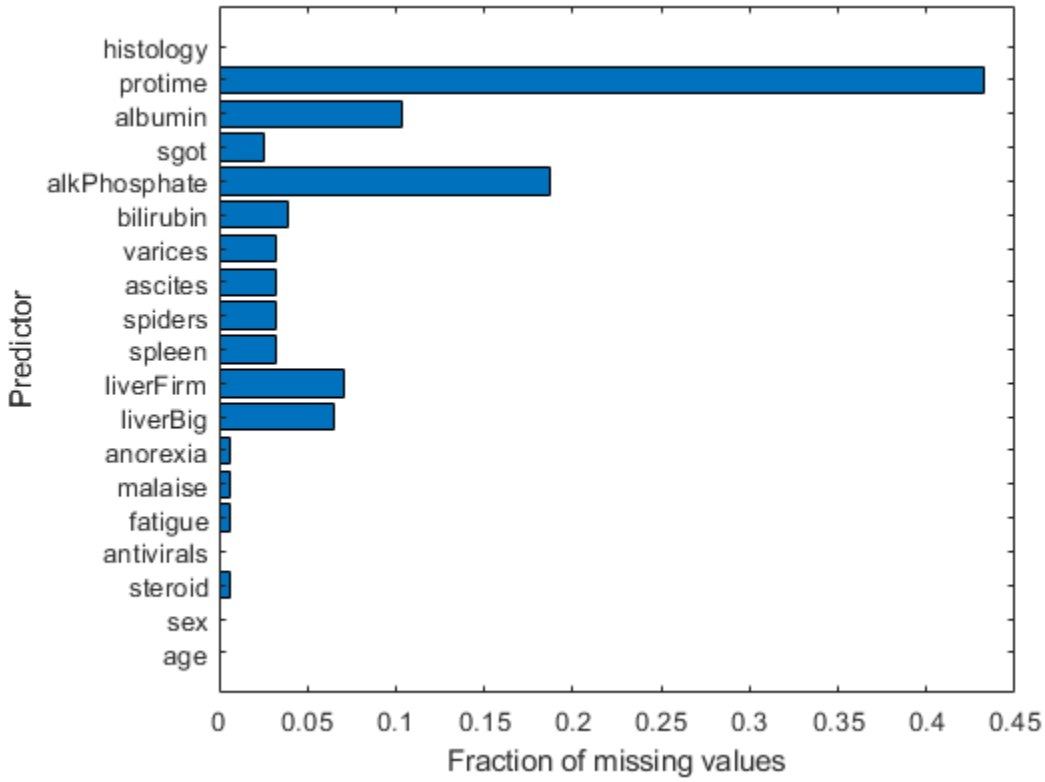
Specify a numeric matrix containing the predictors and a cell vector containing `'Die'` and `'Live'`, which are response categories. The response contains two values: `1` indicates that a patient died, and `2` indicates that a patient lived. Specify a cell array of character vectors for the response using the response categories. The first variable in `hepatitis` contains the response.

```
X = cell2mat(hepatitis(2:end));
ClassNames = {'Die' 'Live'};
Y = ClassNames(hepatitis{:,1});
```

`X` is a numeric matrix containing the 19 predictors. `Y` is a cell array of character vectors containing the response.

Inspect the data for missing values.

```
figure
barh(sum(isnan(X),1)/size(X,1))
h = gca;
h.YTick = 1:numel(VarNames) - 1;
h.YTickLabel = VarNames(2:end);
ylabel('Predictor')
xlabel('Fraction of missing values')
```



Most predictors have missing values, and one has nearly 45% of the missing values. Therefore, use decision trees with surrogate splits for better accuracy. Because the data set is small, training time with surrogate splits should be tolerable.

Create a classification tree template that uses surrogate splits.

```
rng(0,'twister') % For reproducibility
t = templateTree('surrogate','all');
```

Examine the data or the description of the data to see which predictors are categorical.

```
X(1:5,:)
```

```
ans = 5×19

   30.0000    2.0000    1.0000    2.0000    2.0000    2.0000    2.0000    1.0000    2.0000    2.0
   50.0000    1.0000    1.0000    2.0000    1.0000    2.0000    2.0000    1.0000    2.0000    2.0
   78.0000    1.0000    2.0000    2.0000    1.0000    2.0000    2.0000    2.0000    2.0000    2.0
   31.0000    1.0000       NaN    1.0000    2.0000    2.0000    2.0000    2.0000    2.0000    2.0
   34.0000    1.0000    2.0000    2.0000    2.0000    2.0000    2.0000    2.0000    2.0000    2.0
```

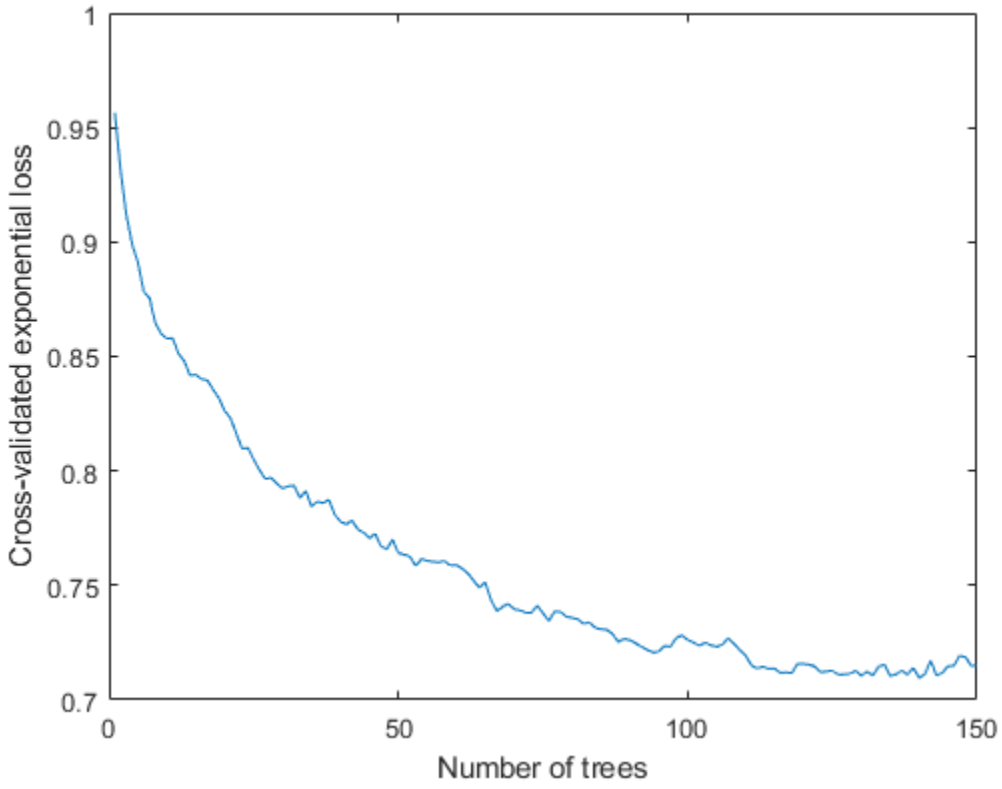
It appears that predictors 2 through 13 are categorical, as well as predictor 19. You can confirm this inference using the data set description at UCI Machine Learning Data Repository.

List the categorical variables.

```
catIdx = [2:13,19];
```

Create a cross-validated ensemble using 150 learners and the `GentleBoost` algorithm.

```
Ensemble = fitcensemble(X,Y,'Method','GentleBoost', ...
    'NumLearningCycles',150,'Learners',t,'PredictorNames',VarNames(2:end), ...
    'LearnRate',0.1,'CategoricalPredictors',catIdx,'KFold',5);
figure
plot(kfoldLoss(Ensemble,'Mode','cumulative','LossFun','exponential'))
xlabel('Number of trees')
ylabel('Cross-validated exponential loss')
```



Inspect the confusion matrix to see which patients the ensemble predicts correctly.

```
[yFit,sFit] = kfoldPredict(Ensemble);
confusionchart(Y,yFit)
```

Of the 123 patient who live, the ensemble predicts correctly that 112 will live. But for the 32 patients who die of hepatitis, the ensemble only predicts correctly that about half will die of hepatitis.

There are two types of error in the predictions of the ensemble:

- Predicting that the patient lives, but the patient dies
- Predicting that the patient dies, but the patient lives

Suppose you believe that the first error is five times worse than the second. Create a new classification cost matrix that reflects this belief.

```
cost.ClassNames = ClassNames;
cost.ClassificationCosts = [0 5; 1 0];
```

Create a new cross-validated ensemble using `cost` as the misclassification cost, and inspect the resulting confusion matrix.

```
EnsembleCost = fitcensemble(X,Y,'Method','GentleBoost', ...
    'NumLearningCycles',150,'Learners',t,'PredictorNames',VarNames(2:end), ...
    'LearnRate',0.1,'CategoricalPredictors',catIdx,'KFold',5,'Cost',cost);
[yFitCost,sFitCost] = kfoldPredict(EnsembleCost);
confusionchart(Y,yFitCost)
```

As expected, the new ensemble does a better job classifying the patients who die. Somewhat surprisingly, the new ensemble also does a better job classifying the patients who live, though the result is not statistically significantly better. The results of the cross validation are random, so this result is simply a statistical fluctuation. The result seems to indicate that the classification of patients who live is not very sensitive to the cost.

Related Examples

- “Surrogate Splits” on page 18-91

Surrogate Splits

When the value of the optimal split predictor for an observation is missing, if you specify to use surrogate splits, the software sends the observation to the left or right child node using the best surrogate predictor. When you have missing data, trees and ensembles of trees with surrogate splits give better predictions. This example shows how to improve the accuracy of predictions for data with missing values by using decision trees with surrogate splits.

Load Sample Data

Load the `ionosphere` data set.

```
load ionosphere
```

Partition the data set into training and test sets. Hold out 30% of the data for testing.

```
rng('default') % For reproducibility
cv = cvpartition(Y,'Holdout',0.3);
```

Identify the training and testing data.

```
Xtrain = X(training(cv),:);
Ytrain = Y(training(cv));
Xtest = X(test(cv),:);
Ytest = Y(test(cv));
```

Suppose half of the values in the test set are missing. Set half of the values in the test set to `NaN`.

```
Xtest(rand(size(Xtest))>0.5) = NaN;
```

Train Random Forest

Train a random forest of 150 classification trees without surrogate splits.

```
templ = templateTree('Reproducible',true);  % For reproducibility of random predictor selections
Mdl = fitcensemble(Xtrain,Ytrain,'Method','Bag','NumLearningCycles',150,'Learners',templ);
```

Create a decision tree template that uses surrogate splits. A tree using surrogate splits does not discard the entire observation when it includes missing data in some predictors.

```
templS = templateTree('Surrogate','On','Reproducible',true);
```

Train a random forest using the template `templS`.

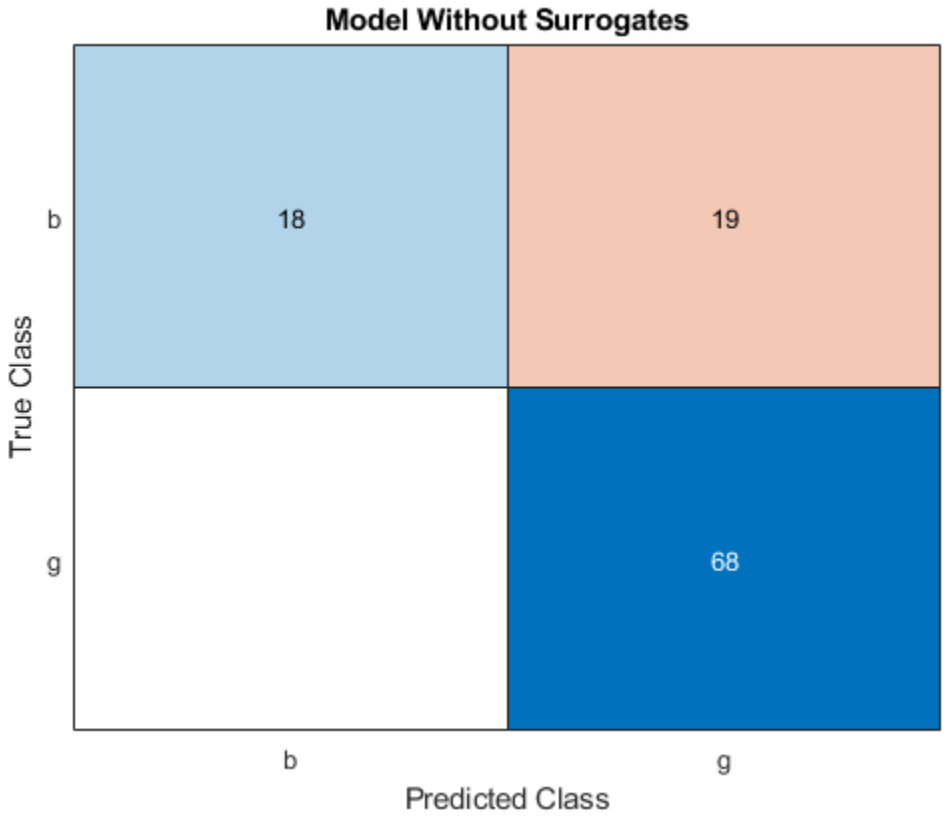
```
Mdls = fitcensemble(Xtrain,Ytrain,'Method','Bag','NumLearningCycles',150,'Learners',templS);
```

Test Accuracy

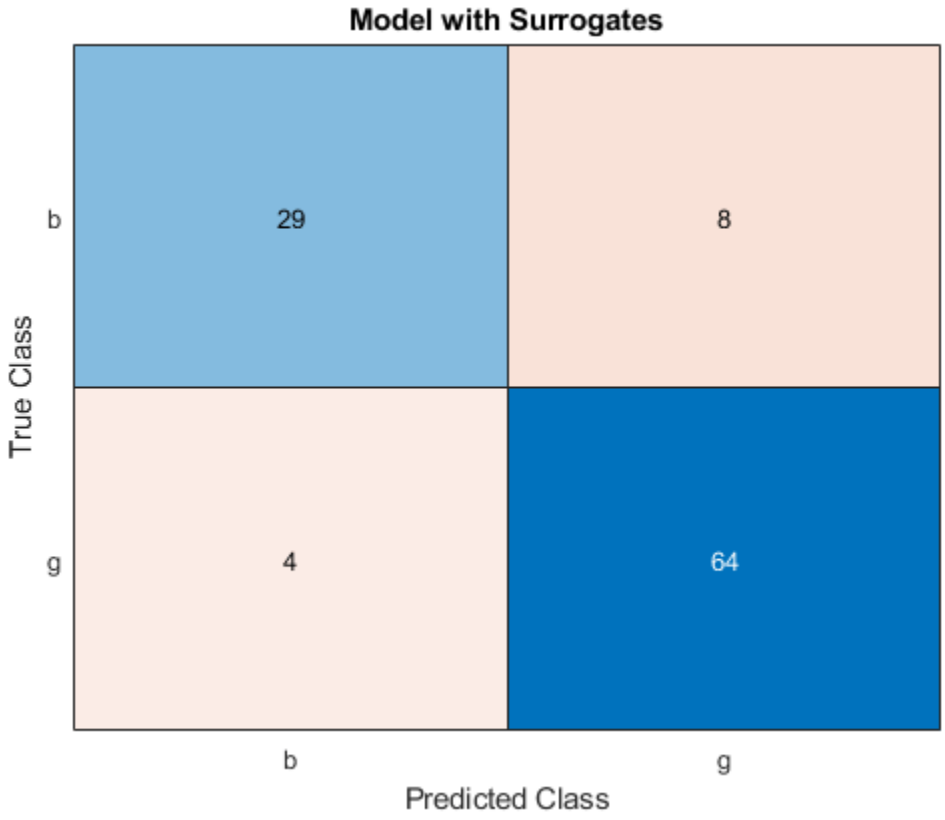
Test the accuracy of predictions with and without surrogate splits.

Predict responses and create confusion matrix charts using both approaches.

```
Ytest_pred = predict(Mdl,Xtest);
figure
cm = confusionchart(Ytest,Ytest_pred);
cm.Title = 'Model Without Surrogates';
```



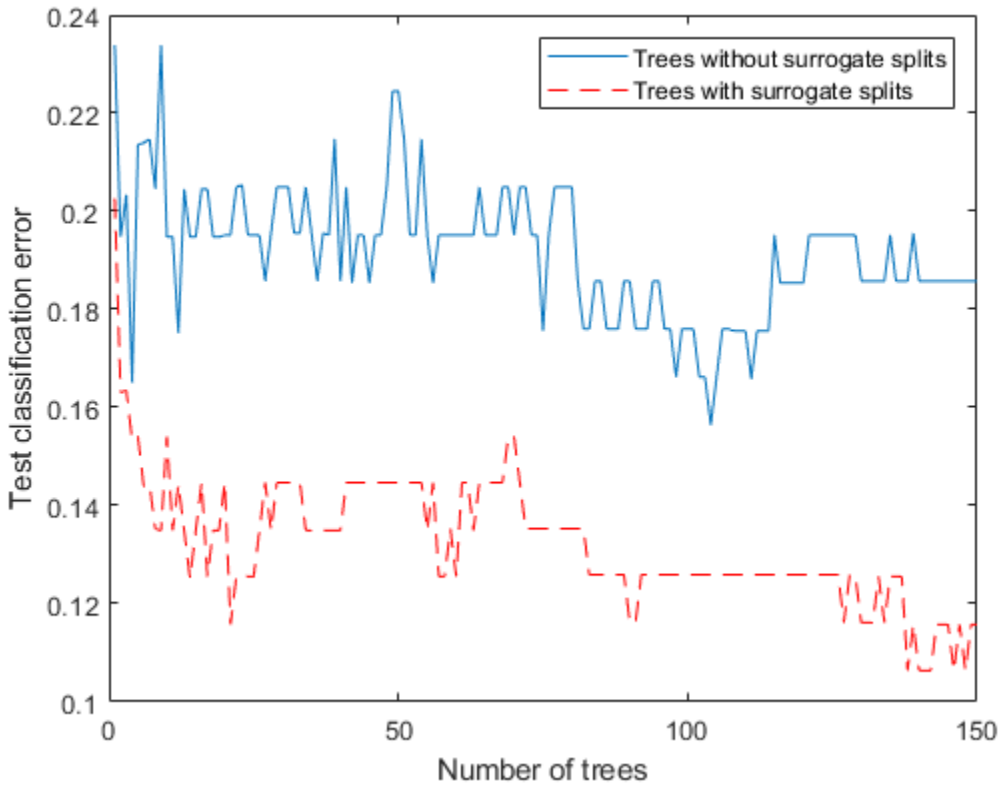
```
Ytest_preds = predict(Mdls,Xtest);
figure
cms = confusionchart(Ytest,Ytest_preds);
cms.Title = 'Model with Surrogates';
```



All off-diagonal elements on the confusion matrix represent misclassified data. A good classifier yields a confusion matrix that looks dominantly diagonal. In this case, the classification error is lower for the model trained with surrogate splits.

Estimate cumulative classification errors. Specify `'Mode','Cumulative'` when estimating classification errors by using the `loss` function. The `loss` function returns a vector in which element `J` indicates the error using the first `J` learners.

```
figure
plot(loss(Mdl,Xtest,Ytest,'Mode','Cumulative'))
hold on
plot(loss(Mdls,Xtest,Ytest,'Mode','Cumulative'),'r--')
legend('Trees without surrogate splits','Trees with surrogate splits')
xlabel('Number of trees')
ylabel('Test classification error')
```



The error value decreases as the number of trees increases, which indicates good performance. The classification error is lower for the model trained with surrogate splits.

Check the statistical significance of the difference in results with by using `compareHoldout`. This function uses the McNemar test.

```
[~,p] = compareHoldout(Mdls,Mdl,Xtest,Xtest,Ytest,'Alternative','greater')
```

```
p = 0.0384
```

The low *p*-value indicates that the ensemble with surrogate splits is better in a statistically significant manner.

Estimate Predictor Importance

Predictor importance estimates can vary depending on whether or not a tree uses surrogate splits. Estimate predictor importance measures by permuting out-of-bag observations. Then, find the five most important predictors.

```
imp = oobPermutedPredictorImportance(Mdl);
[~,ind] = maxk(imp,5)
```

```
ind = 1×5

     5     3    27     8    14
```

```
imps = oobPermutedPredictorImportance(Mdls);
[~,inds] = maxk(imps,5)
```

```
inds = 1×5

     3     5     8    27     7
```

After estimating predictor importance, you can exclude unimportant predictors and train a model again. Eliminating unimportant predictors saves time and memory for predictions, and makes predictions easier to understand.

If the training data includes many predictors and you want to analyze predictor importance, then specify `'NumVariablesToSample'` of the `templateTree` function as `'all'` for the tree learners of the ensemble. Otherwise, the software might not select some predictors, underestimating their importance. For an example, see “Select Predictors for Random Forests” on page 18-60.

LPBoost and TotalBoost for Small Ensembles

This example shows how to obtain the benefits of the `LPBoost` and `TotalBoost` algorithms. These algorithms share two beneficial characteristics:

- They are self-terminating, which means you do not have to figure out how many members to include.
- They produce ensembles with some very small weights, enabling you to safely remove ensemble members.

Load the data

Load the `ionosphere` data set.

```
load ionosphere
```

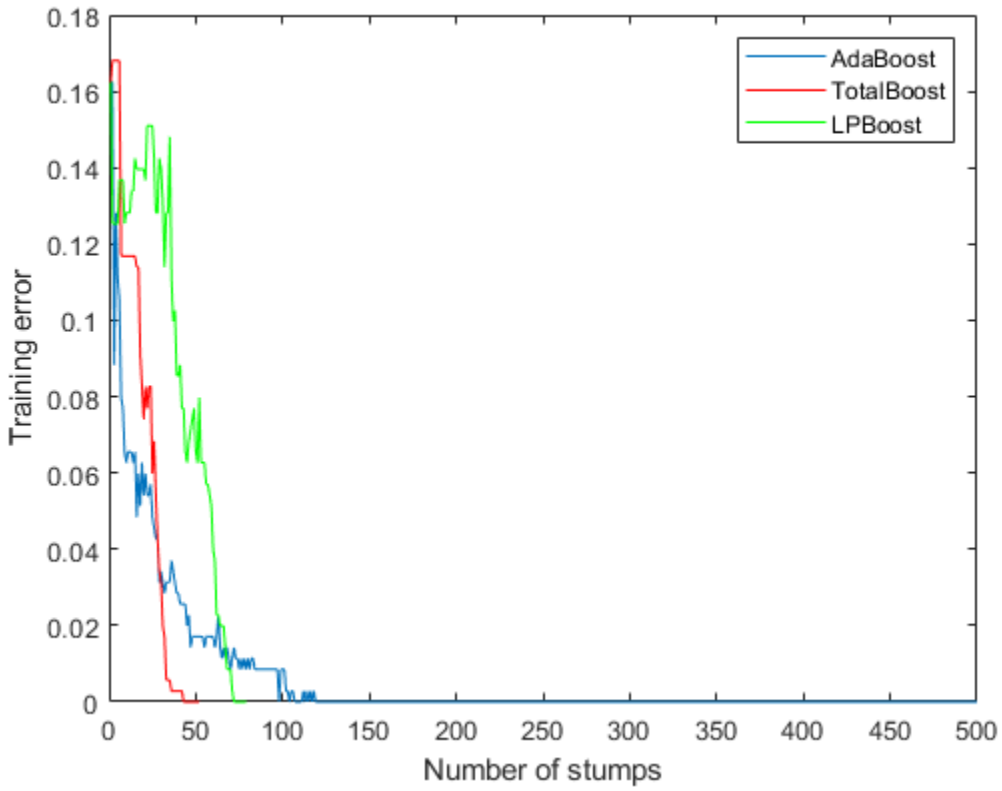
Create the classification ensembles

Create ensembles for classifying the `ionosphere` data using the `LPBoost`, `TotalBoost`, and, for comparison, `AdaBoostM1` algorithms. It is hard to know how many members to include in an ensemble. For `LPBoost` and `TotalBoost`, try using `500`. For comparison, also use `500` for `AdaBoostM1`.

The default weak learners for boosting methods are decision trees with the `MaxNumSplits` property set to `10`. These trees tend to fit better than tree stumps (with `1` maximum split) and may overfit more. Therefore, to prevent overfitting, use tree stumps as weak learners for the ensembles.

```
rng('default') % For reproducibility
T = 500;
treeStump = templateTree('MaxNumSplits',1);
adaStump = fitcensemble(X,Y,'Method','AdaBoostM1','NumLearningCycles',T,'Learners',treeStump);
totalStump = fitcensemble(X,Y,'Method','TotalBoost','NumLearningCycles',T,'Learners',treeStump);
lpStump = fitcensemble(X,Y,'Method','LPBoost','NumLearningCycles',T,'Learners',treeStump);

figure
plot(resubLoss(adaStump,'Mode','Cumulative'));
hold on
plot(resubLoss(totalStump,'Mode','Cumulative'),'r');
plot(resubLoss(lpStump,'Mode','Cumulative'),'g');
hold off
xlabel('Number of stumps');
ylabel('Training error');
legend('AdaBoost','TotalBoost','LPBoost','Location','NE');
```



All three algorithms achieve perfect prediction on the training data after a while.

Examine the number of members in all three ensembles.

```
[adaStump.NTrained totalStump.NTrained lpStump.NTrained]
```

```
ans = 1×3

   500    52    79
```

`AdaBoostM1` trained all `500` members. The other two algorithms stopped training early.

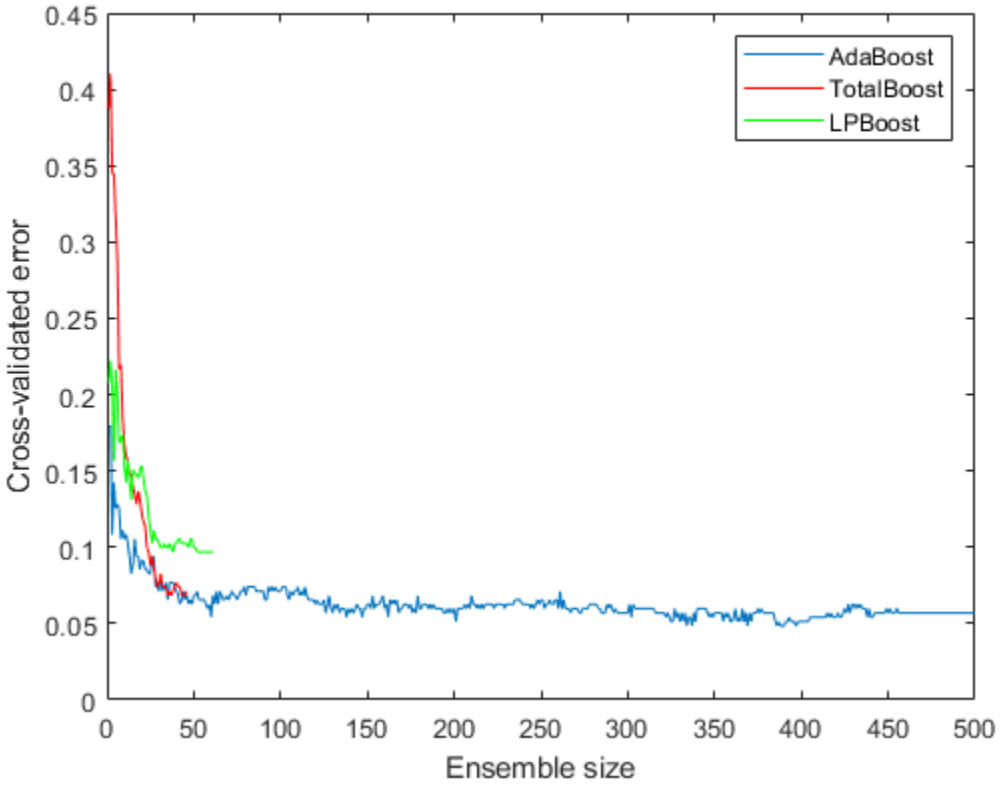
Cross validate the ensembles

Cross validate the ensembles to better determine ensemble accuracy.

```
cvlp = crossval(lpStump,'KFold',5);
cvtotal = crossval(totalStump,'KFold',5);
cvada = crossval(adaStump,'KFold',5);

figure
plot(kfoldLoss(cvada,'Mode','Cumulative'));
hold on
plot(kfoldLoss(cvtotal,'Mode','Cumulative'),'r');
plot(kfoldLoss(cvlp,'Mode','Cumulative'),'g');
hold off
xlabel('Ensemble size');
```

```
ylabel('Cross-validated error');
legend('AdaBoost','TotalBoost','LPBoost','Location','NE');
```



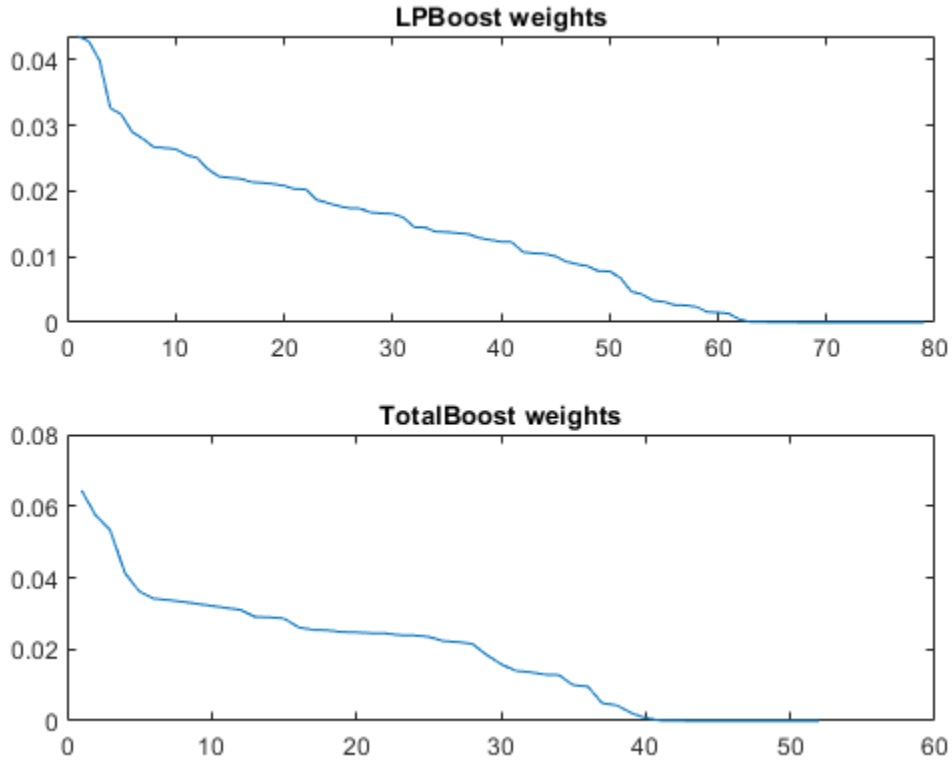
The results show that each boosting algorithm achieves a loss of 10% or lower with 50 ensemble members.

Compact and remove ensemble members

To reduce the ensemble sizes, compact them, and then use `removeLearners`. The question is, how many learners should you remove? The cross-validated loss curves give you one measure. For another, examine the learner weights for `LPBoost` and `TotalBoost` after compacting.

```
cada = compact(adaStump);
clp = compact(lpStump);
ctotal = compact(totalStump);

figure
subplot(2,1,1)
plot(clp.TrainedWeights)
title('LPBoost weights')
subplot(2,1,2)
plot(ctotal.TrainedWeights)
title('TotalBoost weights')
```



Both `LPBoost` and `TotalBoost` show clear points where the ensemble member weights become negligible.

Remove the unimportant ensemble members.

```
cada = removeLearners(cada,150:cada.NTrained);
clp = removeLearners(clp,60:clp.NTrained);
ctotal = removeLearners(ctotal,40:ctotal.NTrained);
```

Check that removing these learners does not affect ensemble accuracy on the training data.

```
[loss(cada,X,Y) loss(clp,X,Y) loss(ctotal,X,Y)]
```

```
ans = 1×3

     0     0     0
```

Check the resulting compact ensemble sizes.

```
s(1) = whos('cada');
s(2) = whos('clp');
s(3) = whos('ctotal');
s.bytes
```

```
ans = 590844

ans = 236030
```

```
ans = 157190
```

The sizes of the compact ensembles are approximately proportional to the number of members in each.

- “Tune RobustBoost” on page 18-101

Tune RobustBoost

The `RobustBoost` algorithm can make good classification predictions even when the training data has noise. However, the default `RobustBoost` parameters can produce an ensemble that does not predict well. This example shows one way of tuning the parameters for better predictive accuracy.

Generate data with label noise. This example has twenty uniform random numbers per observation, and classifies the observation as `1` if the sum of the first five numbers exceeds 2.5 (so is larger than average), and `0` otherwise:

```
rng(0,'twister') % for reproducibility
Xtrain = rand(2000,20);
Ytrain = sum(Xtrain(:,1:5),2) > 2.5;
```

To add noise, randomly switch 10% of the classifications:

```
idx = randsample(2000,200);
Ytrain(idx) = ~Ytrain(idx);
```

Create an ensemble with `AdaBoostM1` for comparison purposes:

```
ada = fitcensemble(Xtrain,Ytrain,'Method','AdaBoostM1', ...
    'NumLearningCycles',300,'Learners','Tree','LearnRate',0.1);
```

Create an ensemble with `RobustBoost`. Because the data has 10% incorrect classification, perhaps an error goal of 15% is reasonable.

```
rb1 = fitcensemble(Xtrain,Ytrain,'Method','RobustBoost', ...
    'NumLearningCycles',300,'Learners','Tree','RobustErrorGoal',0.15, ...
    'RobustMaxMargin',1);
```

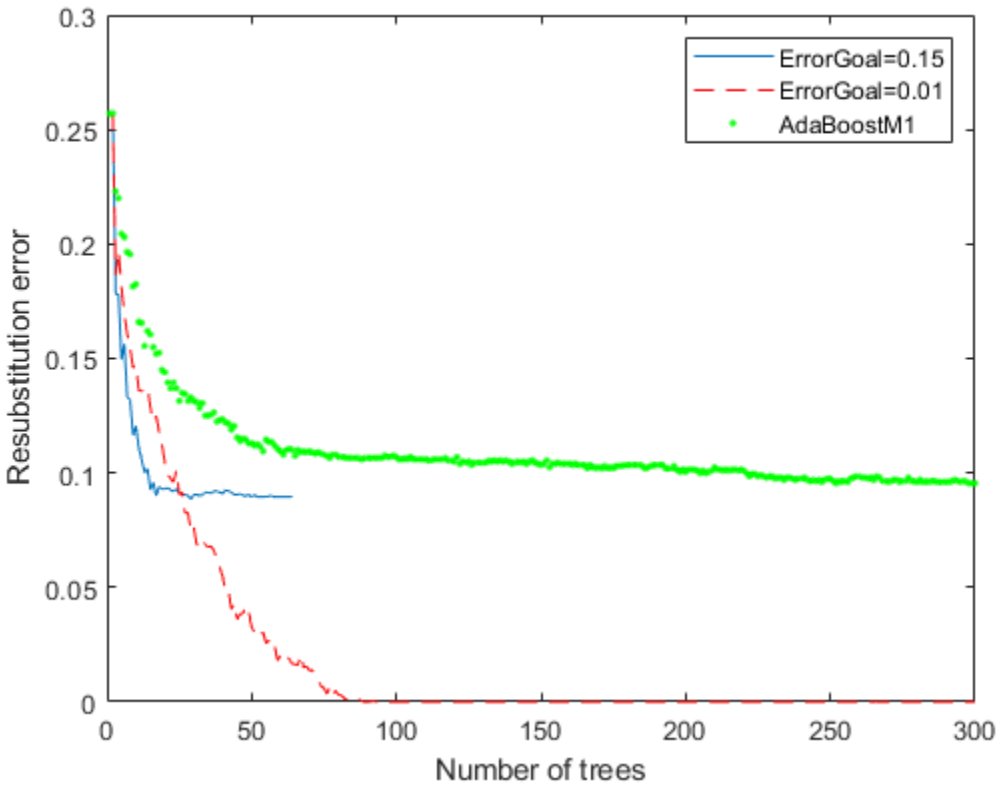
Note that if you set the error goal to a high enough value, then the software returns an error.

Create an ensemble with very optimistic error goal, `0.01`:

```
rb2 = fitcensemble(Xtrain,Ytrain,'Method','RobustBoost', ...
    'NumLearningCycles',300,'Learners','Tree','RobustErrorGoal',0.01);
```

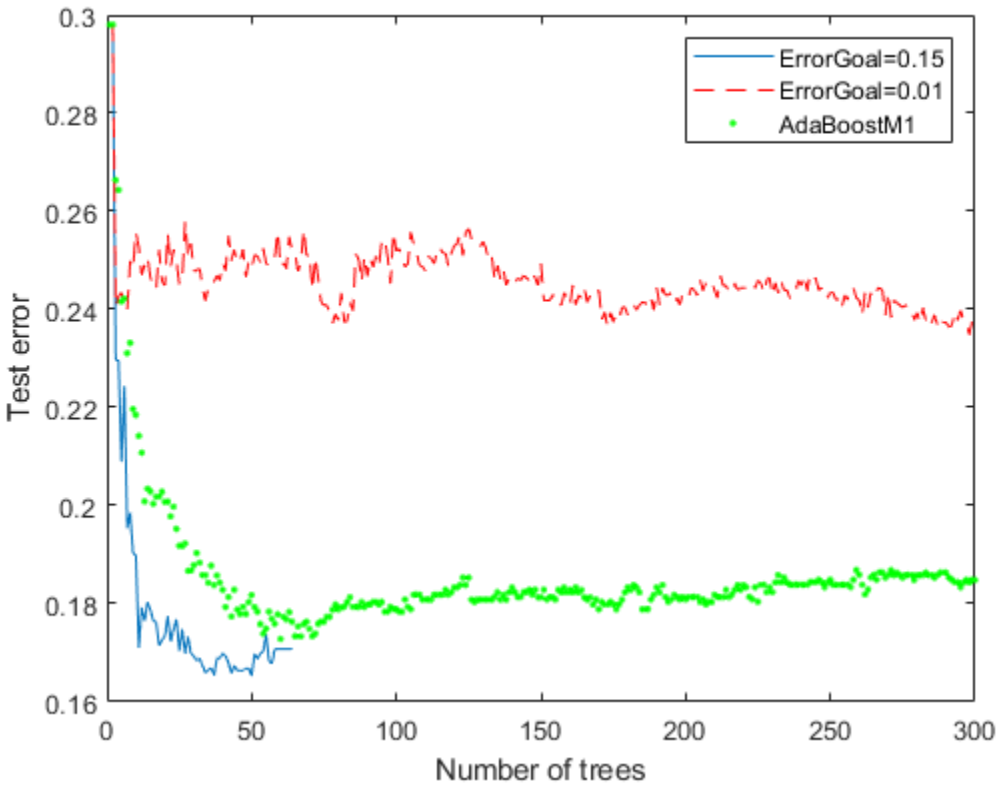
Compare the resubstitution error of the three ensembles:

```
figure
plot(resubLoss(rb1,'Mode','Cumulative'));
hold on
plot(resubLoss(rb2,'Mode','Cumulative'),'r--');
plot(resubLoss(ada,'Mode','Cumulative'),'g.');
hold off;
xlabel('Number of trees');
ylabel('Resubstitution error');
legend('ErrorGoal=0.15','ErrorGoal=0.01',...
    'AdaBoostM1','Location','NE');
```



All the `RobustBoost` curves show lower resubstitution error than the `AdaBoostM1` curve. The error goal of `0.01` curve shows the lowest resubstitution error over most of the range.

```
Xtest = rand(2000,20);
Ytest = sum(Xtest(:,1:5),2) > 2.5;
idx = randsample(2000,200);
Ytest(idx) = ~Ytest(idx);
figure;
plot(loss(rb1,Xtest,Ytest,'Mode','Cumulative'));
hold on
plot(loss(rb2,Xtest,Ytest,'Mode','Cumulative'),'r--');
plot(loss(ada,Xtest,Ytest,'Mode','Cumulative'),'g.');
hold off;
xlabel('Number of trees');
ylabel('Test error');
legend('ErrorGoal=0.15','ErrorGoal=0.01',...
    'AdaBoostM1','Location','NE');
```



The error curve for error goal 0.15 is lowest (best) in the plotted range. `AdaBoostM1` has higher error than the curve for error goal 0.15. The curve for the too-optimistic error goal 0.01 remains substantially higher (worse) than the other algorithms for most of the plotted range.

Random Subspace Classification

This example shows how to use a random subspace ensemble to increase the accuracy of classification. It also shows how to use cross validation to determine good parameters for both the weak learner template and the ensemble.

Load the data

Load the `ionosphere` data. This data has 351 binary responses to 34 predictors.

```
load ionosphere;
[N,D] = size(X)
```

```
N = 351
```

```
D = 34
```

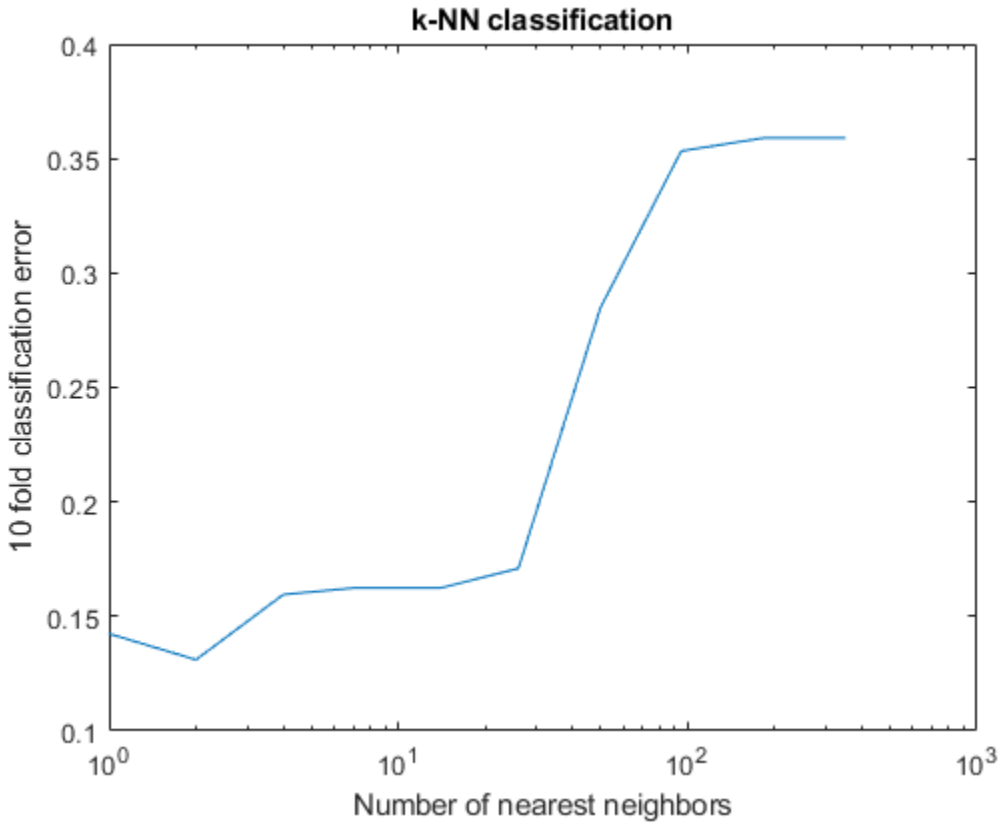
```
resp = unique(Y)
```

```
resp = 2x1 cell
    {'b'}
    {'g'}
```

Choose the number of nearest neighbors

Find a good choice for `k`, the number of nearest neighbors in the classifier, by cross validation. Choose the number of neighbors approximately evenly spaced on a logarithmic scale.

```
rng(8000,'twister') % for reproducibility
K = round(logspace(0,log10(N),10)); % number of neighbors
cvloss = zeros(numel(K),1);
for k=1:numel(K)
    knn = fitcknn(X,Y,...
        'NumNeighbors',K(k),'CrossVal','On');
    cvloss(k) = kfoldLoss(knn);
end
figure; % Plot the accuracy versus k
semilogx(K,cvloss);
xlabel('Number of nearest neighbors');
ylabel('10 fold classification error');
title('k-NN classification');
```



The lowest cross-validation error occurs for `k = 2`.

Create the ensembles

Create ensembles for 2-nearest neighbor classification with various numbers of dimensions, and examine the cross-validated loss of the resulting ensembles.

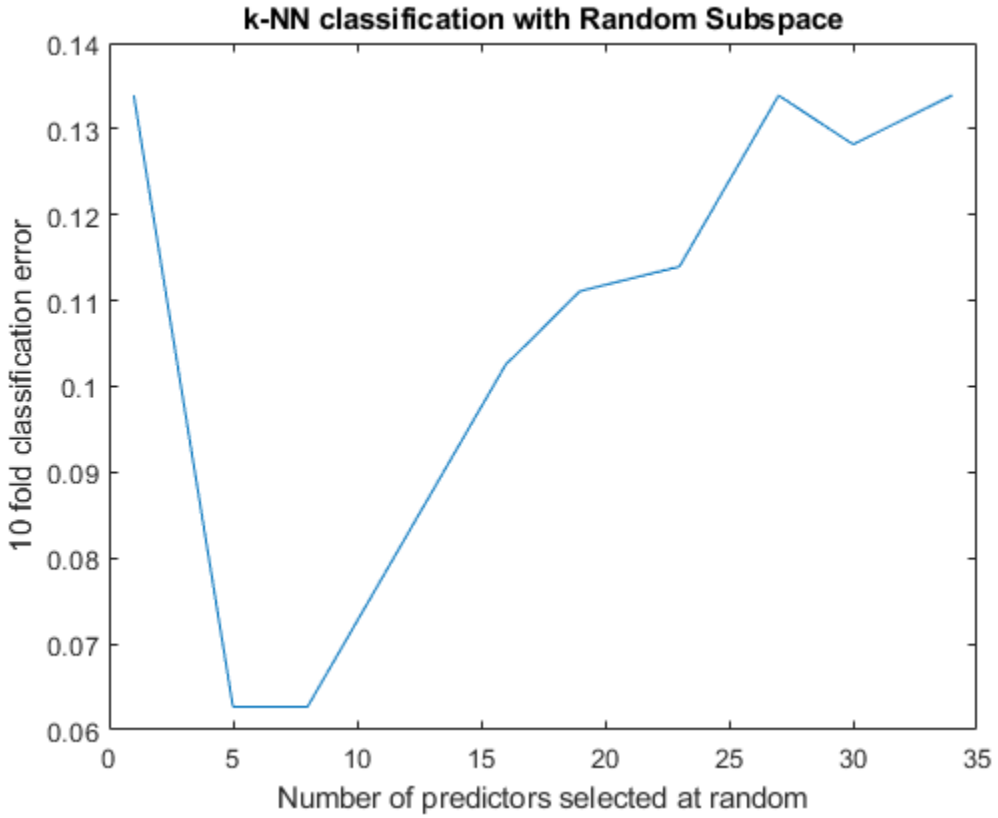
This step takes a long time. To keep track of the progress, print a message as each dimension finishes.

```
NPredToSample = round(linspace(1,D,10)); % linear spacing of dimensions
cvloss = zeros(numel(NPredToSample),1);
learner = templateKNN('NumNeighbors',2);
for npred=1:numel(NPredToSample)
   subspace = fitcensemble(X,Y,'Method','Subspace','Learners',learner, ...
       'NPredToSample',NPredToSample(npred),'CrossVal','On');
   cvloss(npred) = kfoldLoss(subspace);
   fprintf('Random Subspace %i done.\n',npred);
end
```

```
Random Subspace 1 done.
Random Subspace 2 done.
Random Subspace 3 done.
Random Subspace 4 done.
Random Subspace 5 done.
Random Subspace 6 done.
Random Subspace 7 done.
```

```
Random Subspace 8 done.
Random Subspace 9 done.
Random Subspace 10 done.
```

```
figure; % plot the accuracy versus dimension
plot(NPredToSample,cvloss);
xlabel('Number of predictors selected at random');
ylabel('10 fold classification error');
title('k-NN classification with Random Subspace');
```

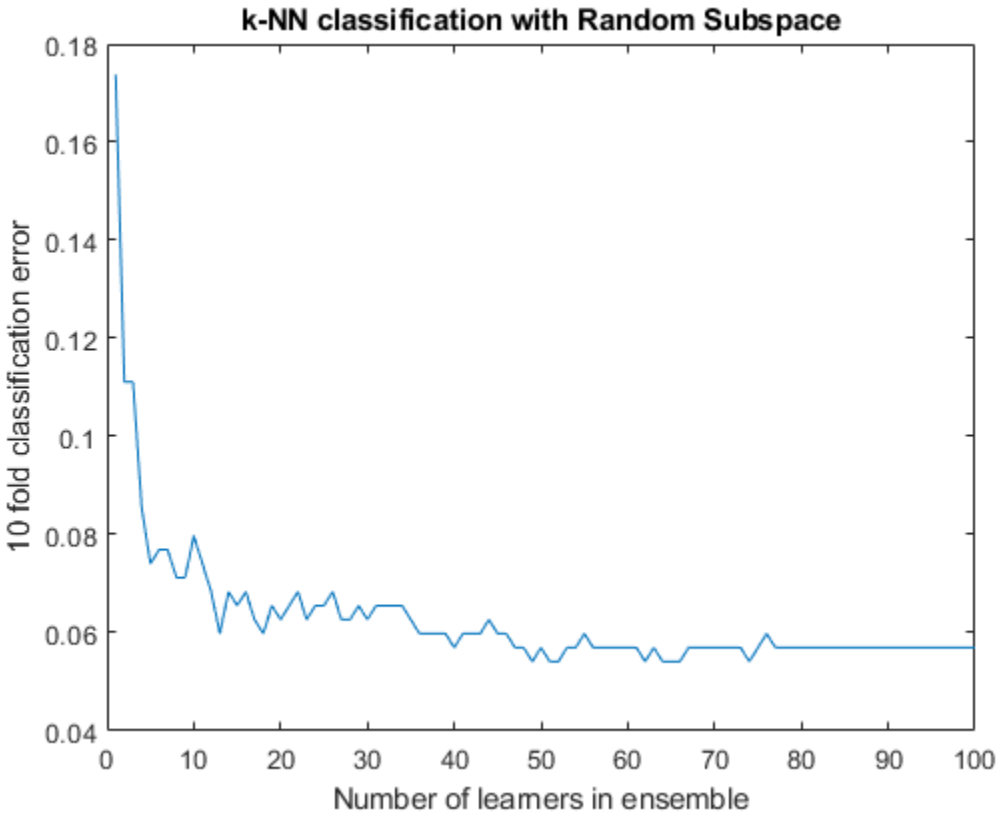


The ensembles that use five and eight predictors per learner have the lowest cross-validated error. The error rate for these ensembles is about 0.06, while the other ensembles have cross-validated error rates that are approximately 0.1 or more.

Find a good ensemble size

Find the smallest number of learners in the ensemble that still give good classification.

```
ens = fitcensemble(X,Y,'Method','Subspace','Learners',learner, ...
       'NPredToSample',5,'CrossVal','on');
figure; % Plot the accuracy versus number in ensemble
plot(kfoldLoss(ens,'Mode','Cumulative'))
xlabel('Number of learners in ensemble');
ylabel('10 fold classification error');
title('k-NN classification with Random Subspace');
```



There seems to be no advantage in an ensemble with more than 50 or so learners. It is possible that 25 learners gives good predictions.

Create a final ensemble

Construct a final ensemble with 50 learners. Compact the ensemble and see if the compacted version saves an appreciable amount of memory.

```
ens = fitcensemble(X,Y,'Method','Subspace','NumLearningCycles',50,...
    'Learners',learner,'NPredToSample',5);
cens = compact(ens);
s1 = whos('ens');
s2 = whos('cens');
[s1.bytes s2.bytes] % si.bytes = size in bytes
```

```
ans = 1×2

     1748467     1518820
```

The compact ensemble is about 10% smaller than the full ensemble. Both give the same predictions.

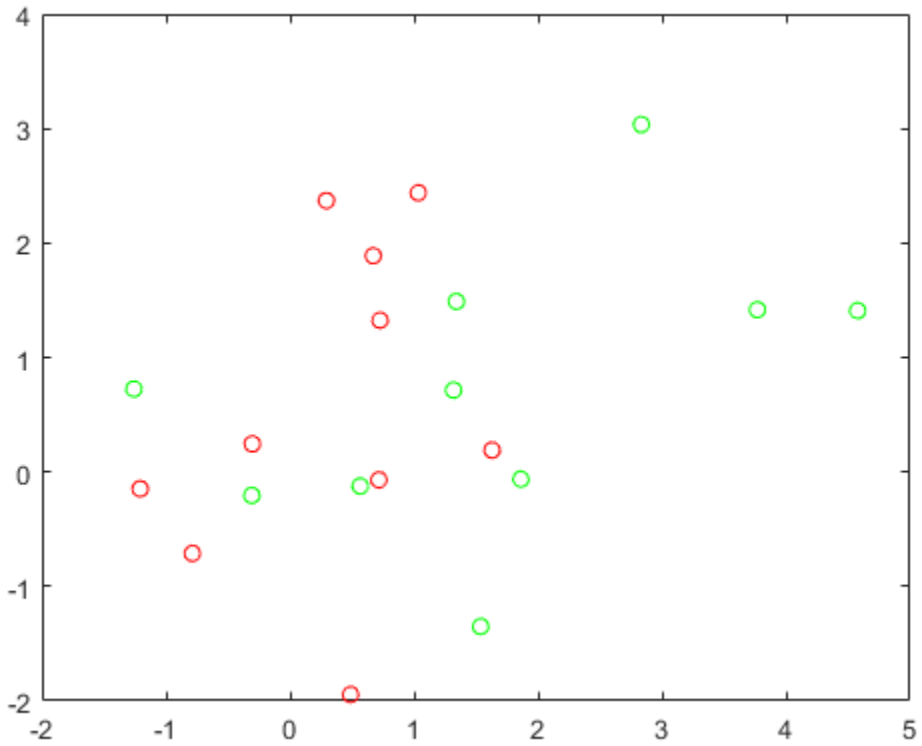
Train Classification Ensemble in Parallel

This example shows how to train a classification ensemble in parallel. The model has ten red and ten green base locations, and red and green populations that are normally distributed and centered at the base locations. The objective is to classify points based on their locations. These classifications are ambiguous because some base locations are near the locations of the other color.

Create and plot ten base locations of each color.

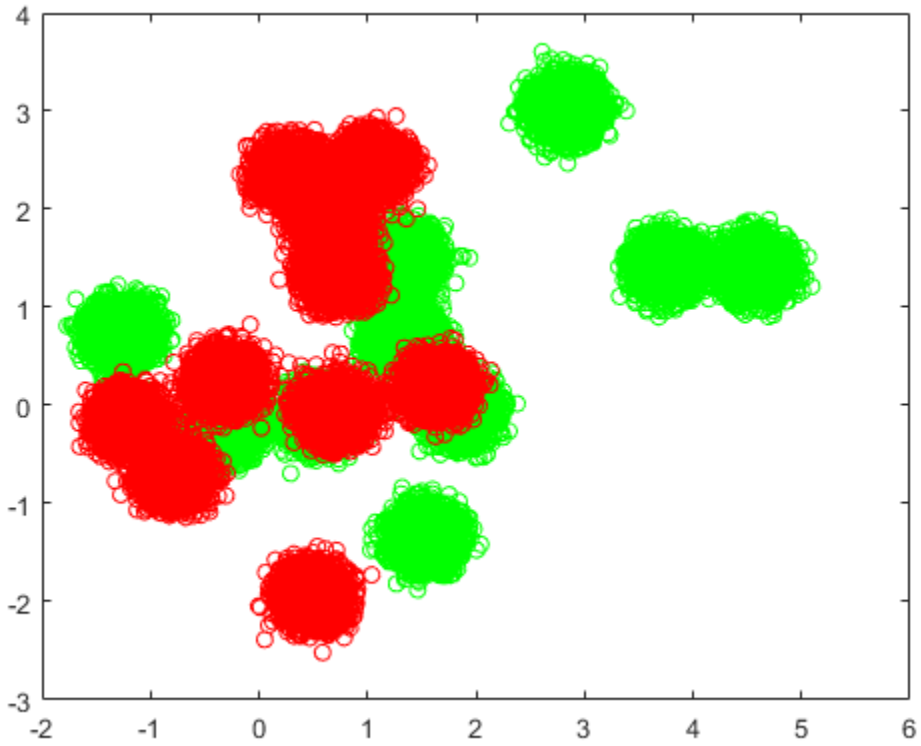
```
rng default % For reproducibility
grnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
plot(grnpop(:,1),grnpop(:,2),'go')
hold on
plot(redpop(:,1),redpop(:,2),'ro')
hold off
```



Create 40,000 points of each color centered on random base points.

```
N = 40000;
redpts = zeros(N,2);grnpts = redpts;
for i = 1:N
    grnpts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);
end
figure
plot(grnpts(:,1),grnpts(:,2),'go')
```

```
hold on
plot(redpts(:,1),redpts(:,2),'ro')
hold off
```



```
cdata = [grnpts;redpts];
grp = ones(2*N,1);
% Green label 1, red label -1
grp(N+1:2*N) = -1;
```

Fit a bagged classification ensemble to the data. For comparison with parallel training, fit the ensemble in serial and return the training time.

```
tic
mdl = fitcensemble(cdata,grp,'Method','Bag');
stime = toc
```

```
stime = 9.0782
```

Evaluate the out-of-bag loss for the fitted model.

```
myerr = oobLoss(mdl)
```

```
myerr = 0.0572
```

Create a bagged classification model in parallel, using a reproducible tree template and parallel substreams. You can create a parallel pool on a cluster or a parallel pool of thread workers on your local machine. To choose the appropriate parallel environment, see Choose Between Thread-Based and Process-Based Environments.

```
parpool
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

ans =

 ProcessPool with properties:

            Connected: true
           NumWorkers: 6
              Cluster: local
        AttachedFiles: {}
    AutoAddClientPath: true
          IdleTimeout: 30 minutes (30 minutes remaining)
          SpmdEnabled: true
```

```
s = RandStream('mrg32k3a');
options = statset("UseParallel",true,"UseSubstreams",true,"Streams",s);
t = templateTree("Reproducible",true);
tic
mdl2 = fitcensemble(cdata,grp,'Method','Bag','Learners',t,'Options',options);
ptime = toc
```

```
ptime = 6.2527
```

On this six-core system, the training process in parallel is faster.

```
speedup = stime/ptime
```

```
speedup = 1.4519
```

Evaluate the out-of-bag loss for this model.

```
myerr2 = oobLoss(mdl2)
```

```
myerr2 = 0.0577
```

The error rate is similar to the rate of the first model.

To demonstrate the reproducibility of the model, reset the random number stream and fit the model again.

```
reset(s);
tic
mdl2 = fitcensemble(cdata,grp,'Method','Bag','Learners',t,'Options',options);
toc
```

```
Elapsed time is 3.953355 seconds.
```

Check that the loss is the same as the previous loss.

```
myerr2 = oobLoss(mdl2)
```

```
myerr2 = 0.0577
```

- “Regression Tree Ensembles”

Bootstrap Aggregation (Bagging) of Regression Trees Using TreeBagger

Statistics and Machine Learning Toolbox™ offers two objects that support bootstrap aggregation (bagging) of regression trees: `TreeBagger` created by using `TreeBagger` and `RegressionBaggedEnsemble` created by using `fitrensemble`. See “Comparison of TreeBagger and Bagged Ensembles” on page 18-44 for differences between `TreeBagger` and `RegressionBaggedEnsemble`.

This example shows the workflow for classification using the features in `TreeBagger` only.

Use a database of 1985 car imports with 205 observations, 25 predictors, and 1 response, which is insurance risk rating, or "symboling." The first 15 variables are numeric and the last 10 are categorical. The symboling index takes integer values from -3 to 3.

Load the data set and split it into predictor and response arrays.

```
load imports-85
Y = X(:,1);
X = X(:,2:end);
isCategorical = [zeros(15,1);ones(size(X,2)-15,1)]; % Categorical variable flag
```

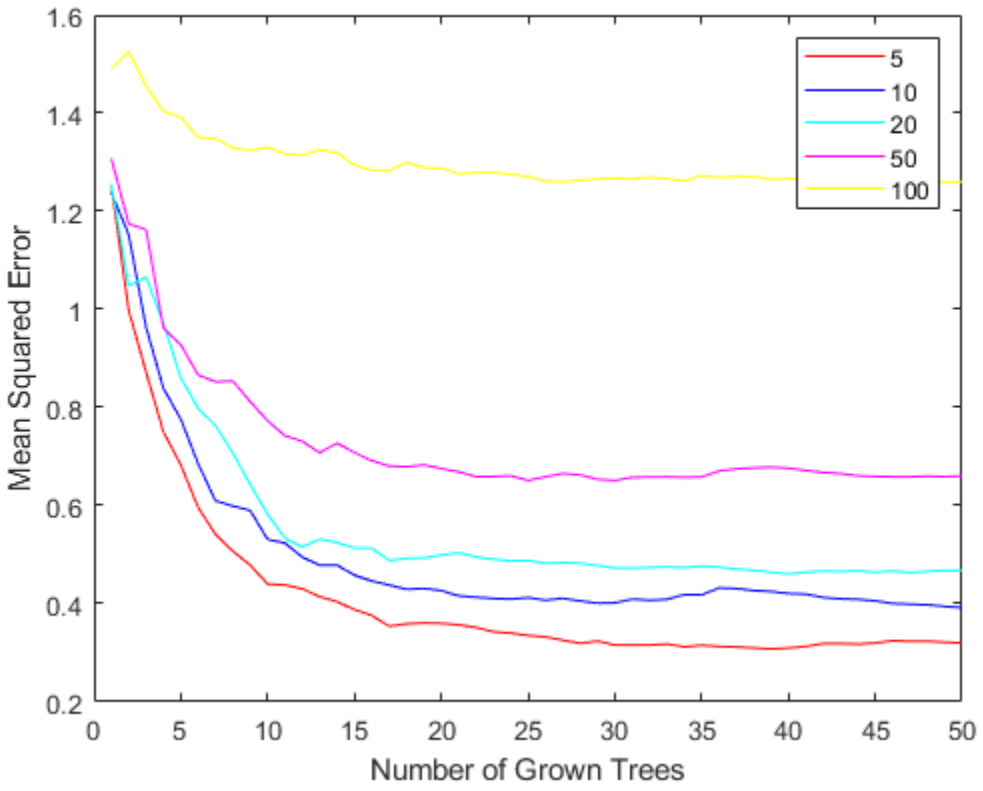
Because bagging uses randomized data drawings, its exact outcome depends on the initial random seed. To reproduce the results in this example, use the random stream settings.

```
rng(1945,'twister')
```

Finding the Optimal Leaf Size

For regression, the general rule is to the set leaf size to 5 and select one third of the input features for decision splits at random. In the following step, verify the optimal leaf size by comparing mean squared errors obtained by regression for various leaf sizes. `oobError` computes MSE versus the number of grown trees. You must set `OOBPred` to `'On'` to obtain out-of-bag predictions later.

```
leaf = [5 10 20 50 100];
col = 'rbcmy';
figure
for i=1:length(leaf)
    b = TreeBagger(50,X,Y,'Method','R','OOBPrediction','On',...
            'CategoricalPredictors',find(isCategorical == 1),...
            'MinLeafSize',leaf(i));
    plot(oobError(b),col(i))
    hold on
end
xlabel('Number of Grown Trees')
ylabel('Mean Squared Error')
legend({'5' '10' '20' '50' '100'},'Location','NorthEast')
hold off
```



The red curve (leaf size 5) yields the lowest MSE values.

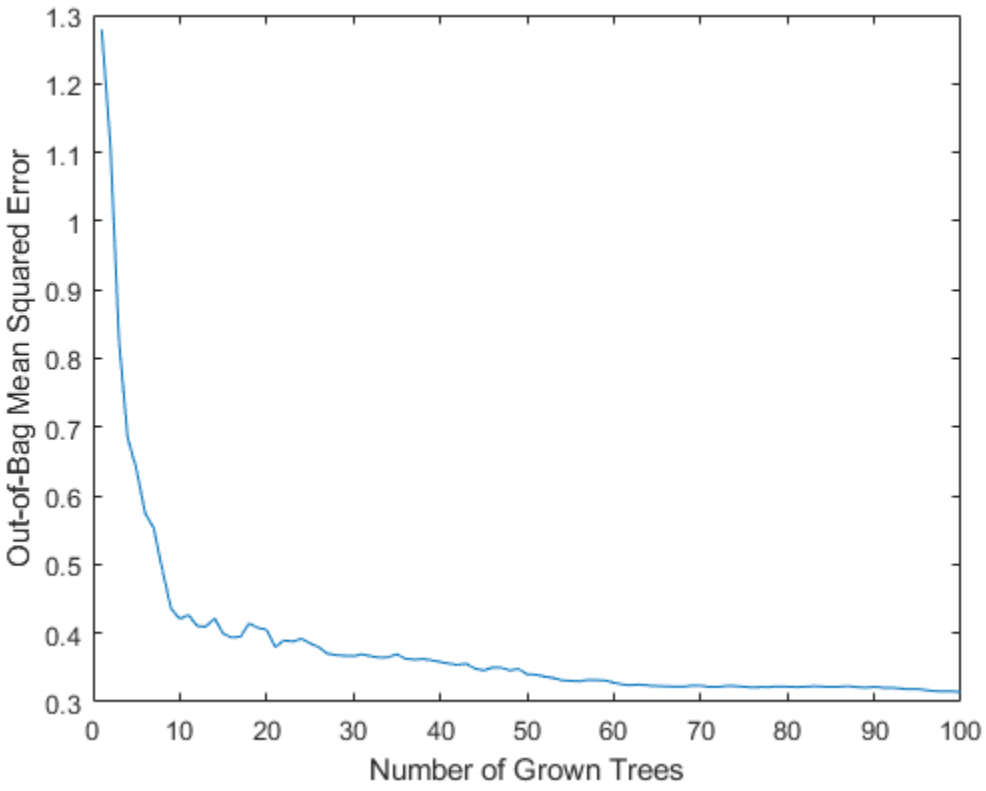
Estimating Feature Importance

In practical applications, you typically grow ensembles with hundreds of trees. For example, the previous code block uses 50 trees for faster processing. Now that you have estimated the optimal leaf size, grow a larger ensemble with 100 trees and use it to estimate feature importance.

```
b = TreeBagger(100,X,Y,'Method','R','OOBPredictorImportance','On',...
    'CategoricalPredictors',find(isCategorical == 1),...
    'MinLeafSize',5);
```

Inspect the error curve again to make sure nothing went wrong during training.

```
figure
plot(oobError(b))
xlabel('Number of Grown Trees')
ylabel('Out-of-Bag Mean Squared Error')
```

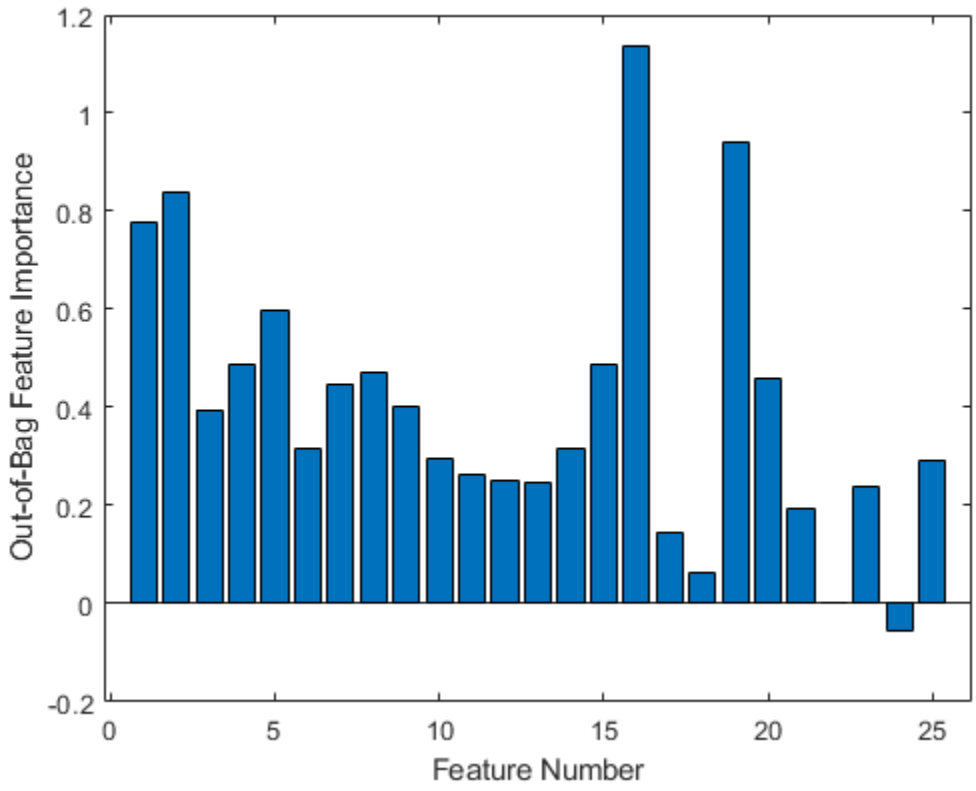


Prediction ability should depend more on important features than unimportant features. You can use this idea to measure feature importance.

For each feature, permute the values of this feature across every observation in the data set and measure how much worse the MSE becomes after the permutation. You can repeat this for each feature.

Plot the increase in MSE due to permuting out-of-bag observations across each input variable. The `OOBPermutedPredictorDeltaError` array stores the increase in MSE averaged over all trees in the ensemble and divided by the standard deviation taken over the trees, for each variable. The larger this value, the more important the variable. Imposing an arbitrary cutoff at 0.7, you can select the four most important features.

```
figure
bar(b.OOBPermutedPredictorDeltaError)
xlabel('Feature Number')
ylabel('Out-of-Bag Feature Importance')
```



```
idxvar = find(b.OOBPermutedPredictorDeltaError>0.7)
```

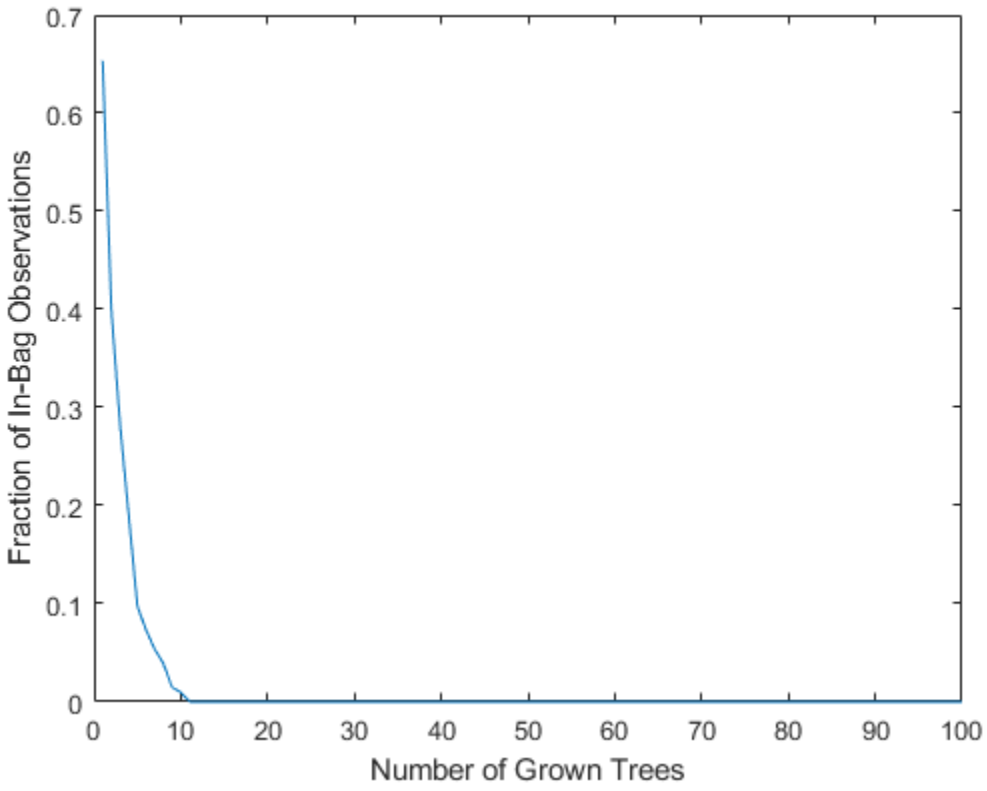
```
idxvar = 1×4

     1     2    16    19
```

```
idxCategorical = find(isCategorical(idxvar)==1);
```

The `OOBIndices` property of `TreeBagger` tracks which observations are out of bag for what trees. Using this property, you can monitor the fraction of observations in the training data that are in bag for all trees. The curve starts at approximately 2/3, which is the fraction of unique observations selected by one bootstrap replica, and goes down to 0 at approximately 10 trees.

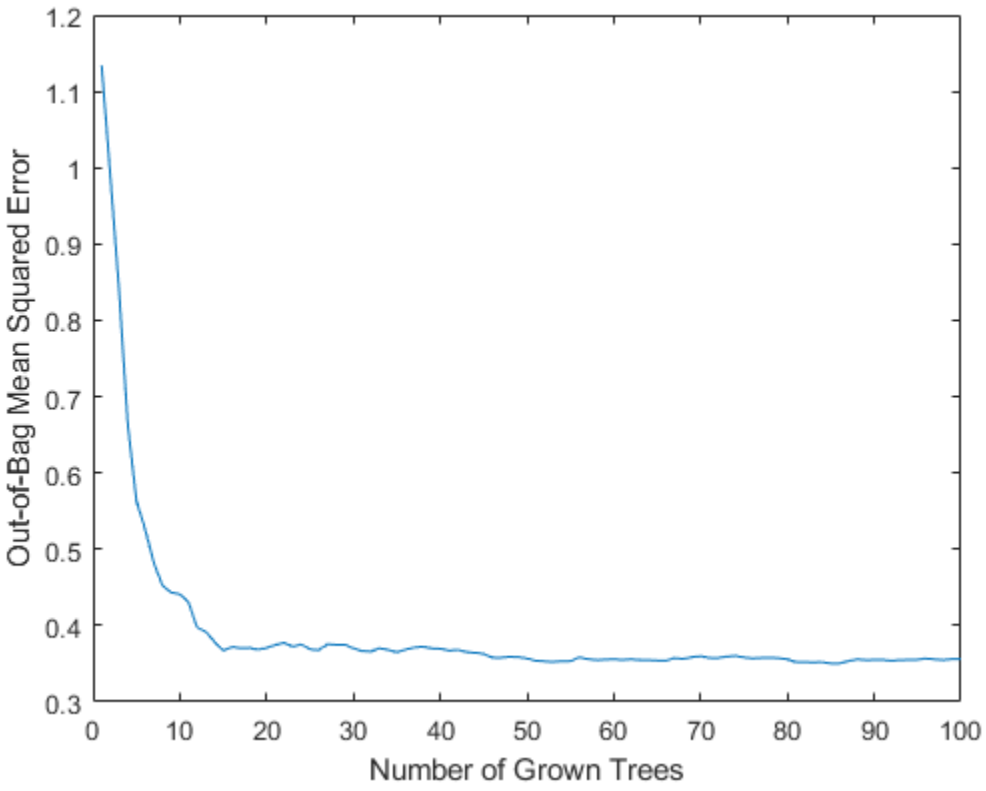
```
finbag = zeros(1,b.NTrees);
for t=1:b.NTrees
    finbag(t) = sum(all(~b.OOBIndices(:,1:t),2));
end
finbag = finbag / size(X,1);
figure
plot(finbag)
xlabel('Number of Grown Trees')
ylabel('Fraction of In-Bag Observations')
```



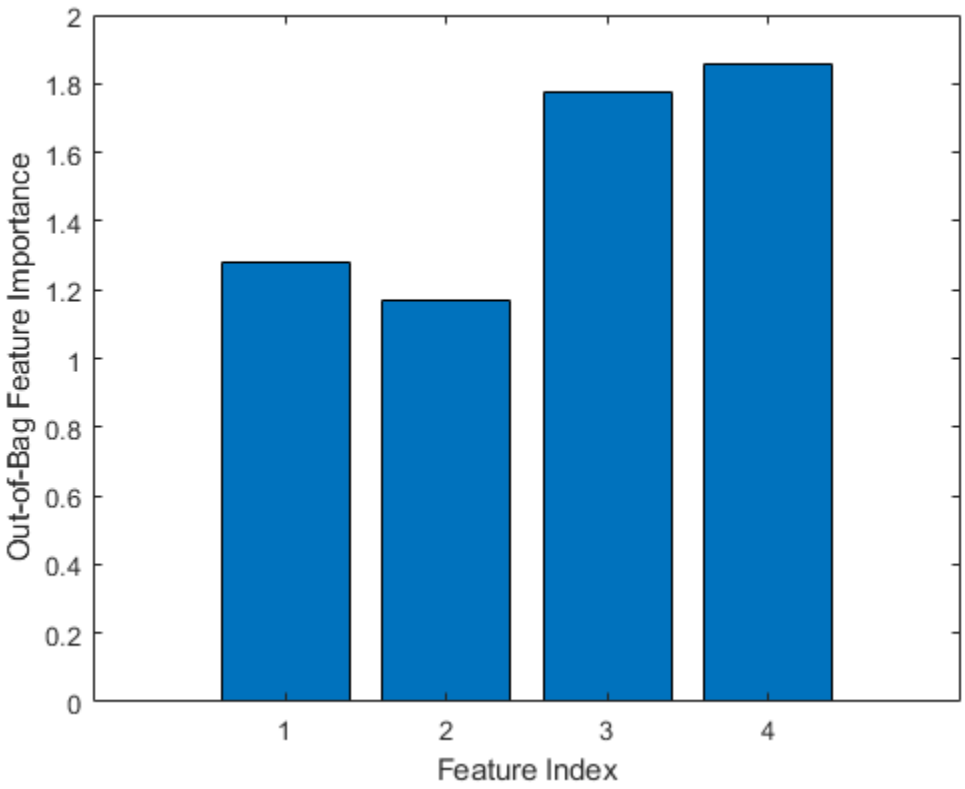
Growing Trees on a Reduced Set of Features

Using just the four most powerful features, determine if it is possible to obtain a similar predictive power. To begin, grow 100 trees on these features only. The first two of the four selected features are numeric and the last two are categorical.

```
b5v = TreeBagger(100,X(:,idxvar),Y,'Method','R',...
    'OOBPredictorImportance','On','CategoricalPredictors',idxCategorical,...
    'MinLeafSize',5);
figure
plot(oobError(b5v))
xlabel('Number of Grown Trees')
ylabel('Out-of-Bag Mean Squared Error')
```



```
figure
bar(b5v.OOBPermutedPredictorDeltaError)
xlabel('Feature Index')
ylabel('Out-of-Bag Feature Importance')
```



These four most powerful features give the same MSE as the full set, and the ensemble trained on the reduced set ranks these features similarly to each other. If you remove features 1 and 2 from the reduced set, then the predictive power of the algorithm might not decrease significantly.

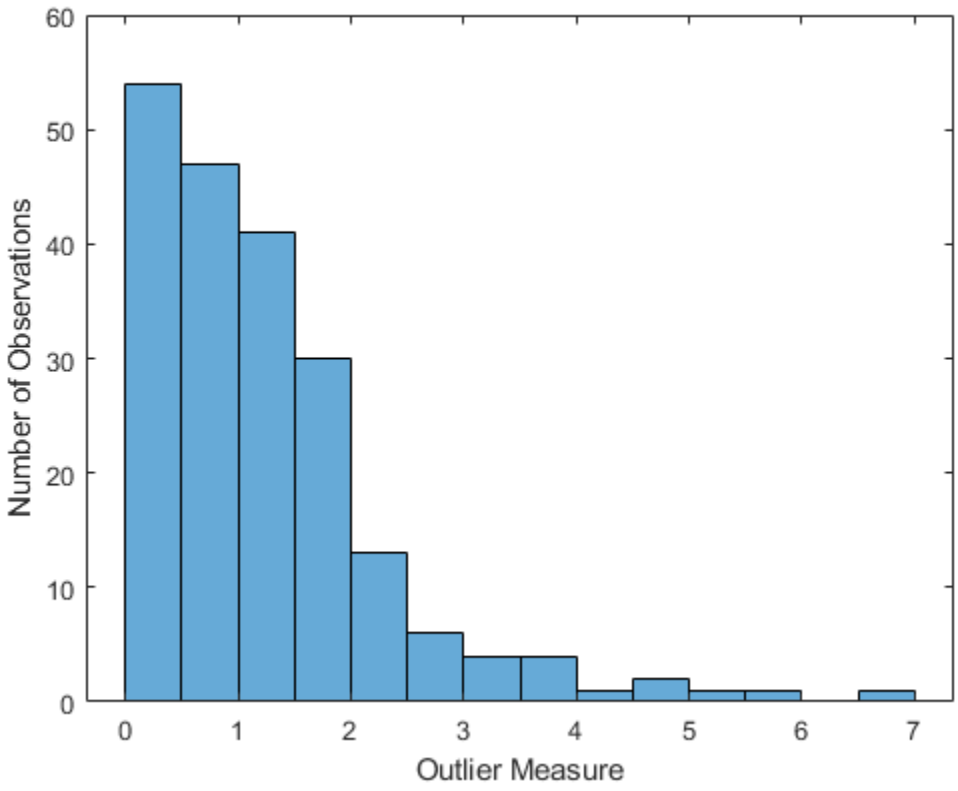
Finding Outliers

To find outliers in the training data, compute the proximity matrix using `fillProximities`.

```
b5v = fillProximities(b5v);
```

The method normalizes this measure by subtracting the mean outlier measure for the entire sample. Then it takes the magnitude of this difference and divides the result by the median absolute deviation for the entire sample.

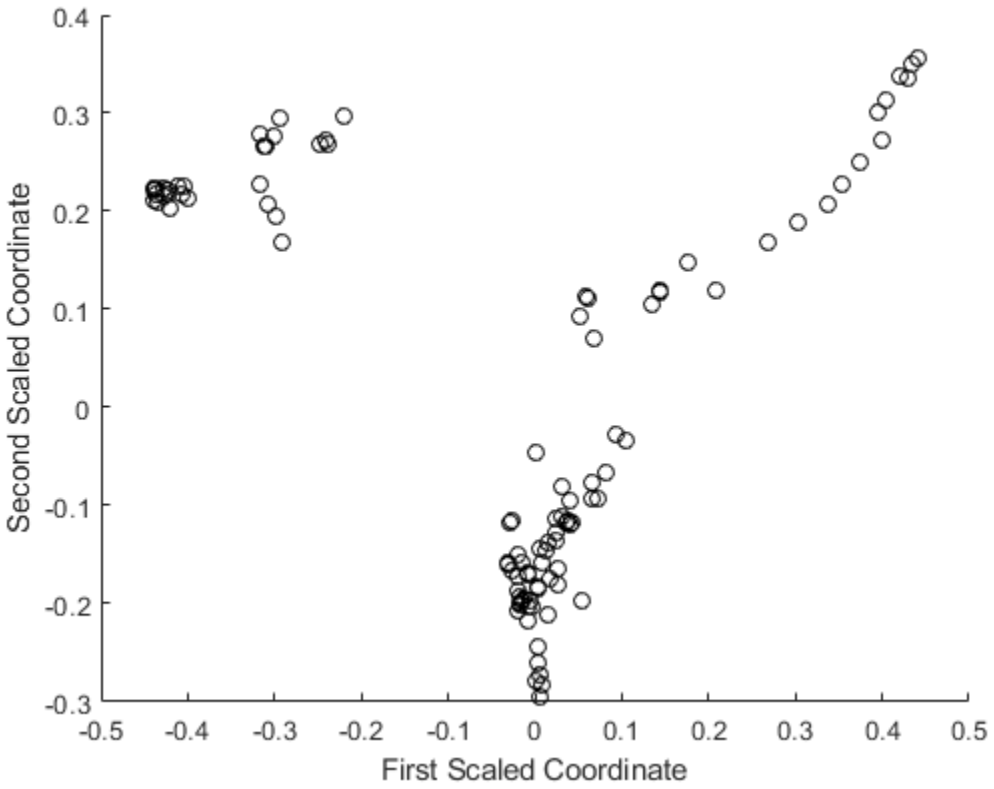
```
figure
histogram(b5v.OutlierMeasure)
xlabel('Outlier Measure')
ylabel('Number of Observations')
```



Discovering Clusters in the Data

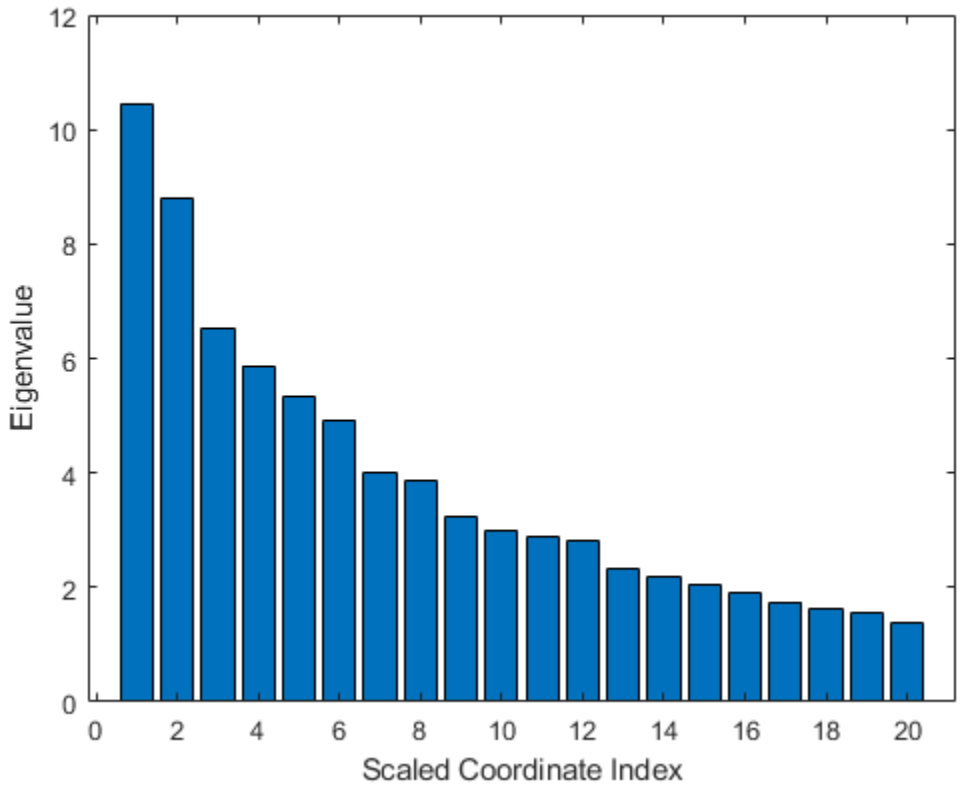
By applying multidimensional scaling to the computed matrix of proximities, you can inspect the structure of the input data and look for possible clusters of observations. The `mdsProx` method returns scaled coordinates and eigenvalues for the computed proximity matrix. If you run it with the `Colors` name-value-pair argument, then this method creates a scatter plot of two scaled coordinates.

```
figure(8)
[~,e] = mdsProx(b5v,'Colors','K');
xlabel('First Scaled Coordinate')
ylabel('Second Scaled Coordinate')
```



Assess the relative importance of the scaled axes by plotting the first 20 eigenvalues.

```
figure
bar(e(1:20))
xlabel('Scaled Coordinate Index')
ylabel('Eigenvalue')
```



Saving the Ensemble Configuration for Future Use

To use the trained ensemble for predicting the response on unseen data, store the ensemble to disk and retrieve it later. If you do not want to compute predictions for out-of-bag data or reuse training data in any other way, there is no need to store the ensemble object itself. Saving the compact version of the ensemble is enough in this case. Extract the compact object from the ensemble.

```
c = compact(b5v)
```

```
c =
  CompactTreeBagger
Ensemble with 100 bagged decision trees:
              Method:           regression
      NumPredictors:                    4

  Properties, Methods
```

You can save the resulting `CompactTreeBagger` model in a `*.mat` file.

Bootstrap Aggregation (Bagging) of Classification Trees Using TreeBagger

Statistics and Machine Learning Toolbox™ offers two objects that support bootstrap aggregation (bagging) of classification trees: `TreeBagger` created by using `TreeBagger` and `ClassificationBaggedEnsemble` created by using `fitcensemble`. See “Comparison of TreeBagger and Bagged Ensembles” on page 18-44 for differences between `TreeBagger` and `ClassificationBaggedEnsemble`.

This example shows the workflow for classification using the features in `TreeBagger` only.

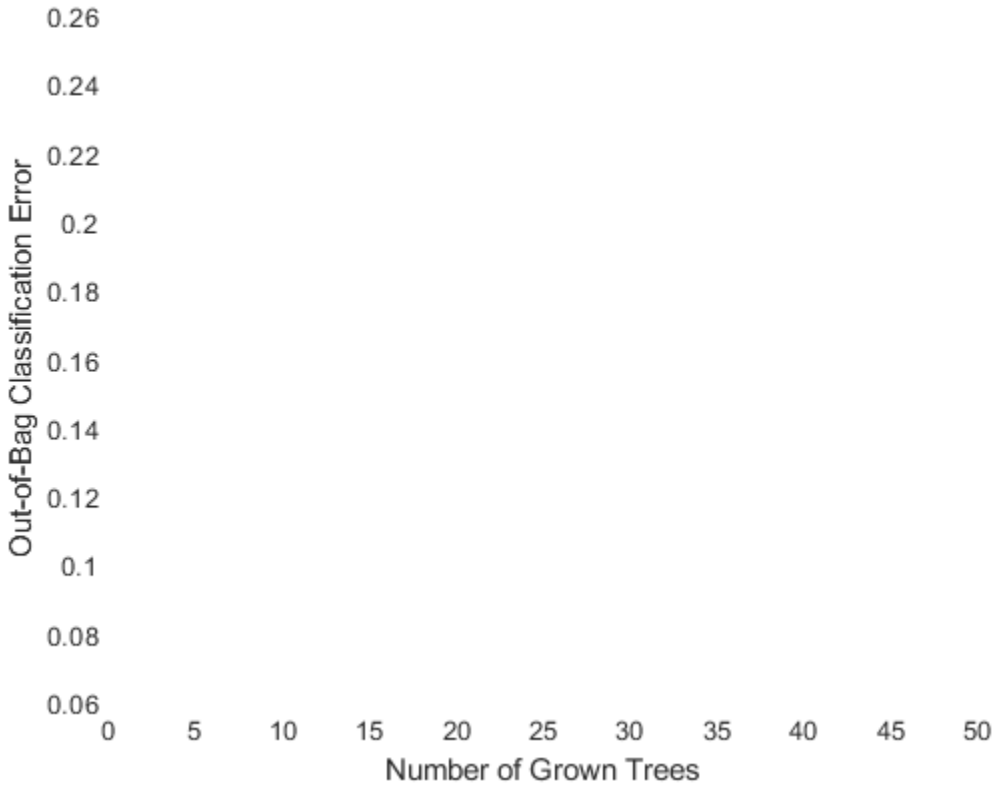
Use ionosphere data with 351 observations and 34 real-valued predictors. The response variable is categorical with two levels:

- `'g'` represents good radar returns.
- `'b'` represents bad radar returns.

The goal is to predict good or bad returns using a set of 34 measurements.

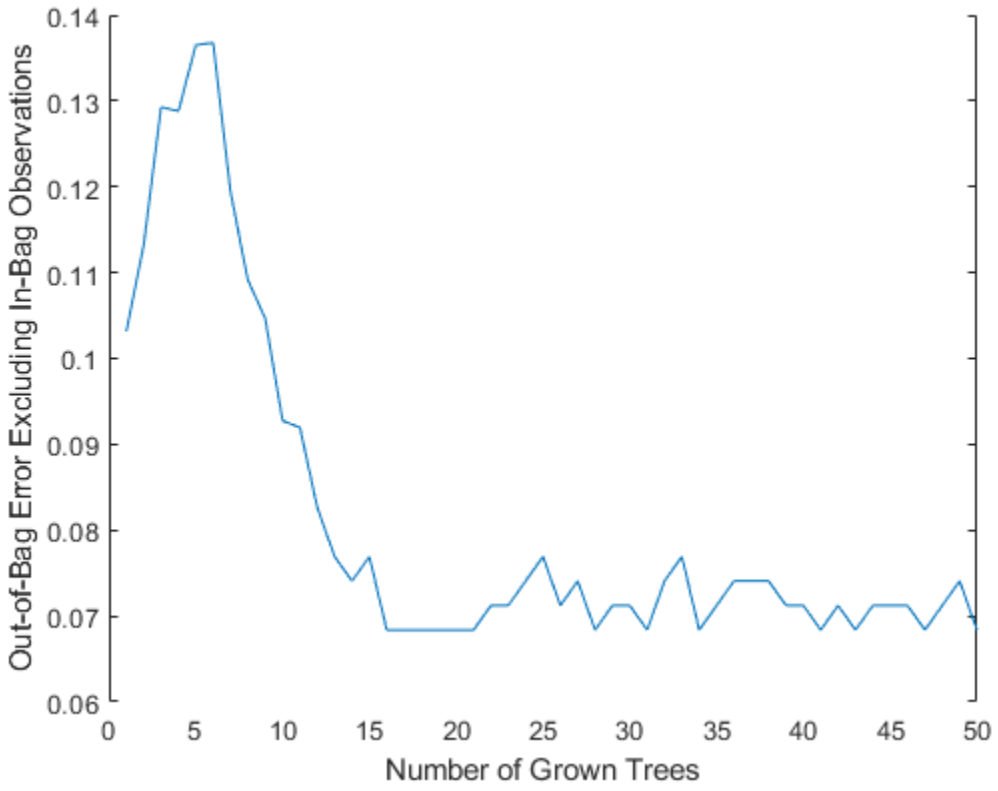
Fix the initial random seed, grow 50 trees, inspect how the ensemble error changes with accumulation of trees, and estimate feature importance. For classification, it is best to set the minimal leaf size to 1 and select the square root of the total number of features for each decision split at random. These settings are defaults for `TreeBagger` used for classification.

```
load ionosphere
rng(1945,'twister')
b = TreeBagger(50,X,Y,'OOBPredictorImportance','On');
figure
plot(oobError(b))
xlabel('Number of Grown Trees')
ylabel('Out-of-Bag Classification Error')
```



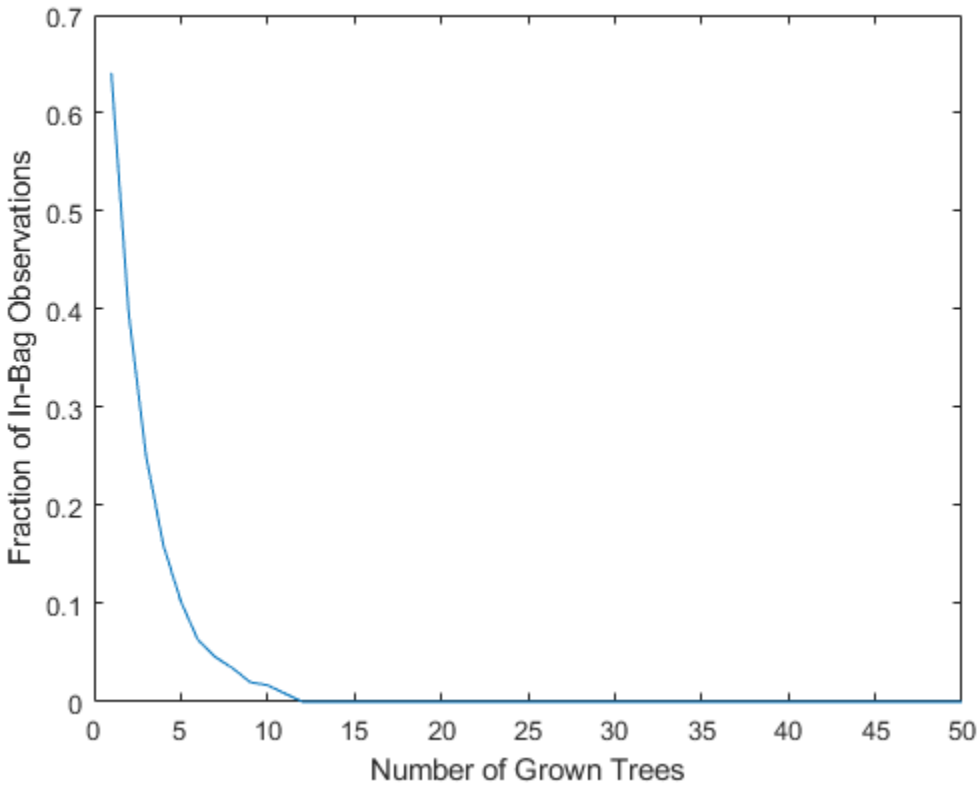
The method trains ensembles with few trees on observations that are in bag for all trees. For such observations, it is impossible to compute the true out-of-bag prediction, and `TreeBagger` returns the most probable class for classification and the sample mean for regression. You can change the default value returned for in-bag observations using the `DefaultYfit` property. If you set the default value to an empty character vector for classification, the method excludes in-bag observations from computation of the out-of-bag error. In this case, the curve is more variable when the number of trees is small, either because some observations are never out of bag (and are therefore excluded) or because their predictions are based on few trees.

```
b.DefaultYfit = '';
figure
plot(oobError(b))
xlabel('Number of Grown Trees')
ylabel('Out-of-Bag Error Excluding In-Bag Observations')
```



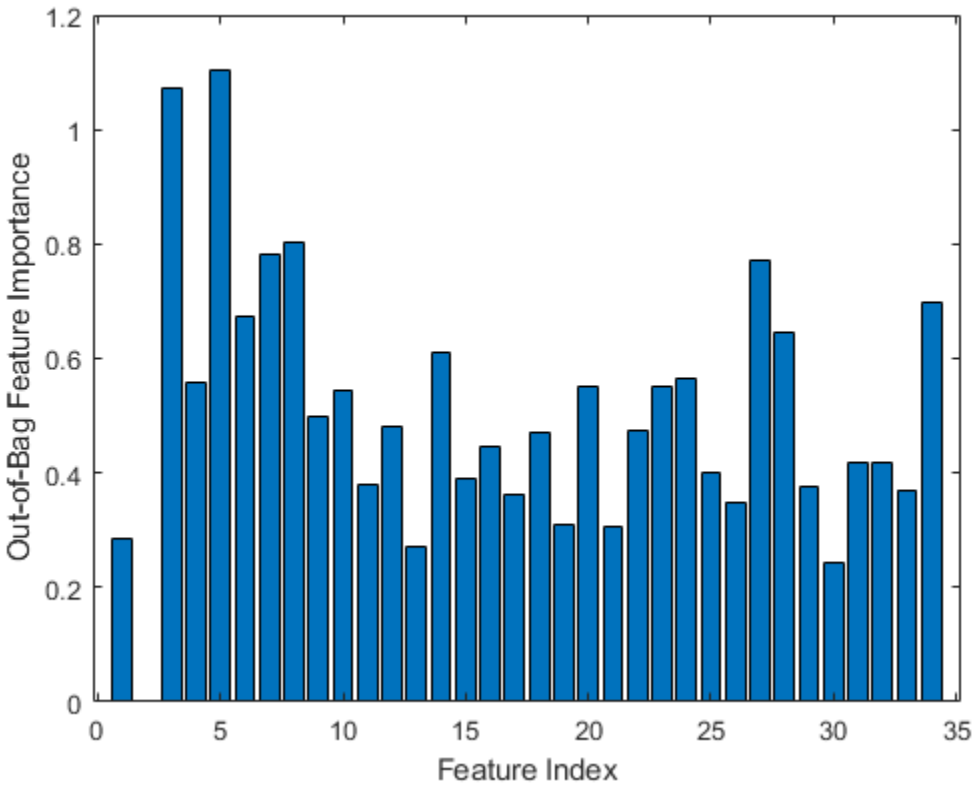
The `OOBIndices` property of `TreeBagger` tracks which observations are out of bag for what trees. Using this property, you can monitor the fraction of observations in the training data that are in bag for all trees. The curve starts at approximately 2/3, which is the fraction of unique observations selected by one bootstrap replica, and goes down to 0 at approximately 10 trees.

```
finbag = zeros(1,b.NumTrees);
for t=1:b.NTrees
    finbag(t) = sum(all(~b.OOBIndices(:,1:t),2));
end
finbag = finbag / size(X,1);
figure
plot(finbag)
xlabel('Number of Grown Trees')
ylabel('Fraction of In-Bag Observations')
```



Estimate feature importance.

```
figure
bar(b.OOBPermutedPredictorDeltaError)
xlabel('Feature Index')
ylabel('Out-of-Bag Feature Importance')
```



Select the features yielding an importance measure greater than 0.75. This threshold is chosen arbitrarily.

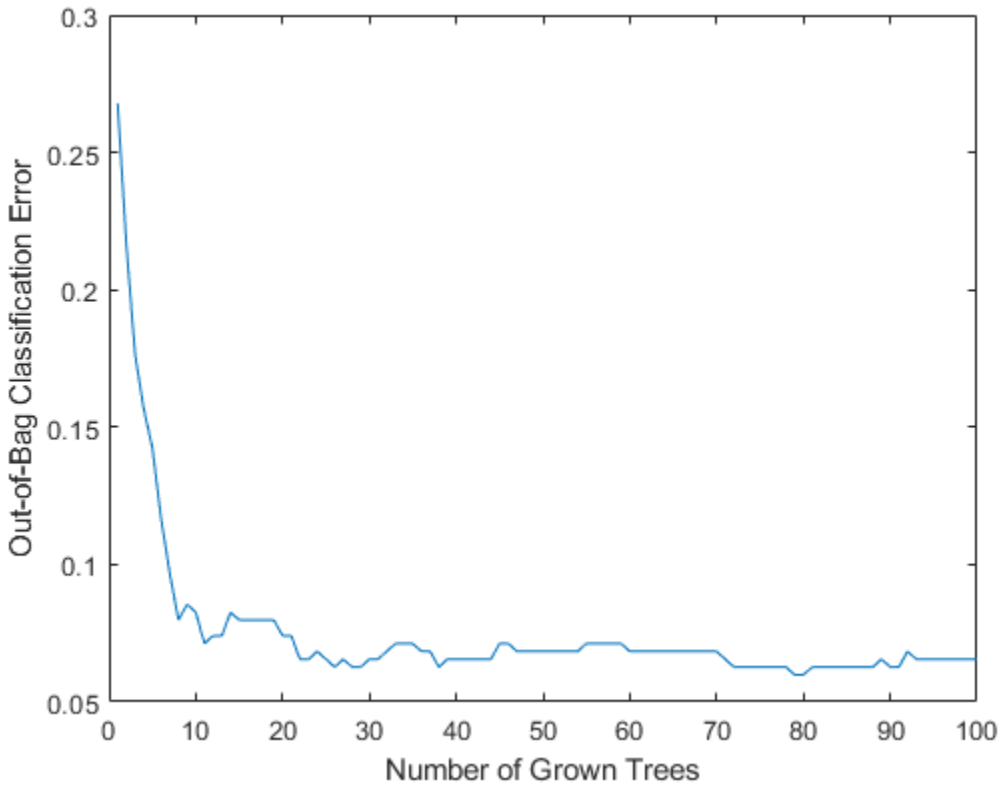
```
idxvar = find(b.OOBPermutedPredictorDeltaError>0.75)
```

```
idxvar = 1×5

     3     5     7     8    27
```

Having selected the most important features, grow a larger ensemble on the reduced feature set. Save time by not permuting out-of-bag observations to obtain new estimates of feature importance for the reduced feature set (set `OOBVarImp` to `'off'`). You would still be interested in obtaining out-of-bag estimates of classification error (set `OOBPred` to `'on'`).

```
b5v = TreeBagger(100,X(:,idxvar),Y,'OOBPredictorImportance','off','OOBPrediction','on');
figure
plot(oobError(b5v))
xlabel('Number of Grown Trees')
ylabel('Out-of-Bag Classification Error')
```

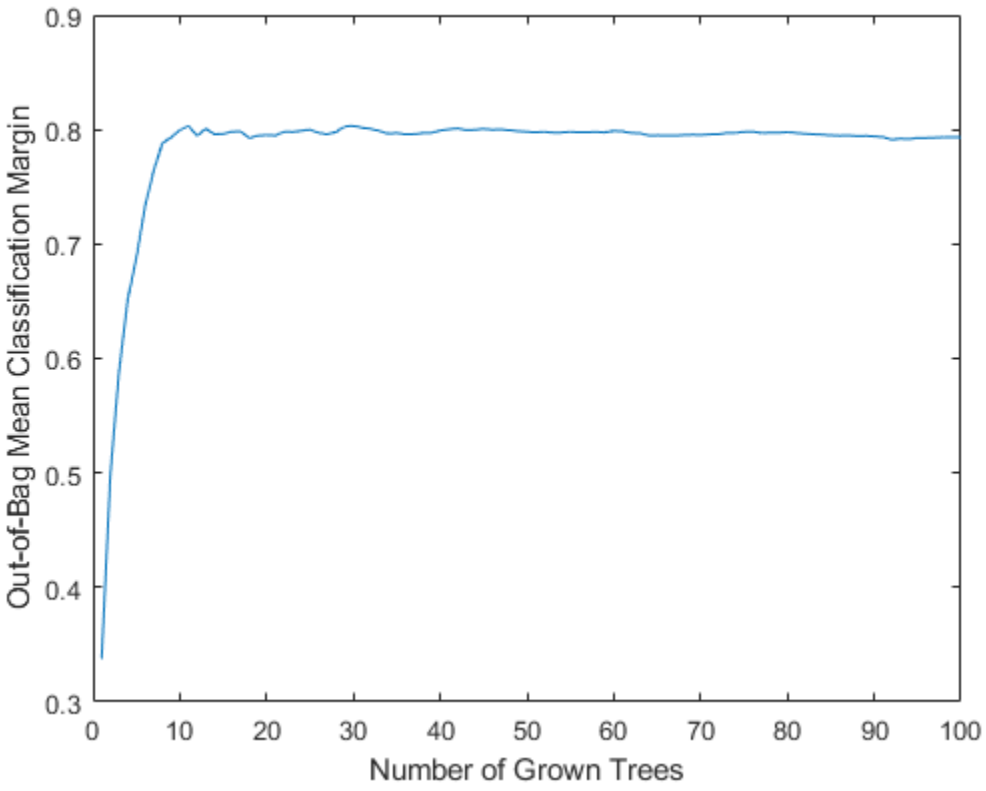


For classification ensembles, in addition to classification error (fraction of misclassified observations), you can also monitor the average classification margin. For each observation, the *margin* is defined as the difference between the score for the true class and the maximal score for other classes predicted by this tree. The cumulative classification margin uses the scores averaged over all trees and the mean cumulative classification margin is the cumulative margin averaged over all observations. The `oobMeanMargin` method with the `'mode'` argument set to `'cumulative'` (default) shows how the mean cumulative margin changes as the ensemble grows: every new element in the returned array represents the cumulative margin obtained by including a new tree in the ensemble. If training is successful, you would expect to see a gradual increase in the mean classification margin.

The method trains ensembles with few trees on observations that are in bag for all trees. For such observations, it is impossible to compute the true out-of-bag prediction, and `TreeBagger` returns the most probable class for classification and the sample mean for regression.

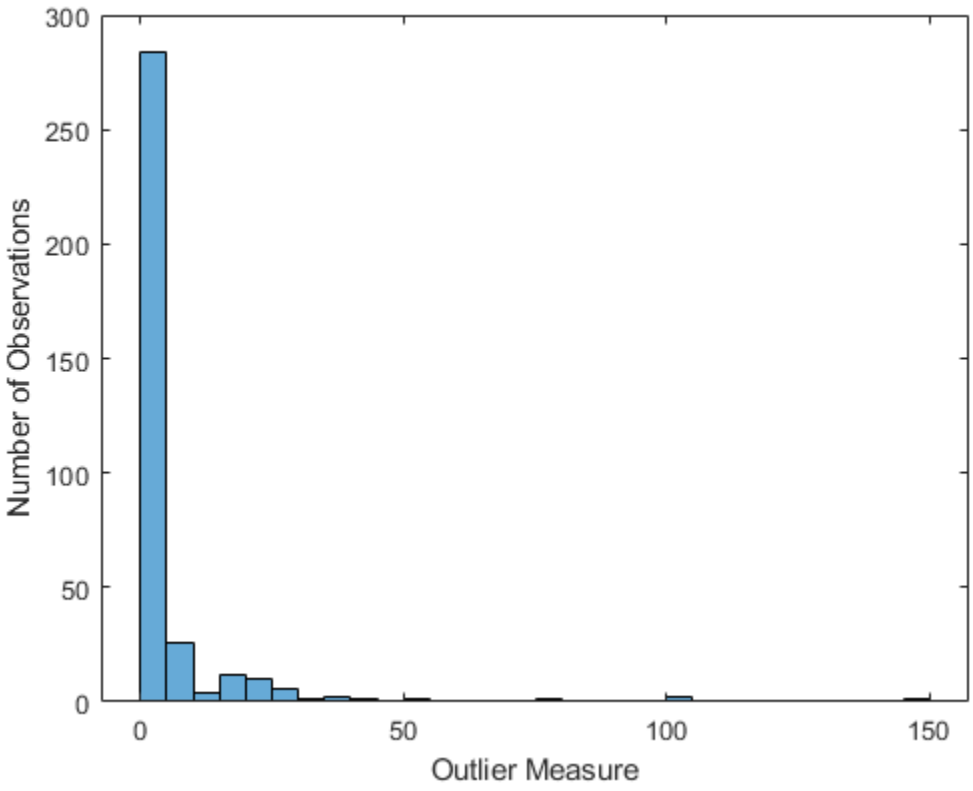
For decision trees, a classification score is the probability of observing an instance of this class in this tree leaf. For example, if the leaf of a grown decision tree has five `'good'` and three `'bad'` training observations in it, the scores returned by this decision tree for any observation fallen on this leaf are 5/8 for the `'good'` class and 3/8 for the `'bad'` class. These probabilities are called `'scores'` for consistency with other classifiers that might not have an obvious interpretation for numeric values of returned predictions.

```
figure
plot(oobMeanMargin(b5v));
xlabel('Number of Grown Trees')
ylabel('Out-of-Bag Mean Classification Margin')
```



Compute the matrix of proximities and examine the distribution of outlier measures. Unlike regression, outlier measures for classification ensembles are computed within each class separately.

```
b5v = fillProximities(b5v);
figure
histogram(b5v.OutlierMeasure)
xlabel('Outlier Measure')
ylabel('Number of Observations')
```



Find the class of the extreme outliers.

```
extremeOutliers = b5v.Y(b5v.OutlierMeasure>40)
```

```
extremeOutliers = 6x1 cell
    {'g'}
    {'g'}
    {'g'}
    {'g'}
    {'g'}
    {'g'}
```

```
percentGood = 100*sum(strcmp(extremeOutliers,'g'))/numel(extremeOutliers)
```

```
percentGood = 100
```

All of the extreme outliers are labeled `'good'`.

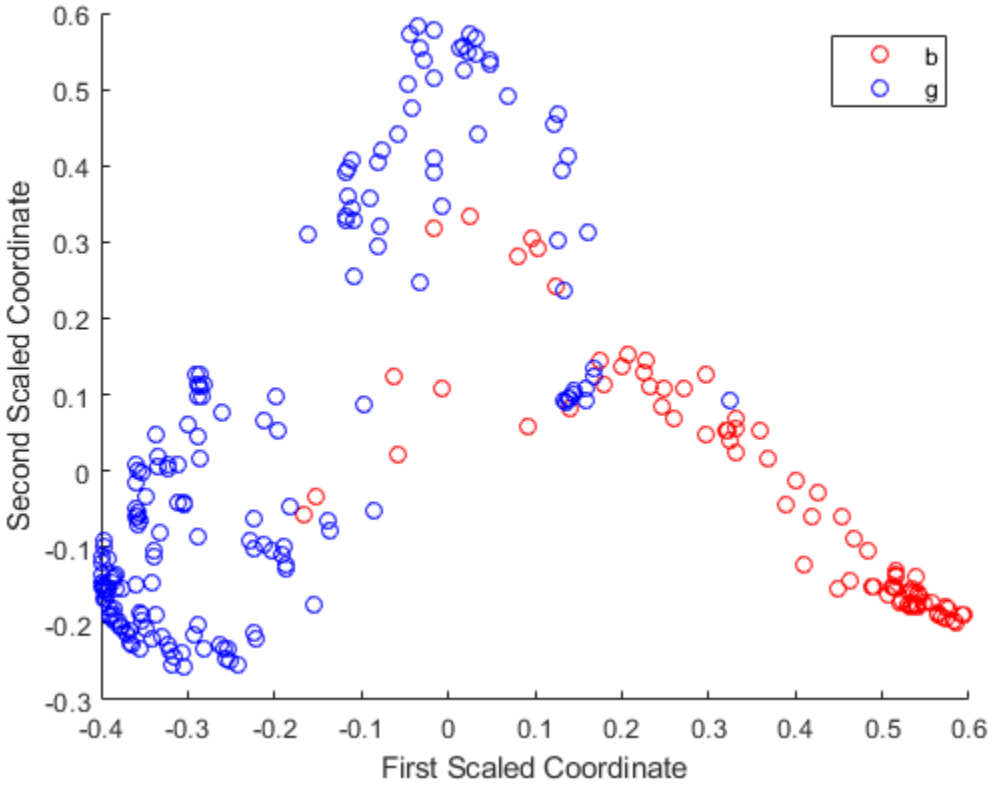
As for regression, you can plot scaled coordinates, displaying the two classes in different colors using the 'Colors' name-value pair argument of `mdsProx`. This argument takes a character vector in which every character represents a color. The software does not rank class names. Therefore, it is best practice to determine the position of the classes in the `ClassNames` property of the ensemble.

```
gPosition = find(strcmp('g',b5v.ClassNames))
```

```
gPosition = 2
```

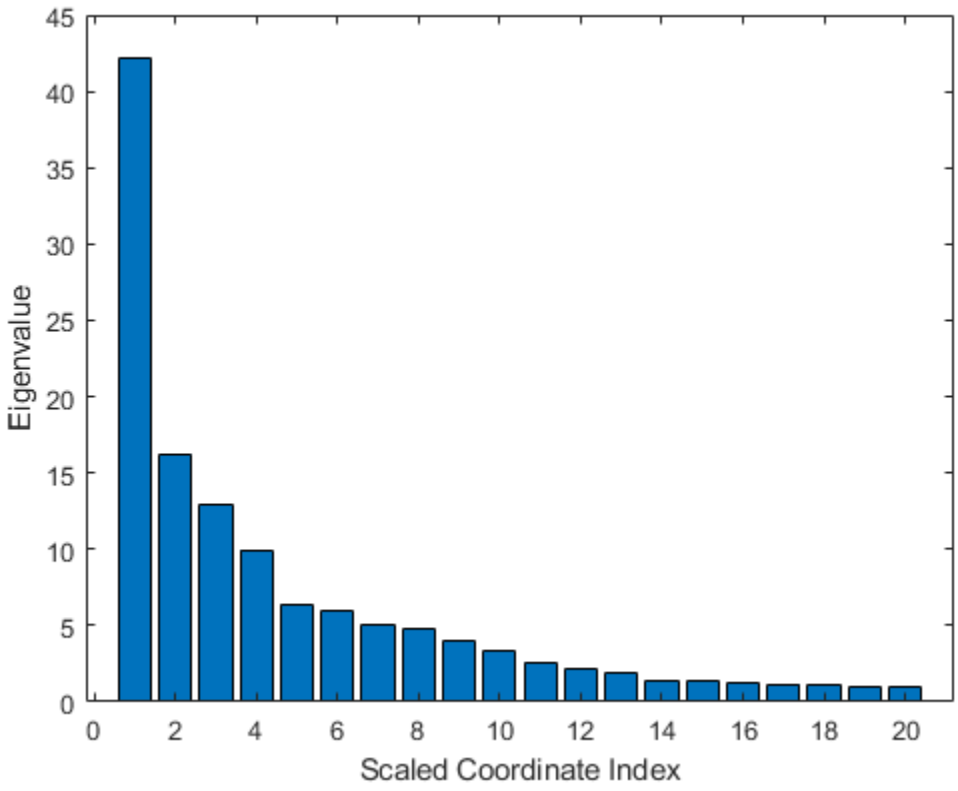
The `'bad'` class is first and the `'good'` class is second. Display scaled coordinates using red for the `'bad'` class and blue for the `'good'` class observations.

```
figure
[s,e] = mdsProx(b5v,'Colors','rb');
xlabel('First Scaled Coordinate')
ylabel('Second Scaled Coordinate')
```



Plot the first 20 eigenvalues obtained by scaling. The first eigenvalue clearly dominates and the first scaled coordinate is most important.

```
figure
bar(e(1:20))
xlabel('Scaled Coordinate Index')
ylabel('Eigenvalue')
```

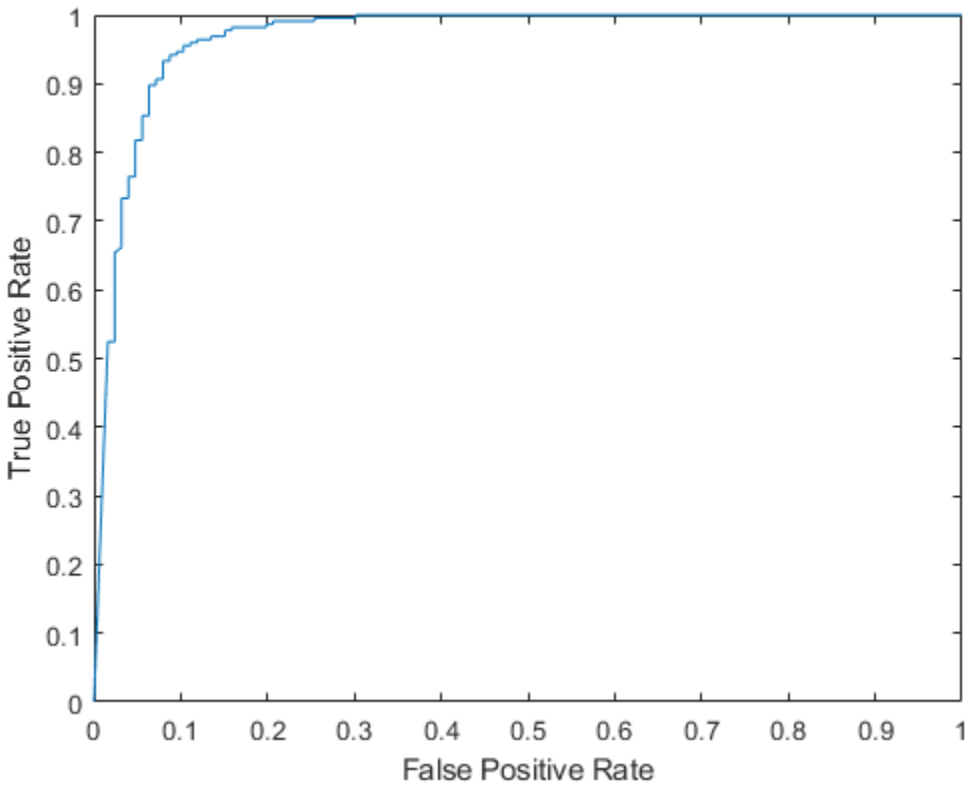


Another way of exploring the performance of a classification ensemble is to plot its Receiver Operating Characteristic (ROC) curve or another performance curve suitable for the current problem. Obtain predictions for out-of-bag observations. For a classification ensemble, the `oobPredict` method returns a cell array of classification labels as the first output argument and a numeric array of scores as the second output argument. The returned array of scores has two columns, one for each class. In this case, the first column is for the `'bad'` class and the second column is for the `'good'` class. One column in the score matrix is redundant because the scores represent class probabilities in tree leaves and by definition add up to 1.

```
[Yfit,Sfit] = oobPredict(b5v);
```

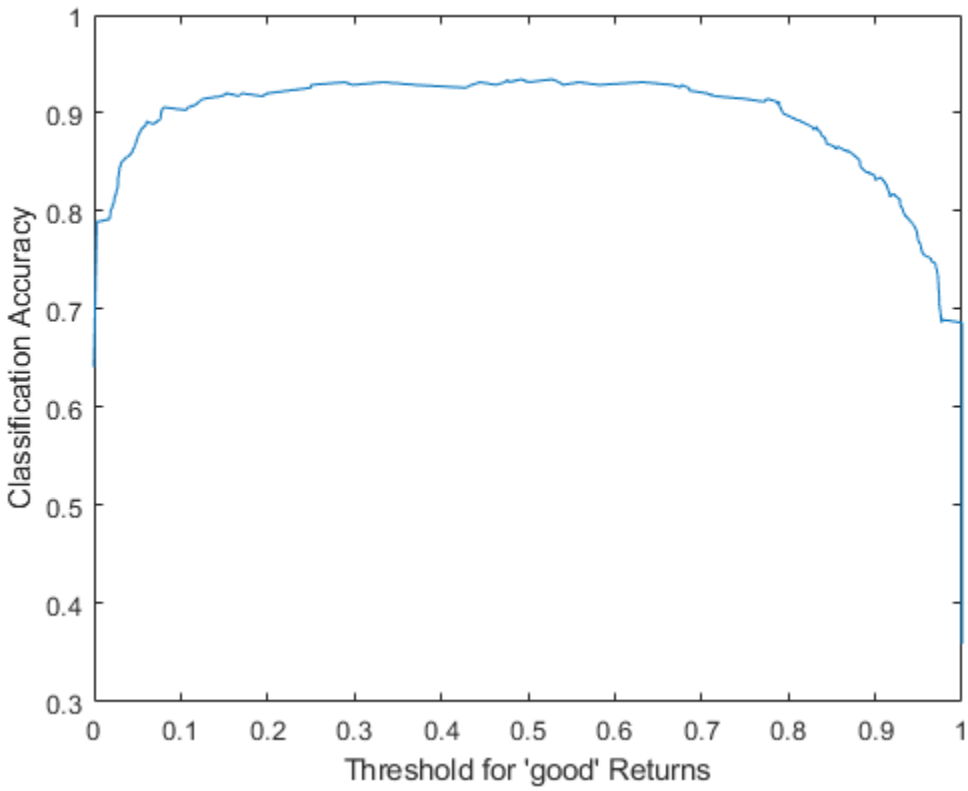
Use `perfcurve` to compute a performance curve. By default, `perfcurve` returns the standard ROC curve, which is the true positive rate versus the false positive rate. `perfcurve` requires true class labels, scores, and the positive class label for input. In this case, choose the `'good'` class as positive.

```
[fpr,tpr] = perfcurve(b5v.Y,Sfit(:,gPosition),'g');
figure
plot(fpr,tpr)
xlabel('False Positive Rate')
ylabel('True Positive Rate')
```



Instead of the standard ROC curve, you might want to plot, for example, ensemble accuracy versus threshold on the score for the `'good'` class. The `ycrit` input argument of `perfcurve` lets you specify the criterion for the y-axis, and the third output argument of `perfcurve` returns an array of thresholds for the positive class score. Accuracy is the fraction of correctly classified observations, or equivalently, 1 minus the classification error.

```
[fpr,accu,thre] = perfcurve(b5v.Y,Sfit(:,gPosition),'g','YCrit','Accu');
figure(20)
plot(thre,accu)
xlabel('Threshold for ''good'' Returns')
ylabel('Classification Accuracy')
```



The curve shows a flat region indicating that any threshold from 0.2 to 0.6 is a reasonable choice. By default, the `perfcurve` assigns classification labels using 0.5 as the boundary between the two classes. You can find exactly what accuracy this corresponds to.

```
accu(abs(thre-0.5)<eps)
```

```
ans = 0.9316
```

The maximal accuracy is a little higher than the default one.

```
[maxaccu,iaccu] = max(accu)
```

```
maxaccu = 0.9345
```

```
iaccu = 99
```

The optimal threshold is therefore.

```
thre(iaccu)
```

```
ans = 0.5278
```

Detect Outliers Using Quantile Regression

This example shows how to detect outliers using quantile random forest. Quantile random forest can detect outliers with respect to the conditional distribution of Y given X. However, this method cannot detect outliers in the predictor data. For outlier detection in the predictor data using a bag of decision trees, see the `OutlierMeasure` property of a `TreeBagger` model.

An *outlier* is an observation that is located far enough from most of the other observations in a data set and can be considered anomalous. Causes of outlying observations include inherent variability or measurement error. Outliers significant affect estimates and inference, so it is important to detect them and decide whether to remove them or consider a robust analysis.

Statistics and Machine Learning Toolbox™ provides several functions to detect outliers, including:

- `zscore` — Compute z scores of observations.
- `trimmean` — Estimate mean of data, excluding outliers.
- `boxplot` — Draw box plot of data.
- `probplot` — Draw probability plot.
- `robustcov` — Estimate robust covariance of multivariate data.
- `fitcsvm` — Fit a one-class support vector machine (SVM) to determine which observations are located far from the decision boundary.
- `dbscan` — Partition observations into clusters and identify outliers using the density-based spatial clustering of application with noise (DBSCAN) algorithm.

Also, MATLAB® provides the `isoutlier` function, which finds outliers in data.

To demonstrate outlier detection, this example:

1. Generates data from a nonlinear model with heteroscedasticity and simulates a few outliers.
2. Grows a quantile random forest of regression trees.
3. Estimates conditional quartiles (Q_1, Q_2, and Q_3) and the interquartile range (IQR) within the ranges of the predictor variables.
4. Compares the observations to the *fences*, which are the quantities $F_1 = Q_1 - 1.5IQR$ and $F_2 = Q_3 + 1.5IQR$. Any observation that is less than F_1 or greater than F_2 is an outlier.

Generate Data

Generate 500 observations from the model

$$y_t = 10 + 3t + t\sin(2t) + \varepsilon_t .$$

t is uniformly distributed between 0 and 4π, and $\varepsilon_t \sim N(0, t + 0.01)$. Store the data in a table.

```
n = 500;
rng('default'); % For reproducibility
t = randsample(linspace(0,4*pi,1e6),n,true)';
epsilon = randn(n,1).*sqrt((t+0.01));
y = 10 + 3*t + t.*sin(2*t) + epsilon;

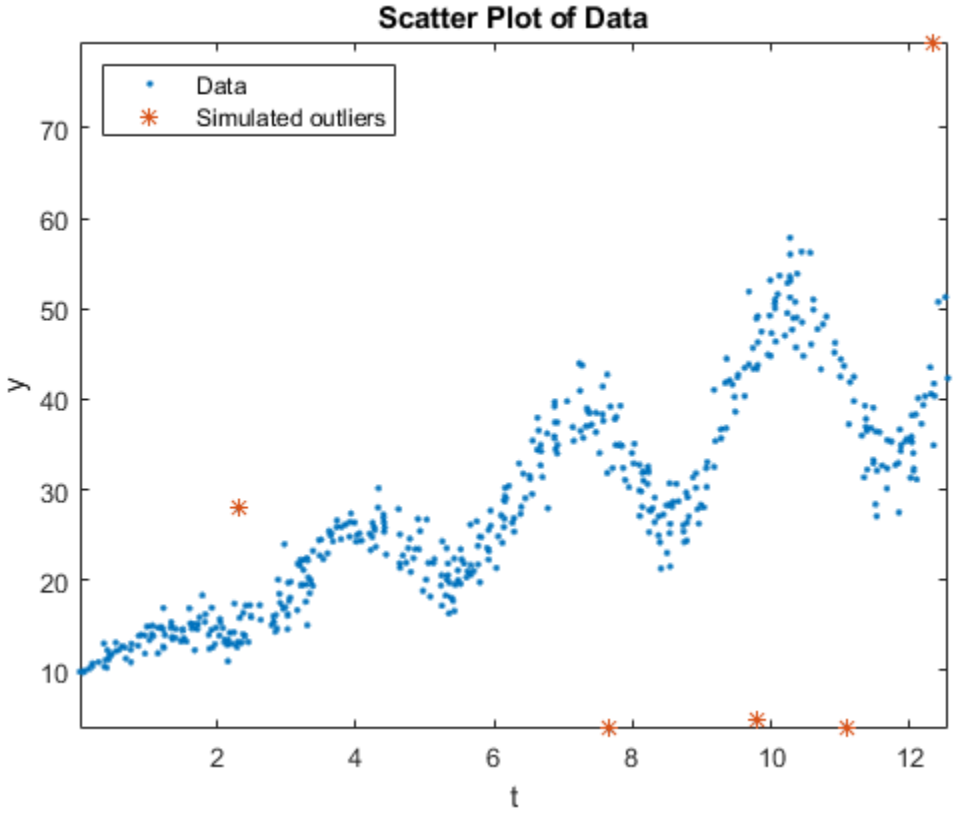
Tbl = table(t,y);
```

Move five observations in a random vertical direction by 90% of the value of the response.

```
numOut = 5;
[~,idx] = datasample(Tbl,numOut);
Tbl.y(idx) = Tbl.y(idx) + randsample([-1 1],numOut,true)'.*(0.9*Tbl.y(idx));
```

Draw a scatter plot of the data and identify the outliers.

```
figure;
plot(Tbl.t,Tbl.y,'.');
hold on
plot(Tbl.t(idx),Tbl.y(idx),'*');
axis tight;
ylabel('y');
xlabel('t');
title('Scatter Plot of Data');
legend('Data','Simulated outliers','Location','NorthWest');
```



Grow Quantile Random Forest

Grow a bag of 200 regression trees using `TreeBagger`.

```
Mdl = TreeBagger(200,Tbl,'y','Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

Predict Conditional Quartiles and Interquartile Ranges

Using quantile regression, estimate the conditional quartiles of 50 equally spaced values within the range of `t`.

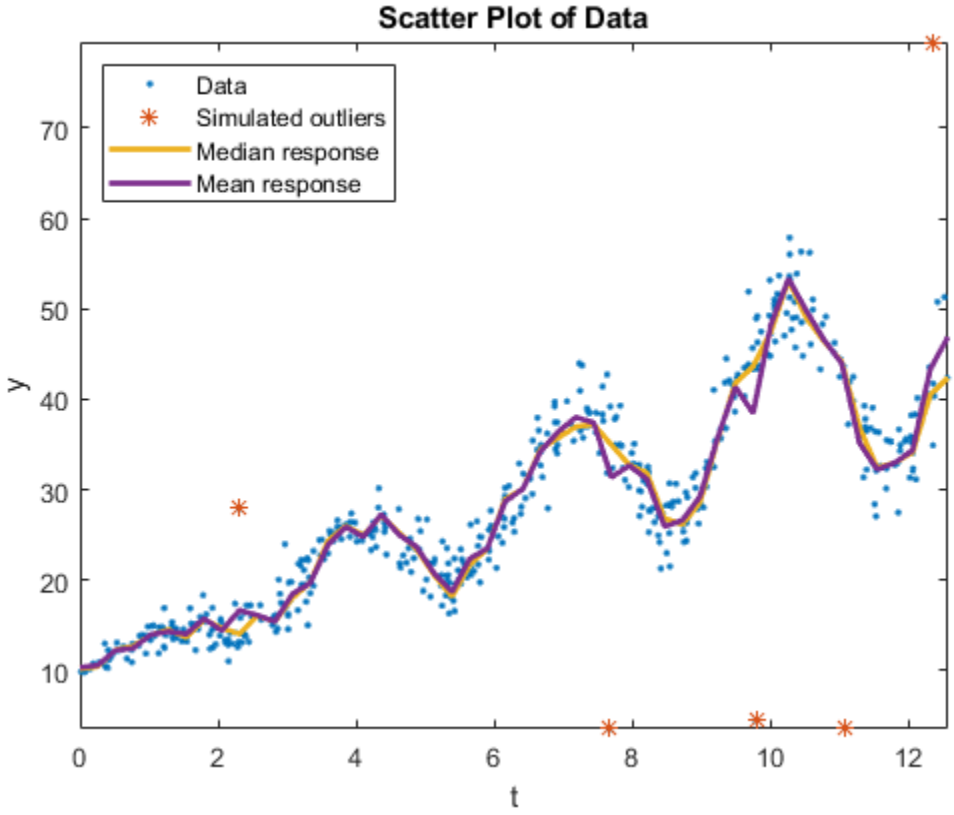
```
tau = [0.25 0.5 0.75];
predT = linspace(0,4*pi,50)';
quartiles = quantilePredict(Mdl,predT,'Quantile',tau);
```

`quartiles` is a 500-by-3 matrix of conditional quartiles. Rows correspond to the observations in `t`, and columns correspond to the probabilities in `tau`.

On the scatter plot of the data, plot the conditional mean and median responses.

```
meanY = predict(Mdl,predT);

plot(predT,[quartiles(:,2) meanY],'LineWidth',2);
legend('Data','Simulated outliers','Median response','Mean response',...
    'Location','NorthWest');
hold off;
```



Although the conditional mean and median curves are close, the simulated outliers can affect the mean curve.

Compute the conditional IQR, F_1, and F_2.

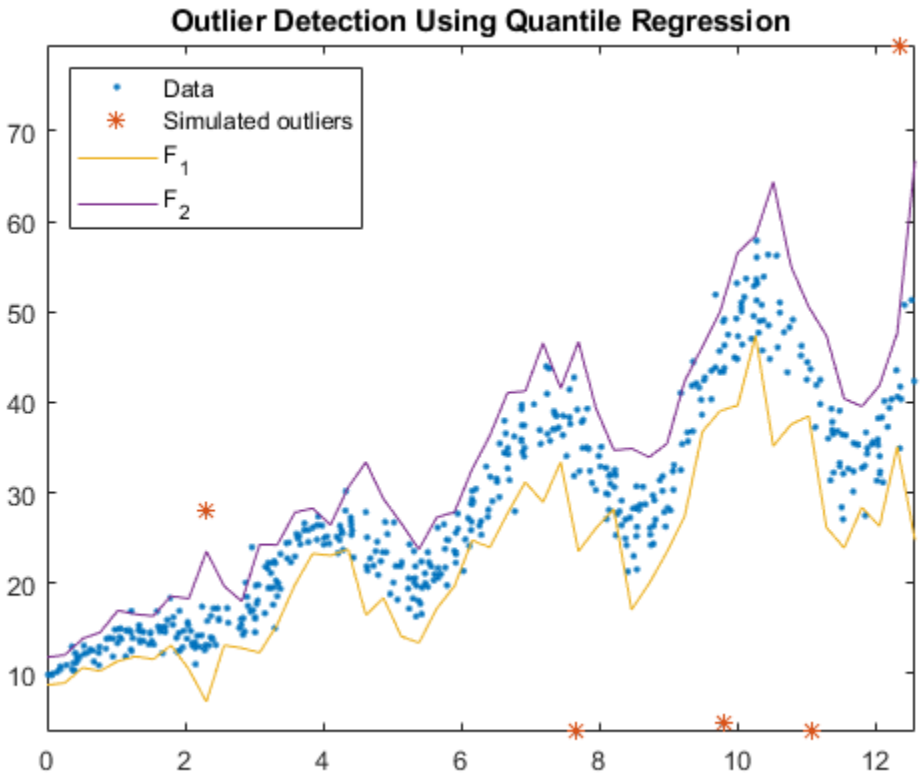
```
iqr = quartiles(:,3) - quartiles(:,1);
k = 1.5;
f1 = quartiles(:,1) - k*iqr;
f2 = quartiles(:,3) + k*iqr;
```

`k = 1.5` means that all observations less than `f1` or greater than `f2` are considered outliers, but this threshold does not disambiguate from extreme outliers. A `k` of 3 identifies extreme outliers.

Compare Observations to Fences

Plot the observations and the fences.

```
figure;
plot(Tbl.t,Tbl.y,'.');
hold on
plot(Tbl.t(idx),Tbl.y(idx),'*');
plot(predT,[f1 f2]);
legend('Data','Simulated outliers','F_1','F_2','Location','NorthWest');
axis tight
title('Outlier Detection Using Quantile Regression')
hold off
```



All simulated outliers fall outside $[F_1, F_2]$, and some observations are outside this interval as well.

Conditional Quantile Estimation Using Kernel Smoothing

This example shows how to estimate conditional quantiles of a response given predictor data using quantile random forest and by estimating the conditional distribution function of the response using kernel smoothing.

For quantile-estimation speed, `quantilePredict`, `oobQuantilePredict`, `quantileError`, and `oobQuantileError` use linear interpolation to predict quantiles in the conditional distribution of the response. However, you can obtain response weights, which comprise the distribution function, and then pass them to `ksdensity` to possibly gain accuracy at the cost of computation speed.

Generate 2000 observations from the model

$$y_t = 0.5 + t + \varepsilon_t.$$

t is uniformly distributed between 0 and 1, and $\varepsilon_t \sim N(0, t^2/2 + 0.01)$. Store the data in a table.

```
n = 2000;
rng('default'); % For reproducibility
t = randsample(linspace(0,1,1e2),n,true)';
epsilon = randn(n,1).*sqrt(t.^2/2 + 0.01);
y = 0.5 + t + epsilon;

Tbl = table(t,y);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 200 weak learners and save the out-of-bag indices.

```
rng('default'); % For reproducibility
Mdl = TreeBagger(200,Tbl,'y','Method','regression',...
    'OOBPrediction','on');
```

`Mdl` is a `TreeBagger` ensemble.

Predict out-of-bag, conditional 0.05 and 0.95 quantiles (90% confidence intervals) for all training-sample observations using `oobQuantilePredict`, that is, by interpolation. Request response weights. Record the execution time.

```
tau = [0.05 0.95];
tic
[quantInterp,yw] = oobQuantilePredict(Mdl,'Quantile',tau);
timeInterp = toc;
```

`quantInterp` is a 94-by-2 matrix of predicted quantiles; rows correspond to the observations in `Mdl.X` and columns correspond to the quantile probabilities in `tau`. `yw` is a 94-by-94 sparse matrix of response weights; rows correspond to training-sample observations and columns correspond to the observations in `Mdl.X`. Response weights are independent of `tau`.

Predict out-of-bag, conditional 0.05 and 0.95 quantiles using kernel smoothing and record the execution time.

```
n = numel(Tbl.y);
quantKS = zeros(n,numel(tau)); % Preallocation

tic
for j = 1:n
```

```
    quantKS(j,:) = ksdensity(Tbl.y,tau,'Function','icdf','Weights',yw(:,j));
end
timeKS = toc;
```

`quantKS` is commensurate with `quantInterp`.

Evaluate the ratio of execution times between kernel smoothing estimation and interpolation.

```
timeKS/timeInterp
```

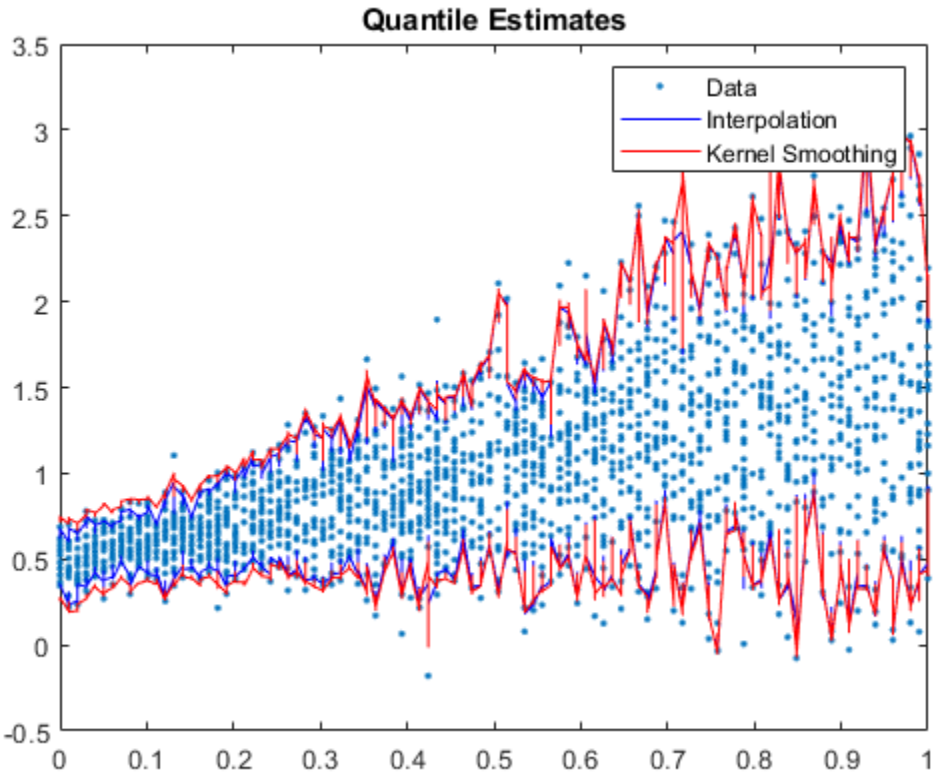
```
ans = 7.7973
```

It takes much more time to execute kernel smoothing than interpolation. This ratio is dependent on the memory of your machine, so your results will vary.

Plot the data with both sets of predicted quantiles.

```
[sT,idx] = sort(t);

figure;
h1 = plot(t,y,'.');
hold on
h2 = plot(sT,quantInterp(idx,:),'b');
h3 = plot(sT,quantKS(idx,:),'r');
legend([h1 h2(1) h3(1)],'Data','Interpolation','Kernel Smoothing');
title('Quantile Estimates')
hold off
```



Both sets of estimated quantiles agree fairly well. However, the quantile intervals from interpolation appear slightly tighter for smaller values of `t` than the ones from kernel smoothing.

Tune Random Forest Using Quantile Error and Bayesian Optimization

This example shows how to implement Bayesian optimization to tune the hyperparameters of a random forest of regression trees using quantile error. Tuning a model using quantile error, rather than mean squared error, is appropriate if you plan to use the model to predict conditional quantiles rather than conditional means.

Load and Preprocess Data

Load the `carsmall` data set. Consider a model that predicts the median fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
rng('default'); % For reproducibility
```

Specify Tuning Parameters

Consider tuning:

- The complexity (depth) of the trees in the forest. Deep trees tend to over-fit, but shallow trees tend to underfit. Therefore, specify that the minimum number of observations per leaf be at most 20.
- When growing the trees, the number of predictors to sample at each node. Specify sampling from 1 through all of the predictors.

`bayesopt`, the function that implements Bayesian optimization, requires you to pass these specifications as `optimizableVariable` objects.

```
maxMinLS = 20;
minLS = optimizableVariable('minLS',[1,maxMinLS],'Type','integer');
numPTS = optimizableVariable('numPTS',[1,size(X,2)-1],'Type','integer');
hyperparametersRF = [minLS; numPTS];
```

`hyperparametersRF` is a 2-by-1 array of `OptimizableVariable` objects.

You should also consider tuning the number of trees in the ensemble. `bayesopt` tends to choose random forests containing many trees because ensembles with more learners are more accurate. If available computation resources is a consideration, and you prefer ensembles with as fewer trees, then consider tuning the number of trees separately from the other parameters or penalizing models containing many learners.

Define Objective Function

Define an objective function for the Bayesian optimization algorithm to optimize. The function should:

- Accept the parameters to tune as an input.
- Train a random forest using `TreeBagger`. In the `TreeBagger` call, specify the parameters to tune and specify returning the out-of-bag indices.

- Estimate the out-of-bag quantile error based on the median.
- Return the out-of-bag quantile error.

```
function oobErr = oobErrRF(params,X)
%oobErrRF Trains random forest and estimates out-of-bag quantile error
%   oobErr trains a random forest of 300 regression trees using the
%   predictor data in X and the parameter specification in params, and then
%   returns the out-of-bag quantile error based on the median. X is a table
%   and params is an array of OptimizableVariable objects corresponding to
%   the minimum leaf size and number of predictors to sample at each node.
randomForest = TreeBagger(300,X,'MPG','Method','regression',...
    'OOBPrediction','on','MinLeafSize',params.minLS,...
    'NumPredictorstoSample',params.numPTS);
oobErr = oobQuantileError(randomForest);
end
```

Minimize Objective Using Bayesian Optimization

Find the model achieving the minimal, penalized, out-of-bag quantile error with respect to tree complexity and number of predictors to sample at each node using Bayesian optimization. Specify the expected improvement plus function as the acquisition function and suppress printing the optimization information.

```
results = bayesopt(@(params)oobErrRF(params,X),hyperparametersRF,...
    'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);
```

Support Vector Machines for Binary Classification

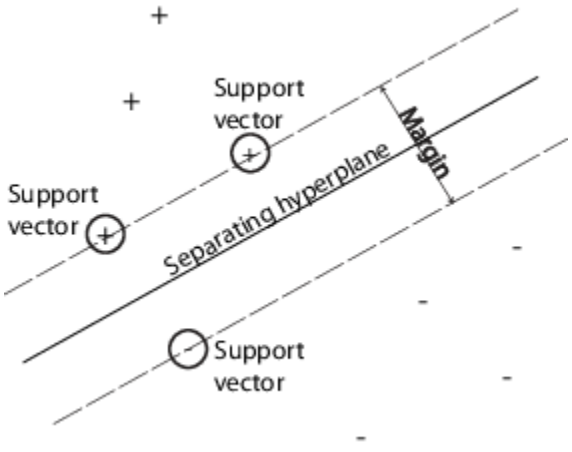
In this section...

Understanding Support Vector Machines

Separable Data

You can use a support vector machine (SVM) when your data has exactly two classes. An SVM classifies data by finding the best hyperplane that separates all data points of one class from those of the other class. The best hyperplane for an SVM means the one with the largest margin between the two classes. Margin means the maximal width of the slab parallel to the hyperplane that has no interior data points.

The support vectors are the data points that are closest to the separating hyperplane; these points are on the boundary of the slab. The following figure illustrates these definitions, with + indicating data points of type 1, and – indicating data points of type –1.



Mathematical Formulation: Primal

This discussion follows Hastie, Tibshirani, and Friedman [1] and Christianini and Shawe-Taylor [2].

The data for training is a set of points (vectors) x_j along with their categories y_j. For some dimension d, the $x_j \in R^d$, and the $y_j = \pm 1$. The equation of a hyperplane is

$$f(x) = x'\beta + b = 0$$

where $\beta \in R^d$ and b is a real number.

The following problem defines the best separating hyperplane (i.e., the decision boundary). Find β and b that minimize $||\beta||$ such that for all data points (x_j, y_j),

$$y_j f(x_j) \geq 1.$$

The support vectors are the x_j on the boundary, those for which $y_j f(x_j) = 1$.

For mathematical convenience, the problem is usually given as the equivalent problem of minimizing $\|\beta\|$. This is a quadratic programming problem. The optimal solution $\left(\widehat{\beta}, \widehat{b}\right)$ enables classification of a vector z as follows:

$$\text{class}(z) = \text{sign}\left(z'\widehat{\beta} + \widehat{b}\right) = \text{sign}\left(\widehat{f}(z)\right).$$

$\widehat{f}(z)$ is the classification score and represents the distance z is from the decision boundary.

Mathematical Formulation: Dual

It is computationally simpler to solve the dual quadratic programming problem. To obtain the dual, take positive Lagrange multipliers α_j multiplied by each constraint, and subtract from the objective function:

$$L_P = \frac{1}{2}\beta'\beta - \sum_j \alpha_j \left(y_j \left(x_j'\beta + b\right) - 1\right),$$

where you look for a stationary point of L_P over β and b. Setting the gradient of L_P to 0, you get

$$\begin{aligned} \beta &= \sum_j \alpha_j y_j x_j \\ 0 &= \sum_j \alpha_j y_j . \end{aligned} \tag{18-1}$$

Substituting into L_P, you get the dual L_D:

$$L_D = \sum_j \alpha_j - \frac{1}{2}\sum_j \sum_k \alpha_j \alpha_k y_j y_k x_j' x_k,$$

which you maximize over $\alpha_j \geq 0$. In general, many α_j are 0 at the maximum. The nonzero α_j in the solution to the dual problem define the hyperplane, as seen in “Equation 18-1”, which gives β as the sum of $\alpha_j y_j x_j$. The data points x_j corresponding to nonzero α_j are the support vectors.

The derivative of L_D with respect to a nonzero α_j is 0 at an optimum. This gives

$$y_j f(x_j) - 1 = 0.$$

In particular, this gives the value of b at the solution, by taking any j with nonzero α_j.

The dual is a standard quadratic programming problem. For example, the Optimization Toolbox `quadprog` solver solves this type of problem.

Nonseparable Data

Your data might not allow for a separating hyperplane. In that case, SVM can use a soft margin, meaning a hyperplane that separates many, but not all data points.

There are two standard formulations of soft margins. Both involve adding slack variables ξ_j and a penalty parameter C.

- The L^1-norm problem is:

  $$\min_{\beta, b, \xi}\left(\frac{1}{2}\beta'\beta + C\sum_j \xi_j\right)$$

  such that

  $$\begin{aligned} y_j f(x_j) &\geq 1 - \xi_j \\ \xi_j &\geq 0. \end{aligned}$$

  The L^1-norm refers to using ξ_j as slack variables instead of their squares. The three solver options `SMO`, `ISDA`, and `L1QP` of `fitcsvm` minimize the L^1-norm problem.
- The L^2-norm problem is:

  $$\min_{\beta, b, \xi}\left(\frac{1}{2}\beta'\beta + C\sum_j \xi_j^2\right)$$

  subject to the same constraints.

In these formulations, you can see that increasing C places more weight on the slack variables ξ_j, meaning the optimization attempts to make a stricter separation between classes. Equivalently, reducing C towards 0 makes misclassification less important.

Mathematical Formulation: Dual

For easier calculations, consider the L^1 dual problem to this soft-margin formulation. Using Lagrange multipliers μ_j, the function to minimize for the L^1-norm problem is:

$$L_P = \frac{1}{2}\beta'\beta + C\sum_j \xi_j - \sum_j \alpha_j\left(y_i f(x_j) - (1 - \xi_j)\right) - \sum_j \mu_j \xi_j,$$

where you look for a stationary point of L_P over β, b, and positive ξ_j. Setting the gradient of L_P to 0, you get

$$\begin{aligned} \beta &= \sum_j \alpha_j y_j x_j \\ \sum_j \alpha_j y_j &= 0 \\ \alpha_j &= C - \mu_j \\ \alpha_j, \mu_j, \xi_j &\geq 0. \end{aligned}$$

These equations lead directly to the dual formulation:

$$\max_{\alpha} \sum_j \alpha_j - \frac{1}{2} \sum_j \sum_k \alpha_j \alpha_k y_j y_k x_j' x_k$$

subject to the constraints

$$\sum_j y_j \alpha_j = 0$$
$$0 \le \alpha_j \le C .$$

The final set of inequalities, $0 \le \alpha_j \le C$, shows why C is sometimes called a box constraint. C keeps the allowable values of the Lagrange multipliers α_j in a "box", a bounded region.

The gradient equation for b gives the solution b in terms of the set of nonzero α_j, which correspond to the support vectors.

You can write and solve the dual of the L^2-norm problem in an analogous manner. For details, see Christianini and Shawe-Taylor [2], Chapter 6.

fitcsvm Implementation

Both dual soft-margin problems are quadratic programming problems. Internally, `fitcsvm` has several different algorithms for solving the problems.

- For one-class or binary classification, if you do not set a fraction of expected outliers in the data (see `OutlierFraction`), then the default solver is Sequential Minimal Optimization (SMO). SMO minimizes the one-norm problem by a series of two-point minimizations. During optimization, SMO respects the linear constraint $\sum_i \alpha_i y_i = 0$, and explicitly includes the bias term in the model. SMO is relatively fast. For more details on SMO, see [3].
- For binary classification, if you set a fraction of expected outliers in the data, then the default solver is the Iterative Single Data Algorithm. Like SMO, ISDA solves the one-norm problem. Unlike SMO, ISDA minimizes by a series on one-point minimizations, does not respect the linear constraint, and does not explicitly include the bias term in the model. For more details on ISDA, see [4].
- For one-class or binary classification, and if you have an Optimization Toolbox license, you can choose to use `quadprog` to solve the one-norm problem. `quadprog` uses a good deal of memory, but solves quadratic programs to a high degree of precision. For more details, see "Quadratic Programming Definition" (Optimization Toolbox).

Nonlinear Transformation with Kernels

Some binary classification problems do not have a simple hyperplane as a useful separating criterion. For those problems, there is a variant of the mathematical approach that retains nearly all the simplicity of an SVM separating hyperplane.

This approach uses these results from the theory of reproducing kernels:

- There is a class of functions $G(x_1,x_2)$ with the following property. There is a linear space S and a function φ mapping x to S such that

  $G(x_1,x_2) = <\varphi(x_1),\varphi(x_2)>$.

  The dot product takes place in the space S.

- This class of functions includes:
  - Polynomials: For some positive integer p,

    $G(x_1,x_2) = (1 + x_1'x_2)^p$.
  - Radial basis function (Gaussian):

    $G(x_1,x_2) = \exp(-\|x_1-x_2)\|^2)$.
  - Multilayer perceptron or sigmoid (neural network): For a positive number p_1 and a negative number p_2,

    $G(x_1,x_2) = \tanh(p_1x_1'x_2 + p_2)$.

    Note

    - Not every set of p_1 and p_2 yields a valid reproducing kernel.
    - `fitcsvm` does not support the sigmoid kernel. Instead, you can define the sigmoid kernel and specify it by using the `'KernelFunction'` name-value pair argument. For details, see "Train SVM Classifier Using Custom Kernel" on page 18-159.

The mathematical approach using kernels relies on the computational method of hyperplanes. All the calculations for hyperplane classification use nothing more than dot products. Therefore, nonlinear kernels can use identical calculations and solution algorithms, and obtain classifiers that are nonlinear. The resulting classifiers are hypersurfaces in some space S, but the space S does not have to be identified or examined.

Using Support Vector Machines

As with any supervised learning model, you first train a support vector machine, and then cross validate the classifier. Use the trained machine to classify (predict) new data. In addition, to obtain satisfactory predictive accuracy, you can use various SVM kernel functions, and you must tune the parameters of the kernel functions.

Training an SVM Classifier

Train, and optionally cross validate, an SVM classifier using `fitcsvm`. The most common syntax is:

```
SVMModel = fitcsvm(X,Y,'KernelFunction','rbf',...
    'Standardize',true,'ClassNames',{'negClass','posClass'});
```

The inputs are:

- `X` — Matrix of predictor data, where each row is one observation, and each column is one predictor.
- `Y` — Array of class labels with each row corresponding to the value of the corresponding row in `X`. `Y` can be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.

- `KernelFunction` — The default value is `'linear'` for two-class learning, which separates the data by a hyperplane. The value `'gaussian'` (or `'rbf'`) is the default for one-class learning, and specifies to use the Gaussian (or radial basis function) kernel. An important step to successfully train an SVM classifier is to choose an appropriate kernel function.
- `Standardize` — Flag indicating whether the software should standardize the predictors before training the classifier.
- `ClassNames` — Distinguishes between the negative and positive classes, or specifies which classes to include in the data. The negative class is the first element (or row of a character array), e.g., `'negClass'`, and the positive class is the second element (or row of a character array), e.g., `'posClass'`. `ClassNames` must be the same data type as `Y`. It is good practice to specify the class names, especially if you are comparing the performance of different classifiers.

The resulting, trained model (`SVMModel`) contains the optimized parameters from the SVM algorithm, enabling you to classify new data.

For more name-value pairs you can use to control the training, see the `fitcsvm` reference page.

Classifying New Data with an SVM Classifier

Classify new data using `predict`. The syntax for classifying new data using a trained SVM classifier (`SVMModel`) is:

```
[label,score] = predict(SVMModel,newX);
```

The resulting vector, `label`, represents the classification of each row in `X`. `score` is an *n*-by-2 matrix of soft scores. Each row corresponds to a row in `X`, which is a new observation. The first column contains the scores for the observations being classified in the negative class, and the second column contains the scores observations being classified in the positive class.

To estimate posterior probabilities rather than scores, first pass the trained SVM classifier (`SVMModel`) to `fitPosterior`, which fits a score-to-posterior-probability transformation function to the scores. The syntax is:

```
ScoreSVMModel = fitPosterior(SVMModel,X,Y);
```

The property `ScoreTransform` of the classifier `ScoreSVMModel` contains the optimal transformation function. Pass `ScoreSVMModel` to `predict`. Rather than returning the scores, the output argument `score` contains the posterior probabilities of an observation being classified in the negative (column 1 of `score`) or positive (column 2 of `score`) class.

Tuning an SVM Classifier

Use the `'OptimizeHyperparameters'` name-value pair argument of `fitcsvm` to find parameter values that minimize the cross-validation loss. The eligible parameters are `'BoxConstraint'`, `'KernelFunction'`, `'KernelScale'`, `'PolynomialOrder'`, and `'Standardize'`. For an example, see “Optimize an SVM Classifier Fit Using Bayesian Optimization” on page 18-163. Alternatively, you can use the `bayesopt` function, as shown in “Optimize a Cross-Validated SVM Classifier Using bayesopt” on page 10-45. The `bayesopt` function allows more flexibility to customize optimization. You can use the `bayesopt` function to optimize any parameters, including parameters that are not eligible to optimize when you use the `fitcsvm` function.

You can also try tuning parameters of your classifier manually according to this scheme:

1. Pass the data to `fitcsvm`, and set the name-value pair argument `'KernelScale','auto'`. Suppose that the trained SVM model is called `SVMModel`. The software uses a heuristic

procedure to select the kernel scale. The heuristic procedure uses subsampling. Therefore, to reproduce results, set a random number seed using `rng` before training the classifier.

2. Cross validate the classifier by passing it to `crossval`. By default, the software conducts 10-fold cross validation.
3. Pass the cross-validated SVM model to `kfoldLoss` to estimate and retain the classification error.
4. Retrain the SVM classifier, but adjust the `'KernelScale'` and `'BoxConstraint'` name-value pair arguments.

   - `BoxConstraint` — One strategy is to try a geometric sequence of the box constraint parameter. For example, take 11 values, from `1e-5` to `1e5` by a factor of 10. Increasing `BoxConstraint` might decrease the number of support vectors, but also might increase training time.
   - `KernelScale` — One strategy is to try a geometric sequence of the RBF sigma parameter scaled at the original kernel scale. Do this by:

     a. Retrieving the original kernel scale, e.g., `ks`, using dot notation: `ks = SVMModel.KernelParameters.Scale`.

     b. Use as new kernel scales factors of the original. For example, multiply `ks` by the 11 values `1e-5` to `1e5`, increasing by a factor of 10.

Choose the model that yields the lowest classification error. You might want to further refine your parameters to obtain better accuracy. Start with your initial parameters and perform another cross-validation step, this time using a factor of 1.2.

Train SVM Classifiers Using a Gaussian Kernel

This example shows how to generate a nonlinear classifier with Gaussian kernel function. First, generate one class of points inside the unit disk in two dimensions, and another class of points in the annulus from radius 1 to radius 2. Then, generates a classifier based on the data with the Gaussian radial basis function kernel. The default linear classifier is obviously unsuitable for this problem, since the model is circularly symmetric. Set the box constraint parameter to `Inf` to make a strict classification, meaning no misclassified training points. Other kernel functions might not work with this strict box constraint, since they might be unable to provide a strict classification. Even though the rbf classifier can separate the classes, the result can be overtrained.

Generate 100 points uniformly distributed in the unit disk. To do so, generate a radius r as the square root of a uniform random variable, generate an angle t uniformly in $(0, 2\pi)$, and put the point at $(r\cos(t), r\sin(t))$.

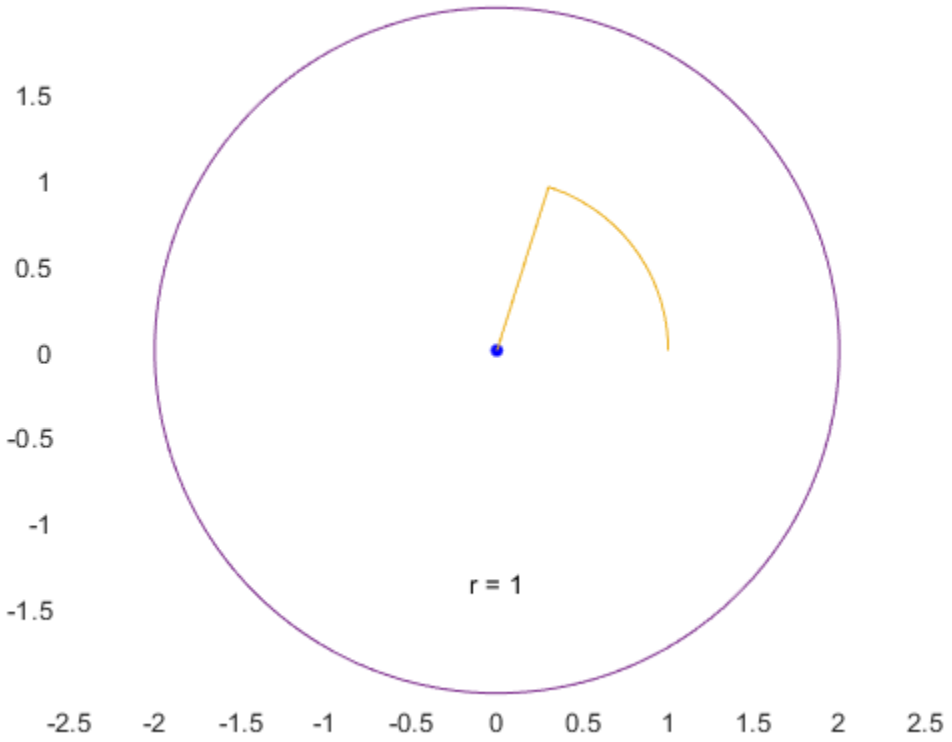
```
rng(1); % For reproducibility
r = sqrt(rand(100,1)); % Radius
t = 2*pi*rand(100,1);  % Angle
data1 = [r.*cos(t), r.*sin(t)]; % Points
```

Generate 100 points uniformly distributed in the annulus. The radius is again proportional to a square root, this time a square root of the uniform distribution from 1 through 4.

```
r2 = sqrt(3*rand(100,1)+1); % Radius
t2 = 2*pi*rand(100,1);      % Angle
data2 = [r2.*cos(t2), r2.*sin(t2)]; % points
```

Plot the points, and plot circles of radii 1 and 2 for comparison.

```
figure;
plot(data1(:,1),data1(:,2),'r.','MarkerSize',15)
hold on
plot(data2(:,1),data2(:,2),'b.','MarkerSize',15)
ezpolar(@(x)1);ezpolar(@(x)2);
axis equal
hold off
```



Put the data in one matrix, and make a vector of classifications.

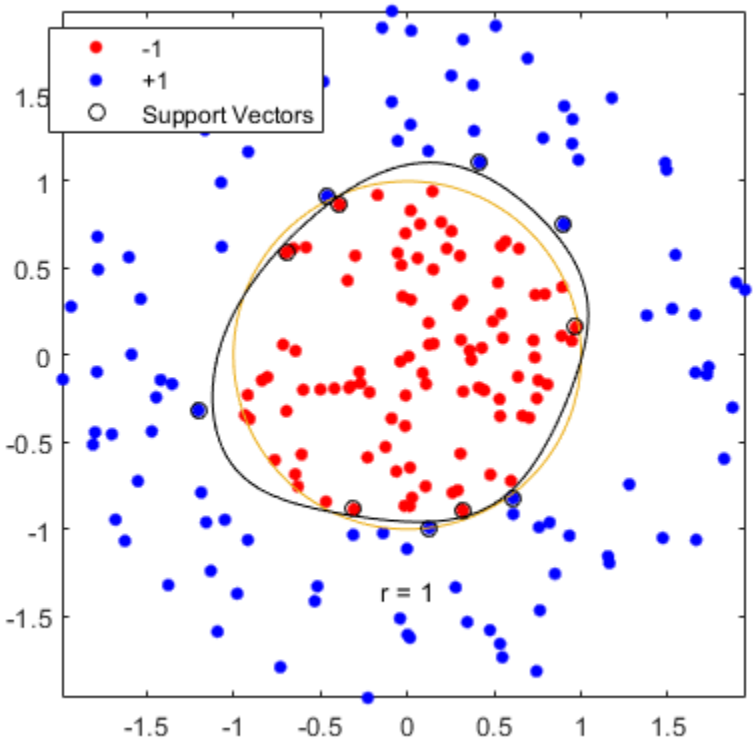
```
data3 = [data1;data2];
theclass = ones(200,1);
theclass(1:100) = -1;
```

Train an SVM classifier with `KernelFunction` set to `'rbf'` and `BoxConstraint` set to `Inf`. Plot the decision boundary and flag the support vectors.

```
%Train the SVM Classifier
cl = fitcsvm(data3,theclass,'KernelFunction','rbf',...
    'BoxConstraint',Inf,'ClassNames',[-1,1]);

% Predict scores over the grid
d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(data3(:,1)):d:max(data3(:,1)),...
    min(data3(:,2)):d:max(data3(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
[~,scores] = predict(cl,xGrid);
```

```
% Plot the data and the decision boundary
figure;
h(1:2) = gscatter(data3(:,1),data3(:,2),theclass,'rb','.');
hold on
ezpolar(@(x)1);
h(3) = plot(data3(cl.IsSupportVector,1),data3(cl.IsSupportVector,2),'ko');
contour(x1Grid,x2Grid,reshape(scores(:,2),size(x1Grid)),[0 0],'k');
legend(h,{'-1','+1','Support Vectors'});
axis equal
hold off
```



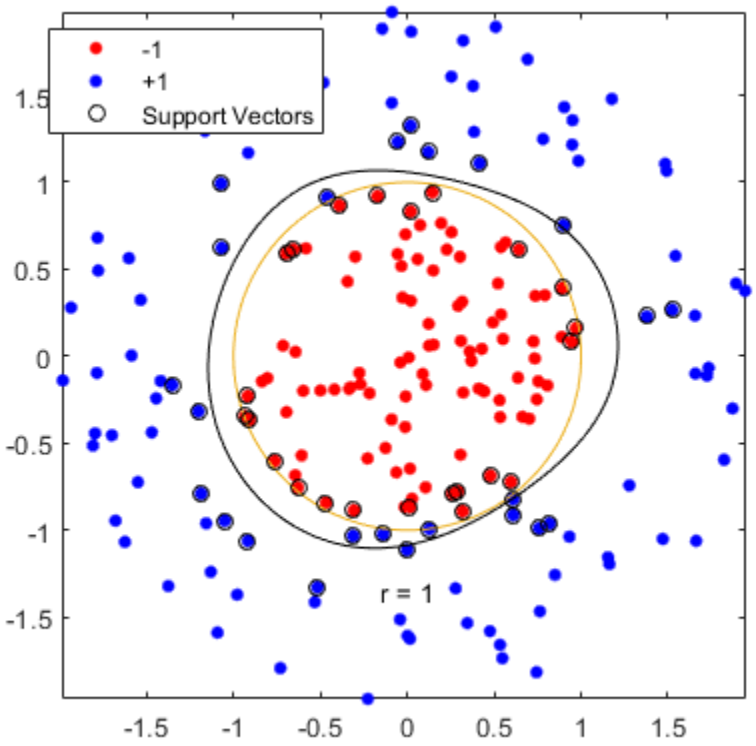
`fitcsvm` generates a classifier that is close to a circle of radius 1. The difference is due to the random training data.

Training with the default parameters makes a more nearly circular classification boundary, but one that misclassifies some training data. Also, the default value of `BoxConstraint` is `1`, and, therefore, there are more support vectors.

```
cl2 = fitcsvm(data3,theclass,'KernelFunction','rbf');
[~,scores2] = predict(cl2,xGrid);

figure;
h(1:2) = gscatter(data3(:,1),data3(:,2),theclass,'rb','.');
hold on
ezpolar(@(x)1);
h(3) = plot(data3(cl2.IsSupportVector,1),data3(cl2.IsSupportVector,2),'ko');
contour(x1Grid,x2Grid,reshape(scores2(:,2),size(x1Grid)),[0 0],'k');
```

```
legend(h,{'-1','+1','Support Vectors'});
axis equal
hold off
```



Train SVM Classifier Using Custom Kernel

This example shows how to use a custom kernel function, such as the sigmoid kernel, to train SVM classifiers, and adjust custom kernel function parameters.

Generate a random set of points within the unit circle. Label points in the first and third quadrants as belonging to the positive class, and those in the second and fourth quadrants in the negative class.

```
rng(1);  % For reproducibility
n = 100; % Number of points per quadrant

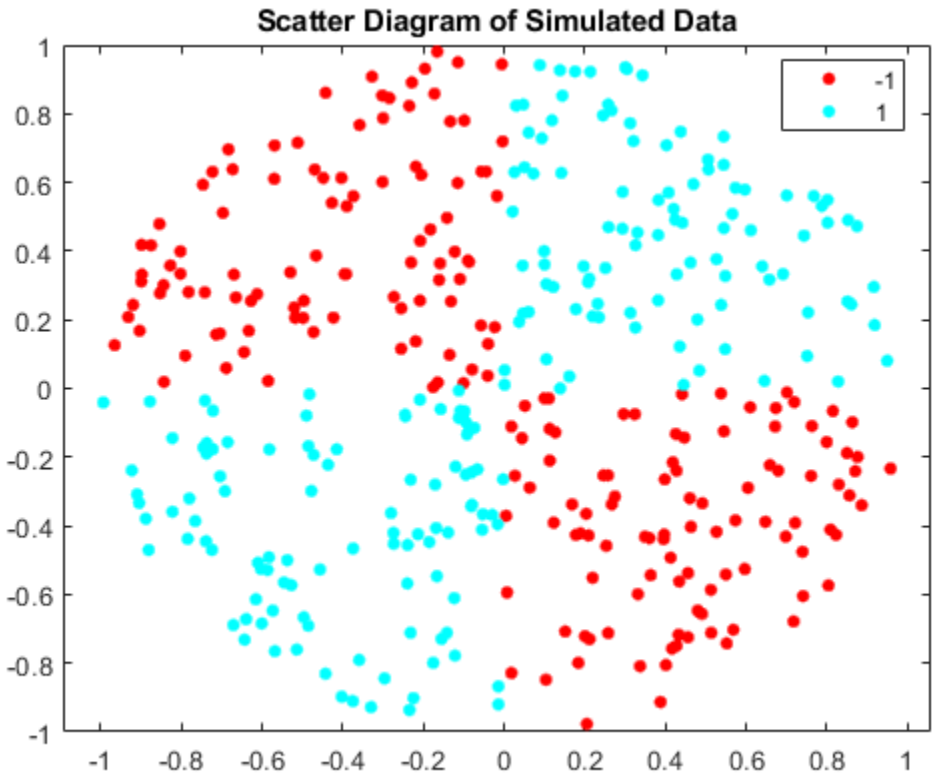
r1 = sqrt(rand(2*n,1));                     % Random radii
t1 = [pi/2*rand(n,1); (pi/2*rand(n,1)+pi)]; % Random angles for Q1 and Q3
X1 = [r1.*cos(t1) r1.*sin(t1)];             % Polar-to-Cartesian conversion

r2 = sqrt(rand(2*n,1));
t2 = [pi/2*rand(n,1)+pi/2; (pi/2*rand(n,1)-pi/2)]; % Random angles for Q2 and Q4
X2 = [r2.*cos(t2) r2.*sin(t2)];

X = [X1; X2];        % Predictors
Y = ones(4*n,1);
Y(2*n + 1:end) = -1; % Labels
```

Plot the data.

```
figure;
gscatter(X(:,1),X(:,2),Y);
title('Scatter Diagram of Simulated Data')
```



Write a function that accepts two matrices in the feature space as inputs, and transforms them into a Gram matrix using the sigmoid kernel.

```
function G = mysigmoid(U,V)
% Sigmoid kernel function with slope gamma and intercept c
gamma = 1;
c = -1;
G = tanh(gamma*U*V' + c);
end
```

Save this code as a file named `mysigmoid` on your MATLAB® path.

Train an SVM classifier using the sigmoid kernel function. It is good practice to standardize the data.

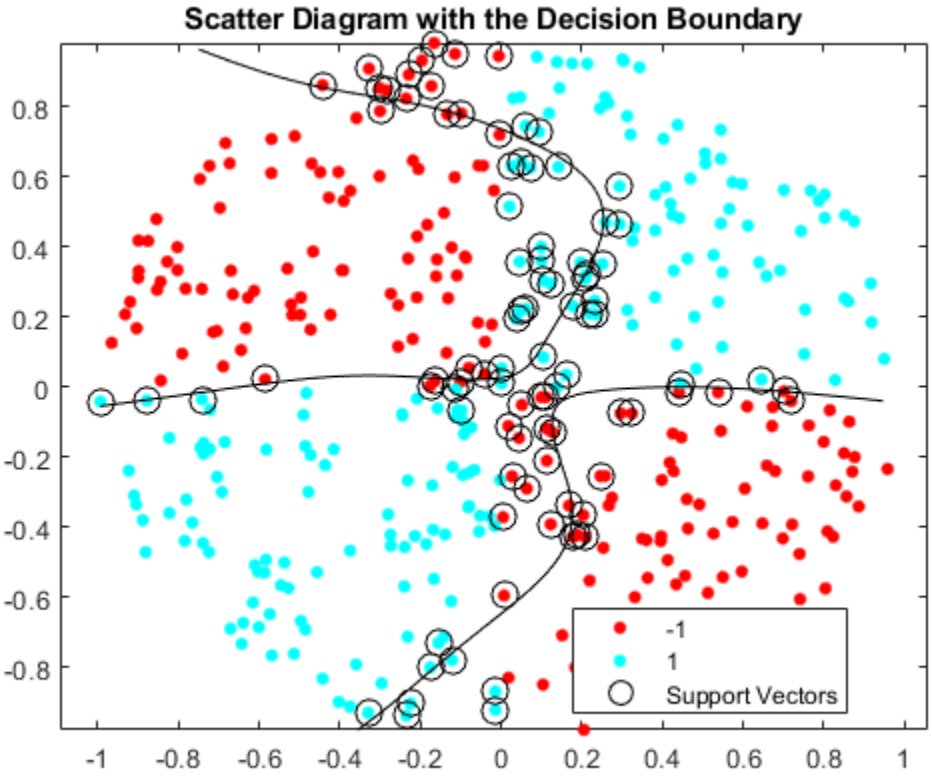
```
Mdl1 = fitcsvm(X,Y,'KernelFunction','mysigmoid','Standardize',true);
```

`Mdl1` is a `ClassificationSVM` classifier containing the estimated parameters.

Plot the data, and identify the support vectors and the decision boundary.

```
    % Compute the scores over a grid
d = 0.02; % Step size of the grid
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];        % The grid
[~,scores1] = predict(Mdl1,xGrid); % The scores

figure;
h(1:2) = gscatter(X(:,1),X(:,2),Y);
hold on
h(3) = plot(X(Mdl1.IsSupportVector,1),...
    X(Mdl1.IsSupportVector,2),'ko','MarkerSize',10);
    % Support vectors
contour(x1Grid,x2Grid,reshape(scores1(:,2),size(x1Grid)),[0 0],'k');
    % Decision boundary
title('Scatter Diagram with the Decision Boundary')
legend({'-1','1','Support Vectors'},'Location','Best');
hold off
```



You can adjust the kernel parameters in an attempt to improve the shape of the decision boundary. This might also decrease the within-sample misclassification rate, but, you should first determine the out-of-sample misclassification rate.

Determine the out-of-sample misclassification rate by using 10-fold cross validation.

```
CVMdl1 = crossval(Mdl1);
misclass1 = kfoldLoss(CVMdl1);
misclass1
```

```
misclass1 =

    0.1350
```

The out-of-sample misclassification rate is 13.5%.

Write another sigmoid function, but Set `gamma = 0.5;`.

```
function G = mysigmoid2(U,V)
% Sigmoid kernel function with slope gamma and intercept c
gamma = 0.5;
c = -1;
G = tanh(gamma*U*V' + c);
end
```

Save this code as a file named `mysigmoid2` on your MATLAB® path.

Train another SVM classifier using the adjusted sigmoid kernel. Plot the data and the decision region, and determine the out-of-sample misclassification rate.

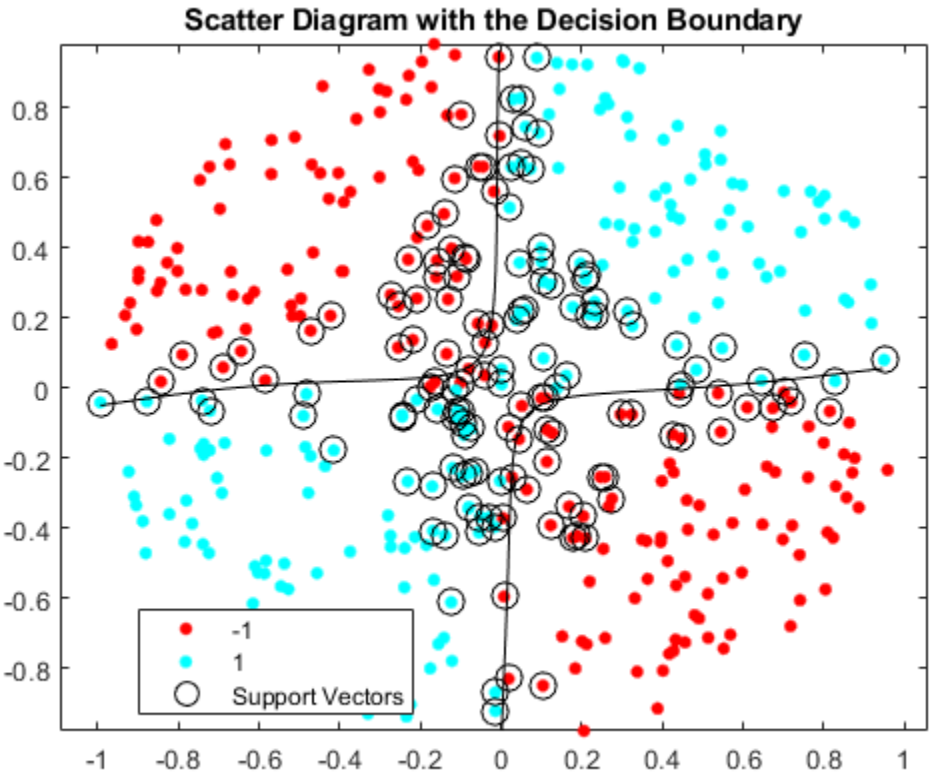
```
Mdl2 = fitcsvm(X,Y,'KernelFunction','mysigmoid2','Standardize',true);
[~,scores2] = predict(Mdl2,xGrid);

figure;
h(1:2) = gscatter(X(:,1),X(:,2),Y);
hold on
h(3) = plot(X(Mdl2.IsSupportVector,1),...
    X(Mdl2.IsSupportVector,2),'ko','MarkerSize',10);
title('Scatter Diagram with the Decision Boundary')
contour(x1Grid,x2Grid,reshape(scores2(:,2),size(x1Grid)),[0 0],'k');
legend({'-1','1','Support Vectors'},'Location','Best');
hold off

CVMdl2 = crossval(Mdl2);
misclass2 = kfoldLoss(CVMdl2);
misclass2
```

```
misclass2 =

    0.0450
```



After the sigmoid slope adjustment, the new decision boundary seems to provide a better within-sample fit, and the cross-validation rate contracts by more than 66%.

Optimize an SVM Classifier Fit Using Bayesian Optimization

This example shows how to optimize an SVM classification using the `fitcsvm` function and `OptimizeHyperparameters` name-value pair. The classification works on locations of points from a Gaussian mixture model. In *The Elements of Statistical Learning*, Hastie, Tibshirani, and Friedman (2009), page 17 describes the model. The model begins with generating 10 base points for a "green" class, distributed as 2-D independent normals with mean (1,0) and unit variance. It also generates 10 base points for a "red" class, distributed as 2-D independent normals with mean (0,1) and unit variance. For each class (green and red), generate 100 random points as follows:

1. Choose a base point *m* of the appropriate color uniformly at random.
2. Generate an independent random point with 2-D normal distribution with mean *m* and variance I/5, where I is the 2-by-2 identity matrix. In this example, use a variance I/50 to show the advantage of optimization more clearly.

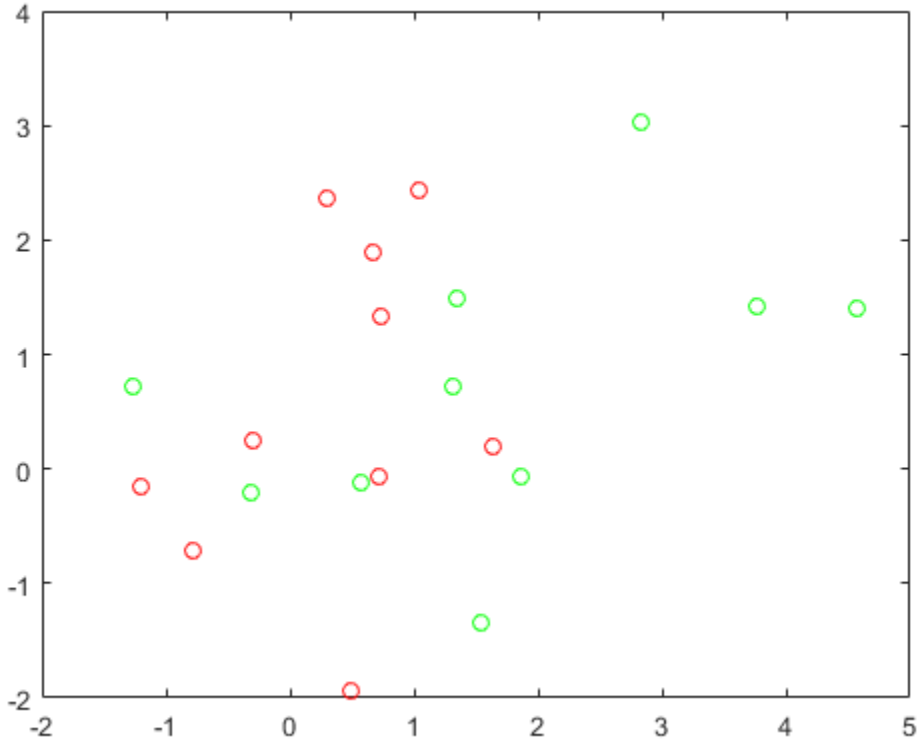
Generate the Points and Classifier

Generate the 10 base points for each class.

```
rng default % For reproducibility
grnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
```

View the base points.

```
plot(grnpop(:,1),grnpop(:,2),'go')
hold on
plot(redpop(:,1),redpop(:,2),'ro')
hold off
```



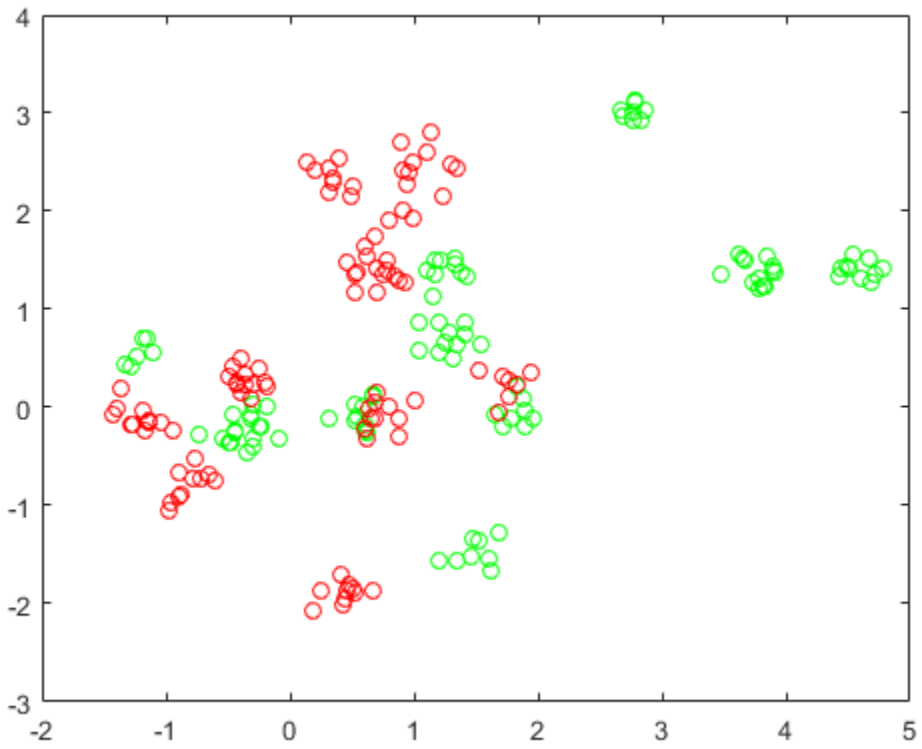
Since some red base points are close to green base points, it can be difficult to classify the data points based on location alone.

Generate the 100 data points of each class.

```
redpts = zeros(100,2);grnpts = redpts;
for i = 1:100
    grnpts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);
end
```

View the data points.

```
figure
plot(grnpts(:,1),grnpts(:,2),'go')
hold on
plot(redpts(:,1),redpts(:,2),'ro')
hold off
```



Prepare Data For Classification

Put the data into one matrix, and make a vector `grp` that labels the class of each point.

```
cdata = [grnpts;redpts];
grp = ones(200,1);
% Green label 1, red label -1
grp(101:200) = -1;
```

Prepare Cross-Validation

Set up a partition for cross-validation. This step fixes the train and test sets that the optimization uses at each step.

```
c = cvpartition(200,'KFold',10);
```

Optimize the Fit

To find a good fit, meaning one with a low cross-validation loss, set options to use Bayesian optimization. Use the same cross-validation partition `c` in all optimizations.

For reproducibility, use the `'expected-improvement-plus'` acquisition function.

```
opts = struct('Optimizer','bayesopt','ShowPlots',true,'CVPartition',c,...
    'AcquisitionFunctionName','expected-improvement-plus');
svmmod = fitcsvm(cdata,grp,'KernelFunction','rbf',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',opts)
```

  Properties, Methods
```

Find the loss of the optimized model.

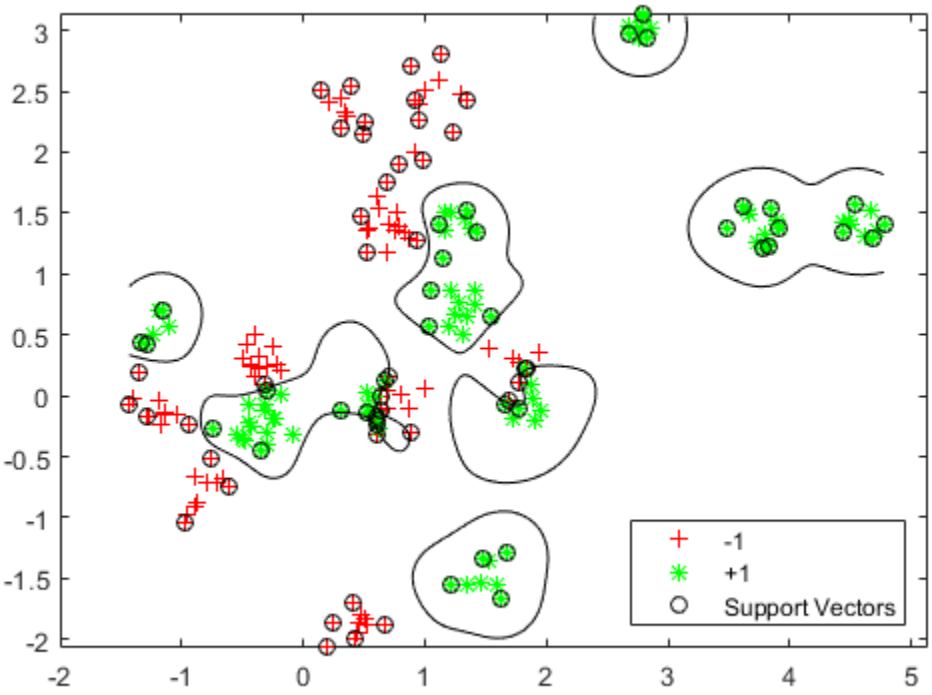
```
lossnew = kfoldLoss(fitcsvm(cdata,grp,'CVPartition',c,'KernelFunction','rbf',...
    'BoxConstraint',svmmod.HyperparameterOptimizationResults.XAtMinObjective.BoxConstraint,...
    'KernelScale',svmmod.HyperparameterOptimizationResults.XAtMinObjective.KernelScale))
```

```
lossnew = 0.0650
```

This loss is the same as the loss reported in the optimization output under "Observed objective function value".

Visualize the optimized classifier.

```
d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(cdata(:,1)):d:max(cdata(:,1)),...
    min(cdata(:,2)):d:max(cdata(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
[~,scores] = predict(svmmod,xGrid);
figure;
h = nan(3,1); % Preallocation
h(1:2) = gscatter(cdata(:,1),cdata(:,2),grp,'rg','+*');
hold on
h(3) = plot(cdata(svmmod.IsSupportVector,1),...
    cdata(svmmod.IsSupportVector,2),'ko');
contour(x1Grid,x2Grid,reshape(scores(:,2),size(x1Grid)),[0 0],'k');
legend(h,{'-1','+1','Support Vectors'},'Location','Southeast');
axis equal
hold off
```



Plot Posterior Probability Regions for SVM Classification Models

This example shows how to predict posterior probabilities of SVM models over a grid of observations, and then plot the posterior probabilities over the grid. Plotting posterior probabilities exposes decision boundaries.

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
y = species(classKeep);
```

Train an SVM classifier using the data. It is good practice to specify the order of the classes.

```
SVMModel = fitcsvm(X,y,'ClassNames',{'setosa','versicolor'});
```

Estimate the optimal score transformation function.

```
rng(1); % For reproducibility
[SVMModel,ScoreParameters] = fitPosterior(SVMModel);
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step
```

```
ScoreParameters
```

```
ScoreParameters = struct with fields:
                       Type: 'step'
                 LowerBound: -0.8431
                 UpperBound: 0.6897
    PositiveClassProbability: 0.5000
```

The optimal score transformation function is the step function because the classes are separable. The fields `LowerBound` and `UpperBound` of `ScoreParameters` indicate the lower and upper end points of the interval of scores corresponding to observations within the class-separating hyperplanes (the margin). No training observation falls within the margin. If a new score is in the interval, then the software assigns the corresponding observation a positive class posterior probability, i.e., the value in the `PositiveClassProbability` field of `ScoreParameters`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

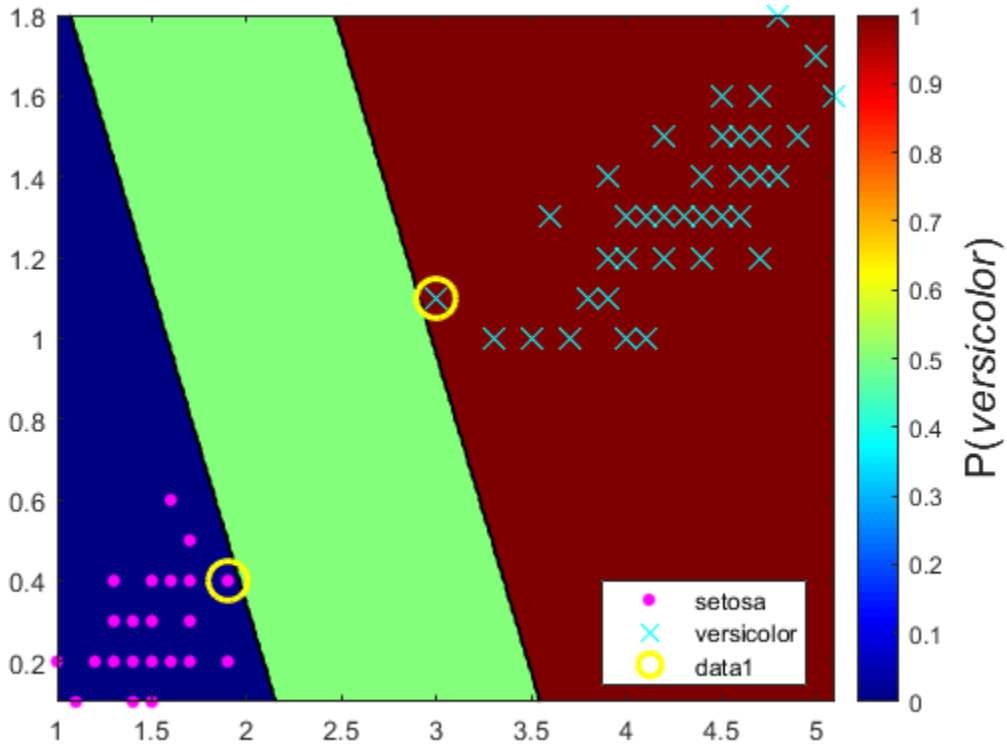
```
xMax = max(X);
xMin = min(X);
d = 0.01;
[x1Grid,x2Grid] = meshgrid(xMin(1):d:xMax(1),xMin(2):d:xMax(2));

[~,PosteriorRegion] = predict(SVMModel,[x1Grid(:),x2Grid(:)]);
```

Plot the positive class posterior probability region and the training data.

```
figure;
contourf(x1Grid,x2Grid,...
        reshape(PosteriorRegion(:,2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.Label.String = 'P({\it{versicolor}})';
h.YLabel.FontSize = 16;
caxis([0 1]);
colormap jet;

hold on
gscatter(X(:,1),X(:,2),y,'mc','.x',[15,10]);
sv = X(SVMModel.IsSupportVector,:);
plot(sv(:,1),sv(:,2),'yo','MarkerSize',15,'LineWidth',2);
axis tight
hold off
```



In two-class learning, if the classes are separable, then there are three regions: one where observations have positive class posterior probability `0`, one where it is `1`, and the other where it is the positive class prior probability.

Analyze Images Using Linear Support Vector Machines

This example shows how to determine which quadrant of an image a shape occupies by training an error-correcting output codes (ECOC) model comprised of linear SVM binary learners. This example also illustrates the disk-space consumption of ECOC models that store support vectors, their labels, and the estimated α coefficients.

Create the Data Set

Randomly place a circle with radius five in a 50-by-50 image. Make 5000 images. Create a label for each image indicating the quadrant that the circle occupies. Quadrant 1 is in the upper right, quadrant 2 is in the upper left, quadrant 3 is in the lower left, and quadrant 4 is in the lower right. The predictors are the intensities of each pixel.

```
d = 50;  % Height and width of the images in pixels
n = 5e4; % Sample size

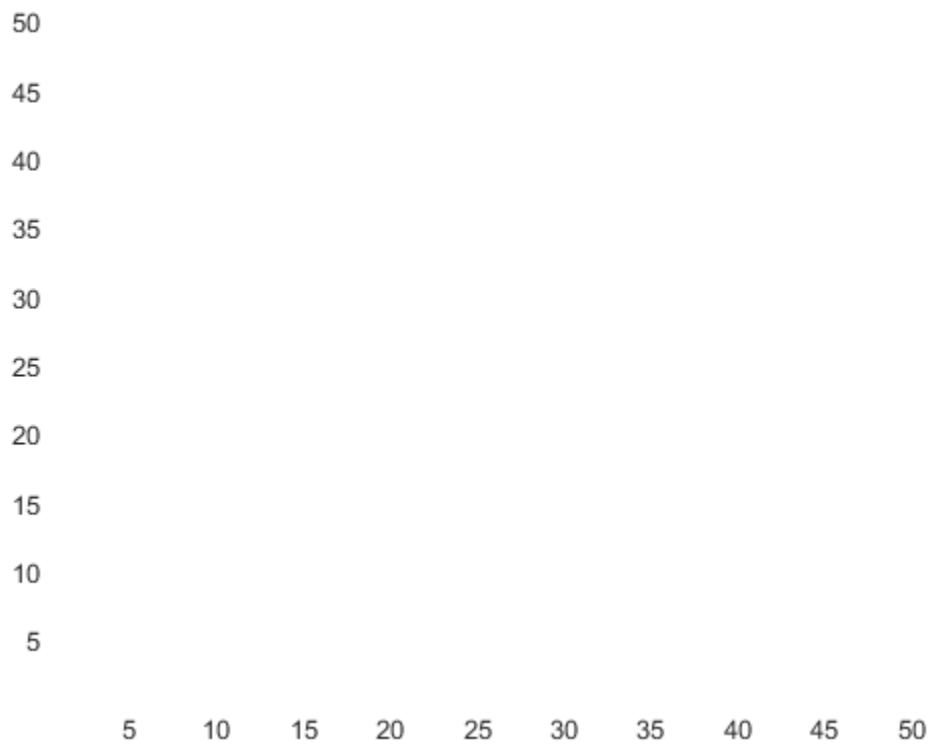
X = zeros(n,d^2); % Predictor matrix preallocation
Y = zeros(n,1);   % Label preallocation
theta = 0:(1/d):(2*pi);
r = 5;            % Circle radius
```

```
rng(1);           % For reproducibility

for j = 1:n
    figmat = zeros(d);                          % Empty image
    c = datasample((r + 1):(d - r - 1),2);   % Random circle center
    x = r*cos(theta) + c(1);                    % Make the circle
    y = r*sin(theta) + c(2);
    idx = sub2ind([d d],round(y),round(x));  % Convert to linear indexing
    figmat(idx) = 1;                            % Draw the circle
    X(j,:) = figmat(:);                 % Store the data
    Y(j) = (c(2) >= floor(d/2)) + 2*(c(2) < floor(d/2)) + ...
        (c(1) < floor(d/2)) + ...
        2*((c(1) >= floor(d/2)) & (c(2) < floor(d/2))); % Determine the quadrant
end
```

Plot an observation.

```
figure
imagesc(figmat)
h = gca;
h.YDir = 'normal';
title(sprintf('Quadrant %d',Y(end)))
```



Train the ECOC Model

Use a 25% holdout sample and specify the training and holdout sample indices.

```
p = 0.25;
CVP = cvpartition(Y,'Holdout',p); % Cross-validation data partition
isIdx = training(CVP);            % Training sample indices
oosIdx = test(CVP);               % Test sample indices
```

Create an SVM template that specifies storing the support vectors of the binary learners. Pass it and the training data to `fitcecoc` to train the model. Determine the training sample classification error.

```
t = templateSVM('SaveSupportVectors',true);
MdlSV = fitcecoc(X(isIdx,:),Y(isIdx),'Learners',t);
isLoss = resubLoss(MdlSV)
```

```
isLoss = 0
```

`MdlSV` is a trained `ClassificationECOC` multiclass model. It stores the training data and the support vectors of each binary learner. For large data sets, such as those in image analysis, the model can consume a lot of memory.

Determine the amount of disk space that the ECOC model consumes.

```
infoMdlSV = whos('MdlSV');
mbMdlSV = infoMdlSV.bytes/1.049e6
```

```
mbMdlSV = 763.6150
```

The model consumes 763.6 MB.

Improve Model Efficiency

You can assess out-of-sample performance. You can also assess whether the model has been overfit with a compacted model that does not contain the support vectors, their related parameters, and the training data.

Discard the support vectors and related parameters from the trained ECOC model. Then, discard the training data from the resulting model by using `compact`.

```
Mdl = discardSupportVectors(MdlSV);
CMdl = compact(Mdl);
info = whos('Mdl','CMdl');
[bytesCMdl,bytesMdl] = info.bytes;
memReduction = 1 - [bytesMdl bytesCMdl]/infoMdlSV.bytes
```

```
memReduction = 1×2

    0.0626    0.9996
```

In this case, discarding the support vectors reduces the memory consumption by about 6%. Compacting and discarding support vectors reduces the size by about 99.96%.

An alternative way to manage support vectors is to reduce their numbers during training by specifying a larger box constraint, such as 100. Though SVM models that use fewer support vectors are more desirable and consume less memory, increasing the value of the box constraint tends to increase the training time.

Remove `MdlSV` and `Mdl` from the workspace.

```
clear Mdl MdlSV
```

Assess Holdout Sample Performance

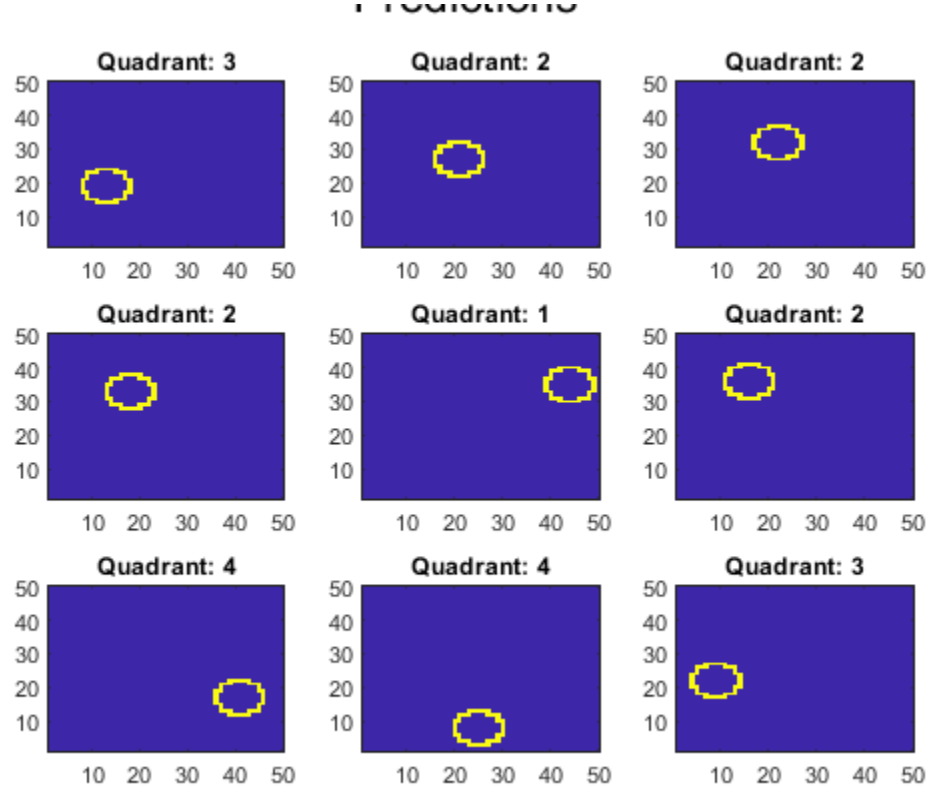
Calculate the classification error of the holdout sample. Plot a sample of the holdout sample predictions.

```
oosLoss = loss(CMdl,X(oosIdx,:),Y(oosIdx))
```

```
oosLoss = 0
```

```
yHat = predict(CMdl,X(oosIdx,:));
nVec = 1:size(X,1);
oosIdx = nVec(oosIdx);

figure;
for j = 1:9
    subplot(3,3,j)
    imagesc(reshape(X(oosIdx(j),:),[d d]))
    h = gca;
    h.YDir = 'normal';
    title(sprintf('Quadrant: %d',yHat(j)))
end
text(-1.33*d,4.5*d + 1,'Predictions','FontSize',17)
```



The model does not misclassify any holdout sample observations.

Assess Neural Network Classifier Performance

Create a feedforward neural network classifier with fully connected layers using `fitcnet`. Use validation data for early stopping of the training process to prevent overfitting the model. Then, use the object functions of the classifier to assess the performance of the model on test data.

Load and Preprocess Sample Data

This example uses the 1994 census data stored in `census1994.mat`. The data set consists of demographic information from the US Census Bureau that you can use to predict whether an individual makes over $50,000 per year.

Load the sample data `census1994`, which contains the training data `adultdata` and the test data `adulttest`. Preview the first few rows of the training data set.

```
load census1994
head(adultdata)
```

```
ans=8×15 table
    age       workClass          fnlwgt      education    education_num       marital_status

    38     Private                2.1565e+05    HS-grad            9          Divorced
    53     Private                2.3472e+05    11th               7          Married-civ-spouse
    28     Private                3.3841e+05    Bachelors         13          Married-civ-spouse
    37     Private                2.8458e+05    Masters           14          Married-civ-spouse
    49     Private                1.6019e+05    9th                5          Married-spouse-absent
    52     Self-emp-not-inc       2.0964e+05    HS-grad            9          Married-civ-spouse
```

Each row contains the demographic information for one adult. The last column, `salary`, shows whether a person has a salary less than or equal to $50,000 per year or greater than $50,000 per year.

Combine the `education_num` and `education` variables in both the training and test data to create a single ordered categorical variable that shows the highest level of education a person has achieved.

```
edOrder = unique(adultdata.education_num,"stable");
edCats = unique(adultdata.education,"stable");
[~,edIdx] = sort(edOrder);

adultdata.education = categorical(adultdata.education, ...
    edCats(edIdx),"Ordinal",true);
adultdata.education_num = [];

adulttest.education = categorical(adulttest.education, ...
    edCats(edIdx),"Ordinal",true);
adulttest.education_num = [];
```

Partition Training Data

Split the training data further using a stratified holdout partition. Create a separate validation data set to stop the model training process early. Reserve approximately 30% of the observations for the validation data set and use the rest of the observations to train the neural network classifier.

```
rng("default") % For reproducibility of the partition
c = cvpartition(adultdata.salary,"Holdout",0.30);
trainingIndices = training(c);
validationIndices = test(c);
tblTrain = adultdata(trainingIndices,:);
tblValidation = adultdata(validationIndices,:);
```

Train Neural Network

Train a neural network classifier by using the training set. Specify the `salary` column of `tblTrain` as the response and the `fnlwgt` column as the observation weights, and standardize the numeric predictors. Evaluate the model at each iteration by using the validation set. Specify to display the training information at each iteration by using the `Verbose` name-value argument. By default, the training process ends early if the validation cross-entropy loss is greater than or equal to the minimum validation cross-entropy loss computed so far, six times in a row. To change the number of times the validation loss is allowed to be greater than or equal to the minimum, specify the `ValidationPatience` name-value argument.

```
Mdl = fitcnet(tblTrain,"salary","Weights","fnlwgt", ...
    "Standardize",true,"ValidationData",tblValidation, ...
    "Verbose",1);
```

```

|========================================================================================|
```

Use the information inside the `TrainingHistory` property of the object `Mdl` to check the iteration that corresponds to the minimum validation cross-entropy loss. The final returned model `Mdl` is the model trained at this iteration.

```
iteration = Mdl.TrainingHistory.Iteration;
valLosses = Mdl.TrainingHistory.ValidationLoss;
[~,minIdx] = min(valLosses);
iteration(minIdx)
```

```
ans = 49
```

Evaluate Test Set Performance

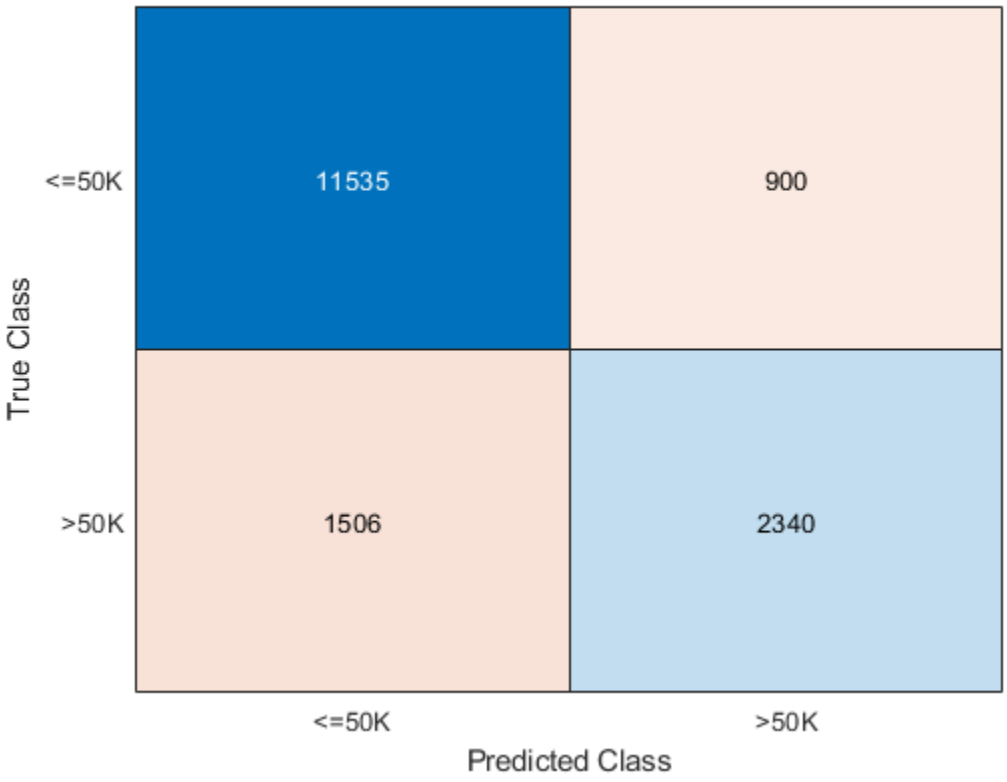
Evaluate the performance of the trained classifier `Mdl` on the test set `adulttest` by using the `predict`, `loss`, `margin`, and `edge` object functions.

Find the predicted labels and classification scores for the observations in the test set.

```
[labels,Scores] = predict(Mdl,adulttest);
```

Create a confusion matrix from the test set results. The diagonal elements indicate the number of correctly classified instances of a given class. The off-diagonal elements are instances of misclassified observations.

```
confusionchart(adulttest.salary,labels)
```



Compute the test set classification accuracy.

```
error = loss(Mdl,adulttest,"salary");
accuracy = (1-error)*100
```

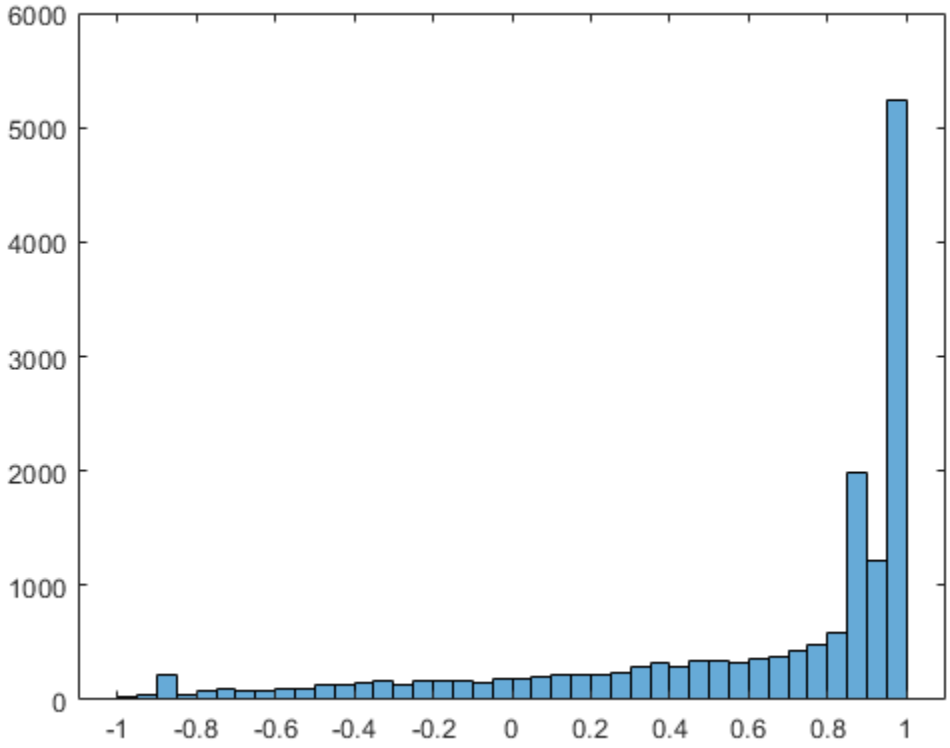
```
accuracy = 85.1306
```

The neural network classifier correctly classifies approximately 85% of the test set observations.

Compute the test set classification margins for the trained neural network. Display a histogram of the margins.

The classification margins are the difference between the classification score for the true class and the classification score for the false class. Because neural network classifiers return scores that are posterior probabilities, classification margins close to 1 indicate confident classifications and negative margin values indicate misclassifications.

```
m = margin(Mdl,adulttest,"salary");
histogram(m)
```



Use the classification edge, or mean of the classification margins, to assess the overall performance of the classifier.

```
meanMargin = edge(Mdl,adulttest,"salary")
```

```
meanMargin = 0.5983
```

Alternatively, compute the weighted classification edge by using observation weights.

```
weightedMeanMargin = edge(Mdl,adulttest,"salary", ...
    "Weight","fnlwgt")
```

```
weightedMeanMargin = 0.6072
```

Visualize the predicted labels and classification scores using scatter plots, in which each point corresponds to an observation. Use the predicted labels to set the color of the points, and use the maximum scores to set the transparency of the points. Points with less transparency are labeled with greater confidence.

First, find the maximum classification score for each test set observation.

```
maxScores = max(Scores,[],2);
```

Create a scatter plot comparing maximum scores across the number of work hours per week and level of education. Because the education variable is categorical, randomly jitter (or space out) the points along the y-dimension.

Change the colormap so that maximum scores corresponding to salaries that are less than or equal to $50,000 per year appear as blue, and maximum scores corresponding to salaries greater than $50,000 per year appear as red.

```
scatter(adulttest.hours_per_week,adulttest.education,[],labels, ...
    "filled","MarkerFaceAlpha","flat","AlphaData",maxScores, ...
    "YJitter","rand");
xlabel("Number of Work Hours Per Week")
ylabel("Education")
```

```
Mdl.ClassNames
```

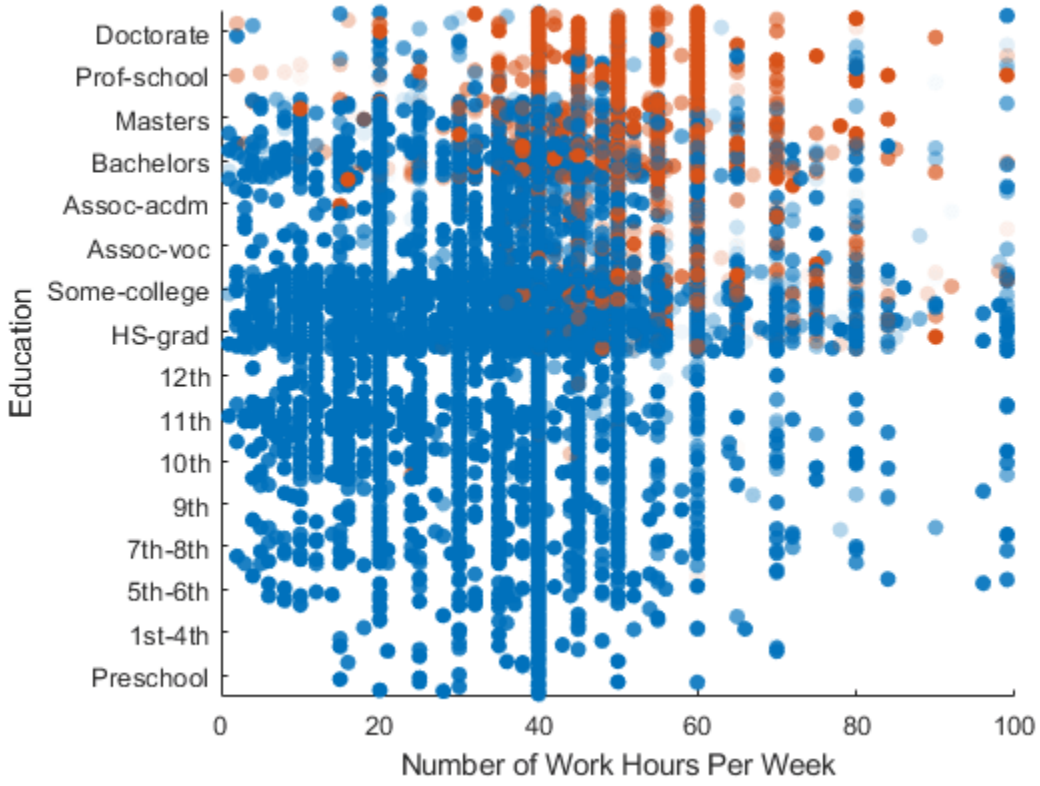
```
ans = 2×1 categorical
     <=50K
     >50K
```

```
colors = lines(2)
```

```
colors = 2×3

         0    0.4470    0.7410
    0.8500    0.3250    0.0980
```

```
colormap(colors);
```



The colors in the scatter plot indicate that, in general, the neural network predicts that people with lower levels of education (12th grade or below) have salaries less than or equal to $50,000 per year. The transparency of some of the points in the lower right of the plot indicates that the model is less confident in this prediction for people who work many hours per week (60 hours or more).

Assess Regression Neural Network Performance

Create a feedforward regression neural network model with fully connected layers using `fitrnet`. Use validation data for early stopping of the training process to prevent overfitting the model. Then, use the object functions of the model to assess its performance on test data.

Load Sample Data

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Convert the `Origin` variable to a categorical variable. Then create a table containing the predictor variables `Acceleration`, `Displacement`, and so on, as well as the response variable `MPG`. Each row contains the measurements for a single car.

```
Origin = categorical(cellstr(Origin));
Tbl = table(Acceleration,Displacement,Horsepower, ...
    Model_Year,Origin,Weight,MPG);
```

Partition Data

Split the data into training, validation, and test sets. First, reserve approximately one third of the observations for the test set. Then, split the remaining data in half to create the training and validation sets.

```
rng("default") % For reproducibility of the data partitions
cvp1 = cvpartition(size(Tbl,1),"Holdout",1/3);
testTbl = Tbl(test(cvp1),:);
remainingTbl = Tbl(training(cvp1),:);

cvp2 = cvpartition(size(remainingTbl,1),"Holdout",1/2);
validationTbl = remainingTbl(test(cvp2),:);
trainTbl = remainingTbl(training(cvp2),:);
```

Train Neural Network

Train a regression neural network model by using the training set. Specify the `MPG` column of `tblTrain` as the response variable, and standardize the numeric predictors. Evaluate the model at each iteration by using the validation set. Specify to display the training information at each iteration by using the `Verbose` name-value argument. By default, the training process ends early if the validation loss is greater than or equal to the minimum validation loss computed so far, six times in a row. To change the number of times the validation loss is allowed to be greater than or equal to the minimum, specify the `ValidationPatience` name-value argument.

```
Mdl = fitrnet(trainTbl,"MPG","Standardize",true, ...
    "ValidationData",validationTbl, ...
    "Verbose",1);
```

```

|========================================================================================|
```

Use the information inside the `TrainingHistory` property of the object `Mdl` to check the iteration that corresponds to the minimum validation mean squared error (MSE). The final returned model `Mdl` is the model trained at this iteration.

```
iteration = Mdl.TrainingHistory.Iteration;
valLosses = Mdl.TrainingHistory.ValidationLoss;
[~,minIdx] = min(valLosses);
iteration(minIdx)
```

```
ans = 23
```

Evaluate Test Set Performance

Evaluate the performance of the trained model `Mdl` on the test set `testTbl` by using the `loss` and `predict` object functions.

Compute the test set mean squared error (MSE). Smaller MSE values indicate better performance.

```
mse = loss(Mdl,testTbl,"MPG")
```

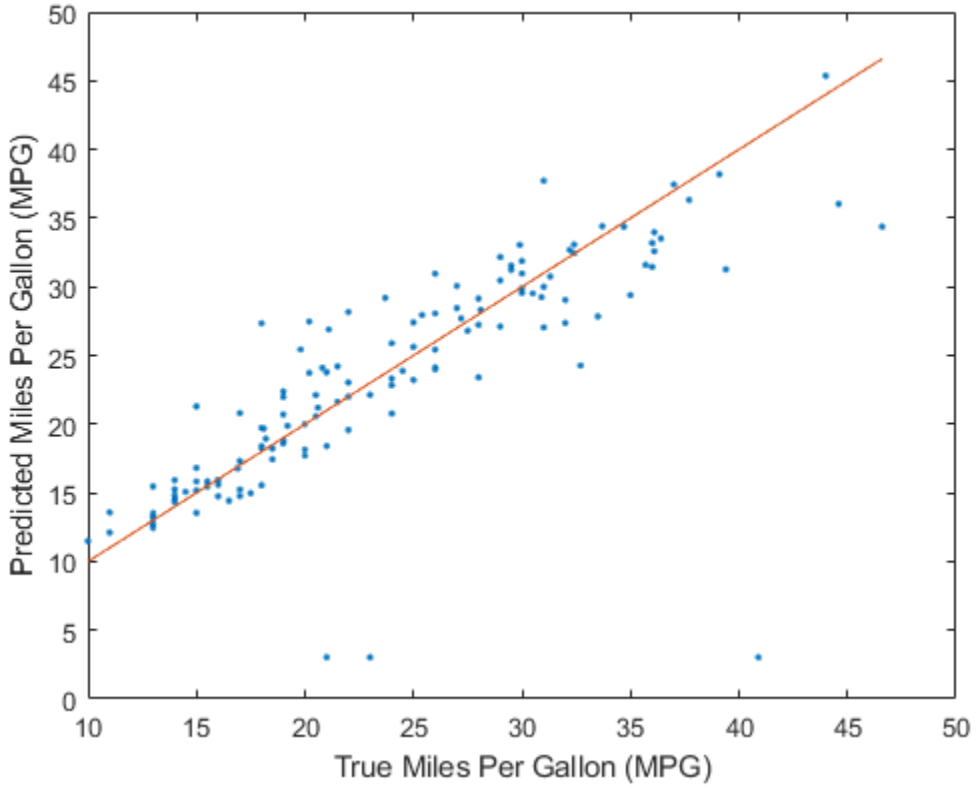
```
mse = 25.4145
```

Compare the predicted test set response values to the true response values. Plot the predicted miles per gallon (MPG) along the vertical axis and the true MPG along the horizontal axis. Points on the

reference line indicate correct predictions. A good model produces predictions that are scattered near the line.

```
predictedY = predict(Mdl,testTbl);

plot(testTbl.MPG,predictedY,".")
hold on
plot(testTbl.MPG,testTbl.MPG)
hold off
xlabel("True Miles Per Gallon (MPG)")
ylabel("Predicted Miles Per Gallon (MPG)")
```

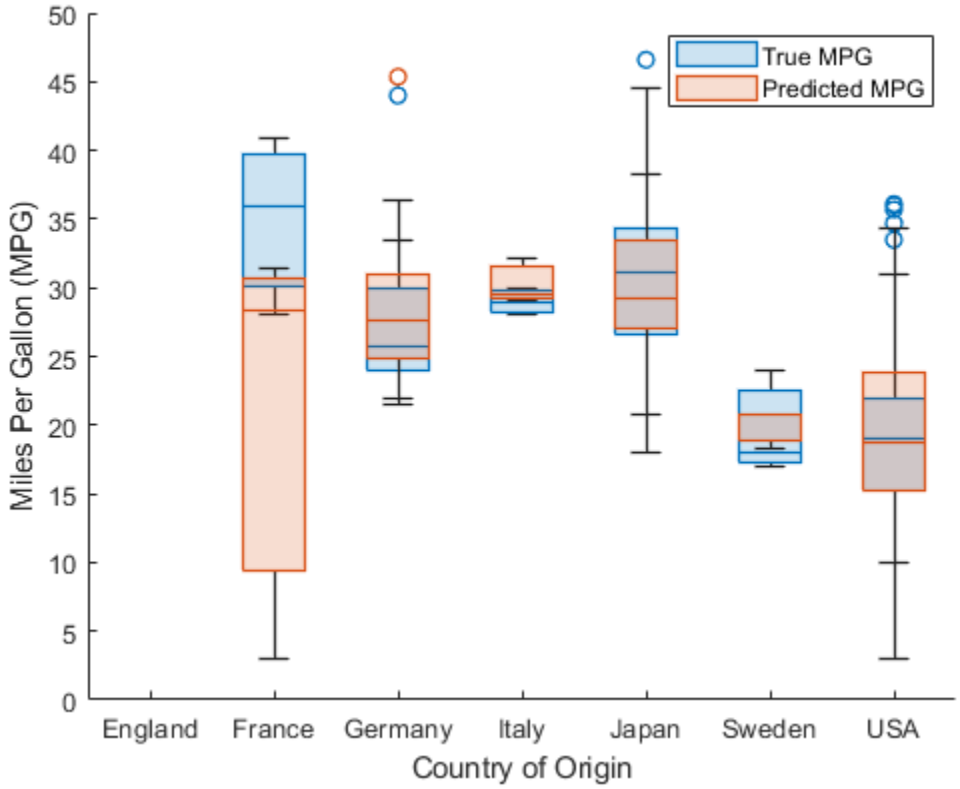


Use box plots to compare the distribution of predicted and true MPG values by country of origin. Create the box plots by using the `boxchart` function. Each box plot displays the median, the lower and upper quartiles, any outliers (computed using the interquartile range), and the minimum and maximum values that are not outliers. In particular, the line inside each box is the sample median, and the circular markers indicate outliers.

For each country of origin, compare the red box plot (showing the distribution of predicted MPG values) to the blue box plot (showing the distribution of true MPG values). Similar distributions for the predicted and true MPG values indicate good predictions.

```
boxchart(testTbl.Origin,testTbl.MPG)
hold on
boxchart(testTbl.Origin,predictedY)
hold off
legend(["True MPG","Predicted MPG"])
```

```
xlabel("Country of Origin")
ylabel("Miles Per Gallon (MPG)")
```



For most countries, the predicted and true MPG values have similar distributions. However, the neural network model tends to underestimate the MPG values for cars made in France. This discrepancy is possibly due to the small number of French cars in the training and test sets.

Compare the range of MPG values for French cars in the training and test sets.

```
trainSummary = grpstats(trainTbl(:,["MPG","Origin"]),"Origin", ...
    ["min","max"])
```

```
trainSummary=6×4 table
               Origin     GroupCount    min_MPG    max_MPG
               _______    __________    _______    _______

    France     France          3          16.2         27
    Germany    Germany        11            20       44.3
    Italy      Italy           1          37.3       37.3
    Japan      Japan          24            20       40.8
    Sweden     Sweden          3            19       21.6
    USA        USA            94             9         39
```

```
testSummary = grpstats(testTbl(:,["MPG","Origin"]),"Origin", ...
    ["min","max"])
```

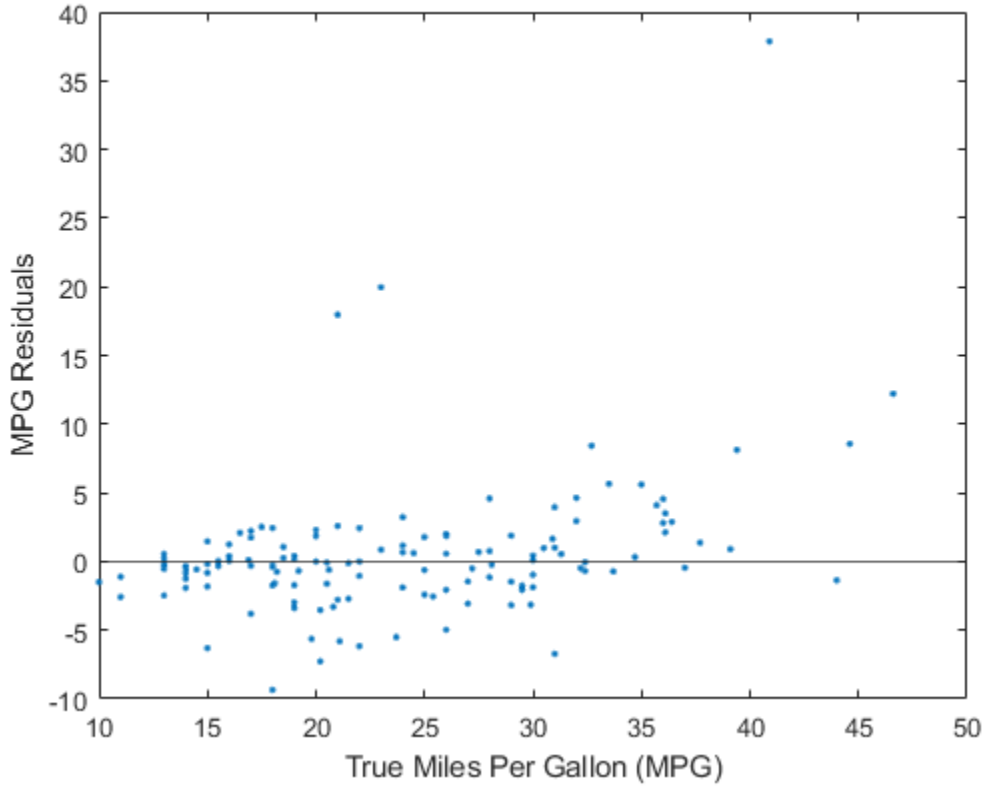
```
testSummary=6×4 table
               Origin     GroupCount    min_MPG    max_MPG
```

France	France	3	28.1	40.9
Germany	Germany	12	21.5	44
Italy	Italy	3	28	30
Japan	Japan	32	18	46.6
Sweden	Sweden	3	17	24
USA	USA	82	10	36.1

In the training set, the MPG values for cars made in France range from 16.2 to 27. However, in the test set, the MPG values for cars made in France range from 28.1 to 40.9.

Plot the test set residuals. A good model usually has residuals scattered roughly symmetrically around 0. Clear patterns in the residuals are a sign that you can improve your model.

```
residuals = testTbl.MPG - predictedY;
plot(testTbl.MPG,residuals,".")
hold on
yline(0)
hold off
xlabel("True Miles Per Gallon (MPG)")
ylabel("MPG Residuals")
```



The plot suggests that some residual values are outliers. Find out more information about the observation with the greatest residual.

```
[outlierResidual,outlierIdx] = max(residuals)
```

```
outlierResidual = 37.8727

outlierIdx = 113

testTbl(outlierIdx,:)

ans=1×7 table
    Acceleration    Displacement    Horsepower    Model_Year    Origin    Weight    MPG
    ____________    ____________    __________    __________    ______    ______    ____

        17.3             85            NaN            80        France     1835     40.9
```

The observation corresponds to a car whose `Horsepower` value is missing and whose country of origin is France, a category with few observations.

Automated Feature Engineering for Classification

The `gencfeatures` function enables you to automate the feature engineering process in the context of a machine learning workflow. Before passing tabular training data to a classifier, you can create new features from the predictors in the data by using `gencfeatures`. Use the returned data to train the classifier.

Generate new features based on your machine learning workflow.

- To generate features for an interpretable binary classifier, use the default `TargetLearner` value of `'linear'` in the call to `gencfeatures`. You can then use the returned data to train a binary linear classifier. For an example, see “Interpret Linear Model with Generated Features” on page 18-190.
- To generate features that can lead to better model accuracy, specify `'TargetLearner','bag'` in the call to `gencfeatures`. You can then use the returned data to train a bagged ensemble classifier. For an example, see “Generate New Features to Improve Bagged Ensemble Accuracy” on page 18-193.

To better understand the generated features, use the `describe` function of the `FeatureTransformer` object. To apply the same training set feature transformations to a test or validation set, use the `transform` function of the `FeatureTransformer` object.

Interpret Linear Model with Generated Features

Use automated feature engineering to generate new features. Train a linear classifier using the generated features. Interpret the relationship between the generated features and the trained model.

Load the `patients` data set. Create a table from a subset of the variables.

```
load patients
Tbl = table(Age,Diastolic,Gender,Height,SelfAssessedHealthStatus, ...
    Systolic,Weight,Smoker);
```

Generate 10 new features from the variables in `Tbl`. Specify the `Smoker` variable as the response. By default, `gencfeatures` assumes that the new features will be used to train a binary linear classifier.

```
rng("default") % For reproducibility
[T,NewTbl] = gencfeatures(Tbl,"Smoker",10)
```

```
T =
  FeatureTransformer with properties:

                    Type: 'classification'
           TargetLearner: 'linear'
    NumEngineeredFeatures: 10
      NumOriginalFeatures: 0
         TotalNumFeatures: 10

```

`T` is a `FeatureTransformer` object that can be used to transform new data, and `newTbl` contains the new features generated from the `Tbl` data.

To better understand the generated features, use the `describe` object function of the `FeatureTransformer` object. For example, inspect the first two generated features.

```
describe(T,1:2)
```

```
                        Type         IsOriginal    InputVariables                      T
                    ___________    ___________    ______________    ____________________________

    zsc(Systolic.^2)    Numeric          false         Systolic       power(  ,2)
                                                                    Standardization with z-sc
    eb8(Diastolic)      Categorical      false         Diastolic      Equal-width binning (numbe
```

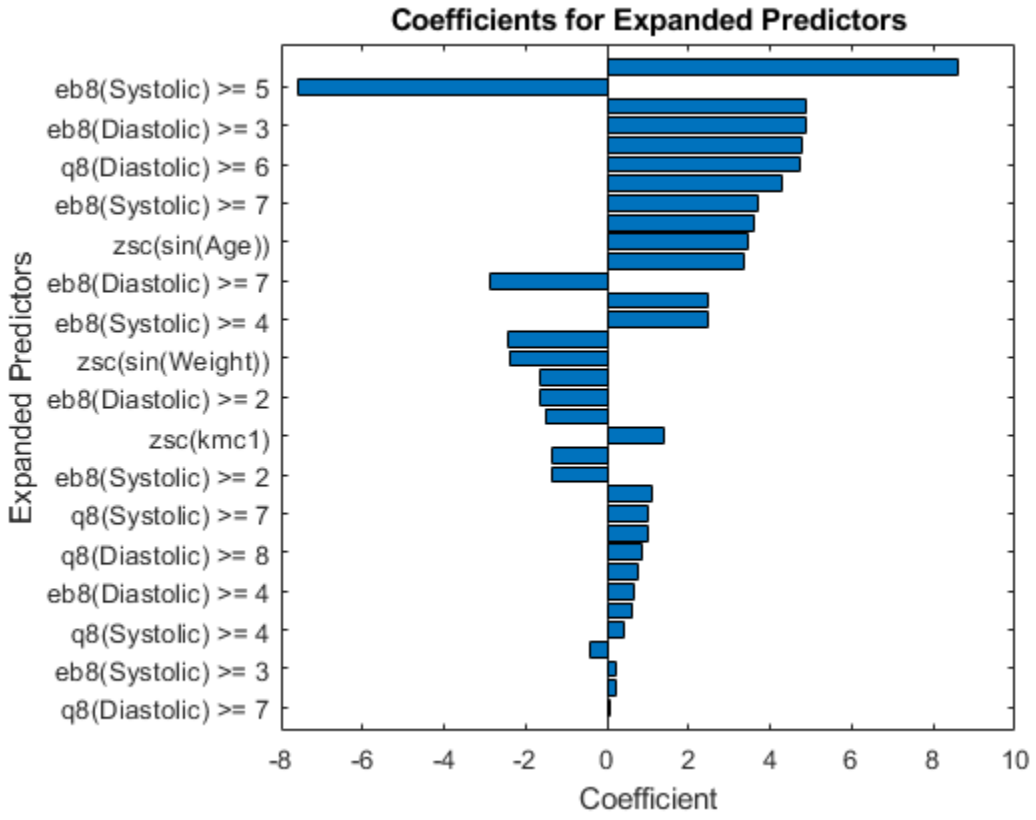
The first feature in `newTbl` is a numeric variable, created by first squaring the values of the `Systolic` variable and then converting the results to z-scores. The second feature in `newTbl` is a categorical variable, created by binning the values of the `Systolic` variable into 50 equiprobable bins.

Use the generated features to fit a linear classifier without any regularization.

```
Mdl = fitclinear(NewTbl,"Smoker","Lambda",0);
```

Plot the coefficients of the predictors used to train `Mdl`. Note that `fitclinear` expands categorical predictors before fitting a model.

```
p = length(Mdl.Beta);
[sortedCoefs,expandedIndex] = sort(Mdl.Beta,"ComparisonMethod","abs");
sortedExpandedPreds = Mdl.ExpandedPredictorNames(expandedIndex);
bar(sortedCoefs,"Horizontal","on")
yticks(1:2:p)
yticklabels(sortedExpandedPreds(1:2:end))
xlabel("Coefficient")
ylabel("Expanded Predictors")
title("Coefficients for Expanded Predictors")
```



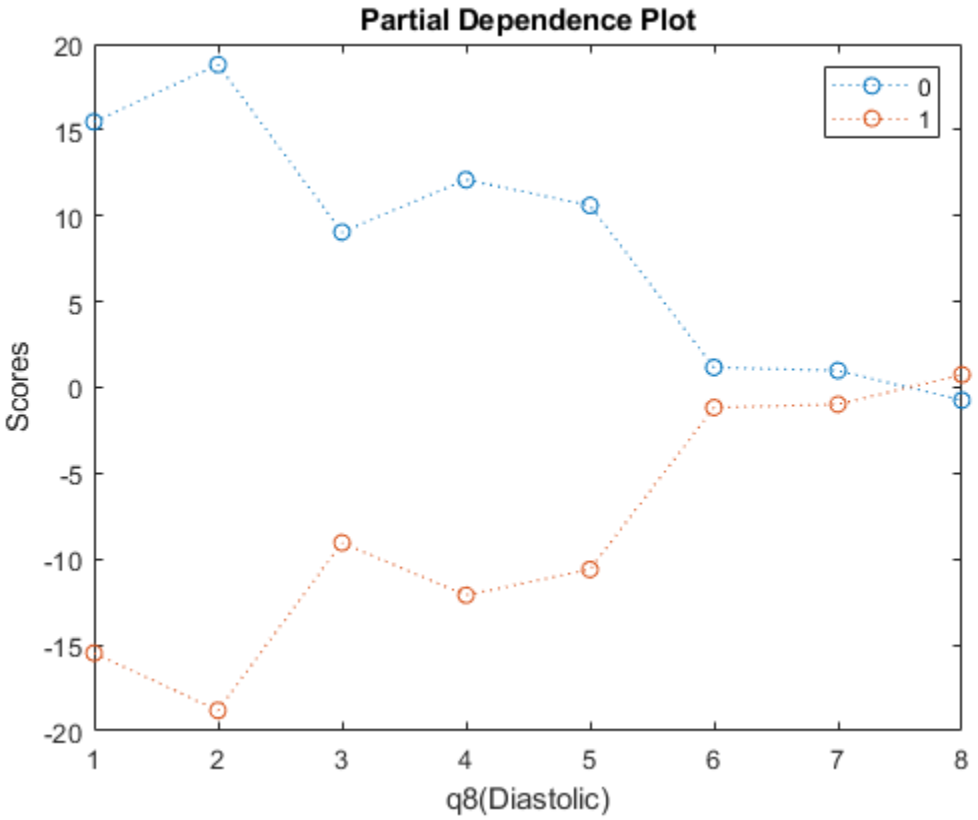
Identify the predictors whose coefficients have larger absolute values.

```
bigCoefs = abs(sortedCoefs) >= 4;
flip(sortedExpandedPreds(bigCoefs))
```

```
ans = 1×7 cell
    {'zsc(Systolic.^2)'}    {'eb8(Systolic) >= 5'}    {'q8(Diastolic) >= 3'}    {'eb8(Diastolic)
```

You can use partial dependence plots to analyze the categorical features whose levels have large coefficients in terms of absolute value. For example, inspect the partial dependence plot for the `q8(Diastolic)` variable, whose levels `q8(Diastolic) >= 3` and `q8(Diastolic) >= 6` have coefficients with large absolute values. These two levels correspond to noticeable changes in the predicted scores.

```
plotPartialDependence(Mdl,"q8(Diastolic)",Mdl.ClassNames,NewTbl);
```



Generate New Features to Improve Bagged Ensemble Accuracy

Use `gencfeatures` to engineer new features before training a bagged ensemble classifier. Before making predictions on new data, apply the same feature transformations to the new data set. Compare the test set performance of the ensemble that uses the engineered features to the test set performance of the ensemble that uses the original features.

Read the sample file `CreditRating_Historical.dat` into a table. The predictor data consists of financial ratios and industry sector information for a list of corporate customers. The response variable consists of credit ratings assigned by a rating agency. Preview the first few rows of the data set.

```
creditrating = readtable("CreditRating_Historical.dat");
head(creditrating)
```

```
ans=8×8 table
     ID      WC_TA     RE_TA     EBIT_TA    MVE_BVTD    S_TA     Industry    Rating
    _____    _____     _____     _______    ________    _____    ________    _______

    62394     0.013     0.104     0.036       0.447      0.142        3       {'BB' }
    48608     0.232     0.335     0.062       1.969      0.281        8       {'A'  }
    42444     0.311     0.367     0.074       1.935      0.366        1       {'A'  }
    48631     0.194     0.263     0.062       1.017      0.228        4       {'BBB'}
    43768     0.121     0.413     0.057       3.647      0.466       12       {'AAA'}
    39255    -0.117    -0.799      0.01       0.179      0.082        4       {'CCC'}
```

```
    62236     0.087     0.158     0.049      0.816      0.324        2        {'BBB'}
    39354     0.005     0.181     0.034      2.597      0.388        7        {'AA' }
```

Because each value in the `ID` variable is a unique customer ID, that is, `length(unique(creditrating.ID))` is equal to the number of observations in `creditrating`, the `ID` variable is a poor predictor. Remove the `ID` variable from the table, and convert the `Industry` variable to a `categorical` variable.

```
creditrating = removevars(creditrating,"ID");
creditrating.Industry = categorical(creditrating.Industry);
```

Convert the `Rating` response variable to an ordinal `categorical` variable.

```
creditrating.Rating = categorical(creditrating.Rating, ...
    ["AAA","AA","A","BBB","BB","B","CCC"],"Ordinal",true);
```

Partition the data into training and test sets. Use approximately 75% of the observations as training data, and 25% of the observations as test data. Partition the data using `cvpartition`.

```
rng("default") % For reproducibility of the partition
c = cvpartition(creditrating.Rating,"Holdout",0.25);
trainingIndices = training(c); % Indices for the training set
testIndices = test(c); % Indices for the test set
creditTrain = creditrating(trainingIndices,:);
creditTest = creditrating(testIndices,:);
```

Use the training data to generate 40 new features to fit a bagged ensemble. By default, the 40 features can include original features if the software considers them to be important variables.

```
[T,newCreditTrain] = gencfeatures(creditTrain,"Rating",40, ...
    "TargetLearner","bag");
T
```

```
T =
  FeatureTransformer with properties:

                    Type: 'classification'
           TargetLearner: 'bag'
    NumEngineeredFeatures: 34
      NumOriginalFeatures: 6
         TotalNumFeatures: 40
```

Because `T.NumOriginalFeatures` is `6`, the function keeps all the original predictors.

Create `newCreditTest` by applying the transformations stored in the object `T` to the test data.

```
newCreditTest = transform(T,creditTest);
```

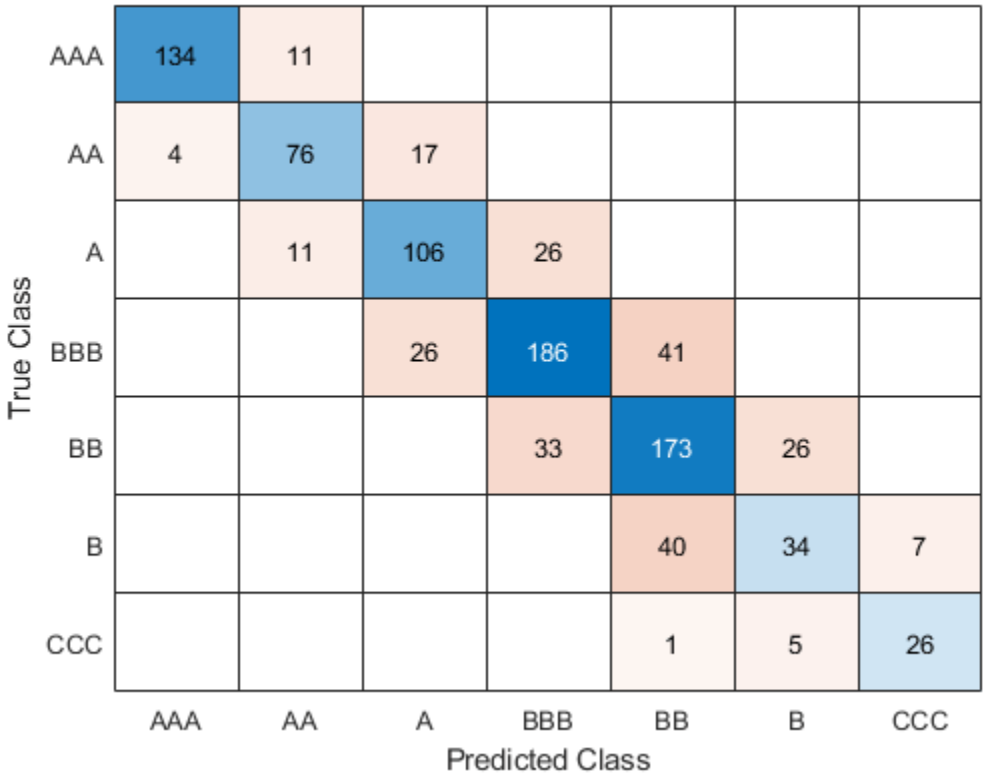
Compare the test set performances of a bagged ensemble trained on the original features and a bagged ensemble trained on the new features.

Train a bagged ensemble using the original training set `creditTrain`. Compute the accuracy of the model on the original test set `creditTest`. Visualize the results using a confusion matrix.

```
originalMdl = fitcensemble(creditTrain,"Rating","Method","Bag");
originalTestAccuracy = 1 - loss(originalMdl,creditTest, ...
    "Rating","LossFun","classiferror")
```

```
originalTestAccuracy = 0.7481
```

```
predictedTestLabels = predict(originalMdl,creditTest);
confusionchart(creditTest.Rating,predictedTestLabels);
```

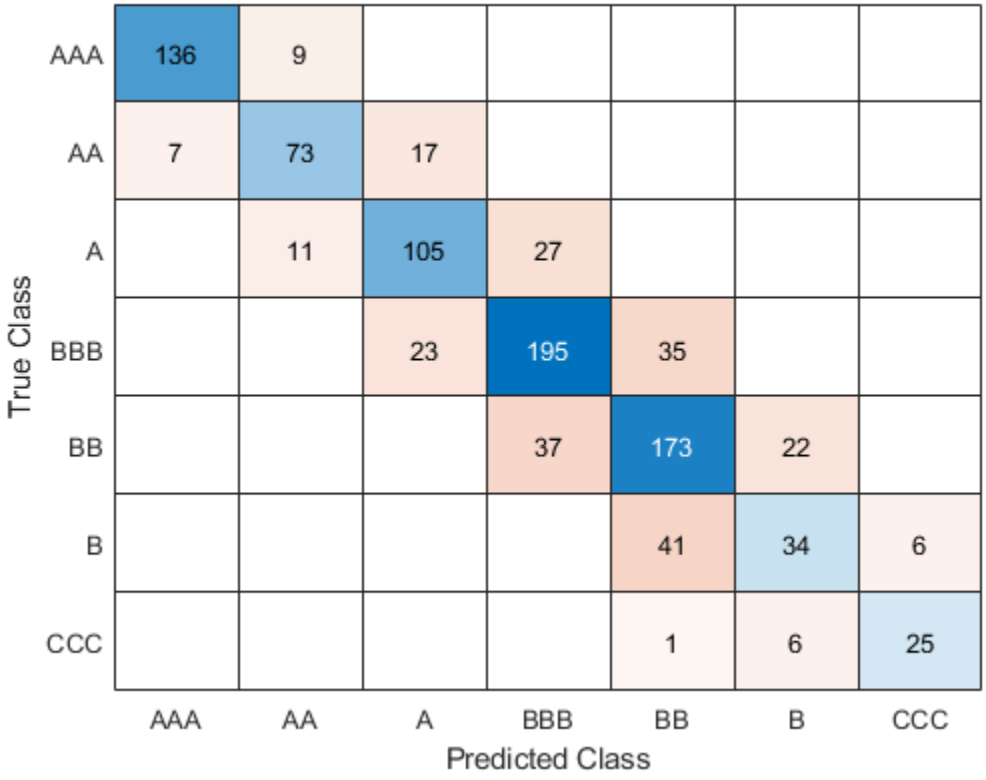


Train a bagged ensemble using the transformed training set `newCreditTrain`. Compute the accuracy of the model on the transformed test set `newCreditTest`. Visualize the results using a confusion matrix.

```
newMdl = fitcensemble(newCreditTrain,"Rating","Method","Bag");
newTestAccuracy = 1 - loss(newMdl,newCreditTest, ...
    "Rating","LossFun","classiferror")
```

```
newTestAccuracy = 0.7543
```

```
newPredictedTestLabels = predict(newMdl,newCreditTest);
confusionchart(newCreditTest.Rating,newPredictedTestLabels)
```



The bagged ensemble trained on the transformed data seems to outperform the bagged ensemble trained on the original data.

Moving Towards Automating Model Selection Using Bayesian Optimization

This example shows how to build multiple classification models for a given training data set, optimize their hyperparameters using Bayesian optimization, and select the model that performs the best on a test data set.

Training several models and tuning their hyperparameters can often take days or weeks. Creating a script to develop and compare multiple models automatically can be much faster. You can also use Bayesian optimization to speed up the process. Instead of training each model with different sets of hyperparameters, you select a few different models and tune their default hyperparameters using Bayesian optimization. Bayesian optimization finds an optimal set of hyperparameters for a given model by minimizing the objective function of the model. This optimization algorithm strategically selects new hyperparameters in each iteration and typically arrives at the optimal set of hyperparameters more quickly than a simple grid search. You can use the script in this example to train several classification models using Bayesian optimization for a given training data set and identify the model that performs best on a test data set.

Alternatively, to choose a classification model automatically across a selection of classifier types and hyperparameter values, use `fitcauto`. For an example, see “Automated Classifier Selection with Bayesian Optimization” on page 18-205.

Load Sample Data

This example uses the 1994 census data stored in `census1994.mat`. The data set consists of demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. The classification task is to fit a model that predicts the salary category of people given their age, working class, education level, marital status, race, and so on.

Load the sample data `census1994` and display the variables in the data set.

```
load census1994
whos
```

```
  Name                 Size              Bytes  Class    Attributes

  Description         20x74               2960  char
  adultdata        32561x15            1872567  table
  adulttest        16281x15             944467  table
```

`census1994` contains the training data set `adultdata` and the test data set `adulttest`. For this example, to reduce the running time, subsample 5000 training and test observations each, from the original tables `adultdata` and `adulttest`, by using the `datasample` function. (You can skip this step if you want to use the complete data sets.)

```
NumSamples = 5000;
s = RandStream('mlfg6331_64'); % For reproducibility
adultdata = datasample(s,adultdata,NumSamples,'Replace',false);
adulttest = datasample(s,adulttest,NumSamples,'Replace',false);
```

Preview the first few rows of the training data set.

```
head(adultdata)
```

```
ans=8×15 table
    age     workClass       fnlwgt       education      education_num      marital_status
```

```

```

Each row represents the attributes of one adult, such as age, education, and occupation. The last column `salary` shows whether a person has a salary less than or equal to $50,000 per year or greater than $50,000 per year.

Understand Data and Choose Classification Models

Statistics and Machine Learning Toolbox™ provides several options for classification, including classification trees, discriminant analysis, naive Bayes, nearest neighbors, support vector machines (SVMs), and classification ensembles. For the complete list of algorithms, see “Classification”.

Before choosing the algorithms to use for your problem, inspect your data set. The census data has several noteworthy characteristics:

- The data is tabular and contains both numeric and categorical variables.
- The data contains missing values.
- The response variable (`salary`) has two classes (binary classification).

Without making any assumptions or using prior knowledge of algorithms that you expect to work well on your data, you simply train all the algorithms that support tabular data and binary classification. Error-correcting output codes (ECOC) models are used for data with more than two classes. Discriminant analysis and nearest neighbor algorithms do not analyze data that contains both numeric and categorical variables. Therefore, the algorithms appropriate for this example are SVMs, a decision tree, an ensemble of decision trees, and a naive Bayes model.

Build Models and Tune Hyperparameters

To speed up the process, customize the hyperparameter optimization options. Specify `'ShowPlots'` as `false` and `'Verbose'` as 0 to disable plot and message displays, respectively. Also, specify `'UseParallel'` as `true` to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox™. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results.

```
hypopts = struct('ShowPlots',false,'Verbose',0,'UseParallel',true);
```

Start a parallel pool.

```
poolobj = gcp;
```

You can fit the training data set and tune parameters easily by calling each fitting function and setting its `'OptimizeHyperparameters'` name-value pair argument to `'auto'`. Create the classification models.

```
% SVMs: SVM with polynomial kernel & SVM with Gaussian kernel
mdls{1} = fitcsvm(adultdata,'salary','KernelFunction','polynomial','Standardize','on', ...
```

```
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions', hypopts);
mdls{2} = fitcsvm(adultdata,'salary','KernelFunction','gaussian','Standardize','on', ...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions', hypopts);

% Decision tree
mdls{3} = fitctree(adultdata,'salary', ...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions', hypopts);

% Ensemble of Decision trees
mdls{4} = fitcensemble(adultdata,'salary','Learners','tree', ...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions', hypopts);

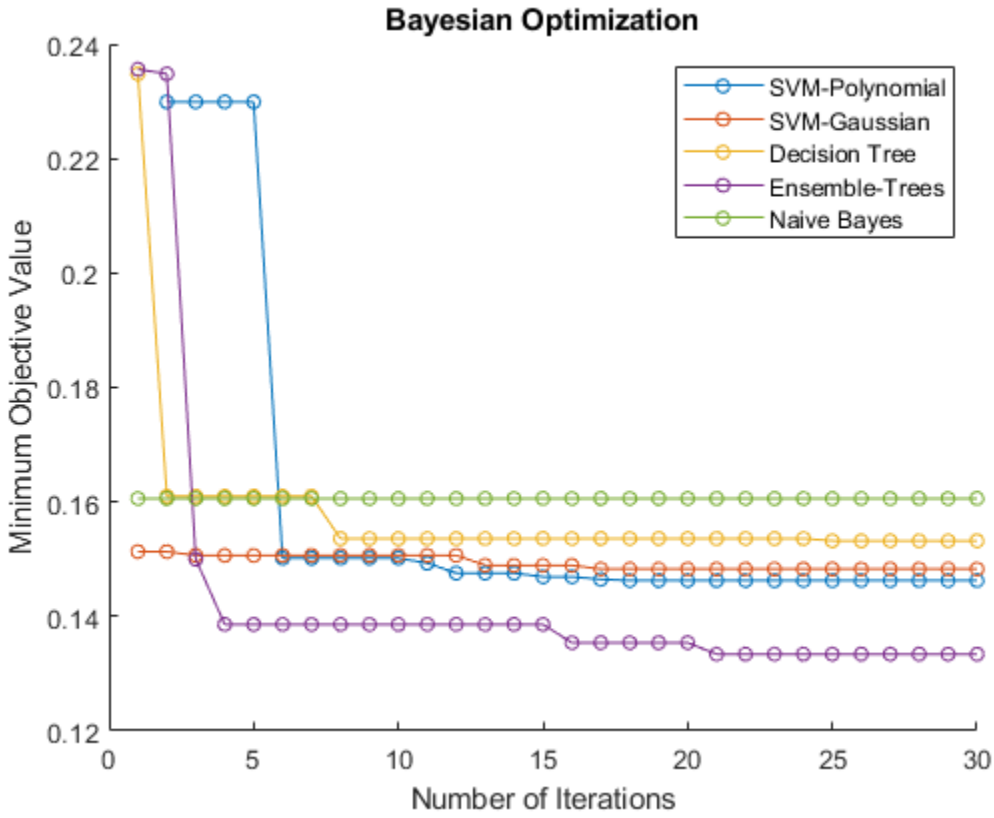
% Naive Bayes
mdls{5} = fitcnb(adultdata,'salary', ...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions', hypopts);
```

```
Warning: It is recommended that you first standardize all numeric predictors when optimizing the
```

Plot Minimum Objective Curves

Extract the Bayesian optimization results from each model and plot the minimum observed value of the objective function for each model over every iteration of the hyperparameter optimization. The objective function value corresponds to the misclassification rate measured by five-fold cross-validation using the training data set. The plot compares the performance of each model.

```
figure
hold on
N = length(mdls);
for i = 1:N
    mdl = mdls{i};
    results = mdls{i}.HyperparameterOptimizationResults;
    plot(results.ObjectiveMinimumTrace,'Marker','o','MarkerSize',5);
end
names = {'SVM-Polynomial','SVM-Gaussian','Decision Tree','Ensemble-Trees','Naive Bayes'};
legend(names,'Location','northeast')
title('Bayesian Optimization')
xlabel('Number of Iterations')
ylabel('Minimum Objective Value')
```



Using Bayesian optimization to find better hyperparameter sets improves the performance of models over several iterations. In this case, the plot indicates that the ensemble of decision trees has the best prediction accuracy for the data. This model performs well consistently over several iterations and different sets of Bayesian optimization hyperparameters.

Check Performance with Test Set

Check the classifier performance with the test data set by using the confusion matrix and the receiver operating characteristic (ROC) curve.

Find the predicted labels and the score values of the test data set.

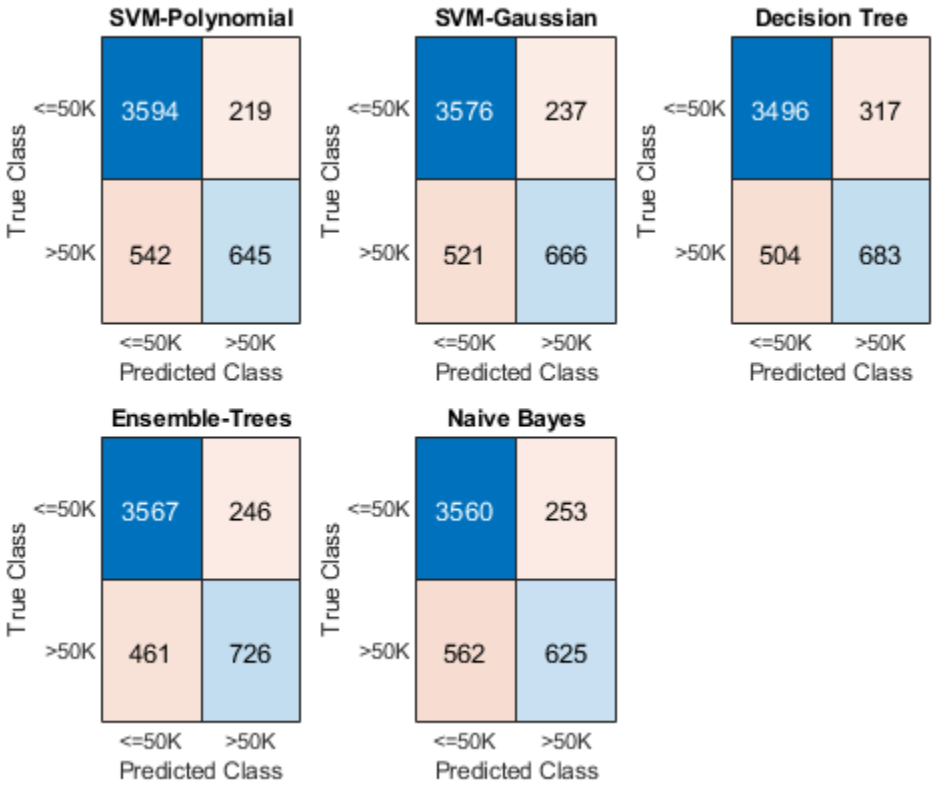
```
label = cell(N,1);
score = cell(N,1);
for i = 1:N
    [label{i},score{i}] = predict(mdls{i},adulttest);
end
```

Confusion Matrix

Obtain the most likely class for each test observation by using the `predict` function of each model. Then compute the confusion matrix with the predicted classes and the known (true) classes of the test data set by using the `confusionchart` function.

```
figure
c = cell(N,1);
for i = 1:N
```

```
    subplot(2,3,i)
    c{i} = confusionchart(adulttest.salary,label{i});
    title(names{i})
end
```



The diagonal elements indicate the number of correctly classified instances of a given class. The off-diagonal elements are instances of misclassified observations.

ROC Curve

Inspect the classifier performance more closely by plotting an ROC curve for each classifier. Use the `perfcurve` function to obtain the X and Y coordinates of the ROC curve and the area under the curve (AUC) value for the computed X and Y.

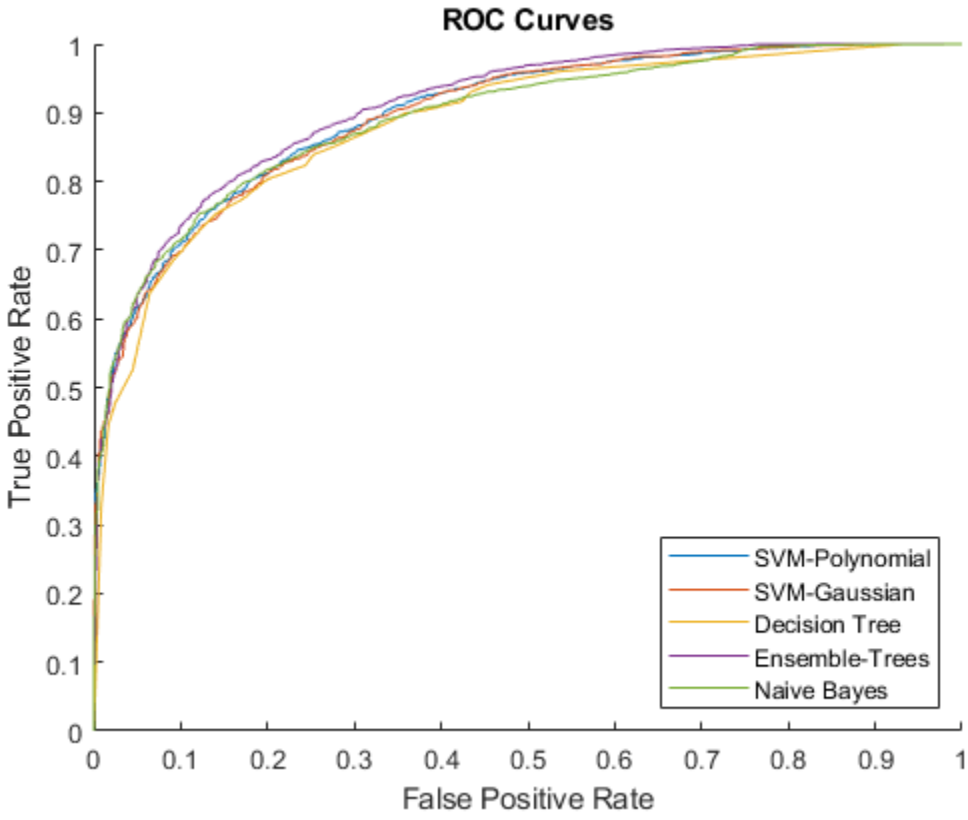
To plot the ROC curves for the score values corresponding to the label `'<=50K'`, check the column order of the score values returned from the `predict` function. The column order is the same as the category order of the response variable in the training data set. Display the category order.

```
c = categories(adultdata.salary)
```

```
c = 2×1 cell
    {'<=50K'}
    {'>50K' }
```

Plot the ROC curves.

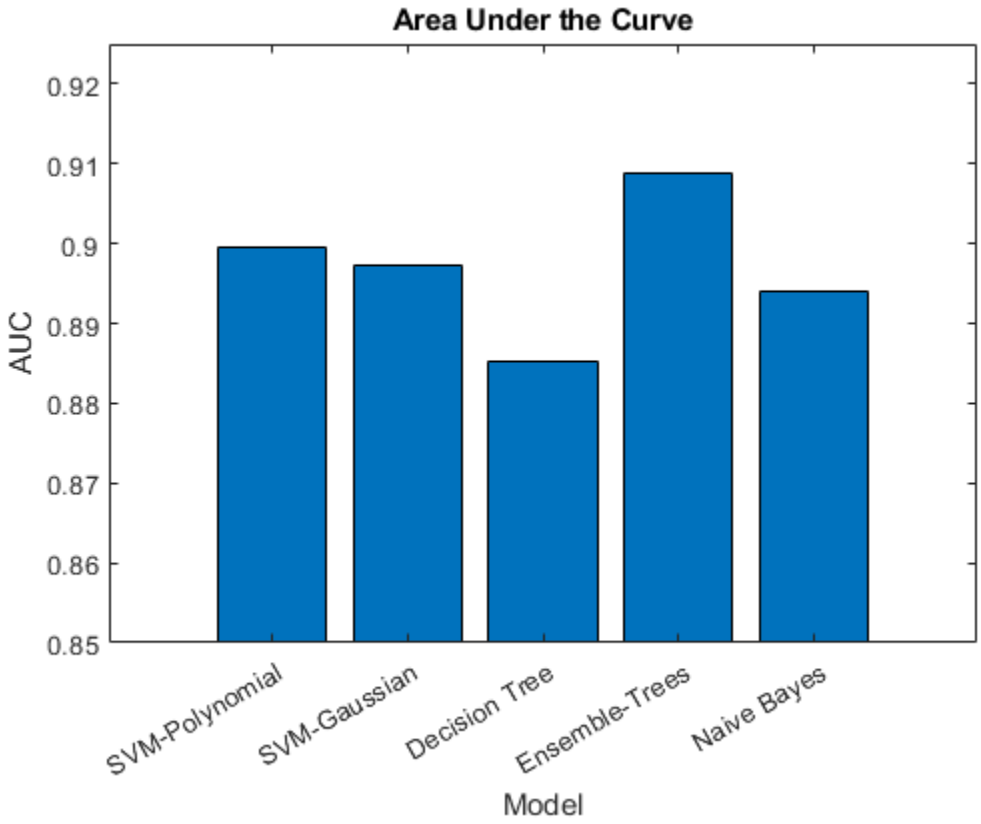
```
figure
hold on
AUC = zeros(1,N);
for i = 1:N
    [X,Y,~,AUC(i)] = perfcurve(adulttest.salary,score{i}(:,1),'<=50K');
    plot(X,Y)
end
title('ROC Curves')
xlabel('False Positive Rate')
ylabel('True Positive Rate')
legend(names,'Location','southeast')
```



An ROC curve shows the true positive rate versus the false positive rate (or, sensitivity versus 1–specificity) for different thresholds of the classifier output.

Now plot the AUC values using a bar graph. For a perfect classifier, whose true positive rate is always 1 regardless of the thresholds, AUC = 1. For a classifier that randomly assigns observations to classes, AUC = 0.5. Larger AUC values indicate better classifier performance.

```
figure
bar(AUC)
title('Area Under the Curve')
xlabel('Model')
ylabel('AUC')
xticklabels(names)
xtickangle(30)
ylim([0.85,0.925])
```

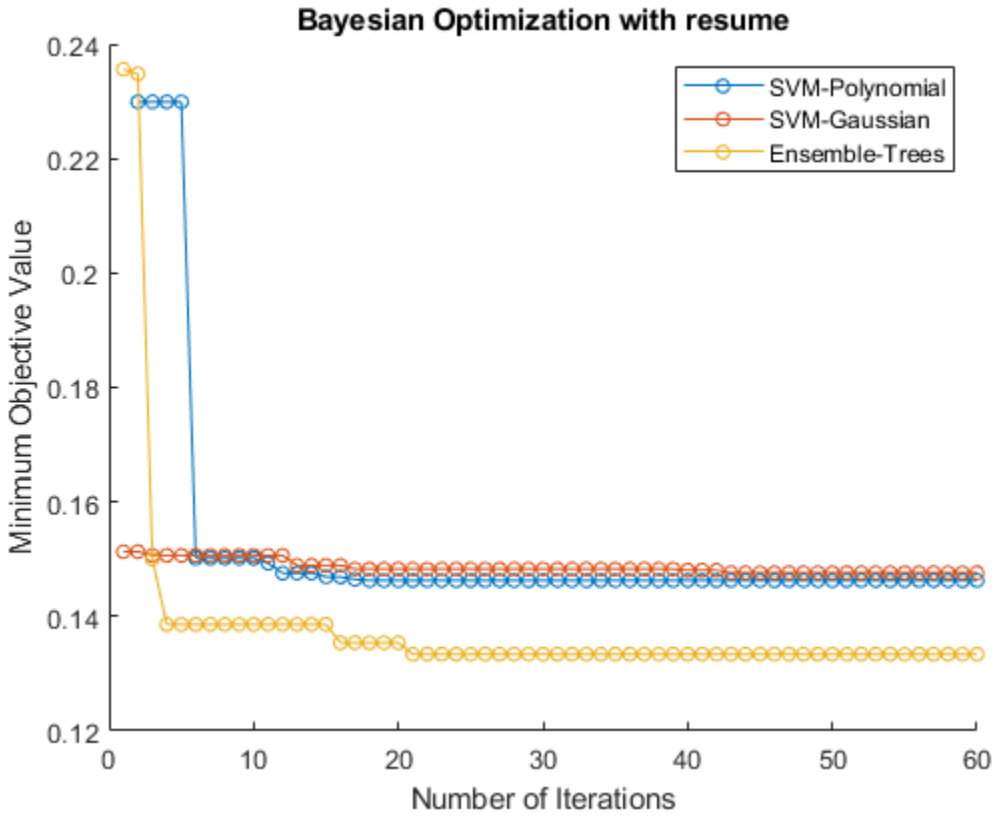


Based on the confusion matrix and the AUC bar graph, the ensemble of decision trees and SVM models achieve better accuracy than the decision tree and naive Bayes models.

Resume Optimization of Most Promising Models

Running Bayesian optimization on all models for further iterations can be computationally expensive. Instead, select a subset of models that have performed well so far and continue the optimization for 30 more iterations by using the `resume` function. Plot the minimum observed values of the objective function for each iteration of Bayesian optimization.

```
figure
hold on
selectedMdls = mdls([1,2,4]);
newresults = cell(1,length(selectedMdls));
for i = 1:length(selectedMdls)
    newresults{i} = resume(selectedMdls{i}.HyperparameterOptimizationResults,'MaxObjectiveEvalua
    plot(newresults{i}.ObjectiveMinimumTrace,'Marker','o','MarkerSize',5)
end
title('Bayesian Optimization with resume')
xlabel('Number of Iterations')
ylabel('Minimum Objective Value')
legend({'SVM-Polynomial','SVM-Gaussian','Ensemble-Trees'},'Location','northeast')
```



The first 30 iterations correspond to the first round of Bayesian optimization. The next 30 iterations correspond to the results of the `resume` function. Resuming optimization is useful because the loss continues to reduce further after the first 30 iterations.

Automated Classifier Selection with Bayesian Optimization

This example shows how to use `fitcauto` to automatically try a selection of classification model types with different hyperparameter values, given training predictor and response data. The function uses Bayesian optimization to select models and their hyperparameter values, and computes the cross-validation classification error for each model. After the optimization is complete, `fitcauto` returns the model, trained on the entire data set, that is expected to best classify new data. Check the model performance on test data.

Load Sample Data

This example uses the 1994 census data stored in `census1994.mat`. The data set consists of demographic information from the US Census Bureau that can be used to predict whether an individual makes over $50,000 per year.

Load the sample data `census1994`, which contains the training data `adultdata` and the test data `adulttest`. Preview the first few rows of the training data set.

```
load census1994
head(adultdata)
```

```

```

Each row contains the demographic information for one adult. The last column `salary` shows whether a person has a salary less than or equal to $50,000 per year or greater than $50,000 per year.

Use Automated Model Selection

Use `fitcauto` to automatically find an appropriate classifier for the data in `adultdata`. Set the observation weights, and specify to run the Bayesian optimization in parallel, which requires Parallel Computing Toolbox™. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results.

Because of the complexity of the optimization, this process can take some time, especially for larger data sets. By default, `fitcauto` provides a plot of the optimization and an iterative display of the optimization results. For more information on how to interpret these results, see “Verbose Display” on page 33-1568.

```
options = struct('UseParallel',true);
[mdl,results] = fitcauto(adultdata,'salary','Weights','fnlwgt', ...
    'HyperparameterOptimizationOptions',options);
```

```
Warning: It is recommended that you first standardize all numeric predictors when optimizing the

```
Optimization completed.
Total iterations: 90
Total elapsed time: 577.1419 seconds
Total time for training and validation: 2558.1542 seconds

Best observed learner is a tree model with:
    MinLeafSize:             25
Observed validation loss: 0.14046
```

```
Time for training and validation: 2.8853 seconds

Best estimated learner (returned model) is a tree model with:
    MinLeafSize:             25
Estimated validation loss: 0.14067
Estimated time for training and validation: 2.8824 seconds

Documentation for fitcauto display
```

The final model returned by `fitcauto` corresponds to the best estimated learner. Before returning the model, the function retrains it using the entire training data (`adultdata`), the listed `Learner` (or model) type, and the displayed hyperparameter values.

Evaluate Test Set Performance

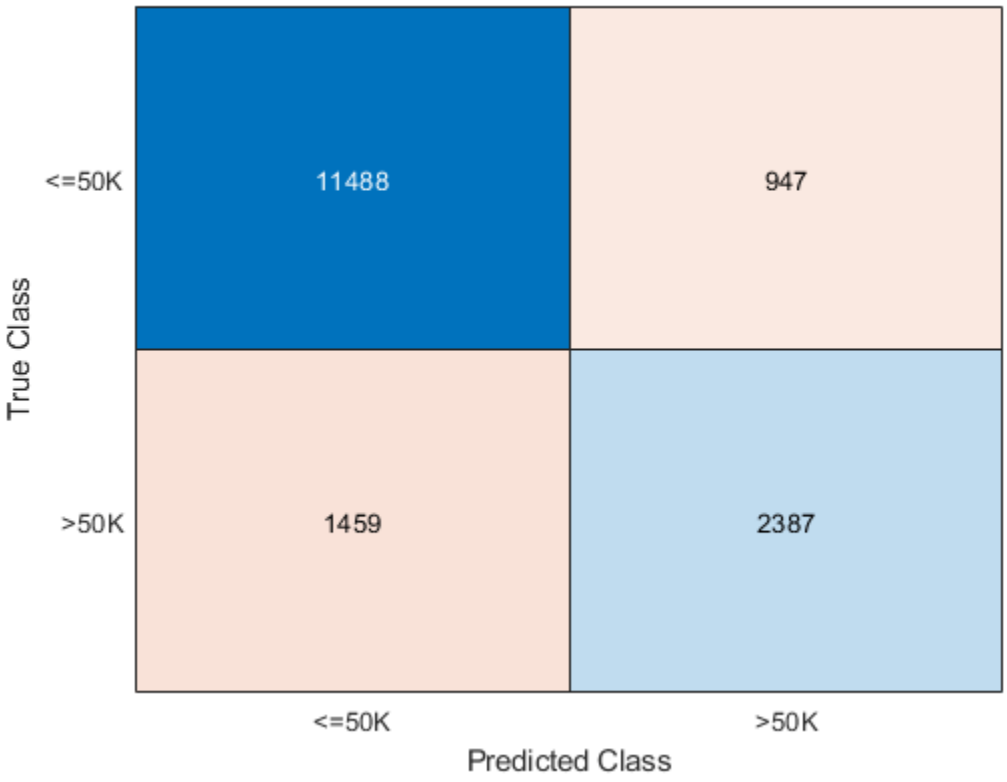
Evaluate the performance of the returned model `mdl` on the test set `adulttest` by using a confusion matrix and a receiver operating characteristic (ROC) curve.

Find the predicted labels and score values for the test set.

```
[labels,scores] = predict(mdl,adulttest);
```

Create a confusion matrix from the test set results. The diagonal elements indicate the number of correctly classified instances of a given class. The off-diagonal elements are instances of misclassified observations.

```
confusionchart(adulttest.salary,labels)
```



Compute the test set classification accuracy. `accuracy` is the percentage of correctly classified test set observations.

```
accuracy = (1-loss(mdl,adulttest,'salary'))*100
```

```
accuracy = 85.1513
```

To plot the ROC curve for the score values corresponding to the label `'<=50K'`, find the column of `scores` that corresponds to that label. The column order of `scores` matches the order of the classes in the trained model.

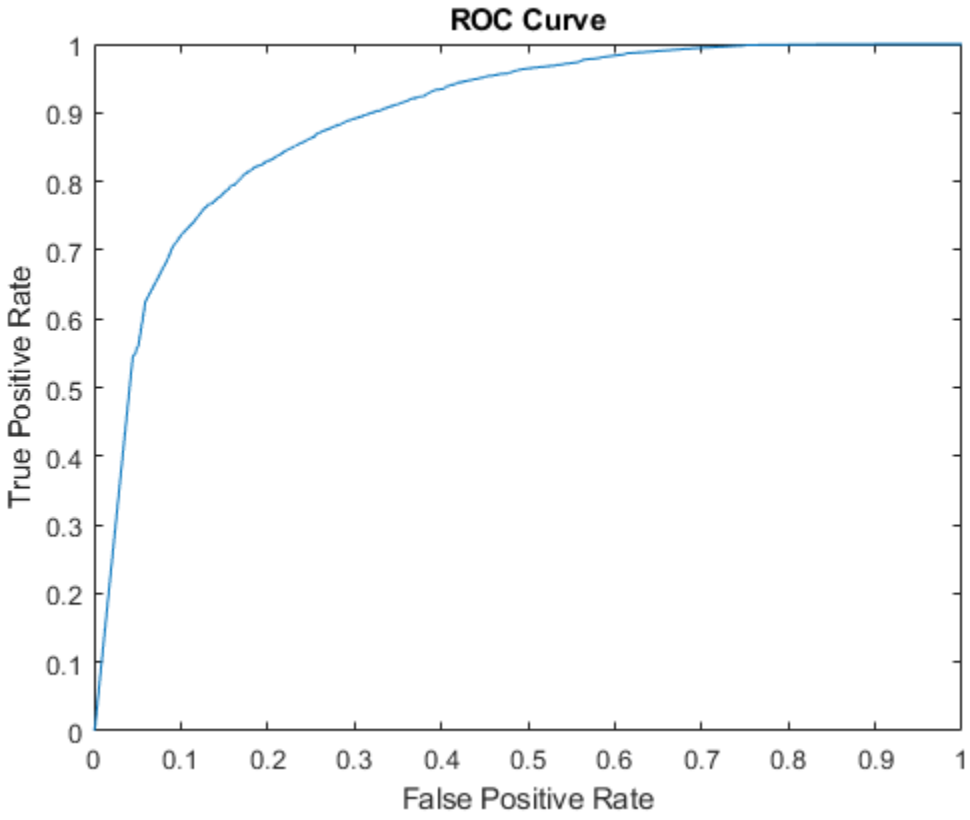
```
mdl.ClassNames
```

```
ans = 2×1 categorical
     <=50K
     >50K
```

Because `'<=50K'` is listed first, the first column of `scores` corresponds to that label.

Plot the ROC curve, and compute the area under the curve (AUC). The ROC curve shows the true positive rate versus the false positive rate for different thresholds of the classifier output. For a perfect classifier, whose true positive rate is always 1 regardless of the threshold, AUC = 1. For a binary classifier that randomly assigns observations to classes, AUC = 0.5. A large AUC value (close to 1) indicates good classifier performance.

```
[X,Y,~,AUC] = perfcurve(adulttest.salary,scores(:,1),'<=50K');
plot(X,Y)
title('ROC Curve')
xlabel('False Positive Rate')
ylabel('True Positive Rate')
```



```
AUC
```

```
AUC = 0.8947
```

Based on the accuracy and AUC values, the classifier performs well on the test data.

Automated Regression Model Selection with Bayesian Optimization

This example shows how to use the `fitrauto` function to automatically try a selection of regression model types with different hyperparameter values, given training predictor and response data. The function uses Bayesian optimization to select models and their hyperparameter values, and computes the following for each model: log(1 + *valLoss*), where *valLoss* is the cross-validation mean squared error (MSE). After the optimization is complete, `fitrauto` returns the model, trained on the entire data set, that is expected to best predict the responses for new data. Check the model performance on test data.

Prepare Data

Load the sample data set `NYCHousing2015`, which includes 10 variables with information on the sales of properties in New York City in 2015. This example uses some of these variables to analyze the sale prices.

```
load NYCHousing2015
```

Instead of loading the sample data set `NYCHousing2015`, you can download the data from the NYC Open Data website and import the data as follows.

```
folder = 'Annualized_Rolling_Sales_Update';
ds = spreadsheetDatastore(folder,"TextType","string","NumHeaderLines",4);
ds.Files = ds.Files(contains(ds.Files,"2015"));
ds.SelectedVariableNames = ["BOROUGH","NEIGHBORHOOD","BUILDINGCLASSCATEGORY","RESIDENTIALUNITS",
    "COMMERCIALUNITS","LANDSQUAREFEET","GROSSSQUAREFEET","YEARBUILT","SALEPRICE","SALEDATE"];
NYCHousing2015 = readall(ds);
```

Preprocess the data set to choose the predictor variables of interest. Some of the preprocessing steps match those in the example “Train Linear Regression Model” on page 11-161.

First, change the variable names to lowercase for readability.

```
NYCHousing2015.Properties.VariableNames = lower(NYCHousing2015.Properties.VariableNames);
```

Next, remove samples with certain problematic values. For example, retain only those samples where at least one of the area measurements `grosssquarefeet` or `landsquarefeet` is nonzero. Assume that a `saleprice` of $0 indicates an ownership transfer without a cash consideration, and remove the samples with that `saleprice` value. Assume that a `yearbuilt` value of 1500 or less is a typo, and remove the corresponding samples.

```
NYCHousing2015(NYCHousing2015.grosssquarefeet == 0 & NYCHousing2015.landsquarefeet == 0,:) = [];
NYCHousing2015(NYCHousing2015.saleprice == 0,:) = [];
NYCHousing2015(NYCHousing2015.yearbuilt <= 1500,:) = [];
```

Convert the `saledate` variable, specified as a `datetime` array, into two numeric columns `MM` (month) and `DD` (day), and remove the `saledate` variable. Ignore the year values because all samples are for the year 2015.

```
[~,NYCHousing2015.MM,NYCHousing2015.DD] = ymd(NYCHousing2015.saledate);
NYCHousing2015.saledate = [];
```

The numeric values in the `borough` variable indicate the names of the boroughs. Change the variable to a categorical variable using the names.

```
NYCHousing2015.borough = categorical(NYCHousing2015.borough,1:5, ...
    ["Manhattan","Bronx","Brooklyn","Queens","Staten Island"]);
```

The `neighborhood` variable has 254 categories. Remove this variable for simplicity.

```
NYCHousing2015.neighborhood = [];
```

Convert the `buildingclasscategory` variable to a categorical variable, and explore the variable by using the `wordcloud` function.

```
NYCHousing2015.buildingclasscategory = categorical(NYCHousing2015.buildingclasscategory);
wordcloud(NYCHousing2015.buildingclasscategory);
```

Assume that you are interested only in one-, two-, and three-family dwellings. Find the sample indices for these dwellings and delete the other samples. Then, change the `buildingclasscategory` variable to an ordinal categorical variable, with integer-valued category names.

```
idx = ismember(string(NYCHousing2015.buildingclasscategory), ...
    ["01  ONE FAMILY DWELLINGS","02  TWO FAMILY DWELLINGS","03  THREE FAMILY DWELLINGS"]);
NYCHousing2015 = NYCHousing2015(idx,:);
NYCHousing2015.buildingclasscategory = categorical(NYCHousing2015.buildingclasscategory, ...
    ["01  ONE FAMILY DWELLINGS","02  TWO FAMILY DWELLINGS","03  THREE FAMILY DWELLINGS"], ...
    ["1","2","3"],'Ordinal',true);
```

The `buildingclasscategory` variable now indicates the number of families in one dwelling.

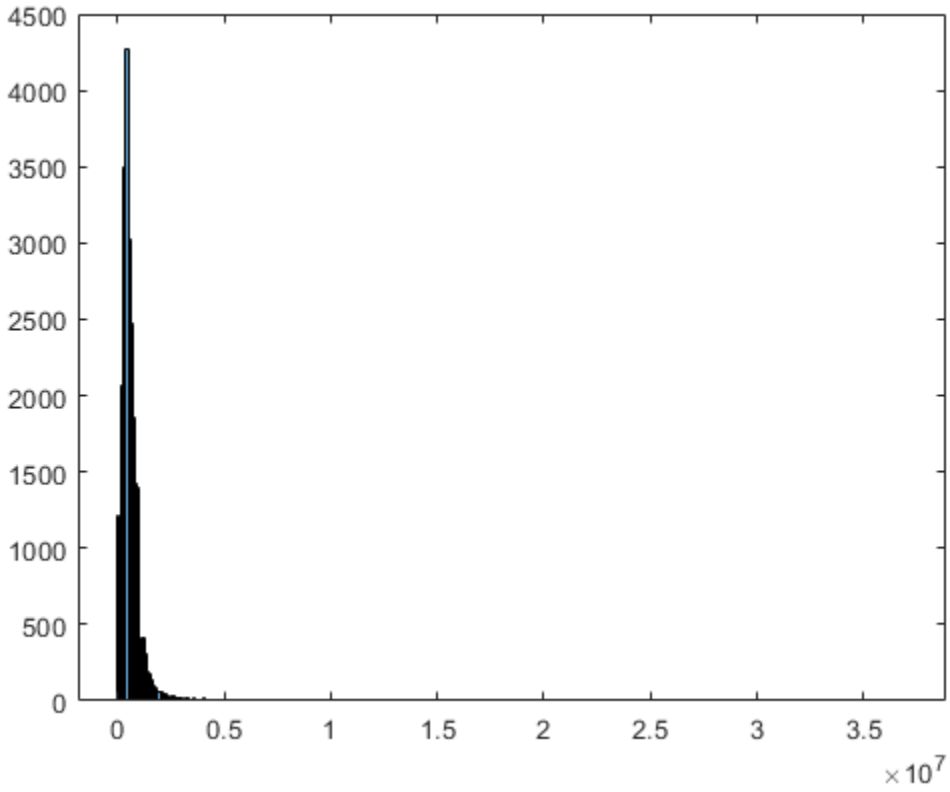
Explore the response variable `saleprice` by using the `summary` function.

```
s = summary(NYCHousing2015);
s.saleprice
```

```
ans = struct with fields:
           Size: [24972 1]
           Type: 'double'
    Description: ''
          Units: ''
     Continuity: []
            Min: 1
         Median: 515000
            Max: 37000000
     NumMissing: 0
```

Create a histogram of the `saleprice` variable.

```
histogram(NYCHousing2015.saleprice)
```



Because the distribution of `saleprice` values is right-skewed, with all values greater than 0, log transform the `saleprice` variable.

```
NYCHousing2015.saleprice = log(NYCHousing2015.saleprice);
```

Similarly, transform the `grosssquarefeet` and `landsquarefeet` variables. Add a value of 1 before taking the logarithm of each variable, in case the variable is equal to 0.

```
NYCHousing2015.grosssquarefeet = log(1 + NYCHousing2015.grosssquarefeet);
NYCHousing2015.landsquarefeet = log(1 + NYCHousing2015.landsquarefeet);
```

Partition Data and Remove Outliers

Partition the data set into a training set and a test set by using `cvpartition`. Use approximately 80% of the observations for the model selection and hyperparameter tuning process, and the other 20% to test the performance of the final model returned by `fitrauto`.

```
rng('default') % For reproducibility of the partition
c = cvpartition(length(NYCHousing2015.saleprice),'Holdout',0.2);
trainData = NYCHousing2015(training(c),:);
testData = NYCHousing2015(test(c),:);
```

Identify and remove the outliers of `saleprice`, `grosssquarefeet`, and `landsquarefeet` from the training data by using the `isoutlier` function.

```
[priceIdx,priceL,priceU] = isoutlier(trainData.saleprice);
trainData(priceIdx,:) = [];

[grossIdx,grossL,grossU] = isoutlier(trainData.grosssquarefeet);
trainData(grossIdx,:) = [];

[landIdx,landL,landU] = isoutlier(trainData.landsquarefeet);
trainData(landIdx,:) = [];
```

Remove the outliers of `saleprice`, `grosssquarefeet`, and `landsquarefeet` from the test data by using the same lower and upper thresholds computed on the training data.

```
testData(testData.saleprice < priceL | testData.saleprice > priceU,:) = [];
testData(testData.grosssquarefeet < grossL | testData.grosssquarefeet > grossU,:) = [];
testData(testData.landsquarefeet < landL | testData.landsquarefeet > landU,:) = [];
```

Use Automated Model Selection

Find an appropriate regression model for the data in `trainData` by using `fitrauto`. Try tree and ensemble learners and run the Bayesian optimization in parallel, which requires Parallel Computing Toolbox™. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. To reduce computational time, use 3-fold cross-validation, rather than 5-fold cross-validation, as part of the optimization process.

Because of the complexity of the optimization, this process can take some time, especially for larger data sets. By default, `fitrauto` provides a plot of the optimization and an iterative display of the optimization results. For more information on how to interpret these results, see “Verbose Display” on page 33-2111.

```
options = struct('UseParallel',true,'Kfold',3);
[mdl,results] = fitrauto(trainData,'saleprice', ...
    'Learners',{'tree','ensemble'},'HyperparameterOptimizationOptions',options);
```

```

_____________________________________________________________
Optimization completed.
Total iterations: 61
Total elapsed time: 150.2458 seconds
Total time for training and validation: 386.9239 seconds

Best observed learner is an ensemble model with:
    Method:             LSBoost
    NumLearningCycles:      486
    LearnRate:         0.038349
    MinLeafSize:             39
Observed log(1 + valLoss): 0.17753
```

```
Time for training and validation: 28.0634 seconds

Best estimated learner (returned model) is an ensemble model with:
    Method:             LSBoost
    NumLearningCycles:      486
    LearnRate:          0.038349
    MinLeafSize:              39
Estimated log(1 + valLoss): 0.17751
Estimated time for training and validation: 28.7325 seconds

Documentation for fitrauto display
```

The final model returned by `fitrauto` corresponds to the best estimated learner. Before returning the model, the function retrains it using the entire training data (`trainData`), the listed `Learner` (or model) type, and the displayed hyperparameter values.

Evaluate Test Set Performance

Evaluate the performance of the returned model `mdl` on the test set `testData`. Compute the test set mean squared error (MSE), and take a log transform of the MSE to match the values in the verbose display of `fitrauto`. Smaller MSE (and log-transformed MSE) values indicate better performance.

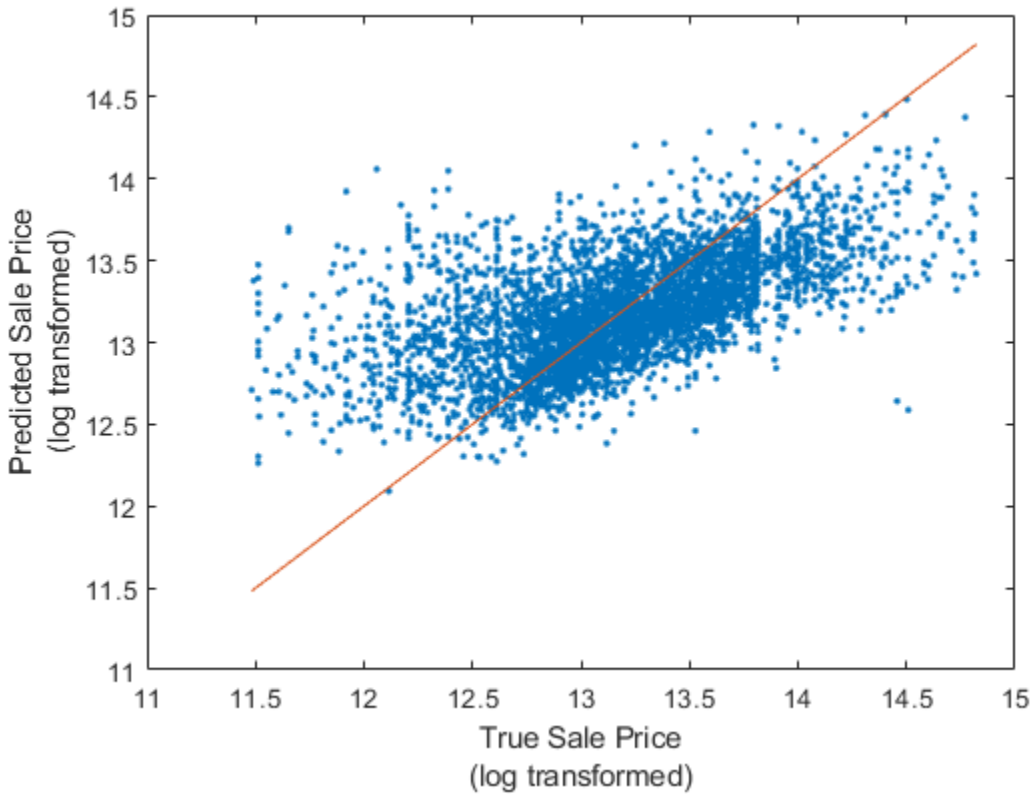
```
testMSE = loss(mdl,testData,'saleprice');
testError = log(1 + testMSE)
```

```
testError = 0.1791
```

Compare the predicted test set response values to the true response values. Plot the predicted sale price along the vertical axis and the true sale price along the horizontal axis. Points on the reference line indicate correct predictions. A good model produces predictions that are scattered near the line.

```
testPredictions = predict(mdl,testData);

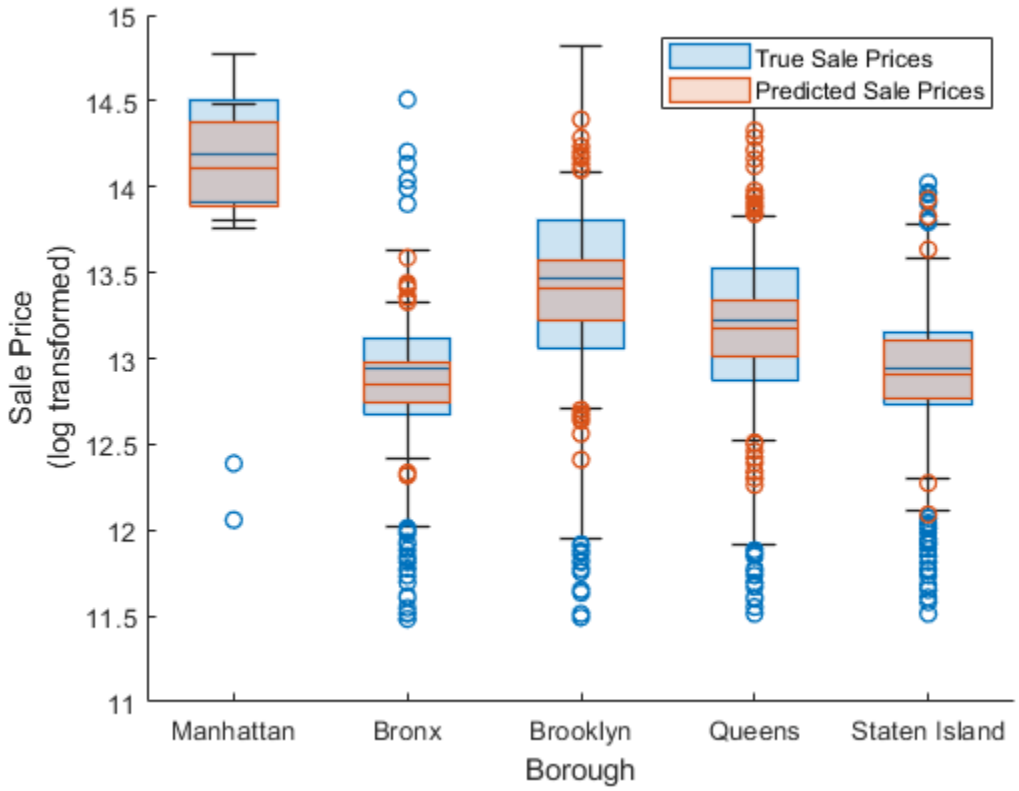
plot(testData.saleprice,testPredictions,'.')
hold on
plot(testData.saleprice,testData.saleprice) % Reference line
hold off
xlabel(["True Sale Price","(log transformed)"])
ylabel(["Predicted Sale Price","(log transformed)"])
```



Use box plots to compare the distribution of predicted and true sale prices by borough. Create the box plots by using the `boxchart` function. Each box plot displays the median, the lower and upper quartiles, any outliers (computed using the interquartile range), and the minimum and maximum values that are not outliers. In particular, the line inside each box is the sample median, and the circular markers indicate outliers.

For each borough, compare the red box plot (showing the distribution of predicted prices) to the blue box plot (showing the distribution of true prices). Similar distributions for the predicted and true sale prices indicate good predictions.

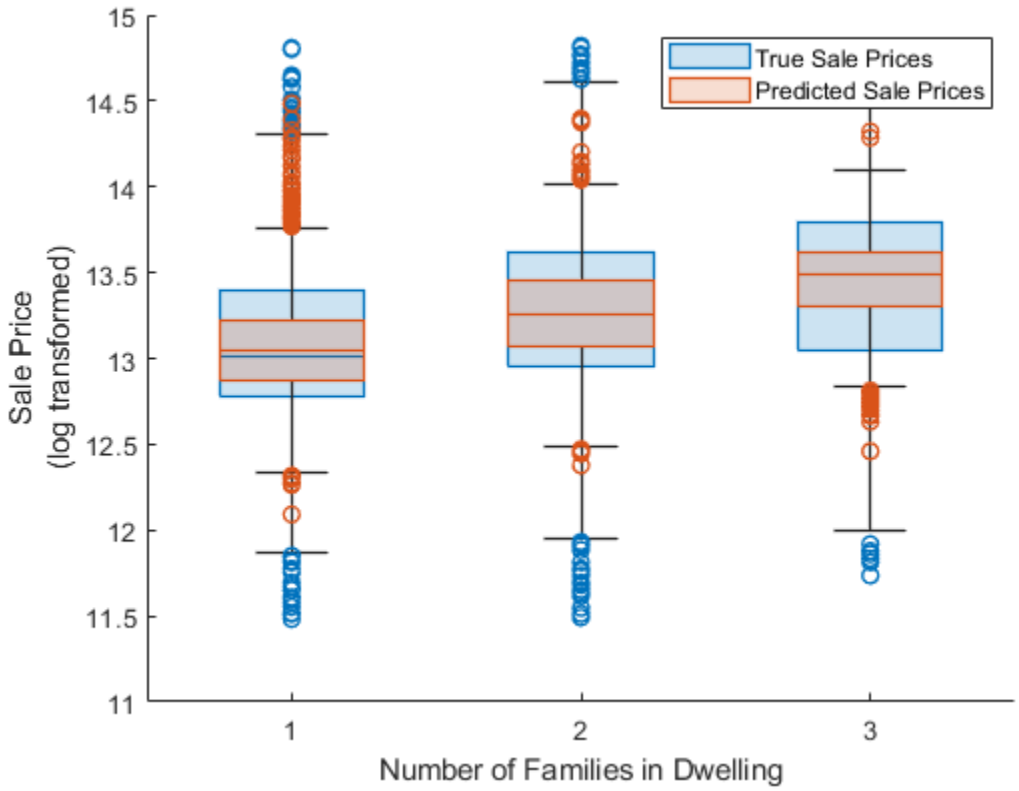
```
boxchart(testData.borough,testData.saleprice)
hold on
boxchart(testData.borough,testPredictions)
hold off
legend(["True Sale Prices","Predicted Sale Prices"])
xlabel("Borough")
ylabel(["Sale Price","(log transformed)"])
```



For all the boroughs, the predicted median sale price closely matches the median true sale price. The predicted sale prices seem to vary less than the true sale prices.

Display box charts that compare the distribution of predicted and true sale prices by the number of families in a dwelling.

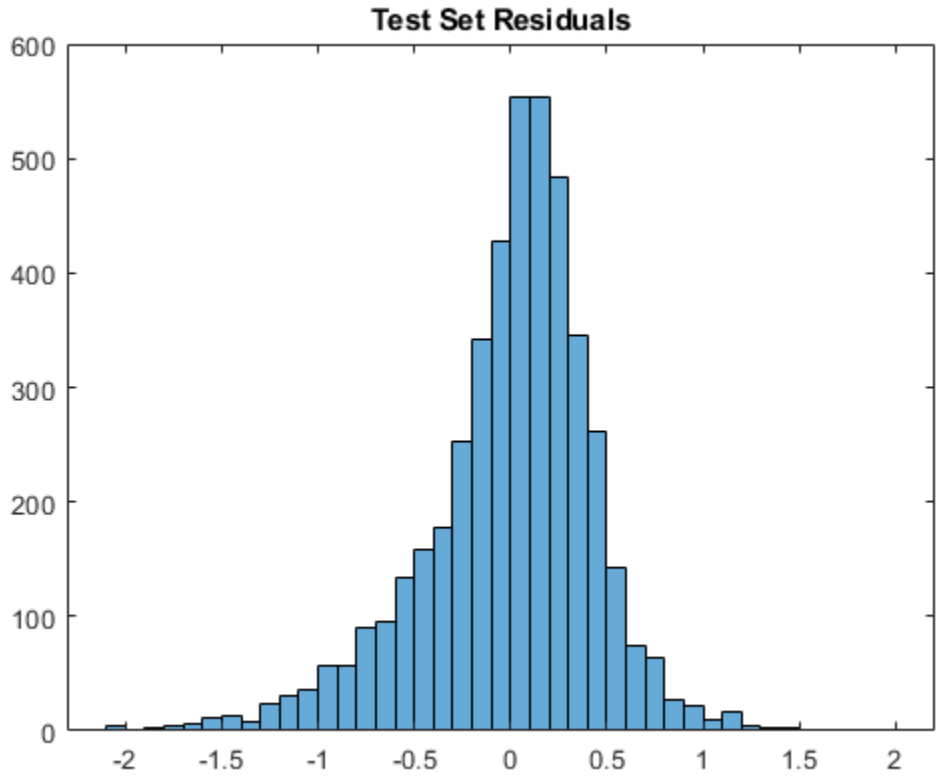
```
boxchart(testData.buildingclasscategory,testData.saleprice)
hold on
boxchart(testData.buildingclasscategory,testPredictions)
hold off
legend(["True Sale Prices","Predicted Sale Prices"])
xlabel("Number of Families in Dwelling")
ylabel(["Sale Price","(log transformed)"])
```



For all dwellings, the predicted median sale price closely matches the median true sale price. The predicted sale prices seem to vary less than the true sale prices.

Plot a histogram of the test set residuals, and check that they are normally distributed. (Recall that the sale prices are log-transformed.)

```
testResiduals = testData.saleprice - testPredictions;
histogram(testResiduals)
title('Test Set Residuals')
```



Although the histogram is slightly left-skewed, it is approximately symmetric about 0.

Credit Rating by Bagging Decision Trees

This example shows how to build an automated credit rating tool.

One of the fundamental tasks in credit risk management is to assign a credit grade to a borrower. Grades are used to rank customers according to their perceived creditworthiness: better grades mean less risky customers; similar grades mean similar level of risk. Grades come in two categories: credit ratings and credit scores. Credit ratings are a small number of discrete classes, usually labeled with letters, such as 'AAA', 'BB-', etc. Credit scores are numeric grades such as '640' or '720'. Credit grades are one of the key elements in regulatory frameworks, such as Basel II (see Basel Committee on Banking Supervision [3]).

Assigning a credit grade involves analyzing information on the borrower. If the borrower is an individual, information of interest could be the individual's income, outstanding debt (mortgage, credit cards), household size, residential status, etc. For corporate borrowers, one may consider certain financial ratios (e.g., sales divided by total assets), industry, etc. Here, we refer to these pieces of information about a borrower as *features* or *predictors*. Different institutions use different predictors, and they may also have different rating classes or score ranges to rank their customers. For relatively small loans offered to a large market of potential borrowers (e.g., credit cards), it is common to use credit scores, and the process of grading a borrower is usually automated. For larger loans, accessible to small- to medium-sized companies and larger corporations, credit ratings are usually used, and the grading process may involve a combination of automated algorithms and expert analysis.

There are rating agencies that keep track of the creditworthiness of companies. Yet, most banks develop an internal methodology to assign credit grades for their customers. Rating a customer internally can be a necessity if the customer has not been rated by a rating agency, but even if a third-party rating exists, an internal rating offers a complementary assessment of a customer's risk profile.

This example shows how MATLAB® can help with the automated stage of a credit rating process. In particular, we take advantage of one of the statistical learning tools readily available in Statistics and Machine Learning Toolbox™, a classification algorithm known as a *bagged decision tree*.

We assume that historical information is available in the form of a data set where each record contains the features of a borrower and the credit rating that was assigned to it. These may be internal ratings, assigned by a committee that followed policies and procedures already in place. Alternatively, the ratings may come from a rating agency, whose ratings are being used to "jump start" a new internal credit rating system.

The existing historical data is the starting point, and it is used to *train* the bagged decision tree that will automate the credit rating. In the vocabulary of statistical learning, this training process falls in the category of *supervised learning*. The classifier is then used to assign ratings to new customers. In practice, these automated or *predicted* ratings would most likely be regarded as tentative, until a credit committee of experts reviews them. The type of classifier we use here can also facilitate the revision of these ratings, because it provides a measure of certainty for the predicted ratings, a *classification score*.

In practice, one needs to train a classifier first, then use it to assign a credit rating to new customers, and finally one also needs to *profile* or *evaluate the quality* or accuracy of the classifier, a process also known as *validation* or *back-testing*. We discuss some readily available back-testing tools, as well.

Loading the Existing Credit Rating Data

We load the historical data from the comma-delimited text file `CreditRating_Historical.dat`. We choose to work with text files here, but users with access to Database Toolbox™ can certainly load this information directly from a database.

The data set contains financial ratios, industry sector, and credit ratings for a list of corporate customers. This is simulated, not real data. The first column is a customer ID. Then we have five columns of financial ratios. These are the same ratios used in Altman's z-score (see Altman [1]; see also Loeffler and Posch [4] for a related analysis).

- Working capital / Total Assets (WC_TA)
- Retained Earnings / Total Assets (RE_TA)
- Earnings Before Interests and Taxes / Total Assets (EBIT_TA)
- Market Value of Equity / Book Value of Total Debt (MVE_BVTD)
- Sales / Total Assets (S_TA)

Next, we have an industry sector label, an integer value ranging from 1 to 12. The last column has the credit rating assigned to the customer. We load the data into a `table` array.

```
creditDS = readtable('CreditRating_Historical.dat');
```

We copy the features into a matrix `X`, and the corresponding classes, the ratings, into a vector `Y`. This is not a required step, since we could access this information directly from the `dataset` or `table` array, but we do it here to simplify some repeated function calls below.

The features to be stored in the matrix `X` are the five financial ratios, and the industry label. `Industry` is a categorical variable, *nominal* in fact, because there is no ordering in the industry sectors. The response variable, the credit ratings, is also categorical, though this is an *ordinal* variable, because, by definition, ratings imply a *ranking* of creditworthiness. We can use this variable "as is" to train our classifier. Here we choose to copy it into an *ordinal array* because this way the outputs come out in the natural order of the ratings and are easier to read. The ordering of the ratings is established by the cell array we pass as a third argument in the definition of `Y`. The credit ratings can also be mapped into numeric values, which can be useful to try alternative methods to analyze the data (e.g., regression). It is always recommended to try different methods in practice.

```
X = [creditDS.WC_TA creditDS.RE_TA creditDS.EBIT_TA creditDS.MVE_BVTD...
     creditDS.S_TA creditDS.Industry];
Y = ordinal(creditDS.Rating);
```

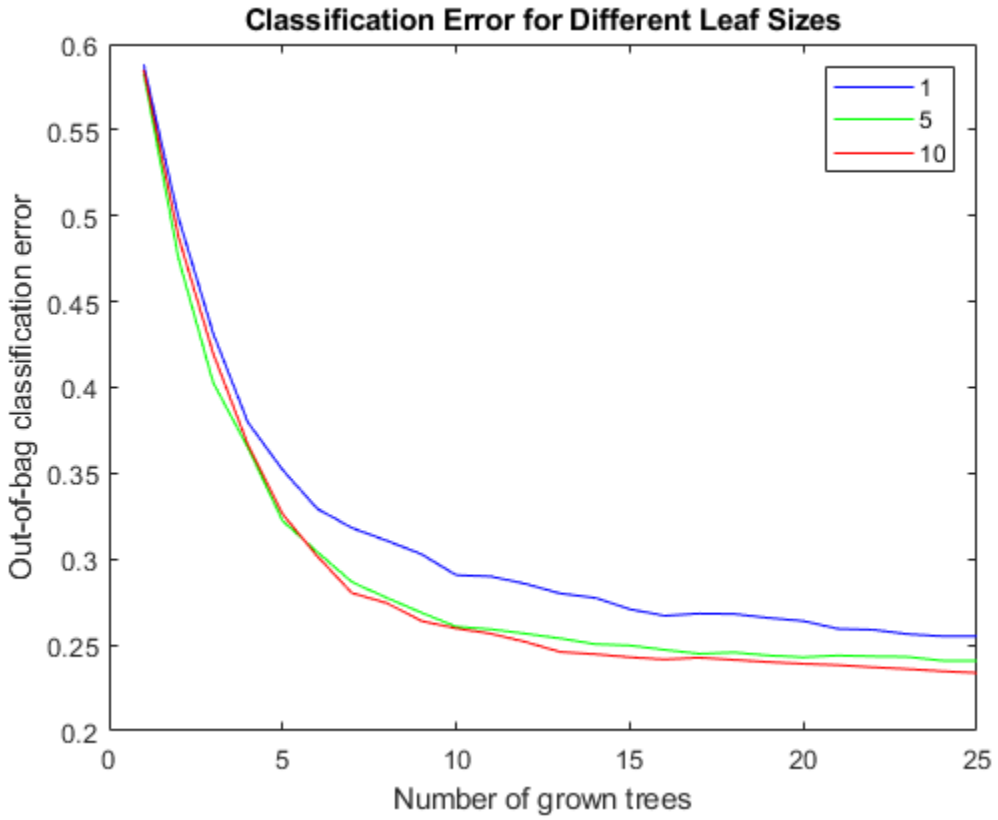
We use the predictors `X` and the response `Y` to fit a particular type of classification ensemble called a *bagged decision tree*. "Bagging," in this context, stands for "bootstrap aggregation." The methodology consists in generating a number of sub-samples, or *bootstrap replicas*, from the data set. These sub-samples are randomly generated, sampling with replacement from the list of customers in the data set. For each replica, a decision tree is grown. Each decision tree is a trained classifier on its own, and could be used in isolation to classify new customers. The predictions of two trees grown from two different bootstrap replicas may be different, though. The ensemble *aggregates* the predictions of all the decision trees that are grown for all the bootstrap replicas. If the majority of the trees predict one particular class for a new customer, it is reasonable to consider that prediction to be more robust than the prediction of any single tree alone. Moreover, if a different class is predicted by a smaller set of trees, that information is useful, too. In fact, the proportion of trees that predict different classes is the basis for the *classification scores* that are reported by the ensemble when classifying new data.

Constructing the Tree Bagger

The first step to construct our classification ensemble will be to find a good leaf size for the individual trees; here we try sizes of 1, 5 and 10. (See Statistics and Machine Learning Toolbox documentation for more on `TreeBagger`.) We start with a small number of trees, 25 only, because we mostly want to compare the initial trend in the classification error for different leaf sizes. For reproducibility and fair comparisons, we reinitialize the random number generator, which is used to sample with replacement from the data, each time we build a classifier.

```
leaf = [1 5 10];
nTrees = 25;
rng(9876,'twister');
savedRng = rng; % save the current RNG settings

color = 'bgr';
for ii = 1:length(leaf)
   % Reinitialize the random number generator, so that the
   % random samples are the same for each leaf size
   rng(savedRng)
   % Create a bagged decision tree for each leaf size and plot out-of-bag
   % error 'oobError'
   b = TreeBagger(nTrees,X,Y,'OOBPrediction','on',...
                             'CategoricalPredictors',6,...
                             'MinLeafSize',leaf(ii));
   plot(oobError(b),color(ii))
   hold on
end
xlabel('Number of grown trees')
ylabel('Out-of-bag classification error')
legend({'1', '5', '10'},'Location','NorthEast')
title('Classification Error for Different Leaf Sizes')
hold off
```



The errors are comparable for the three leaf-size options. We will therefore work with a leaf size of 10, because it results in leaner trees and more efficient computations.

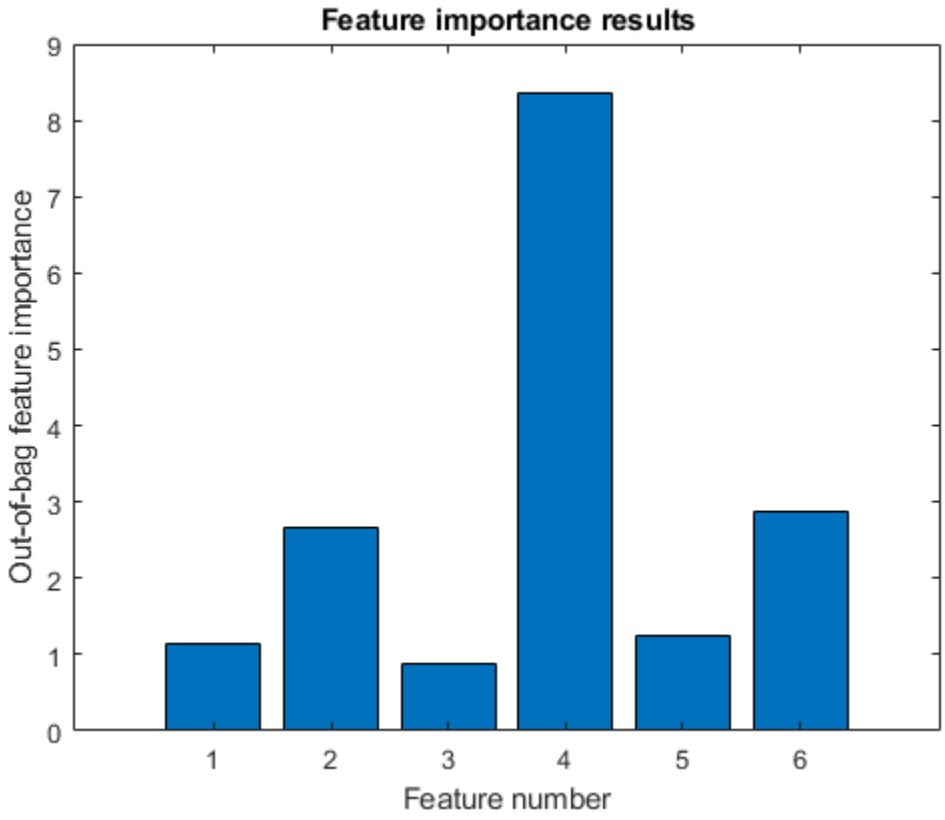
Note that we did not have to split the data into *training* and *test* subsets. This is done internally, it is implicit in the sampling procedure that underlies the method. At each bootstrap iteration, the bootstrap replica is the training set, and any customers left out ("out-of-bag") are used as test points to estimate the out-of-bag classification error reported above.

Next, we want to find out whether all the features are important for the accuracy of our classifier. We do this by turning on the *feature importance* measure (`OOBPredictorImportance`), and plot the results to visually find the most important features. We also try a larger number of trees now, and store the classification error, for further comparisons below.

```
nTrees = 50;
leaf = 10;
rng(savedRng);
b = TreeBagger(nTrees,X,Y,'OOBPredictorImportance','on',...
                          'CategoricalPredictors',6,...
                          'MinLeafSize',leaf);

bar(b.OOBPermutedPredictorDeltaError)
xlabel('Feature number')
ylabel('Out-of-bag feature importance')
title('Feature importance results')

oobErrorFullX = oobError(b);
```



Features 2, 4 and 6 stand out from the rest. Feature 4, market value of equity / book value of total debt (`MVE_BVTD`), is the most important predictor for this data set. This ratio is closely related to the predictors of creditworthiness in structural models, such as Merton's model [5], where the value of the firm's equity is compared to its outstanding debt to determine the default probability.

Information on the industry sector, feature 6 (`Industry`), is also relatively more important than other variables to assess the creditworthiness of a firm for this data set.

Although not as important as `MVE_BVTD`, feature 2, retained earnings / total assets (`RE_TA`), stands out from the rest. There is a correlation between retained earnings and the age of a firm (the longer a firm has existed, the more earnings it can accumulate, in general), and in turn the age of a firm is correlated to its creditworthiness (older firms tend to be more likely to survive in tough times).

Let us fit a new classification ensemble using only predictors `RE_TA`, `MVE_BVTD`, and `Industry`. We compare its classification error with the previous classifier, which uses all features.

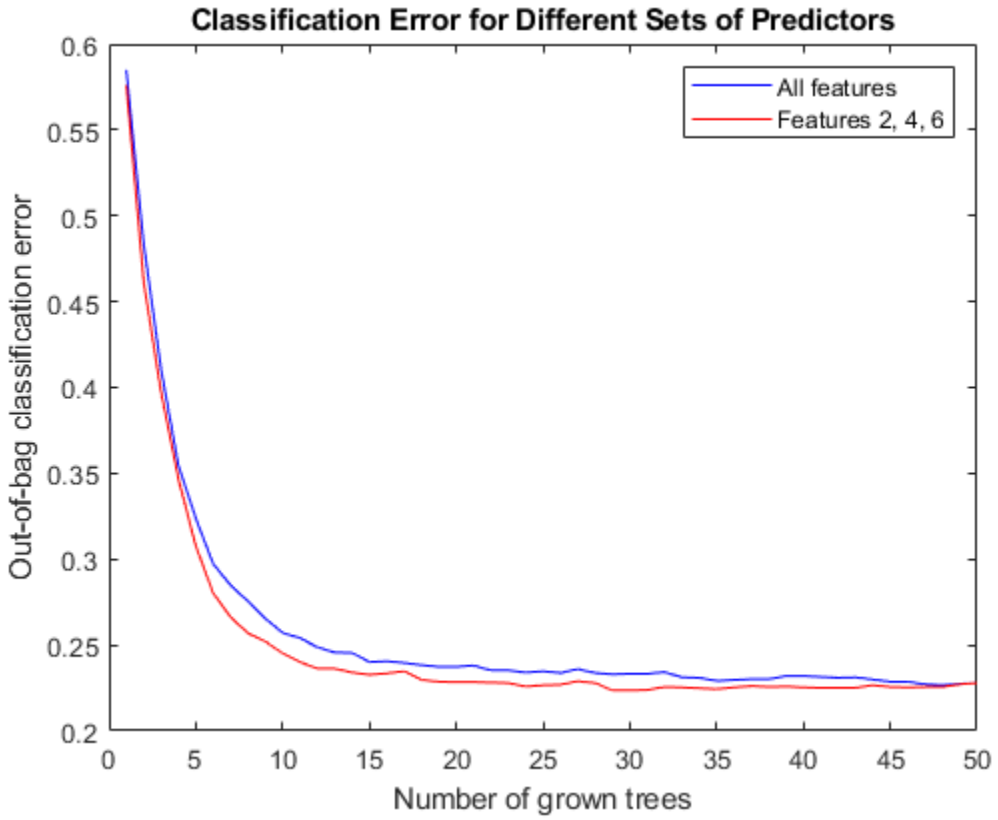
```
X = [creditDS.RE_TA creditDS.MVE_BVTD creditDS.Industry];

rng(savedRng)
b = TreeBagger(nTrees,X,Y,'OOBPrediction','on',...
                          'CategoricalPredictors',3,...
                          'MinLeafSize',leaf);

oobErrorX246 = oobError(b);

plot(oobErrorFullX,'b')
hold on
```

```
plot(oobErrorX246,'r')
xlabel('Number of grown trees')
ylabel('Out-of-bag classification error')
legend({'All features', 'Features 2, 4, 6'},'Location','NorthEast')
title('Classification Error for Different Sets of Predictors')
hold off
```



The accuracy of the classification does not deteriorate significantly when we remove the features with relatively low importance (1, 3, and 5), so we will use the more parsimonious classification ensemble for our predictions.

In this example, we have started with a set of six features only, and used the feature importance measure of the classifier, and the out-of-bag classification error as criteria to screen out three of the variables. Feature selection can be a time consuming process when the initial set of potential predictors contains dozens of variables. Besides the tools we have used here (variable importance and a "visual" comparison of out-of-bag errors), other variable selection tools in Statistics and Machine Learning Toolbox can be helpful for these types of analyses (see documentation). However, in the end, a successful feature selection process requires a combination of quantitative tools and an analyst's judgement.

For example, the variable importance measure we used here is a ranking mechanism that estimates the relative impact of a feature by measuring how much the predictive accuracy of the classifier deteriorates when this feature's values are randomly permuted. The idea is that when the feature in question adds little to the predictive power of the classifier, using altered (in this case permuted) values should not impact the classification results. Relevant information, on the other hand, cannot be randomly swapped without degrading the predictions. Now, if two highly correlated features are

important, they will both rank high in this analysis. In that case, keeping one of these features should suffice for accurate classifications, but one would not know that from the ranking results alone. One would have to check the correlations separately, or use an expert's judgement. That is to say, tools like variable importance or `sequentialfs` can greatly help for feature selection, but an analyst's judgment is a key piece in this process.

At this point, the classifier could be saved (e.g., `save classifier.mat b`), to be loaded in a future session (`load classifier`) to classify new customers. For efficiency, it is recommended to keep a compact version of the classifier once the training process is finished.

```
b = compact(b);
```

Classifying New Data

Here we use the previously constructed classification ensemble to assign credit ratings to new customers. Because the ratings of existing customers need to be reviewed, too, on a regular basis, especially when their financial information has substantially changed, the data set could also contain a list of existing customers under review. We start by loading the new data.

```
newDS = readtable('CreditRating_NewCompanies.dat');
```

To predict the credit rating for this new data, we call the `predict` method on the classifier. The method returns two arguments, the predicted class and the classification score. We certainly want to get both output arguments, since the classification scores contain information on how certain the predicted ratings seem to be. We could copy variables `RE_TA`, `MVE_BVTD` and `Industry` into a matrix `X`, as before, but since we will make only one call to `predict`, we can skip this step and use `newDS` directly.

```
[predClass,classifScore] = predict(b,[newDS.RE_TA newDS.MVE_BVTD newDS.Industry]);
```

At this point, we can create a report. Here we only display on the screen a small report for the first three customers, for illustration purposes, but MATLAB deployment tools could greatly improve the workflow here. For example, credit analysts could run this classification remotely, using a web browser, and get a report, without even having MATLAB on their desktops.

```
for i = 1:3
   fprintf('Customer %d:\n',newDS.ID(i));
   fprintf('   RE/TA    = %5.2f\n',newDS.RE_TA(i));
   fprintf('   MVE/BVTD = %5.2f\n',newDS.MVE_BVTD(i));
   fprintf('   Industry = %2d\n',newDS.Industry(i));
   fprintf('   Predicted Rating : %s\n',predClass{i});
   fprintf('   Classification score : \n');
   for j = 1:length(b.ClassNames)
      if (classifScore(i,j)>0)
         fprintf('      %s : %5.4f \n',b.ClassNames{j},classifScore(i,j));
      end
   end
end
```

```
Customer 60644:
   RE/TA    =  0.22
   MVE/BVTD =  2.40
   Industry =  6
   Predicted Rating : AA
   Classification score :
      A : 0.2874
      AA : 0.6919
```

```
      AAA : 0.0156
      BBB : 0.0051
Customer 33083:
   RE/TA    =  0.24
   MVE/BVTD =  1.51
   Industry =  4
   Predicted Rating : BBB
   Classification score :
      A : 0.0751
      BB : 0.0017
      BBB : 0.9232
Customer 63830:
   RE/TA    =  0.18
   MVE/BVTD =  1.69
   Industry =  7
   Predicted Rating : A
   Classification score :
      A : 0.6629
      AA : 0.0067
      B : 0.0008
      BB : 0.0005
      BBB : 0.3291
```

Keeping records of the predicted ratings and corresponding scores can be useful for periodic assessments of the quality of the classifier. We store this information here in the `table` array `predDS`.

```
classnames = b.ClassNames;
predDS = [table(newDS.ID,predClass),array2table(classifScore)];
predDS.Properties.VariableNames = {'ID','PredRating',classnames{:}};
```

This information could be saved, for example, to a comma-delimited text file `PredictedRatings.dat` using the command

```
  writetable(predDS,'PredictedRatings.dat');
```

or written directly to a database using Database Toolbox.

Back-Testing: Profiling the Classification Process

Validation or *back-testing* is the process of profiling or assessing the quality of the credit ratings. There are many different measures and tests related to this task (see, for example, Basel Committee on Banking Supervision [2]). Here, we focus on the following two questions:

- How accurate are the predicted ratings, as compared to the actual ratings? Here "predicted ratings" refers to those obtained from the automated classification process, and "actual ratings" to those assigned by a credit committee that puts together the predicted ratings and their classification scores, and other pieces of information, such as news and the state of the economy to determine a final rating.
- How well do the actual ratings rank customers according to their creditworthiness? This is done in an *ex-post* analysis performed, for example, one year later, when it is known which companies defaulted during the year.

The file `CreditRating_ExPost.dat` contains "follow up" data on the same companies considered in the previous section. It contains the actual ratings that the committee assigned to these companies,

as well as a "default flag" that indicates whether the corresponding company defaulted within one year of the rating process (if 1) or not (if 0).

```
exPostDS = readtable('CreditRating_ExPost.dat');
```

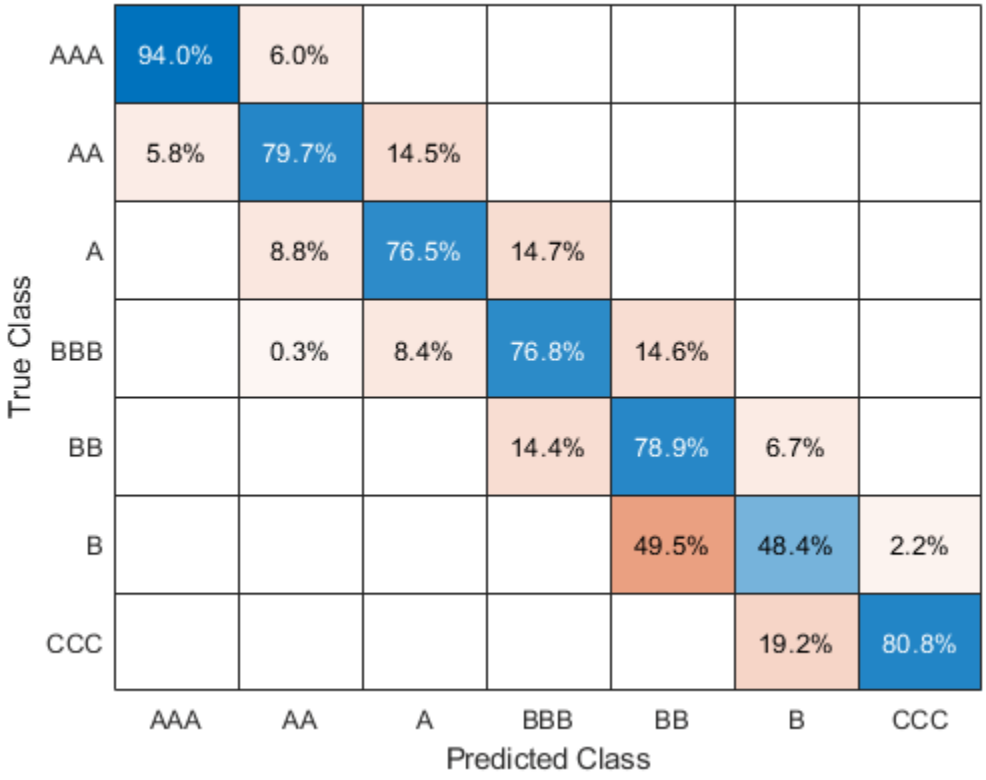
Comparing predicted ratings vs. actual ratings. The rationale to train an automated classifier is to expedite the work of the credit committee. The more accurate the predicted ratings are, the less time the committee has to spend reviewing the predicted ratings. So it is conceivable that the committee wants to have regular checks on how closely the predicted ratings match the final ratings they assign, and to recommend re-training the automated classifier (and maybe include new features, for example) if the mismatch seems concerning.

The first tool we can use to compare predicted vs. actual ratings is a *confusion matrix*, readily available in Statistics and Machine Learning Toolbox:

```
C = confusionchart(exPostDS.Rating,predDS.PredRating);
sortClasses(C,{'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC'})
```

The rows correspond to the actual ratings, and the columns to the predicted ratings. The amount in the position `(i,j)` in the confusion matrix indicates how many customers received an actual rating `i` and were predicted as rating `j`. For example, position `(3,2)` tells us how many customers received a rating of 'A' by the credit committee, but were predicted as 'AA' with the automated classifier. One can also present this matrix in percentage. Normalize each value by the number of observations that has the same true rating.

```
C.Normalization = 'row-normalized';
```

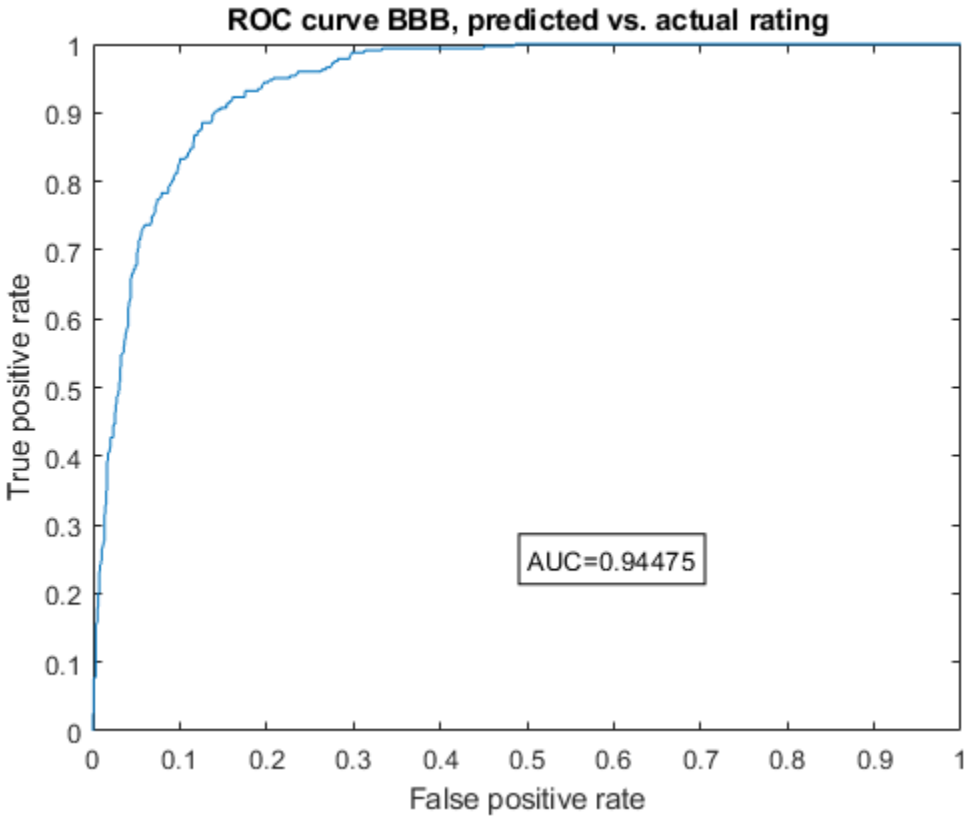


Good agreement between the predicted and the actual ratings would result in values in the main diagonal that dominate the rest of the values in a row, ideally values close to 1. In this case, we actually see an important disagreement for 'B,' since about half of the customers that were rated as 'B' by the credit committee had been predicted as 'BB' by the automated classifier. On the other hand, it is good to see that ratings differ in at most one notch in most cases, with the only exception of 'BBB.'

A confusion matrix could also be used to compare the internal ratings assigned by the institution against third-party ratings; this is often done in practice.

For each specific rating, we can compute yet another measure of agreement between predicted and actual ratings. We can build a *Receiver Operating Characteristic (ROC) curve* using the `perfcurve` function from Statistics and Machine Learning Toolbox, and check the *area under the curve (AUC)*. The `perfcurve` function takes as an argument the actual ratings, which are our benchmark, the standard we are comparing against, and the 'BBB' classification scores determined by the automated process. Let us build a ROC and calculate the AUC for rating 'BBB' in our example.

```
[xVal,yVal,~,auc] = perfcurve(exPostDS.Rating,predDS.BBB,'BBB');
plot(xVal,yVal)
xlabel('False positive rate')
ylabel('True positive rate')
text(0.5,0.25,strcat('AUC=',num2str(auc)),'EdgeColor','k')
title('ROC curve BBB, predicted vs. actual rating')
```



Here is an explanation of how the ROC is built. Recall that for each customer the automated classifier returns a classification score for each of the credit ratings, in particular, for 'BBB,' which can be interpreted as how likely it is that this particular customer should be rated 'BBB.' In order to build the ROC curve, one needs to vary the *classification threshold*. That is, the minimum score to classify a customer as 'BBB.' In other words, if the threshold is `t`, we only classify customers as 'BBB' if their 'BBB' score is greater than or equal to `t`. For example, suppose that company *XYZ* had a 'BBB' score of 0.87. If the actual rating of *XYZ* (the information in `exPostDS.Rating`) is 'BBB,' then *XYZ* would be correctly classified as 'BBB' for any threshold of up to 0.87. This would be a *true positive*, and it would increase what is call the *sensitivity* of the classifier. For any threshold greater than 0.87, this company would not receive a 'BBB' rating, and we would have a *false negative* case. To complete the description, suppose now that *XYZ*'s actual rating is 'BB.' Then it would be correctly rejected as a 'BBB' for thresholds of more than 0.87, becoming a *true negative*, and thus increasing the so called *specificity* of the classifier. However, for thresholds of up to 0.87, it would become a *false positive* (it would be classified as 'BBB,' when it actually is a 'BB'). The ROC curve is constructed by plotting the proportion of true positives (sensitivity), versus false positives (1-specificity), as the threshold varies from 0 to 1.

The AUC, as its name indicates, is the area under the ROC curve. The closer the AUC is to 1, the more accurate the classifier (a perfect classifier would have an AUC of 1). In this example, the AUC seems high enough, but it would be up to the committee to decide which level of AUC for the ratings should trigger a recommendation to improve the automated classifier.

Comparing actual ratings vs. defaults in the following year. A common tool used to assess the ranking of customers implicit in the credit ratings is the *Cumulative Accuracy Profile (CAP)*, and the associated *accuracy ratio* measure. The idea is to measure the relationship between the credit ratings

assigned and the number of defaults observed in the following year. One would expect that fewer defaults are observed for better rating classes. If the default rate were the same for all ratings, the rating system would be no different from a naive (and useless) classification system in which customers were randomly assigned a rating, independently of their creditworthiness.

It is not hard to see that the `perfcurve` function can also be used to construct the CAP. The standard we compare against is not a rating, as before, but the default flag that we loaded from the `CreditRating_ExPost.dat` file. The score we use is a "dummy score" that indicates the ranking in creditworthiness implicit in the list of ratings. The dummy score only needs to satisfy that better ratings get lower dummy scores (they are "less likely to have a default flag of 1"), and that any two customers with the same rating get the same dummy score. A default probability could be passed as a score, of course, but we do not have default probabilities here, and in fact *we do not need to have estimates of the default probabilities to construct the CAP*, because we are not validating default probabilities. All we are assessing with this tool is how well the ratings *rank* customers according to their creditworthiness.

Usually, the CAP of the rating system under consideration is plotted together with the CAP of the "perfect rating system." The latter is a hypothetical credit rating system for which the lowest rating includes all the defaulters, and no other customers. The area under this perfect curve is the maximum possible AUC attainable by a rating system. By convention, the AUC is adjusted for CAPs to subtract the area under the *naive system*'s CAP, that is, the CAP of the system that randomly assigns ratings to customers. The naive system's CAP is simply a straight line from the origin to (1,1), with an AUC of 0.5. The *accuracy ratio* for a rating system is then defined as the ratio of the adjusted AUC (AUC of the system in consideration minus AUC of the naive system) to the maximum accuracy (AUC of the perfect system minus AUC of the naive system).

```
ratingsList = {'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC'};
Nratings = length(ratingsList);
dummyDelta = 1/(Nratings+1);
dummyRank = linspace(dummyDelta,1-dummyDelta,Nratings)';

D = exPostDS.Def_tplus1;
fracTotDef = sum(D)/length(D);
maxAcc = 0.5 - 0.5 * fracTotDef;

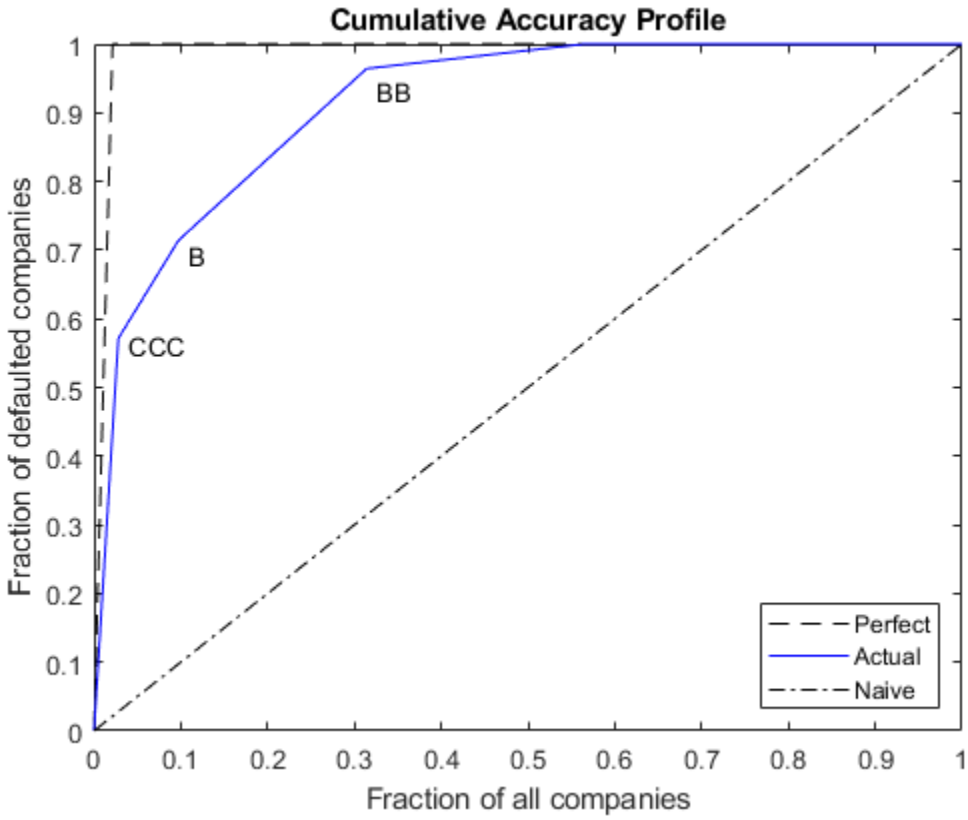
R = double(ordinal(exPostDS.Rating,[],ratingsList));
S = dummyRank(R);
[xVal,yVal,~,auc] = perfcurve(D,S,1);

accRatio = (auc-0.5)/maxAcc;
fprintf('Accuracy ratio for actual ratings: %5.3f\n',accRatio);

xPerfect(1) = 0; xPerfect(2) = fracTotDef; xPerfect(3) = 1;
yPerfect(1) = 0; yPerfect(2) = 1; yPerfect(3) = 1;
xNaive(1) = 0; xNaive(2) = 1;
yNaive(1) = 0; yNaive(2) = 1;

plot(xPerfect,yPerfect,'--k',xVal,yVal,'b',xNaive,yNaive,'-.k')
xlabel('Fraction of all companies')
ylabel('Fraction of defaulted companies')
title('Cumulative Accuracy Profile')
legend({'Perfect','Actual','Naive'},'Location','SouthEast')
text(xVal(2)+0.01,yVal(2)-0.01,'CCC')
text(xVal(3)+0.01,yVal(3)-0.02,'B')
text(xVal(4)+0.01,yVal(4)-0.03,'BB')
```

```
Accuracy ratio for actual ratings: 0.850
```



The key to reading the information of the CAP is in the "kinks," labeled in the plot for ratings 'CCC,' 'B,' and 'BB.' For example, the second kink is associated with the second lowest rating, 'B,' and it is located at (0.097, 0.714). This means that 9.7% of the customers were ranked 'B' *or lower*, and they account for 71.4% of the defaults observed.

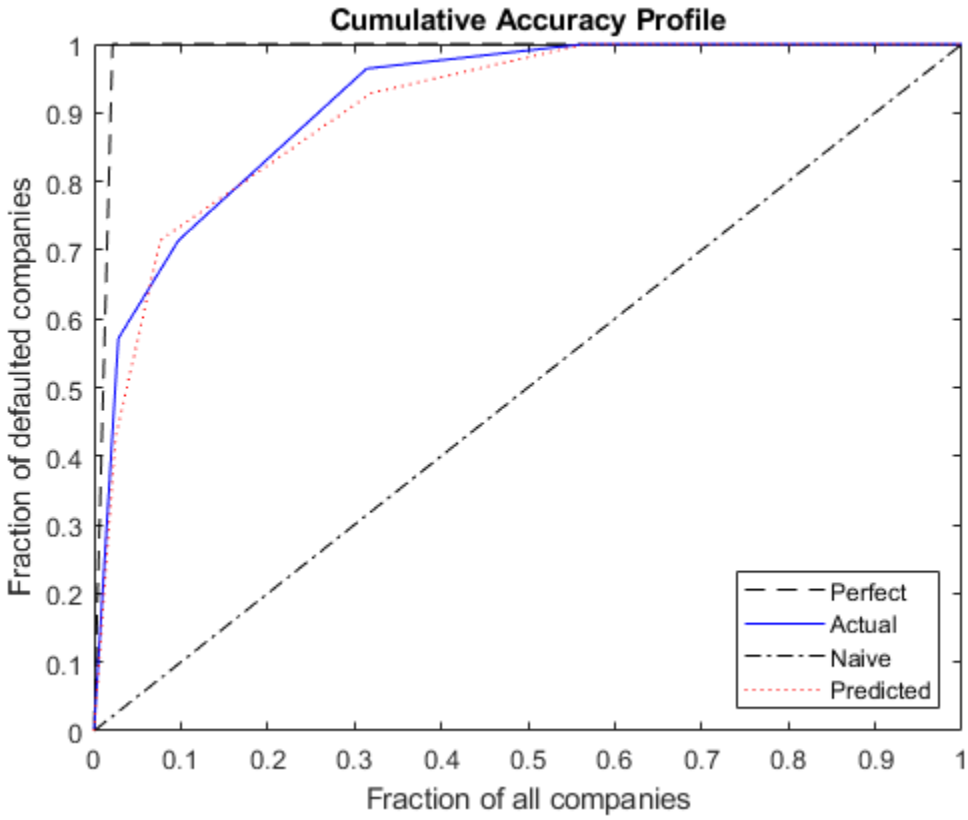
In general, the accuracy ratio should be treated as a relative, rather than an absolute measure. For example, we can add the CAP of the predicted ratings in the same plot, and compute its accuracy ratio to compare it with the accuracy ratio of the actual ratings.

```
Rpred = double(ordinal(predDS.PredRating,[],ratingsList));
Spred = dummyRank(Rpred);
[xValPred,yValPred,~,aucPred] = perfcurve(D,Spred,1);

accRatioPred = (aucPred-0.5)/maxAcc;
fprintf('Accuracy ratio for predicted ratings: %5.3f\n',accRatioPred);

plot(xPerfect,yPerfect,'--k',xVal,yVal,'b',xNaive,yNaive,'-.k',...
   xValPred,yValPred,':r')
xlabel('Fraction of all companies')
ylabel('Fraction of defaulted companies')
title('Cumulative Accuracy Profile')
legend({'Perfect','Actual','Naive','Predicted'},'Location','SouthEast')
```

```
Accuracy ratio for predicted ratings: 0.830
```



The accuracy ratio of the predicted rating is smaller, and its CAP is mostly below the CAP of the actual rating. This is reasonable, since the actual ratings are assigned by the credit committees that take into consideration the predicted ratings *and* extra information that can be important to fine-tune the ratings.

Final Remarks

MATLAB offers a wide range of machine learning tools, besides bagged decision trees, that can be used in the context of credit rating. In Statistics and Machine Learning Toolbox you can find classification tools such as discriminant analysis and naive Bayes classifiers. MATLAB also offers Deep Learning Toolbox™. Also, Database Toolbox and MATLAB deployment tools may provide you with more flexibility to adapt the workflow presented here to your own preferences and needs.

No probabilities of default have been computed here. For credit ratings, the probabilities of default are usually computed based on credit-rating migration history. See the `transprob` reference page in Financial Toolbox™ for more information.

Combine Heterogeneous Models into Stacked Ensemble

This example shows how to build multiple machine learning models for a given training data set, and then combine the models using a technique called *stacking* to improve the accuracy on a test data set compared to the accuracy of the individual models.

Stacking is a technique used to combine several heterogeneous models by training an additional model, often referred to as a *stacked ensemble model*, or *stacked learner*, on the *k*-fold cross-validated predictions (classification scores for classification models and predicted responses for regression models) of the original (base) models. The concept behind stacking is that certain models might correctly classify a test observation while others might fail to do so. The algorithm learns from this diversity of predictions and attempts to combine the models to improve upon the predicted accuracy of the base models.

In this example, you train several heterogeneous classification models on a data set, and then combine the models using stacking.

Load Sample Data

This example uses the 1994 census data stored in `census1994.mat`. The data set consists of demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. The classification task is to fit a model that predicts the salary category of people given their age, working class, education level, marital status, race, and so on.

Load the sample data `census1994` and display the variables in the data set.

```
load census1994
whos
```

```
  Name                 Size              Bytes  Class    Attributes

  Description         20x74               2960  char
  adultdata        32561x15            1872567  table
  adulttest        16281x15             944467  table
```

`census1994` contains the training data set `adultdata` and the test data set `adulttest`. For this example, to reduce the running time, subsample 5000 training and test observations each, from the original tables `adultdata` and `adulttest`, by using the `datasample` function. (You can skip this step if you want to use the complete data sets.)

```
NumSamples = 5e3;
s = RandStream('mlfg6331_64','seed',0); % For reproducibility
adultdata = datasample(s,adultdata,NumSamples,'Replace',false);
adulttest = datasample(s,adulttest,NumSamples,'Replace',false);
```

Some models, such as support vector machines (SVMs), remove observations containing missing values whereas others, such as decision trees, do not remove such observations. To maintain consistency between the models, remove rows containing missing values before fitting the models.

```
adultdata = rmmissing(adultdata);
adulttest = rmmissing(adulttest);
```

Preview the first few rows of the training data set.

```
head(adultdata)
```

```
ans=8×15 table
    age     workClass       fnlwgt       education      education_num      marital_status

    25     Private        2.2022e+05    11th                   7          Never-married
    24     Private        2.2761e+05    10th                   6          Divorced
    51     Private        1.7329e+05    HS-grad                9          Divorced
    54     Private        2.8029e+05    Some-college          10          Married-civ-spouse
    53     Federal-gov         39643    HS-grad                9          Widowed
    52     Private             81859    HS-grad                9          Married-civ-spouse
    37     Private        1.2429e+05    Some-college          10          Married-civ-spouse
```

Each row represents the attributes of one adult, such as age, education, and occupation. The last column `salary` shows whether a person has a salary less than or equal to $50,000 per year or greater than $50,000 per year.

Understand Data and Choose Classification Models

Statistics and Machine Learning Toolbox™ provides several options for classification, including classification trees, discriminant analysis, naive Bayes, nearest neighbors, SVMs, and classification ensembles. For the complete list of algorithms, see “Classification”.

Before choosing the algorithms to use for your problem, inspect your data set. The census data has several noteworthy characteristics:

- The data is tabular and contains both numeric and categorical variables.
- The data contains missing values.
- The response variable (`salary`) has two classes (binary classification).

Without making any assumptions or using prior knowledge of algorithms that you expect to work well on your data, you simply train all the algorithms that support tabular data and binary classification. Error-correcting output codes (ECOC) models are used for data with more than two classes. Discriminant analysis and nearest neighbor algorithms do not analyze data that contains both numeric and categorical variables. Therefore, the algorithms appropriate for this example are an SVM, a decision tree, an ensemble of decision trees, and a naive Bayes model.

Build Base Models

Fit two SVM models, one with a Gaussian kernel and one with a polynomial kernel. Also, fit a decision tree, a naive Bayes model, and an ensemble of decision trees.

```
% SVM with Gaussian kernel
rng('default') % For reproducibility
mdls{1} = fitcsvm(adultdata,'salary','KernelFunction','gaussian', ...
    'Standardize',true,'KernelScale','auto');

% SVM with polynomial kernel
rng('default')
mdls{2} = fitcsvm(adultdata,'salary','KernelFunction','polynomial', ...
    'Standardize',true,'KernelScale','auto');

% Decision tree
rng('default')
mdls{3} = fitctree(adultdata,'salary');
```

```
% Naive Bayes
rng('default')
mdls{4} = fitcnb(adultdata,'salary');

% Ensemble of decision trees
rng('default')
mdls{5} = fitcensemble(adultdata,'salary');
```

Combine Models Using Stacking

If you use only the prediction scores of the base models on the training data, the stacked ensemble might be subject to overfitting. To reduce overfitting, use the *k*-fold cross-validated scores instead. To ensure that you train each model using the same *k*-fold data split, create a `cvpartition` object and pass that object to the `crossval` function of each base model. This example is a binary classification problem, so you only need to consider scores for either the positive or negative class.

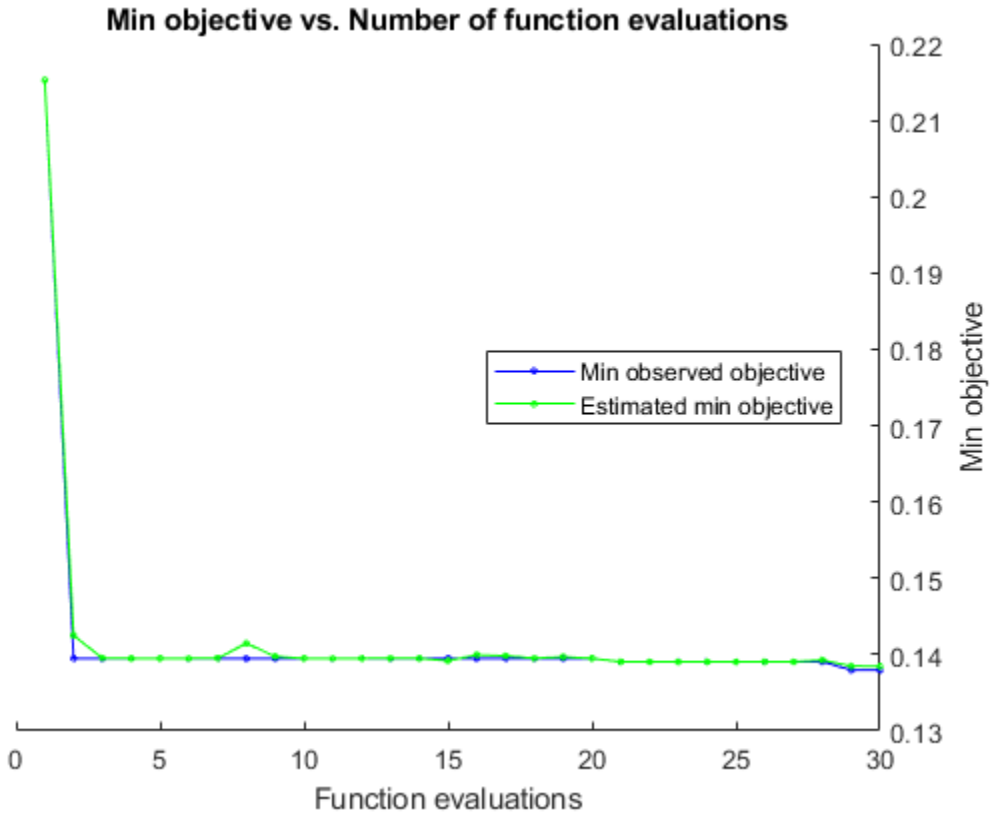
Obtain *k*-fold cross-validation scores.

```
rng('default') % For reproducibility
N = numel(mdls);
Scores = zeros(size(adultdata,1),N);
cv = cvpartition(adultdata.salary,"KFold",5);
for ii = 1:N
    m = crossval(mdls{ii},'cvpartition',cv);
    [~,s] = kfoldPredict(m);
    Scores(:,ii) = s(:,m.ClassNames=='<=50K');
end
```

Create the stacked ensemble by training it on the cross-validated classification scores `Scores` with these options:

- To obtain the best results for the stacked ensemble, optimize its hyperparameters. You can fit the training data set and tune parameters easily by calling the fitting function and setting its `'OptimizeHyperparameters'` name-value pair argument to `'auto'`.
- Specify `'Verbose'` as 0 to disable message displays.
- For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function. Also, for reproducibility of the random forest algorithm, specify the `'Reproducible'` name-value pair argument as `true` for tree learners.

```
rng('default') % For reproducibility
t = templateTree('Reproducible',true);
stckdMdl = fitcensemble(Scores,adultdata.salary, ...
    'OptimizeHyperparameters','auto', ...
    'Learners',t, ...
    'HyperparameterOptimizationOptions',struct('Verbose',0,'AcquisitionFunctionName','expected-i
```



Compare Predictive Accuracy

Check the classifier performance with the test data set by using the confusion matrix and McNemar's hypothesis test.

Predict Labels and Scores on Test Data

Find the predicted labels, scores, and loss values of the test data set for the base models and the stacked ensemble.

First, iterate over the base models to the compute predicted labels, scores, and loss values.

```
label = [];
score = zeros(size(adulttest,1),N);
mdlLoss = zeros(1,numel(mdls));
for i = 1:N
    [lbl,s] = predict(mdls{i},adulttest);
    label = [label,lbl];
    score(:,i) = s(:,m.ClassNames=='<=50K');
    mdlLoss(i) = mdls{i}.loss(adulttest);
end
```

Attach the predictions from the stacked ensemble to `label` and `mdlLoss`.

```
[lbl,s] = predict(stckdMdl,score);
label = [label,lbl];
mdlLoss(end+1) = stckdMdl.loss(score,adulttest.salary);
```

Concatenate the score of the stacked ensemble to the scores of the base models.

```
score = [score,s(:,1)];
```

Display the loss values.

```
names = {'SVM-Gaussian','SVM-Polynomial','Decision Tree','Naive Bayes', ...
    'Ensemble of Decision Trees','Stacked Ensemble'};
array2table(mdlLoss,'VariableNames',names)
```

```
ans=1×6 table
    SVM-Gaussian    SVM-Polynomial    Decision Tree    Naive Bayes    Ensemble of Decision Trees
    ____________    ______________    _____________    ___________    __________________________

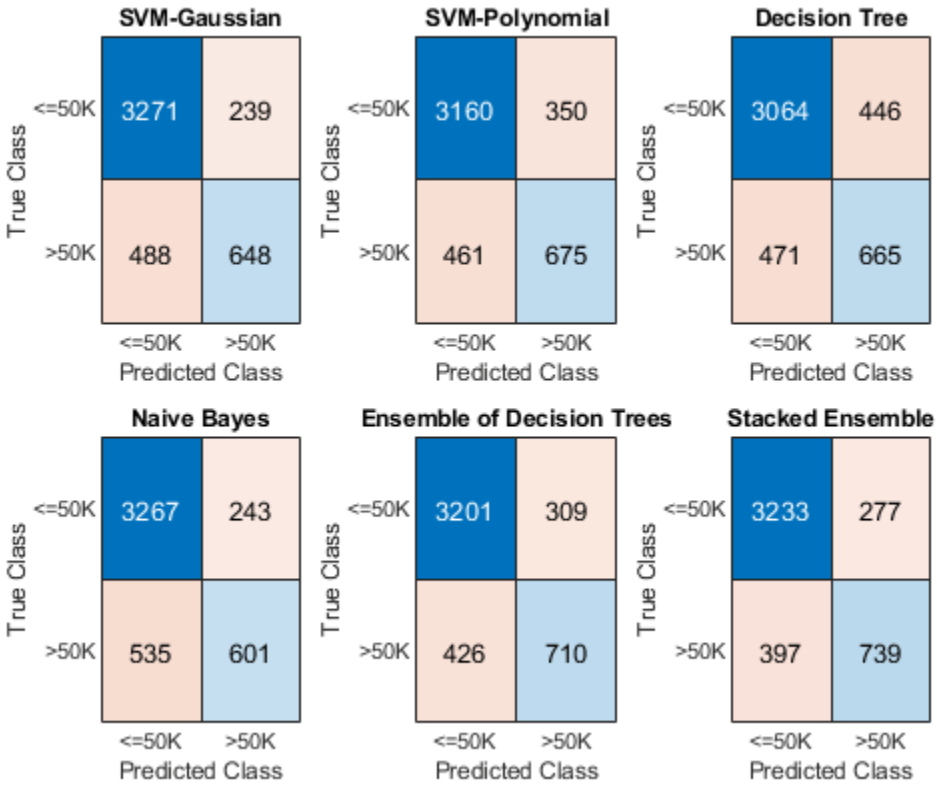
      0.15668          0.17473           0.1975          0.16764               0.15833
```

The loss value of the stacked ensemble is lower than the loss values of the base models.

Confusion Matrix

Compute the confusion matrix with the predicted classes and the known (true) classes of the test data set by using the `confusionchart` function.

```
figure
c = cell(N+1,1);
for i = 1:numel(c)
    subplot(2,3,i)
    c{i} = confusionchart(adulttest.salary,label(:,i));
    title(names{i})
end
```



The diagonal elements indicate the number of correctly classified instances of a given class. The off-diagonal elements are instances of misclassified observations.

McNemar's Hypothesis Test

To test whether the improvement in prediction is significant, use the `testcholdout` function, which conducts McNemar's hypothesis test. Compare the stacked ensemble to the naive Bayes model.

```
[hNB,pNB] = testcholdout(label(:,6),label(:,4),adulttest.salary)
```

```
hNB = logical
   1

pNB = 9.7646e-07
```

Compare the stacked ensemble to the ensemble of decision trees.

```
[hE,pE] = testcholdout(label(:,6),label(:,5),adulttest.salary)
```

```
hE = logical
   1

pE = 1.9357e-04
```

In both cases, the low *p*-value of the stacked ensemble confirms that its predictions are statistically superior to those of the other models.

Label Data Using Semi-Supervised Learning Techniques

This example shows how to use graph-based and self-training semi-supervised learning techniques to label data.

Semi-supervised learning combines aspects of supervised learning, where all of the training data is labeled, and unsupervised learning, where true labels are unknown. That is, some training observations are labeled, but the vast majority are unlabeled. Semi-supervised learning methods try to leverage the underlying structure of the data to fit labels to the unlabeled data.

Statistics and Machine Learning Toolbox™ provides these semi-supervised learning functions for classification:

- `fitsemigraph` constructs a similarity graph with labeled and unlabeled observations as nodes, and distributes label information from labeled observations to unlabeled observations.
- `fitsemiself` iteratively trains a classifier on the data. First, the function trains a classifier on the labeled data alone, and then uses that classifier to make label predictions for the unlabeled data. `fitsemiself` provides scores for the predictions, and then treats the predictions as true labels for the next training cycle of the classifier if the scores are above a certain threshold. This process repeats until the label predictions converge.

Generate Data

Generate data from two half-moon shapes. Determine which moon new points belong to by using graph-based and self-training semi-supervised techniques.

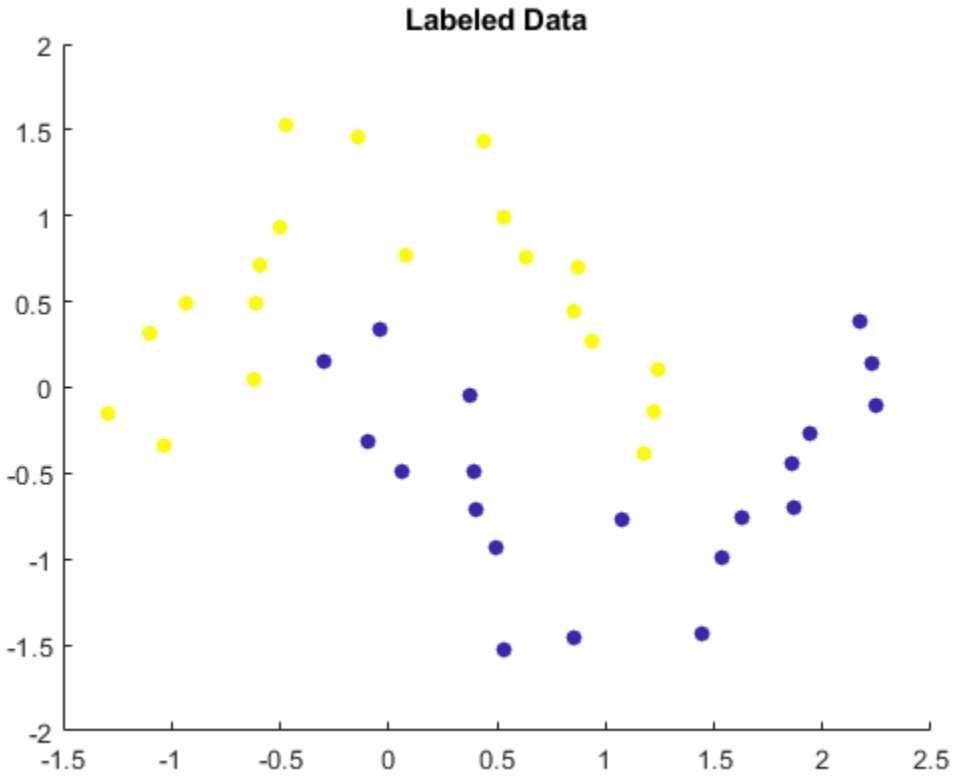
Create the custom function `twomoons` (shown at the end of this example). This function takes an input argument `n` and creates `n` points in each of two interlaced half-moons: a top moon that is concave down and a bottom moon that is concave up.

Generate a set of 40 labeled data points by using the `twomoons` function. Each point in `X` is in one of the two moons, with the corresponding moon label stored in the vector `label`.

```
rng('default') % For reproducibility
[X,label] = twomoons(20);
```

Visualize the points by using a scatter plot. Points in the same moon have the same color.

```
scatter(X(:,1),X(:,2),[],label,'filled')
title('Labeled Data')
```



Generate a set of 400 unlabeled data points by using the `twomoons` function. Each point in `newX` belongs to one of the two moons, but the corresponding moon label is unknown.

```
newX = twomoons(200);
```

Label Data Using Graph-Based Method

Label the unlabeled data in `newX` by using a semi-supervised graph-based method. By default, `fitsemigraph` constructs a similarity graph from the data in `X` and `newX`, and uses a label propagation technique to fit labels to `newX`.

```
graphMdl = fitsemigraph(X,label,newX)
```

```
graphMdl =
  SemiSupervisedGraphModel with properties:

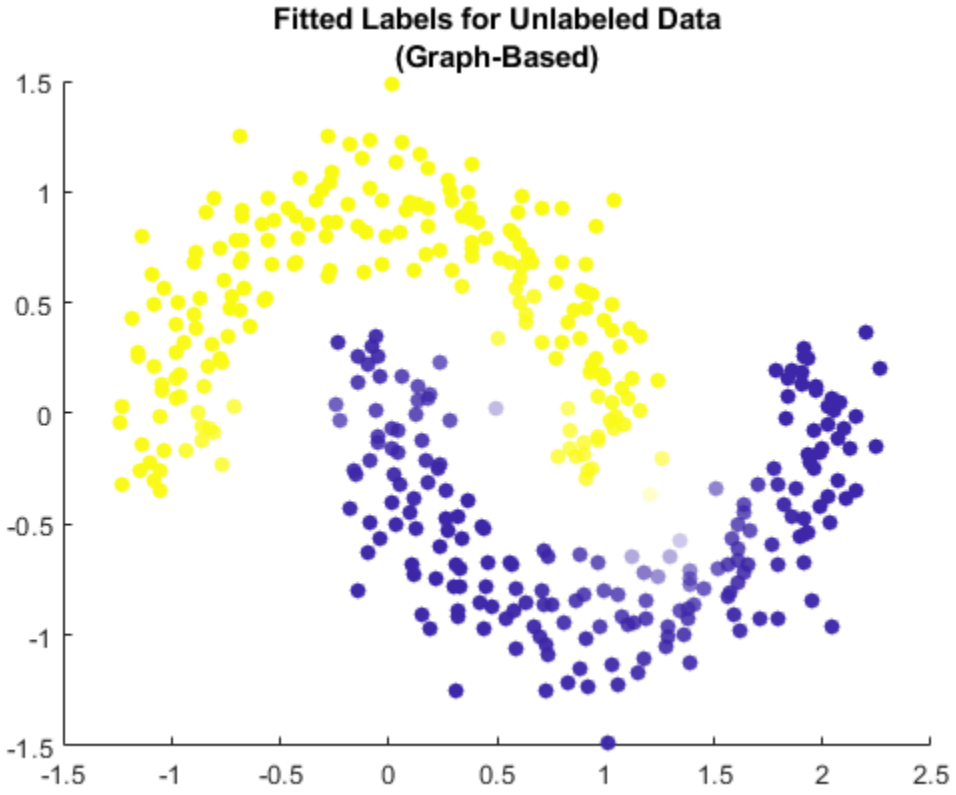
            FittedLabels: [400x1 double]
             LabelScores: [400x2 double]
               ClassNames: [1 2]
            ResponseName: 'Y'
    CategoricalPredictors: []
                  Method: 'labelpropagation'

  Properties, Methods
```

The function returns a `SemiSupervisedGraphModel` object whose `FittedLabels` property contains the fitted labels for the unlabeled data and whose `LabelScores` property contains the associated label scores.

Visualize the fitted label results by using a scatter plot. Use the fitted labels to set the color of the points, and use the maximum label scores to set the transparency of the points. Points with less transparency are labeled with greater confidence.

```
maxGraphScores = max(graphMdl.LabelScores,[],2);
rescaledGraphScores = rescale(maxGraphScores,0.05,0.95);
scatter(newX(:,1),newX(:,2),[],graphMdl.FittedLabels,'filled', ...
    'MarkerFaceAlpha','flat','AlphaData',rescaledGraphScores);
title(["Fitted Labels for Unlabeled Data","(Graph-Based)"])
```



This method seems to label the `newX` points accurately. The two moons are visually distinct, and the points that are labeled with the most uncertainty lie on the boundary between the two shapes.

Label Data Using Self-Training Method

Label the unlabeled data in `newX` by using a semi-supervised self-training method. By default, `fitsemiself` uses a support vector machine (SVM) model with a Gaussian kernel to label the data iteratively.

```
selfSVMMdl = fitsemiself(X,label,newX)
```

```
selfSVMMdl =
  SemiSupervisedSelfTrainingModel with properties:
```

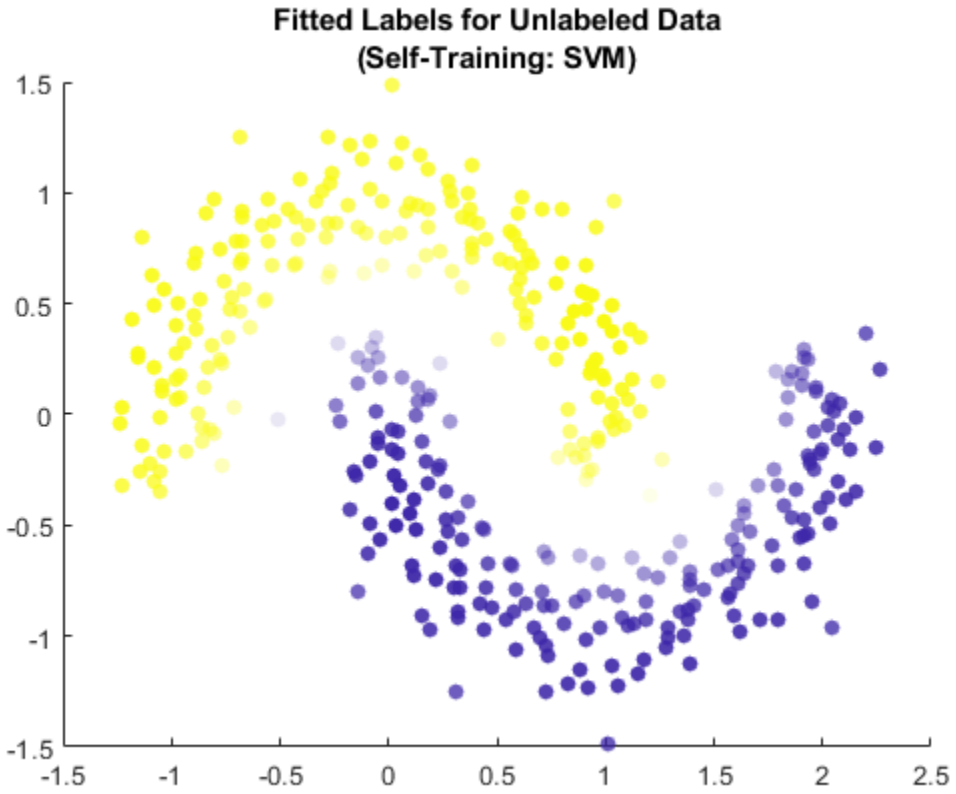
```
           FittedLabels: [400x1 double]
            LabelScores: [400x2 double]
              ClassNames: [1 2]
           ResponseName: 'Y'
  CategoricalPredictors: []
                Learner: [1x1 classreg.learning.classif.CompactClassificationSVM]

  Properties, Methods
```

The function returns a `SemiSupervisedSelfTrainingModel` object whose `FittedLabels` property contains the fitted labels for the unlabeled data and whose `LabelScores` property contains the associated label scores.

Visualize the fitted label results by using a scatter plot. As before, use the fitted labels to set the color of the points, and use the maximum label scores to set the transparency of the points.

```
maxSVMScores = max(selfSVMMdl.LabelScores,[],2);
rescaledSVMScores = rescale(maxSVMScores,0.05,0.95);
scatter(newX(:,1),newX(:,2),[],selfSVMMdl.FittedLabels,'filled', ...
    'MarkerFaceAlpha','flat','AlphaData',rescaledSVMScores);
title(["Fitted Labels for Unlabeled Data","(Self-Training: SVM)"])
```



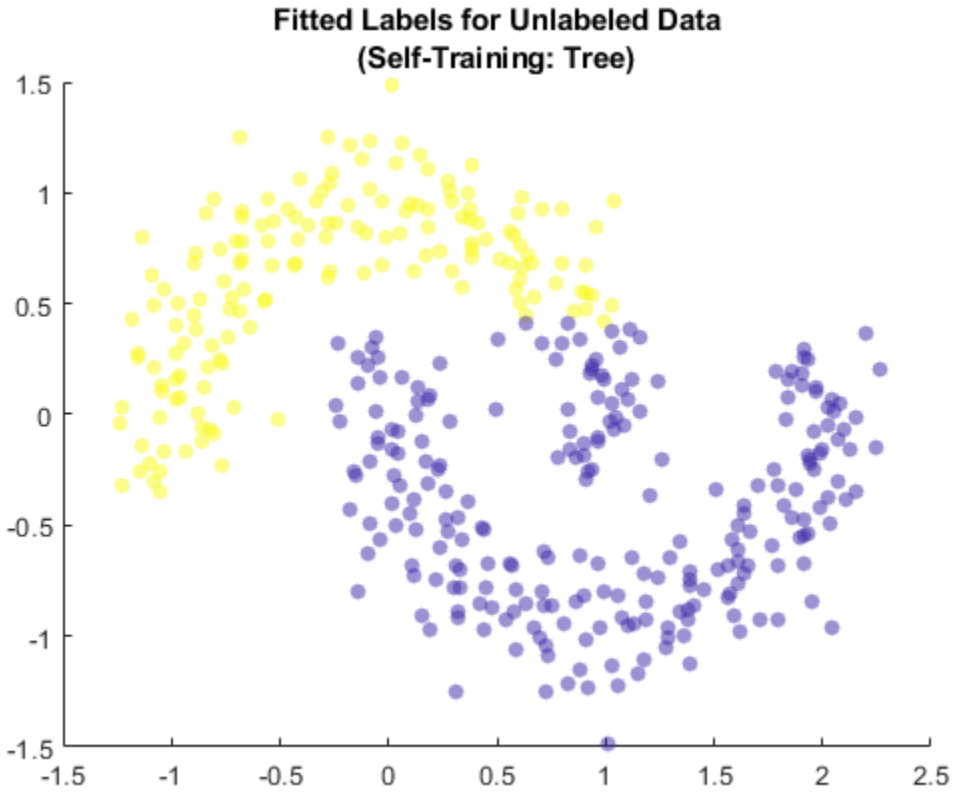
This method, with an SVM learner, also seems to label the newX points accurately. The two moons are visually distinct, and the points that are labeled with the most uncertainty lie on the boundary between the two shapes.

Some learners might not label the unlabeled data as effectively, however. For example, use a tree model instead of the default SVM model to label the data in newX.

```
selfTreeMdl = fitsemiself(X,label,newX,'Learner','tree');
```

Visualize the fitted label results.

```
maxTreeScores = max(selfTreeMdl.LabelScores,[],2);
rescaledTreeScores = rescale(maxTreeScores,0.05,0.95);
scatter(newX(:,1),newX(:,2),[],selfTreeMdl.FittedLabels,'filled', ...
    'MarkerFaceAlpha','flat','AlphaData',rescaledTreeScores);
title(["Fitted Labels for Unlabeled Data","(Self-Training: Tree)"])
```



This method, with a tree learner, mislabels many of the points in the top moon. When you use a semi-supervised self-training method, make sure to use an underlying learner that is appropriate for the structure of your data.

This code creates the function twomoons.

```
function [X,label] = twomoons(n) % Generate two moons, with n points in each moon.

% Specify the radius and relevant angles for the two moons.
noise = (1/6).*randn(n,1);
```

```
radius = 1 + noise;
angle1 = pi + pi/10;
angle2 = pi/10;

% Create the bottom moon with a center at (1,0).
bottomTheta = linspace(-angle1,angle2,n)';
bottomX1 = radius.*cos(bottomTheta) + 1;
bottomX2 = radius.*sin(bottomTheta);

% Create the top moon with a center at (0,0).
topTheta = linspace(angle1,-angle2,n)';
topX1 = radius.*cos(topTheta);
topX2 = radius.*sin(topTheta);

% Return the moon points and their labels.
X = [bottomX1 bottomX2; topX1 topX2];
label = [ones(n,1); 2*ones(n,1)];
end
```

Interpret Machine Learning Models

This topic introduces Statistics and Machine Learning Toolbox features for model interpretation and shows how to interpret a machine learning model (classification and regression).

A machine learning model is often referred to as a "black box" model because it can be difficult to understand how the model makes predictions. Interpretability tools help you overcome this aspect of machine learning algorithms and reveal how predictors contribute (or do not contribute) to predictions. Also, you can validate whether the model uses the correct evidence for its predictions, and find model biases that are not immediately apparent.

Features for Model Interpretation

Use `lime`, `shapley`, and `plotPartialDependence` to explain the contribution of individual predictors to the predictions of a trained classification or regression model.

- `lime` — Local interpretable model-agnostic explanations (LIME [1]) interpret a prediction for a query point by fitting a simple interpretable model for the query point. The simple model acts as an approximation for the trained model and explains model predictions around the query point. The simple model can be either a linear model or a decision tree model. You can use the estimated coefficients of a linear model or the estimated predictor importance of a decision tree model to explain the contribution of individual predictors to the prediction for the query point. For more details, see “LIME” on page 33-3505.
- `shapley` — The Shapley value [2][3] of a predictor for a query point explains the deviation of the prediction (response for regression or class scores for classification) for the query point from the average prediction, due to the predictor. For a query point, the sum of the Shapley values for all features corresponds to the total deviation of the prediction from the average. For more details, see “Shapley Values for Machine Learning Model” on page 18-272.
- `plotPartialDependence` and `partialDependence` — A partial dependence plot (PDP [4]) shows the relationships between a predictor (or a pair of predictors) and the prediction (response for regression or class scores for classification) in the trained model. The partial dependence on the selected predictor is defined by the averaged prediction obtained by marginalizing out the effect of the other variables. Therefore, the partial dependence is a function of the selected predictor that shows the average effect of the selected predictor over the data set. You can also create a set of individual conditional expectation (ICE [5]) plots for each observation, showing the effect of the selected predictor on a single observation. For more details, see “More About” on page 33-4659 on the `plotPartialDependence` reference page.

Some machine learning models support embedded type feature selection, where the model learns predictor importance as part of the model learning process. You can use the estimated predictor importance to explain model predictions. For example:

- Train an ensemble (`ClassificationBaggedEnsemble` or `RegressionBaggedEnsemble`) of bagged decision trees (for example, random forest) and use the `predictorImportance` and `oobPermutedPredictorImportance` functions.
- Train a linear model with lasso regularization, which shrinks the coefficients of the least important predictors. Then use the estimated coefficients as measures for predictor importance. For example, use `fitclinear` or `fitrlinear` and specify the `'Regularization'` name-value argument as `'lasso'`.

For a list of machine learning models that support embedded type feature selection, see “Embedded Type Feature Selection” on page 15-54.

Use Statistics and Machine Learning Toolbox features for three levels of model interpretation: local, cohort, and global.

Level	Objective	Use Case	Statistics and Machine Learning Toolbox Feature
Local interpretation	Explain a prediction for a single query point.	• Identify important predictors for an individual prediction. • Examine a counterintuitive prediction.	Use `lime` and `shapley` for a specified query point.
Cohort interpretation	Explain how a trained model makes predictions for a subset of the entire data set.	Validate predictions for a particular group of samples.	• Use `lime` and `shapley` for multiple query points. After creating a `lime` or `shapley` object, you can call the object function `fit` multiple times to interpret predictions for other query points. • Pass a subset of data when you call `lime`, `shapley`, and `plotPartialDependence`. The features interpret the trained model using the specified subset instead of the entire training data set.
Global interpretation	Explain how a trained model makes predictions for the entire data set.	• Demonstrate how a trained model works. • Compare different models.	• Use `plotPartialDependence` to create PDPs and ICE plots for the predictors of interest. • Find important predictors from a trained model that supports “Embedded Type Feature Selection” on page 15-54.

Interpret Classification Model

This example trains an ensemble of bagged decision trees using the random forest algorithm, and interprets the trained model using interpretability features. Use the object functions (`oobPermutedPredictorImportance` and `predictorImportance`) of the trained model to find important predictors in the model. Also, use `lime` and `shapley` to interpret the predictions for specified query points. Then use `plotPartialDependence` to create a plot that shows the relationships between an important predictor and predicted classification scores.

Train Classification Ensemble Model

Load the `CreditRating_Historical` data set. The data set contains customer IDs and their financial ratios, industry labels, and credit ratings.

```
tbl = readtable('CreditRating_Historical.dat');
```

Display the first three rows of the table.

```
head(tbl,3)
```

```
ans=3×8 table
     ID      WC_TA    RE_TA    EBIT_TA    MVE_BVTD    S_TA     Industry    Rating
    _____    _____    _____    _______    ________    _____    ________    ______

    62394    0.013    0.104     0.036      0.447      0.142       3        {'BB'}
    48608    0.232    0.335     0.062      1.969      0.281       8        {'A' }
    42444    0.311    0.367     0.074      1.935      0.366       1        {'A' }
```

Create a table of predictor variables by removing the columns containing customer IDs and ratings from `tbl`.

```
tblX = removevars(tbl,["ID","Rating"]);
```

Train an ensemble of bagged decision trees by using the `fitcensemble` function and specifying the ensemble aggregation method as random forest (`'Bag'`). For reproducibility of the random forest algorithm, specify the `'Reproducible'` name-value argument as `true` for tree learners. Also, specify the class names to set the order of the classes in the trained model.

```
rng('default') % For reproducibility
t = templateTree('Reproducible',true);
blackbox = fitcensemble(tblX,tbl.Rating, ...
    'Method','Bag','Learners',t, ...
    'CategoricalPredictors','Industry', ...
    'ClassNames',{'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC'});
```

`blackbox` is a `ClassificationBaggedEnsemble` model.

Use Model-Specific Interpretability Features

`ClassificationBaggedEnsemble` supports two object functions, `oobPermutedPredictorImportance` and `predictorImportance`, which find important predictors in the trained model.

Estimate out-of-bag predictor importance by using the `oobPermutedPredictorImportance` function. The function randomly permutes out-of-bag data across one predictor at a time, and estimates the increase in the out-of-bag error due to this permutation. The larger the increase, the more important the feature.

```
Imp1 = oobPermutedPredictorImportance(blackbox);
```

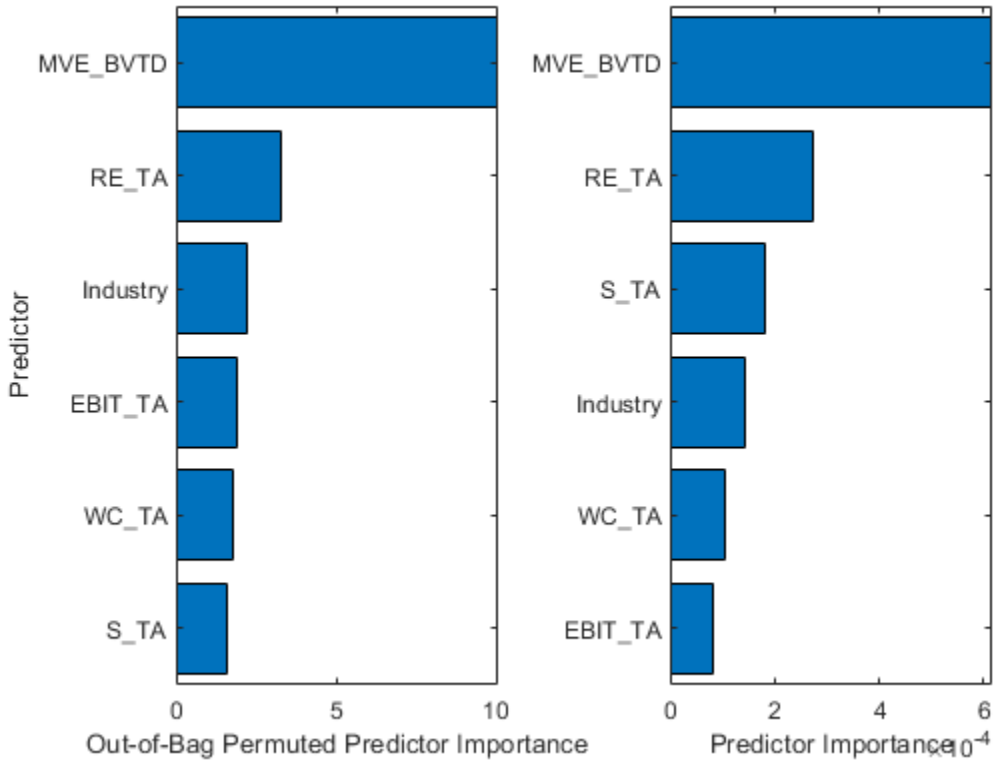
Estimate predictor importance by using the `predictorImportance` function. The function estimates predictor importance by summing changes in the node risk due to splits on each predictor and dividing the sum by the number of branch nodes.

```
Imp2 = predictorImportance(blackbox);
```

Create a table containing the predictor importance estimates, and use the table to create horizontal bar graphs. To display an existing underscore in any predictor name, change the `TickLabelInterpreter` value of the axes to `'none'`.

```
table_Imp = table(Imp1',Imp2', ...
    'VariableNames',{'Out-of-Bag Permuted Predictor Importance','Predictor Importance'}, ...
    'RowNames',blackbox.PredictorNames);
tiledlayout(1,2)
```

```
ax1 = nexttile;
table_Imp1 = sortrows(table_Imp,'Out-of-Bag Permuted Predictor Importance');
barh(categorical(table_Imp1.Row,table_Imp1.Row),table_Imp1.('Out-of-Bag Permuted Predictor Impor
xlabel('Out-of-Bag Permuted Predictor Importance')
ylabel('Predictor')
ax2 = nexttile;
table_Imp2 = sortrows(table_Imp,'Predictor Importance');
barh(categorical(table_Imp2.Row,table_Imp2.Row),table_Imp2.('Predictor Importance'))
xlabel('Predictor Importance')
ax1.TickLabelInterpreter = 'none';
ax2.TickLabelInterpreter = 'none';
```



Both object functions identify `MVE_BVTD` and `RE_TA` as the two most important predictors.

Specify Query Point

Find the observations whose `Rating` is `'AAA'` and choose four query points among them.

```
tblX_AAA = tblX(strcmp(tbl.Rating,'AAA'),:);
queryPoint = datasample(tblX_AAA,4,'Replace',false)
```

```
queryPoint=4×6 table
    WC_TA    RE_TA    EBIT_TA    MVE_BVTD    S_TA     Industry
    _____    _____    _______    ________    _____    ________

    0.331    0.531     0.077      7.116      0.522       12
     0.26    0.515     0.065      3.394      0.515        1
    0.121    0.413     0.057      3.647      0.466       12
```

```
    0.617    0.766     0.126      4.442      0.483        9
```

Use LIME with Linear Simple Models

Explain the predictions for the query points using `lime` with linear simple models. `lime` generates a synthetic data set and fits a simple model to the synthetic data set.

Create a `lime` object using `tblX_AAA` so that `lime` generates a synthetic data set using only the observations whose `Rating` is `'AAA'`, not the entire data set.

```
explainer_lime = lime(blackbox,tblX_AAA);
```

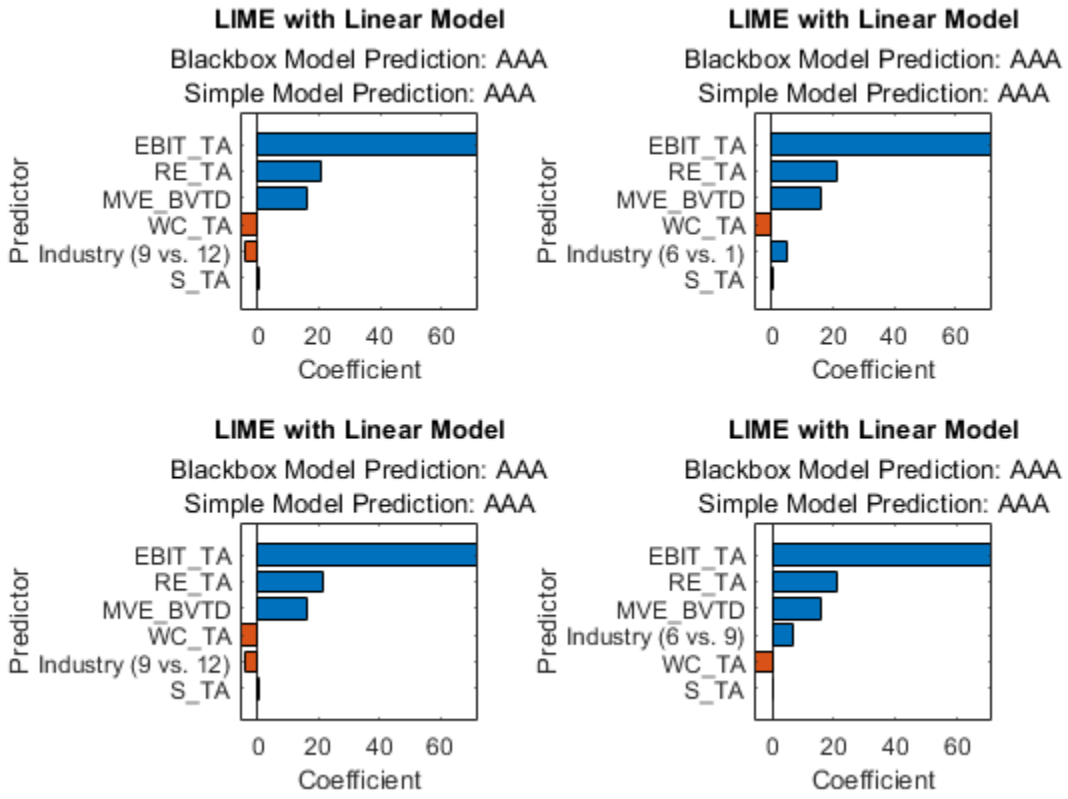
The default value of “'DataLocality'” on page 33-0 for `lime` is `'global'`, which implies that, by default, `lime` generates a global synthetic data set and uses it for any query points. `lime` uses different observation weights so that weight values are more focused on the observations near the query point. Therefore, you can interpret each simple model as an approximation of the trained model for a specific query point.

Fit simple models for the four query points by using the object function `fit`. Specify the third input (the number of important predictors to use in the simple model) as 6 to use all six predictors.

```
explainer_lime1 = fit(explainer_lime,queryPoint(1,:),6);
explainer_lime2 = fit(explainer_lime,queryPoint(2,:),6);
explainer_lime3 = fit(explainer_lime,queryPoint(3,:),6);
explainer_lime4 = fit(explainer_lime,queryPoint(4,:),6);
```

Plot the coefficients of the simple models by using the object function `plot`.

```
tiledlayout(2,2)
ax1 = nexttile; plot(explainer_lime1);
ax2 = nexttile; plot(explainer_lime2);
ax3 = nexttile; plot(explainer_lime3);
ax4 = nexttile; plot(explainer_lime4);
ax1.TickLabelInterpreter = 'none';
ax2.TickLabelInterpreter = 'none';
ax3.TickLabelInterpreter = 'none';
ax4.TickLabelInterpreter = 'none';
```



All simple models identify `EBIT_TA`, `RE_TA`, and `MVE_BVTD` as the three most important predictors. The positive coefficients for the predictors suggest that increasing the predictor values leads to an increase in the predicted scores in the simple models.

For a categorical predictor, the `plot` function displays only the most important dummy variable of the categorical predictor. Therefore, each bar graph displays a different dummy variable.

Compute Shapley Values

The Shapley value of a predictor for a query point explains the deviation of the predicted score for the query point from the average score, due to the predictor. Create a `shapley` object using `tblX_AAA` so that `shapley` computes the expected contribution based on the samples for `'AAA'`.

```
explainer_shapley = shapley(blackbox,tblX_AAA);
```

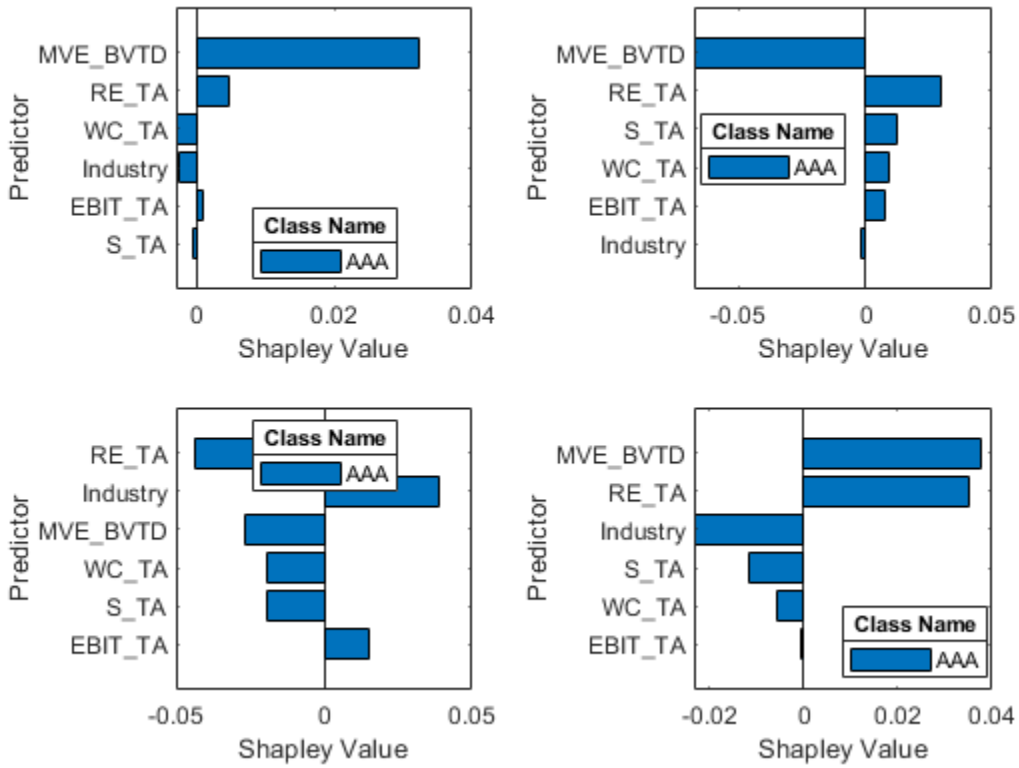
Compute the Shapley values for the query points by using the object function `fit`.

```
explainer_shapley1 = fit(explainer_shapley,queryPoint(1,:));
explainer_shapley2 = fit(explainer_shapley,queryPoint(2,:));
explainer_shapley3 = fit(explainer_shapley,queryPoint(3,:));
explainer_shapley4 = fit(explainer_shapley,queryPoint(4,:));
```

Plot the Shapley values by using the object function `plot`.

```
tiledlayout(2,2)
ax1 = nexttile; plot(explainer_shapley1)
ax2 = nexttile; plot(explainer_shapley2)
```

```
ax3 = nexttile; plot(explainer_shapley3)
ax4 = nexttile; plot(explainer_shapley4)
ax1.TickLabelInterpreter = 'none';
ax2.TickLabelInterpreter = 'none';
ax3.TickLabelInterpreter = 'none';
ax4.TickLabelInterpreter = 'none';
```



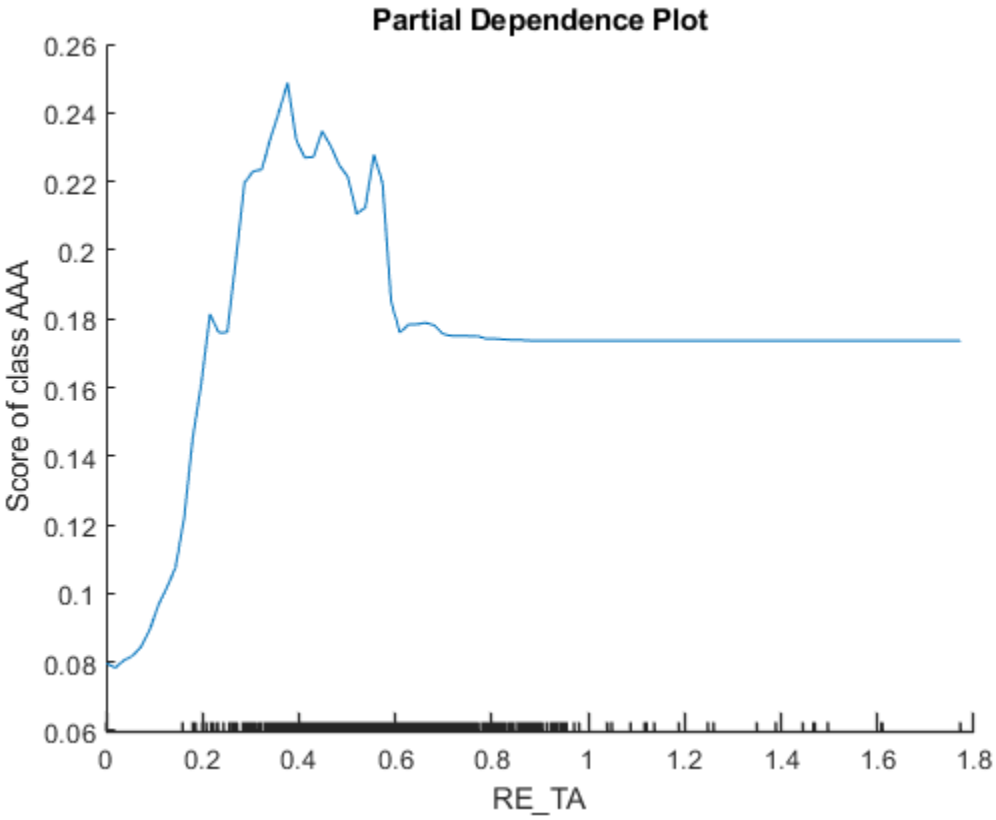
`MVE_BVTD` and `RE_TA` are two of the three most important predictors for all four query points.

The Shapley values of `MVE_BVTD` are positive for the first and fourth query points, and negative for the second and third query points. The `MVE_BVTD` values are about 7 and 4 for the first and fourth query points, respectively, and the value for both the second and third query points is about 3.5. According to the Shapley values for the four query points, a large `MVE_BVTD` value leads to an increase in the predicted score, and a small `MVE_BVTD` value leads to a decrease in the predicted scores compared to the average. The results are consistent with the results from `lime`.

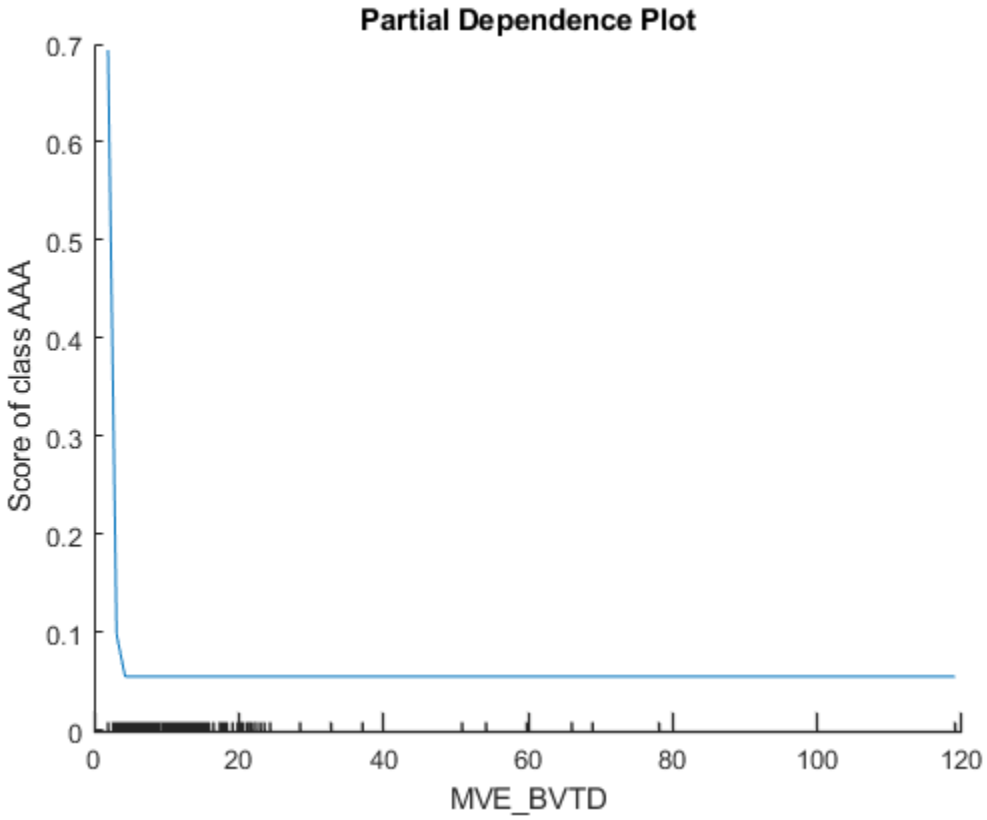
Create Partial Dependence Plot (PDP)

A PDP plot shows the averaged relationships between the predictor and the predicted score in the trained model. Create PDPs for `RE_TA` and `MVE_BVTD`, which the other interpretability tools identify as important predictors. Pass `tblx_AAA` to `plotPartialDependence` so that the function computes the expectation of the predicted scores using only the samples for `'AAA'`.

```
figure
plotPartialDependence(blackbox,'RE_TA','AAA',tblX_AAA)
```



```
plotPartialDependence(blackbox,'MVE_BVTD','AAA',tblX_AAA)
```



The minor ticks in the *x*-axis represent the unique values of the predictor in `tbl_AAA`. The plot for `MVE_BVTD` shows that the predicted score is large when the `MVE_BVTD` value is small. The score value decreases as the `MVE_BVTD` value increases until it reaches about 5, and then the score value stays unchanged as the `MVE_BVTD` value increases. The dependency on `MVE_BVTD` in the subset `tbl_AAA` identified by `plotPartialDependence` is not consistent with the local contributions of `MVE_BVTD` at the four query points identified by `lime` and `shapley`.

Interpret Regression Model

The model interpretation workflow for a regression problem is similar to the workflow for a classification problem, as demonstrated in the example “Interpret Classification Model” on page 18-257.

This example trains a Gaussian process regression (GPR) model and interprets the trained model using interpretability features. Use a kernel parameter of the GPR model to estimate predictor weights. Also, use `lime` and `shapley` to interpret the predictions for specified query points. Then use `plotPartialDependence` to create a plot that shows the relationships between an important predictor and predicted responses.

Train GPR Model

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table containing the predictor variables `Acceleration`, `Cylinders`, and so on

```
tbl = table(Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight);
```

Train a GPR model of the response variable `MPG` by using the `fitrgp` function. Specify `'KernelFunction'` as `'ardsquaredexponential'` to use the squared exponential kernel with a separate length scale per predictor.

```
blackbox = fitrgp(tbl,MPG,'ResponseName','MPG','CategoricalPredictors',[2 5], ...
    'KernelFunction','ardsquaredexponential');
```

`blackbox` is a `RegressionGP` model.

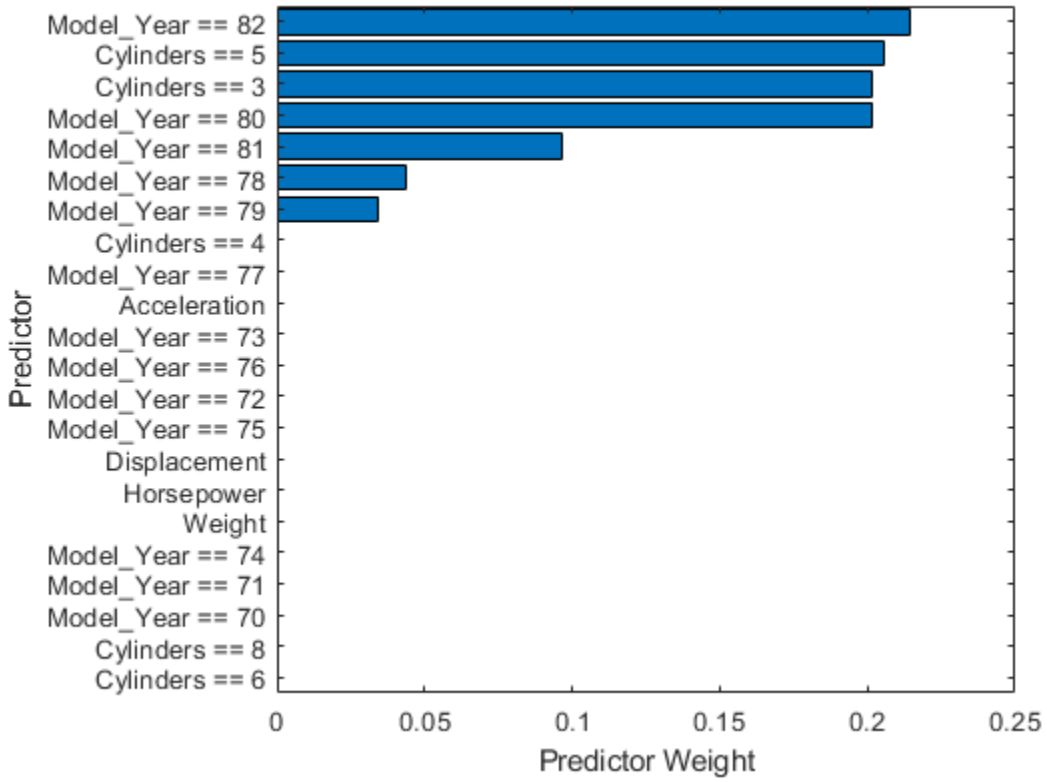
Use Model-Specific Interpretability Features

You can compute predictor weights (predictor importance) from the learned length scales of the kernel function used in the model. The length scales define how far apart a predictor can be for the response values to become uncorrelated. Find the normalized predictor weights by taking the exponential of the negative learned length scales.

```
sigmaL = blackbox.KernelInformation.KernelParameters(1:end-1); % Learned length scales
weights = exp(-sigmaL); % Predictor weights
weights = weights/sum(weights); % Normalized predictor weights
```

Create a table containing the normalized predictor weights, and use the table to create horizontal bar graphs. To display an existing underscore in any predictor name, change the `TickLabelInterpreter` value of the axes to `'none'`.

```
tbl_weight = table(weights,'VariableNames',{'Predictor Weight'}, ...
    'RowNames',blackbox.ExpandedPredictorNames);
tbl_weight = sortrows(tbl_weight,'Predictor Weight');
b = barh(categorical(tbl_weight.Row,tbl_weight.Row),tbl_weight.('Predictor Weight'));
b.Parent.TickLabelInterpreter = 'none';
xlabel('Predictor Weight')
ylabel('Predictor')
```



The predictor weights indicate that multiple dummy variables for the categorical predictors `Model_Year` and `Cylinders` are important.

Specify Query Point

Find the observations whose `MPG` values are smaller than the 0.25 quantile of `MPG`. From the subset, choose four query points that do not include missing values.

```
rng('default') % For reproducibility
idx_subset = find(MPG < quantile(MPG,0.25));
tbl_subset = tbl(idx_subset,:);
queryPoint = datasample(rmmissing(tbl_subset),4,'Replace',false)
```

```
queryPoint=4×6 table
    Acceleration    Cylinders    Displacement    Horsepower    Model_Year    Weight
    ____________    _________    ____________    __________    __________    ______

        13.2            8            318            150           76          3940
        14.9            8            302            130           77          4295
          14            8            360            215           70          4615
        13.7            8            318            145           77          4140
```

Use LIME with Tree Simple Models

Explain the predictions for the query points using `lime` with decision tree simple models. `lime` generates a synthetic data set and fits a simple model to the synthetic data set.

Create a `lime` object using `tbl_subset` so that `lime` generates a synthetic data set using the subset instead of the entire data set. Specify `'SimpleModelType'` as `'tree'` to use a decision tree simple model.

```
explainer_lime = lime(blackbox,tbl_subset,'SimpleModelType','tree');
```

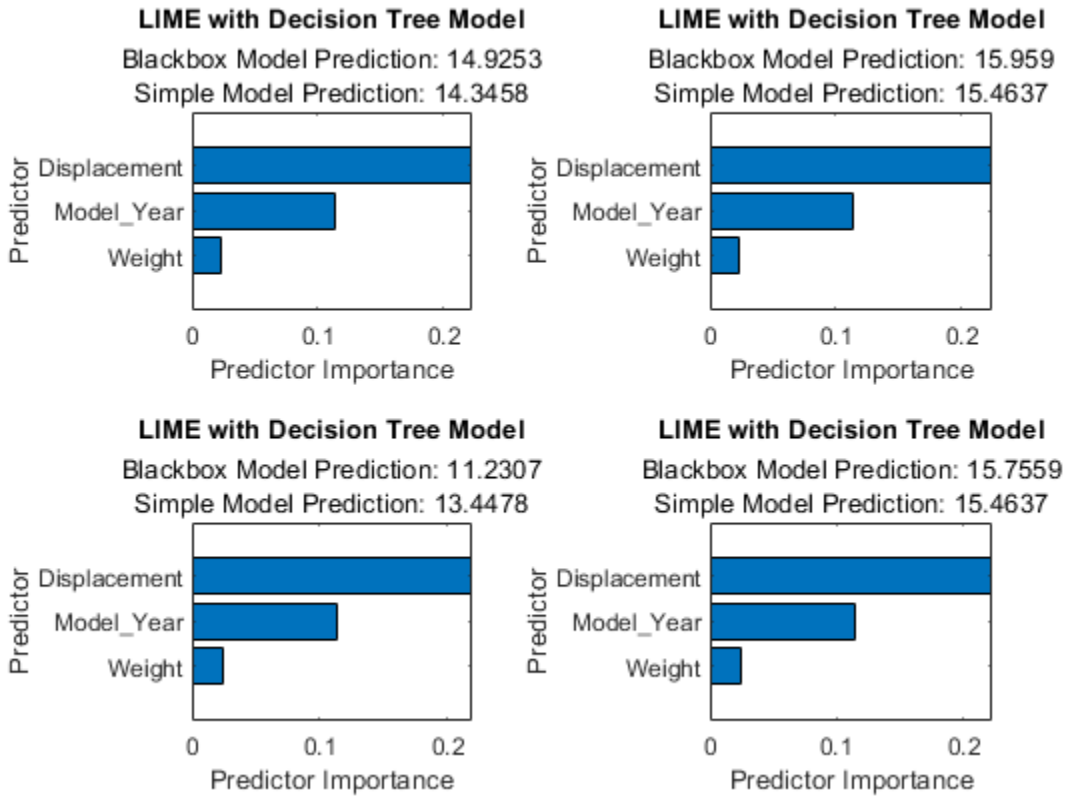
The default value of "'DataLocality'" on page 33-0 for `lime` is `'global'`, which implies that, by default, `lime` generates a global synthetic data set and uses it for any query points. `lime` uses different observation weights so that weight values are more focused on the observations near the query point. Therefore, you can interpret each simple model as an approximation of the trained model for a specific query point.

Fit simple models for the four query points by using the object function `fit`. Specify the third input (the number of important predictors to use in the simple model) as 6. With this setting, the software specifies the maximum number of decision splits (or branch nodes) as 6 so that the fitted decision tree uses at most all predictors.

```
explainer_lime1 = fit(explainer_lime,queryPoint(1,:),6);
explainer_lime2 = fit(explainer_lime,queryPoint(2,:),6);
explainer_lime3 = fit(explainer_lime,queryPoint(3,:),6);
explainer_lime4 = fit(explainer_lime,queryPoint(4,:),6);
```

Plot the predictor importance by using the object function `plot`.

```
tiledlayout(2,2)
ax1 = nexttile; plot(explainer_lime1);
ax2 = nexttile; plot(explainer_lime2);
ax3 = nexttile; plot(explainer_lime3);
ax4 = nexttile; plot(explainer_lime4);
ax1.TickLabelInterpreter = 'none';
ax2.TickLabelInterpreter = 'none';
ax3.TickLabelInterpreter = 'none';
ax4.TickLabelInterpreter = 'none';
```



All simple models identify `Displacement`, `Model_Year`, and `Weight` as important predictors.

Compute Shapley Values

The Shapley value of a predictor for a query point explains the deviation of the predicted response for the query point from the average response, due to the predictor. Create a `shapley` object for the model `blackbox` using `tbl_subset` so that `shapley` computes the expected contribution based on the observations in `tbl_subset`.

```
explainer_shapley = shapley(blackbox,tbl_subset);
```

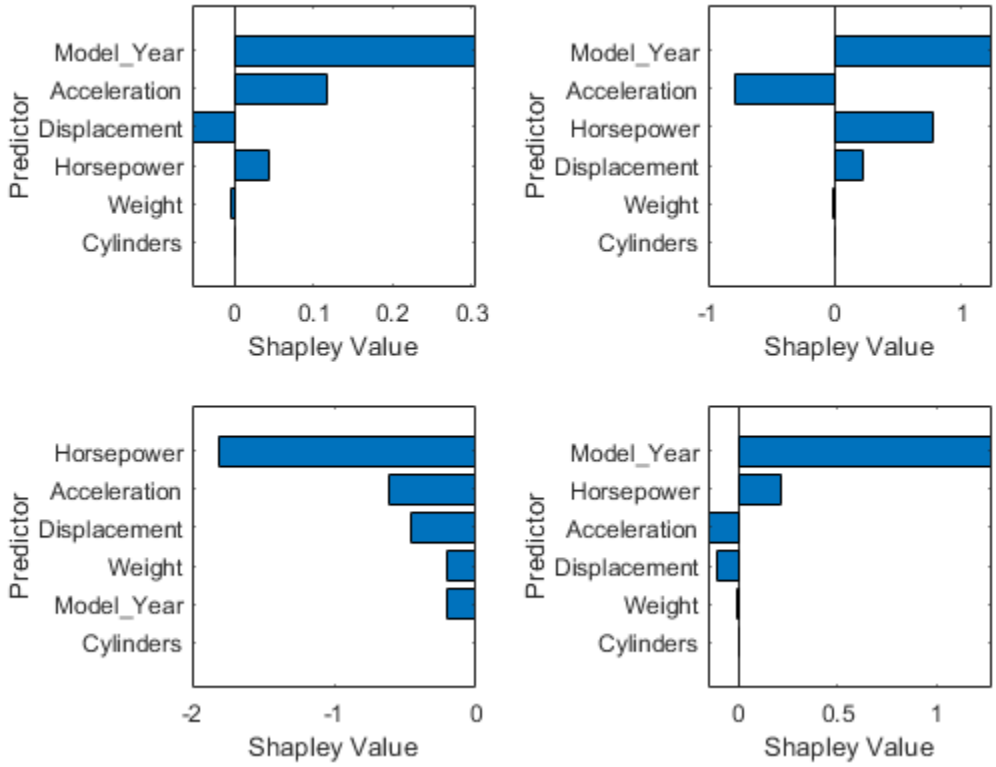
Compute the Shapley values for the query points by using the object function `fit`.

```
explainer_shapley1 = fit(explainer_shapley,queryPoint(1,:));
explainer_shapley2 = fit(explainer_shapley,queryPoint(2,:));
explainer_shapley3 = fit(explainer_shapley,queryPoint(3,:));
explainer_shapley4 = fit(explainer_shapley,queryPoint(4,:));
```

Plot the Shapley values by using the object function `plot`.

```
tiledlayout(2,2)
ax1 = nexttile; plot(explainer_shapley1)
ax2 = nexttile; plot(explainer_shapley2)
ax3 = nexttile; plot(explainer_shapley3)
ax4 = nexttile; plot(explainer_shapley4)
ax1.TickLabelInterpreter = 'none';
ax2.TickLabelInterpreter = 'none';
```

```
ax3.TickLabelInterpreter = 'none';
ax4.TickLabelInterpreter = 'none';
```

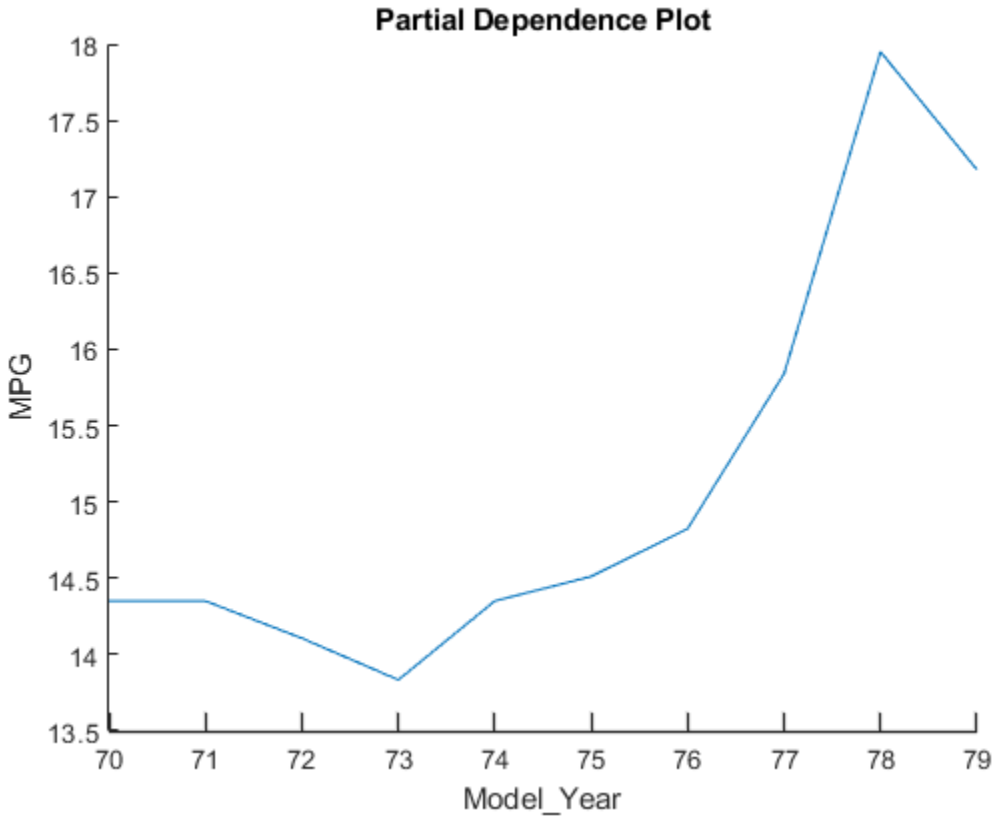


`Model_Year` is the most important predictor for the first, second, and fourth query points, and the Shapley values of `Model_Year` are positive for the three query points. The `Model_Year` value is 76 or 77 for these three points, and the value for the third query point is 70. According to the Shapley values for the four query points, a small `Model_Year` value leads to a decrease in the predicted response, and a large `Model_Year` value leads to an increase in the predicted response compared to the average.

Create Partial Dependence Plot (PDP)

A PDP plot shows the averaged relationships between the predictor and the predicted response in the trained model. Create a PDP for `Model_Year`, which the other interpretability tools identify as an important predictor. Pass `tbl_subset` to `plotPartialDependence` so that the function computes the expectation of the predicted responses using only the samples in `tbl_subset`.

```
figure
plotPartialDependence(blackbox,'Model_Year',tbl_subset)
```



The plot shows the same trend identified by the Shapley values for the four query points. The predicted response (`MPG`) value increases as the `Model_Year` value increases.

Shapley Values for Machine Learning Model

You can compute Shapley values for a machine learning model by using a `shapley` object. Use the values to interpret the contributions of individual features in the model to the prediction for a query point. There are two ways to compute Shapley values:

- Create a `shapley` object for a machine learning model with a specified query point by using the `shapley` function. The function computes the Shapley values of all features in the model for the query point.
- Create a `shapley` object for a machine learning model by using the `shapley` function and, then compute the Shapley values for a specified query point by using the `fit` function.

This topic defines Shapley values, describes two available algorithms for computing Shapley values, provides examples for each, and shows how to reduce the cost of computing Shapley values.

What Is a Shapley Value?

In game theory, the Shapley value of a player is the average marginal contribution of the player in a cooperative game. That is, Shapley values are fair allocations, to individual players, of the total gain generated from a cooperative game. In the context of machine learning prediction, the Shapley value of a feature for a query point explains the contribution of the feature to a prediction (response for regression or score of each class for classification) at the specified query point. The Shapley value corresponds to the deviation of the prediction for the query point from the average prediction, due to the feature. For each query point, the sum of the Shapley values for all features corresponds to the total deviation of the prediction from the average.

The Shapley value of the ith feature for the query point x is defined by the value function v:

$$\varphi_i(v_x) = \frac{1}{M} \sum_{S \subseteq \mathcal{M} \setminus \{i\}} \frac{v_x(S \cup \{i\}) - v_x(S)}{\frac{(M-1)!}{|S|!(M-|S|-1)!}} \tag{18-2}$$

- M is the number of all features.
- $\mathcal{M}$ is the set of all features.
- $|S|$ is the cardinality of the set S, or the number of elements in the set S.
- $v_x(S)$ is the value function of the features in a set S for the query point x. The value of the function indicates the expected contribution of the features in S to the prediction for the query point x.

Shapley Value Computation Algorithms

`shapley` offers two algorithms: kernelSHAP [1], which uses interventional distributions for the value function, and the extension to kernelSHAP [2], which uses conditional distributions for the value function. You can specify the algorithm to use by setting the `'Method'` name-value argument of the `shapley` function or the `fit` function.

The difference between the two algorithms is the definition of the value function. Both algorithms define the value function such that the sum of the Shapley values of a query point over all features corresponds to the total deviation of the prediction for the query point from the average.

$$\sum_{i=1}^{M} \varphi_i(v_x) = f(x) - E[f(x)] .$$

Therefore, the value function $v_x(S)$ must correspond to the expected contribution of the features in S to the prediction (f) for the query point x. The two algorithms compute the expected contribution by using artificial samples created from the specified data (X). You must provide X through the machine learning model input or a separate data input argument when you create a `shapley` object. In the artificial samples, the values for the features in S come from the query point. For the rest of the features (features in S^c, the complement of S), the kernelSHAP algorithm generates samples using interventional distributions, whereas the extension to the kernelSHAP algorithm generates samples using conditional distributions.

KernelSHAP ('Method','interventional-kernel')

`shapley` uses the kernelSHAP algorithm by default.

The kernelSHAP algorithm defines the value function of the features in S at the query point x as the expected prediction with respect to the interventional distribution D, which is the joint distribution of the features in S^c:

$$v_x(S) = E_D[f(x_S, X_{S^c})],$$

where x_S is the query point value for the features in S, and X_{S^c} are the features in S^c.

To evaluate the value function $v_x(S)$ at the query point x, with the assumption that the features are not highly correlated, `shapley` uses the values in the data X as samples of the interventional distribution D for the features in S^c:

$$v_x(S) = E_D[f(x_S, X_{S^c})] \approx \frac{1}{N}\sum_{j=1}^{N} f\left(x_S, (X_{S^c})_j\right),$$

where N is the number of observations, and $(X_{S^c})_j$ contains the values of the features in S^c for the jth observation.

For example, suppose you have three features in X and four observations: (x_{11},x_{12},x_{13}), (x_{21},x_{22},x_{23}), (x_{31},x_{32},x_{33}), and (x_{41},x_{42},x_{43}). Assume that S includes the first feature, and S^c includes the rest. In this case, the value function of the first feature evaluated at the query point (x_{41},x_{42},x_{43}) is

$$v_x(S) = \frac{1}{4}[f(x_{41}, x_{12}, x_{13}) + f(x_{41}, x_{22}, x_{23}) + f(x_{41}, x_{32}, x_{33}) + f(x_{41}, x_{42}, x_{43})].$$

The kernelSHAP algorithm is computationally less expensive than the extension to the kernelSHAP algorithm, supports ordered categorical predictors, and can handle missing values in X. However, the algorithm requires the feature independence assumption and uses out-of-distribution samples [3]. The artificial samples created with a mix of the query point and the data X can contain unrealistic observations. For example, (x_{41},x_{12},x_{13}) might be a sample that does not occur in the full joint distribution of the three features.

Extension to KernelSHAP ('Method','conditional-kernel')

Specify `'Method','conditional-kernel'` to use the extension to the kernelSHAP algorithm.

the extension to the kernelSHAP algorithm defines the value function of the features in S at the query point x using the conditional distribution of X_{S^c}, given that X_S has the query point values:

$$v_x(S) = E_{X_{S^c}|X_S = x_S}[f(x_S, X_{S^c})].$$

To evaluate the value function $v_x(S)$ at the query point x, `shapley` uses nearest neighbors of the query point, which correspond to 10% of the observations in the data X. This approach uses more realistic samples than the kernelSHAP algorithm and does not require the feature independence assumption. However, this algorithm is computationally more expensive, does not support ordered categorical predictors, and cannot handle `NaN`s in continuous features. Also, the algorithm might assign a nonzero Shapley value to a dummy feature that does not contribute to the prediction, if the dummy feature is correlated with an important feature [3].

Specify Shapley Value Computation Algorithm

This example trains a linear classification model and computes Shapley values using both the kernelSHAP algorithm (`'Method','interventional-kernel'`) and the extension to the kernelSHAP algorithm (`'Method','conditional-kernel'`).

Train Linear Classification Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a linear classification model. Specify the objective function minimization technique (`'Solver'` name-value argument) as the limited-memory Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (`'lbfgs'`) for better accuracy of linear coefficients.

```
Mdl = fitclinear(X,Y,'Solver','lbfgs')
```

```
Mdl =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: {'b'  'g'}
    ScoreTransform: 'none'
              Beta: [34x1 double]
              Bias: -3.7100
            Lambda: 0.0028
           Learner: 'svm'

  Properties, Methods
```

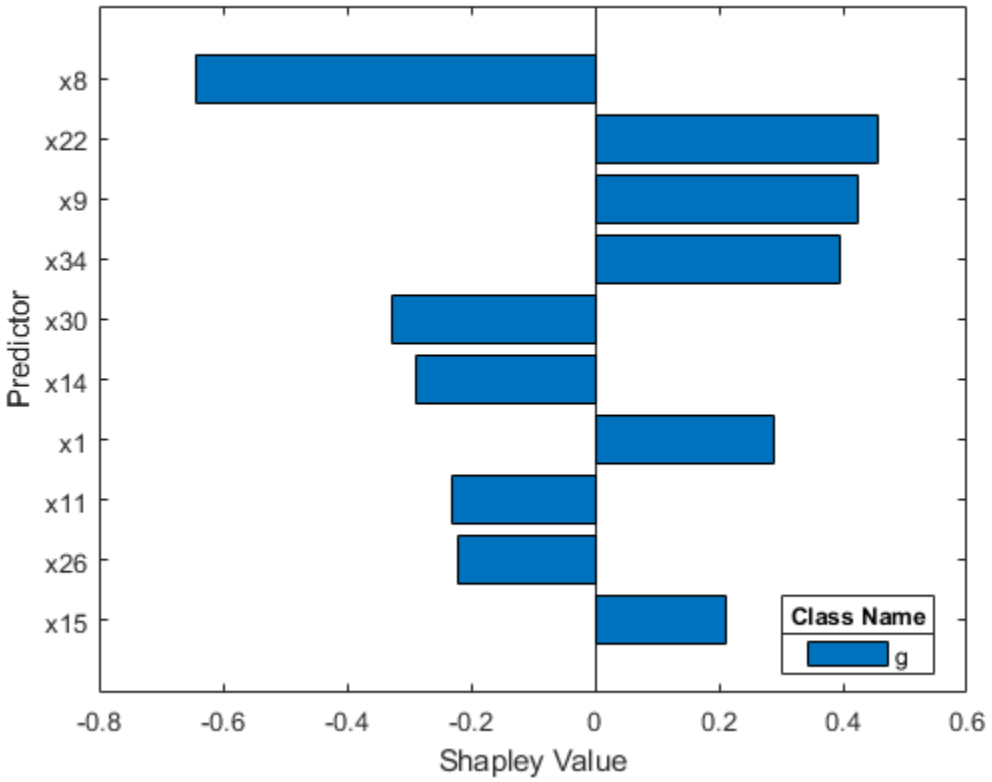
Shapley Values with Interventional Distribution

Compute the Shapley values for the first observation using the kernelSHAP algorithm, which uses the interventional distribution for the value function evaluation. You do not have to specify the `'Method'` value because `'interventional-kernel'` is the default.

```
queryPoint = X(1,:);
explainer1 = shapley(Mdl,X,'QueryPoint',queryPoint);
```

For a classification model, `shapley` computes Shapley values using the predicted class score for each class. Plot the Shapley values for the predicted class by using the `plot` function.

```
plot(explainer1)
```



The horizontal bar graph shows the Shapley values for the 10 most important variables, sorted by their absolute values. Each Shapley value explains the deviation of the score for the query point from the average score of the predicted class, due to the corresponding variable.

For a linear model where you assume features are independent from one another, you can compute the interventional Shapley values for the positive class (or the second class in `Mdl.ClassNames`, `'g'`) from the estimated coefficients (`Mdl.Beta`) [1].

```
linearSHAPValues = (Mdl.Beta'.*(queryPoint-mean(X)))';
```

Create a table containing the Shapley values computed from the kernelSHAP algorithm and the values from the coefficients.

```
t = table(explainer1.ShapleyValues.Predictor,explainer1.ShapleyValues.g,linearSHAPValues, ...
    'VariableNames',{'Predictor','KernelSHAP Value','LinearSHAP Value'})
```

```
t=34×3 table
    Predictor    KernelSHAP Value    LinearSHAP Value

⋮
```

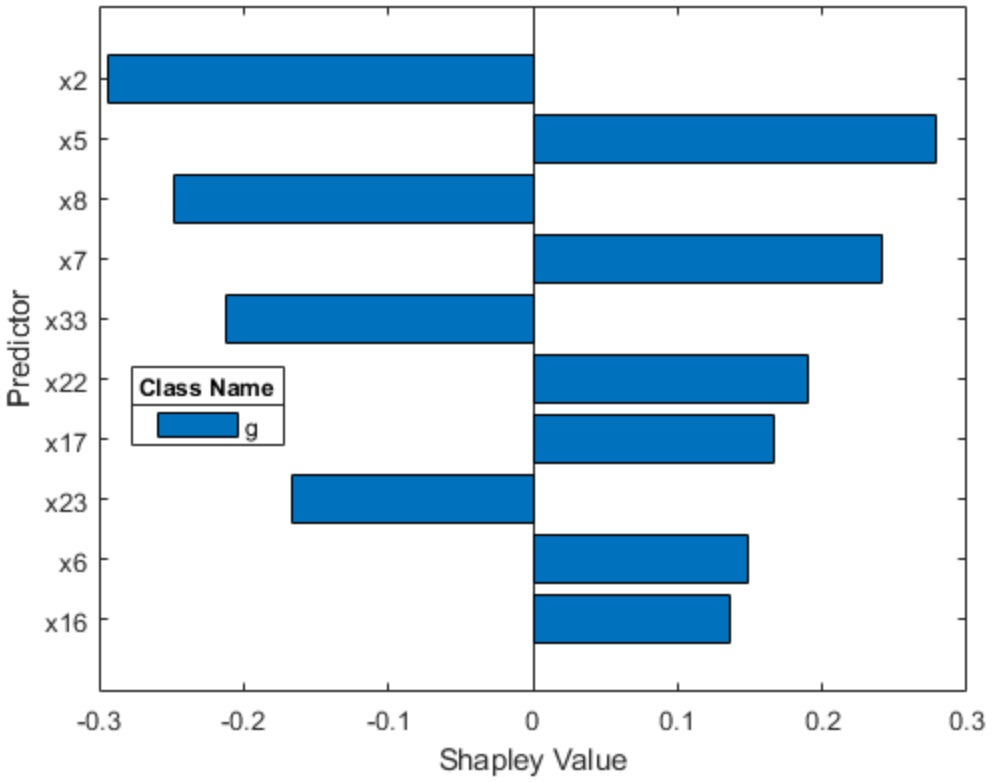
Shapley Values with Conditional Distribution

Compute the Shapley values for the first observation using the extension to the kernelSHAP algorithm, which uses the conditional distribution for the value function evaluation.

```
explainer2 = shapley(Mdl,X,'QueryPoint',queryPoint,'Method','conditional-kernel');
```

Plot the Shapley values.

```
plot(explainer2)
```



The two algorithms identify different sets for the 10 most important variables. Only the two variables `x8` and `x22` are common to both sets.

Complexity of Computing Shapley Values

The computational cost for Shapley values increases if the number of observations or features is large.

Large Number of Observations

Computing the value function (v) can be computationally expensive if you have a large number of observations, for example, more than 1000. For faster computation, use a smaller sample of the observations when you create a `shapley` object, or compute Shapley values in parallel by specifying `'UseParallel'` as `true` when you compute the values using the `shapley` or `fit` function. Computing in parallel requires Parallel Computing Toolbox.

Large Number of Features

Computing the summand in "Equation 18-2" for all available subsets S can be computationally expensive when M (the number of features) is large. The total number of subsets to consider is 2^M. Instead of computing the summand for all subsets, you can specify the maximum number of subsets for Shapley value computation by using the `'MaxNumSubsets'` name-value argument. `shapley` chooses subsets to use based on their weight values. The weight of a subset is proportional to 1/(denominator of the summand), which corresponds to 1 over the binomial coefficient: $1/\binom{M-1}{|S|}$. Therefore, a subset with a high or low value of cardinality has a large weight value. `shapley` includes the subsets with the highest weight first, and then includes the other subsets in descending order based on their weight values.

Reduce Computational Cost

This example shows how to reduce the computational cost for Shapley values when you have a large number of both observations and features.

Train Regression Ensemble

Load the sample data set `NYCHousing2015`.

```
load NYCHousing2015
```

The data set includes 55,246 observations of 10 variables with information on the sales of properties in New York City in 2015. This example uses these variables to analyze the sale prices (`SALEPRICE`).

Preprocess the data set. Convert the `datetime` array (`SALEDATE`) to the month numbers.

```
NYCHousing2015.SALEDATE = month(NYCHousing2015.SALEDATE);
```

Train a regression ensemble.

```
Mdl = fitrensemble(NYCHousing2015,'SALEPRICE');
```

Compute Shapley Values with Default Options

Compute the Shapley values of all predictor variables for the first observation. Measure the time required to compute the Shapley values by using `tic` and `toc`.

```
tic
explainer1 = shapley(Mdl,'QueryPoint',NYCHousing2015(1,:));

Warning: Computation can be slow because the predictor data has over 1000 observations. Use a sma

toc

Elapsed time is 492.365307 seconds.
```

As the warning message indicates, the computation can be slow because the predictor data has over 1000 observations.

Specify Options to Reduce Computational Cost

`shapley` provides several options to reduce the computational cost when you have a large number of observations or features.

- Large number of observations — Use a smaller sample of the training data and compute Shapley values in parallel by specifying `'UseParallel'` as `true`.
- Large number of features — Specify the `'MaxNumSubsets'` name-value argument to limit the number of subsets included in the computation.

Compute the Shapley values again using a smaller sample of the training data and the parallel computing option. Also, specify the maximum number of subsets as `2^5`.

```
NumSamples = 5e2;
Tbl = datasample(NYCHousing2015,NumSamples,'Replace',false);
tic
explainer2 = shapley(Mdl,Tbl,'QueryPoint',NYCHousing2015(1,:), ...
    'UseParallel',true,'MaxNumSubsets',2^5);

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

toc

Elapsed time is 52.183287 seconds.
```

Specifying the additional options reduces the time required to compute the Shapley values.

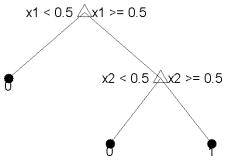
Decision Trees

Decision Trees

Decision trees, or classification trees and regression trees, predict responses to data. To predict a response, follow the decisions in the tree from the root (beginning) node down to a leaf node. The leaf node contains the response. Classification trees give responses that are nominal, such as `'true'` or `'false'`. Regression trees give numeric responses.

Statistics and Machine Learning Toolbox trees are binary. Each step in a prediction involves checking the value of one predictor (variable). For example, here is a simple classification tree:



This tree predicts classifications based on two predictors, `x1` and `x2`. To predict, start at the top node, represented by a triangle (Δ). The first decision is whether `x1` is smaller than `0.5`. If so, follow the left branch, and see that the tree classifies the data as type `0`.

If, however, `x1` exceeds `0.5`, then follow the right branch to the lower-right triangle node. Here the tree asks if `x2` is smaller than `0.5`. If so, then follow the left branch to see that the tree classifies the data as type `0`. If not, then follow the right branch to see that the tree classifies the data as type `1`.

To learn how to prepare your data for classification or regression using decision trees, see “Steps in Supervised Learning” on page 18-4.

Train Classification Tree

This example shows how to train a classification tree.

Create a classification tree using the entire `ionosphere` data set.

```
load ionosphere % Contains X and Y variables
Mdl = fitctree(X,Y)
```

```
Mdl =
  ClassificationTree
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}
           ScoreTransform: 'none'
          NumObservations: 351

  Properties, Methods
```

Train Regression Tree

This example shows how to train a regression tree.

Create a regression tree using all observation in the `carsmall` data set. Consider the `Horsepower` and `Weight` vectors as predictor variables, and the `MPG` vector as the response.

```
load carsmall % Contains Horsepower, Weight, MPG
X = [Horsepower Weight];

Mdl = fitrtree(X,MPG)

Mdl =
  RegressionTree
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
          NumObservations: 94

  Properties, Methods
```

View Decision Tree

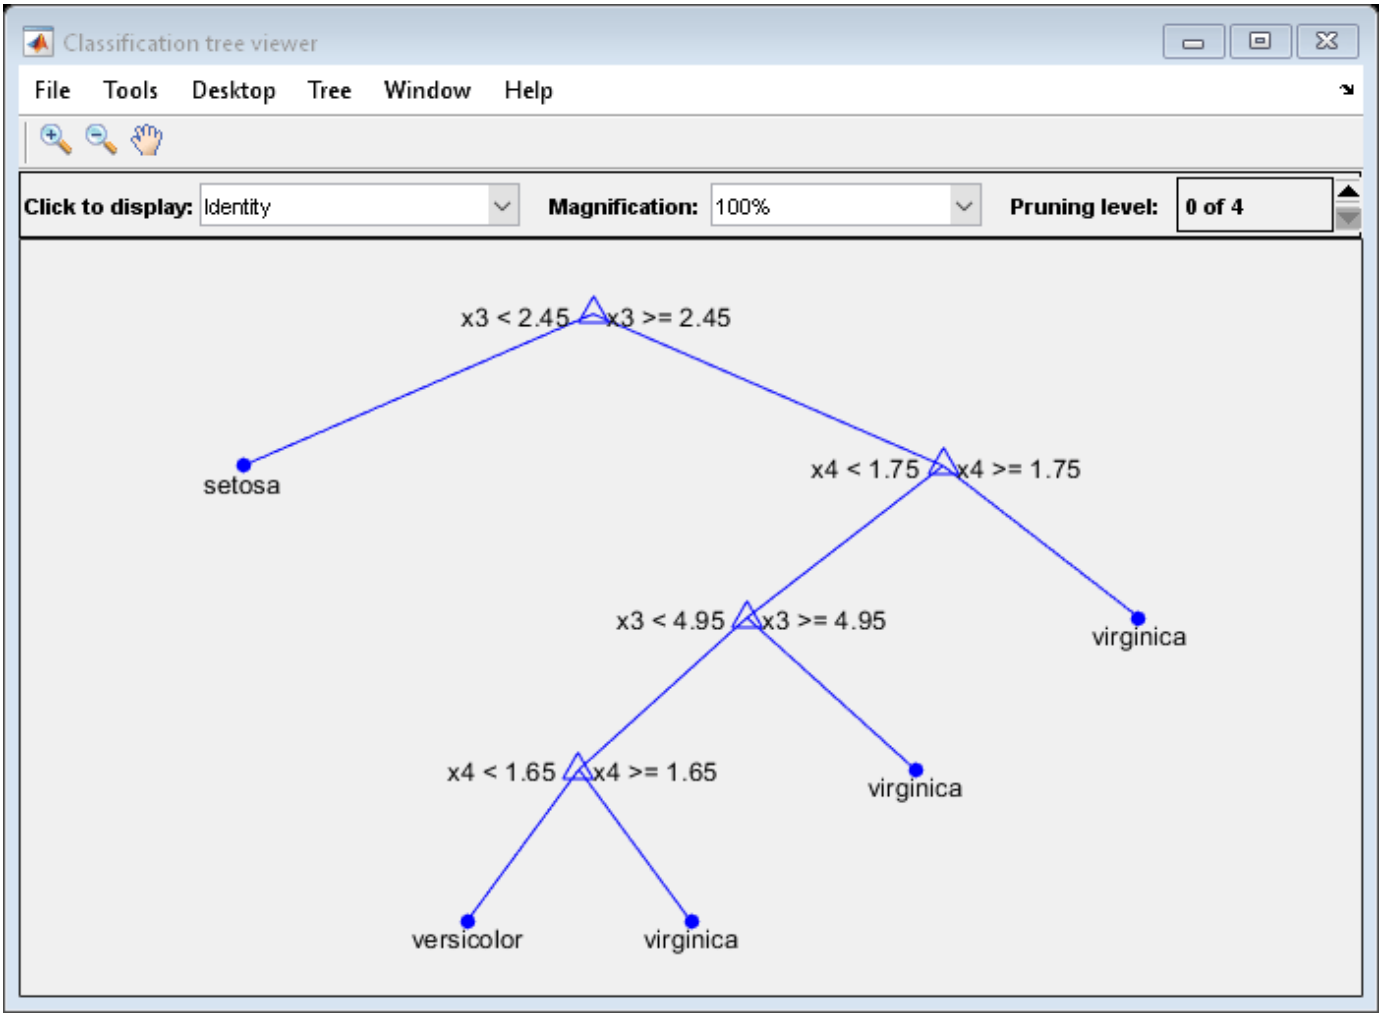
This example shows how to view a classification or regression tree. There are two ways to view a tree: `view(tree)` returns a text description and `view(tree,'mode','graph')` returns a graphic description of the tree.

Create and view a classification tree.

```
load fisheriris % load the sample data
ctree = fitctree(meas,species); % create classification tree
view(ctree) % text description
```

```
Decision tree for classification
1  if x3<2.45 then node 2 elseif x3>=2.45 then node 3 else setosa
2  class = setosa
3  if x4<1.75 then node 4 elseif x4>=1.75 then node 5 else versicolor
4  if x3<4.95 then node 6 elseif x3>=4.95 then node 7 else versicolor
5  class = virginica
6  if x4<1.65 then node 8 elseif x4>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica
```

```
view(ctree,'mode','graph') % graphic description
```



Now, create and view a regression tree.

```
load carsmall % load the sample data, contains Horsepower, Weight, MPG
X = [Horsepower Weight];
rtree = fitrtree(X,MPG,'MinParent',30); % create classification tree
view(rtree) % text description

Decision tree for regression
1  if x2<3085.5 then node 2 elseif x2>=3085.5 then node 3 else 23.7181
2  if x1<89 then node 4 elseif x1>=89 then node 5 else 28.7931
3  if x1<115 then node 6 elseif x1>=115 then node 7 else 15.5417
4  if x2<2162 then node 8 elseif x2>=2162 then node 9 else 30.9375
5  fit = 24.0882
6  fit = 19.625
7  fit = 14.375
8  fit = 33.3056
9  fit = 29

view(rtree,'mode','graph') % graphic description
```

Growing Decision Trees

By default, `fitctree` and `fitrtree` use the standard CART algorithm [1] to create decision trees. That is, they perform the following steps:

1. Start with all input data, and examine all possible binary splits on every predictor.
2. Select a split with best optimization criterion.
   - A split might lead to a child node having too few observations (less than the `MinLeafSize` parameter). To avoid this, the software chooses a split that yields the best optimization criterion subject to the `MinLeafSize` constraint.
3. Impose the split.
4. Repeat recursively for the two child nodes.

The explanation requires two more items: description of the optimization criterion and stopping rule.

Stopping rule: Stop splitting when any of the following hold:

- The node is pure.
  - For classification, a node is pure if it contains only observations of one class.
  - For regression, a node is pure if the mean squared error (MSE) for the observed response in this node drops below the MSE for the observed response in the entire data multiplied by the tolerance on quadratic error per node (`QuadraticErrorTolerance` parameter).
- There are fewer than `MinParentSize` observations in this node.
- Any split imposed on this node produces children with fewer than `MinLeafSize` observations.
- The algorithm splits `MaxNumSplits` nodes.

Optimization criterion:

- Regression: mean-squared error (MSE). Choose a split to minimize the MSE of predictions compared to the training data.
- Classification: One of three measures, depending on the setting of the `SplitCriterion` name-value pair:
  - `'gdi'` (Gini's diversity index, the default)
  - `'twoing'`
  - `'deviance'`

  For details, see `ClassificationTree` “More About” on page 33-585.

For alternative split predictor selection techniques, see “Choose Split Predictor Selection Technique” on page 19-14.

For a continuous predictor, a tree can split halfway between any two adjacent unique values found for this predictor. For a categorical predictor with L levels, a classification tree needs to consider $2^{L-1}-1$ splits to find the optimal split. Alternatively, you can choose a heuristic algorithm to find a good split, as described in “Splitting Categorical Predictors in Classification Trees” on page 19-25.

For dual-core systems and above, `fitctree` and `fitrtree` parallelize training decision trees using Intel® Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Prediction Using Classification and Regression Trees

This example shows how to predict class labels or responses using trained classification and regression trees.

After creating a tree, you can easily predict responses for new data. Suppose `Xnew` is new data that has the same number of columns as the original data `X`. To predict the classification or regression based on the tree (`Mdl`) and the new data, enter

```
Ynew = predict(Mdl,Xnew)
```

For each row of data in `Xnew`, `predict` runs through the decisions in `Mdl` and gives the resulting prediction in the corresponding element of `Ynew`. For more information on classification tree prediction, see the `predict`. For regression, see `predict`.

For example, find the predicted classification of a point at the mean of the `ionosphere` data.

```
load ionosphere
CMdl = fitctree(X,Y);
Ynew = predict(CMdl,mean(X))
```

```
Ynew = 1x1 cell array
    {'g'}
```

Find the predicted `MPG` of a point at the mean of the `carsmall` data.

```
load carsmall
X = [Horsepower Weight];
RMdl = fitrtree(X,MPG);
Ynew = predict(RMdl,mean(X))
```

```
Ynew = 28.7931
```

- “Improving Classification Trees and Regression Trees” on page 19-13

Predict Out-of-Sample Responses of Subtrees

This example hows how to predict out-of-sample responses of regression trees, and then plot the results.

Load the `carsmall` data set. Consider `Weight` as a predictor of the response `MPG`.

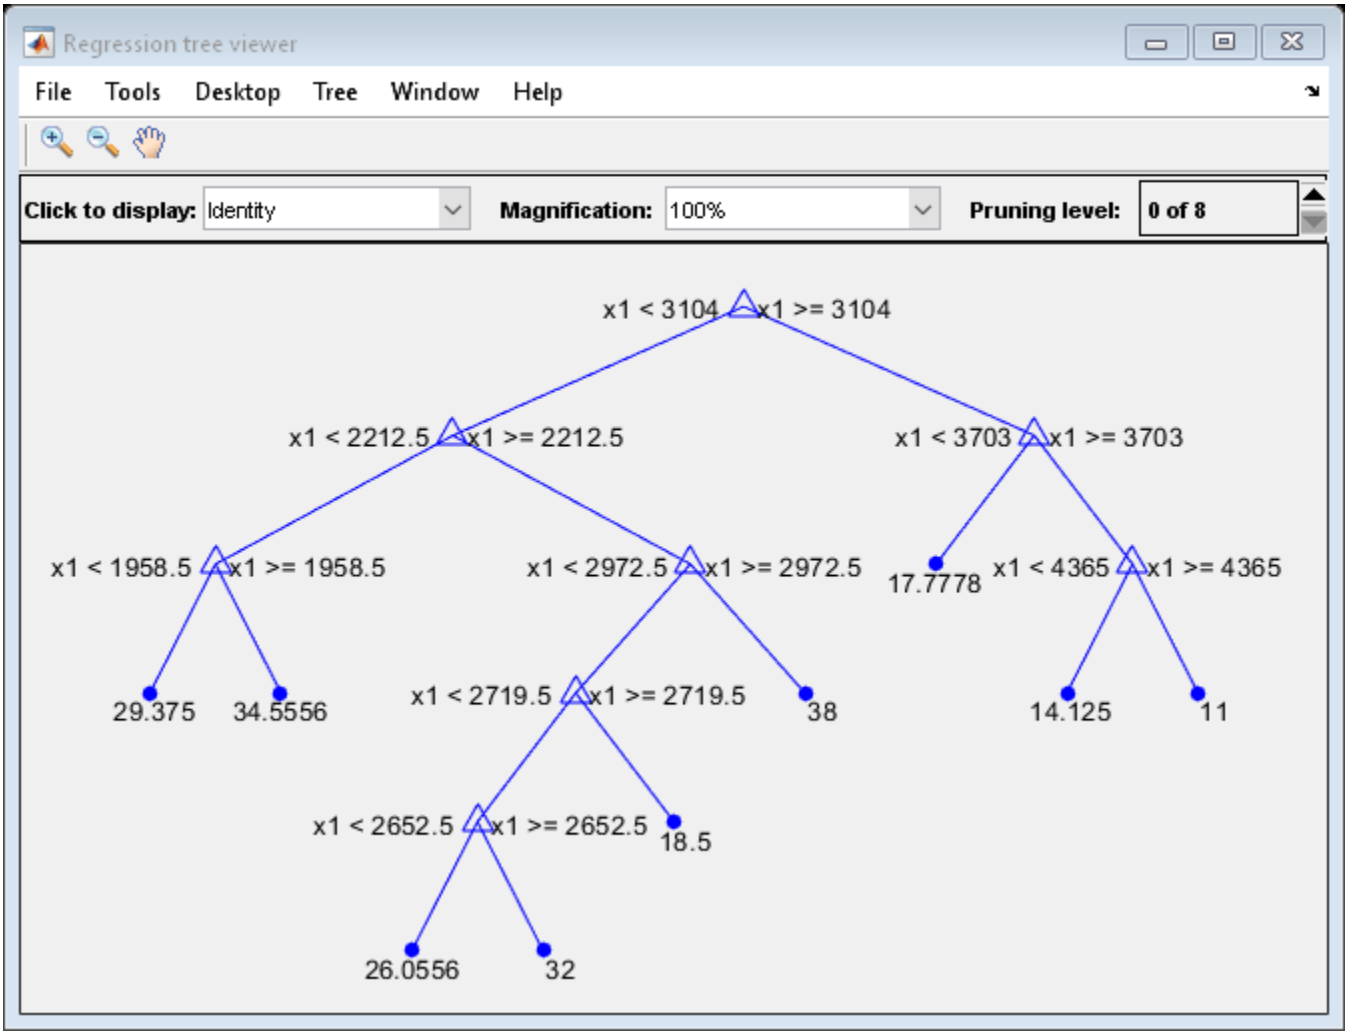
```
load carsmall
idxNaN = isnan(MPG + Weight);
X = Weight(~idxNaN);
Y = MPG(~idxNaN);
n = numel(X);
```

Partition the data into training (50%) and validation (50%) sets.

```
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a regression tree using the training observations.

```
Mdl = fitrtree(X(idxTrn),Y(idxTrn));
view(Mdl,'Mode','graph')
```



Compute fitted values of the validation observations for each of several subtrees.

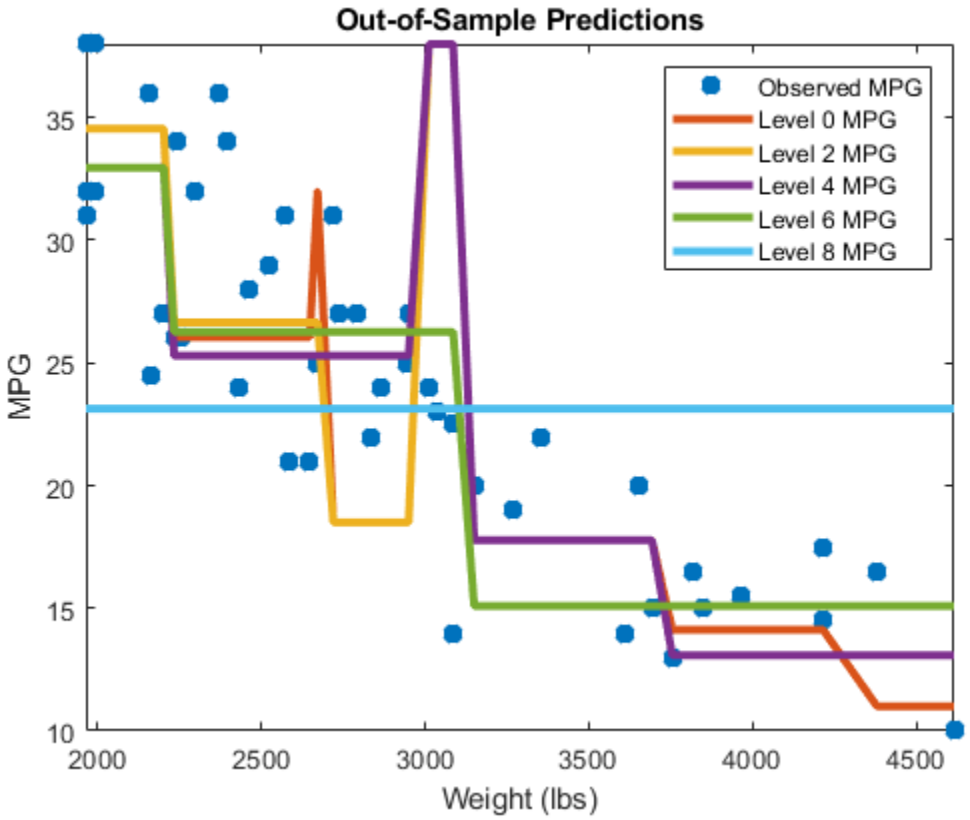
```
m = max(Mdl.PruneList);
pruneLevels = 0:2:m; % Pruning levels to consider
z = numel(pruneLevels);
Yfit = predict(Mdl,X(idxVal),'SubTrees',pruneLevels);
```

`Yfit` is an n-by- z matrix of fitted values in which the rows correspond to observations and the columns correspond to a subtree.

Plot `Yfit` and `Y` against `X`.

```
figure;
sortDat = sortrows([X(idxVal) Y(idxVal) Yfit],1); % Sort all data with respect to X
plot(sortDat(:,1),sortDat(:,2),'*');
hold on;
plot(repmat(sortDat(:,1),1,size(Yfit,2)),sortDat(:,3:end));
lev = cellstr(num2str((pruneLevels)','Level %d MPG'));
legend(['Observed MPG'; lev])
title 'Out-of-Sample Predictions'
xlabel 'Weight (lbs)';
```

```
ylabel 'MPG';
h = findobj(gcf);
axis tight;
set(h(4:end),'LineWidth',3) % Widen all lines
```



The values of `Yfit` for lower pruning levels tend to follow the data more closely than higher levels. Higher pruning levels tend to be flat for large `X` intervals.

Improving Classification Trees and Regression Trees

In this section...

You can tune trees by setting name-value pairs in `fitctree` and `fitrtree`. The remainder of this section describes how to determine the quality of a tree, how to decide which name-value pairs to set, and how to control the size of a tree.

Examining Resubstitution Error

Resubstitution error is the difference between the response training data and the predictions the tree makes of the response based on the input training data. If the resubstitution error is high, you cannot expect the predictions of the tree to be good. However, having low resubstitution error does not guarantee good predictions for new data. Resubstitution error is often an overly optimistic estimate of the predictive error on new data.

Classification Tree Resubstitution Error

This example shows how to examine the resubstitution error of a classification tree.

Load Fisher's iris data.

```
load fisheriris
```

Train a default classification tree using the entire data set.

```
Mdl = fitctree(meas,species);
```

Examine the resubstitution error.

```
resuberror = resubLoss(Mdl)
```

```
resuberror = 0.0200
```

The tree classifies nearly all the Fisher iris data correctly.

Cross Validation

To get a better sense of the predictive accuracy of your tree for new data, cross validate the tree. By default, cross validation splits the training data into 10 parts at random. It trains 10 new trees, each one on nine parts of the data. It then examines the predictive accuracy of each new tree on the data not included in training that tree. This method gives a good estimate of the predictive accuracy of the resulting tree, since it tests the new trees on new data.

Cross Validate a Regression Tree

This example shows how to examine the resubstitution and cross-validation accuracy of a regression tree for predicting mileage based on the `carsmall` data.

Load the `carsmall` data set. Consider acceleration, displacement, horsepower, and weight as predictors of MPG.

```
load carsmall
X = [Acceleration Displacement Horsepower Weight];
```

Grow a regression tree using all of the observations.

```
rtree = fitrtree(X,MPG);
```

Compute the in-sample error.

```
resuberror = resubLoss(rtree)
```

```
resuberror = 4.7188
```

The resubstitution loss for a regression tree is the mean-squared error. The resulting value indicates that a typical predictive error for the tree is about the square root of 4.7, or a bit over 2.

Estimate the cross-validation MSE.

```
rng 'default';
cvrtree = crossval(rtree);
cvloss = kfoldLoss(cvrtree)
```

```
cvloss = 23.5706
```

The cross-validated loss is almost 25, meaning a typical predictive error for the tree on new data is about 5. This demonstrates that cross-validated loss is usually higher than simple resubstitution loss.

Choose Split Predictor Selection Technique

The standard CART algorithm tends to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors. That is, the predictor-selection process at each node is biased. Also, standard CART tends to miss the important interactions between pairs of predictors and the response.

To mitigate selection bias and increase detection of important interactions, you can specify usage of the curvature or interaction tests using the `'PredictorSelection'` name-value pair argument. Using the curvature or interaction test has the added advantage of producing better predictor importance estimates than standard CART.

This table summarizes the supported predictor-selection techniques.

Technique	'PredictorSelection' Value	Description	Training speed	When to specify
Standard CART [1]	Default	Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors.	Baseline for comparison	Specify if any of these conditions are true: • All predictors are continuous • Predictor importance is not the analysis goal • For boosting decision trees
Curvature test [2][3]	'curvature'	Selects the split predictor that minimizes the *p*-value of chi-square tests of independence between each predictor and the response.	Comparable to standard CART	Specify if any of these conditions are true: • The predictor variables are heterogeneous • Predictor importance is an analysis goal • Enhance tree interpretation
Interaction test [3]	'interaction-curvature'	Chooses the split predictor that minimizes the *p*-value of chi-square tests of independence between each predictor and the response (that is, conducts curvature tests), and that minimizes the *p*-value of a chi-square test of independence between each pair of predictors and response.	Slower than standard CART, particularly when data set contains many predictor variables.	Specify if any of these conditions are true: • The predictor variables are heterogeneous • You suspect associations between pairs of predictors and the response • Predictor importance is an analysis goal • Enhance tree interpretation

For more details on predictor selection techniques:

- For classification trees, see `PredictorSelection` and “Node Splitting Rules” on page 33-1928.
- For regression trees, see `PredictorSelection` and “Node Splitting Rules” on page 33-2413.

Control Depth or “Leafiness”

When you grow a decision tree, consider its simplicity and predictive power. A deep tree with many leaves is usually highly accurate on the training data. However, the tree is not guaranteed to show a comparable accuracy on an independent test set. A leafy tree tends to overtrain (or overfit), and its

test accuracy is often far less than its training (resubstitution) accuracy. In contrast, a shallow tree does not attain high training accuracy. But a shallow tree can be more robust — its training accuracy could be close to that of a representative test set. Also, a shallow tree is easy to interpret. If you do not have enough data for training and test, estimate tree accuracy by cross validation.

`fitctree` and `fitrtree` have three name-value pair arguments that control the depth of resulting decision trees:

- `MaxNumSplits` — The maximal number of branch node splits is `MaxNumSplits` per tree. Set a large value for `MaxNumSplits` to get a deep tree. The default is `size(X,1) - 1`.
- `MinLeafSize` — Each leaf has at least `MinLeafSize` observations. Set small values of `MinLeafSize` to get deep trees. The default is `1`.
- `MinParentSize` — Each branch node in the tree has at least `MinParentSize` observations. Set small values of `MinParentSize` to get deep trees. The default is `10`.

If you specify `MinParentSize` and `MinLeafSize`, the learner uses the setting that yields trees with larger leaves (i.e., shallower trees):

```
MinParent = max(MinParentSize,2*MinLeafSize)
```

If you supply `MaxNumSplits`, the software splits a tree until one of the three splitting criteria is satisfied.

For an alternative method of controlling the tree depth, see “Pruning” on page 19-19.

Select Appropriate Tree Depth

This example shows how to control the depth of a decision tree, and how to choose an appropriate depth.

Load the `ionosphere` data.

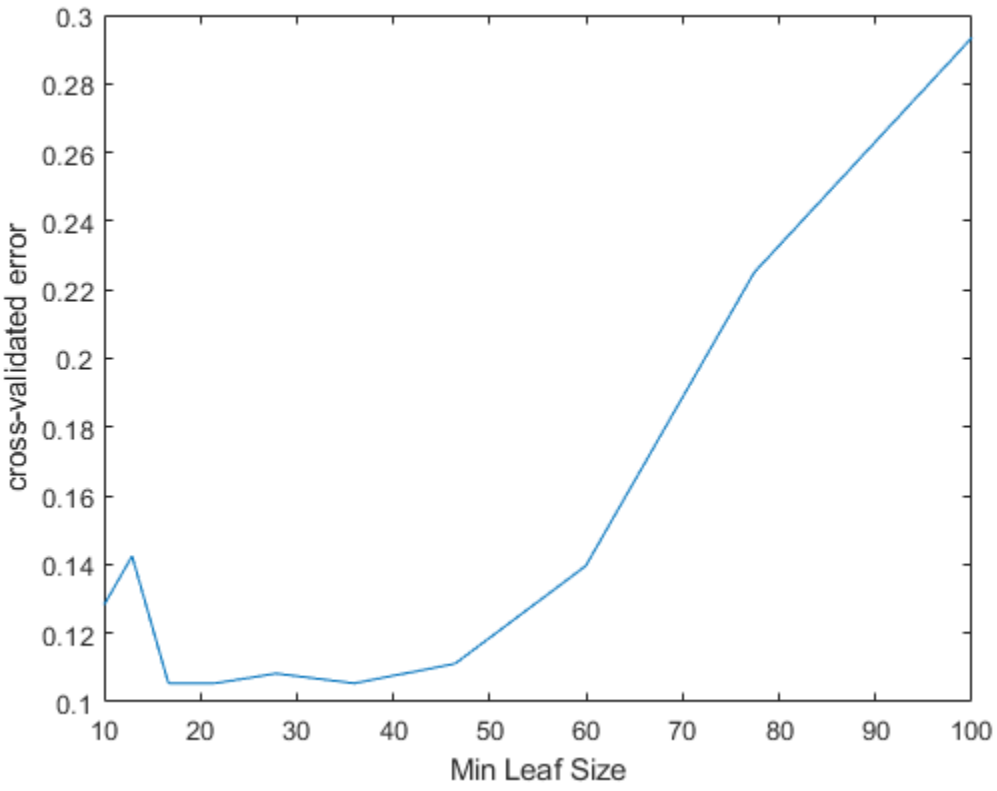
```
load ionosphere
```

Generate an exponentially spaced set of values from `10` through `100` that represent the minimum number of observations per leaf node.

```
leafs = logspace(1,2,10);
```

Create cross-validated classification trees for the `ionosphere` data. Specify to grow each tree using a minimum leaf size in `leafs`.

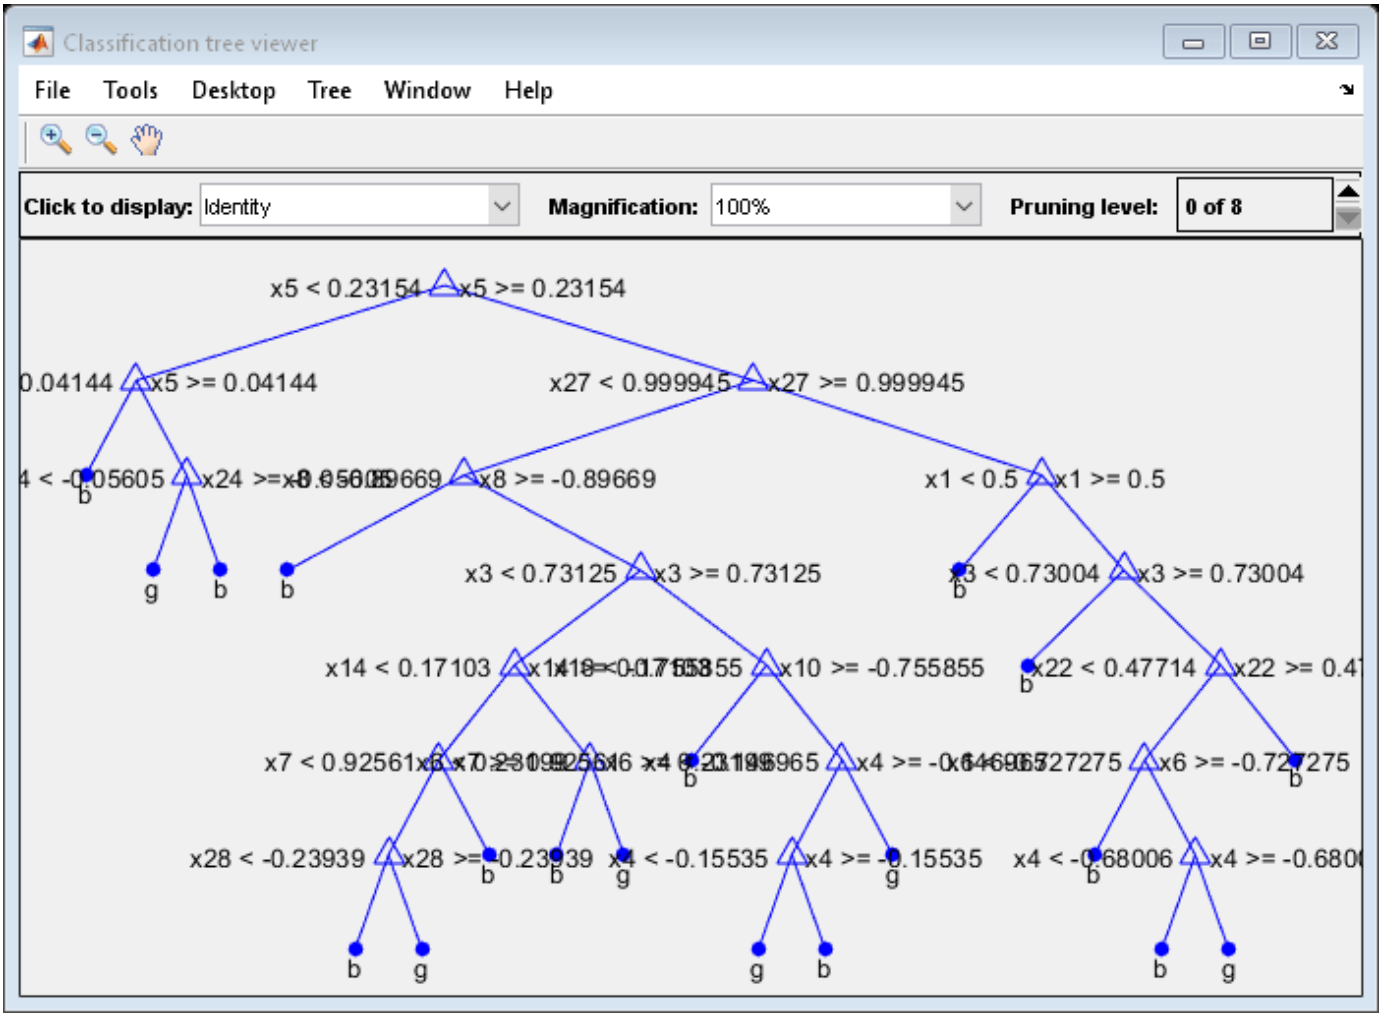
```
rng('default')
N = numel(leafs);
err = zeros(N,1);
for n=1:N
    t = fitctree(X,Y,'CrossVal','On',...
        'MinLeafSize',leafs(n));
    err(n) = kfoldLoss(t);
end
plot(leafs,err);
xlabel('Min Leaf Size');
ylabel('cross-validated error');
```



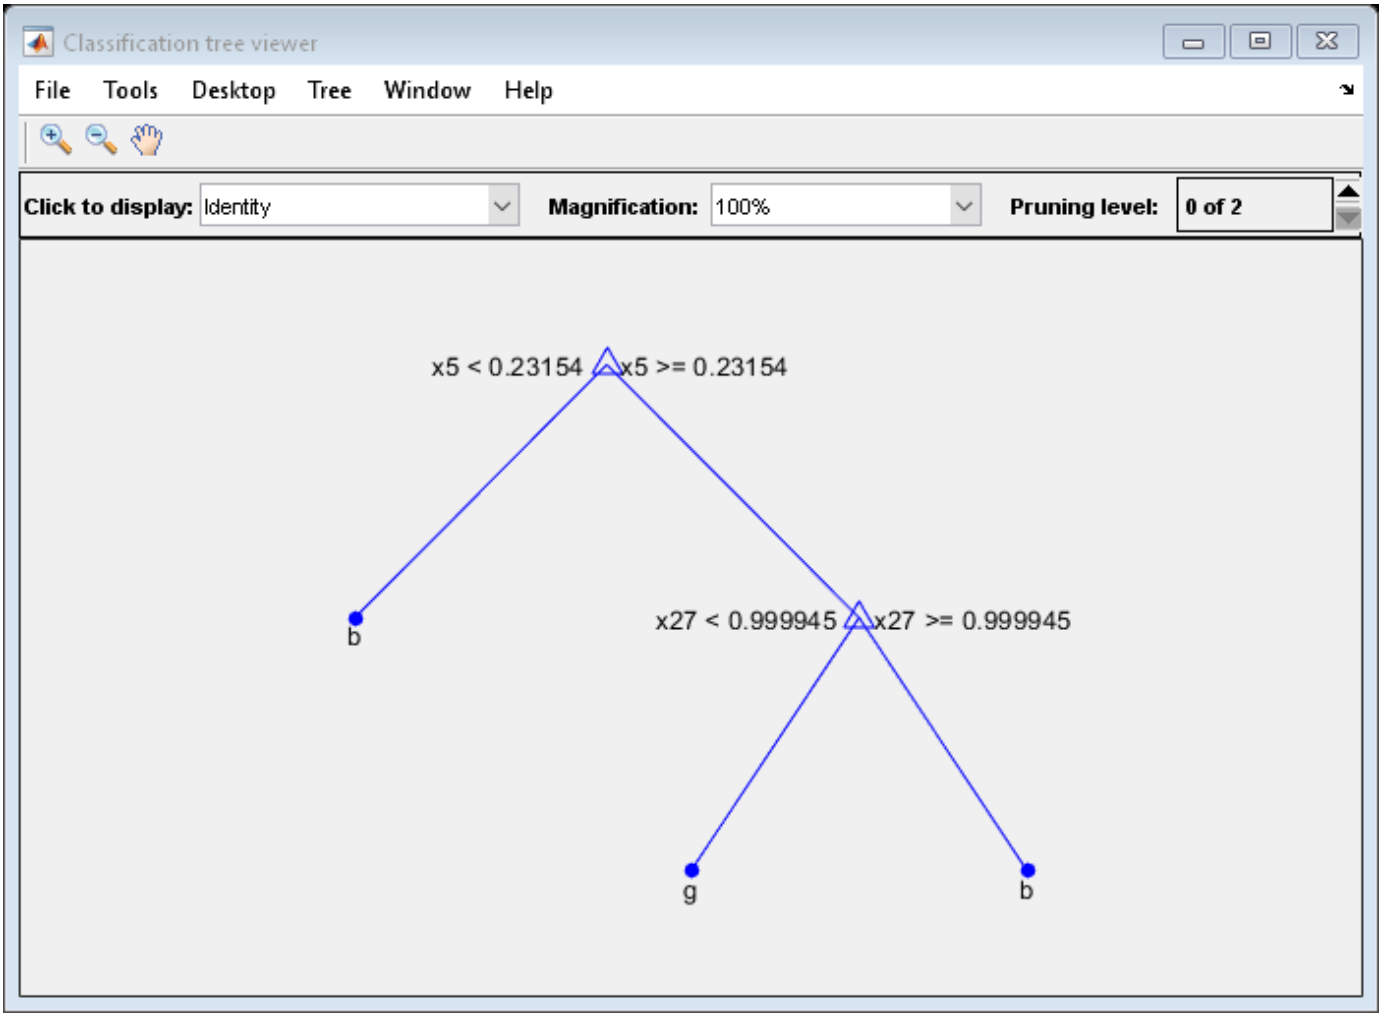
The best leaf size is between about `20` and `50` observations per leaf.

Compare the near-optimal tree with at least `40` observations per leaf with the default tree, which uses `10` observations per parent node and `1` observation per leaf.

```
DefaultTree = fitctree(X,Y);
view(DefaultTree,'Mode','Graph')
```



```
OptimalTree = fitctree(X,Y,'MinLeafSize',40);
view(OptimalTree,'mode','graph')
```



```
resubOpt = resubLoss(OptimalTree);
lossOpt = kfoldLoss(crossval(OptimalTree));
resubDefault = resubLoss(DefaultTree);
lossDefault = kfoldLoss(crossval(DefaultTree));
resubOpt,resubDefault,lossOpt,lossDefault
```

```
resubOpt = 0.0883

resubDefault = 0.0114

lossOpt = 0.1054

lossDefault = 0.1054
```

The near-optimal tree is much smaller and gives a much higher resubstitution error. Yet, it gives similar accuracy for cross-validated data.

Pruning

Pruning optimizes tree depth (leafiness) by merging leaves on the same tree branch. “Control Depth or “Leafiness”” on page 19-15 describes one method for selecting the optimal depth for a tree. Unlike

in that section, you do not need to grow a new tree for every node size. Instead, grow a deep tree, and prune it to the level you choose.

Prune a tree at the command line using the `prune` method (classification) or `prune` method (regression). Alternatively, prune a tree interactively with the tree viewer:

```
view(tree,'mode','graph')
```

To prune a tree, the tree must contain a pruning sequence. By default, both `fitctree` and `fitrtree` calculate a pruning sequence for a tree during construction. If you construct a tree with the `'Prune'` name-value pair set to `'off'`, or if you prune a tree to a smaller level, the tree does not contain the full pruning sequence. Generate the full pruning sequence with the `prune` method (classification) or `prune` method (regression).

Prune a Classification Tree

This example creates a classification tree for the `ionosphere` data, and prunes it to a good level.

Load the `ionosphere` data:

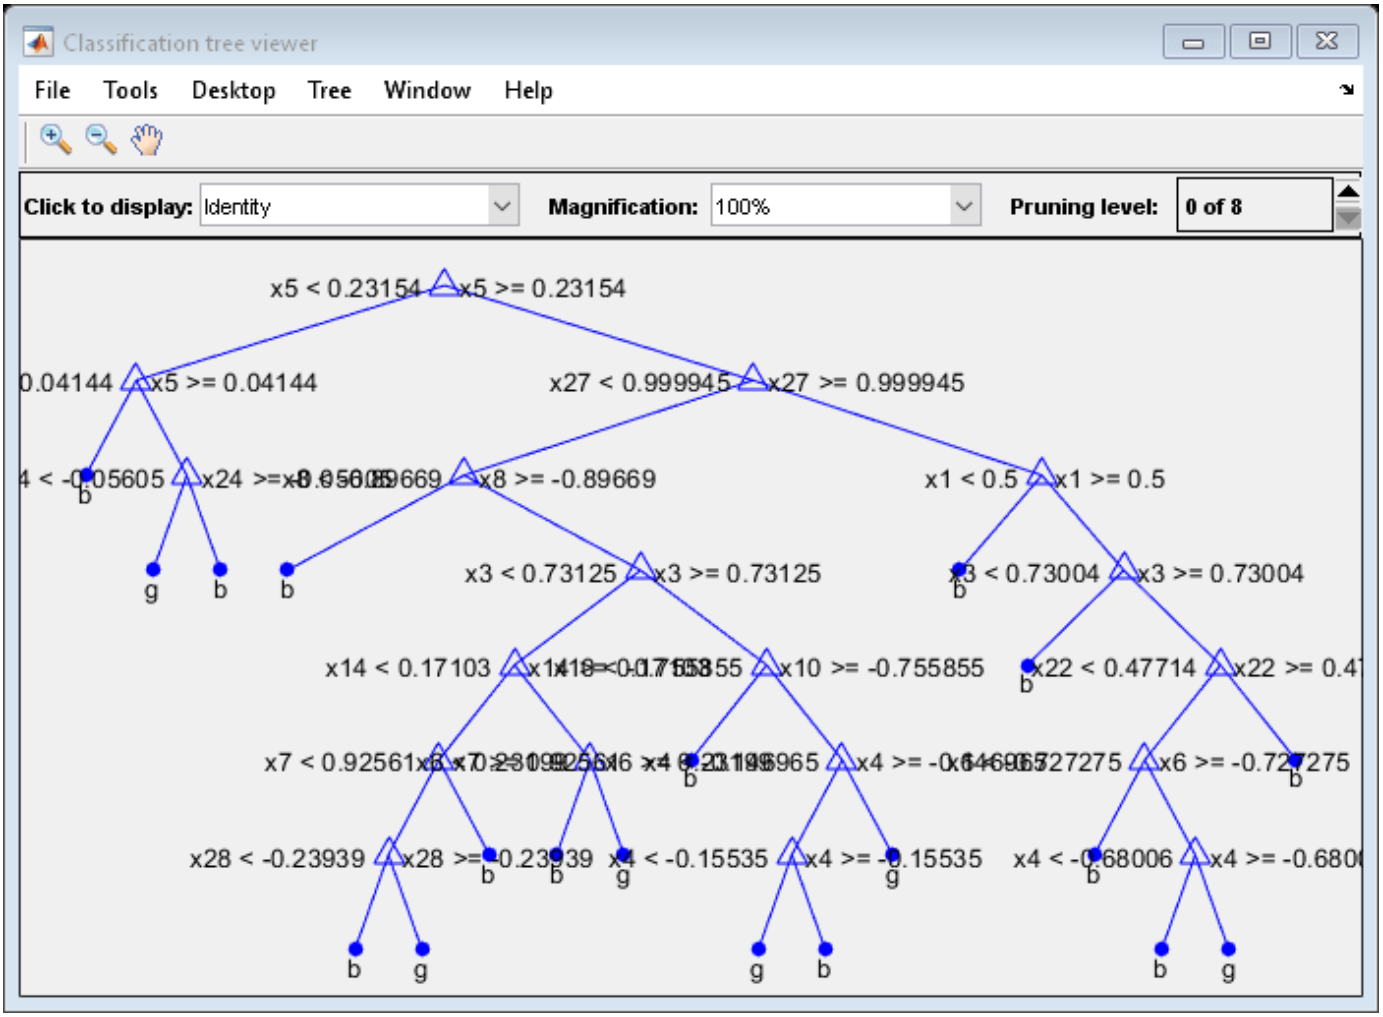
```
load ionosphere
```

Construct a default classification tree for the data:

```
tree = fitctree(X,Y);
```

View the tree in the interactive viewer:

```
view(tree,'Mode','Graph')
```



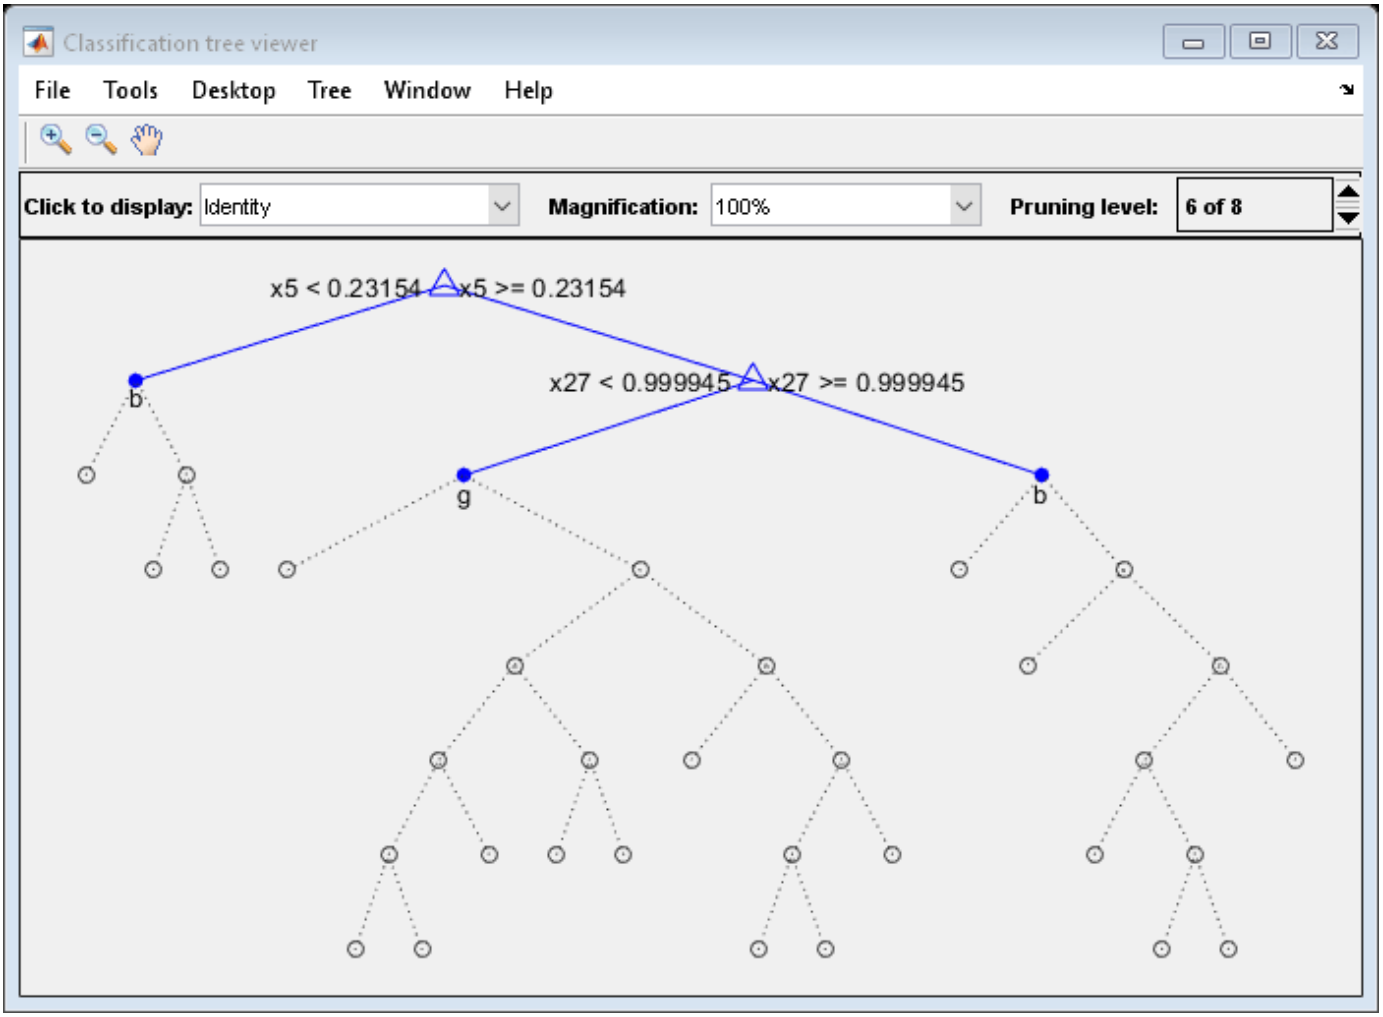
Find the optimal pruning level by minimizing cross-validated loss:

```
[~,~,~,bestlevel] = cvLoss(tree,...
    'SubTrees','All','TreeSize','min')
```

```
bestlevel = 6
```

Prune the tree to level 6:

```
view(tree,'Mode','Graph','Prune',6)
```



Alternatively, use the interactive window to prune the tree.

The pruned tree is the same as the near-optimal tree in the "Select Appropriate Tree Depth" example.

Set `'TreeSize'` to `'SE'` (default) to find the maximal pruning level for which the tree error does not exceed the error from the best level plus one standard deviation:

```
[~,~,~,bestlevel] = cvLoss(tree,'SubTrees','All')
```

```
bestlevel = 6
```

In this case the level is the same for either setting of `'TreeSize'`.

Prune the tree to use it for other purposes:

```
tree = prune(tree,'Level',6);
view(tree,'Mode','Graph')
```

Splitting Categorical Predictors in Classification Trees

In this section...

Challenges in Splitting Multilevel Predictors

When you grow a classification tree, finding an optimal binary split for a categorical predictor with many levels is more computationally challenging than finding a split for a continuous predictor. For a continuous predictor, a tree can split halfway between any two adjacent, unique values of the predictor. In contrast, to find an exact, optimal binary split for a categorical predictor with L levels, a classification tree must consider $2^{L-1}–1$ splits. To obtain this formula:

1. Count the number of ways to assign L distinct values to the left and right nodes. There are 2^L ways.
2. Divide 2^L by 2, because left and right can be swapped.
3. Discard the case that has an empty node.

For regression problems and binary classification problems, the software uses the exact search algorithm through a computational shortcut[1]. The tree can order the categories by mean response (for regression) or class probability for one of the classes (for classification). Then, the optimal split is one of the L – 1 splits for the ordered list. Therefore, computational challenges arise only when you grow classification trees for data with $K \geq 3$ classes.

Algorithms for Categorical Predictor Split

To reduce computation, the software offers several heuristic algorithms for finding a good split. You can choose an algorithm for splitting categorical predictors by using the `'AlgorithmForCategorical'` name-value pair argument when you grow a classification tree using `fitctree` or when you create a classification learner using `templateTree` for a classification ensemble (`fitcensemble`) or a multiclass ECOC model (`fitcecoc`).

If you do not specify an algorithm, the software selects the optimal algorithm for each split using the known number of classes and levels of a categorical predictor. If the predictor has at most `MaxNumCategories` levels, the software splits categorical predictors using the exact search algorithm. Otherwise, the software chooses a heuristic search algorithm based on the number of classes and levels. The default `MaxNumCategories` level is 10. Depending on your platform, the software cannot perform an exact search on categorical predictors with more than 32 or 64 levels.

The available heuristic algorithms are: pull left by purity, principal component-based partitioning, and one-versus-all by class.

Pull Left by Purity

The pull left by purity algorithm starts with all L categorical levels on the right branch. The algorithm then takes these actions:

1. Inspect the K categories that have the largest class probabilities for each class.

2. Move the category with the maximum value of the split criterion to the left branch.
3. Continue moving categories from right to left, recording the split criterion at each move, until the right child has only one category remaining.

Out of this sequence, the selected split is the one that maximizes the split criterion.

Select this algorithm by specifying `'AlgorithmForCategorical','PullLeft'` in `fitctree` or `templateTree`.

Principal Component-Based Partitioning

The principal component-based partitioning algorithm[2] finds a close-to-optimal binary partition of the L predictor levels by searching for a separating hyperplane. The hyperplane is perpendicular to the first principal component of the weighted covariance matrix of the centered class probability matrix.

The algorithm assigns a score to each of the L categories, computed as the inner product between the found principal component and the vector of class probabilities for that category. Then, the selected split is one of the L – 1 splits that maximizes the split criterion.

Select this algorithm by specifying `'AlgorithmForCategorical','PCA'` in `fitctree` or `templateTree`.

One-Versus-All by Class

The one-versus-all by class algorithm starts with all L categorical levels on the right branch. For each of the K classes, the algorithm orders the categories based on their probability for that class.

For the first class, the algorithm moves each category to the left branch in order, recording the split criterion at each move. Then the algorithm repeats this process for the remaining classes. Out of this sequence, the selected split is the one that maximizes the split criterion.

Select this algorithm by specifying `'AlgorithmForCategorical','OVAbyClass'` in `fitctree` or `templateTree`.

Inspect Data with Multilevel Categorical Predictors

This example shows how to inspect a data set that includes categorical predictors with many levels (categories) and how to train a binary decision tree for classification.

Load Sample Data

Load the `census1994` file. This data set consists of demographic data from the US Census Bureau to predict whether an individual makes over $50,000 a year. Specify a cell array of character vectors containing the variable names.

```
load census1994
VarNames = adultdata.Properties.VariableNames;
```

Some variable names in the `adultdata` table contain the _ character. Replace instances of _ with a space.

```
VarNames = strrep(VarNames,'_',' ');
```

Specify the predictor data `tbl` and the response vector `Y`.

```
tbl = adultdata(:,1:end-1);
Y = categorical(adultdata.salary);
```

Inspect Categorical Predictors

Some categorical variables have many levels (categories). Count the number of levels of each categorical predictor.

Find the indexes of categorical predictors that are not numeric in the `tbl` table by using `varfun` and `isnumeric`. The `varfun` function applies the `isnumeric` function to each variable of the table `tbl`.

```
cat = ~varfun(@isnumeric,tbl,'OutputFormat','uniform');
```

Define an anonymous function to count the number of categories in a categorical predictor using `numel` and `categories`.

```
countNumCats = @(var)numel(categories(categorical(var)));
```

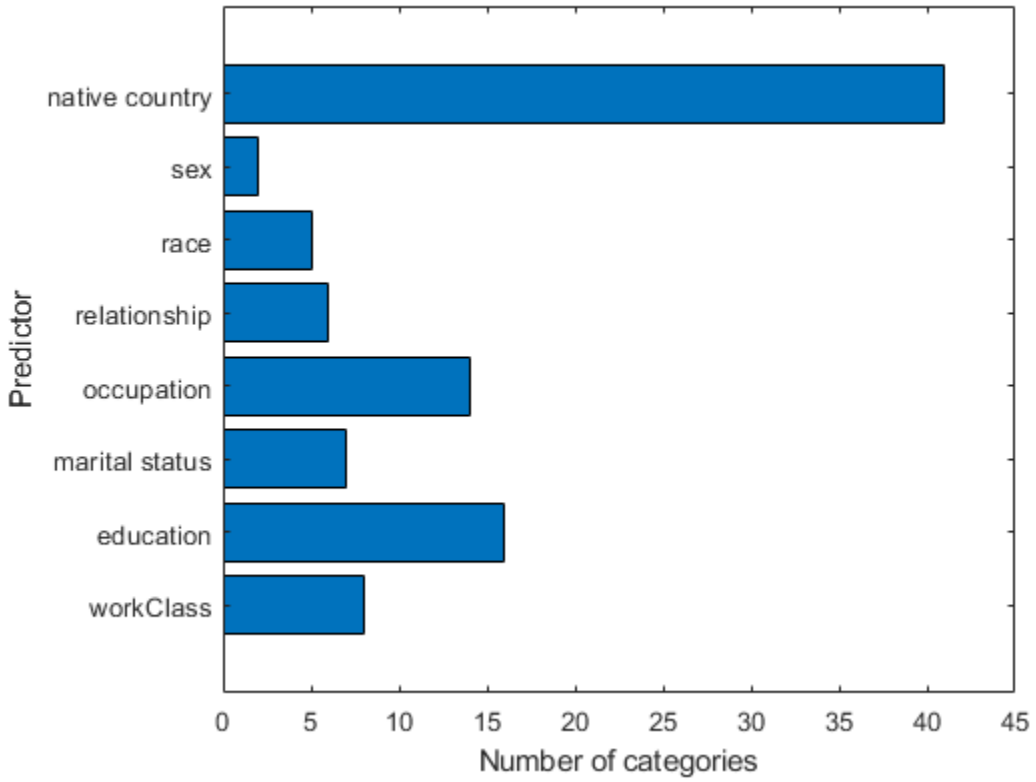
The anonymous function `countNumCats` converts a predictor to a categorical array, then counts the unique, nonempty categories of the predictor.

Use `varfun` and `countNumCats` to count the number of categories for the categorical predictors in `tbl`.

```
numCat = varfun(@(var)countNumCats(var),tbl(:,cat),'OutputFormat','uniform');
```

Plot the number of categories for each categorical predictor.

```
figure
barh(numCat);
h = gca;
h.YTickLabel = VarNames(cat);
ylabel('Predictor')
xlabel('Number of categories')
```



Train Model

For binary classification, the software uses a computational shortcut to find an optimal split for categorical predictors with many categories. For classification with more than two classes, you can choose an exact algorithm or a heuristic algorithm to find a good split by using the `'AlgorithmForCategorical'` name-value pair argument of `fitctree` or `templateTree`. By default, the software selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor.

Train a classification tree using `tbl` and `Y`. The response vector `Y` has two classes, so the software uses the exact algorithm for categorical predictor splits.

```
Mdl = fitctree(tbl,Y)
```

```
Mdl =
  ClassificationTree
             PredictorNames: {1x14 cell}
               ResponseName: 'Y'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
                ClassNames: [<=50K    >50K]
           ScoreTransform: 'none'
          NumObservations: 32561
```

```
Properties, Methods
```

Discriminant Analysis

Discriminant Analysis Classification

Discriminant analysis is a classification method. It assumes that different classes generate data based on different Gaussian distributions.

- To train (create) a classifier, the fitting function estimates the parameters of a Gaussian distribution for each class (see “Creating Discriminant Analysis Model” on page 20-4).
- To predict the classes of new data, the trained classifier finds the class with the smallest misclassification cost (see “Prediction Using Discriminant Analysis Models” on page 20-6).

Linear discriminant analysis is also known as the Fisher discriminant, named for its inventor, Sir R. A. Fisher [1].

Create Discriminant Analysis Classifiers

This example shows how to train a basic discriminant analysis classifier to classify irises in Fisher's iris data.

Load the data.

```
load fisheriris
```

Create a default (linear) discriminant analysis classifier.

```
MdlLinear = fitcdiscr(meas,species);
```

To visualize the classification boundaries of a 2-D linear classification of the data, see “Create and Visualize Discriminant Analysis Classifier” on page 20-9.

Classify an iris with average measurements.

```
meanmeas = mean(meas);
meanclass = predict(MdlLinear,meanmeas)
```

```
meanclass = 1x1 cell array
    {'versicolor'}
```

Create a quadratic classifier.

```
MdlQuadratic = fitcdiscr(meas,species,'DiscrimType','quadratic');
```

To visualize the classification boundaries of a 2-D quadratic classification of the data, see “Create and Visualize Discriminant Analysis Classifier” on page 20-9.

Classify an iris with average measurements using the quadratic classifier.

```
meanclass2 = predict(MdlQuadratic,meanmeas)
```

```
meanclass2 = 1x1 cell array
    {'versicolor'}
```

Creating Discriminant Analysis Model

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. In other words, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
  - For linear discriminant analysis, the model has the same covariance matrix for each class; only the means vary.
  - For quadratic discriminant analysis, both means and covariances of each class vary.

Under this modeling assumption, `fitcdiscr` infers the mean and covariance parameters of each class.

- For linear discriminant analysis, it computes the sample mean of each class. Then it computes the sample covariance by first subtracting the sample mean of each class from the observations of that class, and taking the empirical covariance matrix of the result.
- For quadratic discriminant analysis, it computes the sample mean of each class. Then it computes the sample covariances by first subtracting the sample mean of each class from the observations of that class, and taking the empirical covariance matrix of each class.

The `fit` method does not use prior probabilities or costs for fitting.

Weighted Observations

`fitcdiscr` constructs weighted classifiers using the following scheme. Suppose M is an N-by-K class membership matrix:

$M_{nk} = 1$ if observation n is from class k
$M_{nk} = 0$ otherwise.

The estimate of the class mean for unweighted data is

$$\widehat{\mu}_k = \frac{\sum_{n=1}^{N} M_{nk} x_n}{\sum_{n=1}^{N} M_{nk}}.$$

For weighted data with positive weights w_n, the natural generalization is

$$\widehat{\mu}_k = \frac{\sum_{n=1}^{N} M_{nk} w_n x_n}{\sum_{n=1}^{N} M_{nk} w_n}.$$

The unbiased estimate of the pooled-in covariance matrix for unweighted data is

$$\widehat{\Sigma} = \frac{\sum_{n=1}^{N} \sum_{k=1}^{K} M_{nk} (x_n - \widehat{\mu}_k)(x_n - \widehat{\mu}_k)^T}{N - K}.$$

For quadratic discriminant analysis, `fitcdiscr` uses $K = 1$.

For weighted data, assuming the weights sum to 1, the unbiased estimate of the pooled-in covariance matrix is

$$\widehat{\Sigma} = \frac{\sum_{n=1}^{N}\sum_{k=1}^{K} M_{nk} w_n (x_n - \widehat{\mu}_k)(x_n - \widehat{\mu}_k)^T}{1 - \sum_{k=1}^{K} \frac{W_k^{(2)}}{W_k}},$$

where

- $W_k = \sum_{n=1}^{N} M_{nk} w_n$ is the sum of the weights for class k.
- $W_k^{(2)} = \sum_{n=1}^{N} M_{nk} w_n^2$ is the sum of squared weights per class.

Prediction Using Discriminant Analysis Models

`predict` uses three quantities to classify observations: posterior probability on page 20-6, prior probability on page 20-6, and cost on page 20-7.

`predict` classifies so as to minimize the expected classification cost:

$$\widehat{y} = \underset{y = 1, \ldots, K}{\operatorname{argmin}} \sum_{k=1}^{K} \widehat{P}(k|x) C(y|k),$$

where

- $\widehat{y}$ is the predicted classification.
- K is the number of classes.
- $\widehat{P}(k|x)$ is the posterior probability of class k for observation x.
- $C(y|k)$ is the cost of classifying an observation as y when its true class is k.

The space of `X` values divides into regions where a classification `Y` is a particular value. The regions are separated by straight lines for linear discriminant analysis, and by conic sections (ellipses, hyperbolas, or parabolas) for quadratic discriminant analysis. For a visualization of these regions, see “Create and Visualize Discriminant Analysis Classifier” on page 20-9.

Posterior Probability

The posterior probability that a point x belongs to class k is the product of the prior probability on page 20-6 and the multivariate normal density. The density function of the multivariate normal with 1-by-d mean μ_k and d-by-d covariance Σ_k at a 1-by-d point x is

$$P(x|k) = \frac{1}{\left((2\pi)^d |\Sigma_k|\right)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)\Sigma_k^{-1}(x - \mu_k)^T\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k, and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k. Then the posterior probability that an observation x is of class k is

$$\widehat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, namely, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- `'uniform'` — The prior probability of class `k` is 1 over the total number of classes.
- `'empirical'` — The prior probability of class `k` is the number of training samples of class `k` divided by the total number of training samples.
- A numeric vector — The prior probability of class `k` is the `j`th element of the `Prior` vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

There are two costs associated with discriminant analysis classification: the true misclassification cost per class, and the expected misclassification cost per observation.

True Misclassification Cost per Class

`Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is `0` for correct classification, and `1` for incorrect classification.

You can set any cost matrix you like when creating a classifier. Pass the cost matrix in the `Cost` name-value pair in `fitcdiscr`.

After you create a classifier `obj`, you can set a custom cost using dot notation:

```
obj.Cost = B;
```

`B` is a square matrix of size `K`-by-`K` when there are `K` classes. You do not need to retrain the classifier when you set a new cost.

Expected Misclassification Cost per Observation

Suppose you have `Nobs` observations that you want to classify with a trained discriminant analysis classifier `obj`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(obj,Xnew)
```

returns, among other outputs, a cost matrix of size `Nobs`-by-`K`. Each row of the cost matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^{K} \widehat{P}(i|X(n))C(k|i),$$

where

- K is the number of classes.
- $\widehat{P}(i|X(n))$ is the posterior probability on page 20-6 of class i for observation $Xnew(n)$.
- $C(k|i)$ is the cost on page 20-7 of classifying an observation as k when its true class is i.

Create and Visualize Discriminant Analysis Classifier

This example shows how to perform linear and quadratic classification of Fisher iris data.

Load the sample data.

```
load fisheriris
```

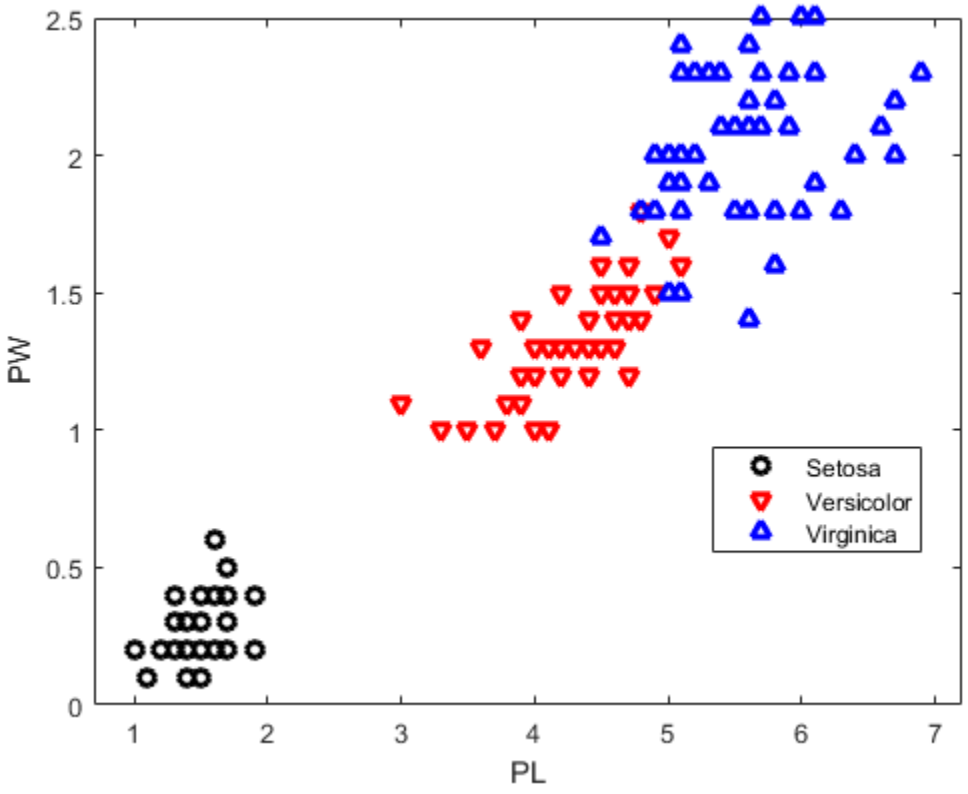
The column vector, `species` , consists of iris flowers of three different species, setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Use petal length (third column in `meas`) and petal width (fourth column in `meas`) measurements. Save these as variables PL and PW, respectively.

```
PL = meas(:,3);
PW = meas(:,4);
```

Plot the data, showing the classification, that is, create a scatter plot of the measurements, grouped by species.

```
h1 = gscatter(PL,PW,species,'krb','ov^',[],'off');
h1(1).LineWidth = 2;
h1(2).LineWidth = 2;
h1(3).LineWidth = 2;
legend('Setosa','Versicolor','Virginica','Location','best')
hold on
```



Create a linear classifier.

```
X = [PL,PW];
MdlLinear = fitcdiscr(X,species);
```

Retrieve the coefficients for the linear boundary between the second and third classes.

```
MdlLinear.ClassNames([2 3])
```

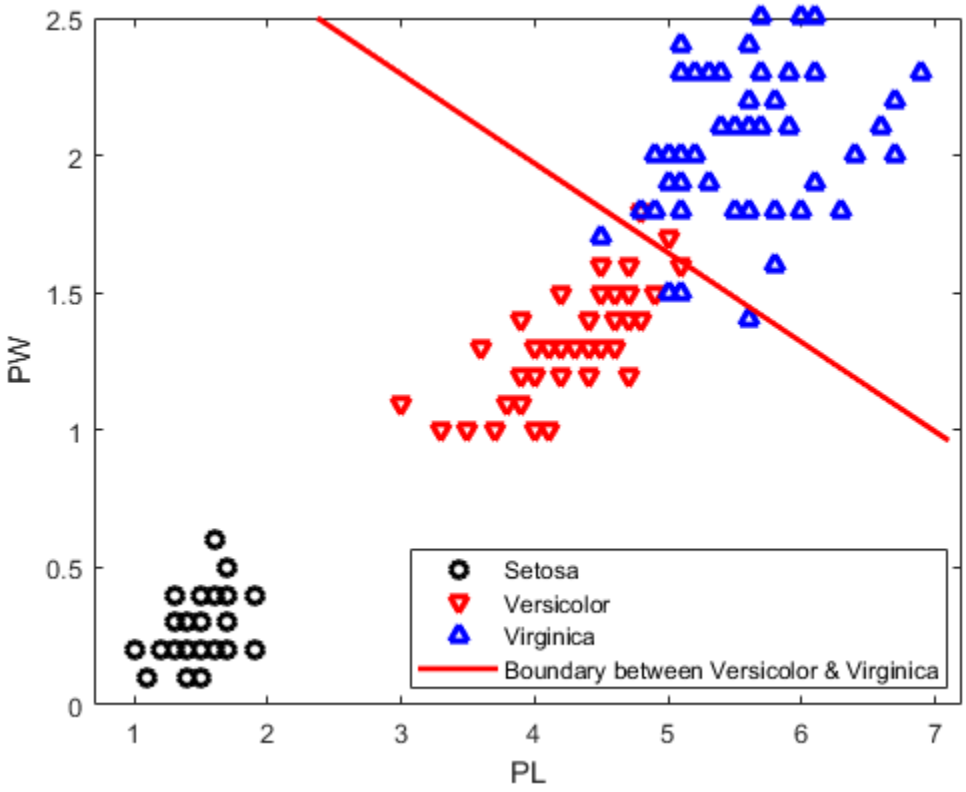
```
ans = 2x1 cell
    {'versicolor'}
    {'virginica' }
```

```
K = MdlLinear.Coeffs(2,3).Const;
L = MdlLinear.Coeffs(2,3).Linear;
```

Plot the curve that separates the second and third classes

$$K + [x_1\ x_2]L = 0\,.$$

```
f = @(x1,x2) K + L(1)*x1 + L(2)*x2;
h2 = fimplicit(f,[.9 7.1 0 2.5]);
h2.Color = 'r';
h2.LineWidth = 2;
h2.DisplayName = 'Boundary between Versicolor & Virginica';
```



Retrieve the coefficients for the linear boundary between the first and second classes.

```

Improving Discriminant Analysis Models

In this section...

Deal with Singular Data

Discriminant analysis needs data sufficient to fit Gaussian models with invertible covariance matrices. If your data is not sufficient to fit such a model uniquely, `fitcdiscr` fails. This section shows methods for handling failures.

Tip To obtain a discriminant analysis classifier without failure, set the `DiscrimType` name-value pair to `'pseudoLinear'` or `'pseudoQuadratic'` in `fitcdiscr`.

“Pseudo” discriminants never fail, because they use the pseudoinverse of the covariance matrix Σ_k (see `pinv`).

Example: Singular Covariance Matrix

When the covariance matrix of the fitted classifier is singular, `fitcdiscr` can fail:

```
load popcorn
X = popcorn(:,[1 2]);
X(:,3) = 0; % a zero-variance column
Y = popcorn(:,3);
ppcrn = fitcdiscr(X,Y);

Error using ClassificationDiscriminant (line 635)
Predictor x3 has zero variance. Either exclude this predictor or set 'discrimType' to
'pseudoLinear' or 'diagLinear'.

Error in classreg.learning.FitTemplate/fit (line 243)
            obj = this.MakeFitObject(X,Y,W,this.ModelParameters,fitArgs{:});

Error in fitcdiscr (line 296)
            this = fit(temp,X,Y);
```

To proceed with linear discriminant analysis, use a `pseudoLinear` or `diagLinear` discriminant type:

```
ppcrn = fitcdiscr(X,Y,...
    'discrimType','pseudoLinear');
meanpredict = predict(ppcrn,mean(X))

meanpredict =
    3.5000
```

Choose a Discriminant Type

There are six types of discriminant analysis classifiers: linear and quadratic, with diagonal and pseudo variants of each type.

Tip To see if your covariance matrix is singular, set `discrimType` to `'linear'` or `'quadratic'`. If the matrix is singular, the `fitcdiscr` method fails for `'quadratic'`, and the `Gamma` property is nonzero for `'linear'`.

To obtain a quadratic classifier even when your covariance matrix is singular, set `DiscrimType` to `'pseudoQuadratic'` or `'diagQuadratic'`.

```
obj = fitcdiscr(X,Y,'DiscrimType','pseudoQuadratic') % or 'diagQuadratic'
```

Choose a classifier type by setting the `discrimType` name-value pair to one of:

- `'linear'` (default) — Estimate one covariance matrix for all classes.
- `'quadratic'` — Estimate one covariance matrix for each class.
- `'diagLinear'` — Use the diagonal of the `'linear'` covariance matrix, and use its pseudoinverse if necessary.
- `'diagQuadratic'` — Use the diagonals of the `'quadratic'` covariance matrices, and use their pseudoinverses if necessary.
- `'pseudoLinear'` — Use the pseudoinverse of the `'linear'` covariance matrix if necessary.
- `'pseudoQuadratic'` — Use the pseudoinverses of the `'quadratic'` covariance matrices if necessary.

`fitcdiscr` can fail for the `'linear'` and `'quadratic'` classifiers. When it fails, it returns an explanation, as shown in “Deal with Singular Data” on page 20-15.

`fitcdiscr` always succeeds with the diagonal and pseudo variants. For information about pseudoinverses, see `pinv`.

You can set the discriminant type using dot notation after constructing a classifier:

```
obj.DiscrimType = 'discrimType'
```

You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

Examine the Resubstitution Error and Confusion Matrix

The resubstitution error is the difference between the response training data and the predictions the classifier makes of the response based on the input training data. If the resubstitution error is high, you cannot expect the predictions of the classifier to be good. However, having low resubstitution error does not guarantee good predictions for new data. Resubstitution error is often an overly optimistic estimate of the predictive error on new data.

The confusion matrix shows how many errors, and which types, arise in resubstitution. When there are `K` classes, the confusion matrix `R` is a `K`-by-`K` matrix with

`R(i,j)` = the number of observations of class `i` that the classifier predicts to be of class `j`.

Example: Resubstitution Error of a Discriminant Analysis Classifier

Examine the resubstitution error of the default discriminant analysis classifier for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
resuberror = resubLoss(obj)

resuberror =
    0.0200
```

The resubstitution error is very low, meaning `obj` classifies nearly all the Fisher iris data correctly. The total number of misclassifications is:

```
resuberror * obj.NumObservations

ans =
    3.0000
```

To see the details of the three misclassifications, examine the confusion matrix:

```
R = confusionmat(obj.Y,resubPredict(obj))

R =
    50     0     0
     0    48     2
     0     1    49

obj.ClassNames

ans =
    'setosa'
    'versicolor'
    'virginica'
```

- `R(1,:) = [50 0 0]` means `obj` classifies all 50 setosa irises correctly.
- `R(2,:) = [0 48 2]` means `obj` classifies 48 versicolor irises correctly, and misclassifies two versicolor irises as virginica.
- `R(3,:) = [0 1 49]` means `obj` classifies 49 virginica irises correctly, and misclassifies one virginica iris as versicolor.

Cross Validation

Typically, discriminant analysis classifiers are robust and do not exhibit overtraining when the number of predictors is much less than the number of observations. Nevertheless, it is good practice to cross validate your classifier to ensure its stability.

Cross Validating a Discriminant Analysis Classifier

This example shows how to perform five-fold cross validation of a quadratic discriminant analysis classifier.

Load the sample data.

```
load fisheriris
```

Create a quadratic discriminant analysis classifier for the data.

```
quadisc = fitcdiscr(meas,species,'DiscrimType','quadratic');
```

Find the resubstitution error of the classifier.

```
qerror = resubLoss(quadisc)
```

```
qerror = 0.0200
```

The classifier does an excellent job. Nevertheless, resubstitution error can be an optimistic estimate of the error when classifying new data. So proceed to cross validation.

Create a cross-validation model.

```
cvmodel = crossval(quadisc,'kfold',5);
```

Find the cross-validation loss for the model, meaning the error of the out-of-fold observations.

```
cverror = kfoldLoss(cvmodel)
```

```
cverror = 0.0200
```

The cross-validated loss is as low as the original resubstitution loss. Therefore, you can have confidence that the classifier is reasonably accurate.

Change Costs and Priors

Sometimes you want to avoid certain misclassification errors more than others. For example, it might be better to have oversensitive cancer detection instead of undersensitive cancer detection. Oversensitive detection gives more false positives (unnecessary testing or treatment). Undersensitive detection gives more false negatives (preventable illnesses or deaths). The consequences of underdetection can be high. Therefore, you might want to set costs to reflect the consequences.

Similarly, the training data `Y` can have a distribution of classes that does not represent their true frequency. If you have a better estimate of the true frequency, you can include this knowledge in the classification `Prior` property.

Example: Setting Custom Misclassification Costs

Consider the Fisher iris data. Suppose that the cost of classifying a versicolor iris as virginica is 10 times as large as making any other classification error. Create a classifier from the data, then incorporate this cost and then view the resulting classifier.

1 Load the Fisher iris data and create a default (linear) classifier as in “Example: Resubstitution Error of a Discriminant Analysis Classifier” on page 20-16:

```
load fisheriris
obj = fitcdiscr(meas,species);
resuberror = resubLoss(obj)

resuberror =
    0.0200

R = confusionmat(obj.Y,resubPredict(obj))

R =
    50     0     0
     0    48     2
     0     1    49
```

```
obj.ClassNames

ans =
    'setosa'
    'versicolor'
    'virginica'
```

`R(2,:) = [0 48 2]` means `obj` classifies 48 versicolor irises correctly, and misclassifies two versicolor irises as virginica.

2 Change the cost matrix to make fewer mistakes in classifying versicolor irises as virginica:

```
obj.Cost(2,3) = 10;
R2 = confusionmat(obj.Y,resubPredict(obj))

R2 =
    50     0     0
     0    50     0
     0     7    43
```

`obj` now classifies all versicolor irises correctly, at the expense of increasing the number of misclassifications of virginica irises from 1 to 7.

Example: Setting Alternative Priors

Consider the Fisher iris data. There are 50 irises of each kind in the data. Suppose that, in a particular region, you have historical data that shows virginica are five times as prevalent as the other kinds. Create a classifier that incorporates this information.

1 Load the Fisher iris data and make a default (linear) classifier as in “Example: Resubstitution Error of a Discriminant Analysis Classifier” on page 20-16:

```
load fisheriris
obj = fitcdiscr(meas,species);
resuberror = resubLoss(obj)

resuberror =
    0.0200

R = confusionmat(obj.Y,resubPredict(obj))

R =
    50     0     0
     0    48     2
     0     1    49

obj.ClassNames

ans =
    'setosa'
    'versicolor'
    'virginica'
```

`R(3,:) = [0 1 49]` means `obj` classifies 49 virginica irises correctly, and misclassifies one virginica iris as versicolor.

2 Change the prior to match your historical data, and examine the confusion matrix of the new classifier:

```
obj.Prior = [1 1 5];
R2 = confusionmat(obj.Y,resubPredict(obj))

R2 =
    50     0     0
     0    46     4
     0     0    50
```

The new classifier classifies all virginica irises correctly, at the expense of increasing the number of misclassifications of versicolor irises from 2 to 4.

Regularize Discriminant Analysis Classifier

This example shows how to make a more robust and simpler model by trying to remove predictors without hurting the predictive power of the model. This is especially important when you have many predictors in your data. Linear discriminant analysis uses the two regularization parameters, “Gamma and Delta” on page 33-1124, to identify and remove redundant predictors. The `cvshrink` method helps identify appropriate settings for these parameters.

Load data and create a classifier.

Create a linear discriminant analysis classifier for the `ovariancancer` data. Set the `SaveMemory` and `FillCoeffs` name-value pair arguments to keep the resulting model reasonably small. For computational ease, this example uses a random subset of about one third of the predictors to train the classifier.

```
load ovariancancer
rng(1); % For reproducibility
numPred = size(obs,2);
obs = obs(:,randsample(numPred,ceil(numPred/3)));
Mdl = fitcdiscr(obs,grp,'SaveMemory','on','FillCoeffs','off');
```

Cross validate the classifier.

Use 25 levels of `Gamma` and 25 levels of `Delta` to search for good parameters. This search is time consuming. Set `Verbose` to `1` to view the progress.

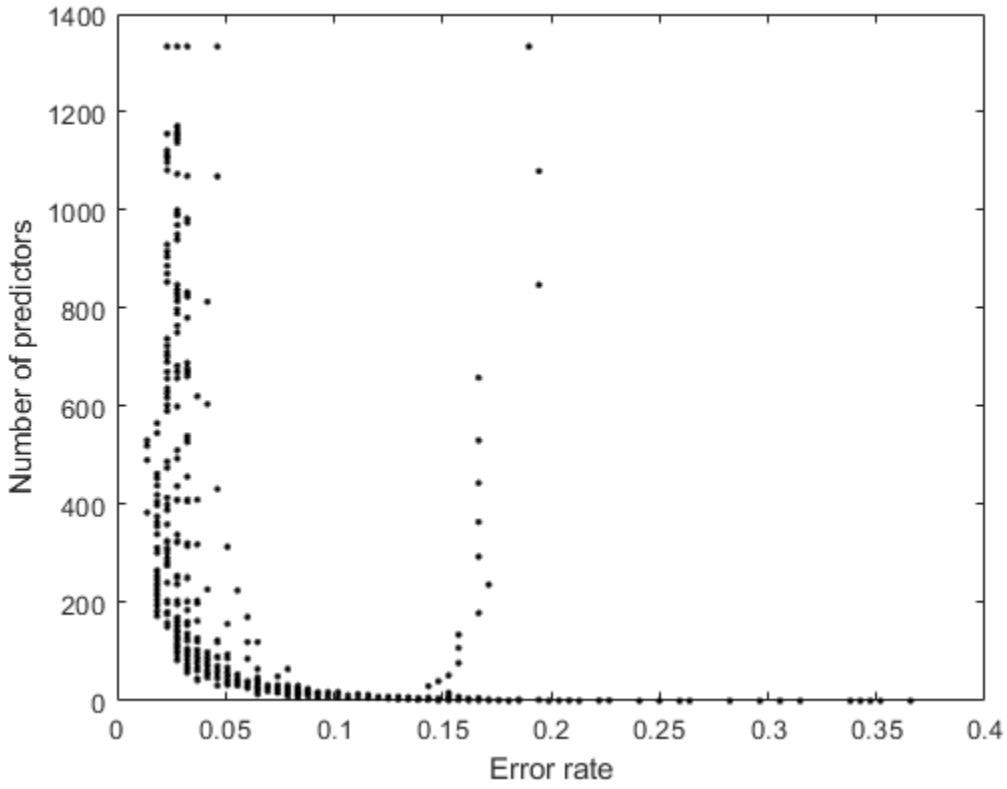
```
[err,gamma,delta,numpred] = cvshrink(Mdl,...
    'NumGamma',24,'NumDelta',24,'Verbose',1);
```

```
Done building cross-validated model.
Processing Gamma step 1 out of 25.
Processing Gamma step 2 out of 25.
Processing Gamma step 3 out of 25.
Processing Gamma step 4 out of 25.
Processing Gamma step 5 out of 25.
Processing Gamma step 6 out of 25.
Processing Gamma step 7 out of 25.
Processing Gamma step 8 out of 25.
Processing Gamma step 9 out of 25.
Processing Gamma step 10 out of 25.
Processing Gamma step 11 out of 25.
Processing Gamma step 12 out of 25.
Processing Gamma step 13 out of 25.
Processing Gamma step 14 out of 25.
Processing Gamma step 15 out of 25.
Processing Gamma step 16 out of 25.
Processing Gamma step 17 out of 25.
Processing Gamma step 18 out of 25.
Processing Gamma step 19 out of 25.
Processing Gamma step 20 out of 25.
Processing Gamma step 21 out of 25.
Processing Gamma step 22 out of 25.
Processing Gamma step 23 out of 25.
Processing Gamma step 24 out of 25.
Processing Gamma step 25 out of 25.
```

Examine the quality of the regularized classifiers.

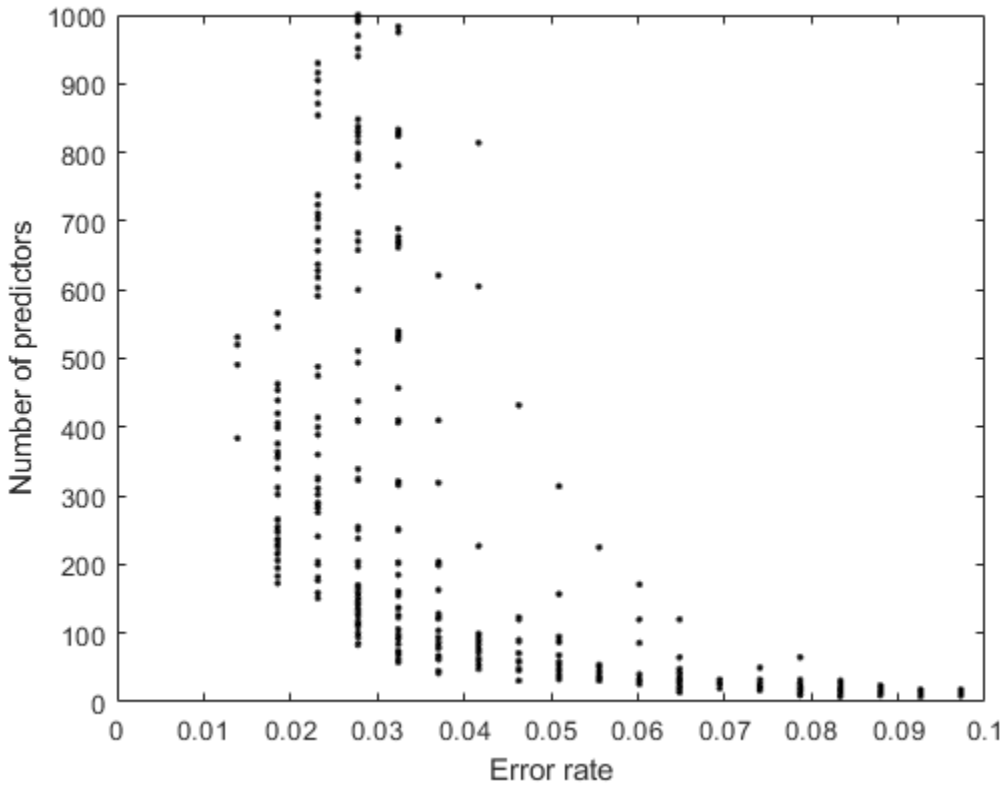
Plot the number of predictors against the error.

```
plot(err,numpred,'k.')
xlabel('Error rate')
ylabel('Number of predictors')
```



Examine the lower-left part of the plot more closely.

```
axis([0 .1 0 1000])
```



There is a clear tradeoff between lower number of predictors and lower error.

Choose an optimal tradeoff between model size and accuracy.

Multiple pairs of `Gamma` and `Delta` values produce about the same minimal error. Display the indices of these pairs and their values.

First, find the minimal error value.

```
minerr = min(min(err))
```

```
minerr = 0.0139
```

Find the subscripts of `err` producing minimal error.

```
[p,q] = find(err < minerr + 1e-4);
```

Convert from subscripts to linear indices.

```
idx = sub2ind(size(delta),p,q);
```

Display the `Gamma` and `Delta` values.

```
[gamma(p) delta(idx)]
```

```
ans = 4×2

    0.7202    0.1145
```

```
    0.7602    0.1131
    0.8001    0.1128
    0.8001    0.1410
```

These points have as few as 29% of the total predictors with nonzero coefficients in the model.

```
numpred(idx)/ceil(numPred/3)*100
```

```
ans = 4×1

   39.8051
   38.9805
   36.8066
   28.7856
```

To further lower the number of predictors, you must accept larger error rates. For example, to choose the `Gamma` and `Delta` that give the lowest error rate with 200 or fewer predictors.

```
low200 = min(min(err(numpred <= 200)));
lownum = min(min(numpred(err == low200)));
[low200 lownum]
```

```
ans = 1×2

    0.0185  173.0000
```

You need 173 predictors to achieve an error rate of 0.0185, and this is the lowest error rate among those that have 200 predictors or fewer.

Display the `Gamma` and `Delta` that achieve this error/number of predictors.

```
[r,s] = find((err == low200) & (numpred == lownum));
[gamma(r); delta(r,s)]
```

```
ans = 2×1

    0.6403
    0.2399
```

Set the regularization parameters.

To set the classifier with these values of `Gamma` and `Delta`, use dot notation.

```
Mdl.Gamma = gamma(r);
Mdl.Delta = delta(r,s);
```

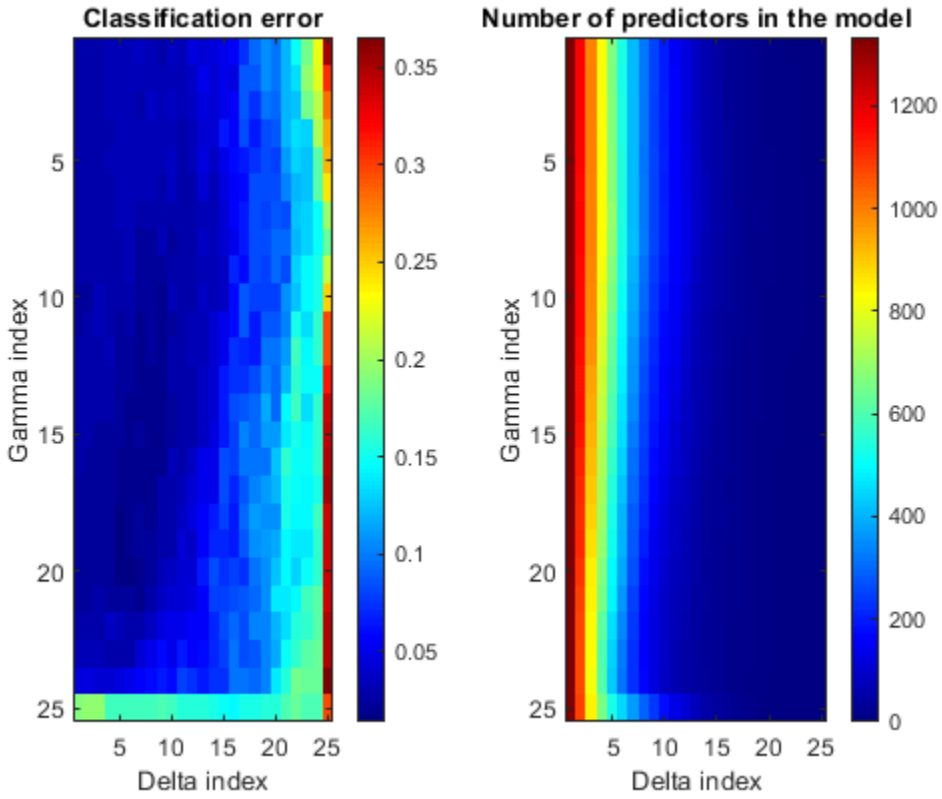
Heatmap plot

To compare the `cvshrink` calculation to that in Guo, Hastie, and Tibshirani [1], plot heatmaps of error and number of predictors against `Gamma` and the index of the `Delta` parameter. (The `Delta` parameter range depends on the value of the `Gamma` parameter. So to get a rectangular plot, use the `Delta` index, not the parameter itself.)

```
% Create the Delta index matrix
indx = repmat(1:size(delta,2),size(delta,1),1);
```

```
figure
subplot(1,2,1)
imagesc(err)
colorbar
colormap('jet')
title('Classification error')
xlabel('Delta index')
ylabel('Gamma index')

subplot(1,2,2)
imagesc(numpred)
colorbar
title('Number of predictors in the model')
xlabel('Delta index')
ylabel('Gamma index')
```



You see the best classification error when `Delta` is small, but fewest predictors when `Delta` is large.

Examine the Gaussian Mixture Assumption

Discriminant analysis assumes that the data comes from a Gaussian mixture model (see “Creating Discriminant Analysis Model” on page 20-4). If the data appears to come from a Gaussian mixture model, you can expect discriminant analysis to be a good classifier. Furthermore, the default linear discriminant analysis assumes that all class covariance matrices are equal. This section shows methods to check these assumptions:

In this section...
“Bartlett Test of Equal Covariance Matrices for Linear Discriminant Analysis” on page 20-27
“Q-Q Plot” on page 20-29
“Mardia Kurtosis Test of Multivariate Normality” on page 20-31

Bartlett Test of Equal Covariance Matrices for Linear Discriminant Analysis

The Bartlett test (see Box [1]) checks equality of the covariance matrices of the various classes. If the covariance matrices are equal, the test indicates that linear discriminant analysis is appropriate. If not, consider using quadratic discriminant analysis, setting the `DiscrimType` name-value pair argument to `'quadratic'` in `fitcdiscr`.

The Bartlett test assumes normal (Gaussian) samples, where neither the means nor covariance matrices are known. To determine whether the covariances are equal, compute the following quantities:

- Sample covariance matrices per class Σ_i, $1 \le i \le k$, where k is the number of classes.
- Pooled-in covariance matrix Σ.
- Test statistic V:

  $$V = (n-k)\log(|\Sigma|) - \sum_{i=1}^{k}(n_i-1)\log(|\Sigma_i|)$$

  where n is the total number of observations, n_i is the number of observations in class i, and $|\Sigma|$ means the determinant of the matrix Σ.
- Asymptotically, as the number of observations in each class n_i becomes large, V is distributed approximately χ^2 with $kd(d+1)/2$ degrees of freedom, where d is the number of predictors (number of dimensions in the data).

The Bartlett test is to check whether V exceeds a given percentile of the χ^2 distribution with $kd(d+1)/2$ degrees of freedom. If it does, then reject the hypothesis that the covariances are equal.

Bartlett Test of Equal Covariance Matrices

Check whether the Fisher iris data is well modeled by a single Gaussian covariance, or whether it is better modeled as a Gaussian mixture by performing a Bartlett test of equal covariance matrices.

Load the `fisheriris` data set.

```
load fisheriris;
prednames = {'SepalLength','SepalWidth','PetalLength','PetalWidth'};
```

When all the class covariance matrices are equal, a linear discriminant analysis is appropriate.

Train a linear discriminant analysis model (the default type) using the Fisher iris data.

```
L = fitcdiscr(meas,species,'PredictorNames',prednames);
```

When the class covariance matrices are not equal, a quadratic discriminant analysis is appropriate.

Train a quadratic discriminant analysis model using the Fisher iris data and compute statistics

```
Q = fitcdiscr(meas,species,'PredictorNames',prednames,'DiscrimType','quadratic');
```

Store as variables the number of observations `N`, dimension of the data set `D`, number of classes `K`, and number of observations in each class `Nclass`.

```
[N,D] = size(meas)
```

```
N = 150
```

```
D = 4
```

```
K = numel(unique(species))
```

```
K = 3
```

```
Nclass = grpstats(meas(:,1),species,'numel')'
```

```
Nclass = 1×3

    50    50    50
```

Compute the test statistic `V`.

```
SigmaL = L.Sigma;
SigmaQ = Q.Sigma;
V = (N-K)*log(det(SigmaL));
for k=1:K
    V = V - (Nclass(k)-1)*log(det(SigmaQ(:,:,k)));
end
V
```

```
V = 146.6632
```

Compute the *p*-value.

```
nu = K*D*(D+1)/2;
pval1 = chi2cdf(V,nu,'upper')
```

```
pval1 = 2.6091e-17
```

Because `pval1` is smaller than 0.05, the Bartlett test rejects the hypothesis of equal covariance matrices. The result indicates to use quadratic discriminant analysis, as opposed to linear discriminant analysis.

Q-Q Plot

A Q-Q plot graphically shows whether an empirical distribution is close to a theoretical distribution. If the two are equal, the Q-Q plot lies on a 45° line. If not, the Q-Q plot strays from the 45° line.

Compare Q-Q Plots for Linear and Quadratic Discriminants

Analyze the Q-Q plots to check whether the Fisher iris data is better modeled by a single Gaussian covariance or as a Gaussian mixture.

Load the `fisheriris` data set.

```
load fisheriris;
prednames = {'SepalLength','SepalWidth','PetalLength','PetalWidth'};
```

When all the class covariance matrices are equal, a linear discriminant analysis is appropriate.

Train a linear discriminant analysis model.

```
L = fitcdiscr(meas,species,'PredictorNames',prednames);
```

When the class covariance matrices are not equal, a quadratic discriminant analysis is appropriate.

Train a quadratic discriminant analysis model using the Fisher iris data.

```
Q = fitcdiscr(meas,species,'PredictorNames',prednames,'DiscrimType','quadratic');
```

Compute the number of observations, dimension of the data set, and expected quantiles.

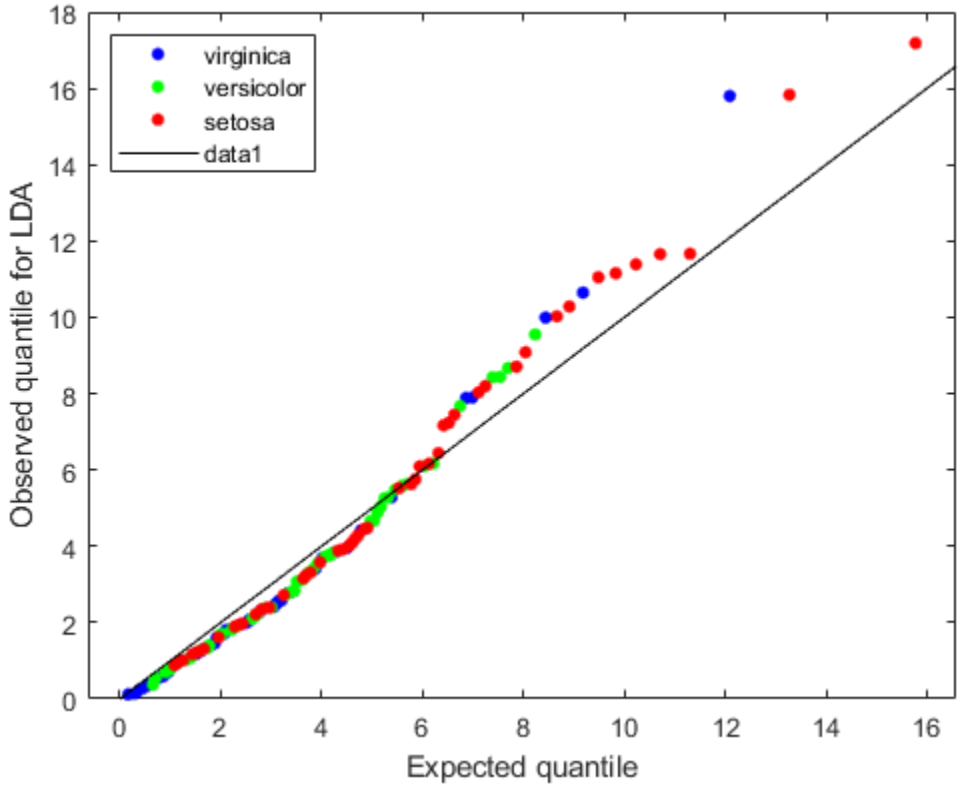
```
[N,D] = size(meas);
expQuant = chi2inv(((1:N)-0.5)/N,D);
```

Compute the observed quantiles for the linear discriminant model.

```
obsL = mahal(L,L.X,'ClassLabels',L.Y);
[obsL,sortedL] = sort(obsL);
```

Graph the Q-Q plot for the linear discriminant.

```
figure;
gscatter(expQuant,obsL,L.Y(sortedL),'bgr',[],[],'off');
legend('virginica','versicolor','setosa','Location','NW');
xlabel('Expected quantile');
ylabel('Observed quantile for LDA');
line([0 20],[0 20],'color','k');
```



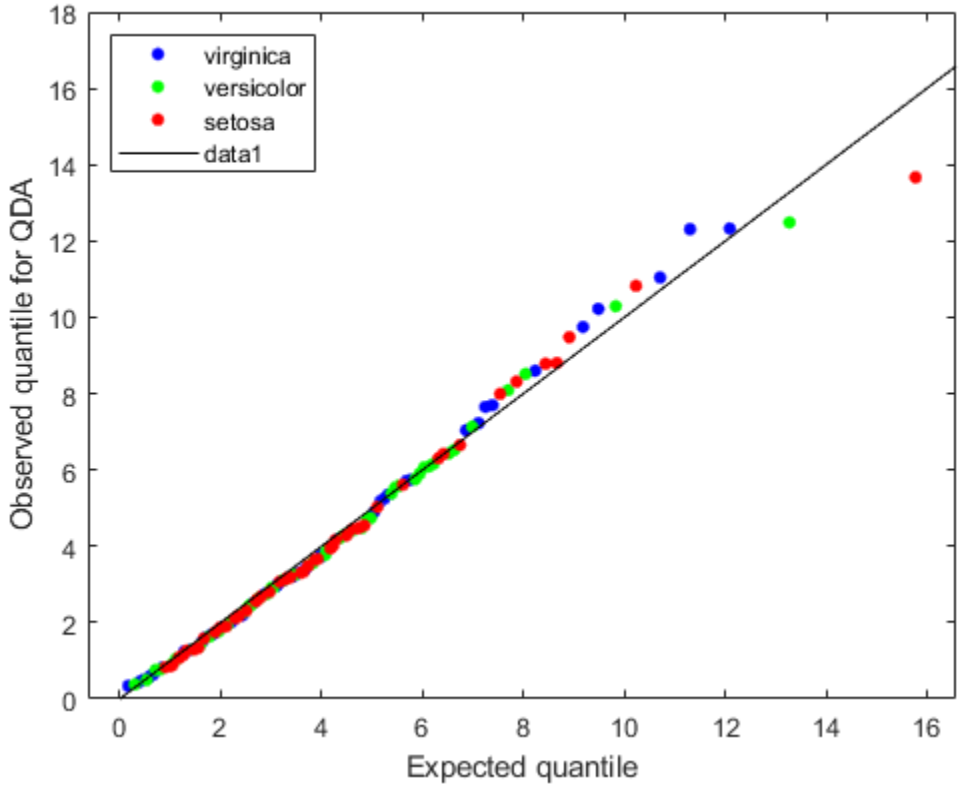
The expected and observed quantiles agree somewhat. The deviation of the plot from the 45° line upward indicates that the data has heavier tails than a normal distribution. The plot shows three possible outliers at the top: two observations from class `'setosa'` and one observation from class `'virginica'`.

Compute the observed quantiles for the quadratic discriminant model.

```
obsQ = mahal(Q,Q.X,'ClassLabels',Q.Y);
[obsQ,sortedQ] = sort(obsQ);
```

Graph the Q-Q plot for the quadratic discriminant.

```
figure;
gscatter(expQuant,obsQ,Q.Y(sortedQ),'bgr',[],[],'off');
legend('virginica','versicolor','setosa','Location','NW');
xlabel('Expected quantile');
ylabel('Observed quantile for QDA');
line([0 20],[0 20],'color','k');
```



The Q-Q plot for the quadratic discriminant shows a better agreement between the observed and expected quantiles. The plot shows only one possible outlier from class `'setosa'`. The Fisher iris data is better modeled as a Gaussian mixture with covariance matrices that are not required to be equal across classes.

Mardia Kurtosis Test of Multivariate Normality

The Mardia kurtosis test (see Mardia [2]) is an alternative to examining a Q-Q plot. It gives a numeric approach to deciding if data matches a Gaussian mixture model.

In the Mardia kurtosis test you compute M, the mean of the fourth power of the Mahalanobis distance of the data from the class means. If the data is normally distributed with a constant covariance matrix (and is thus suitable for linear discriminant analysis), M is asymptotically distributed as normal with mean $d(d + 2)$ and variance $8d(d + 2)/n$, where

- d is the number of predictors (number of dimensions in the data).
- n is the total number of observations.

The Mardia test is two sided: check whether M is close enough to $d(d + 2)$ with respect to a normal distribution of variance $8d(d + 2)/n$.

Mardia Kurtosis Test for Linear and Quadratic Discriminants

Perform a Mardia kurtosis tests to check whether the Fisher iris data is approximately normally distributed for both linear and quadratic discriminant analyses.

Load the `fisheriris` data set.

```
load fisheriris;
prednames = {'SepalLength','SepalWidth','PetalLength','PetalWidth'};
```

When all the class covariance matrices are equal, a linear discriminant analysis is appropriate.

Train a linear discriminant analysis model.

```
L = fitcdiscr(meas,species,'PredictorNames',prednames);
```

When the class covariance matrices are not equal, a quadratic discriminant analysis is appropriate.

Train a quadratic discriminant analysis model using the Fisher iris data.

```
Q = fitcdiscr(meas,species,'PredictorNames',prednames,'DiscrimType','quadratic');
```

Compute the mean and variance of the asymptotic distribution.

```
[N,D] = size(meas);
meanKurt = D*(D+2)
```

```
meanKurt = 24
```

```
varKurt = 8*D*(D+2)/N
```

```
varKurt = 1.2800
```

Compute the *p*-value for the Mardia kurtosis test on the linear discriminant model.

```
mahL = mahal(L,L.X,'ClassLabels',L.Y);
meanL = mean(mahL.^2);
[~,pvalL] = ztest(meanL,meanKurt,sqrt(varKurt))
```

```
pvalL = 0.0208
```

Because `pvalL` is smaller than 0.05, the Mardia kurtosis test rejects the hypothesis of the data being normally distributed with a constant covariance matrix.

Compute the *p*-value for the Mardia kurtosis test on the quadratic discriminant model.

```
mahQ = mahal(Q,Q.X,'ClassLabels',Q.Y);
meanQ = mean(mahQ.^2);
[~,pvalQ] = ztest(meanQ,meanKurt,sqrt(varKurt))
```

```
pvalQ = 0.7230
```

Because `pvalQ` is greater than 0.05, the data is consistent with the multivariate normal distribution.

The results indicate to use quadratic discriminant analysis, as opposed to linear discriminant analysis.

Naive Bayes

Naive Bayes Classification

The naive Bayes classifier is designed for use when predictors are independent of one another within each class, but it appears to work well in practice even when that independence assumption is not valid. It classifies data in two steps:

1. Training step: Using the training data, the method estimates the parameters of a probability distribution, assuming predictors are conditionally independent given the class.
2. Prediction step: For any unseen test data, the method computes the posterior probability of that sample belonging to each class. The method then classifies the test data according the largest posterior probability.

The class-conditional independence assumption greatly simplifies the training step since you can estimate the one-dimensional class-conditional density for each predictor individually. While the class-conditional independence between predictors is not true in general, research shows that this optimistic assumption works well in practice. This assumption of class-conditional independence of the predictors allows the naive Bayes classifier to estimate the parameters required for accurate classification while using less training data than many other classifiers. This makes it particularly effective for data sets containing many predictors.

Supported Distributions

The training step in naive Bayes classification is based on estimating $P(X|Y)$, the probability or probability density of predictors `X` given class `Y`. The naive Bayes classification model `ClassificationNaiveBayes` and training function `fitcnb` provide support for normal (Gaussian), kernel, multinomial, and multivariate, multinomial predictor conditional distributions. To specify distributions for the predictors, use the `DistributionNames` name-value pair argument of `fitcnb`. You can specify one type of distribution for all predictors by supplying the character vector or string scalar corresponding to the distribution name, or specify different distributions for the predictors by supplying a length D string array or cell array of character vectors, where D is the number of predictors (that is, the number of columns of X).

Normal (Gaussian) Distribution

The `'normal'` distribution (specify using `'normal'`) is appropriate for predictors that have normal distributions in each class. For each predictor you model with a normal distribution, the naive Bayes classifier estimates a separate normal distribution for each class by computing the mean and standard deviation of the training data in that class.

Kernel Distribution

The `'kernel'` distribution (specify using `'kernel'`) is appropriate for predictors that have a continuous distribution. It does not require a strong assumption such as a normal distribution and you can use it in cases where the distribution of a predictor may be skewed or have multiple peaks or modes. It requires more computing time and more memory than the normal distribution. For each predictor you model with a kernel distribution, the naive Bayes classifier computes a separate kernel density estimate for each class based on the training data for that class. By default the kernel is the normal kernel, and the classifier selects a width automatically for each class and predictor. The software supports specifying different kernels for each predictor, and different widths for each predictor or class.

Multivariate Multinomial Distribution

The multivariate, multinomial distribution (specify using `'mvmn'`) is appropriate for a predictor whose observations are categorical. Naive Bayes classifier construction using a multivariate multinomial predictor is described below. To illustrate the steps, consider an example where observations are labeled 0, 1, or 2, and a predictor the weather when the sample was conducted.

1. Record the distinct categories represented in the observations of the entire predictor. For example, the distinct categories (or predictor levels) might include sunny, rain, snow, and cloudy.
2. Separate the observations by response class. For example, segregate observations labeled 0 from observations labeled 1 and 2, and observations labeled 1 from observations labeled 2.
3. For each response class, fit a multinomial model using the category relative frequencies and total number of observations. For example, for observations labeled 0, the estimated probability it was sunny is $p_{sunny|0}$ = (number of sunny observations with label 0)/(number of observations with label 0), and similar for the other categories and response labels.

The class-conditional, multinomial random variables comprise a multivariate multinomial random variable.

Here are some other properties of naive Bayes classifiers that use multivariate multinomial.

- For each predictor you model with a multivariate multinomial distribution, the naive Bayes classifier:
  - Records a separate set of distinct predictor levels for each predictor
  - Computes a separate set of probabilities for the set of predictor levels for each class.
- The software supports modeling continuous predictors as multivariate multinomial. In this case, the predictor levels are the distinct occurrences of a measurement. This can lead a predictor having many predictor levels. It is good practice to discretize such predictors.

If an *observation* is a set of successes for various categories (represented by all of the predictors) out of a fixed number of independent trials, then specify that the predictors comprise a multinomial distribution. For details, see “Multinomial Distribution” on page 21-3.

Multinomial Distribution

The multinomial distribution (specify using `'DistributionNames','mn'`) is appropriate when, given the class, each *observation* is a multinomial random variable. That is, observation, or row, j of the predictor data X represents D categories, where x_{jd} is the number of successes for category (i.e., predictor) d in $n_j = \sum_{d=1}^{D} x_{jd}$ independent trials. The steps to train a naive Bayes classifier are outlined next.

1. For each class, fit a multinomial distribution for the predictors given the class by:
   a. Aggregating the weighted, category counts over all observations. Additionally, the software implements additive smoothing [1].
   b. Estimating the D category probabilities within each class using the aggregated category counts. These category probabilities compose the probability parameters of the multinomial distribution.
2. Let a new observation have a total count of m. Then, the naive Bayes classifier:

a Sets the total count parameter of each multinomial distribution to m

b For each class, estimates the class posterior probability using the estimated multinomial distributions

c Predicts the observation into the class corresponding to the highest posterior probability

Consider the so-called the bag-of-tokens model, where there is a bag containing a number of tokens of various types and proportions. Each predictor represents a distinct type of token in the bag, an observation is n independent draws (i.e., with replacement) of tokens from the bag, and the data is a vector of counts, where element d is the number of times token d appears.

A machine-learning application is the construction of an email spam classifier, where each predictor represents a word, character, or phrase (i.e., token), an observation is an email, and the data are counts of the tokens in the email. One predictor might count the number of exclamation points, another might count the number of times the word "money" appears, and another might count the number of times the recipient's name appears. This is a naive Bayes model under the further assumption that the total number of tokens (or the total document length) is independent of response class.

Other properties of naive Bayes classifiers that use multinomial observations include:

- Classification is based on the relative frequencies of the categories. If $n_j = 0$ for observation j, then classification is not possible for that observation.
- The predictors are not conditionally independent since they must sum to n_j.
- Naive Bayes is not appropriate when n_j provides information about the class. That is, this classifier requires that n_j is independent of the class.
- If you specify that the predictors are conditionally multinomial, then the software applies this specification to all predictors. In other words, you cannot include `'mn'` in a cell array when specifying `'DistributionNames'`.

If a *predictor* is categorical, i.e., is multinomial within a response class, then specify that it is multivariate multinomial. For details, see “Multivariate Multinomial Distribution” on page 21-3.

Plot Posterior Classification Probabilities

This example shows how to visualize posterior classification probabilities predicted by a naive Bayes classification model.

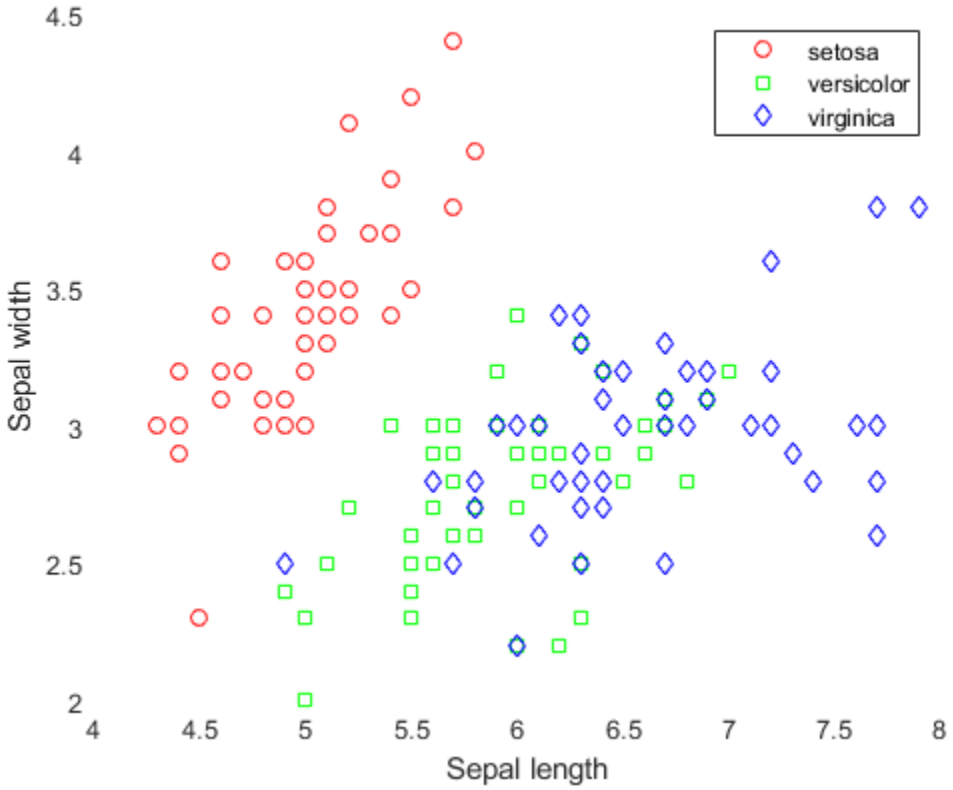
Load Fisher's iris data set.

```
load fisheriris
X = meas(:,1:2);
Y = species;
labels = unique(Y);
```

X is a numeric matrix that contains two petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Visualize the data using a scatter plot. Group the variables by iris species.

```
figure;
gscatter(X(:,1), X(:,2), species,'rgb','osd');
xlabel('Sepal length');
ylabel('Sepal width');
```



Train a naive Bayes classifier.

```
mdl = fitcnb(X,Y);
```

`mdl` is a trained `ClassificationNaiveBayes` classifier.

Create a grid of points spanning the entire space within some bounds of the data. The data in `X(:,1)` ranges between 4.3 and 7.9. The data in `X(:,2)` ranges between 2 and 4.4.

```
[xx1, xx2] = meshgrid(4:.01:8,2:.01:4.5);
XGrid = [xx1(:) xx2(:)];
```

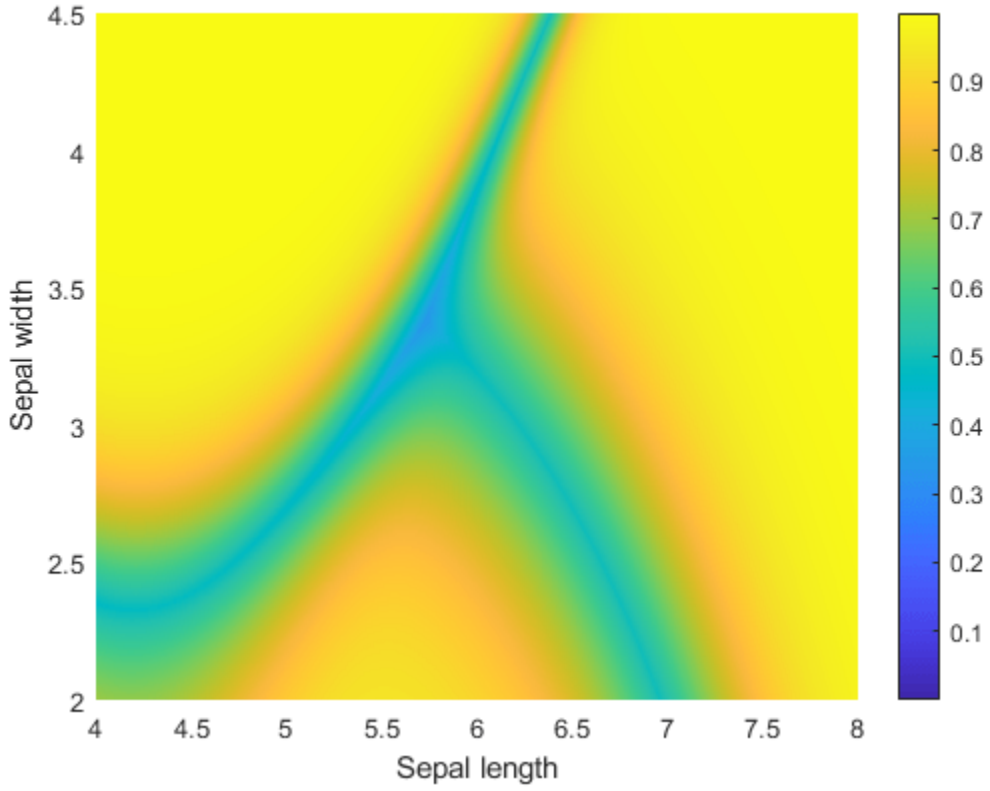
Predict the iris species and posterior class probabilities of each observation in `XGrid` using `mdl`.

```
[predictedspecies,Posterior,~] = predict(mdl,XGrid);
```

Plot the posterior probability distribution for each species.

```
sz = size(xx1);
s = max(Posterior,[],2);

figure
hold on
surf(xx1,xx2,reshape(Posterior(:,1),sz),'EdgeColor','none')
surf(xx1,xx2,reshape(Posterior(:,2),sz),'EdgeColor','none')
surf(xx1,xx2,reshape(Posterior(:,3),sz),'EdgeColor','none')
xlabel('Sepal length');
ylabel('Sepal width');
colorbar
view(2)
hold off
```



The closer an observation gets to the decision surface, the less probable it is that the data belongs to a certain species.

Plot the classification probability distributions individually.

```
figure('Units','Normalized','Position',[0.25,0.55,0.4,0.35]);
hold on
surf(xx1,xx2,reshape(Posterior(:,1),sz),'FaceColor','red','EdgeColor','none')
surf(xx1,xx2,reshape(Posterior(:,2),sz),'FaceColor','blue','EdgeColor','none')
surf(xx1,xx2,reshape(Posterior(:,3),sz),'FaceColor','green','EdgeColor','none')
xlabel('Sepal length');
ylabel('Sepal width');
zlabel('Probability');
legend(labels)
title('Classification Probability')
alpha(0.2)
view(3)
hold off
```

Classification and Regression for High-Dimensional Data

Classification Learner

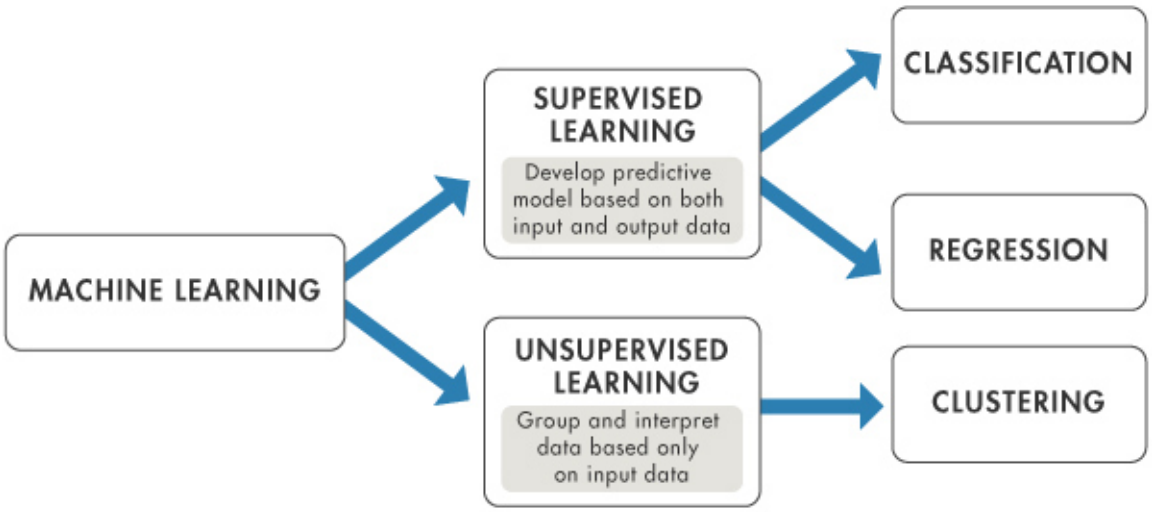
Machine Learning in MATLAB

In this section...

What Is Machine Learning?

Machine learning teaches computers to do what comes naturally to humans: learn from experience. Machine learning algorithms use computational methods to “learn” information directly from data without relying on a predetermined equation as a model. The algorithms adaptively improve their performance as the number of samples available for learning increases.

Machine learning uses two types of techniques: supervised learning, which trains a model on known input and output data so that it can predict future outputs, and unsupervised learning, which finds hidden patterns or intrinsic structures in input data.



The aim of supervised machine learning is to build a model that makes predictions based on evidence in the presence of uncertainty. A supervised learning algorithm takes a known set of input data and known responses to the data (output) and trains a model to generate reasonable predictions for the response to new data. Supervised learning uses classification and regression techniques to develop predictive models.

- Classification techniques predict categorical responses, for example, whether an email is genuine or spam, or whether a tumor is cancerous or benign. Classification models classify input data into categories. Typical applications include medical imaging, image and speech recognition, and credit scoring.

- Regression techniques predict continuous responses, for example, changes in temperature or fluctuations in power demand. Typical applications include electricity load forecasting and algorithmic trading.

Unsupervised learning finds hidden patterns or intrinsic structures in data. It is used to draw inferences from datasets consisting of input data without labeled responses. Clustering is the most common unsupervised learning technique. It is used for exploratory data analysis to find hidden patterns or groupings in data. Applications for clustering include gene sequence analysis, market research, and object recognition.

Selecting the Right Algorithm

Choosing the right algorithm can seem overwhelming—there are dozens of supervised and unsupervised machine learning algorithms, and each takes a different approach to learning. There is no best method or one size fits all. Finding the right algorithm is partly based on trial and error—even highly experienced data scientists cannot tell whether an algorithm will work without trying it out. Highly flexible models tend to overfit data by modeling minor variations that could be noise. Simple models are easier to interpret but might have lower accuracy. Therefore, choosing the right algorithm requires trading off one benefit against another, including model speed, accuracy, and complexity. Trial and error is at the core of machine learning—if one approach or algorithm does not work, you try another. MATLAB provides tools to help you try out a variety of machine learning models and choose the best.

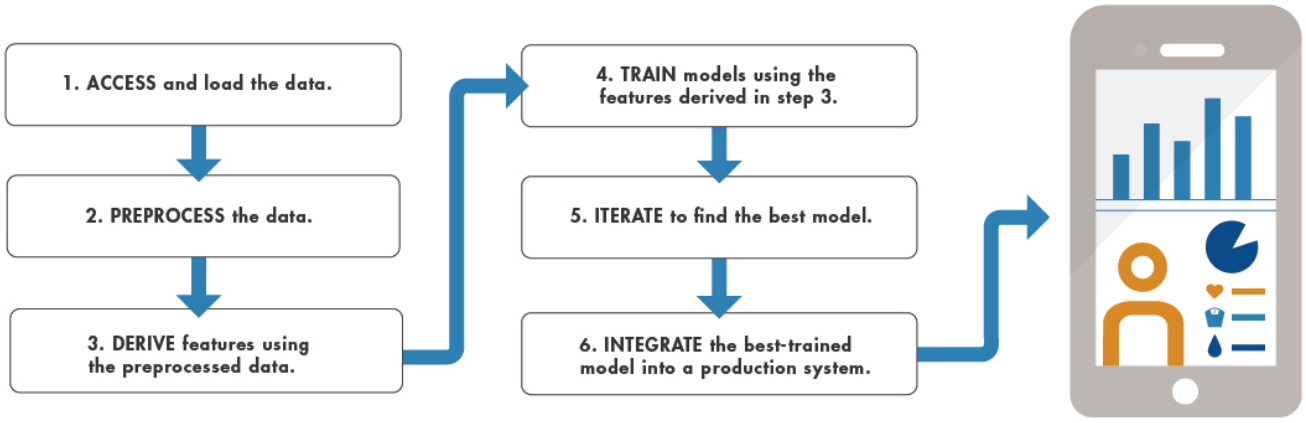
To find MATLAB apps and functions to help you solve machine learning tasks, consult the following table. Some machine learning tasks are made easier by using apps, and others use command-line features.

Task	MATLAB Apps and Functions	Product	Learn More
Classification to predict categorical responses	Use the Classification Learner app to automatically train a selection of models and help you choose the best. You can generate MATLAB code to work with scripts. For more options, you can use the command-line interface.	Statistics and Machine Learning Toolbox	"Train Classification Models in Classification Learner App" on page 23-6 Classification Functions
Regression to predict continuous responses	Use the Regression Learner app to automatically train a selection of models and help you choose the best. You can generate MATLAB code to work with scripts and other function options. For more options, you can use the command-line interface.	Statistics and Machine Learning Toolbox	"Train Regression Models in Regression Learner App" on page 23-7 Regression Functions
Clustering	Use cluster analysis functions.	Statistics and Machine Learning Toolbox	"Cluster Analysis"
Computational finance tasks such as credit scoring	Use tools for modeling credit risk analysis.	Financial Toolbox™ and Risk Management Toolbox™	"Credit Risk" (Financial Toolbox)
Deep learning with neural networks for classification and regression	Use pretrained networks and functions to train convolutional neural networks.	Deep Learning Toolbox™	"Deep Learning in MATLAB" (Deep Learning Toolbox)
Facial recognition, motion detection, and object detection	Use deep learning tools for image processing and computer vision.	Deep Learning Toolbox and Computer Vision Toolbox™	"Recognition, Object Detection, and Semantic Segmentation" (Computer Vision Toolbox)

The following systematic machine learning workflow can help you tackle machine learning challenges. You can complete the entire workflow in MATLAB.



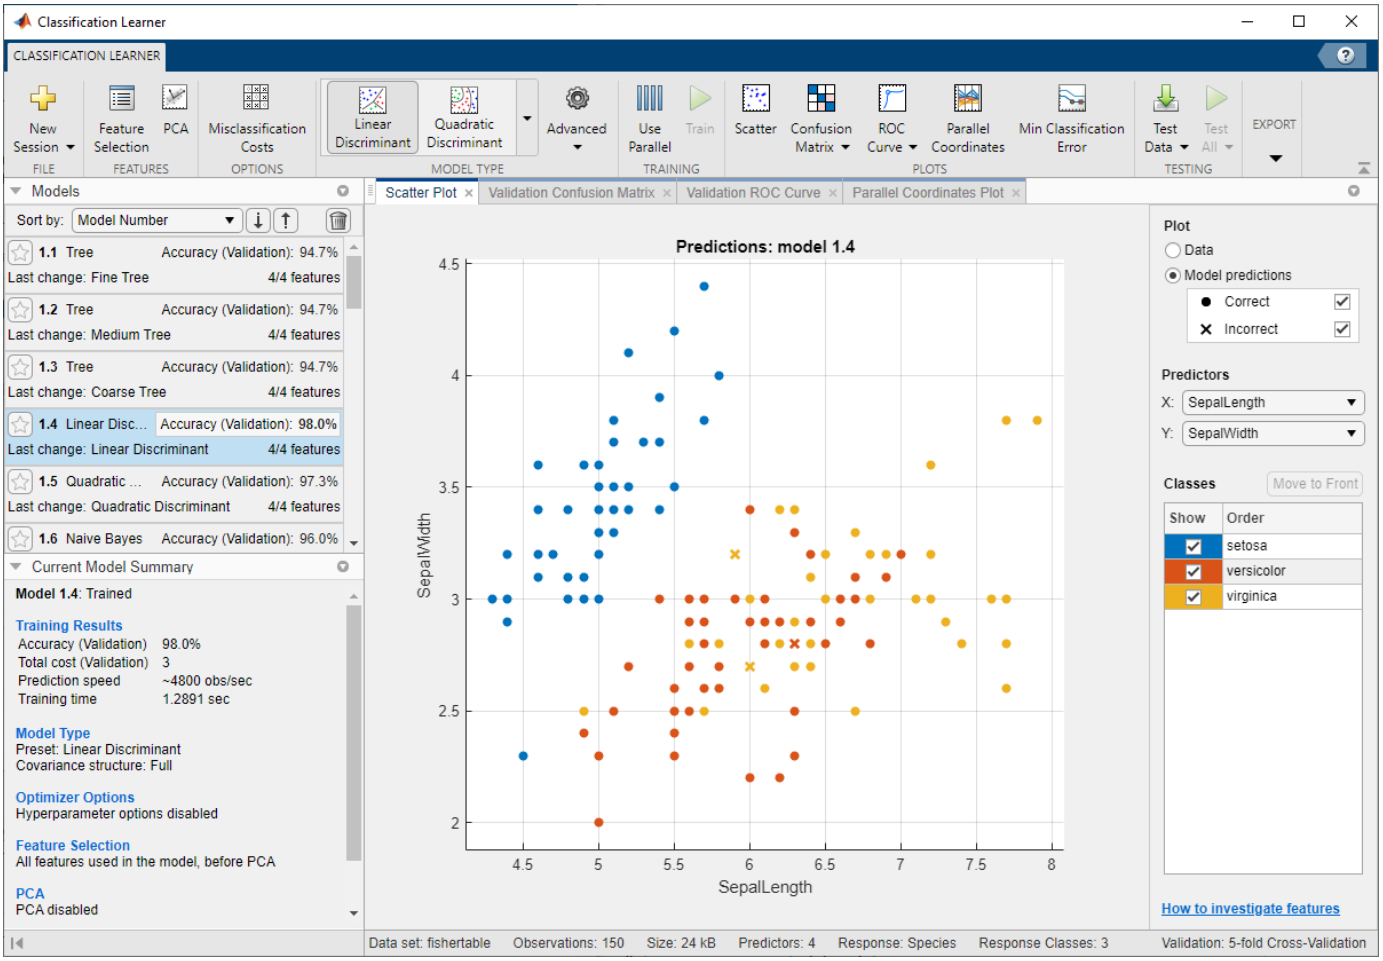
To integrate the best trained model into a production system, you can deploy Statistics and Machine Learning Toolbox machine learning models using MATLAB Compiler™. For many models, you can generate C-code for prediction using MATLAB Coder.

Train Classification Models in Classification Learner App

Use the Classification Learner app to train models to classify data using supervised machine learning. The app lets you explore supervised machine learning interactively using various classifiers.

- Automatically train a selection of models to help you choose the best model. Model types include decision trees, discriminant analysis, support vector machines, logistic regression, nearest neighbors, naive Bayes, ensemble, and neural network classifiers.
- Explore your data, specify validation schemes, select features, and visualize results. By default, the app protects against overfitting by applying cross-validation. Alternatively, you can select holdout validation. Validation results help you choose the best model for your data. Plots and performance measures reflect the validated model results.
- Export models to the workspace to make predictions with new data. The app always trains a model on full data in addition to a model with the specified validation scheme, and the full model is the model you export.
- Generate MATLAB code from the app to create scripts, train with new data, work with huge data sets, or modify the code for further analysis.

To learn more, see “Train Classification Models in Classification Learner App” on page 23-10.



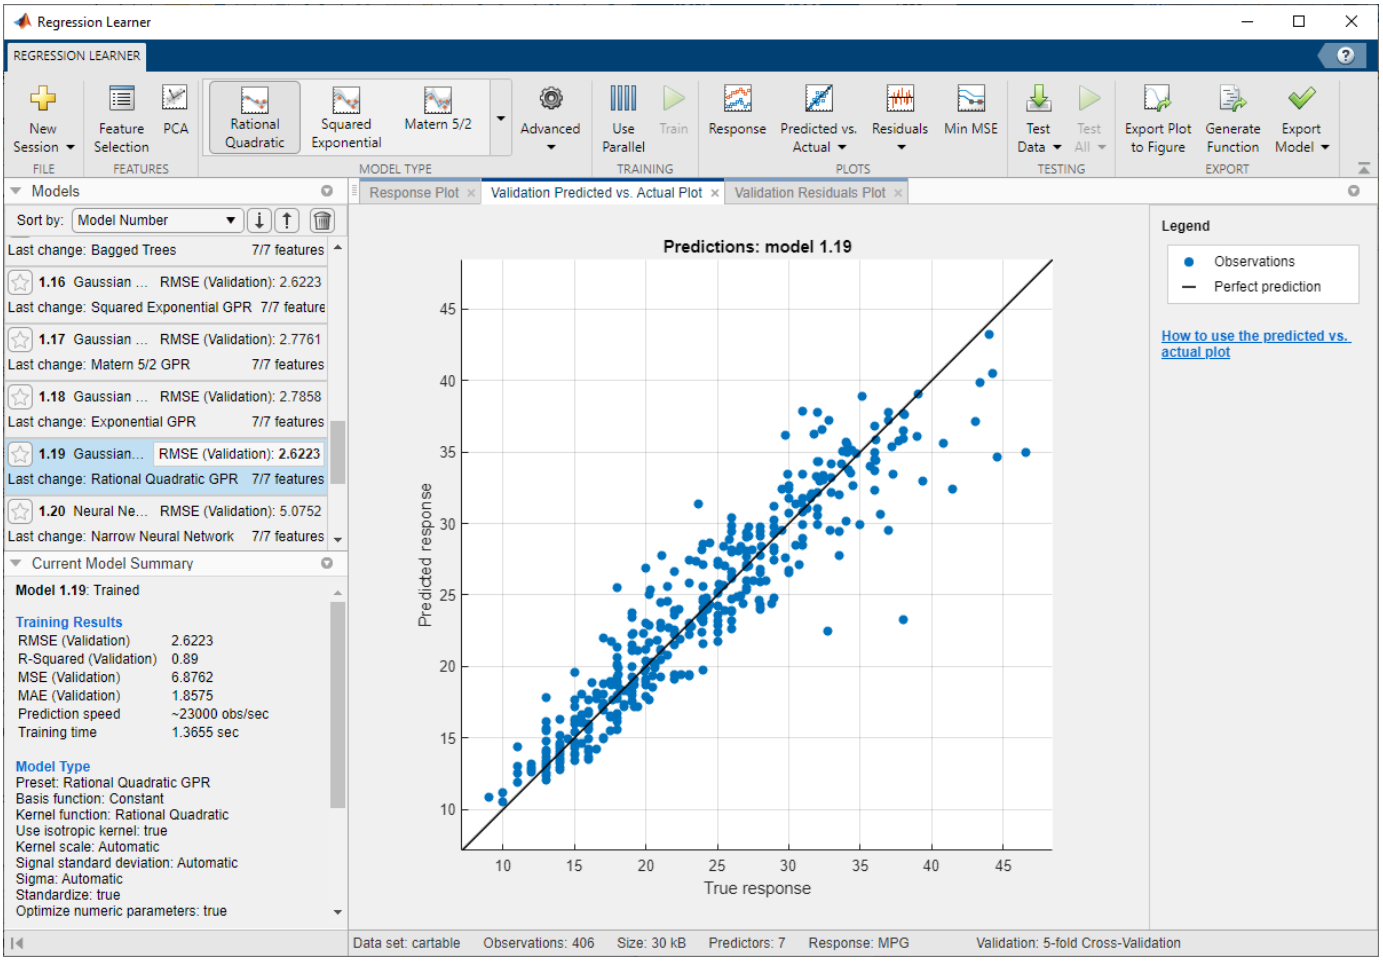
For more options, you can use the command-line interface. See “Classification”.

Train Regression Models in Regression Learner App

Use the Regression Learner app to train models to predict continuous data using supervised machine learning. The app lets you explore supervised machine learning interactively using various regression models.

- Automatically train a selection of models to help you choose the best model. Model types include linear regression models, regression trees, Gaussian process regression models, support vector machines, ensembles of regression trees, and neural network regression models.
- Explore your data, select features, and visualize results. Similar to Classification Learner, the Regression Learner applies cross-validation by default. The results and visualizations reflect the validated model. Use the results to choose the best model for your data.
- Export models to the workspace to make predictions with new data. The app always trains a model on full data in addition to a model with the specified validation scheme, and the full model is the model you export.
- Generate MATLAB code from the app to create scripts, train with new data, work with huge data sets, or modify the code for further analysis.

To learn more, see “Train Regression Models in Regression Learner App” on page 24-2.



For more options, you can use the command-line interface. See “Regression”.

Train Neural Networks for Deep Learning

Deep Learning Toolbox enables you to perform deep learning with convolutional neural networks for classification, regression, feature extraction, and transfer learning. The toolbox provides simple MATLAB commands for creating and interconnecting the layers of a deep neural network. Examples and pretrained networks make it easy to use MATLAB for deep learning, even without extensive knowledge of advanced computer vision algorithms or neural networks.

To learn more, see “Deep Learning in MATLAB” (Deep Learning Toolbox).

Train Classification Models in Classification Learner App

In this section...

You can use Classification Learner to train models of these classifiers: decision trees, discriminant analysis, support vector machines, logistic regression, nearest neighbors, naive Bayes, ensembles, and neural networks. In addition to training models, you can explore your data, select features, specify validation schemes, and evaluate results. You can export a model to the workspace to use the model with new data or generate MATLAB code to learn about programmatic classification.

Training a model in Classification Learner consists of two parts:

- Validated Model: Train a model with a validation scheme. By default, the app protects against overfitting by applying cross-validation. Alternatively, you can choose holdout validation. The validated model is visible in the app.
- Full Model: Train a model on full data without validation. The app trains this model simultaneously with the validated model. However, the model trained on full data is not visible in the app. When you choose a classifier to export to the workspace, Classification Learner exports the full model.

The app displays the results of the validated model. Diagnostic measures, such as model accuracy, and plots, such as a scatter plot or the confusion matrix chart, reflect the validated model results. You can automatically train a selection of or all classifiers, compare validation results, and choose the best model that works for your classification problem. When you choose a model to export to the workspace, Classification Learner exports the full model. Because Classification Learner creates a model object of the full model during training, you experience no lag time when you export the model. You can use the exported model to make predictions on new data.

To get started by training a selection of model types, see “Automated Classifier Training” on page 23-10. If you already know what classifier type you want to train, see “Manual Classifier Training” on page 23-13.

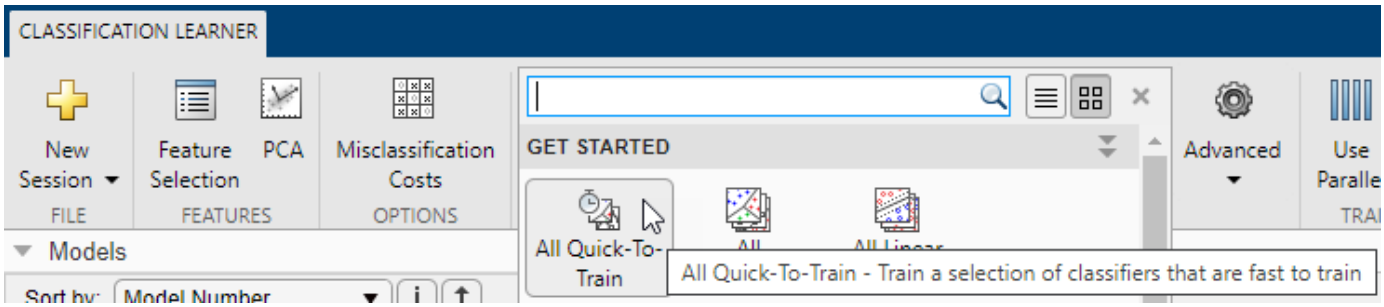
Automated Classifier Training

You can use Classification Learner to automatically train a selection of different classification models on your data.

- Get started by automatically training multiple models at once. You can quickly try a selection of models, then explore promising models interactively.
- If you already know what classifier type you want, train individual classifiers instead. See “Manual Classifier Training” on page 23-13.

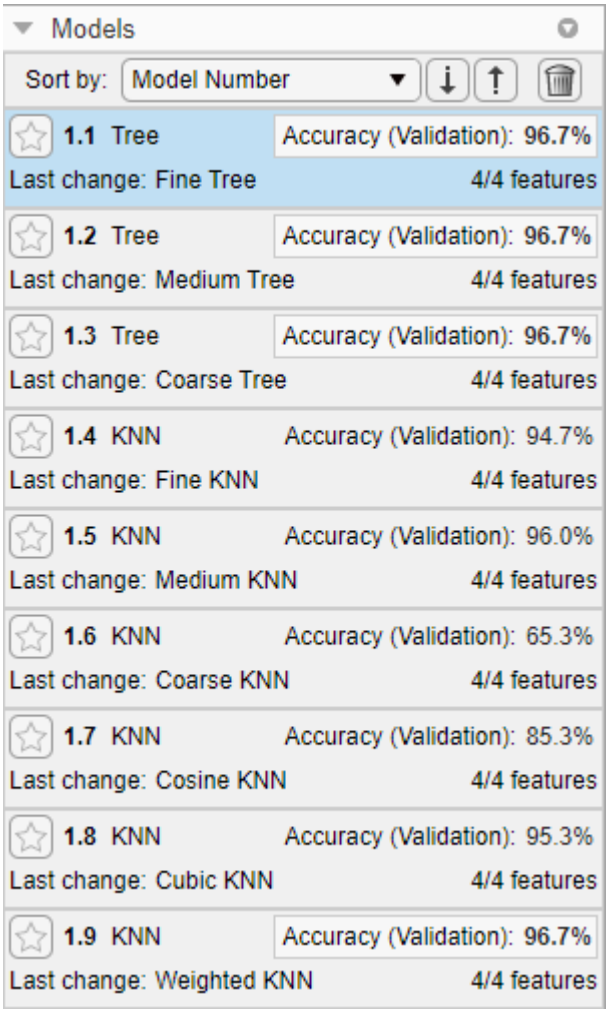
1. On the **Apps** tab, in the **Machine Learning** group, click **Classification Learner**.
2. Click **New Session** and select data from the workspace or from file. Specify a response variable and variables to use as predictors. See “Select Data and Validation for Classification Problem” on page 23-18.

3 On the **Classification Learner** tab, in the **Model Type** section, click **All Quick-To-Train**. This option will train all the model presets available for your data set that are fast to fit.



4 Click **Train**. 
Note If you have Parallel Computing Toolbox, you can train the models in parallel. See “Parallel Classifier Training” on page 23-14.

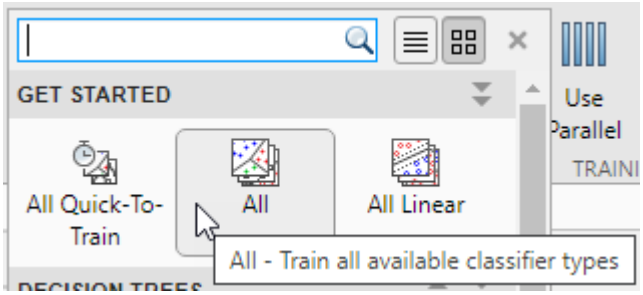
A selection of model types appears in the **Models** pane. When they finish training, the best percentage **Accuracy (Validation)** score is highlighted in a box.



5 Click models in the **Models** pane to explore results in the plots.

For next steps, see “Manual Classifier Training” on page 23-13 or “Compare and Improve Classification Models” on page 23-14.

6 To try all the nonoptimizable classifier model presets available for your data set, click **All**, then click **Train**.



Manual Classifier Training

If you want to explore individual model types, or if you already know what classifier type you want, you can train classifiers one at a time, or a train a group of the same type.

1 Choose a classifier. On the **Classification Learner** tab, in the **Model Type** section, click a classifier type. To see all available classifier options, click the arrow on the far right of the **Model Type** section to expand the list of classifiers. The nonoptimizable model options in the **Model Type** gallery are preset starting points with different settings, suitable for a range of different classification problems.

   To read a description of each classifier, switch to the details view.

   For more information on each option, see “Choose Classifier Options” on page 23-22.

2 After selecting a classifier, click **Train**. 
   Repeat to try different classifiers.

   Tip Try decision trees and discriminants first. If the models are not accurate enough predicting the response, try other classifiers with higher flexibility. To avoid overfitting, look for a model of lower flexibility that provides sufficient accuracy.

3 If you want to try all nonoptimizable models of the same or different types, then select one of the **All** options in the **Model Type** gallery.

   Alternatively, if you want to automatically tune hyperparameters of a specific model type, select the corresponding **Optimizable** model and perform hyperparameter optimization. For more information, see “Hyperparameter Optimization in Classification Learner App” on page 23-54.

For next steps, see “Compare and Improve Classification Models” on page 23-14

Parallel Classifier Training

You can train models in parallel using Classification Learner if you have Parallel Computing Toolbox. Parallel training allows you to train multiple classifiers at once and continue working.

To control parallel training, toggle the **Use Parallel** button in the app toolstrip. The **Use Parallel** button is only available if you have Parallel Computing Toolbox.

1. The first time you click **Train** after clicking the **Use Parallel** button, you see a dialog box while the app opens a parallel pool of workers. After the pool opens, you can train multiple classifiers at once.
2. When classifiers are training in parallel, you see progress indicators on each training and queued model in the **Models** pane, and you can cancel individual models if you want. During training, you can examine results and plots from models, and initiate training of more classifiers.

If you have Parallel Computing Toolbox, then parallel training is available in Classification Learner, and you do not need to set the `UseParallel` option of the `statset` function.

Note You cannot perform hyperparameter optimization in parallel. The app disables the **Use Parallel** button when you select an optimizable model. If you then select a nonoptimizable model, the button is off by default.

Compare and Improve Classification Models

1. Click models in the **Models** pane to explore the results in the plots. Compare model performance by inspecting results in the scatter plot and confusion matrix. Examine the **Accuracy (Validation)** score reported for each model.

   Additionally, you can compare the models by using the **Sort by** options in the **Models** pane. Delete any unwanted model by selecting the model and clicking the **Delete selected model** button in the upper right of the pane, or right-clicking the model and selecting **Delete model**.

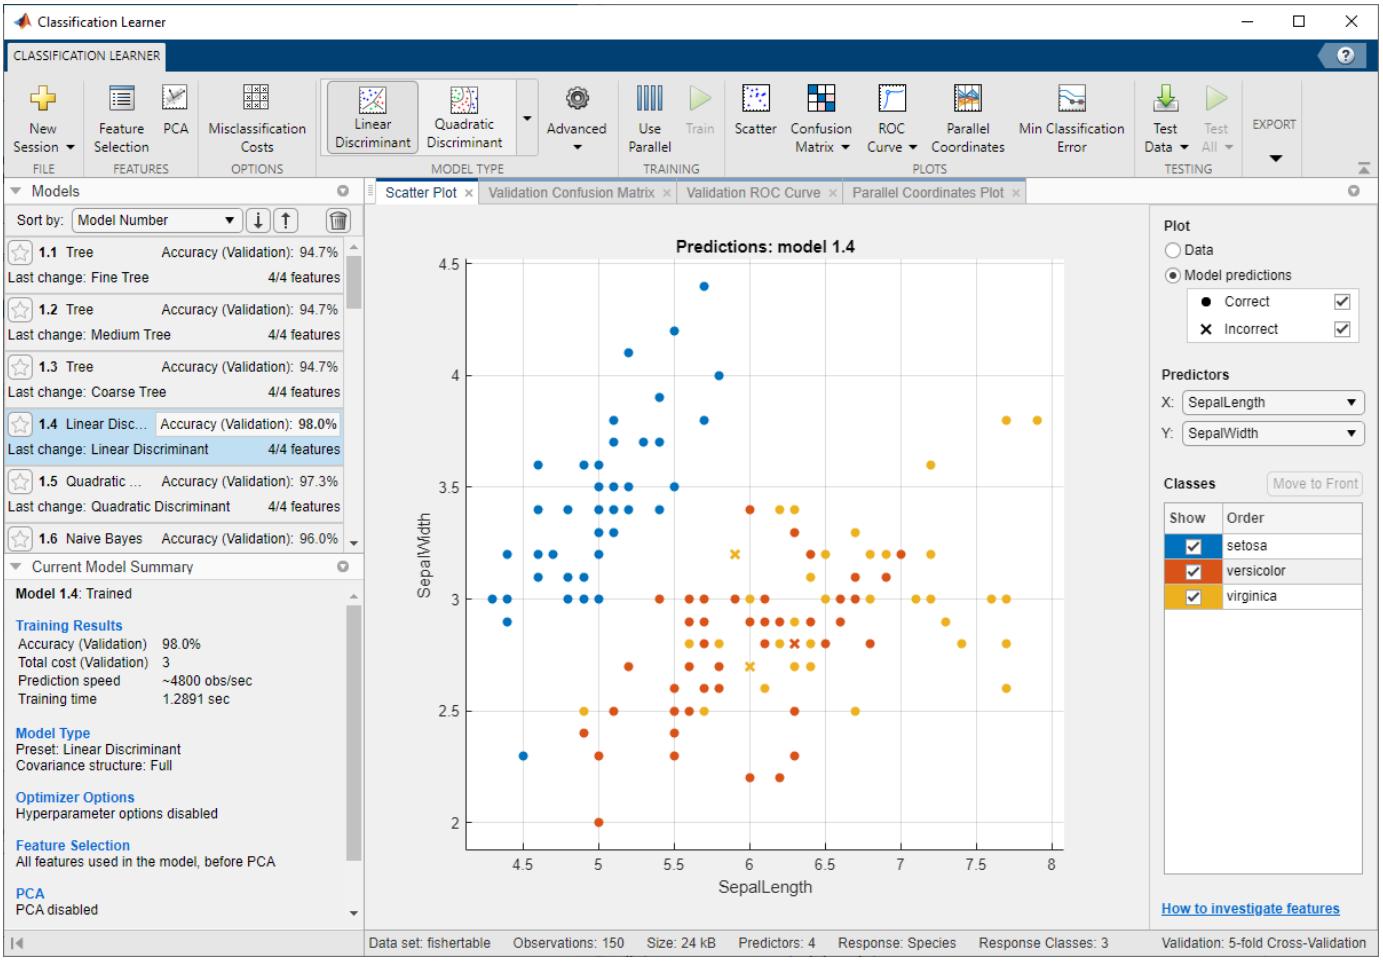
   See “Assess Classifier Performance in Classification Learner” on page 23-65.
2. Select the best model in the **Models** pane and then try including and excluding different features in the model. Click **Feature Selection**. 
   Try the parallel coordinates plot to help you identify features to remove. See if you can improve the model by removing features with low predictive power. Specify predictors to include in the model, and train new models using the new options. Compare results among the models in the **Models** pane.

You can also try transforming features with PCA to reduce dimensionality. 
See “Feature Selection and Feature Transformation Using Classification Learner App” on page 23-42.

3. To improve the model further, you can try changing classifier parameter settings in the Advanced dialog box, and then train using the new options. To learn how to control model flexibility, see “Choose Classifier Options” on page 23-22. For information on how to tune model parameter settings automatically, see “Hyperparameter Optimization in Classification Learner App” on page 23-54.
4. If feature selection, PCA, or new parameter settings improve your model, try training **All** model types with the new settings. See if another model type does better with the new settings.

Tip To avoid overfitting, look for a model of lower flexibility that provides sufficient accuracy. For example, look for simple models such as decision trees and discriminants that are fast and easy to interpret. If the models are not accurate enough predicting the response, choose other classifiers with higher flexibility, such as ensembles. To learn about the model flexibility, see “Choose Classifier Options” on page 23-22.

The figure shows the app with a **Models** pane containing various classifier types.



Tip For a step-by-step example comparing different classifiers, see “Train Decision Trees Using Classification Learner App” on page 23-83.

For next steps, generate code to train the model with different data, or export trained models to the workspace to make predictions using new data. See “Export Classification Model to Predict New Data” on page 23-77.

Select Data and Validation for Classification Problem

In this section...

Select Data from Workspace

Tip In Classification Learner, tables are the easiest way to use your data, because they can contain numeric and label data. Use the Import Tool to bring your data into the MATLAB workspace as a table, or use the table functions to create a `table` from workspace variables. See “Tables”.

1. Load your data into the MATLAB workspace.

   Predictor and response variables can be numeric, categorical, string, or logical vectors, cell arrays of character vectors, or character arrays. Note: If your response variable is a string vector, then the predictions of the trained model form a cell array of character vectors.

   Combine the predictor data into one variable, either a table or a matrix. You can additionally combine your predictor data and response variable, or you can keep them separate.

   For example data sets, see “Example Data for Classification” on page 23-19.
2. On the **Apps** tab, click **Classification Learner**.
3. In Classification Learner, on the **Classification Learner** tab, in the **File** section, click **New Session > From Workspace**.
4. In the New Session from Workspace dialog box, under **Data Set Variable**, select a table or matrix from the list of workspace variables.

   If you select a matrix, choose whether to use rows or columns for observations by clicking the option buttons.
5. Under **Response**, observe the default response variable. The app tries to select a suitable response variable from the data set variable and treats all other variables as predictors.

   If you want to use a different response variable, you can:

   - Use the list to select another variable from the data set variable.
   - Select a separate workspace variable by clicking the **From workspace** option button and then selecting a variable from the list.
6. Under **Predictors**, add or remove predictors using the check boxes. Add or remove all predictors by clicking **Add All** or **Remove All**. You can also add or remove multiple predictors by selecting them in the table, and then clicking **Add N** or **Remove N**, where **N** is the number of selected predictors. The **Add All** and **Remove All** buttons change to **Add N** and **Remove N** when you select multiple predictors.
7. To accept the default validation scheme and continue, click **Start Session**. The default validation option is 5-fold cross-validation, which protects against overfitting.

Tip If you have a large data set you might want to switch to holdout validation. To learn more, see “Choose Validation Scheme” on page 23-20.

Note If you prefer loading data into the app directly from the command line, you can specify the predictor data, response variable, and validation type to use in Classification Learner in the command line call to `classificationLearner`. For more information, see **Classification Learner**.

For next steps, see “Train Classification Models in Classification Learner App” on page 23-10.

Import Data from File

1. On the **Classification Learner** tab, in the **File** section, select **New Session** > **From File**.
2. Select a file type in the list, such as spreadsheets, text files, or comma separated values (`.csv`) files, or select **All Files** to browse for other file types such as `.dat`.

Example Data for Classification

To get started using Classification Learner, try the following example data sets.

Name	Size	Description
Fisher Iris	Number of predictors: 4 Number of observations: 150 Number of classes: 3 Response: species	Measurements from three species of iris. Try to classify the species. For a step-by-step example, see “Train Decision Trees Using Classification Learner App” on page 23-83.
	Create a table from the `.csv` file: `fishertable = readtable('fisheriris.csv');`	
Credit Rating	Number of predictors: 6 Number of observations: 3932 Number of classes: 7 Response: Rating	Financial ratios and industry sectors information for a list of corporate customers. The response variable consists of credit ratings (AAA, AA, A, BBB, BB, B, CCC) assigned by a rating agency.
	Create a table from the `CreditRating_Historical.dat` file: `creditrating = readtable('CreditRating_Historical.dat');`	
Cars	Number of predictors: 7 Number of observations: 100 Number of classes: 7 Response: Origin	Measurements of cars, in 1970, 1976, and 1982. Try to classify the country of origin.

	Create a table from variables in the `carsmall.mat` file:
	
	`load carsmall`
	`cartable = table(Acceleration, Cylinders, Displacement,...`
	`Horsepower, Model_Year, MPG, Weight, Origin);`	

Name	Size	Description
Arrhythmia	Number of predictors: 279 Number of observations: 452 Number of classes: 16 Response: Class (Y)	Patient information and response variables that indicate the presence and absence of cardiac arrhythmia. Misclassifying a patient as "normal" has more severe consequences than false positives classified as “has arrhythmia”.

	Create a table from the `.mat` file:
	
	`load arrhythmia`
	`Arrhythmia = array2table(X);`
	`Arrhythmia.Class = categorical(Y);`	

Ovarian Cancer	Number of predictors: 4000 Number of observations: 216 Number of classes: 2 Response: Group	Ovarian cancer data generated using the WCX2 protein array. Includes 95 controls and 121 ovarian cancers.

	Create a table from the `.mat` file:
	
	`load ovariancancer`
	`ovariancancer = array2table(obs);`
	`ovariancancer.Group = categorical(grp);`	

Ionosphere	Number of predictors: 34 Number of observations: 351 Number of classes: 2 Response: Group (Y)	Signals from a phased array of 16 high-frequency antennas. Good (“g”) returned radar signals are those showing evidence of some type of structure in the ionosphere. Bad (“b”) signals are those that pass through the ionosphere.

	Create a table from the `.mat` file:
	
	`load ionosphere`
	`ionosphere = array2table(X);`
	`ionosphere.Group = Y;`	

Choose Validation Scheme

Choose a validation method to examine the predictive accuracy of the fitted models. Validation estimates model performance on new data compared to the training data, and helps you choose the best model. Validation protects against overfitting. Choose a validation scheme before training any models, so that you can compare all the models in your session using the same validation scheme.

Tip Try the default validation scheme and click **Start Session** to continue. The default option is 5-fold cross-validation, which protects against overfitting.

If you have a large data set and training models takes too long using cross-validation, reimport your data and try the faster holdout validation instead.

- **Cross-Validation**: Select a number of folds (or divisions) to partition the data set.

  If you choose *k* folds, then the app:

1. Partitions the data into *k* disjoint sets or folds
2. For each validation fold:
   a. Trains a model using the training-fold observations (observations not in the validation fold)
   b. Assesses model performance using validation-fold data
3. Calculates the average validation error over all folds

This method gives a good estimate of the predictive accuracy of the final model trained with all the data. It requires multiple fits but makes efficient use of all the data, so it is recommended for small data sets.

- **Holdout Validation**: Select a percentage of the data to use as a validation set. The app trains a model on the training set and assesses its performance with the validation set. The model used for validation is based on only a portion of the data, so **Holdout Validation** is recommended only for large data sets. The final model is trained with the full data set.
- **Resubstitution Validation**: No protection against overfitting. The app uses all of the data for training and computes the error rate on the same data. Without any separate validation data, you get an unrealistic estimate of the model's performance on new data. That is, the training sample accuracy is likely to be unrealistically high, and the predictive accuracy is likely to be lower.

  To help you avoid overfitting to the training data, choose another validation scheme instead.

Note The validation scheme only affects the way that Classification Learner computes validation metrics. The final model is always trained using the full data set.

All the classification models you train after selecting data use the same validation scheme that you select in this dialog box. You can compare all the models in your session using the same validation scheme.

To change the validation selection and train new models, you can select data again, but you lose any trained models. The app warns you that importing data starts a new session. Save any trained models you want to keep to the workspace, and then import the data.

For next steps training models, see "Train Classification Models in Classification Learner App" on page 23-10.

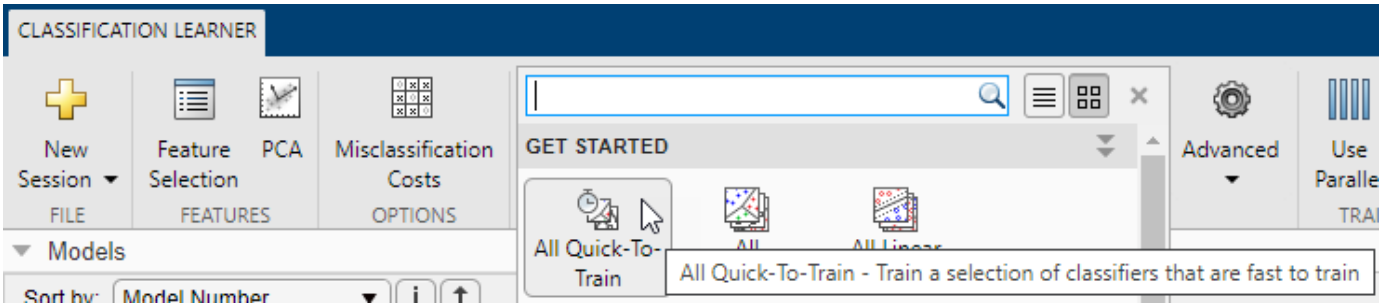
Choose Classifier Options

In this section...

Choose a Classifier Type

You can use Classification Learner to automatically train a selection of different classification models on your data. Use automated training to quickly try a selection of model types, then explore promising models interactively. To get started, try these options first:



Get Started Classifier Buttons	Description
All Quick-To-Train	Try this first. The app will train all the model types available for your data set that are typically fast to fit.
All Linear	Try this if you expect linear boundaries between the classes in your data. This option fits only Linear SVM and Linear Discriminant.
All	Use this to train all available nonoptimizable model types. Trains every type regardless of any prior trained models. Can be time-consuming.

See “Automated Classifier Training” on page 23-10.

If you want to explore classifiers one at a time, or you already know what classifier type you want, you can select individual models or train a group of the same type. To see all available classifier options, on the **Classification Learner** tab, click the arrow in the **Model Type** section to expand the list of classifiers. The nonoptimizable model options in the **Model Type** gallery are preset starting points with different settings, suitable for a range of different classification problems. To use

optimizable model options and tune model hyperparameters automatically, see “Hyperparameter Optimization in Classification Learner App” on page 23-54.

For help choosing the best classifier type for your problem, see the table showing typical characteristics of different supervised learning algorithms. Use the table as a guide for your final choice of algorithms. Decide on the tradeoff you want in speed, memory usage, flexibility, and interpretability. The best classifier type depends on your data.

Tip To avoid overfitting, look for a model of lower flexibility that provides sufficient accuracy. For example, look for simple models such as decision trees and discriminants that are fast and easy to interpret. If the models are not accurate enough predicting the response, choose other classifiers with higher flexibility, such as ensembles. To control flexibility, see the details for each classifier type.

Characteristics of Classifier Types

Classifier	Prediction Speed	Memory Usage	Interpretability
“Decision Trees” on page 23-26 	Fast	Small	Easy
“Discriminant Analysis” on page 23-29 	Fast	Small for linear, large for quadratic	Easy
“Logistic Regression” on page 23-30 	Fast	Medium	Easy
“Naive Bayes Classifiers” on page 23-30 	Medium for simple distributions Slow for kernel distributions or high-dimensional data	Small for simple distributions Medium for kernel distributions or high-dimensional data	Easy
“Support Vector Machines” on page 23-31 	Medium for linear Slow for others	Medium for linear. All others: medium for multiclass, large for binary.	Easy for Linear SVM. Hard for all other kernel types.
“Nearest Neighbor Classifiers” on page 23-34 	Slow for cubic Medium for others	Medium	Hard
“Ensemble Classifiers” on page 23-37 	Fast to medium depending on choice of algorithm	Low to high depending on choice of algorithm	Hard
“Neural Network Classifiers” on page 23-39 	Fast	Medium	Hard

The tables on this page describe general characteristics of speed and memory usage for all the nonoptimizable preset classifiers. The classifiers were tested with various data sets (up to 7000 observations, 80 predictors, and 50 classes), and the results define the following groups:

Speed

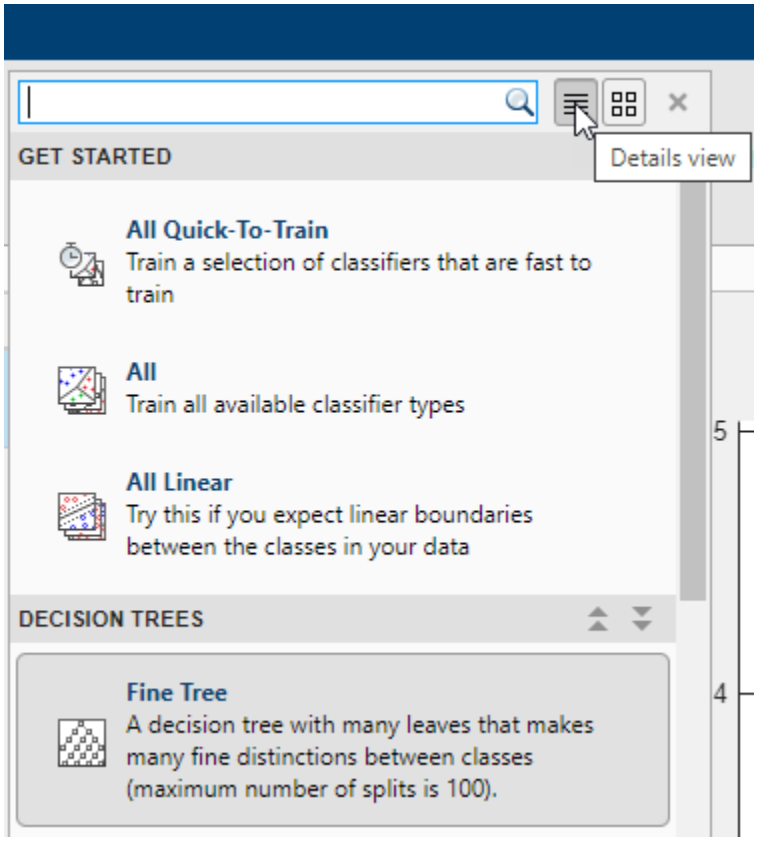
- Fast 0.01 second
- Medium 1 second
- Slow 100 seconds

Memory

- Small 1MB
- Medium 4MB
- Large 100MB

These tables provide a general guide. Your results depend on your data and the speed of your machine.

To read a description of each classifier in Classification Learner, switch to the details view.



Tip After you choose a classifier type (for example, decision trees), try training using each of the classifiers. The nonoptimizable options in the **Model Type** gallery are starting points with different settings. Try them all to see which option produces the best model with your data.

For workflow instructions, see “Train Classification Models in Classification Learner App” on page 23-10.

Categorical Predictor Support

In Classification Learner, the **Model Type** gallery shows as available the classifier types that support your selected data.

Classifier	All predictors numeric	All predictors categorical	Some categorical, some numeric
Decision Trees	Yes	Yes	Yes
Discriminant Analysis	Yes	No	No
Logistic Regression	Yes	Yes	Yes
Naive Bayes	Yes	Yes	Yes
SVM	Yes	Yes	Yes
Nearest Neighbor	Euclidean distance only	Hamming distance only	No
Ensembles	Yes	Yes, except Subspace Discriminant	Yes, except any Subspace
Neural Networks	Yes	Yes	Yes

Decision Trees

Decision trees are easy to interpret, fast for fitting and prediction, and low on memory usage, but they can have low predictive accuracy. Try to grow simpler trees to prevent overfitting. Control the depth with the **Maximum number of splits** setting.

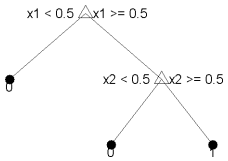
Tip Model flexibility increases with the **Maximum number of splits** setting.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Coarse Tree 	Fast	Small	Easy	Low Few leaves to make coarse distinctions between classes (maximum number of splits is 4).
Medium Tree 	Fast	Small	Easy	Medium Medium number of leaves for finer distinctions between classes (maximum number of splits is 20).
Fine Tree 	Fast	Small	Easy	High Many leaves to make many fine distinctions between classes (maximum number of splits is 100).

Tip In the **Model Type** gallery click **All Trees** to try each of the nonoptimizable decision tree options. Train them all to see which settings produce the best model with your data. Select the best

model in the **Models** pane. To try to improve your model, try feature selection, and then try changing some advanced options.

You train classification trees to predict responses to data. To predict a response, follow the decisions in the tree from the root (beginning) node down to a leaf node. The leaf node contains the response. Statistics and Machine Learning Toolbox trees are binary. Each step in a prediction involves checking the value of one predictor (variable). For example, here is a simple classification tree:

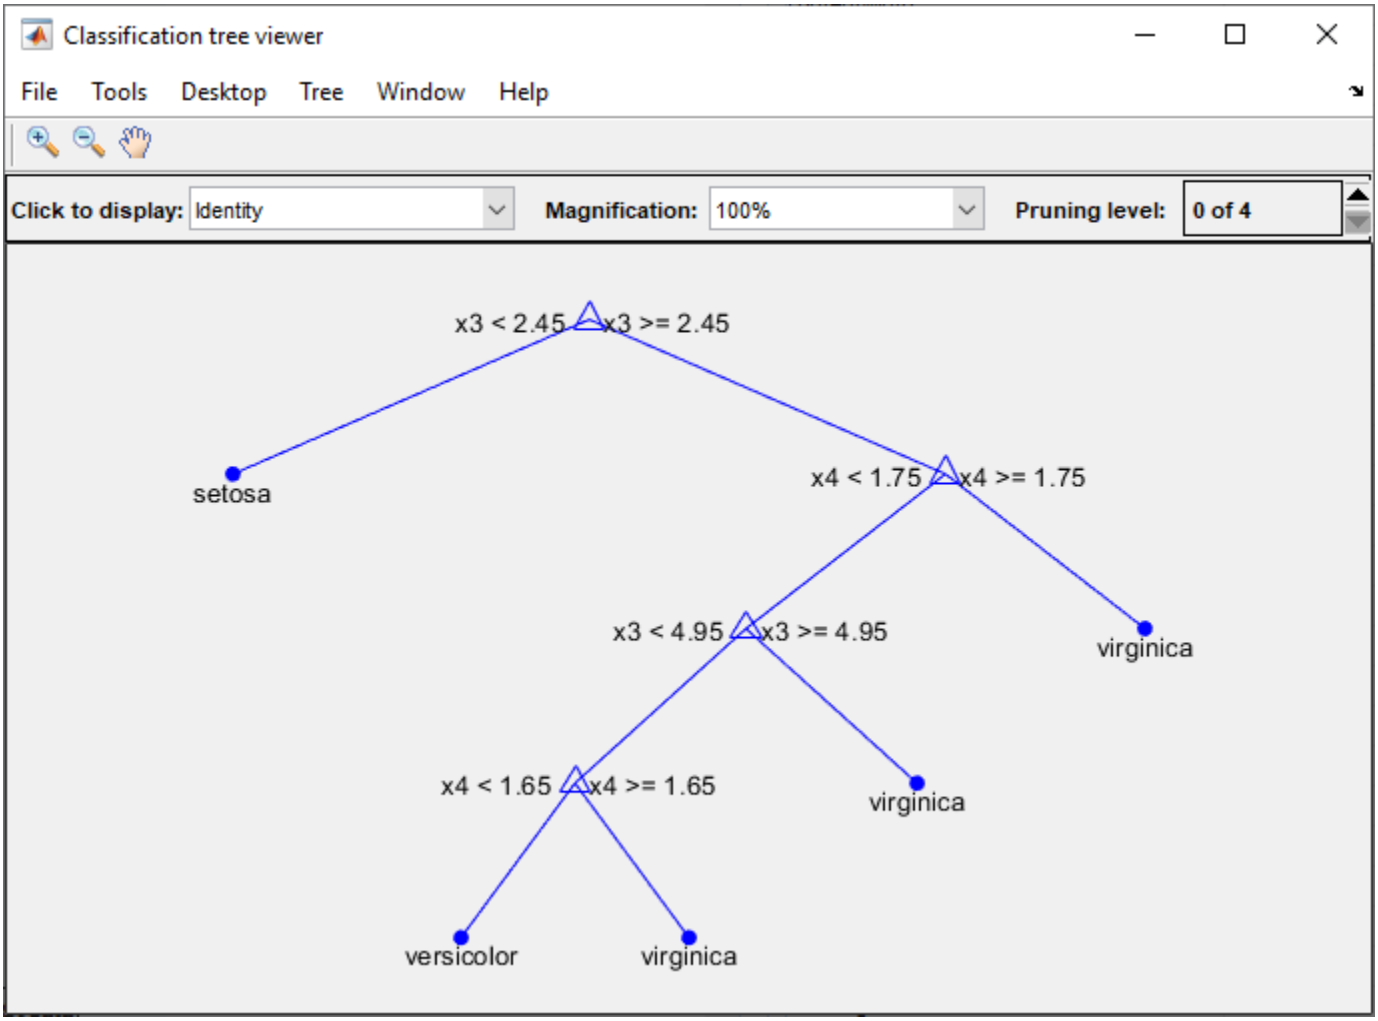


This tree predicts classifications based on two predictors, `x1` and `x2`. To predict, start at the top node. At each decision, check the values of the predictors to decide which branch to follow. When the branches reach a leaf node, the data is classified either as type `0` or `1`.

You can visualize your decision tree model by exporting the model from the app, and then entering:

```
view(trainedModel.ClassificationTree,'Mode','graph')
```

The figure shows an example fine tree trained with the `fisheriris` data.



Tip For an example, see “Train Decision Trees Using Classification Learner App” on page 23-83.

Advanced Tree Options

Classification trees in Classification Learner use the `fitctree` function. You can set these options:

- **Maximum number of splits**

  Specify the maximum number of splits or branch points to control the depth of your tree. When you grow a decision tree, consider its simplicity and predictive power. To change the number of splits, click the buttons or enter a positive integer value in the **Maximum number of splits** box.

  - A fine tree with many leaves is usually highly accurate on the training data. However, the tree might not show comparable accuracy on an independent test set. A leafy tree tends to overtrain, and its validation accuracy is often far lower than its training (or resubstitution) accuracy.

  - In contrast, a coarse tree does not attain high training accuracy. But a coarse tree can be more robust in that its training accuracy can approach that of a representative test set. Also, a coarse tree is easy to interpret.
- **Split criterion**

  Specify the split criterion measure for deciding when to split nodes. Try each of the three settings to see if they improve the model with your data.

  Split criterion options are `Gini's diversity index`, `Twoing rule`, or `Maximum deviance reduction` (also known as cross entropy).

  The classification tree tries to optimize to pure nodes containing only one class. Gini's diversity index (the default) and the deviance criterion measure node impurity. The twoing rule is a different measure for deciding how to split a node, where maximizing the twoing rule expression increases node purity.

  For details of these split criteria, see `ClassificationTree` “More About” on page 33-585.
- **Surrogate decision splits** — Only for missing data.

  Specify surrogate use for decision splits. If you have data with missing values, use surrogate splits to improve the accuracy of predictions.

  When you set **Surrogate decision splits** to `On`, the classification tree finds at most 10 surrogate splits at each branch node. To change the number, click the buttons or enter a positive integer value in the **Maximum surrogates per node** box.

  When you set **Surrogate decision splits** to `Find All`, the classification tree finds all surrogate splits at each branch node. The `Find All` setting can use considerable time and memory.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Classification Learner App” on page 23-54.

Discriminant Analysis

Discriminant analysis is a popular first classification algorithm to try because it is fast, accurate and easy to interpret. Discriminant analysis is good for wide datasets.

Discriminant analysis assumes that different classes generate data based on different Gaussian distributions. To train a classifier, the fitting function estimates the parameters of a Gaussian distribution for each class.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Linear Discriminant 	Fast	Small	Easy	Low Creates linear boundaries between classes.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Quadratic Discriminant 	Fast	Large	Easy	Low Creates nonlinear boundaries between classes (ellipse, parabola or hyperbola).

Advanced Discriminant Options

Discriminant analysis in Classification Learner uses the `fitcdiscr` function. For both linear and quadratic discriminants, you can change the **Covariance structure** option. If you have predictors with zero variance or if any of the covariance matrices of your predictors are singular, training can fail using the default, `Full` covariance structure. If training fails, select the `Diagonal` covariance structure instead.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Classification Learner App” on page 23-54.

Logistic Regression

If you have 2 classes, logistic regression is a popular simple classification algorithm to try because it is easy to interpret. The classifier models the class probabilities as a function of the linear combination of predictors.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Logistic Regression 	Fast	Medium	Easy	Low You cannot change any parameters to control model flexibility.

Logistic regression in Classification Learner uses the `fitglm` function. You cannot set any options for this classifier in the app.

Naive Bayes Classifiers

Naive Bayes classifiers are easy to interpret and useful for multiclass classification. The naive Bayes algorithm leverages Bayes theorem and makes the assumption that predictors are conditionally independent, given the class. Use these classifiers if this independence assumption is valid for predictors in your data. However, the algorithm still appears to work well when the independence assumption is not valid.

For kernel naive Bayes classifiers, you can control the kernel smoother type with the **Kernel Type** setting, and control the kernel smoothing density support with the **Support** setting.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Gaussian Naive Bayes 	Medium Slow for high-dimensional data	Small Medium for high-dimensional data	Easy	Low You cannot change any parameters to control model flexibility.
Kernel Naive Bayes 	Slow	Medium	Easy	Medium You can change settings for **Kernel Type** and **Support** to control how the classifier models predictor distributions.

Naive Bayes in Classification Learner uses the `fitcnb` function.

Advanced Naive Bayes Options

For kernel naive Bayes classifiers, you can set these options:

- **Kernel Type** — Specify the kernel smoother type. Try setting each of these options to see if they improve the model with your data.

  Kernel type options are `Gaussian`, `Box`, `Epanechnikov`, or `Triangle`.
- **Support** — Specify the kernel smoothing density support. Try setting each of these options to see if they improve the model with your data.

  Support options are `Unbounded` (all real values) or `Positive` (all positive real values).

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Classification Learner App” on page 23-54.

For next steps training models, see “Train Classification Models in Classification Learner App” on page 23-10.

Support Vector Machines

In Classification Learner, you can train SVMs when your data has two or more classes.

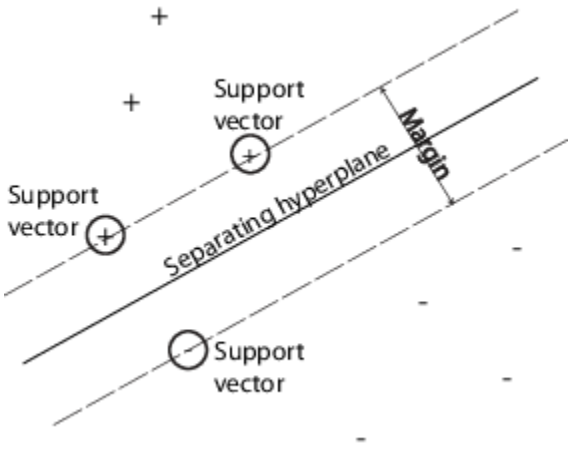
Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Linear SVM 	Binary: Fast Multiclass: Medium	Medium	Easy	Low Makes a simple linear separation between classes.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Quadratic SVM 	Binary: Fast Multiclass: Slow	Binary: Medium Multiclass: Large	Hard	Medium
Cubic SVM 	Binary: Fast Multiclass: Slow	Binary: Medium Multiclass: Large	Hard	Medium
Fine Gaussian SVM 	Binary: Fast Multiclass: Slow	Binary: Medium Multiclass: Large	Hard	High — decreases with kernel scale setting. Makes finely detailed distinctions between classes, with kernel scale set to `sqrt(P)/4`.
Medium Gaussian SVM 	Binary: Fast Multiclass: Slow	Binary: Medium Multiclass: Large	Hard	Medium Medium distinctions, with kernel scale set to `sqrt(P)`.
Coarse Gaussian SVM 	Binary: Fast Multiclass: Slow	Binary: Medium Multiclass: Large	Hard	Low Makes coarse distinctions between classes, with kernel scale set to `sqrt(P)*4`, where P is the number of predictors.

Tip Try training each of the nonoptimizable support vector machine options in the **Model Type** gallery. Train them all to see which settings produce the best model with your data. Select the best model in the **Models** pane. To try to improve your model, try feature selection, and then try changing some advanced options.

An SVM classifies data by finding the best hyperplane that separates data points of one class from those of the other class. The best hyperplane for an SVM means the one with the largest margin between the two classes. Margin means the maximal width of the slab parallel to the hyperplane that has no interior data points.

The support vectors are the data points that are closest to the separating hyperplane; these points are on the boundary of the slab. The following figure illustrates these definitions, with + indicating data points of type 1, and – indicating data points of type –1.



SVMs can also use a soft margin, meaning a hyperplane that separates many, but not all data points.

For an example, see “Train Support Vector Machines Using Classification Learner App” on page 23-98.

Advanced SVM Options

If you have exactly two classes, Classification Learner uses the `fitcsvm` function to train the classifier. If you have more than two classes, the app uses the `fitcecoc` function to reduce the multiclass classification problem to a set of binary classification subproblems, with one SVM learner for each subproblem. To examine the code for the binary and multiclass classifier types, you can generate code from your trained classifiers in the app.

You can set these options in the app:

- **Kernel function**

  Specify the Kernel function to compute the classifier.

  - Linear kernel, easiest to interpret
  - Gaussian or Radial Basis Function (RBF) kernel
  - Quadratic
  - Cubic
- **Box constraint level**

  Specify the box constraint to keep the allowable values of the Lagrange multipliers in a box, a bounded region.

  To tune your SVM classifier, try increasing the box constraint level. Click the buttons or enter a positive scalar value in the **Box constraint level** box. Increasing the box constraint level can decrease the number of support vectors, but also can increase training time.

  The Box Constraint parameter is the soft-margin penalty known as C in the primal equations, and is a hard “box” constraint in the dual equations.
- **Kernel scale mode**

  Specify manual kernel scaling if desired.

When you set **Kernel scale mode** to `Auto`, then the software uses a heuristic procedure to select the scale value. The heuristic procedure uses subsampling. Therefore, to reproduce results, set a random number seed using `rng` before training the classifier.

When you set **Kernel scale mode** to `Manual`, you can specify a value. Click the buttons or enter a positive scalar value in the **Manual kernel scale** box. The software divides all elements of the predictor matrix by the value of the kernel scale. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

Tip Model flexibility decreases with the kernel scale setting.

- **Multiclass method**

  Only for data with 3 or more classes. This method reduces the multiclass classification problem to a set of binary classification subproblems, with one SVM learner for each subproblem. `One-vs-One` trains one learner for each pair of classes. It learns to distinguish one class from the other. `One-vs-All` trains one learner for each class. It learns to distinguish one class from all others.

- **Standardize data**

  Specify whether to scale each coordinate distance. If predictors have widely different scales, standardizing can improve the fit.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Classification Learner App” on page 23-54.

Nearest Neighbor Classifiers

Nearest neighbor classifiers typically have good predictive accuracy in low dimensions, but might not in high dimensions. They have high memory usage, and are not easy to interpret.

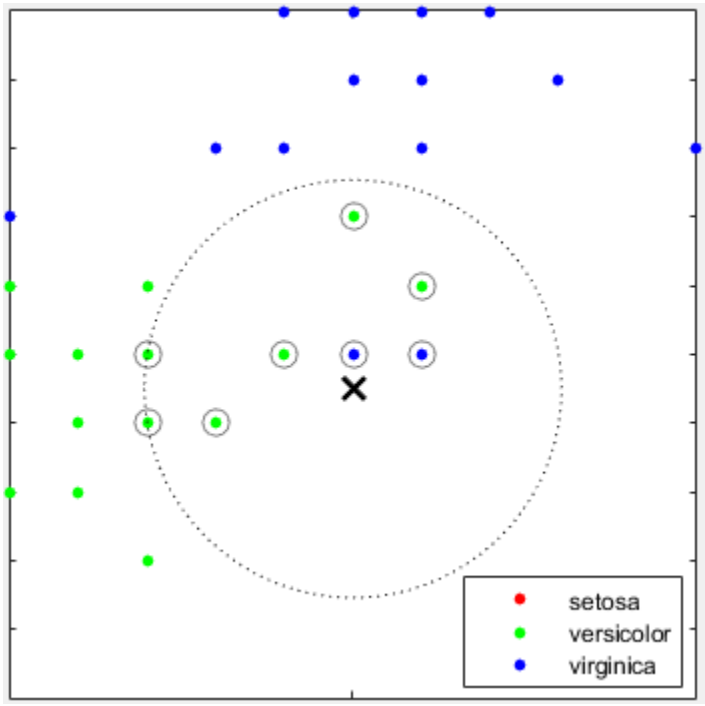
Tip Model flexibility decreases with the **Number of neighbors** setting.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Fine KNN 	Medium	Medium	Hard	Finely detailed distinctions between classes. The number of neighbors is set to 1.
Medium KNN 	Medium	Medium	Hard	Medium distinctions between classes. The number of neighbors is set to 10.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Coarse KNN 	Medium	Medium	Hard	Coarse distinctions between classes. The number of neighbors is set to 100.
Cosine KNN 	Medium	Medium	Hard	Medium distinctions between classes, using a Cosine distance metric. The number of neighbors is set to 10.
Cubic KNN 	Slow	Medium	Hard	Medium distinctions between classes, using a cubic distance metric. The number of neighbors is set to 10.
Weighted KNN 	Medium	Medium	Hard	Medium distinctions between classes, using a distance weight. The number of neighbors is set to 10.

Tip Try training each of the nonoptimizable nearest neighbor options in the **Model Type** gallery. Train them all to see which settings produce the best model with your data. Select the best model in the **Models** pane. To try to improve your model, try feature selection, and then (optionally) try changing some advanced options.

What is *k*-Nearest Neighbor classification? Categorizing query points based on their distance to points (or neighbors) in a training dataset can be a simple yet effective way of classifying new points. You can use various metrics to determine the distance. Given a set X of n points and a distance function, *k*-nearest neighbor (*k*NN) search lets you find the k closest points in X to a query point or set of points. *k*NN-based algorithms are widely used as benchmark machine learning rules.



For an example, see “Train Nearest Neighbor Classifiers Using Classification Learner App” on page 23-101.

Advanced KNN Options

Nearest Neighbor classifiers in Classification Learner use the `fitcknn` function. You can set these options:

- **Number of neighbors**

  Specify the number of nearest neighbors to find for classifying each point when predicting. Specify a fine (low number) or coarse classifier (high number) by changing the number of neighbors. For example, a fine KNN uses one neighbor, and a coarse KNN uses 100. Many neighbors can be time consuming to fit.
- **Distance metric**

  You can use various metrics to determine the distance to points. For definitions, see the class `ClassificationKNN`.
- **Distance weight**

  Specify the distance weighting function. You can choose `Equal` (no weights), `Inverse` (weight is 1/distance), or `Squared Inverse` (weight is $1/\text{distance}^2$).
- **Standardize data**

  Specify whether to scale each coordinate distance. If predictors have widely different scales, standardizing can improve the fit.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Classification Learner App” on page 23-54.

Ensemble Classifiers

Ensemble classifiers meld results from many weak learners into one high-quality ensemble model. Qualities depend on the choice of algorithm.

Tip Model flexibility increases with the **Number of learners** setting.

All ensemble classifiers tend to be slow to fit because they often need many learners.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Ensemble Method	Model Flexibility
Boosted Trees 	Fast	Low	Hard	`AdaBoost`, with `Decision Tree` learners	Medium to high — increases with **Number of learners** or **Maximum number of splits** setting. **Tip** Boosted trees can usually do better than bagged, but might require parameter tuning and more learners
Bagged Trees 	Medium	High	Hard	Random forest `Bag`, with `Decision Tree` learners	High — increases with **Number of learners** setting. **Tip** Try this classifier first.
Subspace Discriminant 	Medium	Low	Hard	`Subspace`, with `Discriminant` learners	Medium — increases with **Number of learners** setting. Good for many predictors
Subspace KNN 	Medium	Medium	Hard	`Subspace`, with `Nearest Neighbor` learners	Medium — increases with **Number of learners** setting. Good for many predictors

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Ensemble Method	Model Flexibility
RUSBoost Trees 	Fast	Low	Hard	`RUSBoost`, with `Decision Tree` learners	Medium — increases with **Number of learners** or **Maximum number of splits** setting. Good for skewed data (with many more observations of 1 class)
GentleBoost or LogitBoost — not available in the **Model Type** gallery. If you have 2 class data, select manually.	Fast	Low	Hard	`GentleBoost` or `LogitBoost`, with `Decision Tree` learners Choose `Boosted Trees` and change to `GentleBoost` method.	Medium — increases with **Number of learners** or **Maximum number of splits** setting. For binary classification only

Bagged trees use Breiman's `'random forest'` algorithm. For reference, see Breiman, L. Random Forests. Machine Learning 45, pp. 5–32, 2001.

Tips

- Try bagged trees first. Boosted trees can usually do better but might require searching many parameter values, which is time-consuming.
- Try training each of the nonoptimizable ensemble classifier options in the **Model Type** gallery. Train them all to see which settings produce the best model with your data. Select the best model in the **Models** pane. To try to improve your model, try feature selection, PCA, and then (optionally) try changing some advanced options.
- For boosting ensemble methods, you can get fine detail with either deeper trees or larger numbers of shallow trees. As with single tree classifiers, deep trees can cause overfitting. You need to experiment to choose the best tree depth for the trees in the ensemble, in order to trade-off data fit with tree complexity. Use the **Number of learners** and **Maximum number of splits** settings.

For an example, see “Train Ensemble Classifiers Using Classification Learner App” on page 23-104.

Advanced Ensemble Options

Ensemble classifiers in Classification Learner use the `fitcensemble` function. You can set these options:

- For help choosing **Ensemble method** and **Learner type**, see the Ensemble table. Try the presets first.
- **Maximum number of splits**

  For boosting ensemble methods, specify the maximum number of splits or branch points to control the depth of your tree learners. Many branches tend to overfit, and simpler trees can be more

robust and easy to interpret. Experiment to choose the best tree depth for the trees in the ensemble.

- **Number of learners**

  Try changing the number of learners to see if you can improve the model. Many learners can produce high accuracy, but can be time consuming to fit. Start with a few dozen learners, and then inspect the performance. An ensemble with good predictive power can need a few hundred learners.

- **Learning rate**

  Specify the learning rate for shrinkage. If you set the learning rate to less than 1, the ensemble requires more learning iterations but often achieves better accuracy. 0.1 is a popular choice.

- **Subspace dimension**

  For subspace ensembles, specify the number of predictors to sample in each learner. The app chooses a random subset of the predictors for each learner. The subsets chosen by different learners are independent.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Classification Learner App” on page 23-54.

Neural Network Classifiers

Neural network models typically have good predictive accuracy and can be used for multiclass classification; however, they are not easy to interpret.

Model flexibility increases with the size and number of fully connected layers in the neural network.

Tip In the **Model Type** gallery, click **All Neural Networks**  to try each of the preset neural network options and see which settings produce the best model with your data. Select the best model in the **Models** pane, and try to improve that model by using feature selection and changing some advanced options.

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Narrow Neural Network 	Fast	Medium	Hard	Medium — increases with **Size of each fully connected layer** setting
Medium Neural Network 	Fast	Medium	Hard	Medium — increases with **Size of each fully connected layer** setting

Classifier Type	Prediction Speed	Memory Usage	Interpretability	Model Flexibility
Wide Neural Network 	Fast	Medium	Hard	Medium — increases with **Size of each fully connected layer** setting
Bilayered Neural Network 	Fast	Medium	Hard	High — increases with **Size of each fully connected layer** setting
Trilayered Neural Network 	Fast	Medium	Hard	High — increases with **Size of each fully connected layer** setting

Each model is a feedforward, fully connected neural network for classification. The first fully connected layer of the neural network has a connection from the network input (predictor data), and each subsequent layer has a connection from the previous layer. Each fully connected layer multiplies the input by a weight matrix and then adds a bias vector. An activation function follows each fully connected layer. The final fully connected layer and the subsequent softmax activation function produce the network's output, namely classification scores (posterior probabilities) and predicted labels. For more information, see “Neural Network Structure” on page 33-1823.

For an example, see “Train Neural Network Classifiers Using Classification Learner App” on page 23-117.

Advanced Neural Network Options

Neural network classifiers in Classification Learner use the `fitcnet` function. You can set these options:

- **Number of fully connected layers** — Specify the number of fully connected layers in the neural network, excluding the final fully connected layer for classification. You can choose a maximum of three fully connected layers.
- **Size of each fully connected layer** — Specify the size of each fully connected layer, excluding the final fully connected layer. If you choose to create a neural network with multiple fully connected layers, consider specifying layers with decreasing sizes.
- **Activation** — Specify the activation function for all fully connected layers, excluding the final fully connected layer. The activation function for the last fully connected layer is always softmax. Choose from the following activation functions: `ReLU`, `Tanh`, `Sigmoid`, and `None`.
- **Iteration limit** — Specify the maximum number of training iterations.
- **Regularization term strength** — Specify the ridge (L2) regularization penalty term.
- **Standardize data** — Specify whether to standardize the numeric predictors. If predictors have widely different scales, standardizing can improve the fit. Standardizing the data is highly recommended.

Feature Selection and Feature Transformation Using Classification Learner App

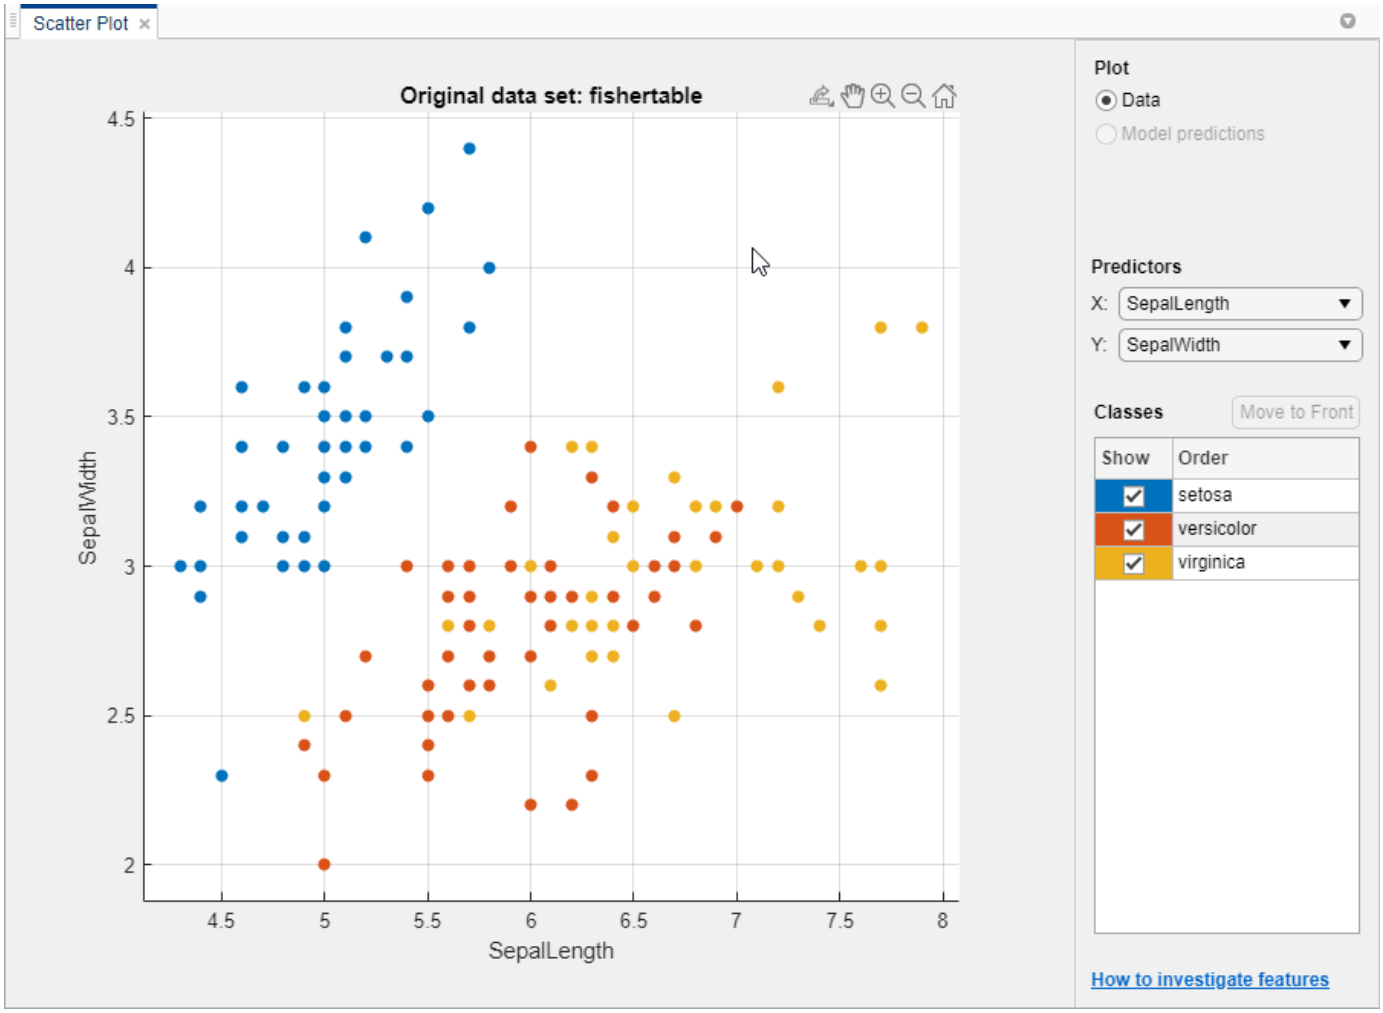
In this section...

Investigate Features in the Scatter Plot

In Classification Learner, try to identify predictors that separate classes well by plotting different pairs of predictors on the scatter plot. The plot can help you investigate features to include or exclude. You can visualize training data and misclassified points on the scatter plot.

Before you train a classifier, the scatter plot shows the data. If you have trained a classifier, the scatter plot shows model prediction results. Switch to plotting only the data by selecting **Data** in the **Plot** controls.

- Choose features to plot using the **X** and **Y** lists under **Predictors**.
- Look for predictors that separate classes well. For example, plotting the `fisheriris` data, you can see that sepal length and sepal width separate one of the classes well (`setosa`). You need to plot other predictors to see if you can separate the other two classes.



- Show or hide specific classes using the check boxes under **Show**.
- Change the stacking order of the plotted classes by selecting a class under **Classes** and then clicking **Move to Front**.
- Investigate finer details by zooming in and out and panning across the plot. To enable zooming or panning, hover the mouse over the scatter plot and click the corresponding button on the toolbar that appears above the top right of the plot.
- If you identify predictors that are not useful for separating out classes, then try using **Feature Selection** to remove them and train classifiers including only the most useful predictors.

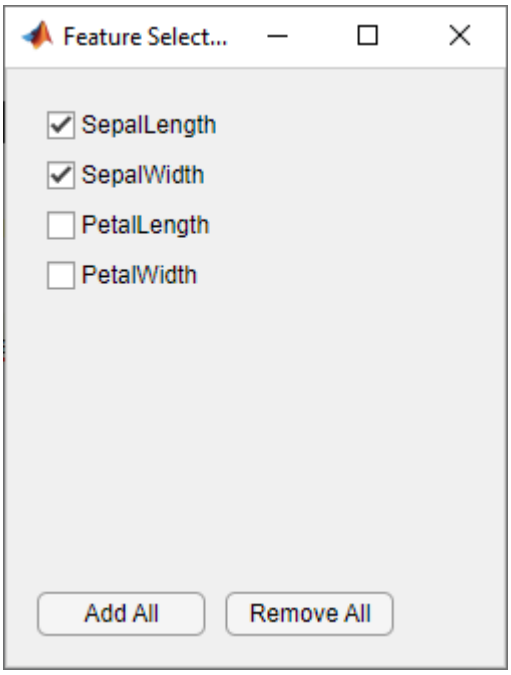
After you train a classifier, the scatter plot shows model prediction results. You can show or hide correct or incorrect results and visualize the results by class. See “Plot Classifier Results” on page 23-66.

You can export the scatter plots you create in the app to figures. See “Export Plots in Classification Learner App” on page 23-72.

Select Features to Include

In Classification Learner, you can specify different features (or predictors) to include in the model. See if you can improve models by removing features with low predictive power. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily without some predictors.

1. On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**.
2. In the Feature Selection dialog box, clear the check boxes for the predictors you want to exclude.



Tip You can close the Feature Selection dialog box, or move it. Your choices in the dialog box remain.

3. Click **Train** to train a new model using the new predictor options.
4. Observe the new model in the **Models** pane. The **Current Model Summary** pane displays how many predictors are excluded.
5. To check which predictors are included in a trained model, click the model in the **Models** pane and observe the check boxes in the Feature Selection dialog box.
6. You can try to improve the model by including different features in the model.

For an example using feature selection, see “Train Decision Trees Using Classification Learner App” on page 23-83.

Transform Features with PCA in Classification Learner

Use principal component analysis (PCA) to reduce the dimensionality of the predictor space. Reducing the dimensionality can create classification models in Classification Learner that help prevent overfitting. PCA linearly transforms predictors in order to remove redundant dimensions, and generates a new set of variables called principal components.

1. On the **Classification Learner** tab, in the **Features** section, select **PCA**.
2. In the Advanced PCA Options dialog box, select the **Enable PCA** check box.

   You can close the PCA dialog box, or move it. Your choices in the dialog box remain.
3. When you next click **Train**, the `pca` function transforms your selected features before training the classifier.
4. By default, PCA keeps only the components that explain 95% of the variance. In the PCA dialog box, you can change the percentage of variance to explain by selecting the **Explained variance** value. A higher value risks overfitting, while a lower value risks removing useful dimensions.
5. If you want to manually limit the number of PCA components, in the **Component reduction criterion** list, select `Specify number of components`. Select the **Number of numeric components** value. The number of components cannot be larger than the number of numeric predictors. PCA is not applied to categorical predictors.

Check PCA options for trained models in the **Current Model Summary** pane information. Check the explained variance percentages to decide whether to change the number of components. For example:

```
PCA is keeping enough components to explain 95% variance.
After training, 2 components were kept.
Explained variance per component (in order): 92.5%, 5.3%, 1.7%, 0.5%
```

To learn more about how Classification Learner applies PCA to your data, generate code for your trained classifier. For more information on PCA, see the `pca` function.

Investigate Features in the Parallel Coordinates Plot

To investigate features to include or exclude, use the parallel coordinates plot. You can visualize high-dimensional data on a single plot to see 2-D patterns. The plot can help you understand relationships between features and identify useful predictors for separating classes. You can visualize training data and misclassified points on the parallel coordinates plot. When you plot classifier results, misclassified points have dashed lines.

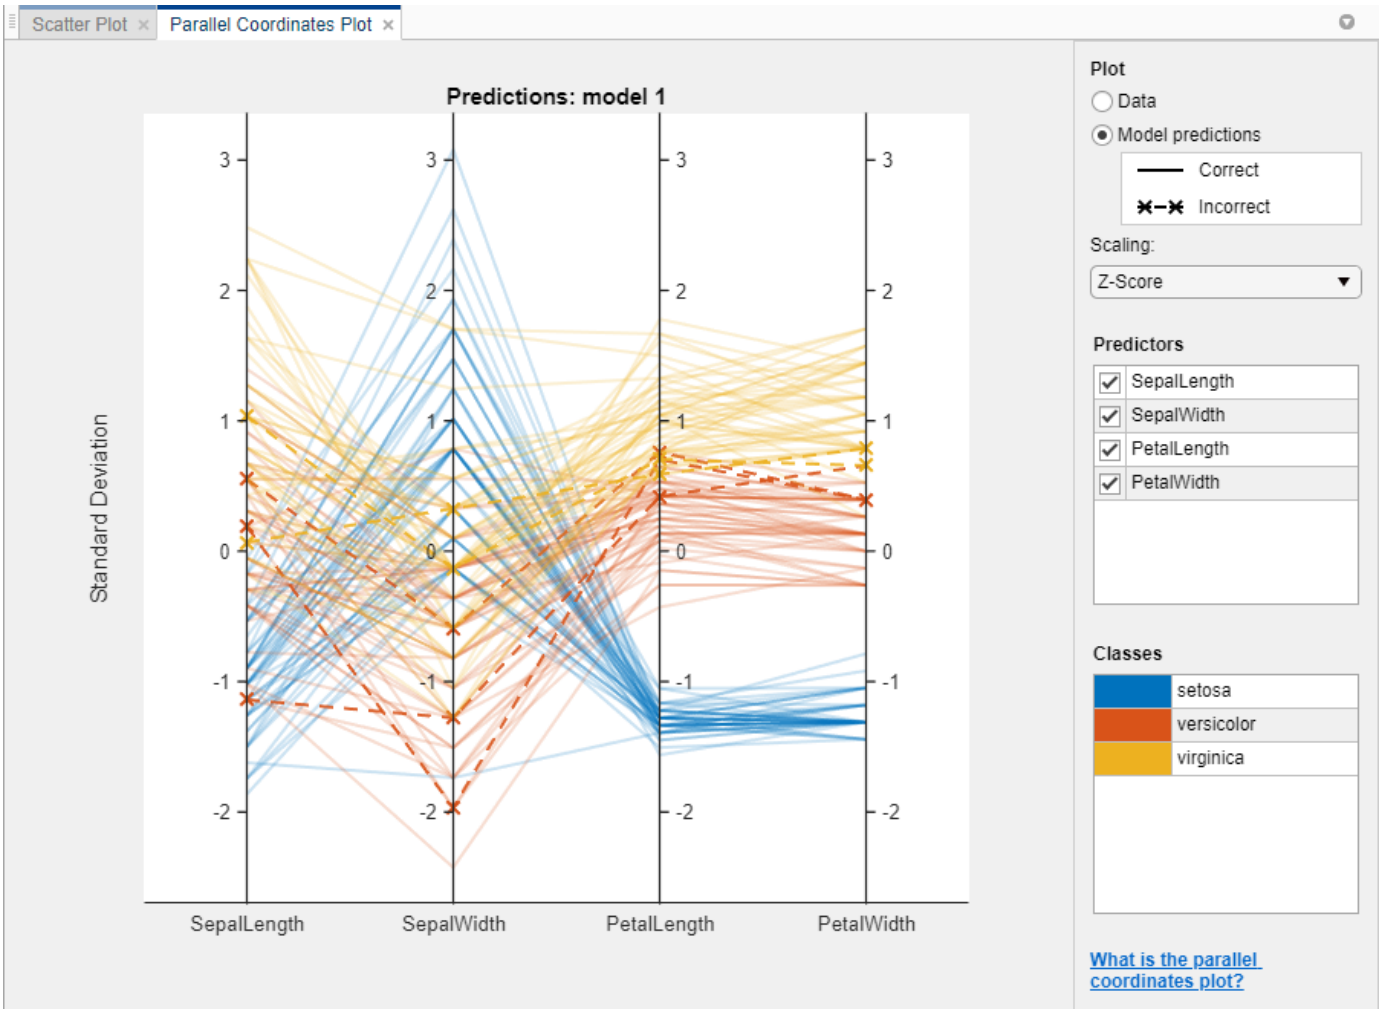
1. On the **Classification Learner** tab, in the **Plots** section, click **Parallel Coordinates**.
2. On the plot, drag the *X* tick labels to reorder the predictors. Changing the order can help you identify predictors that separate classes well.
3. To specify which predictors to plot, use the **Predictors** check boxes. A good practice is to plot a few predictors at a time. If your data has many predictors, the plot shows the first 10 predictors by default.
4. If the predictors have significantly different scales, scale the data for easier visualization. Try different options in the **Scaling** list:

   - `None` displays raw data along coordinate rulers that have the same minimum and maximum limits.
   - `Range` displays raw data along coordinate rulers that have independent minimum and maximum limits.
   - `Z-Score` displays z-scores (with a mean of 0 and a standard deviation of 1) along each coordinate ruler.
   - `Zero Mean` displays data centered to have a mean of 0 along each coordinate ruler.

- `Unit Variance` displays values scaled by standard deviation along each coordinate ruler.
- `L2 Norm` displays 2-norm values along each coordinate ruler.

5 If you identify predictors that are not useful for separating out classes, use **Feature Selection** to remove them and train classifiers including only the most useful predictors.

The plot of the `fisheriris` data shows the petal length and petal width features separate the classes best.



You can export the parallel coordinates plots you create in the app to figures. See “Export Plots in Classification Learner App” on page 23-72.

Misclassification Costs in Classification Learner App

In this section...

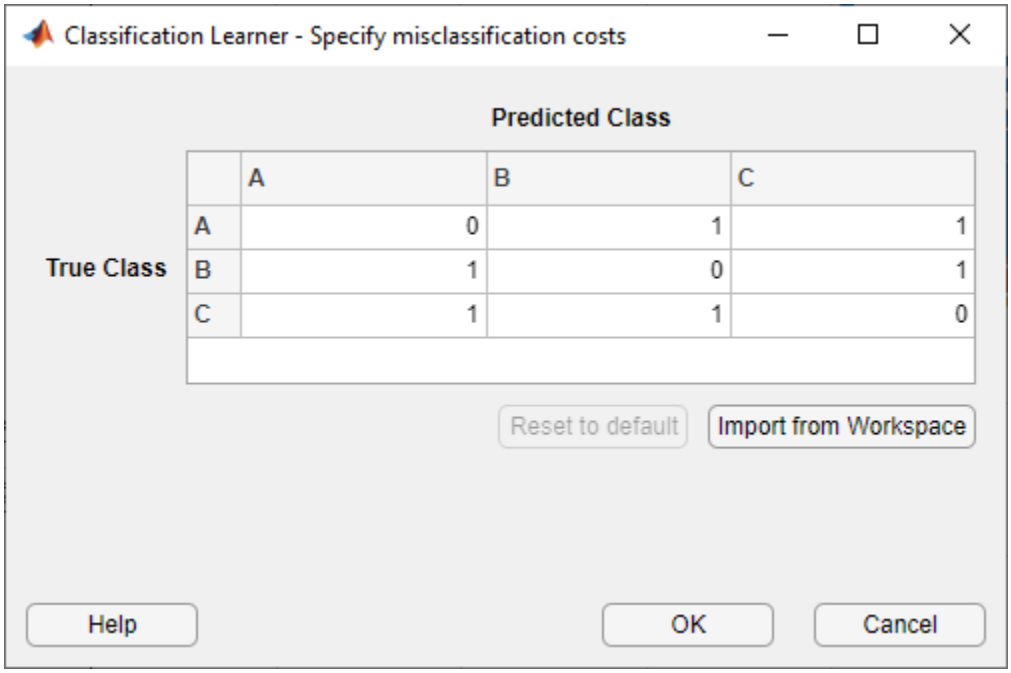
By default, the Classification Learner app creates models that assign the same penalty to all misclassifications during training. For a given observation, the app assigns a penalty of 0 if the observation is classified correctly and a penalty of 1 if the observation is classified incorrectly. In some cases, this assignment is inappropriate. For example, suppose you want to classify patients as either healthy or sick. The cost of misclassifying a sick person as healthy might be five times the cost of misclassifying a healthy person as sick. For cases where you know the cost of misclassifying observations of one class into another, and the costs vary across the classes, specify the misclassification costs before training your models.

Note Custom misclassification costs are not supported for logistic regression and neural network models.

Specify Misclassification Costs

In the Classification Learner app, in the **Options** section of the **Classification Learner** tab, select **Misclassification Costs**. The app opens a dialog box that shows the default misclassification costs (cost matrix) as a table with row and column labels determined by the classes in the response variable. The rows of the table correspond to the true classes, and the columns correspond to the predicted classes. You can interpret the cost matrix in this way: the entry in row i and column j is the cost of misclassifying ith class observations into the jth class. The diagonal entries of the cost matrix must be 0, and the off-diagonal entries must be nonnegative real numbers.

You can specify your own misclassification costs in two ways: by entering values directly into the table in the dialog box or by importing a workspace variable that contains the cost values.



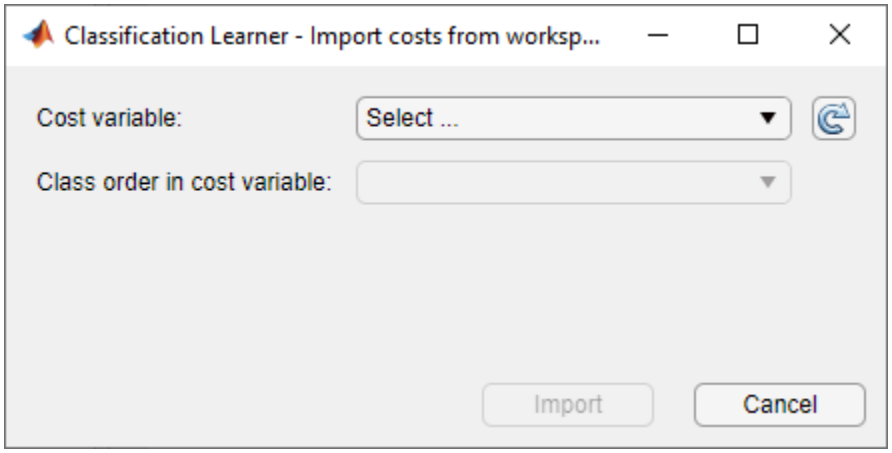
Note A scaled version of the cost matrix gives the same classification results (for example, confusion matrix and accuracy), but with a different total misclassification cost. That is, if `CostMat` is the misclassification cost matrix and `a` is a positive, real scalar, then a model trained with the cost matrix `a*CostMat` has the same confusion matrix as that model trained with `CostMat`.

Enter Costs Directly in Dialog Box

In the misclassification costs dialog box, double-click an entry in the table that you want to edit. Delete the value and type the correct misclassification cost for the entry. When you are done editing the table, click **OK** to save your changes.

Import Workspace Variable Containing Costs

In the misclassification costs dialog box, click **Import from Workspace**. The app opens a dialog box for importing costs from a variable in the MATLAB workspace.



From the **Cost variable** list, select the cost matrix or structure that contains the misclassification costs.

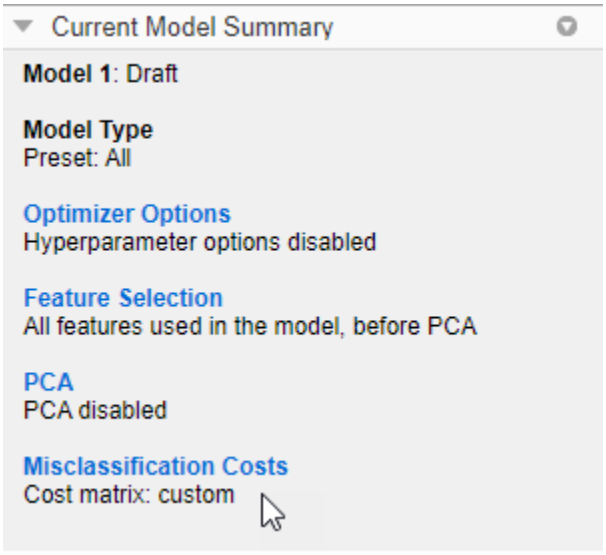
- Cost matrix – The matrix must contain the misclassification costs. The diagonal entries must be 0, and the off-diagonal entries must be nonnegative real numbers. By default, the app uses the class order shown in the previous misclassification costs dialog box to interpret the cost matrix values.

  To specify the order of the classes in the cost matrix, create a separate workspace variable containing the class names in the correct order. In the import dialog box, select the appropriate variable from the **Class order in cost variable** list. The workspace variable containing the class names must be a categorical vector, logical vector, numeric vector, string array, or cell array of character vectors. The class names must match (in spelling and capitalization) the class names in the response variable.
- Structure – The structure must contain the fields `ClassificationCosts` and `ClassNames` with these specifications:

  - `ClassificationCosts` – Matrix that contains misclassification costs.
  - `ClassNames` – Names of the classes. The order of the classes in `ClassNames` determines the order of the rows and columns of `ClassificationCosts`. The variable `ClassNames` must be a categorical vector, logical vector, numeric vector, string array, or cell array of character vectors. The class names must match (in spelling and capitalization) the class names in the response variable.

After specifying the cost variable and the class order in the cost variable, click **Import**. The app updates the table in the misclassification costs dialog box.

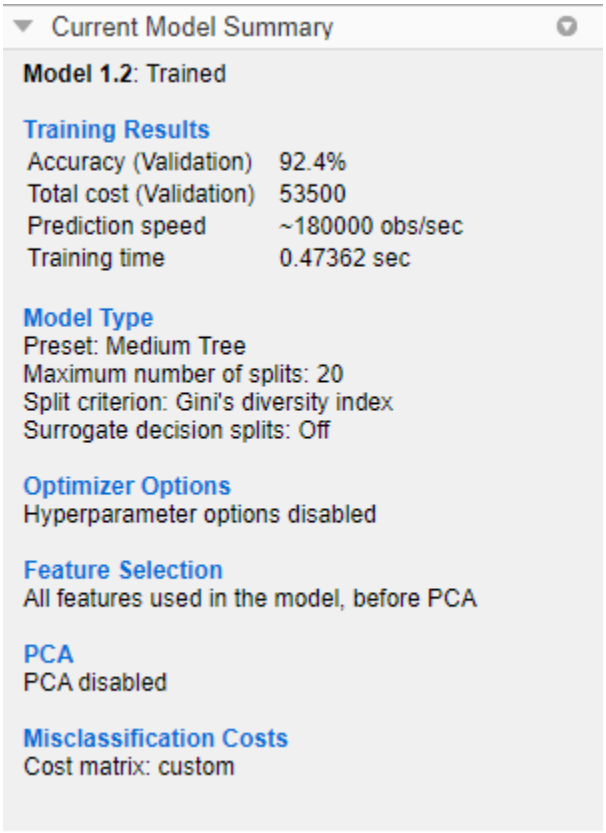
After you specify a cost matrix that differs from the default, the app updates the **Current Model Summary** pane for new models. In the **Current Model Summary** pane, under **Misclassification Costs**, the app lists the cost matrix as "custom". For models that use the default misclassification costs, the app lists the cost matrix as "default".



Assess Model Performance

After specifying misclassification costs, you can train and tune your models as usual. However, using custom misclassification costs can change how you assess the performance of a model. For example, instead of choosing the model with the best accuracy, choose a model that has good accuracy and a low total misclassification cost. The total misclassification cost for a model is `sum(CostMat.*ConfusionMat,'all')`, where `CostMat` is the misclassification cost matrix and `ConfusionMat` is the confusion matrix for the model. The confusion matrix shows how the model classifies observations in each class. See “Check Performance Per Class in the Confusion Matrix” on page 23-67.

To inspect the total misclassification cost of a trained model, select the model in the **Models** pane. In the **Current Model Summary** pane, look at the **Training Results** section. The total misclassification cost is listed below the accuracy of the model.



Misclassification Costs in Exported Model and Generated Code

After you train a model with custom misclassification costs and export it from the app, you can find the custom costs inside the exported model. For example, if you export a tree model as a structure named `trainedModel`, you can use the following code to access the cost matrix and the order of the classes in the matrix.

```
trainedModel.ClassificationTree.Cost
trainedModel.ClassificationTree.ClassNames
```

For ensemble and binary SVM models, the app uses the misclassification costs to adjust the model prior class probabilities. Therefore, the `Cost` property of the exported model is reset to the default cost matrix, but the `Prior` property is updated.

When you generate MATLAB code for a model trained with custom misclassification costs, the generated code includes a cost matrix that is passed to the training function through the `'Cost'` name-value pair argument.

Hyperparameter Optimization in Classification Learner App

In this section...

After you choose a particular type of model to train, for example a decision tree or a support vector machine (SVM), you can tune your model by selecting different advanced options. For example, you can change the maximum number of splits for a decision tree or the box constraint of an SVM. Some of these options are internal parameters of the model, or hyperparameters, that can strongly affect its performance. Instead of manually selecting these options, you can use hyperparameter optimization within the Classification Learner app to automate the selection of hyperparameter values. For a given model type, the app tries different combinations of hyperparameter values by using an optimization scheme that seeks to minimize the model classification error, and returns a model with the optimized hyperparameters. You can use the resulting model as you would any other trained model.

Note Because hyperparameter optimization can lead to an overfitted model, the recommended approach is to create a separate test set before importing your data into the Classification Learner app. After you train your optimizable model, you can see how it performs on your test set. For an example, see “Train Classifier Using Hyperparameter Optimization in Classification Learner App” on page 23-128.

To perform hyperparameter optimization in Classification Learner, follow these steps:

1. Choose a model type and decide which hyperparameters to optimize. See “Select Hyperparameters to Optimize” on page 23-54.

   Note Hyperparameter optimization is not supported for logistic regression or neural network models.

2. (Optional) Specify how the optimization is performed. For more information, see “Optimization Options” on page 23-59.
3. Train your model. Use the “Minimum Classification Error Plot” on page 23-61 to track the optimization results.
4. Inspect your trained model. See “Optimization Results” on page 23-62.

Select Hyperparameters to Optimize

In the Classification Learner app, in the **Model Type** section of the **Classification Learner** tab, click the arrow to open the gallery. The gallery includes optimizable models that you can train using hyperparameter optimization.

After you select an optimizable model, you can choose which of its hyperparameters you want to optimize. In the **Model Type** section, select **Advanced > Advanced**. The app opens a dialog box in which you can select **Optimize** check boxes for the hyperparameters that you want to optimize.

Under **Values**, specify the fixed values for the hyperparameters that you do not want to optimize or that are not optimizable.

This table describes the hyperparameters that you can optimize for each type of model and the search range of each hyperparameter. It also includes the additional hyperparameters for which you can specify fixed values.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
Optimizable Tree 	• **Maximum number of splits** – The software searches among integers log-scaled in the range `[1,max(2,n–1)]`, where `n` is the number of observations. • **Split criterion** – The software searches among `Gini's diversity index`, `Twoing rule`, and `Maximum deviance reduction`.	• **Surrogate decision splits** • **Maximum surrogates per node**	For more information, see “Advanced Tree Options” on page 23-28.
Optimizable Discriminant 	• **Discriminant type** – The software searches among `Linear`, `Quadratic`, `Diagonal Linear`, and `Diagonal Quadratic`.		• The **Discriminant type** optimizable hyperparameter combines the preset model types (**Linear Discriminant** and **Quadratic Discriminant**) with the **Covariance structure** advanced option of the preset models. For more information, see “Advanced Discriminant Options” on page 23-30.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
Optimizable Naive Bayes 	• **Distribution names** – The software searches between `Gaussian` and `Kernel`. • **Kernel type** – The software searches among `Gaussian`, `Box`, `Epanechnikov`, and `Triangle`.	• **Support**	• The `Gaussian` value of the **Distribution names** optimizable hyperparameter specifies a **Gaussian Naive Bayes** model. Similarly, the `Kernel` **Distribution names** value specifies a **Kernel Naive Bayes** model. For more information, see “Advanced Naive Bayes Options” on page 23-31.
Optimizable SVM 	• **Kernel function** – The software searches among `Gaussian`, `Linear`, `Quadratic`, and `Cubic`. • **Box constraint level** – The software searches among positive values log-scaled in the range `[0.001,1000]`. • **Kernel scale** – The software searches among positive values log-scaled in the range `[0.001,1000]`. • **Multiclass method** – The software searches between `One-vs-One` and `One-vs-All`. • **Standardize data** – The software searches between `true` and `false`.		• The **Kernel scale** optimizable hyperparameter combines the **Kernel scale mode** and **Manual kernel scale** advanced options of the preset SVM models. • You can optimize the **Kernel scale** optimizable hyperparameter only when the **Kernel function** value is `Gaussian`. Unless you specify a value for **Kernel scale** by clearing the **Optimize** check box, the app uses the **Manual** value of `1` by default when the **Kernel function** has a value other than `Gaussian`. For more information, see “Advanced SVM Options” on page 23-33.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes

Optimizable KNN 	• **Number of neighbors** – The software searches among integers log-scaled in the range `[1,max(2,round(n/2))]`, where `n` is the number of observations.
	• **Distance metric** – The software searches among:
	  • `Euclidean`
	  • `City block`
	  • `Chebyshev`
	  • `Minkowski (cubic)`
	  • `Mahalanobis`
	  • `Cosine`
	  • `Correlation`
	  • `Spearman`
	  • `Hamming`
	  • `Jaccard`
	• **Distance weight** – The software searches among `Equal`, `Inverse`, and `Squared inverse`.
	• **Standardize** – The software searches between `true` and `false`.
			For more information, see “Advanced KNN Options” on page 23-36.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
Optimizable Ensemble 	• **Ensemble method** – The software searches among `AdaBoost`, `RUSBoost`, `LogitBoost`, `GentleBoost`, and `Bag`. • **Maximum number of splits** – The software searches among integers log-scaled in the range `[1,max(2,n–1)]`, where `n` is the number of observations. • **Number of learners** – The software searches among integers log-scaled in the range `[10,500]`. • **Learning rate** – The software searches among real values log-scaled in the range `[0.001,1]`. • **Number of predictors to sample** – The software searches among integers in the range `[1,max(2,p)]`, where `p` is the number of predictor variables.	• **Learner type**	• The `AdaBoost`, `LogitBoost`, and `GentleBoost` values of the **Ensemble method** optimizable hyperparameter specify a **Boosted Trees** model. Similarly, the `RUSBoost` **Ensemble method** value specifies an **RUSBoosted Trees** model, and the `Bag` **Ensemble method** value specifies a **Bagged Trees** model. • The `LogitBoost` and `GentleBoost` values are available only for binary classification. • The **Number of predictors to sample** optimizable hyperparameter is not available in the advanced options of the preset ensemble models. • You can optimize the **Number of predictors to sample** optimizable hyperparameter only when the **Ensemble method** value is `Bag`. Unless you specify a value for **Number of predictors to sample** by clearing the **Optimize** check box, the app uses the default value of **Select All** when the

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
			Ensemble method has a value other than `Bag`. For more information, see “Advanced Ensemble Options” on page 23-38.

Optimization Options

By default, the Classification Learner app performs hyperparameter tuning by using Bayesian optimization. The goal of Bayesian optimization, and optimization in general, is to find a point that minimizes an objective function. In the context of hyperparameter tuning in the app, a point is a set of hyperparameter values, and the objective function is the loss function, or the classification error. For more information on the basics of Bayesian optimization, see “Bayesian Optimization Workflow” on page 10-25.

You can specify how the hyperparameter tuning is performed. For example, you can change the optimization method to grid search or limit the training time. On the **Classification Learner** tab, in the **Model Type** section, select **Advanced > Optimizer Options**. The app opens a dialog box in which you can select optimization options.

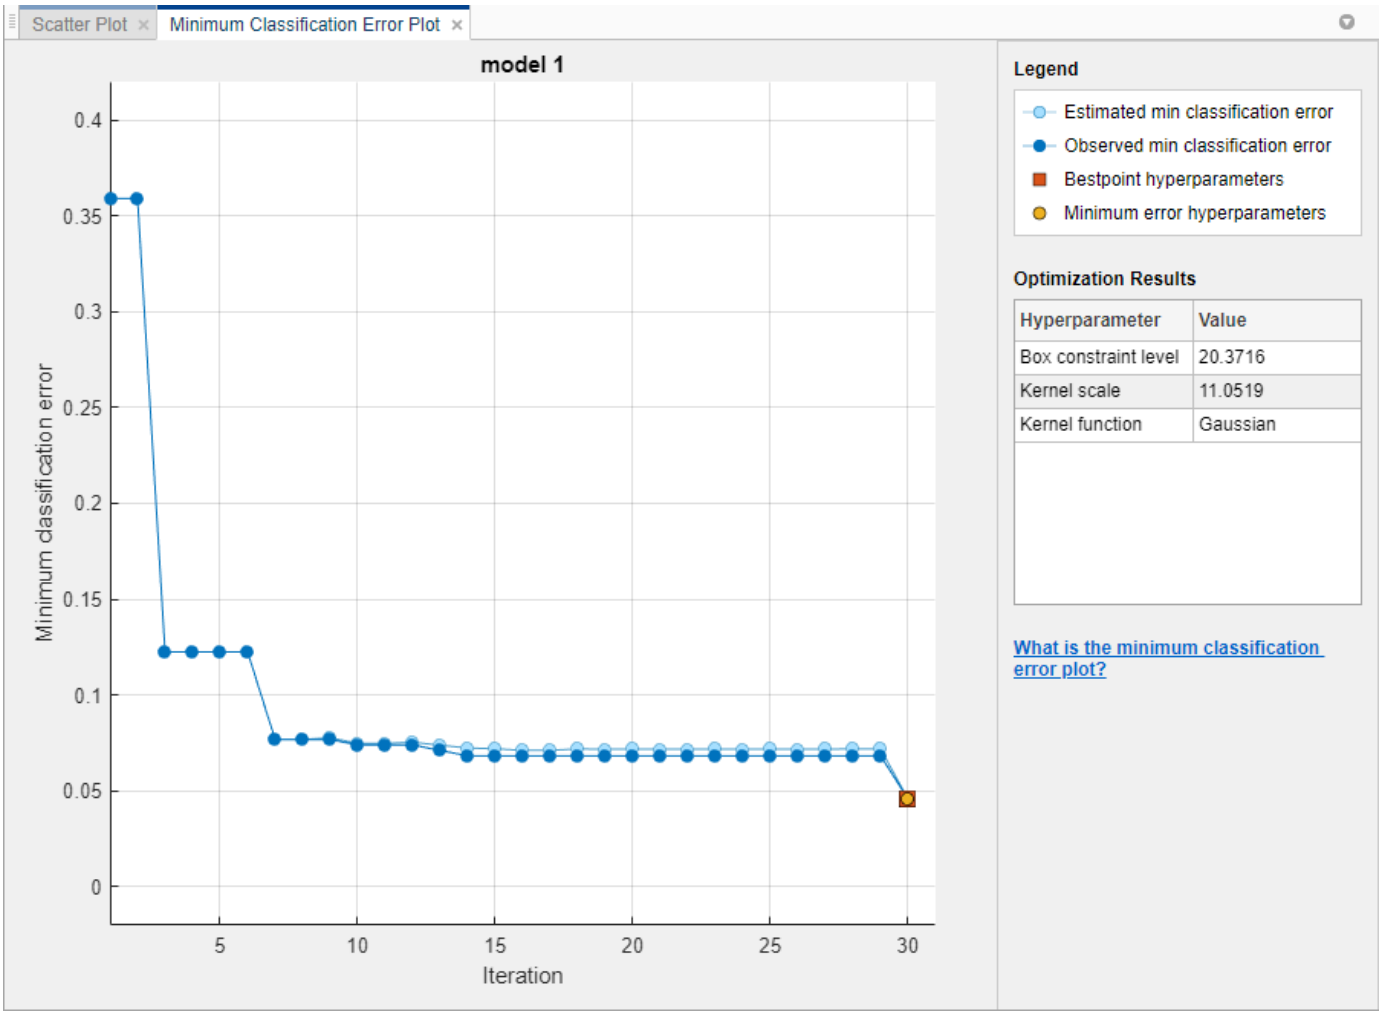
This table describes the available optimization options and their default values.

Option	Description
Optimizer	The optimizer values are: • `Bayesopt` (default) – Use Bayesian optimization. Internally, the app calls the `bayesopt` function. • `Grid search` – Use grid search with the number of values per dimension determined by the **Number of grid divisions** value. The app searches in a random order, using uniform sampling without replacement from the grid. • `Random search` – Search at random among points, where the number of points corresponds to the **Iterations** value.

Option	Description
Acquisition function	When the app performs Bayesian optimization for hyperparameter tuning, it uses the acquisition function to determine the next set of hyperparameter values to try. The acquisition function values are: • `Expected improvement per second plus` (default) • `Expected improvement` • `Expected improvement plus` • `Expected improvement per second` • `Lower confidence bound` • `Probability of improvement` For details on how these acquisition functions work in the context of Bayesian optimization, see “Acquisition Function Types” on page 10-3.
Iterations	Each iteration corresponds to a combination of hyperparameter values that the app tries. When you use Bayesian optimization or random search, specify a positive integer that sets the number of iterations. The default value is `30`. When you use grid search, the app ignores the **Iterations** value and evaluates the loss at every point in the entire grid. You can set a training time limit to stop the optimization process prematurely.
Training time limit	To set a training time limit, select this option and set the **Maximum training time in seconds** option. By default, the app does not have a training time limit.
Maximum training time in seconds	Set the training time limit in seconds as a positive real number. The default value is `300`. The run time can exceed the training time limit because this limit does not interrupt an iteration evaluation.
Number of grid divisions	When you use grid search, set a positive integer as the number of values the app tries for each numeric hyperparameter. The app ignores this value for categorical hyperparameters. The default value is `10`.

Minimum Classification Error Plot

After specifying which model hyperparameters to optimize and setting any additional optimization options (optional), train your optimizable model. On the **Classification Learner** tab, in the **Training** section, click **Train**. The app creates a **Minimum Classification Error Plot** that it updates as the optimization runs.



Note When you train an optimizable model, the app disables the **Use Parallel** button. After the training is complete, the app makes the button available again when you select a nonoptimizable model. The button is off by default.

The minimum classification error plot displays the following information:

- **Estimated minimum classification error** – Each light blue point corresponds to an estimate of the minimum classification error computed by the optimization process when considering all the sets of hyperparameter values tried so far, including the current iteration.

  The estimate is based on an upper confidence interval of the current classification error objective model, as mentioned in the **Bestpoint hyperparameters** description.

If you use grid search or random search to perform hyperparameter optimization, the app does not display these light blue points.

- **Observed minimum classification error** – Each dark blue point corresponds to the observed minimum classification error computed so far by the optimization process. For example, at the third iteration, the dark blue point corresponds to the minimum of the classification error observed in the first, second, and third iterations.
- **Bestpoint hyperparameters** – The red square indicates the iteration that corresponds to the optimized hyperparameters. You can find the values of the optimized hyperparameters listed in the upper right of the plot under **Optimization Results**.

  The optimized hyperparameters do not always provide the observed minimum classification error. When the app performs hyperparameter tuning by using Bayesian optimization (see “Optimization Options” on page 23-59 for a brief introduction), it chooses the set of hyperparameter values that minimizes an upper confidence interval of the classification error objective model, rather than the set that minimizes the classification error. For more information, see the `'Criterion','min-visited-upper-confidence-interval'` name-value pair argument of `bestPoint`.
- **Minimum error hyperparameters** – The yellow point indicates the iteration that corresponds to the hyperparameters that yield the observed minimum classification error.

  For more information, see the `'Criterion','min-observed'` name-value pair argument of `bestPoint`.

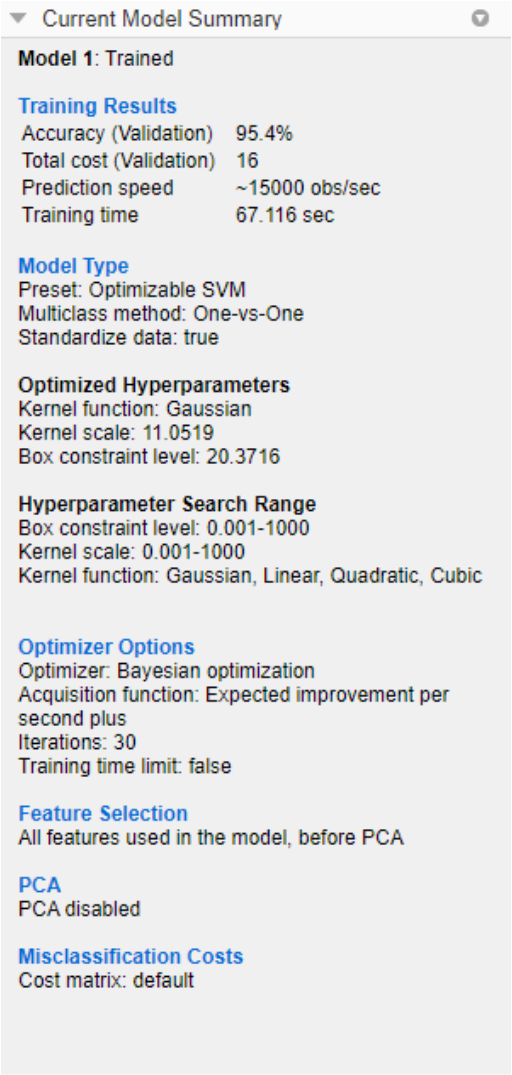
  If you use grid search to perform hyperparameter optimization, the **Bestpoint hyperparameters** and the **Minimum error hyperparameters** are the same.

Missing points in the plot correspond to `NaN` minimum classification error values.

Optimization Results

When the app finishes tuning model hyperparameters, it returns a model trained with the optimized hyperparameter values (**Bestpoint hyperparameters**). The model metrics, displayed plots, and exported model correspond to this trained model with fixed hyperparameter values.

To inspect the optimization results of a trained optimizable model, select the model in the **Models** pane and look at the **Current Model Summary** pane.



The **Current Model Summary** pane includes these sections:

- **Training Results** – Shows the performance of the optimizable model
- **Model Type** – Displays the type of optimizable model and lists any fixed hyperparameter values
- **Optimized Hyperparameters** – Lists the values of the optimized hyperparameters
- **Hyperparameter Search Range** – Displays the search ranges for the optimized hyperparameters
- **Optimizer Options** – Shows the selected optimizer options

When you perform hyperparameter tuning using Bayesian optimization and you export the resulting trained optimizable model to the workspace as a structure, the structure includes a `BayesianOptimization` object in the `HyperParameterOptimizationResult` field. The object contains the results of the optimization performed in the app.

When you generate MATLAB code from a trained optimizable model, the generated code uses the fixed and optimized hyperparameter values of the model to train on new data. The generated code does not include the optimization process. For information on how to perform Bayesian optimization when you use a fit function, see “Bayesian Optimization Using a Fit Function” on page 10-26.

Assess Classifier Performance in Classification Learner

In this section...

After training classifiers in Classification Learner, you can compare models based on accuracy scores, visualize results by plotting class predictions, and check performance using confusion matrix and ROC curve.

- If you use *k*-fold cross-validation, then the app computes the accuracy scores using the observations in the *k* validation folds and reports the average cross-validation error. It also makes predictions on the observations in these validation folds and computes the confusion matrix and ROC curve based on these predictions.

  Note When you import data into the app, if you accept the defaults, the app automatically uses cross-validation. To learn more, see “Choose Validation Scheme” on page 23-20.

- If you use hold-out validation, the app computes the accuracy scores using the observations in the validation fold and makes predictions on these observations. The app also computes the confusion matrix and ROC curve based on these predictions.
- If you use resubstitution validation, the score is the resubstitution accuracy based on all the training data, and the predictions are resubstitution predictions.

Check Performance in the Models Pane

After training a model in Classification Learner, check the **Models** pane to see which model has the best overall accuracy in percent. The best **Accuracy (Validation)** score is highlighted in a box. This score is the validation accuracy. The validation accuracy score estimates a model's performance on new data compared to the training data. Use the score to help you choose the best model.

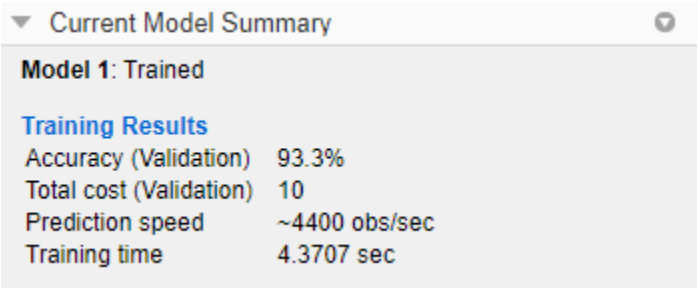
- For cross-validation, the score is the accuracy on all observations, counting each observation when it was in a held-out (validation) fold.
- For holdout validation, the score is the accuracy on the held-out observations.
- For resubstitution validation, the score is the resubstitution accuracy against all the training data observations.

The best overall score might not be the best model for your goal. A model with a slightly lower overall accuracy might be the best classifier for your goal. For example, false positives in a particular class might be important to you. You might want to exclude some predictors where data collection is expensive or difficult.

To find out how the classifier performed in each class, examine the confusion matrix.

View and Compare Model Metrics

You can view model metrics in the **Current Model Summary** pane and use these metrics to assess and compare models. The **Training Results** metrics are calculated on the validation set. The **Test Results** metrics, if displayed, are calculated on an imported test set. For more information, see “Evaluate Test Set Model Performance” on page 23-69.



To copy the information in the **Current Model Summary** pane, you can right-click into the pane and select **Copy text**.

Model Metrics

Metric	Description	Tip
Accuracy	Percentage of observations that are correctly classified	Look for larger accuracy values.
Total cost	Total misclassification cost	Look for smaller total cost values. Make sure the accuracy value is still large.

You can sort the models based on the different model metrics. To select a metric for model sorting, use the **Sort by** list at the top of the **Models** pane.

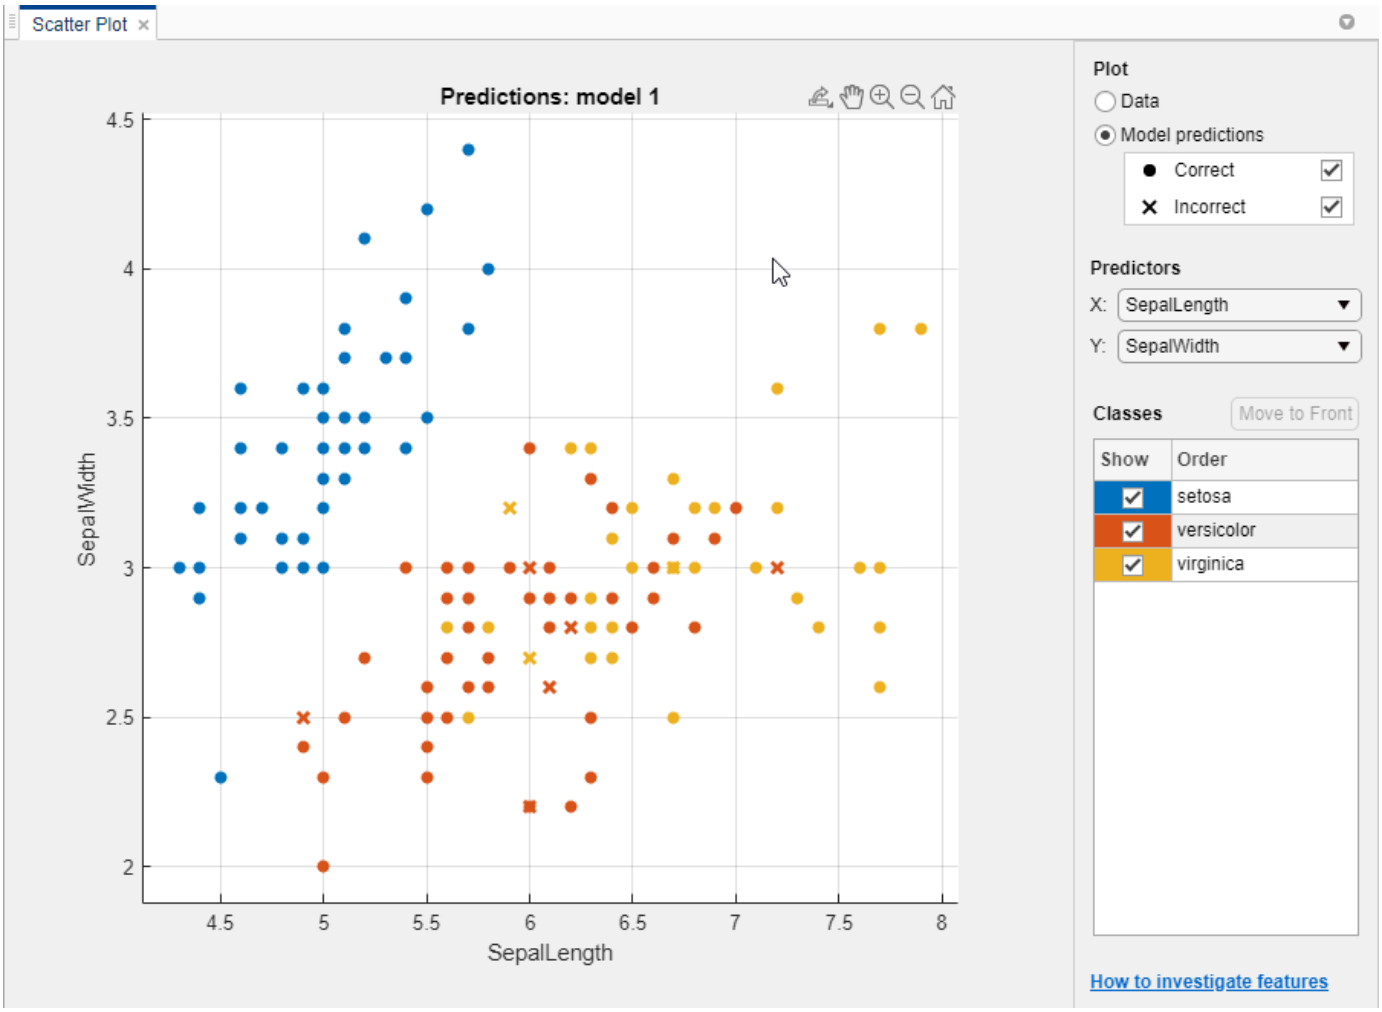
You can also delete unwanted models listed in the **Models** pane. Select the model you want to delete and click the **Delete selected model** button in the upper right of the pane, or right-click the model and select **Delete model**. You cannot delete the last remaining model in the **Models** pane.

Plot Classifier Results

In the scatter plot, view the classifier results. After you train a classifier, the scatter plot switches from displaying the data to showing model predictions. If you are using holdout or cross-validation, then these predictions are the predictions on the held-out (validation) observations. In other words, each prediction is obtained using a model that was trained without using the corresponding observation. To investigate your results, use the controls on the right. You can:

- Choose whether to plot model predictions or the data alone.
- Show or hide correct or incorrect results using the check boxes under **Model predictions**.
- Choose features to plot using the **X** and **Y** lists under **Predictors**.
- Visualize results by class by showing or hiding specific classes using the check boxes under **Show**.
- Change the stacking order of the plotted classes by selecting a class under **Classes** and then clicking **Move to Front**.

- Zoom in and out, or pan across the plot. To enable zooming or panning, hover the mouse over the scatter plot and click the corresponding button on the toolbar that appears above the top right of the plot.



See also “Investigate Features in the Scatter Plot” on page 23-42.

To export the scatter plots you create in the app to figures, see “Export Plots in Classification Learner App” on page 23-72.

Check Performance Per Class in the Confusion Matrix

Use the confusion matrix plot to understand how the currently selected classifier performed in each class. To view the confusion matrix after training a model, click **Confusion Matrix** and select **Validation Data** in the **Plots** section of the **Classification Learner** tab. The confusion matrix helps you identify the areas where the classifier has performed poorly.

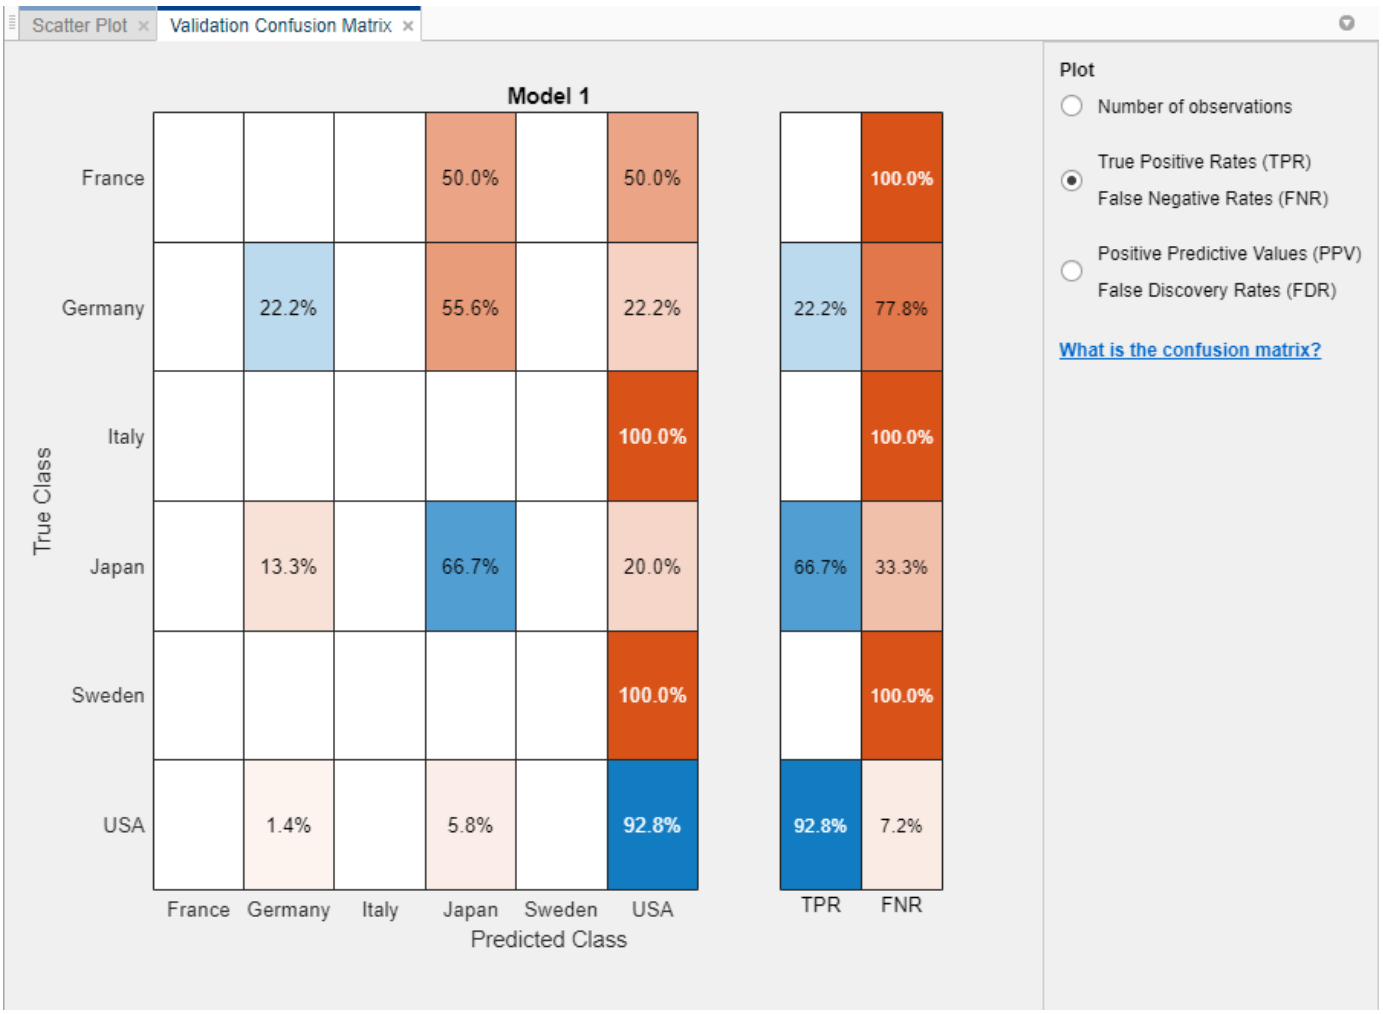
When you open the plot, the rows show the true class, and the columns show the predicted class. If you are using holdout or cross-validation, then the confusion matrix is calculated using the predictions on the held-out (validation) observations. The diagonal cells show where the true class

and predicted class match. If these diagonal cells are blue, the classifier has classified observations of this true class are classified correctly.

The default view shows the number of observations in each cell.

To see how the classifier performed per class, under **Plot**, select the **True Positive Rates (TPR)**, **False Negative Rates (FNR)** option. The TPR is the proportion of correctly classified observations per true class. The FNR is the proportion of incorrectly classified observations per true class. The plot shows summaries per true class in the last two columns on the right.

Tip Look for areas where the classifier performed poorly by examining cells off the diagonal that display high percentages and are orange. The higher the percentage, the darker the hue of the cell color. In these orange cells, the true class and the predicted class do not match. The data points are misclassified.



In this example, which uses the `carsmall` data set, the second row from the top shows all cars with the true class Germany. The columns show the predicted classes. 22.2% of the cars from Germany are correctly classified, so **22.2%** is the true positive rate for correctly classified points in this class, shown in the blue cell in the **TPR** column.

The other cars in the Germany row are misclassified: 55.6% of the cars are incorrectly classified as from Japan, and 22.2% are classified as from USA. The false negative rate for incorrectly classified points in this class is **77.8%**, shown in the orange cell in the **FNR** column.

If you want to see numbers of observations (cars, in this example) instead of percentages, under **Plot**, select **Number of observations**.

If false positives are important in your classification problem, plot results per predicted class (instead of true class) to investigate false discovery rates. To see results per predicted class, under **Plot**, select the **Positive Predictive Values (PPV)**, **False Discovery Rates (FDR)** option. The PPV is the proportion of correctly classified observations per predicted class. The FDR is the proportion of incorrectly classified observations per predicted class. With this option selected, the confusion matrix now includes summary rows below the table. Positive predictive values are shown in blue for the correctly predicted points in each class, and false discovery rates are shown in orange for the incorrectly predicted points in each class.

If you decide there are too many misclassified points in the classes of interest, try changing classifier settings or feature selection to search for a better model.

To export the confusion matrix plots you create in the app to figures, see “Export Plots in Classification Learner App” on page 23-72.

Check the ROC Curve

To view the ROC curve after training a model, on the **Classification Learner** tab, in the **Plots** section, click **ROC Curve** and select **Validation Data**. View the receiver operating characteristic (ROC) curve showing true and false positive rates. The ROC curve shows true positive rate versus false positive rate for the currently selected trained classifier. You can select different classes to plot.

The marker on the plot shows the performance of the currently selected classifier. The marker shows the values of the false positive rate (FPR) and the true positive rate (TPR) for the currently selected classifier. For example, a false positive rate (FPR) of 0.2 indicates that the current classifier assigns 20% of the observations incorrectly to the positive class. A true positive rate of 0.9 indicates that the current classifier assigns 90% of the observations correctly to the positive class.

A perfect result with no misclassified points is a right angle to the top left of the plot. A poor result that is no better than random is a line at 45 degrees. The **Area Under Curve** number is a measure of the overall quality of the classifier. Larger **Area Under Curve** values indicate better classifier performance. Compare classes and trained models to see if they perform differently in the ROC curve.

For more information, see `perfcurve`.

To export the ROC curve plots you create in the app to figures, see “Export Plots in Classification Learner App” on page 23-72.

Evaluate Test Set Model Performance

After training a model in Classification Learner, you can evaluate the model performance on a test set in the app. This process allows you to check whether the validation accuracy provides a good estimate for the model performance on new data.

1. Import a test data set into Classification Learner.

   - If the test data set is in the MATLAB workspace, then in the **Testing** section on the **Classification Learner** tab, click **Test Data** and select **From Workspace**.
   - If the test data set is in a file, then in the **Testing** section, click **Test Data** and select **From File**. Select a file type in the list, such as a spreadsheet, text file, or comma-separated values (`.csv`) file, or select **All Files** to browse for other file types such as `.dat`.

   In the Import Test Data dialog box, select the test data set from the **Test Data Set Variable** list. The test set must have the same variables as the predictors imported for training and validation. The unique values in the test response variable must be a subset of the classes in the full response variable.

2. Compute the test set metrics.

   - To compute test metrics for a single model, select the trained model in the **Models** pane. On the **Classification Learner** tab, in the **Testing** section, click **Test All** and select **Test Selected**.
   - To compute test metrics for all trained models, click **Test All** and select **Test All** in the **Testing** section.

   The app computes the test set performance of each model trained on the full data set, including training and validation data.

3. Compare the validation accuracy with the test accuracy.

   In the **Current Model Summary** pane, the app displays the validation metrics and test metrics under the **Training Results** section and **Test Results** section, respectively. You can check if the validation accuracy gives a good estimate for the test accuracy.

   You can also visualize the test results using plots.

   - Display a confusion matrix. In the **Plots** section on the **Classification Learner** tab, click **Confusion Matrix** and select **Test Data**.
   - Display an ROC curve. In the **Plots** section, click **ROC Curve** and select **Test Data**.

For an example, see “Check Classifier Performance Using Test Set in Classification Learner App” on page 23-137. For an example that uses test set metrics in a hyperparameter optimization workflow, see “Train Classifier Using Hyperparameter Optimization in Classification Learner App” on page 23-128.

Export Plots in Classification Learner App

After you create plots interactively in the Classification Learner app, you can export your app plots to MATLAB figures. You can then copy, save, or customize the new figures. Choose among the available plots: scatter plot on page 23-42, parallel coordinates plot on page 23-45, confusion matrix on page 23-67, ROC curve on page 23-69, and minimum classification error plot on page 23-61.

- Before exporting a plot, make sure the plot in the app displays the same data that you want in the new figure.
- On the **Classification Learner** tab, in the **Export** section, click **Export Plot to Figure**. The app creates a figure from the selected plot.
  - The new figure might not have the same interactivity options as the plot in the Classification Learner app. For example, data tips for the exported scatter plot show only X,Y values for the selected point, not the detailed information displayed in the app.
  - Additionally, the figure might have a different axes toolbar than the one in the app plot. For plots in Classification Learner, an axes toolbar appears above the top right of the plot. The buttons available on the toolbar depend on the contents of the plot. The toolbar can include buttons to export the plot as an image, add data tips, pan or zoom the data, and restore the view.

- Copy, save, or customize the new figure, which is displayed in the figure window.
  - To copy the figure, select **Edit > Copy Figure**. For more information, see “Copy Figure to Clipboard from Edit Menu”.
  - To save the figure, select **File > Save As**. Alternatively, you can follow the workflow described in “Customize Figure Before Saving”.
  - To customize the figure, click the Edit Plot button  on the figure toolbar. Right-click the section of the plot that you want to edit. You can change the listed properties, which might include **Color**, **Font**, **Line Style**, and other properties. Or, you can use the **Property Inspector** to change the figure properties.

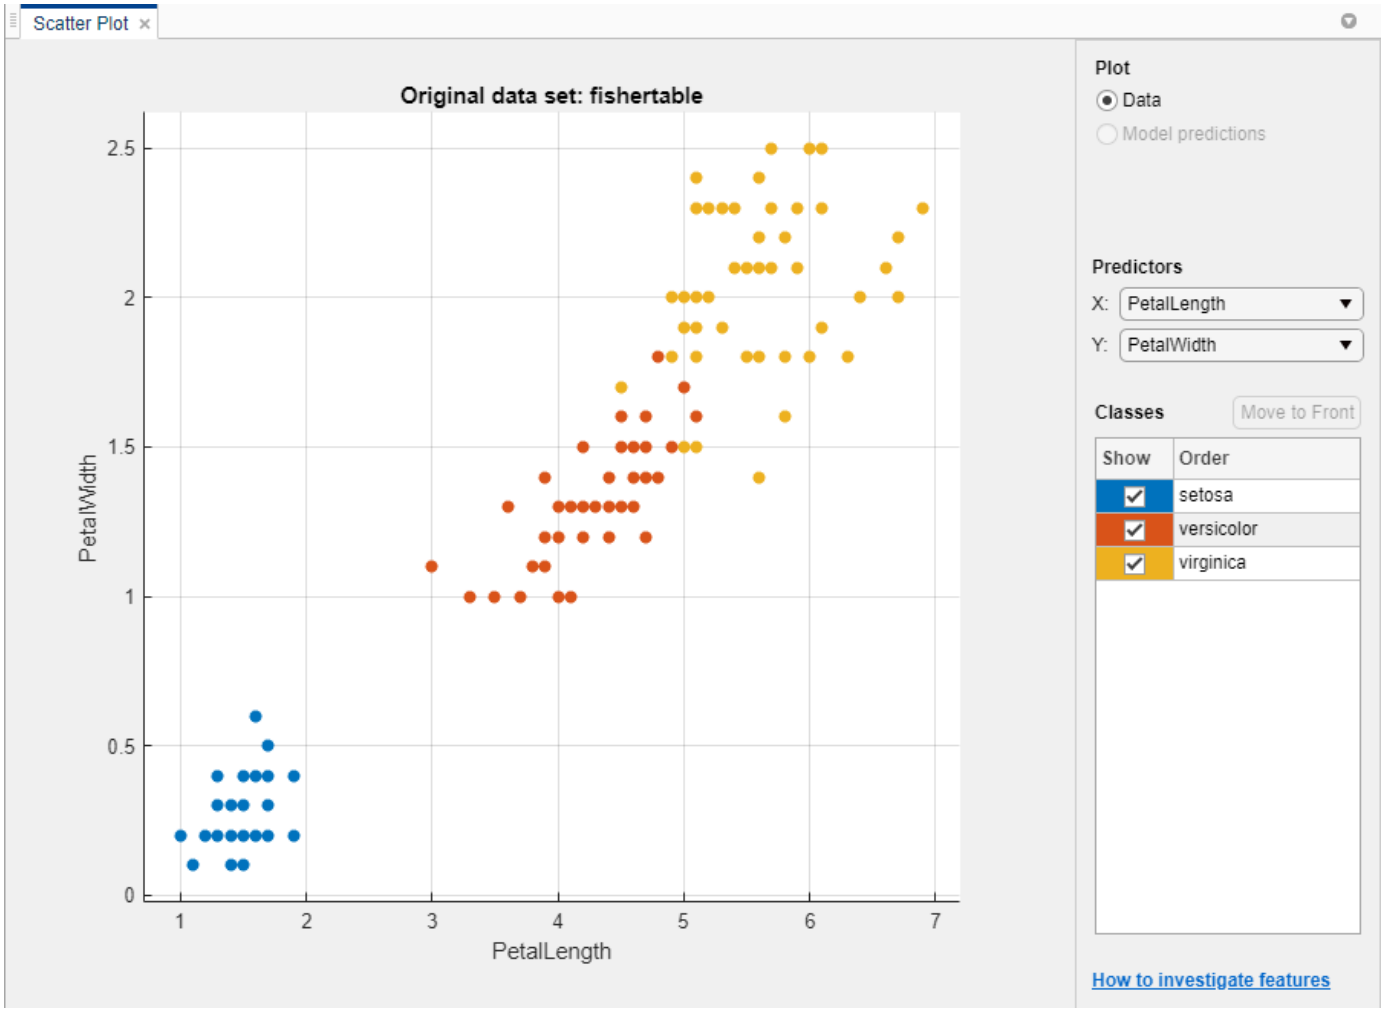
As an example, export a scatter plot in the app to a figure, customize the figure, and save the modified figure.

1. In the MATLAB Command Window, read the sample file `fisheriris.csv` into a table.

   ```
   fishertable = readtable('fisheriris.csv');
   ```

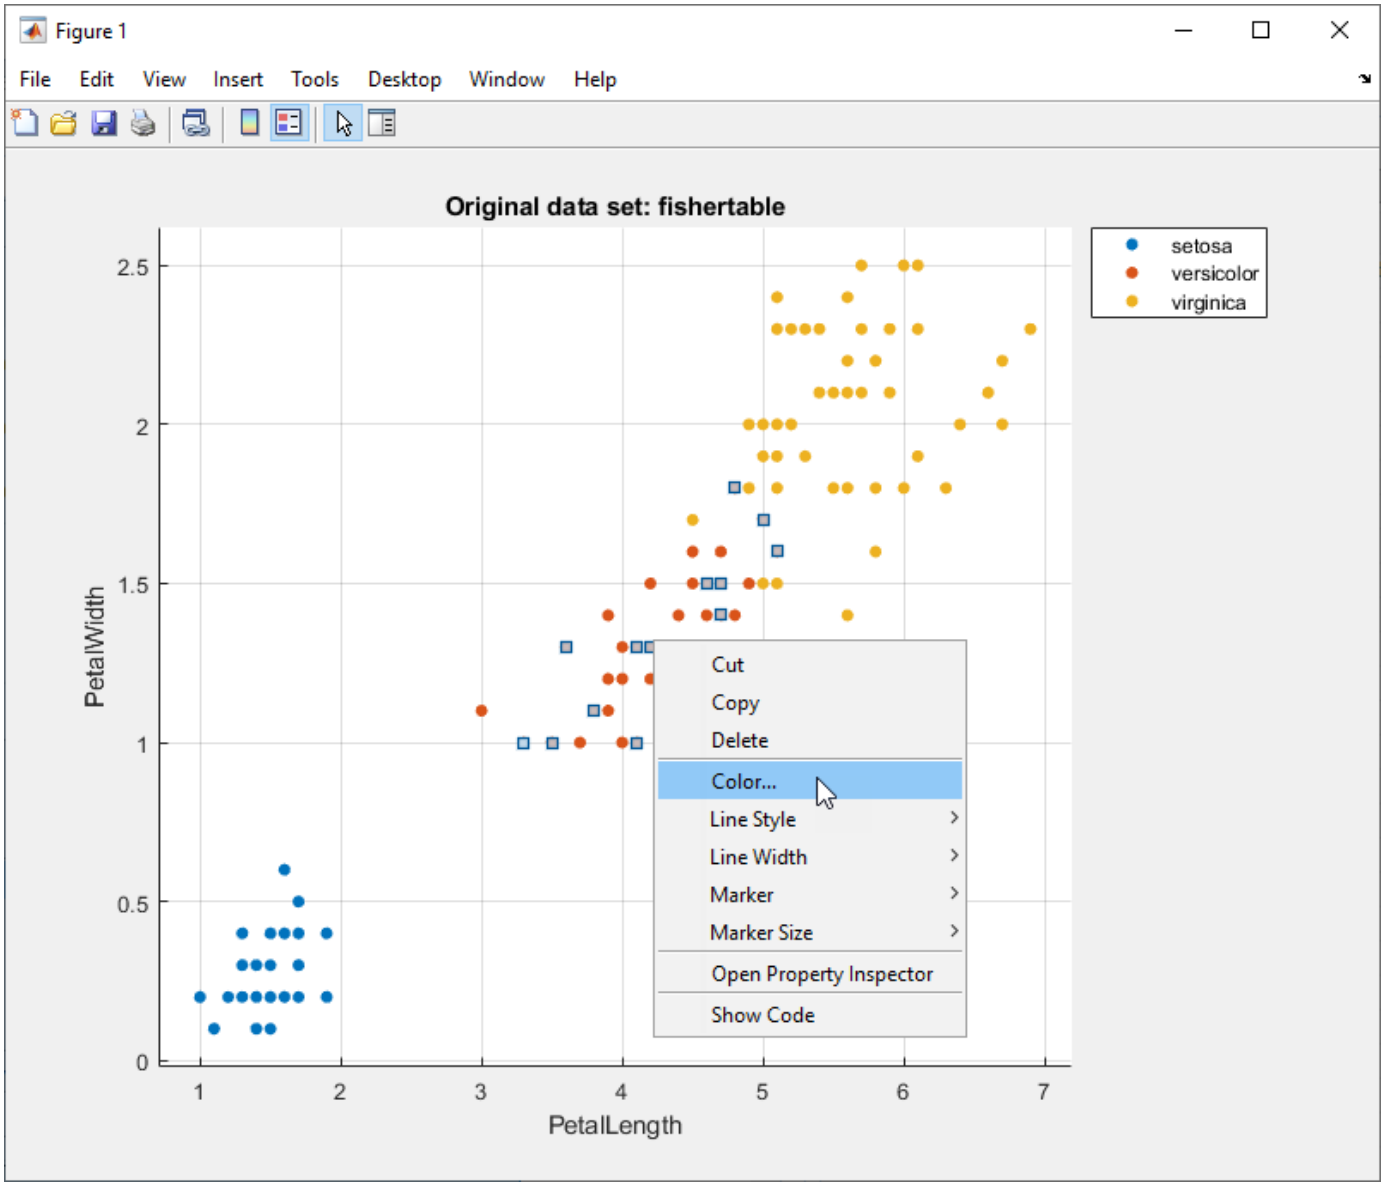
2. Click the **Apps** tab.
3. In the **Apps** section, click the arrow to open the gallery. Under **Machine Learning and Deep Learning**, click **Classification Learner**.
4. On the **Classification Learner** tab, in the **File** section, click **New Session**  .
5. In the New Session from Workspace dialog box, select the table `fishertable` from the **Workspace Variable** list.
6. Click **Start Session**. Classification Learner creates a scatter plot of the data by default.

7 Change the predictors in the scatter plot to `PetalLength` and `PetalWidth`.



8 On the **Classification Learner** tab, in the **Export** section, click **Export Plot to Figure**.

9 In the new figure, click the Edit Plot button on the figure toolbar. Right-click the points in the plot corresponding to the versicolor irises. In the context menu, select **Color**.



10 In the Color dialog box, select a new color and click **OK**.

11 To save the figure, select **File** > **Save As**. Specify the saved file location, name, and type.

Export Classification Model to Predict New Data

In this section...

Export the Model to the Workspace to Make Predictions for New Data

After you create classification models interactively in Classification Learner, you can export your best model to the workspace. You can then use the trained model to make predictions using new data.

Note The final model Classification Learner exports is always trained using the full data set. The validation scheme that you use only affects the way that the app computes validation metrics. You can use the validation metrics and various plots that visualize results to pick the best model for your classification problem.

Here are the steps for exporting a model to the MATLAB workspace:

1. In Classification Learner, select the model you want to export in the **Models** pane.
2. On the **Classification Learner** tab, in the **Export** section, click one of the export options:
   - If you want to include the data used for training the model, then select **Export Model**.

     You export the trained model to the workspace as a structure containing a classification object, such as a `ClassificationTree`, `ClassificationDiscriminant`, `ClassificationSVM`, `ClassificationNaiveBayes`, `ClassificationKNN`, `ClassificationEnsemble`, `ClassificationNeuralNetwork`, and so on.
   - If you do not want to include the training data, select **Export Compact Model**. This option exports the model with unnecessary data removed where possible. For some classifiers this is a compact classification object that does not include the training data (for example, `CompactClassificationTree`). You can use a compact classification object for making predictions of new data, but you can use fewer other methods with it.
3. In the Export Model dialog box, edit the name for your exported variable if you want, and then click **OK**. The default name for your exported model, `trainedModel`, increments every time you export to avoid overwriting your classifiers (for example, `trainedModel1`).

   The new variable (for example, `trainedModel`) appears in your workspace.

   The app displays information about the exported model in the command window. Read the message to learn how to make predictions with new data.

Make Predictions for New Data

After you export a model to the workspace from Classification Learner, or run the code generated from the app, you get a `trainedModel` structure that you can use to make predictions using new

data. The structure contains a classification object and a function for prediction. The structure allows you to make predictions for models that include principal component analysis (PCA).

1. To use the exported classifier to make predictions for new data, `T`, use the form:

   ```
   yfit = C.predictFcn(T)
   ```

   where `C` is the name of your variable (for example, `trainedModel`).

   Supply the data `T` with the same format and data type as the training data used in the app (table or matrix).

   - If you supply a table, ensure it contains the same predictor names as your training data. The `predictFcn` function ignores additional variables in tables. Variable formats and types must match the original training data.
   - If you supply a matrix, it must contain the same predictor columns or rows as your training data, in the same order and format. Do not include a response variable, any variables that you did not import in the app, or other unused variables.

   The output `yfit` contains a class prediction for each data point.
2. Examine the fields of the exported structure. For help making predictions, enter:

   ```
   C.HowToPredict
   ```

You can also extract the classification object from the exported structure for further analysis (for example, `trainedModel.ClassificationSVM`, `trainedModel.ClassificationTree`, and so on, depending on your model type). Be aware that if you used feature transformation such as PCA in the app, you will need to take account of this transformation by using the information in the PCA fields of the structure.

Generate MATLAB Code to Train the Model with New Data

After you create classification models interactively in Classification Learner, you can generate MATLAB code for your best model. You can then use the code to train the model with new data.

Generate MATLAB code to:

- Train on huge data sets. Explore models in the app trained on a subset of your data, then generate code to train a selected model on a larger data set
- Create scripts for training models without needing to learn syntax of the different functions
- Examine the code to learn how to train classifiers programmatically
- Modify the code for further analysis, for example to set options that you cannot change in the app
- Repeat your analysis on different data and automate training

1. In Classification Learner, in the **Models** pane, select the model you want to generate code for.
2. On the **Classification Learner** tab, in the **Export** section, click **Generate Function**.

   The app generates code from your session and displays the file in the MATLAB Editor. The file includes the predictors and response, the classifier training methods, and validation methods. Save the file.

3. To retrain your classifier model, call the function from the command line with your original data or new data as the input argument or arguments. New data must have the same shape as the original data.

   Copy the first line of the generated code, excluding the word `function`, and edit the `trainingData` input argument to reflect the variable name of your training data or new data. Similarly, edit the `responseData` input argument (if applicable).

   For example, to retrain a classifier trained with the `fishertable` data set, enter:

   ```
   [trainedModel,validationAccuracy] = trainClassifier(fishertable)
   ```

   The generated code returns a `trainedModel` structure that contains the same fields as the structure you create when you export a classifier from Classification Learner to the workspace.

4. If you want to automate training the same classifier with new data, or learn how to programmatically train classifiers, examine the generated code. The code shows you how to:

   - Process the data into the right shape
   - Train a classifier and specify all the classifier options
   - Perform cross-validation
   - Compute validation accuracy
   - Compute validation predictions and scores

   Note If you generate MATLAB code from a trained optimizable model, the generated code does not include the optimization process.

Generate C Code for Prediction

If you train one of the models in this table using Classification Learner, you can generate C code for prediction.

Model Type	Underlying Model Object
Decision Tree	`ClassificationTree` or `CompactClassificationTree`
Discriminant Analysis	`ClassificationDiscriminant` or `CompactClassificationDiscriminant`
Naive Bayes	`ClassificationNaiveBayes` or `CompactClassificationNaiveBayes`
Support Vector Machine	`ClassificationSVM` (binary), `CompactClassificationSVM` (binary), `ClassificationECOC` (multiclass), or `CompactClassificationECOC` (multiclass)
Nearest Neighbor	`ClassificationKNN`
Ensemble	`ClassificationEnsemble`, `CompactClassificationEnsemble`, or `ClassificationBaggedEnsemble`

Note You can generate C code for prediction using a logistic regression model. However, because the underlying model for logistic regression is a `GeneralizedLinearModel` or `CompactGeneralizedLinearModel` object, this process requires you to add extra lines of code in the prediction entry-point function to convert numeric predictions to class predictions. For an example, see “Code Generation for Logistic Regression Model Trained in Classification Learner” on page 32-144.

C code generation requires:

- MATLAB Coder license
- Appropriate model (binary or multiclass)

1. For example, train an SVM model in Classification Learner, and then export the model to the workspace.

   Find the underlying classification model object in the exported structure. Examine the fields of the structure to find the model object, for example, `C.ClassificationSVM`, where `C` is the name of your structure.

   The underlying model object depends on what type of SVM you trained (binary or multiclass) and whether you exported a compact model. The model object can be `ClassificationSVM`, `CompactClassificationSVM`, `ClassificationECOC`, or `CompactClassificationECOC`.

2. Use the function `saveLearnerForCoder` to prepare the model for code generation: `saveLearnerForCoder(Mdl,filename)`. For example:

   ```
   saveLearnerForCoder(C.ClassificationSVM,'mySVM')
   ```

3. Create a function that loads the saved model and makes predictions on new data. For example:

   ```
   function label = classifyX (X) %#codegen
   %CLASSIFYX Classify using SVM Model
   %  CLASSIFYX classifies the measurements in X
   %  using the SVM model in the file mySVM.mat, and then
   %  returns class labels in label.

   CompactMdl = loadLearnerForCoder('mySVM');
   label = predict(CompactMdl,X);
   end
   ```

4. Generate a MEX function from your function. For example:

   ```
   codegen classifyX.m -args {data}
   ```

   The `%#codegen` compilation directive indicates that the MATLAB code is intended for code generation. To ensure that the MEX function can use the same input, specify the data in the workspace as arguments to the function using the `-args` option. Specify `data` as a matrix containing only the predictor columns used to train the model.

5. Use the MEX function to make predictions. For example:

   ```
   labels = classifyX_mex(data);
   ```

If you used feature selection or PCA feature transformation in the app, then you need to take additional steps. If you used manual feature selection, supply the same columns in `X`. The `X` argument is the input to your function.

If you used PCA in the app, use the information in the PCA fields of the exported structure to take account of this transformation. It does not matter whether you imported a table or a matrix into the app, as long as X contains the matrix columns in the same order. Before generating code, follow these steps:

1. Save the PCACenters and PCACoefficients fields of the trained classifier structure, `C`, to file using the following command:

   ```
   save('pcaInfo.mat','-struct','C','PCACenters','PCACoefficients');
   ```

2. In your function file, include additional lines to perform the PCA transformation. Create a function that loads the saved model, performs PCA, and makes predictions on new data. For example:

   ```
   function label = classifyX (X) %#codegen
   %CLASSIFYX Classify using SVM Model
   %  CLASSIFYX classifies the measurements in X
   %  using the SVM model in the file mySVM.mat,
   %  and then returns class labels in label.
   % If you used manual feature selection in the app, ensure that X
   % contains only the columns you included in the model.

   CompactMdl = loadLearnerForCoder('mySVM');
   pcaInfo = coder.load('pcaInfo.mat','PCACenters','PCACoefficients');
   PCACenters = pcaInfo.PCACenters;
   PCACoefficients = pcaInfo.PCACoefficients;

   % Performs PCA transformation
   pcaTransformedX = bsxfun(@minus,X,PCACenters)*PCACoefficients;

   [label,scores] = predict(CompactMdl,pcaTransformedX);
   end
   ```

For a more detailed example, see “Code Generation and Classification Learner App” on page 32-31. For more information on the C code generation workflow and limitations, see “Code Generation”.

Deploy Predictions Using MATLAB Compiler

After you export a model to the workspace from Classification Learner, you can deploy it using MATLAB Compiler.

Suppose you export the trained model to MATLAB Workspace based on the instructions in “Export Model to Workspace” on page 24-54, with the name `trainedModel`. To deploy predictions, follow these steps.

- Save the `trainedModel` structure in a .mat file.

  ```
  save mymodel trainedModel
  ```

- Write the code to be compiled. This code must load the trained model and use it to make a prediction. It must also have a pragma, so the compiler recognizes that Statistics and Machine Learning Toolbox code is needed in the compiled application. This pragma could be any function in the toolbox.

  ```
  function ypred = mypredict(tbl)
  %#function fitctree
  load('mymodel.mat');
  ```

```
ypred = trainedModel.predictFcn(tbl);
end
```

- Compile as a standalone application.

```
mcc -m mypredict.m
```

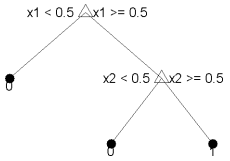
Train Decision Trees Using Classification Learner App

This example shows how to create and compare various classification trees using Classification Learner, and export trained models to the workspace to make predictions for new data.

You can train classification trees to predict responses to data. To predict a response, follow the decisions in the tree from the root (beginning) node down to a leaf node. The leaf node contains the response.

Statistics and Machine Learning Toolbox trees are binary. Each step in a prediction involves checking the value of one predictor (variable). For example, here is a simple classification tree:

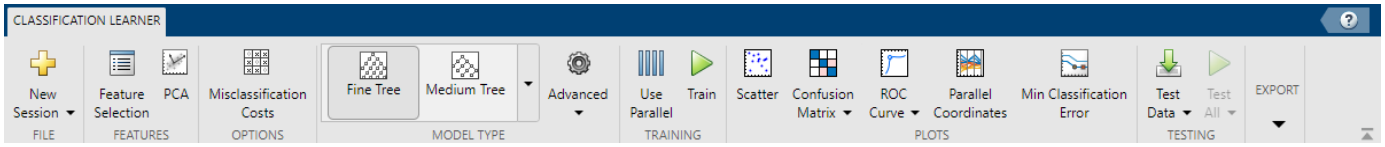


This tree predicts classifications based on two predictors, `x1` and `x2`. To predict, start at the top node. At each decision, check the values of the predictors to decide which branch to follow. When the branches reach a leaf node, the data is classified either as type `0` or `1`.

1. In MATLAB, load the `fisheriris` data set and create a table of measurement predictors (or features) using variables from the data set to use for a classification.

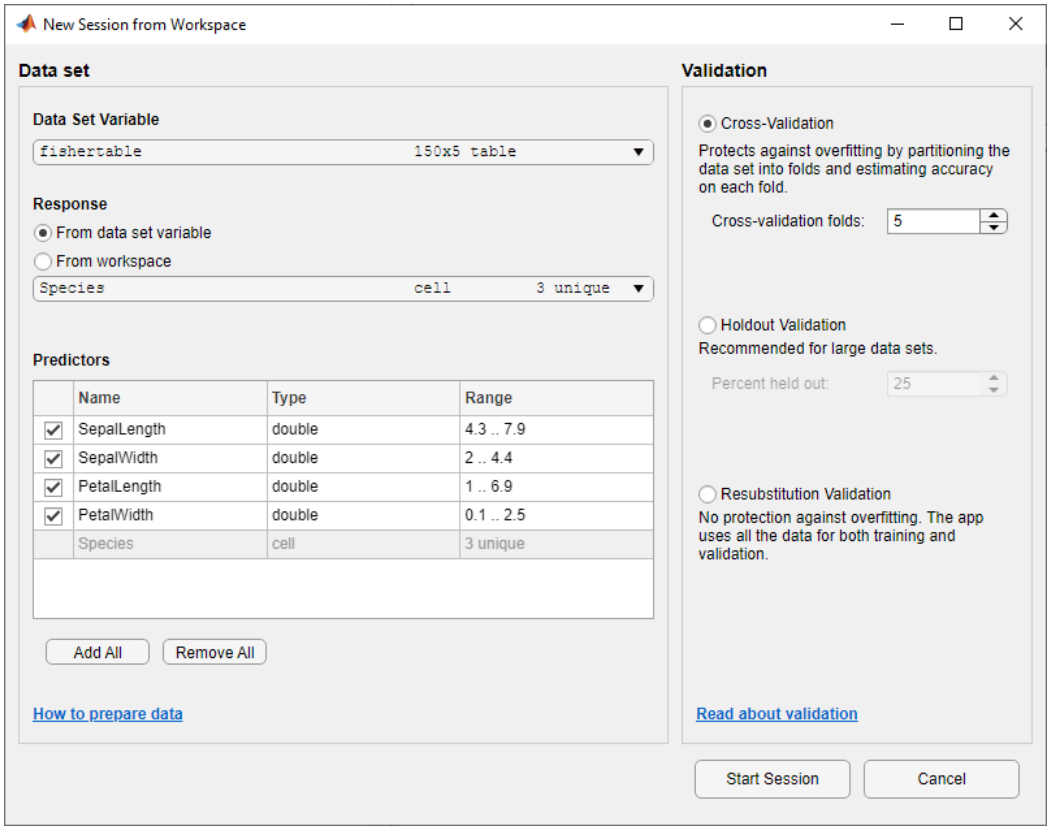
   ```
   fishertable = readtable('fisheriris.csv');
   ```

2. On the **Apps** tab, in the **Machine Learning and Deep Learning** group, click **Classification Learner**.
3. On the **Classification Learner** tab, in the **File** section, click **New Session > From Workspace**.



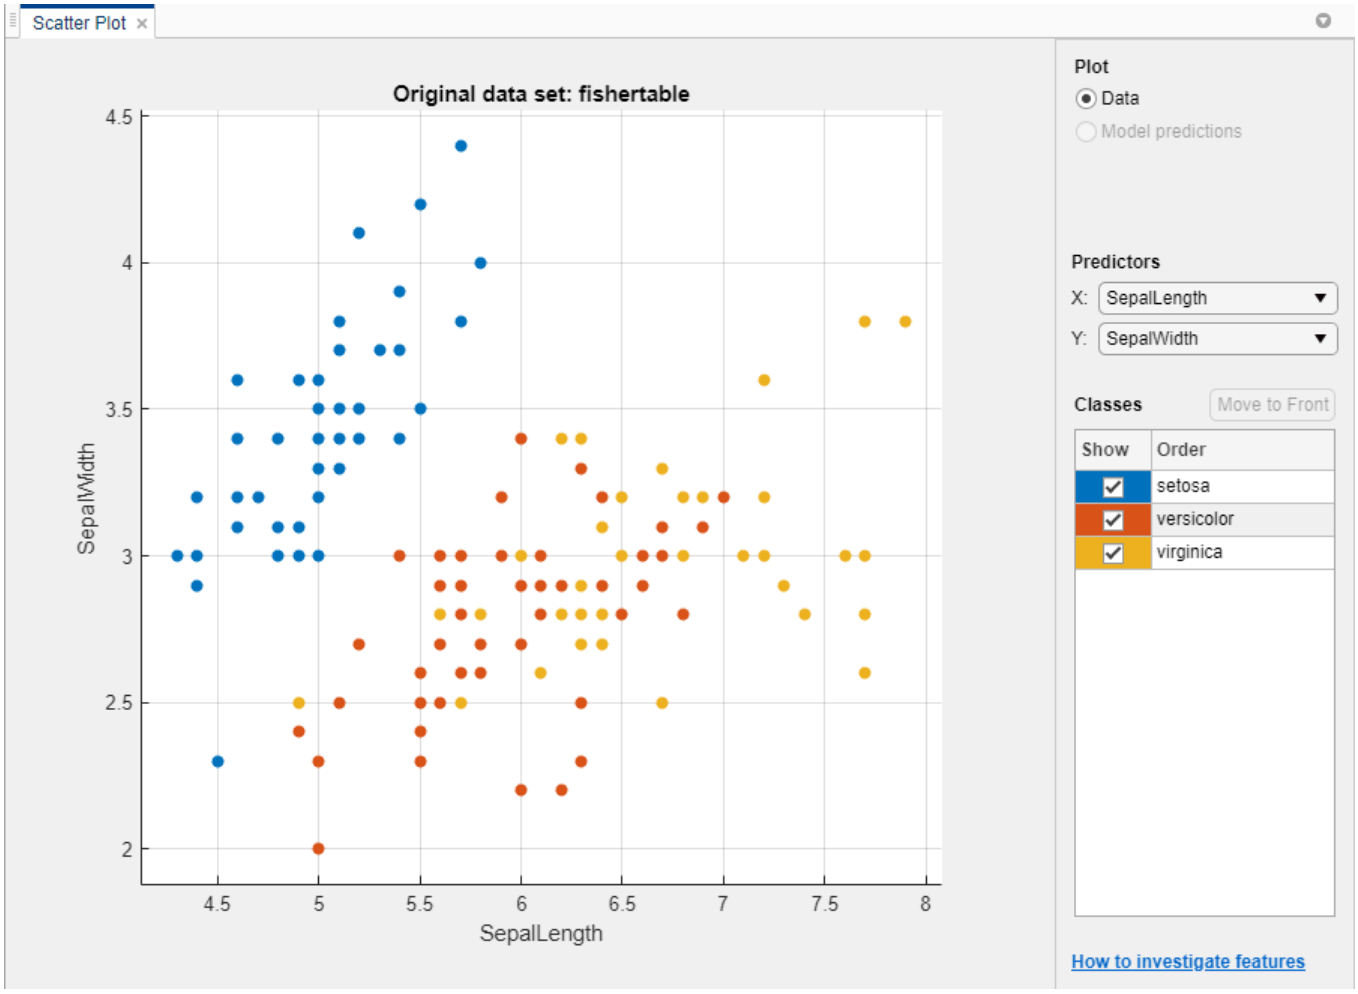
4. In the New Session from Workspace dialog box, select the table `fishertable` from the **Data Set Variable** list (if necessary).

   Observe that the app has selected response and predictor variables based on their data type. Petal and sepal length and width are predictors, and species is the response that you want to classify. For this example, do not change the selections.



5 To accept the default validation scheme and continue, click **Start Session**. The default validation option is cross-validation, to protect against overfitting.

Classification Learner creates a scatter plot of the data.



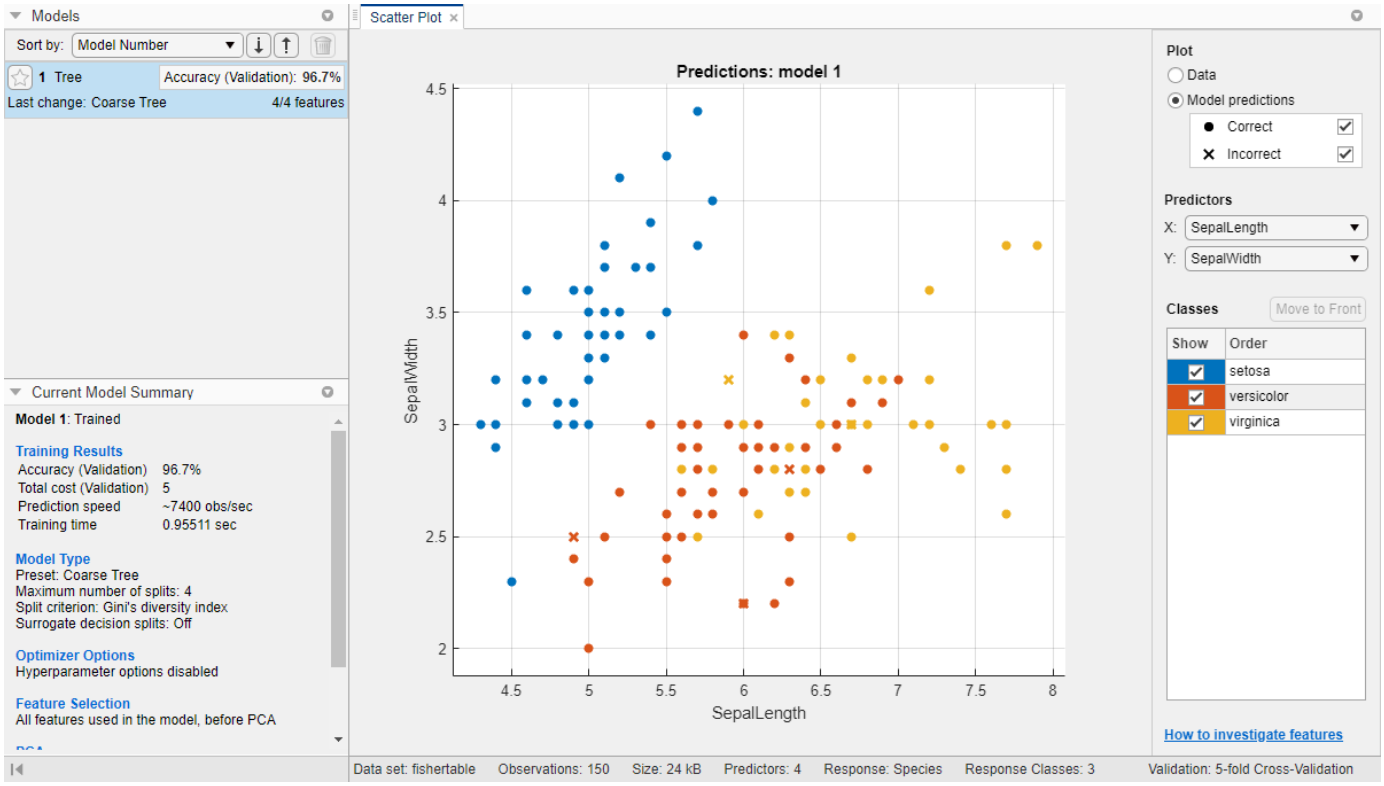
6 Use the scatter plot to investigate which variables are useful for predicting the response. Select different options on the **X** and **Y** lists under **Predictors** to visualize the distribution of species and measurements. Observe which variables separate the species colors most clearly.

   Observe that the `setosa` species (blue points) is easy to separate from the other two species with all four predictors. The `versicolor` and `virginica` species are much closer together in all predictor measurements, and overlap especially when you plot sepal length and width. `setosa` is easier to predict than the other two species.

7 To create a classification tree model, on the **Classification Learner** tab, in the **Model Type** section, click the down arrow to expand the gallery and click **Coarse Tree**. Then click **Train**.

   The app creates a simple classification tree, and plots the results.

   Observe the **Coarse Tree** model in the **Models** pane. Check the model validation score in the **Accuracy (Validation)** box. The model has performed well.



Note With validation, there is some randomness in the results, so your model validation score results can vary from those shown.

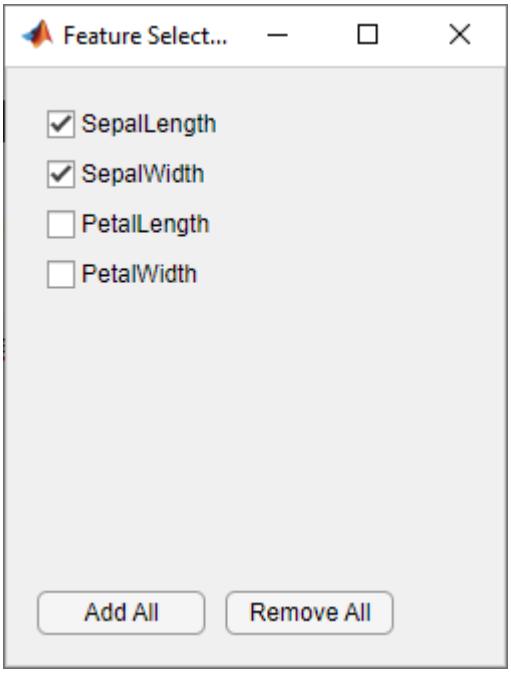
8. Examine the scatter plot. An X indicates misclassified points. The blue points (`setosa` species) are all correctly classified, but some of the other two species are misclassified. Under **Plot**, switch between the **Data** and **Model Predictions** options. Observe the color of the incorrect (X) points. Alternatively, while plotting model predictions, to view only the incorrect points, clear the **Correct** check box.
9. Train a different model to compare. Click **Medium Tree**, and then click **Train**.

   When you click **Train**, the app displays a new model in the **Models** pane.
10. Observe the **Medium Tree** model in the **Models** pane. The model validation score is no better than the coarse tree score. The app outlines in a box the **Accuracy (Validation)** score of the best model. Click each model in the **Models** pane to view and compare the results.
11. Examine the scatter plot for the **Medium Tree** model. The medium tree classifies as many points correctly as the previous coarse tree. You want to avoid overfitting, and the coarse tree performs well, so base all further models on the coarse tree.
12. Select **Coarse Tree** in the **Models** pane. To try to improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power.

    On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**.

    In the Feature Selection dialog box, clear the check boxes for **PetalLength** and **PetalWidth** to exclude them from the predictors. A new draft model appears in the **Models** pane with your new settings 2/4 features, based on the coarse tree.

Click **Train** to train a new tree model using the new predictor options.



13 Observe the third model in the **Models** pane. It is also a **Coarse Tree** model, trained using only 2 of 4 predictors. The app displays how many predictors are excluded. To check which predictors are included, click a model in the **Models** pane and observe the check boxes in the Feature Selection dialog box. The model with only sepal measurements has a much lower accuracy score than the petals-only model.

14 Train another model including only the petal measurements. Change the selections in the Feature Selection dialog box and click **Train**.

The model trained using only petal measurements performs comparably to the models containing all predictors. The models predict no better using all the measurements compared to only the petal measurements. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily without some predictors.

15 Repeat to train two more models including only the width measurements and then the length measurements. There is not much difference in score between several of the models.

16 Choose a best model among those of similar scores by examining the performance in each class. Select the coarse tree that includes all the predictors. To inspect the accuracy of the predictions in each class, on the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. Use this plot to understand how the currently selected classifier performed in each class. View the matrix of true class and predicted class results.

Look for areas where the classifier performed poorly by examining cells off the diagonal that display high numbers and are red. In these red cells, the true class and the predicted class do not match. The data points are misclassified.

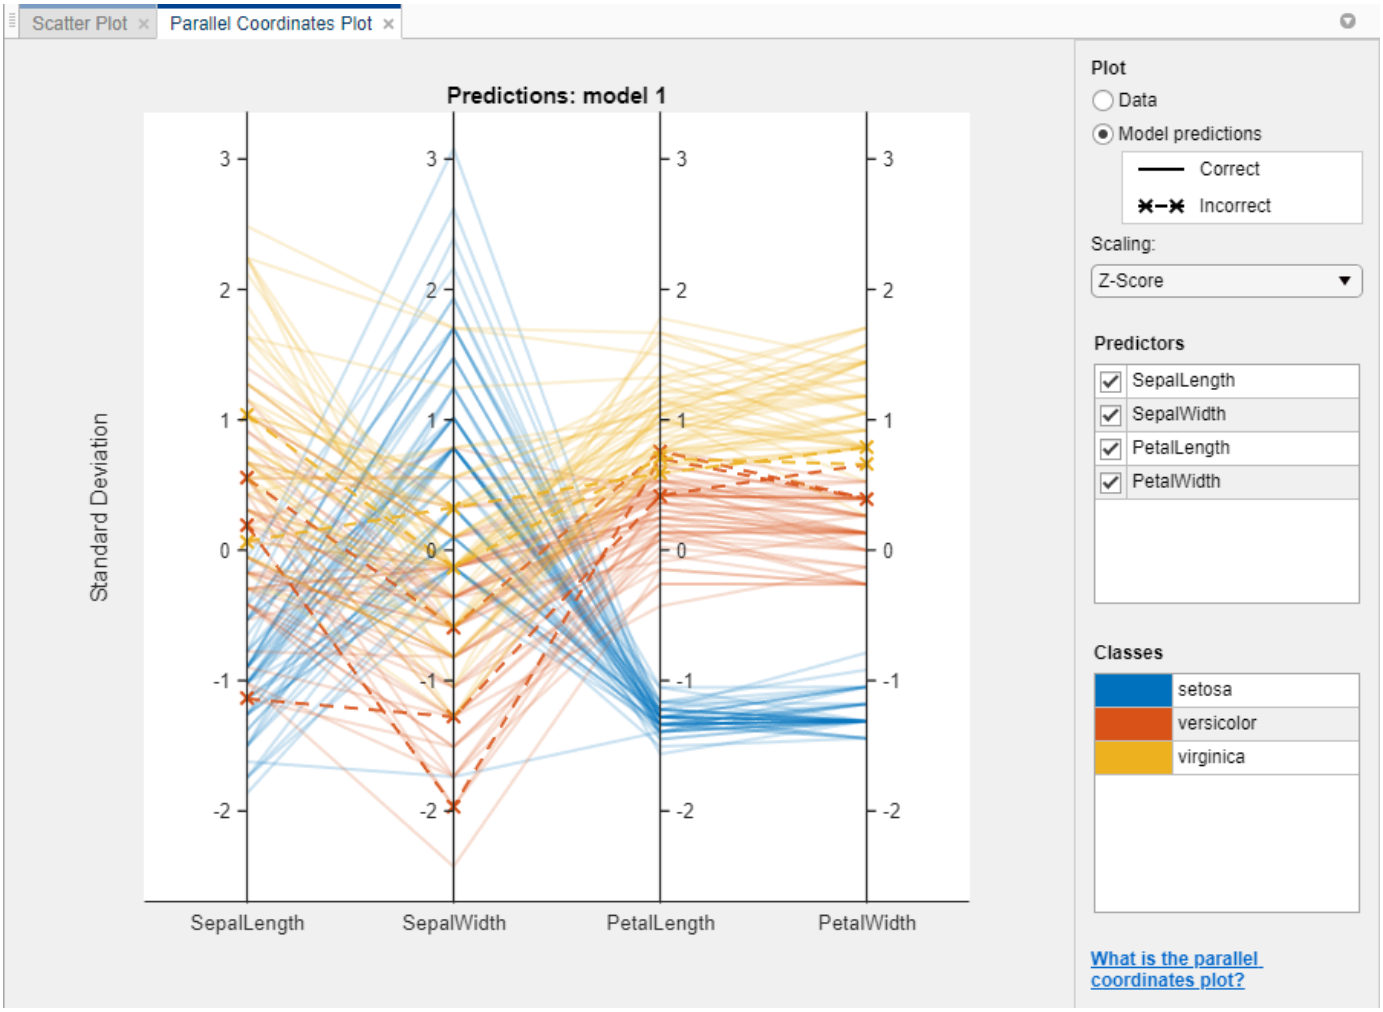
Note With validation, there is some randomness in the results, so your confusion matrix results can vary from those shown.

In this figure, examine the third cell in the middle row. In this cell, true class is `versicolor`, but the model misclassified the points as `virginica`. For this model, the cell shows 2 misclassified (your results can vary). To view percentages instead of numbers of observations, select the **True Positive Rates** option under **Plot** controls.

You can use this information to help you choose the best model for your goal. If false positives in this class are very important to your classification problem, then choose the best model at predicting this class. If false positives in this class are not very important, and models with fewer predictors do better in other classes, then choose a model to tradeoff some overall accuracy to exclude some predictors and make future data collection easier.

17 Compare the confusion matrix for each model in the **Models** pane. Check the Feature Selection dialog box to see which predictors are included in each model.

18 To investigate features to include or exclude, use the scatter plot and the parallel coordinates plot. On the **Classification Learner** tab, in the **Plots** section, click **Parallel Coordinates**. You can see that petal length and petal width are the features that separate the classes best.



19 To learn about model settings, choose a model in the **Models** pane and view the advanced settings. The nonoptimizable model options in the **Model Type** gallery are preset starting points, and you can change further settings. On the **Classification Learner** tab, in the **Model Type** section, click **Advanced**. Compare the simple and medium tree models in the **Models** pane, and observe the differences in the Advanced Tree Options dialog box. The **Maximum Number of Splits** setting controls tree depth.

To try to improve the coarse tree model further, try changing the **Maximum Number of Splits** setting, then train a new model by clicking **Train**.

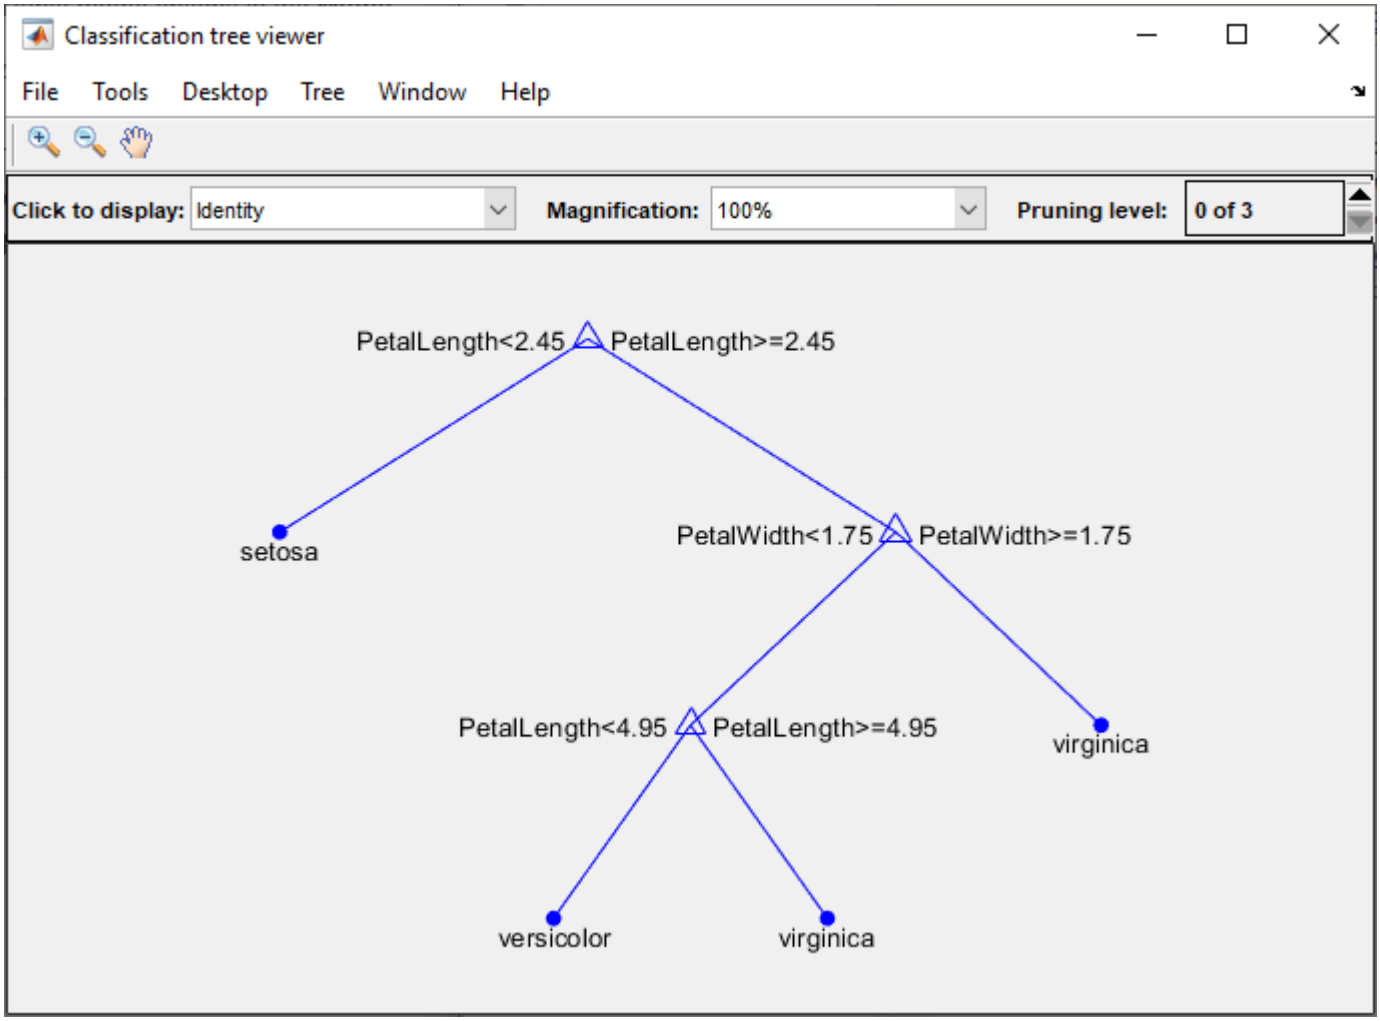
View the settings for the selected trained model in the **Current Model Summary** pane, or in the Advanced dialog box.

20 To export the best trained model to the workspace, on the **Classification Learner** tab, in the **Export** section, click **Export Model**. In the Export Model dialog box, click **OK** to accept the default variable name `trainedModel`.

Look in the command window to see information about the results.

21 To visualize your decision tree model, enter:

```
view(trainedModel.ClassificationTree,'Mode','graph')
```



22 You can use the exported classifier to make predictions on new data. For example, to make predictions for the `fishertable` data in your workspace, enter:

```
yfit = trainedModel.predictFcn(fishertable)
```

The output `yfit` contains a class prediction for each data point.

23 If you want to automate training the same classifier with new data, or learn how to programmatically train classifiers, you can generate code from the app. To generate code for the best trained model, on the **Classification Learner** tab, in the **Export** section, click **Generate Function**.

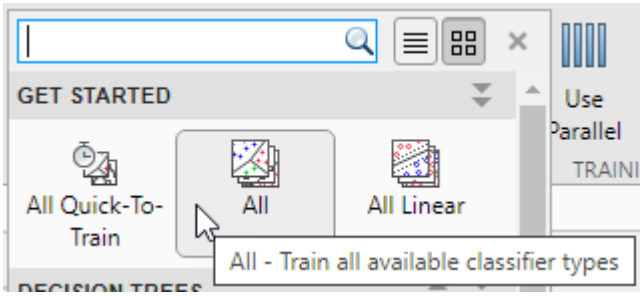
The app generates code from your model and displays the file in the MATLAB Editor. To learn more, see “Generate MATLAB Code to Train the Model with New Data” on page 23-78.

This example uses Fisher's 1936 iris data. The iris data contains measurements of flowers: the petal length, petal width, sepal length, and sepal width for specimens from three species. Train a classifier to predict the species based on the predictor measurements.

Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To try all the nonoptimizable classifier model presets available for your data set:

1. Click the arrow on the far right of the **Model Type** section to expand the list of classifiers.
2. Click **All**, then click **Train**.



To learn about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

Train Discriminant Analysis Classifiers Using Classification Learner App

This example shows how to construct discriminant analysis classifiers in the Classification Learner app, using the `fisheriris` data set. You can use discriminant analysis with two or more classes in Classification Learner.

1. In MATLAB, load the `fisheriris` data set.

   ```
   fishertable = readtable('fisheriris.csv');
   ```

2. On the **Apps** tab, in the **Machine Learning and Deep Learning** group, click **Classification Learner**.
3. On the **Classification Learner** tab, in the **File** section, click **New Session > From Workspace**.

   In the New Session from Workspace dialog box, select the table `fishertable` from the **Data Set Variable** list (if necessary). Observe that the app has selected response and predictor variables based on their data type. Petal and sepal length and width are predictors, and species is the response that you want to classify. For this example, do not change the selections.

4. Click **Start Session**.

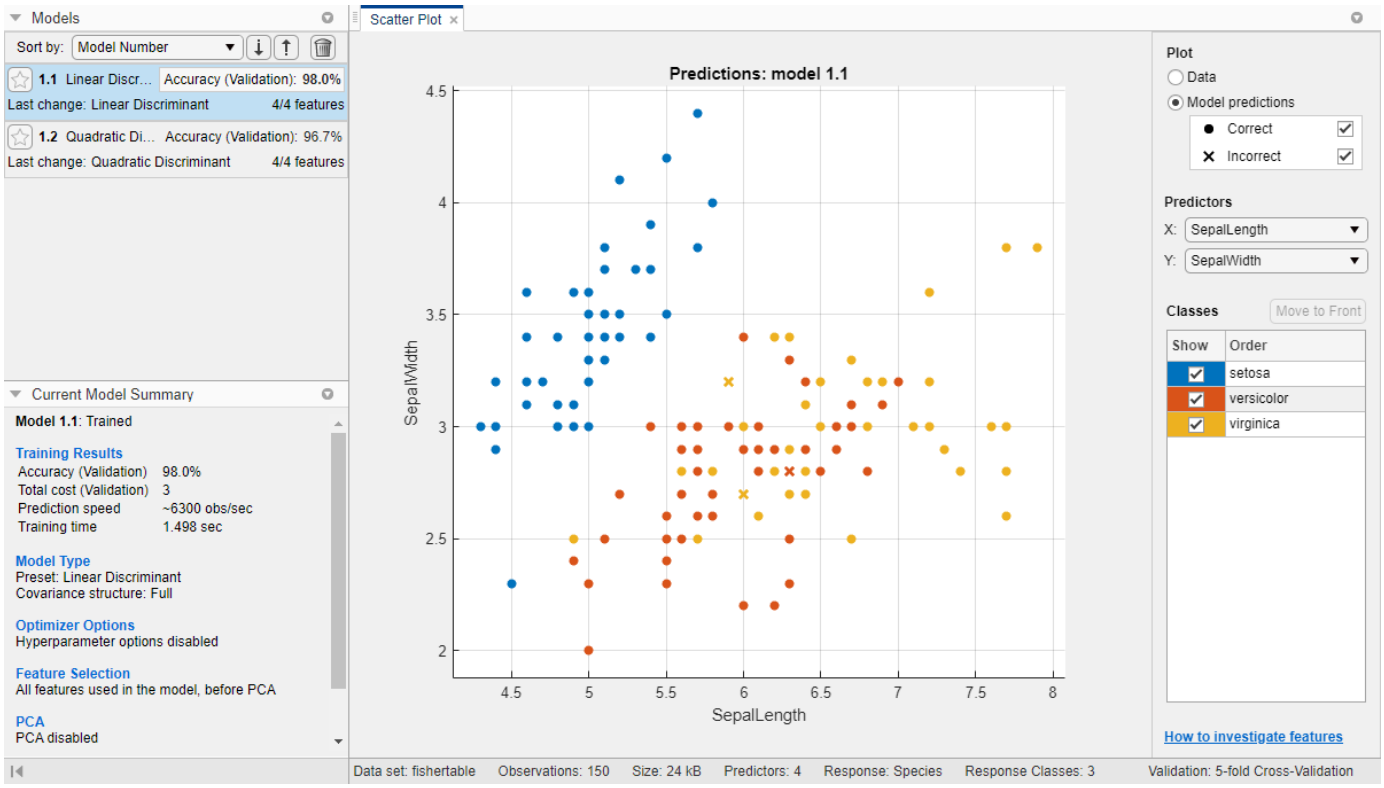
   Classification Learner creates a scatter plot of the data.

5. Use the scatter plot to visualize which variables are useful for predicting the response. Select different variables in the X- and Y-axis controls. Observe which variables separate the classes most clearly.
6. To train both nonoptimizable discriminant analysis classifiers, on the **Classification Learner** tab, in the **Model Type** section, click the down arrow to expand the list of classifiers, and under **Discriminant Analysis**, click **All Discriminants**.

Then click **Train** 
.

Tip If you have Parallel Computing Toolbox, you can train all the models (**All Discriminants**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.

Classification Learner trains one of each classification option in the gallery, linear and quadratic discriminants, and highlights the best score. The app outlines in a box the **Accuracy (Validation)** score of the best model.



7 Select a model in the **Models** pane to view the results. Examine the scatter plot for the trained model and try plotting different predictors. Misclassified points are shown as an X.

8 To inspect the accuracy of the predictions in each class, on the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. View the matrix of true class and predicted class results.

9 Select the other model in the **Models** pane to compare.

For information on the strengths of different model types, see “Discriminant Analysis” on page 23-29.

10 Choose the best model in the **Models** pane (the best score is highlighted in a box). To improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power.

On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**. In the Feature Selection dialog box, specify predictors to remove from the model, and click **Train** to train a new model using the new options. Compare results among the classifiers in the **Models** pane.

11 To investigate features to include or exclude, use the parallel coordinates plot. On the **Classification Learner** tab, in the **Plots** section, select **Parallel Coordinates**.

12 Choose the best model in the **Models** pane. To try to improve the model further, try changing classifier settings. On the **Classification Learner** tab, in the **Model Type** section, click **Advanced**. Try changing a setting, then train the new model by clicking **Train**. For information on settings, see “Discriminant Analysis” on page 23-29.

13 To export the trained model to the workspace, select the Classification Learner tab and click **Export model**. See “Export Classification Model to Predict New Data” on page 23-77.

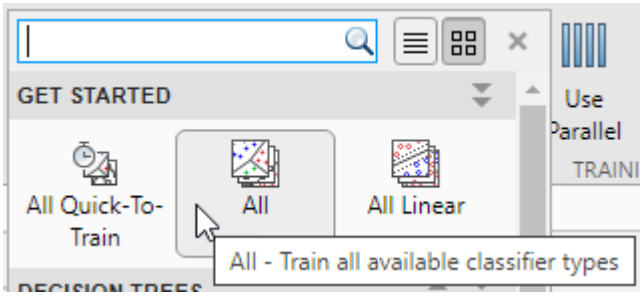
14 To examine the code for training this classifier, click **Generate Function**.

Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To try all the nonoptimizable classifier model presets available for your data set:

1 Click the arrow on the far right of the **Model Type** section to expand the list of classifiers.

2 Click **All**, then click **Train**.



To learn about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

Train Logistic Regression Classifiers Using Classification Learner App

This example shows how to construct logistic regression classifiers in the Classification Learner app, using the `ionosphere` data set that contains two classes. You can use logistic regression with two classes in Classification Learner. In the `ionosphere` data, the response variable is categorical with two levels: `g` represents good radar returns, and `b` represents bad radar returns.

1. In MATLAB, load the `ionosphere` data set and define some variables from the data set to use for a classification.

   ```
   load ionosphere
   ionosphere = array2table(X);
   ionosphere.Group = Y;
   ```

   Alternatively, you can load the `ionosphere` data set and keep the `X` and `Y` data as separate variables.

2. On the **Apps** tab, in the **Machine Learning and Deep Learning** group, click **Classification Learner**.

3. On the **Classification Learner** tab, in the **File** section, click **New Session > From Workspace**.

   In the New Session from Workspace dialog box, select the table `ionosphere` from the **Data Set Variable** list. Observe that the app has selected `Group` for the response variable, and the rest as predictors. `Group` has two levels.

   Alternatively, if you kept your predictor data `X` and response variable `Y` as two separate variables, you can first select the matrix `X` from the **Data Set Variable** list. Then, under **Response**, click the **From workspace** option button and select `Y` from the list. The `Y` variable is the same as the `Group` variable.

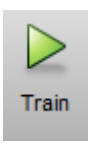
4. Click **Start Session**.

   Classification Learner creates a scatter plot of the data.

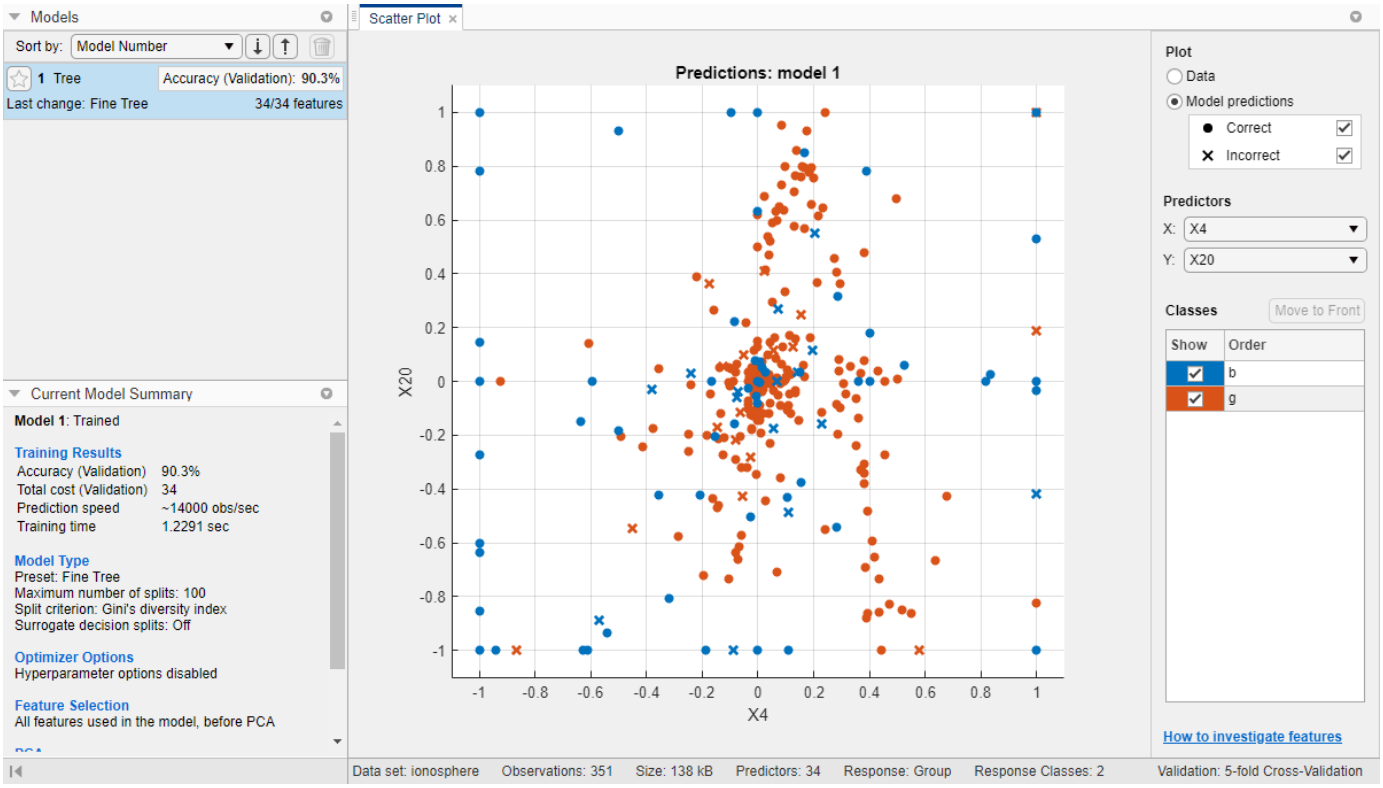
5. Use the scatter plot to visualize which variables are useful for predicting the response. Select different variables in the X- and Y-axis controls. Observe which variables separate the class colors most clearly.

6. To train the logistic regression classifier, on the **Classification Learner** tab, in the **Model Type** section, click the down arrow to expand the list of classifiers, and under **Logistic Regression Classifiers**, click **Logistic Regression**.

   Then click **Train**.



Classification Learner trains the model. The app outlines in a box the **Accuracy (Validation)** score of the best model (in this case, there is only one model).



7 Select the model in the **Models** pane to view the results. Examine the scatter plot for the trained model and try plotting different predictors. Misclassified points are shown as an X.

8 To inspect the accuracy of the predictions in each class, on the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. View the matrix of true class and predicted class results.

9 Choose the best model in the **Models** pane (the best score is highlighted in a box). To improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power.

   On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**. In the Feature Selection dialog box, specify predictors to remove from the model, and click **Train** to train a new model using the new options. Compare results among the classifiers in the **Models** pane.

10 To investigate features to include or exclude, use the parallel coordinates plot. On the **Classification Learner** tab, in the **Plots** section, select **Parallel Coordinates**.

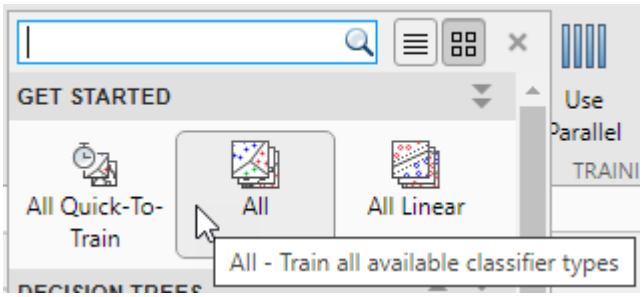
11 To export the trained model to the workspace, select the Classification Learner tab and click **Export model**. See “Export Classification Model to Predict New Data” on page 23-77.

12 To examine the code for training this classifier, click **Generate Function**.

Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To try all the nonoptimizable classifier model presets available for your data set:

1. Click the arrow on the far right of the **Model Type** section to expand the list of classifiers.
2. Click **All**, then click **Train**.



To learn about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

Train Support Vector Machines Using Classification Learner App

This example shows how to construct support vector machine (SVM) classifiers in the Classification Learner app, using the `ionosphere` data set that contains two classes. You can use a support vector machine (SVM) with two or more classes in Classification Learner. An SVM classifies data by finding the best hyperplane that separates all data points of one class from those of another class. In the `ionosphere` data, the response variable is categorical with two levels: `g` represents good radar returns, and `b` represents bad radar returns.

1. In MATLAB, load the `ionosphere` data set and define some variables from the data set to use for a classification.

   ```
   load ionosphere
   ionosphere = array2table(X);
   ionosphere.Group = Y;
   ```

   Alternatively, you can load the `ionosphere` data set and keep the `X` and `Y` data as separate variables.

2. On the **Apps** tab, in the **Machine Learning and Deep Learning** group, click **Classification Learner**.

3. On the **Classification Learner** tab, in the **File** section, click **New Session > From Workspace**.

   In the New Session from Workspace dialog box, select the table `ionosphere` from the **Data Set Variable** list. Observe that the app has selected response and predictor variables based on their data type. The response variable `Group` has two levels. All the other variables are predictors.

   Alternatively, if you kept your predictor data `X` and response variable `Y` as two separate variables, you can first select the matrix `X` from the **Data Set Variable** list. Then, under **Response**, click the **From workspace** option button and select `Y` from the list. The `Y` variable is the same as the `Group` variable.

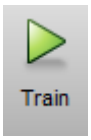
4. Click **Start Session**.

   Classification Learner creates a scatter plot of the data.

5. Use the scatter plot to visualize which variables are useful for predicting the response. Select different variables in the X- and Y-axis controls. Observe which variables separate the class colors most clearly.

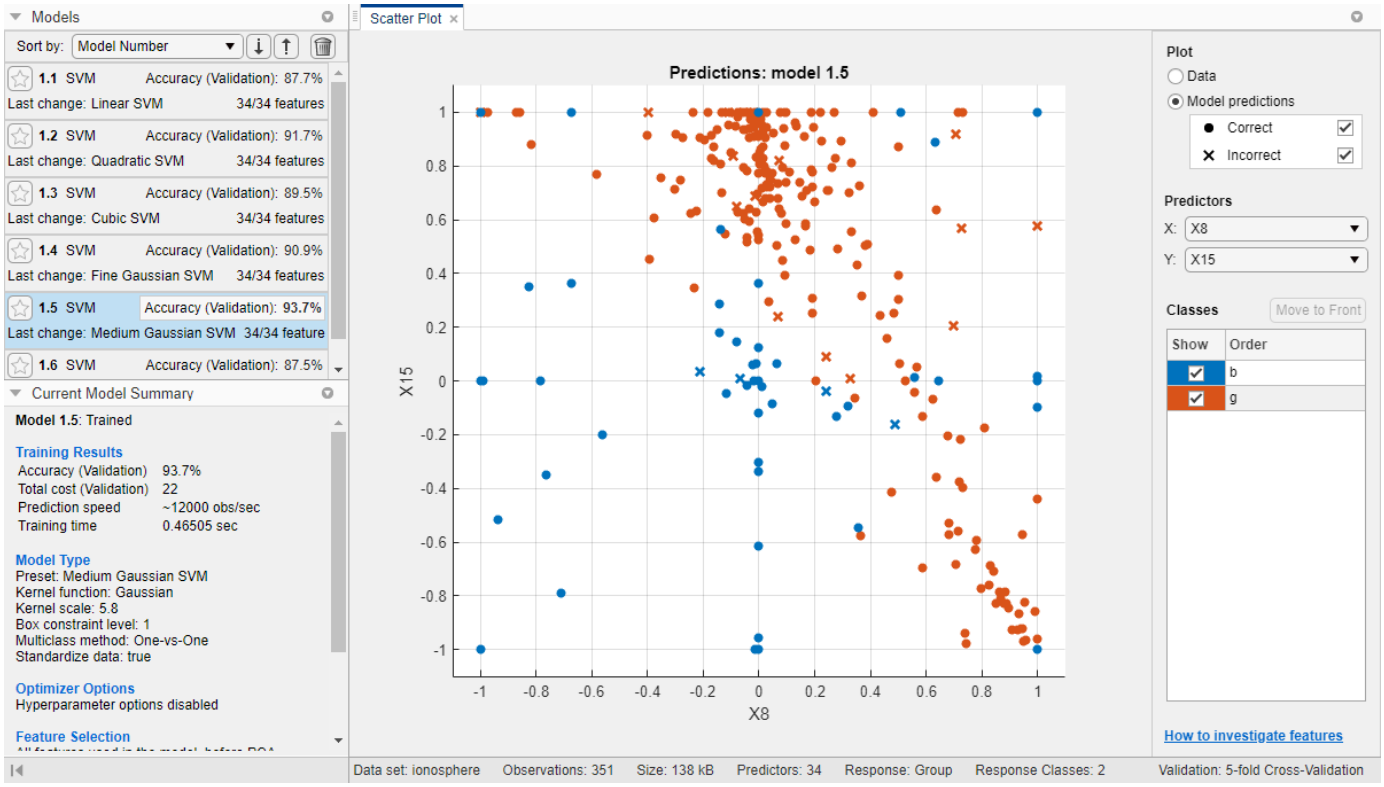
6. To create a selection of SVM models, on the **Classification Learner** tab, in the **Model Type** section, click the down arrow to expand the list of classifiers, and under **Support Vector Machines**, click **All SVMs**.

   Then click **Train**.



Tip If you have Parallel Computing Toolbox, you can train all the models (**All SVMs**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.

Classification Learner trains one of each nonoptimizable SVM classification option in the gallery, and highlights the best score. The app outlines in a box the **Accuracy (Validation)** score of the best model.



7 Select a model in the **Models** pane to view the results. Examine the scatter plot for the trained model and try plotting different predictors. Misclassified points are shown as an X.

8 To inspect the accuracy of the predictions in each class, on the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. View the matrix of true class and predicted class results.

9 Select the other models in the **Models** pane to compare.

10 Choose the best model (the best score is highlighted in a box). To improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power.

On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**. In the Feature Selection dialog box, specify predictors to remove from the model, and click **Train** to train a new model using the new options. Compare results among the classifiers in the **Models** pane.

11 To investigate features to include or exclude, use the parallel coordinates plot. On the **Classification Learner** tab, in the **Plots** section, select **Parallel Coordinates**.

12 Choose the best model in the **Models** pane. To try to improve the model further, try changing SVM settings. On the **Classification Learner** tab, in the **Model Type** section, click **Advanced**. Try changing a setting, then train the new model by clicking **Train**. For information on settings, see “Support Vector Machines” on page 23-31.

13 To export the trained model to the workspace, select the Classification Learner tab and click **Export model**. See “Export Classification Model to Predict New Data” on page 23-77.

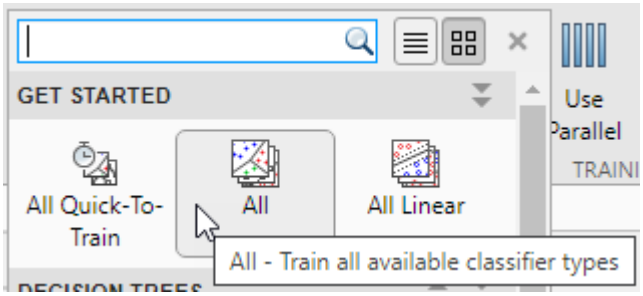
14 To examine the code for training this classifier, click **Generate Function**. For SVM models, see also “Generate C Code for Prediction” on page 23-79.

Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To try all the nonoptimizable classifier model presets available for your data set:

1 Click the arrow on the far right of the **Model Type** section to expand the list of classifiers.

2 Click **All**, then click **Train**.



To learn about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

Train Nearest Neighbor Classifiers Using Classification Learner App

This example shows how to construct nearest neighbors classifiers in the Classification Learner app.

1. In MATLAB, load the `fisheriris` data set and define some variables from the data set to use for a classification.

   ```
   fishertable = readtable('fisheriris.csv');
   ```

2. On the **Apps** tab, in the **Machine Learning and Deep Learning** group, click **Classification Learner**.
3. On the **Classification Learner** tab, in the **File** section, click **New Session > From Workspace**.

   In the New Session from Workspace dialog box, select the table `fishertable` from the **Data Set Variable** list (if necessary). Observe that the app has selected response and predictor variables based on their data type. Petal and sepal length and width are predictors, and species is the response that you want to classify. For this example, do not change the selections.

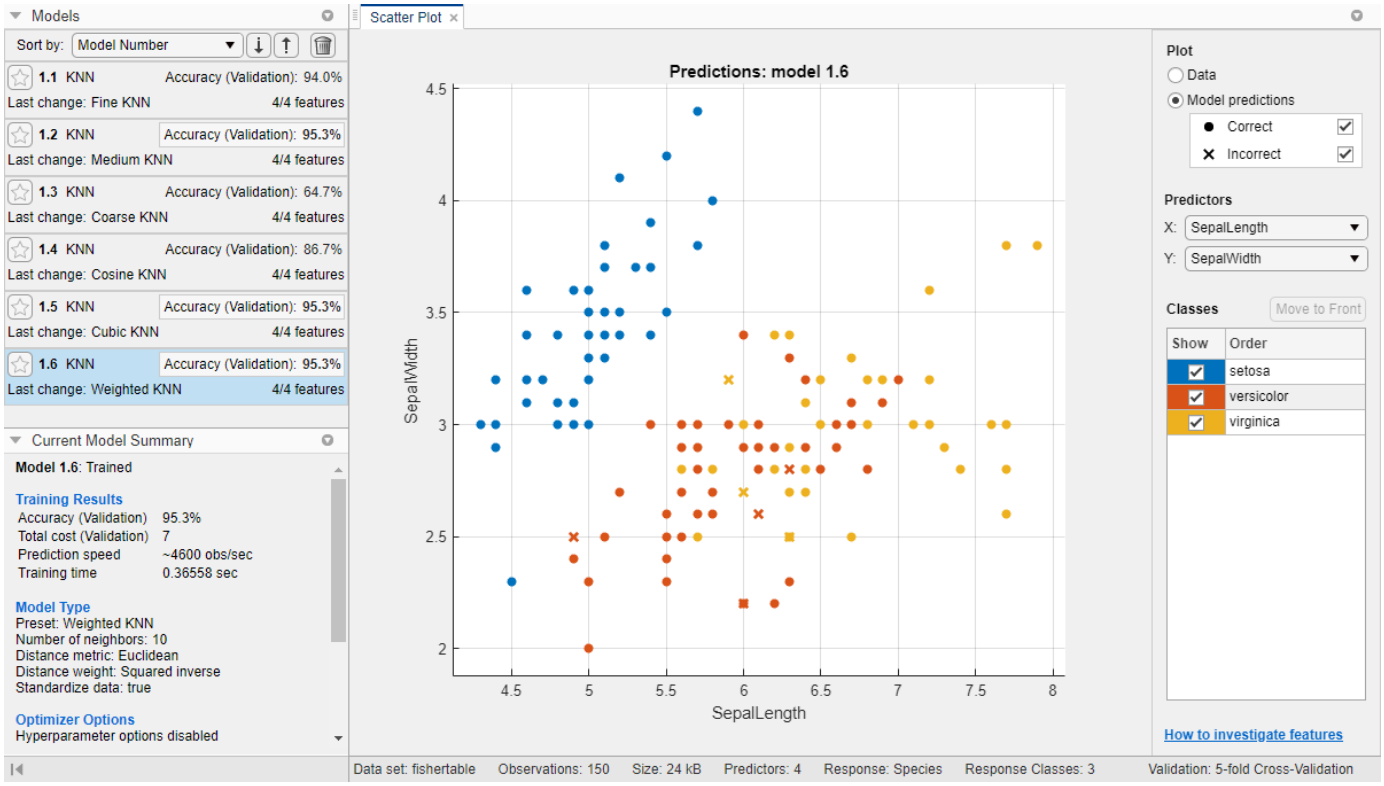
4. Click **Start Session**.

   The app creates a scatter plot of the data.

5. Use the scatter plot to investigate which variables are useful for predicting the response. To visualize the distribution of species and measurements, select different options on the **Variable on X axis** and **Variable on Y axis** menus. Observe which variables separate the species colors most clearly.
6. To create a selection of nearest neighbors models, on the **Classification Learner** tab, on the far right of the **Model Type** section, click the arrow to expand the list of classifiers, and under **Nearest Neighbor Classifiers**, click **All KNNs**.

7. In the **Training** section, click **Train**. 
Tip If you have Parallel Computing Toolbox, you can train all the models (**All KNNs**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.

Classification Learner trains one of each nonoptimizable nearest neighbor classification option in the gallery, and highlights the best score. The app outlines in a box the **Accuracy (Validation)** score of the best model.



8. Select a model in the **Models** pane to view the results. Examine the scatter plot for the trained model. An X indicates a misclassified point.
9. To inspect the accuracy of the predictions in each class, on the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. View the matrix of true class and predicted class results.
10. Select the other models in the **Models** pane to compare.
11. Choose the best model (the best score is highlighted in a box). To improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power.

    On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**. In the Feature Selection dialog box, select predictors to remove from the model, and click **Train** to train a new model using the new options. Compare results among the classifiers in the **Models** pane.
12. To investigate features to include or exclude, use the parallel coordinates plot. On the **Classification Learner** tab, in the **Plots** section, select **Parallel Coordinates**.
13. Choose the best model in the **Models** pane. To try to improve the model further, try changing settings. On the **Classification Learner** tab, in the **Model Type** section, click **Advanced**. Try changing a setting, and then train the new model by clicking **Train**. For information on settings and the strengths of different nearest neighbor model types, see “Nearest Neighbor Classifiers” on page 23-34.
14. To export the trained model to the workspace, in the **Export** section of the toolstrip, click **Export model**. See “Export Classification Model to Predict New Data” on page 23-77.

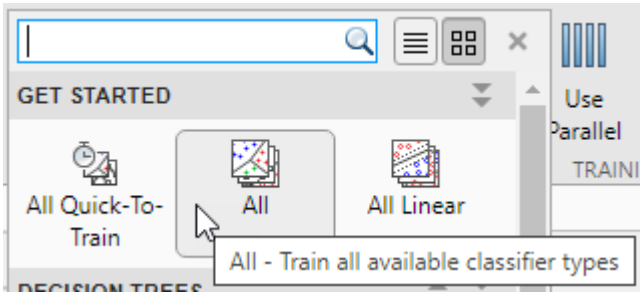
15 To examine the code for training this classifier, click **Generate Function**.

Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To try all the nonoptimizable classifier model presets available for your data set:

1 Click the arrow on the far right of the **Model Type** section to expand the list of classifiers.

2 Click **All**, then click **Train**.



To learn about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

Train Ensemble Classifiers Using Classification Learner App

This example shows how to construct ensembles of classifiers in the Classification Learner app. Ensemble classifiers meld results from many weak learners into one high-quality ensemble predictor. Qualities depend on the choice of algorithm, but ensemble classifiers tend to be slow to fit because they often need many learners.

1. In MATLAB, load the `fisheriris` data set and define some variables from the data set to use for a classification.

   ```
   fishertable = readtable('fisheriris.csv');
   ```

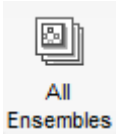
2. On the **Apps** tab, in the **Machine Learning and Deep Learning** group, click **Classification Learner**.
3. On the **Classification Learner** tab, in the **File** section, click **New Session > From Workspace**.

   In the New Session from Workspace dialog box, select the table `fishertable` from the **Data Set Variable** list (if necessary). Observe that the app has selected response and predictor variables based on their data type. Petal and sepal length and width are predictors. Species is the response that you want to classify. For this example, do not change the selections.

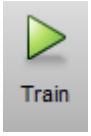
4. Click **Start Session**.

   Classification Learner creates a scatter plot of the data.

5. Use the scatter plot to investigate which variables are useful for predicting the response. Select different variables in the X- and Y-axis controls to visualize the distribution of species and measurements. Observe which variables separate the species colors most clearly.
6. To create a selection of ensemble models, on the **Classification Learner** tab, in the **Model Type** section, click the down arrow to expand the list of classifiers, then under **Ensemble Classifiers**, click **All Ensembles**.



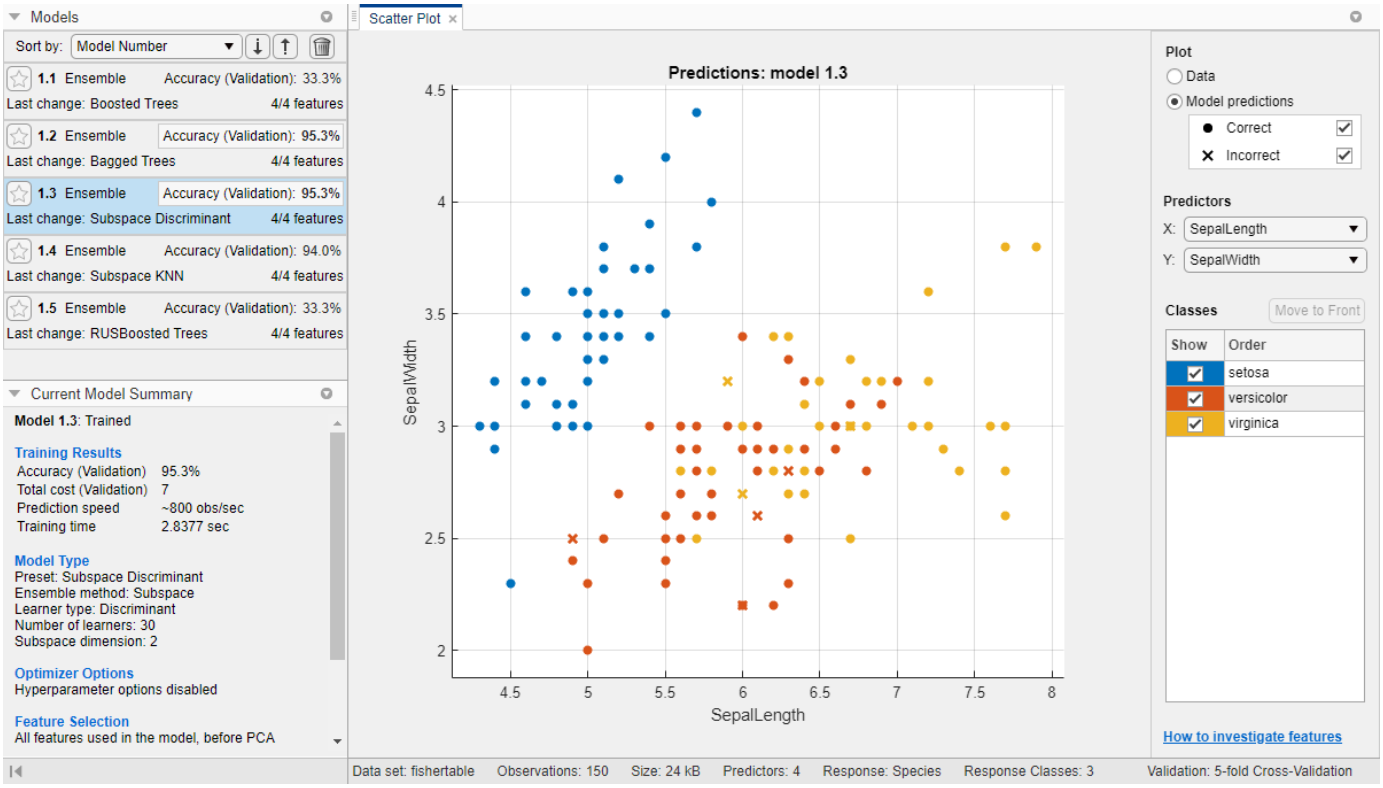
7. In the **Training** section, click **Train**.



Tip If you have Parallel Computing Toolbox, you can train all the models (**All Ensembles**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.

Classification Learner trains one of each nonoptimizable ensemble classification option in the gallery, and highlights the best score. The app outlines in a box the **Accuracy (Validation)** score of the best model.

8 Select a model in the **Models** pane to view the results. Examine the scatter plot for the trained model. Misclassified points are shown as an X.



9 To inspect the accuracy of the predictions in each class, on the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. View the matrix of true class and predicted class results.

10 Select the other models in the **Models** pane to compare.

11 Choose the best model (the best score is highlighted in the **Accuracy (Validation)** box). To improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power.

On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**. In the Feature Selection dialog box, specify predictors to remove from the model, and click **Train** to train a new model using the new options. Compare results among the classifiers in the **Models** pane.

12 To investigate features to include or exclude, use the scatter and parallel coordinates plots. On the **Classification Learner** tab, in the **Plots** section, select **Parallel Coordinates**.

13 Choose the best model in the **Models** pane. To try to improve the model further, try changing settings. On the **Classification Learner** tab, in the **Model Type** section, click **Advanced**. Try changing a setting, then train the new model by clicking **Train**.

For information on the settings to try and the strengths of different ensemble model types, see “Ensemble Classifiers” on page 23-37.

14 To export the trained model to the workspace, select the Classification Learner tab and click **Export model**. See “Export Classification Model to Predict New Data” on page 23-77.

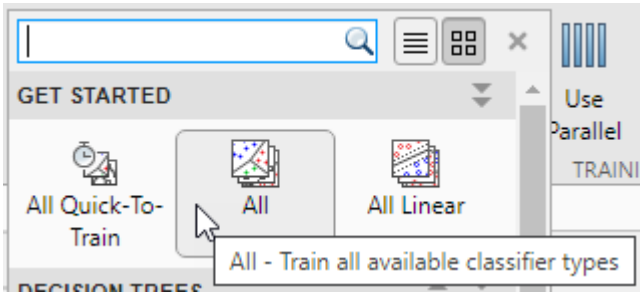
15 To examine the code for training this classifier, click **Generate Function**.

Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To try all the nonoptimizable classifier model presets available for your data set:

1 Click the arrow on the far right of the **Model Type** section to expand the list of classifiers.

2 Click **All**, then click **Train**.



To learn about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

Train Naive Bayes Classifiers Using Classification Learner App

This example shows how to create and compare different naive Bayes classifiers using the Classification Learner app, and export trained models to the workspace to make predictions for new data.

Naive Bayes classifiers leverage Bayes theorem and make the assumption that predictors are independent of one another within each class. However, the classifiers appear to work well even when the independence assumption is not valid. You can use naive Bayes with two or more classes in Classification Learner. The app allows you to train a Gaussian naive Bayes model or a kernel naive Bayes model individually or simultaneously.

This table lists the available naive Bayes models in Classification Learner and the probability distributions used by each model to fit predictors.

Model	Numerical Predictor	Categorical Predictor
Gaussian naive Bayes	Gaussian distribution (or normal distribution)	multivariate multinomial distribution
Kernel naive Bayes	Kernel distribution You can specify the kernel type and support. Classification Learner automatically determines the kernel width using the underlying `fitcnb` function.	multivariate multinomial distribution

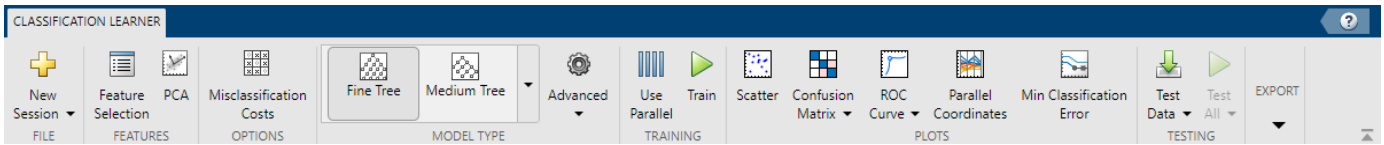
This example uses Fisher's iris data set, which contains measurements of flowers (petal length, petal width, sepal length, and sepal width) for specimens from three species. Train naive Bayes classifiers to predict the species based on the predictor measurements.

1. In the MATLAB Command Window, load the Fisher iris data set and create a table of measurement predictors (or features) using variables from the data set.

   ```
   fishertable = readtable('fisheriris.csv');
   ```

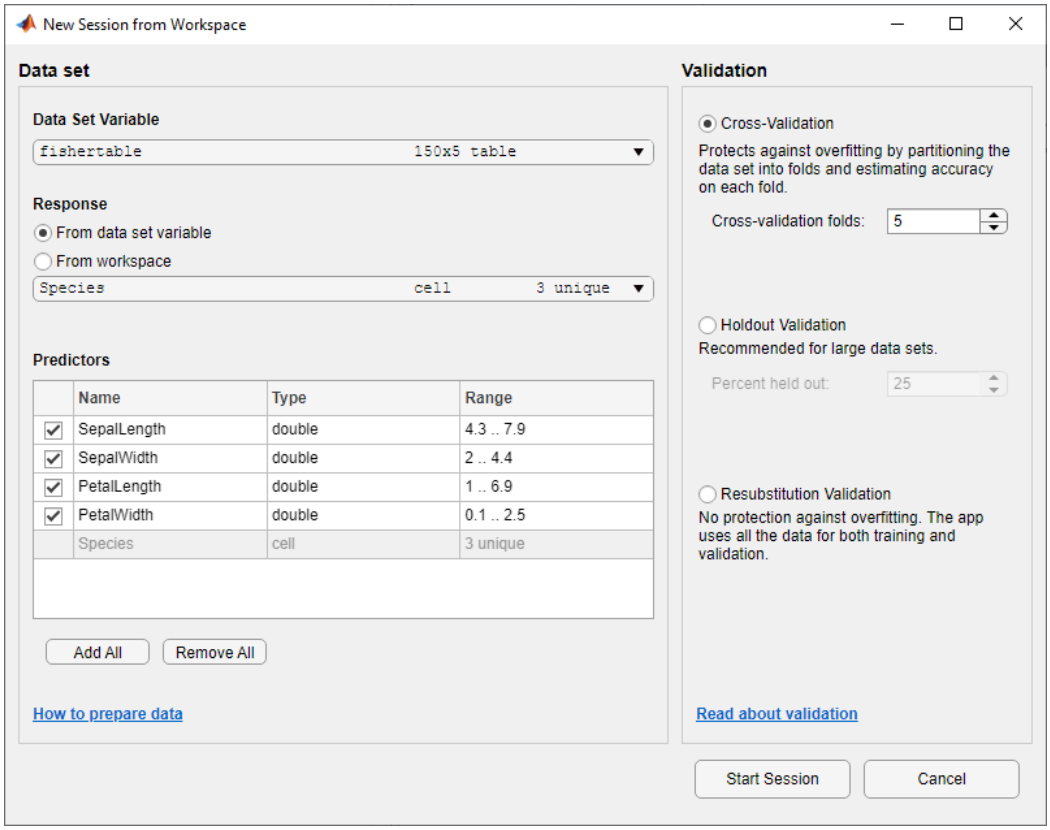
2. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.

3. On the **Classification Learner** tab, in the **File** section, select **New Session > From Workspace**.



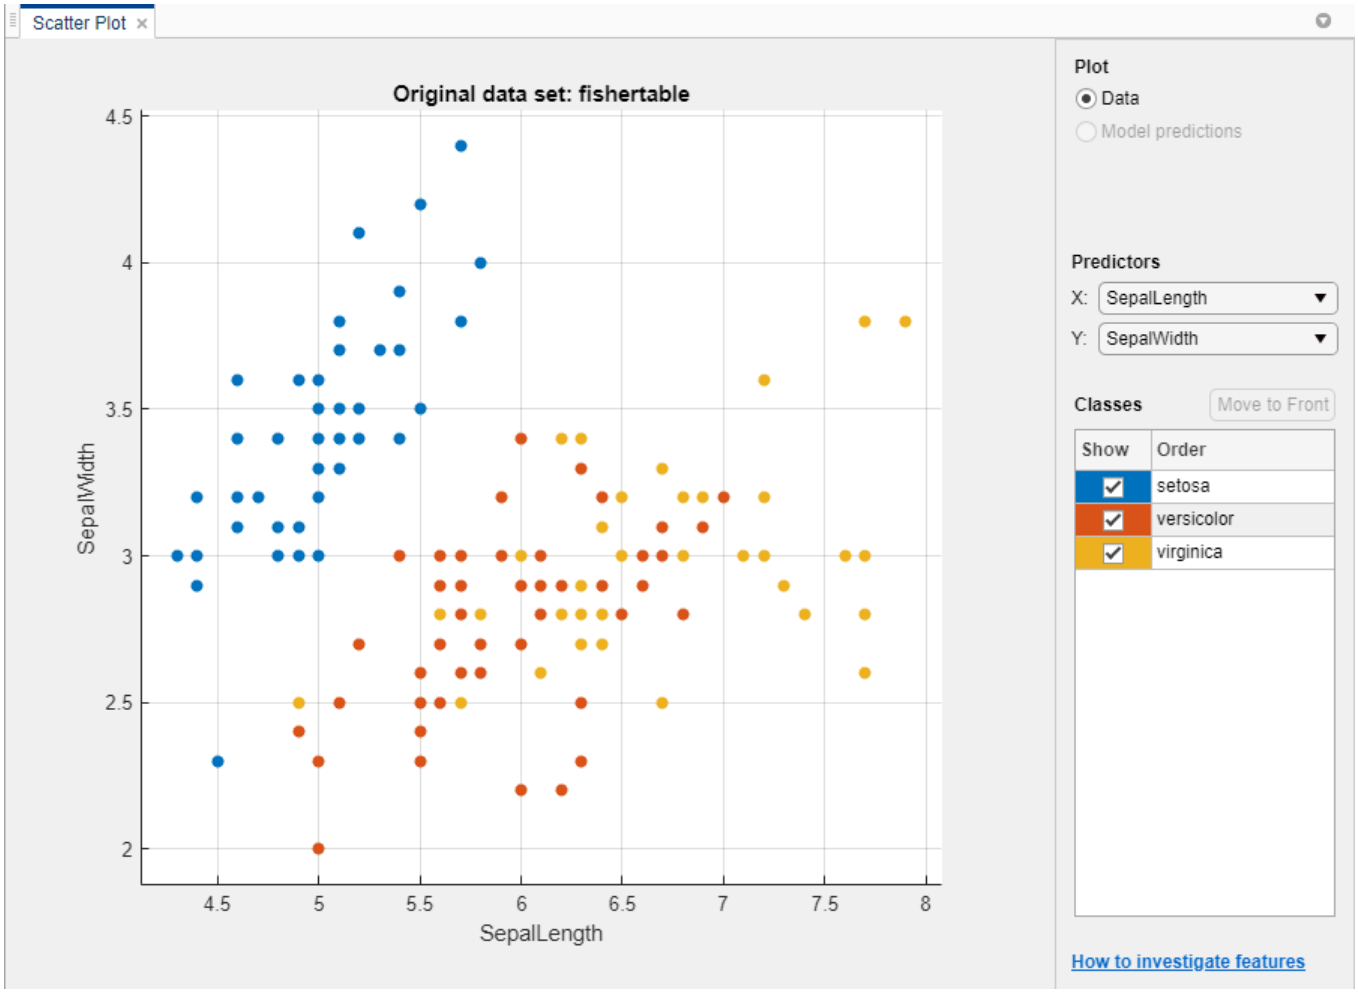
4. In the New Session from Workspace dialog box, select the table `fishertable` from the **Data Set Variable** list (if necessary).

   As shown in the dialog box, the app selects the response and predictor variables based on their data type. Petal and sepal length and width are predictors, and species is the response that you want to classify. For this example, do not change the selections.



5 To accept the default validation scheme and continue, click **Start Session**. The default validation option is cross-validation, to protect against overfitting.

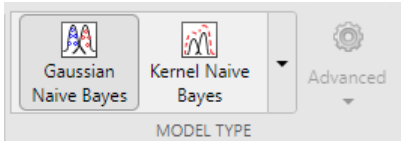
Classification Learner creates a scatter plot of the data.



6 Use the scatter plot to investigate which variables are useful for predicting the response. Select different options on the **X** and **Y** lists under **Predictors** to visualize the distribution of species and measurements. Observe which variables separate the species colors most clearly.

The `setosa` species (blue points) is easy to separate from the other two species with all four predictors. The `versicolor` and `virginica` species are much closer together in all predictor measurements and overlap, especially when you plot sepal length and width. `setosa` is easier to predict than the other two species.

7 Create a naive Bayes model. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Naive Bayes Classifiers** group, click **Gaussian Naive Bayes**. Note that Classification Learner disables the **Advanced** button in the **Model Type** section, because this type of model has no advanced settings.

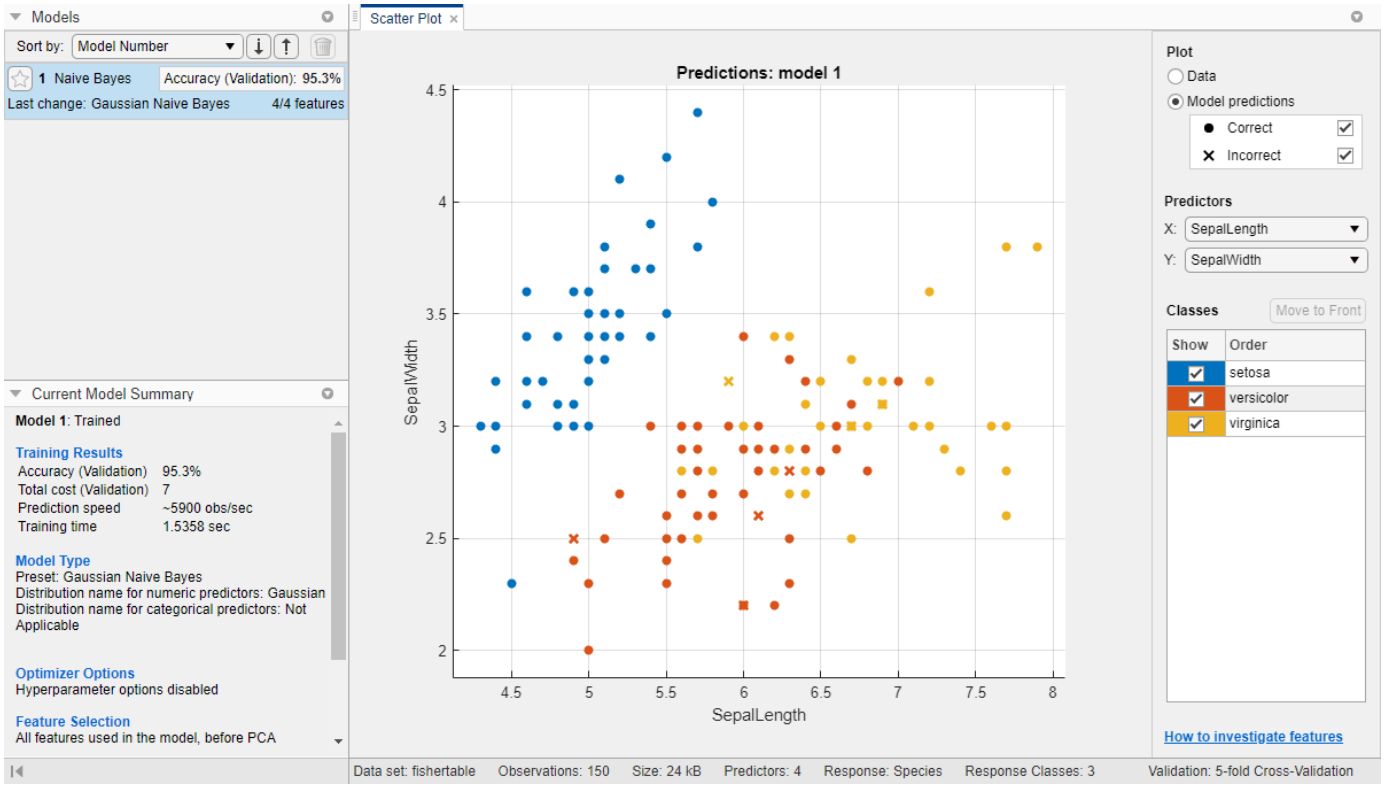


In the **Training** section, click **Train**.

The app creates a Gaussian naive Bayes model, and plots the results.

The app display the **Gaussian Naive Bayes** model in the **Models** pane. Check the model validation score in the **Accuracy (Validation)** box. The score shows that the model performs well.

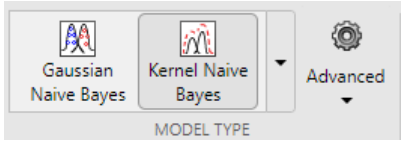
For the **Gaussian Naive Bayes** model, by default, the app models the distribution of numerical predictors using the Gaussian distribution, and models the distribution of categorical predictors using the multivariate multinomial distribution (MVMN).



Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

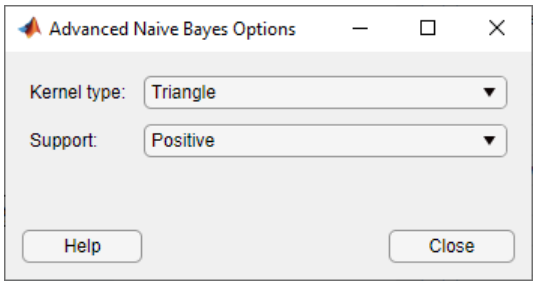
8 Examine the scatter plot. An X indicates misclassified points. The blue points (`setosa` species) are all correctly classified, but the other two species have misclassified points. Under **Plot**, switch between the **Data** and **Model predictions** options. Observe the color of the incorrect (X) points. Or, to view only the incorrect points, clear the **Correct** check box.

9 Train a kernel naive Bayes model for comparison. On the **Classification Learner** tab, in the **Model Type** section, click **Kernel Naive Bayes**. Note that Classification Learner enables the **Advanced** button, because this type of model has advanced settings.



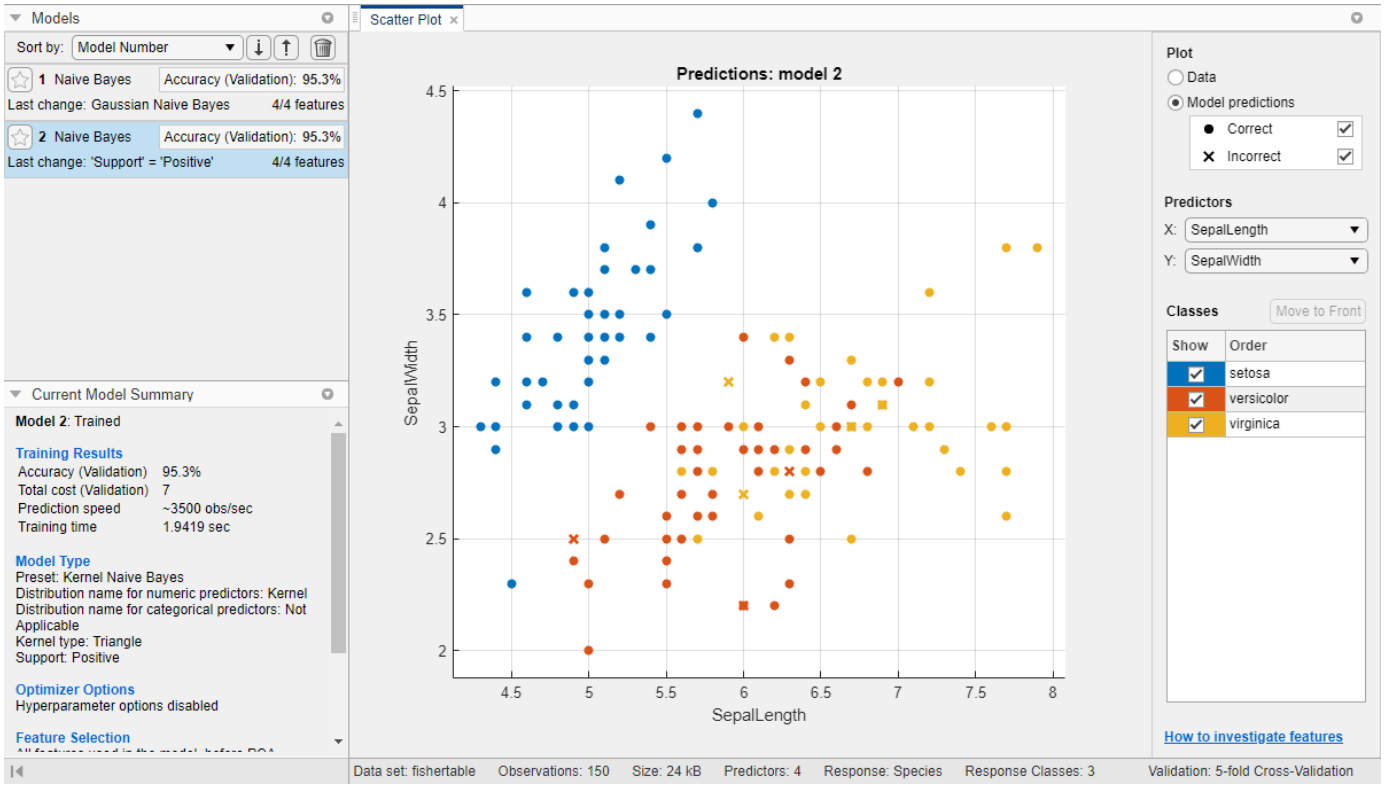
The app displays a draft kernel naive Bayes model in the **Models** pane.

In the **Model Type** section, click **Advanced** to change settings in the Advanced Naive Bayes Options dialog box. Select `Triangle` from the **Kernel Type** list, and select `Positive` from the **Support** list.



Note The settings in the Advanced Naive Bayes Options dialog box are available for continuous data only. Pointing to **Kernel Type** displays the tooltip "Specify Kernel smoothing function for continuous variables," and pointing to **Support** displays the tooltip "Specify Kernel smoothing density support for continuous variables."

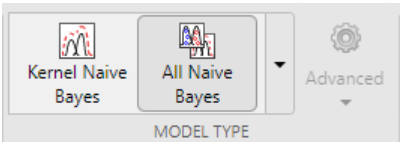
In the **Training** section, click **Train** to train the new model.



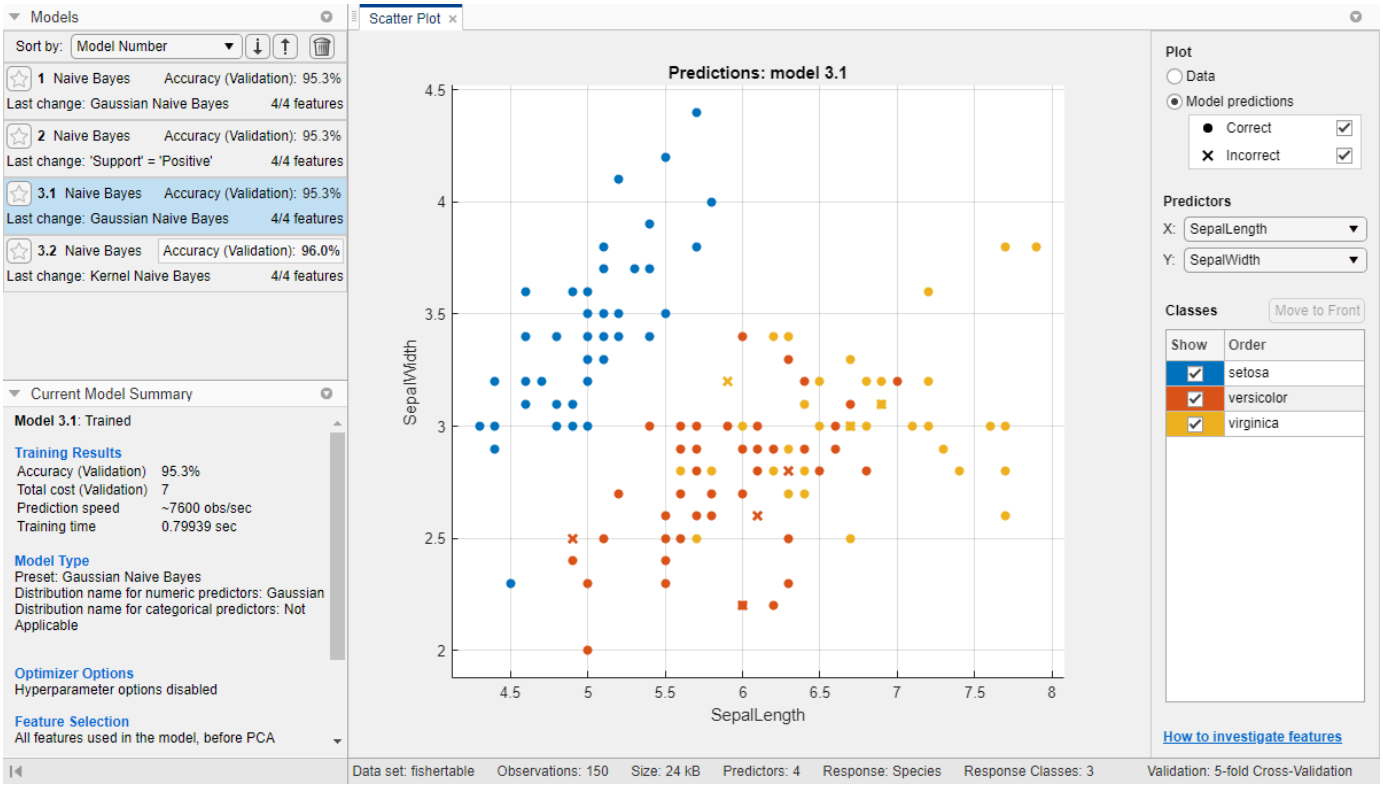
The **Models** pane now includes the new kernel naive Bayes model. Its model validation score is better than the score for the Gaussian naive Bayes model. The app highlights the **Accuracy (Validation)** score of the best model by outlining it in a box.

10 In the **Models** pane, click each model to view and compare the results.

11 Train a Gaussian naive Bayes model and a kernel naive Bayes model simultaneously. On the **Classification Learner** tab, in the **Model Type** section, click **All Naive Bayes**. Classification Learner disables the **Advanced** button. In the **Training** section, click **Train**.



The app trains one of each naive Bayes model type and highlights the **Accuracy (Validation)** score of the best model or models.



12 In the **Models** pane, click a model to view the results. Examine the scatter plot for the trained model and try plotting different predictors. Misclassified points appear as an X.

13 To inspect the accuracy of the predictions in each class, on the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. The app displays a matrix of true class and predicted class results.

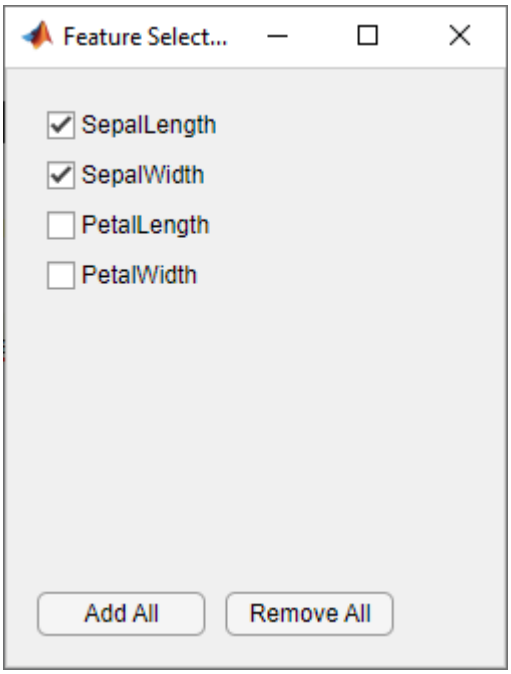
Note Validation introduces some randomness into the results. Your confusion matrix results can vary from the results shown in this example.

14 In the **Models** pane, click the other models and compare their results.

15 In the **Models** pane, click the model with the highest **Accuracy (Validation)** score. To improve the model, try modifying its features. For example, see if you can improve the model by removing features with low predictive power.

On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**.

In the Feature Selection dialog box, clear the check boxes for **PetalLength** and **PetalWidth** to exclude them from the predictors. A new draft model (model 4) appears in the **Models** pane with the new settings (2/4 features), based on the kernel naive Bayes model (model 3.2).



In the **Training** section, click **Train** to train a new kernel naive Bayes model using the new predictor options.

The **Models** pane now includes model 4. It is also a kernel naive Bayes model, trained using only 2 of 4 predictors.

16 To determine which predictors are included, click a model in the **Models** pane, then click **Feature Selection** in the **Features** section and note which check boxes are selected. The model with only sepal measurements (model 4) has a much lower **Accuracy (Validation)** score than the models containing all predictors.

17 Train another kernel naive Bayes model including only the petal measurements. Change the selections in the Feature Selection dialog box and click **Train**.

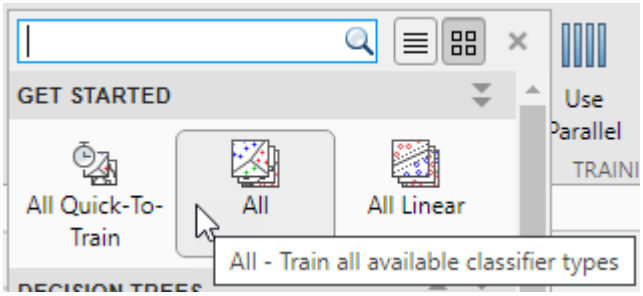
The model trained using only petal measurements (model 5) performs comparably to the model containing all predictors. The models predict no better using all the measurements compared to only the petal measurements. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily without some predictors.

18. To investigate features to include or exclude, use the parallel coordinates plot. On the **Classification Learner** tab, in the **Plots** section, click **Parallel Coordinates**.
19. In the **Models** pane, click the model with the highest **Accuracy (Validation)** score. To improve the model further, try changing naive Bayes settings (if available). On the **Classification Learner** tab, in the **Model Type** section, click **Advanced**. Recall that the **Advanced** button is enabled only for some models. Change a setting, then train the new model by clicking **Train**.
20. Export the trained model to the workspace. On the **Classification Learner** tab, in the **Export** section, select **Export Model > Export Model**. See “Export Classification Model to Predict New Data” on page 23-77.
21. Examine the code for training this classifier. In the **Export** section, click **Generate Function**.

Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To try all the nonoptimizable classifier model presets available for your data set:

1. Click the arrow on the **Model Type** section to open the gallery of classifiers.
2. In the **Get Started** group, click **All**, then click **Train** in the **Training** section.



For information about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

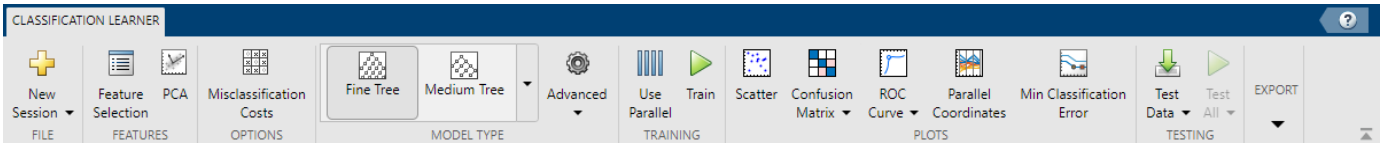
Train Neural Network Classifiers Using Classification Learner App

This example shows how to create and compare neural network classifiers in the Classification Learner app, and export trained models to the workspace to make predictions for new data.

1. In the MATLAB Command Window, load the `fisheriris` data set, and create a table from the variables in the data set to use for classification.

   ```
   fishertable = readtable('fisheriris.csv');
   ```

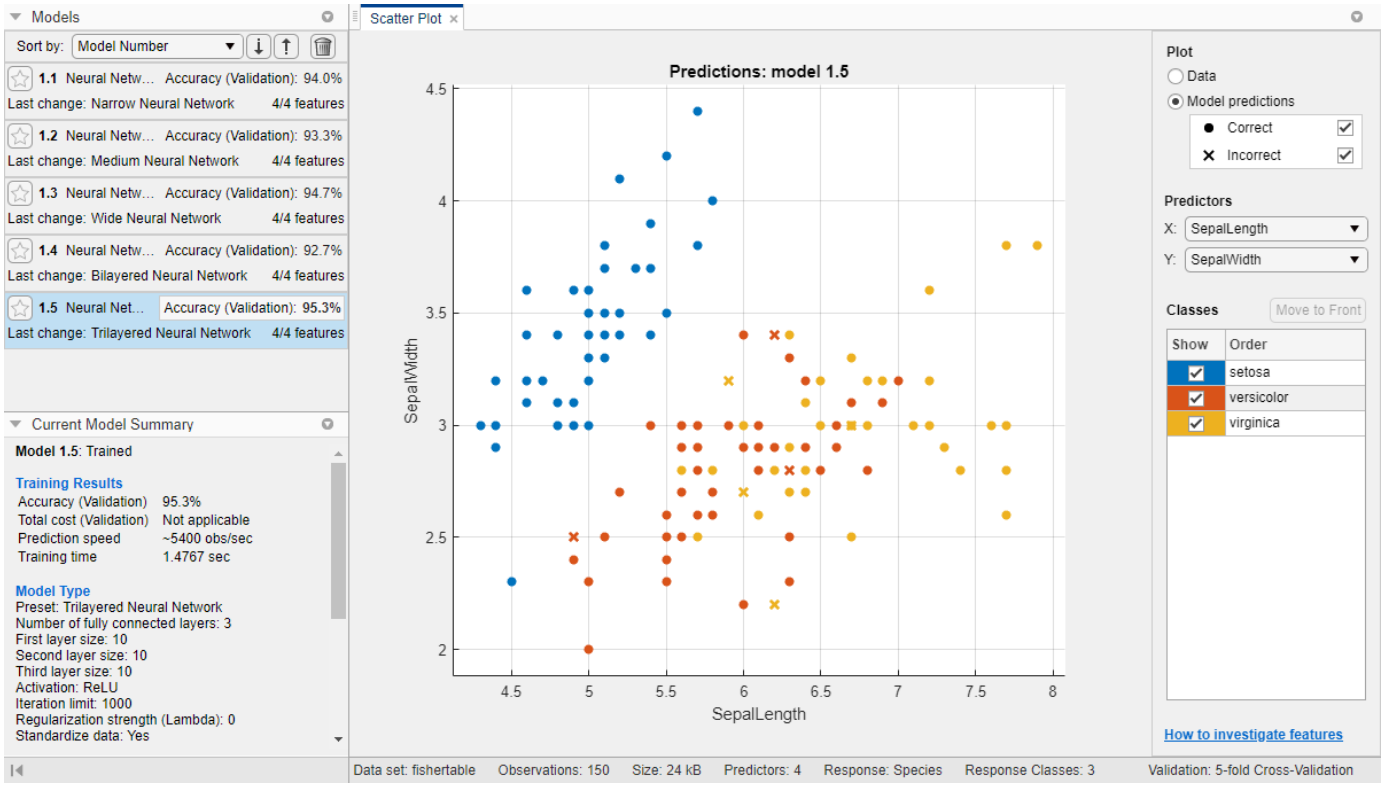
2. Click the **Apps** tab, and then click the **Show more** arrow on the right to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.
3. On the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.



4. In the New Session from Workspace dialog box, select the table `fishertable` from the **Data Set Variable** list (if necessary). Observe that the app has selected response and predictor variables based on their data types. Petal and sepal length and width are predictors, and species is the response that you want to classify. For this example, do not change the selections.
5. To accept the default validation scheme and continue, click **Start Session**. The default validation option is 5-fold cross-validation, to protect against overfitting.

   Classification Learner creates a scatter plot of the data.
6. Use the scatter plot to investigate which variables are useful for predicting the response. Select different options in the **X** and **Y** lists under **Predictors** to visualize the distribution of species and measurements. Note which variables separate the species colors most clearly.
7. Create a selection of neural network models. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Neural Network Classifiers** group, click **All Neural Networks**.
8. In the **Training** section, click **Train**. Classification Learner trains one of each neural network classification option in the gallery. In the **Models** pane, the app outlines the **Accuracy (Validation)** score of the best model.

   Tip If you have Parallel Computing Toolbox, you can train all the models (**All Neural Networks**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.
9. Select a model in the **Models** pane to view the results. Examine the scatter plot for the trained model. Correctly classified points are marked with an O, and incorrectly classified points are marked with an X.



Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

10 Inspect the accuracy of the predictions in each class. On the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. View the matrix of true class and predicted class results.

11 Select the other models in the list for comparison.

12 Choose the best model in the **Models** pane (the best score is highlighted in the **Accuracy (Validation)** box). To improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power.

On the **Classification Learner** tab, in the **Features** section, click **Feature Selection**. In the Feature Selection dialog box, specify predictors to remove from the model, and click **Train** to train a new model using the new options. Compare results among the classifiers in the **Models** pane.

13 To investigate features to include or exclude, use the scatter and parallel coordinates plots. On the **Classification Learner** tab, in the **Plots** section, select **Parallel Coordinates**.

14 Choose the best model in the **Models** pane. To try to improve the model further, change its advanced settings. On the **Classification Learner** tab, in the **Model Type** section, click **Advanced** and select **Advanced**. Try changing some of the settings, like the sizes of the fully connected layers or the regularization strength, and then train the new model by clicking **Train**.

To learn more about neural network model settings, see “Neural Network Classifiers” on page 23-39.

15 You can export a full or compact version of the trained model to the workspace. On the **Classification Learner** tab, in the **Export** section, click **Export Model** and select either **Export Model** or **Export Compact Model**. See “Export Classification Model to Predict New Data” on page 23-77.

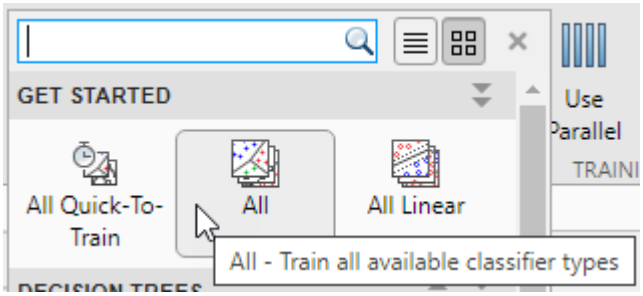
16 To examine the code for training this classifier, click **Generate Function** in the **Export** section.

Tip Use the same workflow to evaluate and compare the other classifier types you can train in Classification Learner.

To train all the nonoptimizable classifier model presets available for your data set:

1 On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery of models.

2 In the **Get Started** group, click **All**. Then, in the **Training** section, click **Train**.



To learn about other classifier types, see “Train Classification Models in Classification Learner App” on page 23-10.

Train and Compare Classifiers Using Misclassification Costs in Classification Learner App

This example shows how to create and compare classifiers that use specified misclassification costs in the Classification Learner app. Specify the misclassification costs before training, and use the accuracy and total misclassification cost results to compare the trained models.

1 In the MATLAB Command Window, read the sample file `CreditRating_Historical.dat` into a table. The predictor data consists of financial ratios and industry sector information for a list of corporate customers. The response variable consists of credit ratings assigned by a rating agency. Combine all the `A` ratings into one rating. Do the same for the `B` and `C` ratings, so that the response variable has three distinct ratings. Among the three ratings, `A` is considered the best and `C` the worst.

```
creditrating = readtable('CreditRating_Historical.dat');
Rating = categorical(creditrating.Rating);
Rating = mergecats(Rating,{'AAA','AA','A'},'A');
Rating = mergecats(Rating,{'BBB','BB','B'},'B');
Rating = mergecats(Rating,{'CCC','CC','C'},'C');
creditrating.Rating = Rating;
```

2 Assume these are the costs associated with misclassifying the credit ratings of customers.

		Customer Predicted Rating		
		A	B	C
Customer True Rating	A	$0	$100	$200
	B	$500	$0	$100
	C	$1000	$500	$0

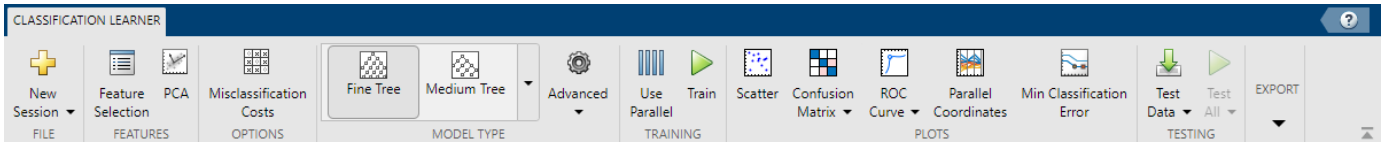
For example, the cost of misclassifying a `C` rating customer as an `A` rating customer is $1000. The costs indicate that classifying a customer with bad credit as a customer with good credit is more costly than classifying a customer with good credit as a customer with bad credit.

Create a matrix variable that contains the misclassification costs. Create another variable that specifies the class names and their order in the matrix variable.

```
ClassificationCosts = [0 100 200; 500 0 100; 1000 500 0];
ClassNames = categorical({'A','B','C'});
```

Tip Alternatively, you can specify misclassification costs directly inside the Classification Learner app. See “Specify Misclassification Costs” on page 23-48 for more information.

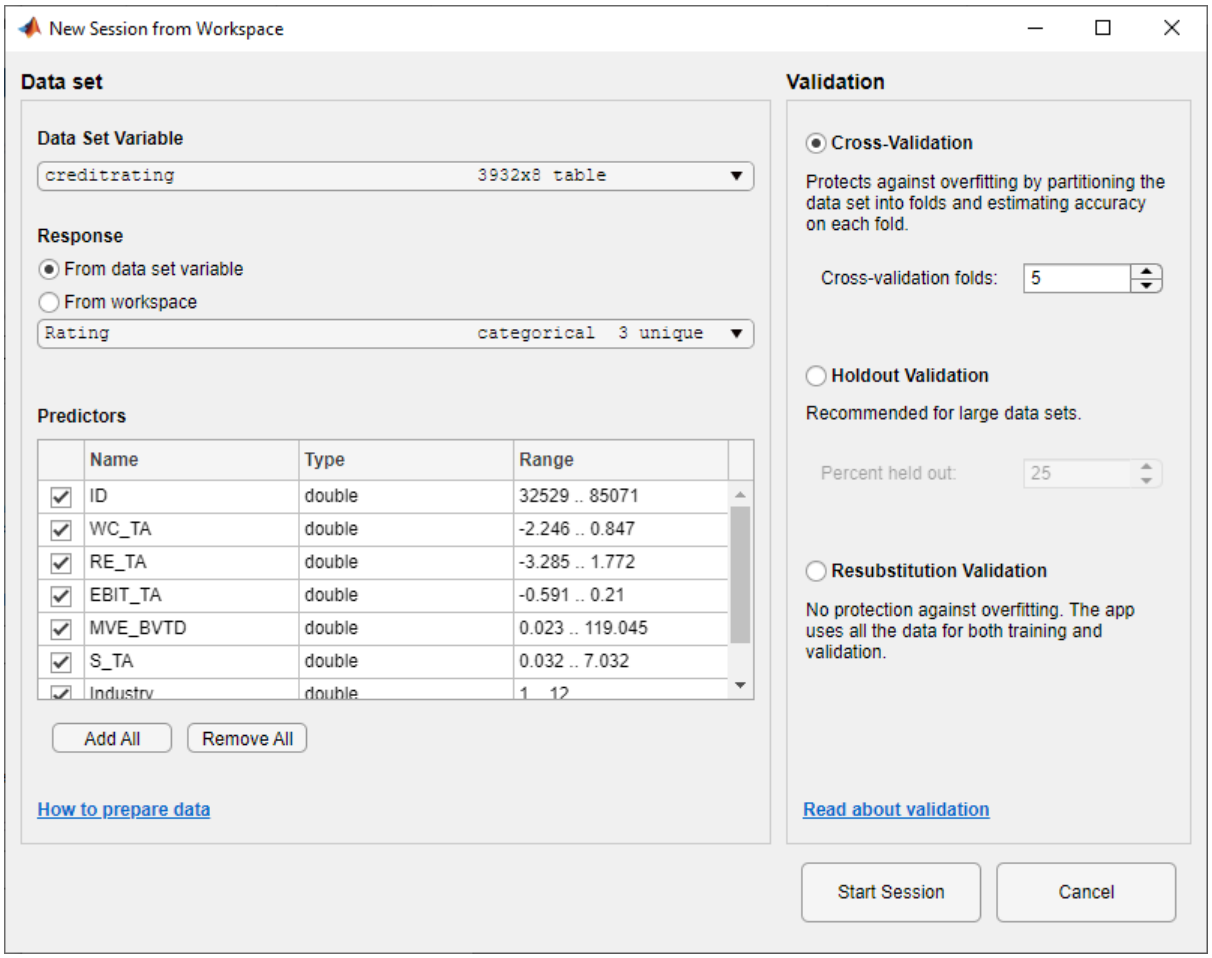
3 Open Classification Learner. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.



4 On the **Classification Learner** tab, in the **File** section, select **New Session > From Workspace**.

5 In the New Session from Workspace dialog box, select the table `creditrating` from the **Data Set Variable** list.

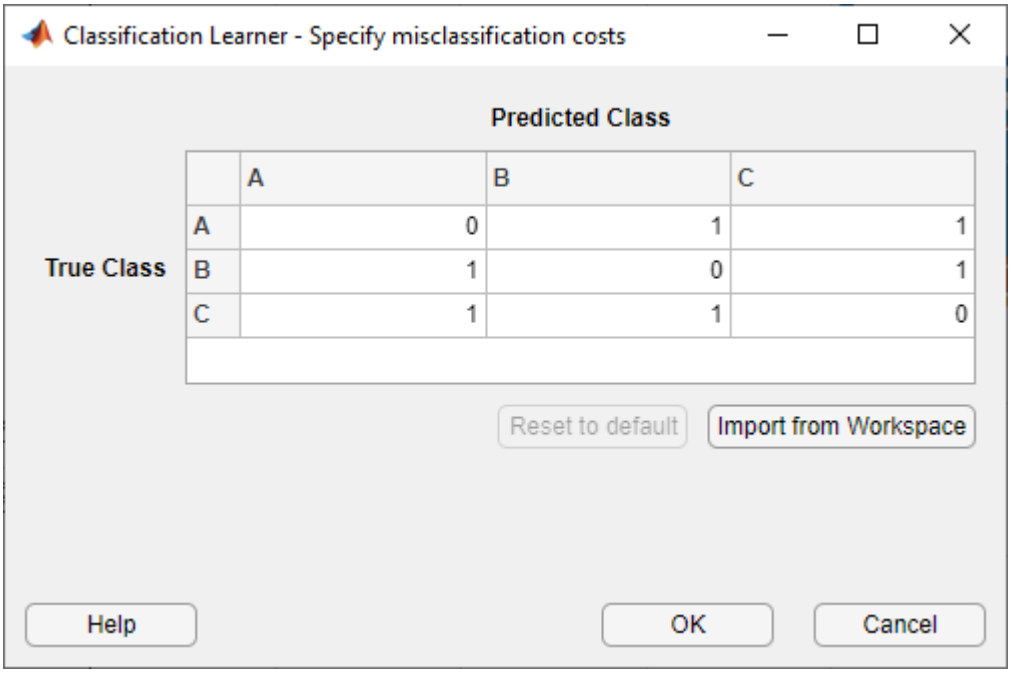
As shown in the dialog box, the app selects the response and predictor variables based on their data type. The default response variable is the `Rating` variable. The default validation option is cross-validation, to protect against overfitting. For this example, do not change the default settings.



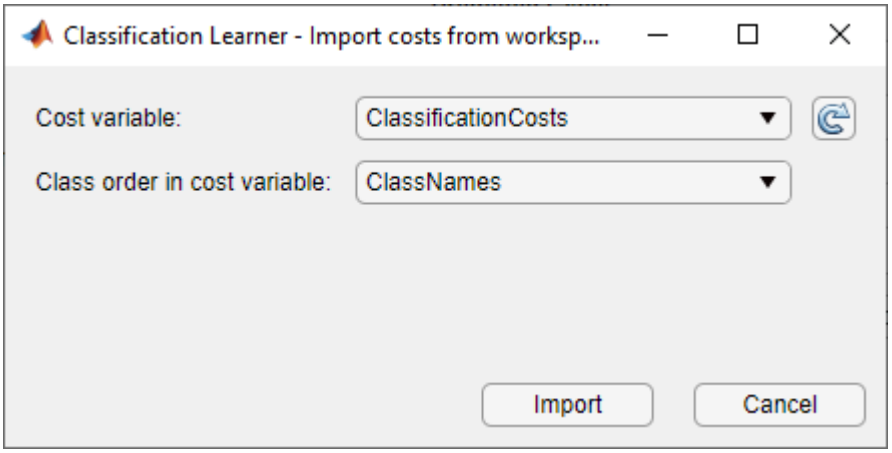
6 To accept the default settings, click **Start Session**.

7 Specify the misclassification costs. On the **Classification Learner** tab, in the **Options** section, click **Misclassification Costs**. The app opens a dialog box showing the default misclassification costs.

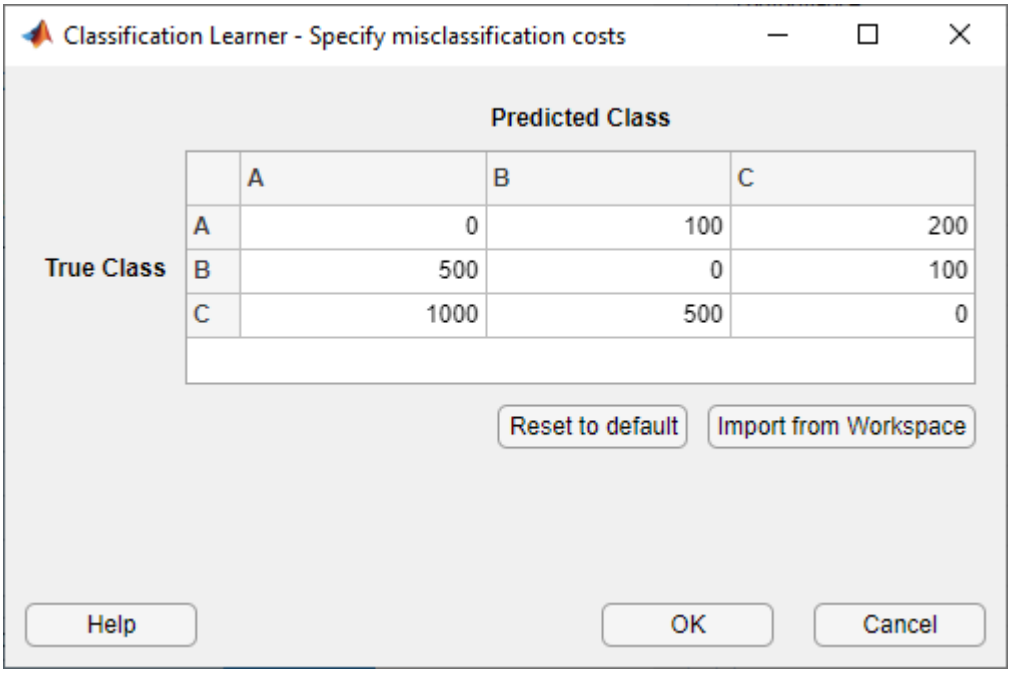
In the dialog box, click **Import from Workspace**.



In the import dialog box, select `ClassificationCosts` as the cost variable and `ClassNames` as the class order in the cost variable. Click **Import**.



The app updates the values in the misclassification costs dialog box. Click **OK** to save your changes.



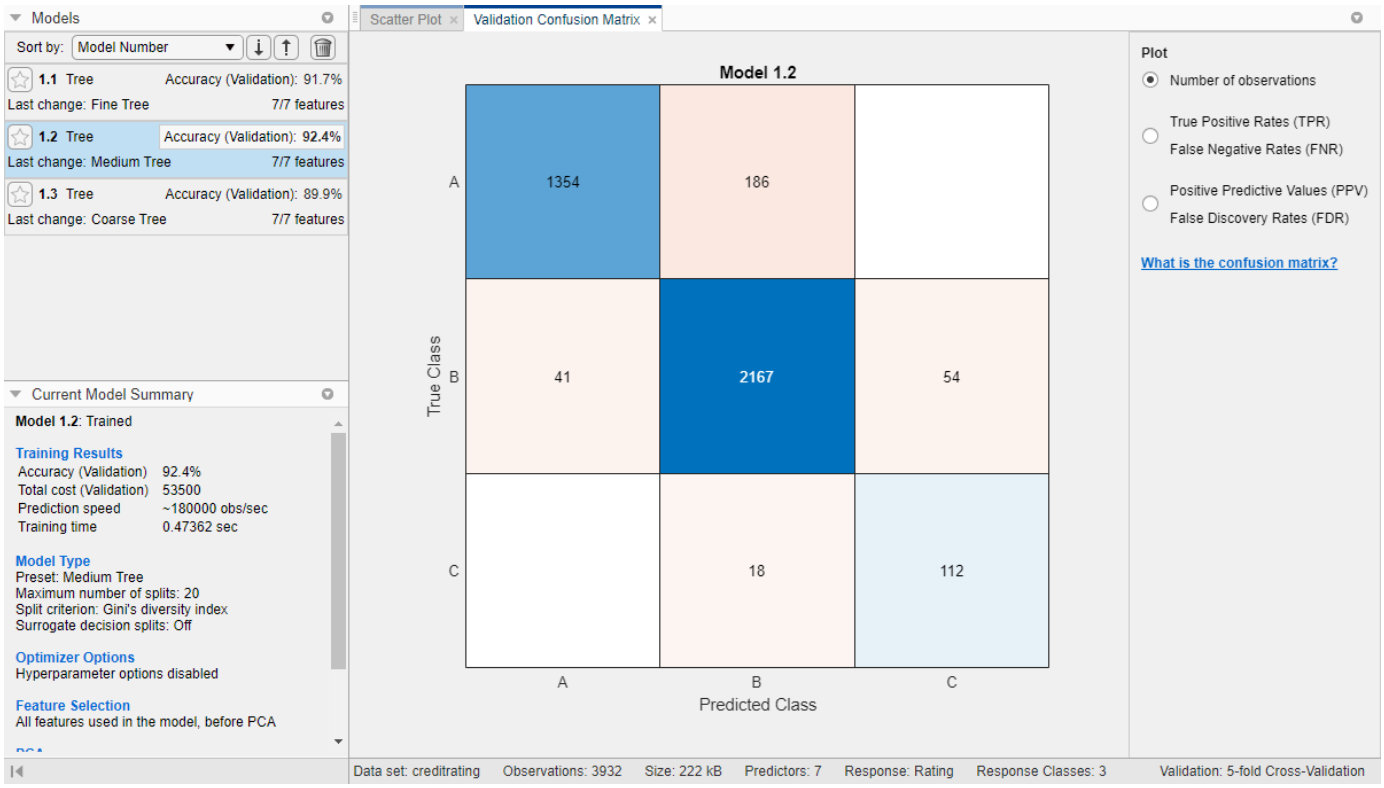
8 Train fine, medium, and coarse trees simultaneously. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Decision Trees** group, click **All Trees**. In the **Training** section, click **Train**. The app trains one of each tree model type and displays the models in the **Models** pane.

Tip If you have Parallel Computing Toolbox, you can train all the models (**All Trees**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.

Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

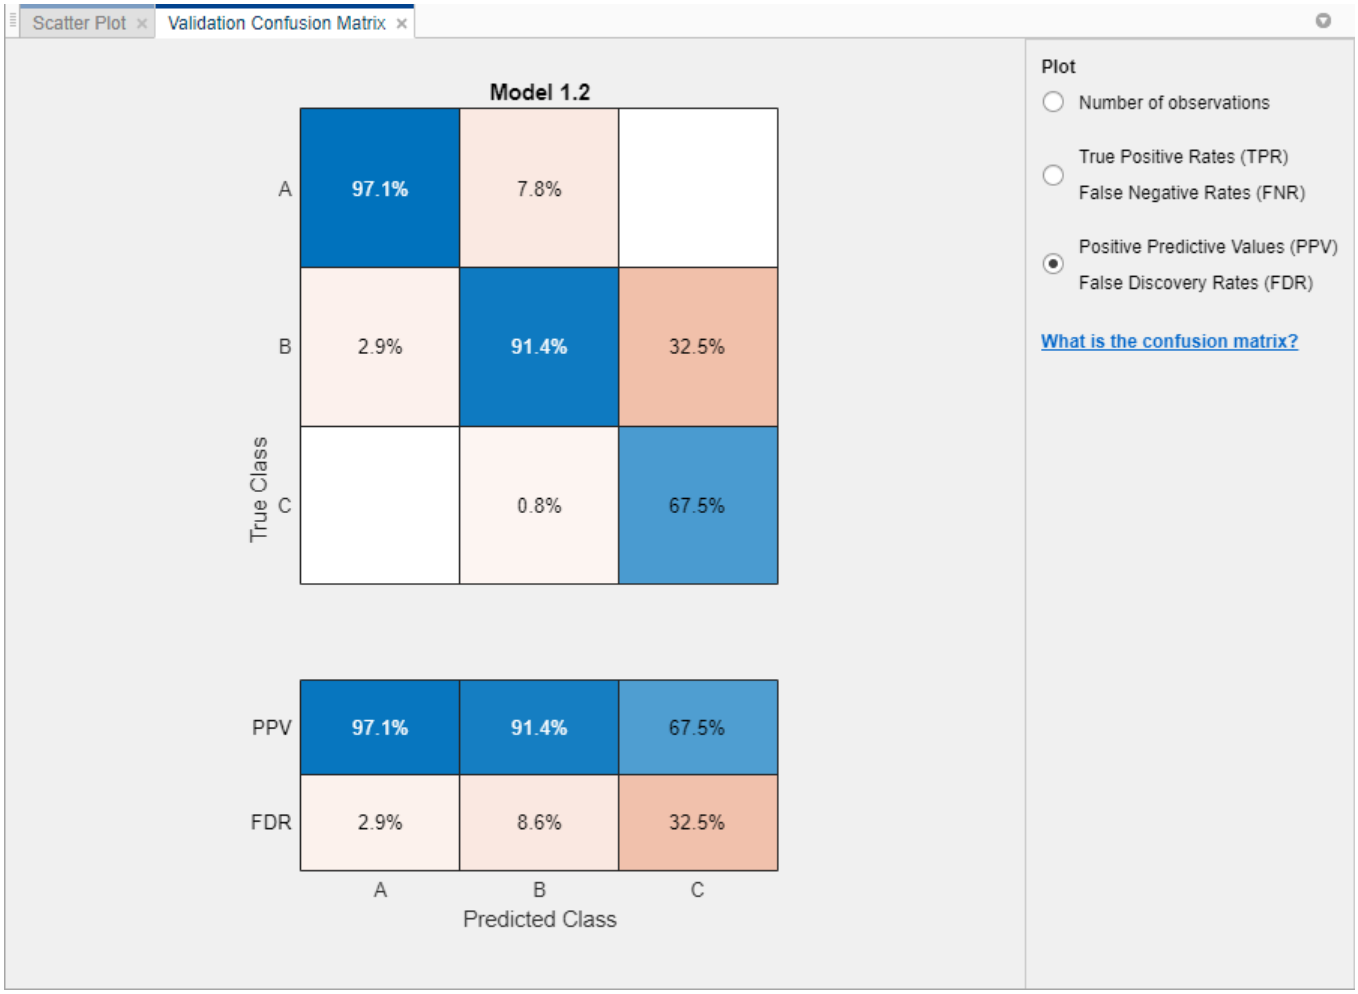
9 In the **Models** pane, click a model to view the results, which are displayed in the **Current Model Summary** pane. Each model has a validation accuracy score that indicates the percentage of correctly predicted responses. In the **Models** pane, the app highlights the highest **Accuracy (Validation)** score by outlining it in a box.

10 Inspect the accuracy of the predictions in each class. On the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**. The app displays a matrix of true class and predicted class results for the selected model (in this case, for the medium tree).

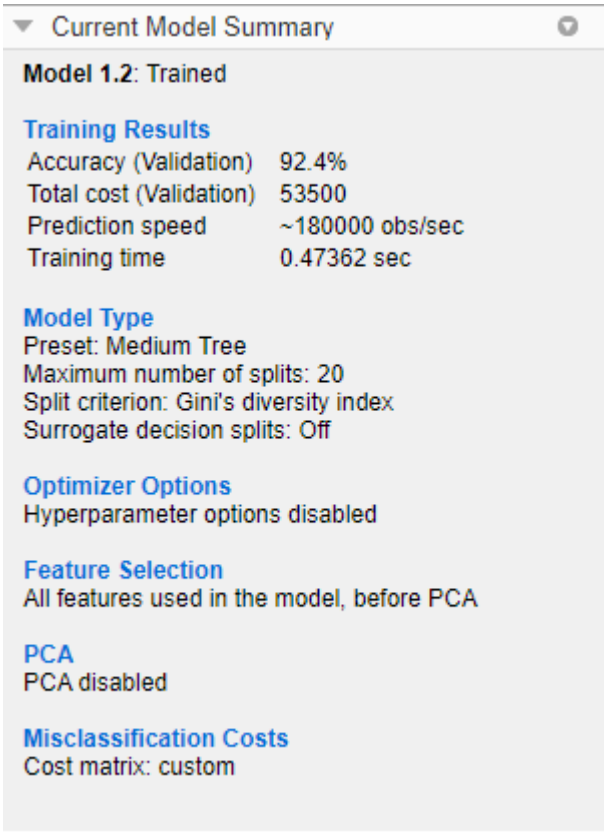


11 You can also plot results per predicted class to investigate false discovery rates. Under **Plot**, select the **Positive Predictive Values (PPV) False Discovery Rates (FDR)** option.

In the confusion matrix for the medium tree, the entries below the diagonal have small percentage values. These values indicate that the model tries to avoid assigning a credit rating that is higher than the true rating for a customer.



12 Compare the total misclassification costs of the tree models. To inspect the total misclassification cost of a model, select the model in the **Models** pane, and then view the **Training Results** section of the **Current Model Summary** pane. For example, the medium tree has these results.



In general, choose a model that has high accuracy and low total misclassification cost. In this example, the medium tree has the highest validation accuracy value and the lowest total misclassification cost of the three models.

You can perform feature selection and transformation or tune your model just as you do in the workflow without misclassification costs. However, always check the total misclassification cost of your model when assessing its performance. For differences in the exported model and exported code when you use misclassification costs, see “Misclassification Costs in Exported Model and Generated Code” on page 23-52.

Train Classifier Using Hyperparameter Optimization in Classification Learner App

This example shows how to tune hyperparameters of a classification support vector machine (SVM) model by using hyperparameter optimization in the Classification Learner app. Compare the test set performance of the trained optimizable SVM to that of the best-performing preset SVM model.

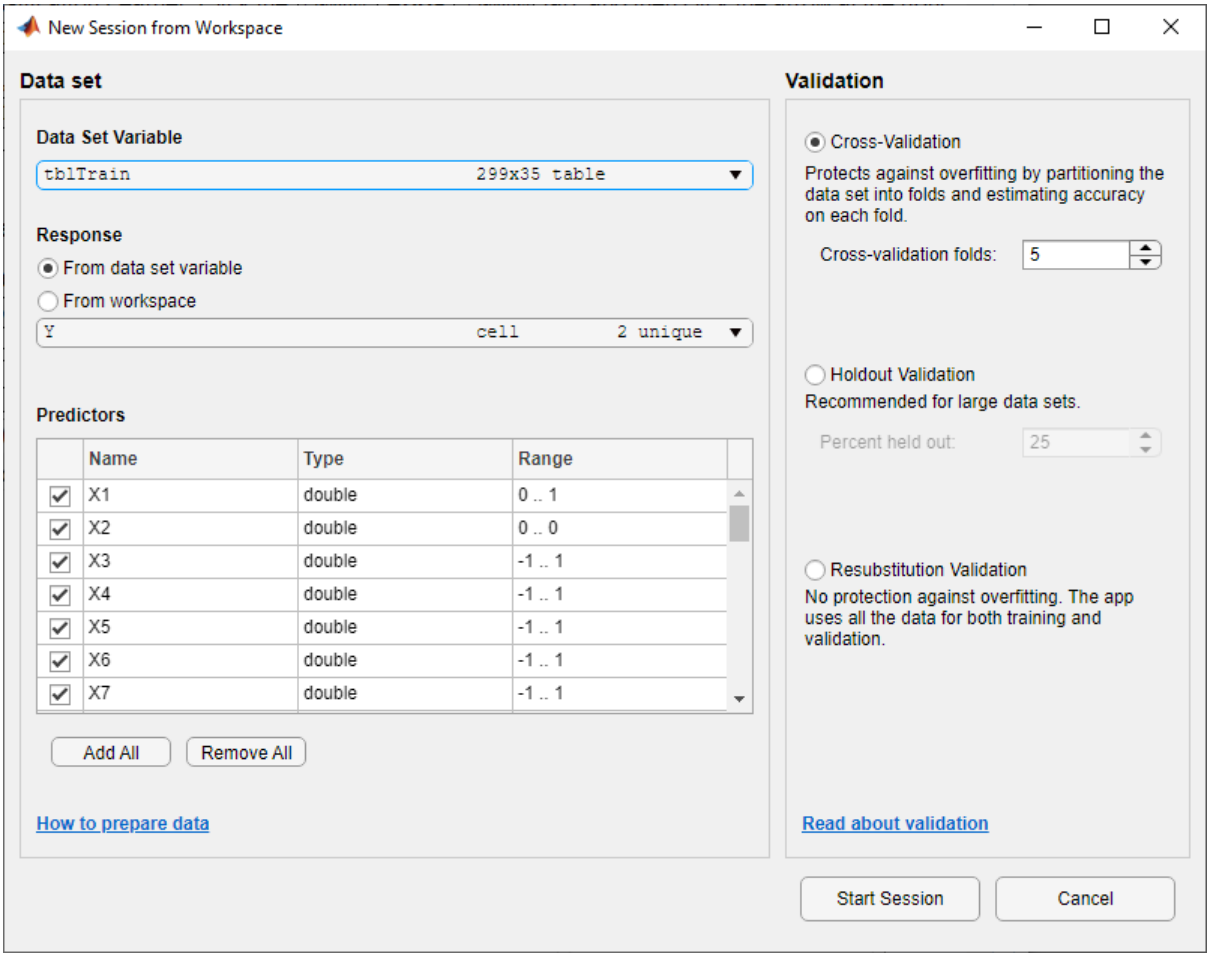
1. In the MATLAB Command Window, load the `ionosphere` data set, and create a table containing the data. Separate the table into training and test sets.

   ```
   load ionosphere
   tbl = array2table(X);
   tbl.Y = Y;

   rng('default') % For reproducibility of the data split
   partition = cvpartition(Y,'Holdout',0.15);
   idxTrain = training(partition); % Indices for the training set
   tblTrain = tbl(idxTrain,:);
   tblTest = tbl(~idxTrain,:);
   ```

2. Open Classification Learner. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.
3. On the **Classification Learner** tab, in the **File** section, select **New Session > From Workspace**.
4. In the New Session from Workspace dialog box, select the `tblTrain` table from the **Data Set Variable** list.

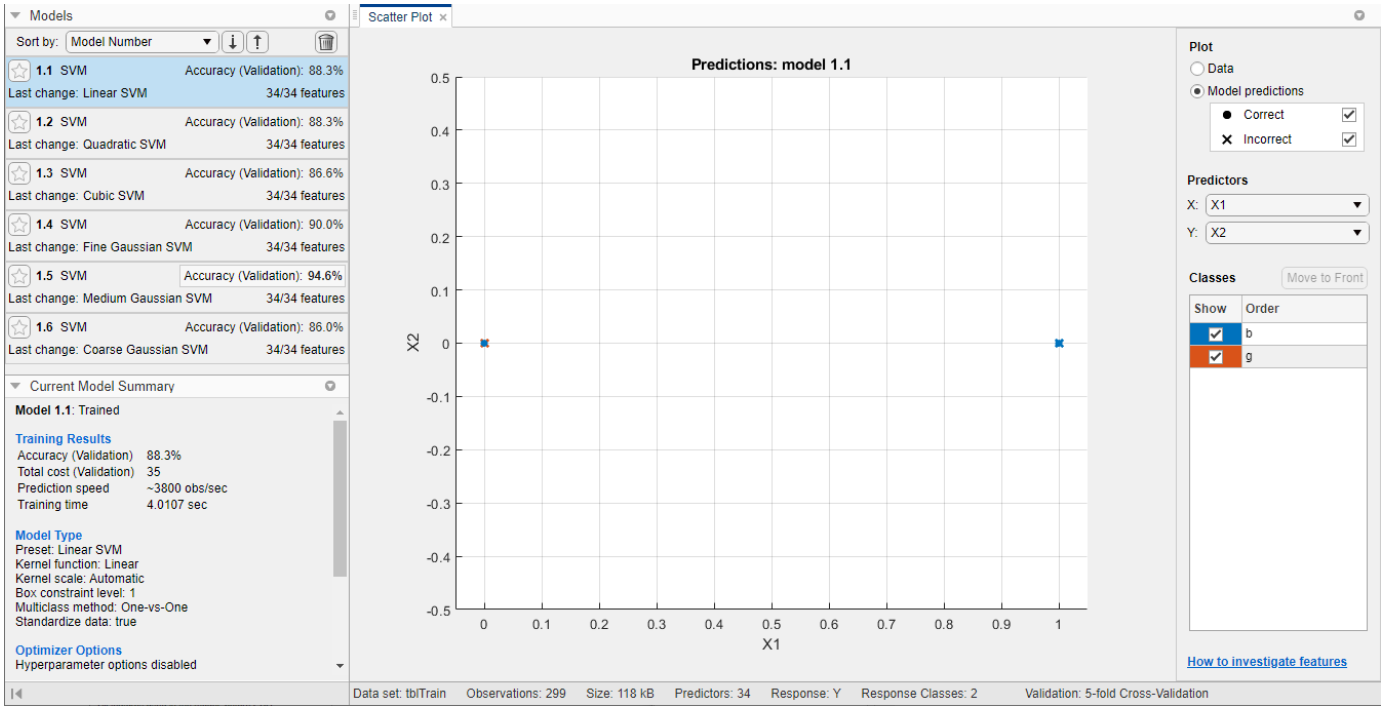
   As shown in the dialog box, the app selects the response and predictor variables. The default response variable is `Y`. The default validation option is 5-fold cross-validation, to protect against overfitting. For this example, do not change the default settings.



5 To accept the default options and continue, click **Start Session**.

6 Train all preset SVM models. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Support Vector Machines** group, click **All SVMs**. In the **Training** section, click **Train**. The app trains one of each SVM model type and displays the models in the **Models** pane.

Tip If you have Parallel Computing Toolbox, you can train all the SVM models (**All SVMs**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the SVM models simultaneously.

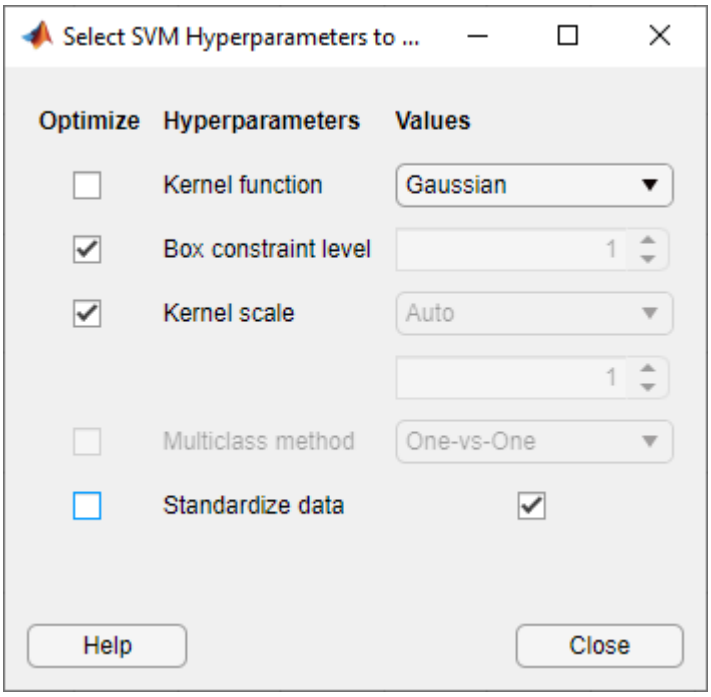


The app displays a scatter plot of the `ionosphere` data. Correctly classified points are marked with an O, and incorrectly classified points are marked with an X. The **Models** pane on the left shows the validation accuracy for each model.

Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

7. Select an optimizable SVM model to train. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Support Vector Machines** group, click **Optimizable SVM**. The app disables the **Use Parallel** button when you select an optimizable model.

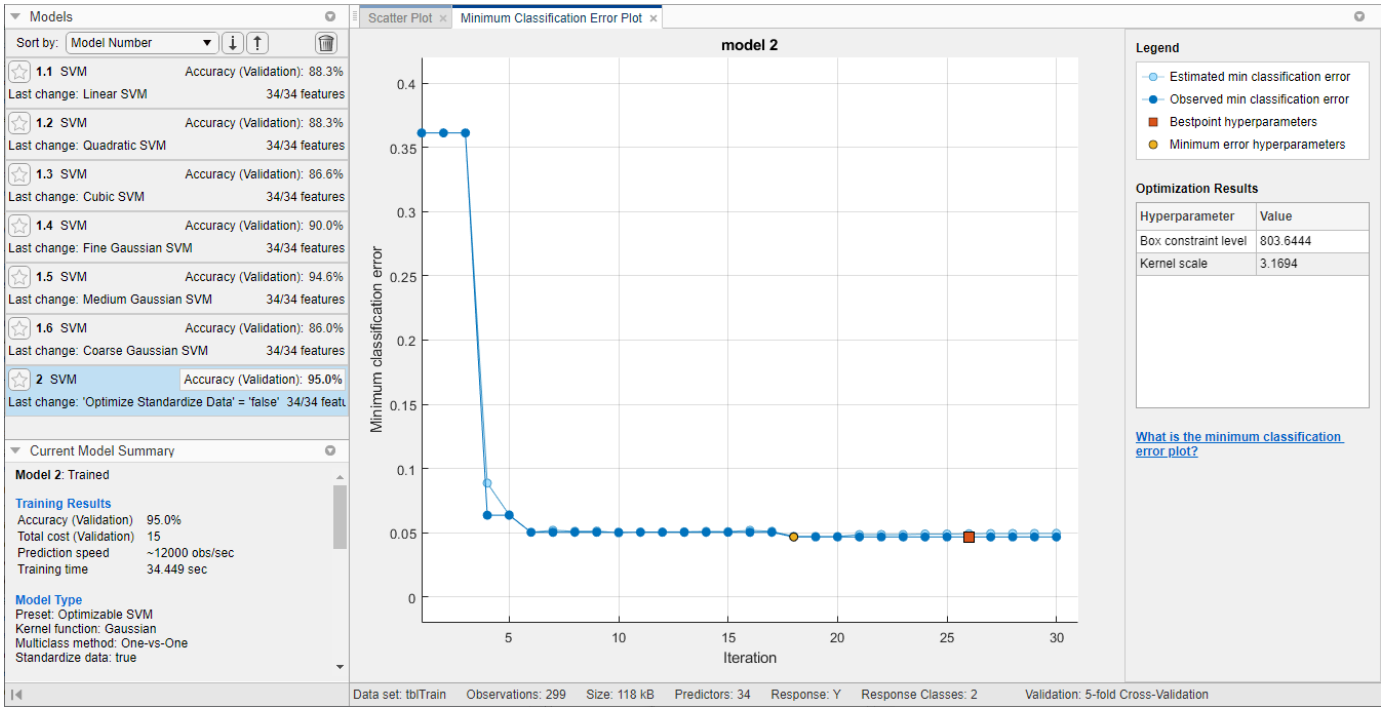
8. Select the model hyperparameters to optimize. In the **Model Type** section, select **Advanced > Advanced**. The app opens a dialog box in which you can select **Optimize** check boxes for the hyperparameters that you want to optimize. By default, all the check boxes for the available hyperparameters are selected. For this example, clear the **Optimize** check boxes for **Kernel function** and **Standardize data**. By default, the app disables the **Optimize** check box for **Kernel scale** whenever the kernel function has a fixed value other than `Gaussian`. Select a `Gaussian` kernel function, and select the **Optimize** check box for **Kernel scale**.



9 In the **Training** section, click **Train**.

10 The app displays a **Minimum Classification Error Plot** as it runs the optimization process. At each iteration, the app tries a different combination of hyperparameter values and updates the plot with the minimum validation classification error observed up to that iteration, indicated in dark blue. When the app completes the optimization process, it selects the set of optimized hyperparameters, indicated by a red square. For more information, see “Minimum Classification Error Plot” on page 23-61.

The app lists the optimized hyperparameters in both the **Optimization Results** section to the right of the plot and the **Optimized Hyperparameters** section of the **Current Model Summary** pane.



Note In general, the optimization results are not reproducible.

11 Compare the trained preset SVM models to the trained optimizable model. In the **Models** pane, the app highlights the highest **Accuracy (Validation)** by outlining it in a box. In this example, the trained optimizable SVM model outperforms the six preset models.

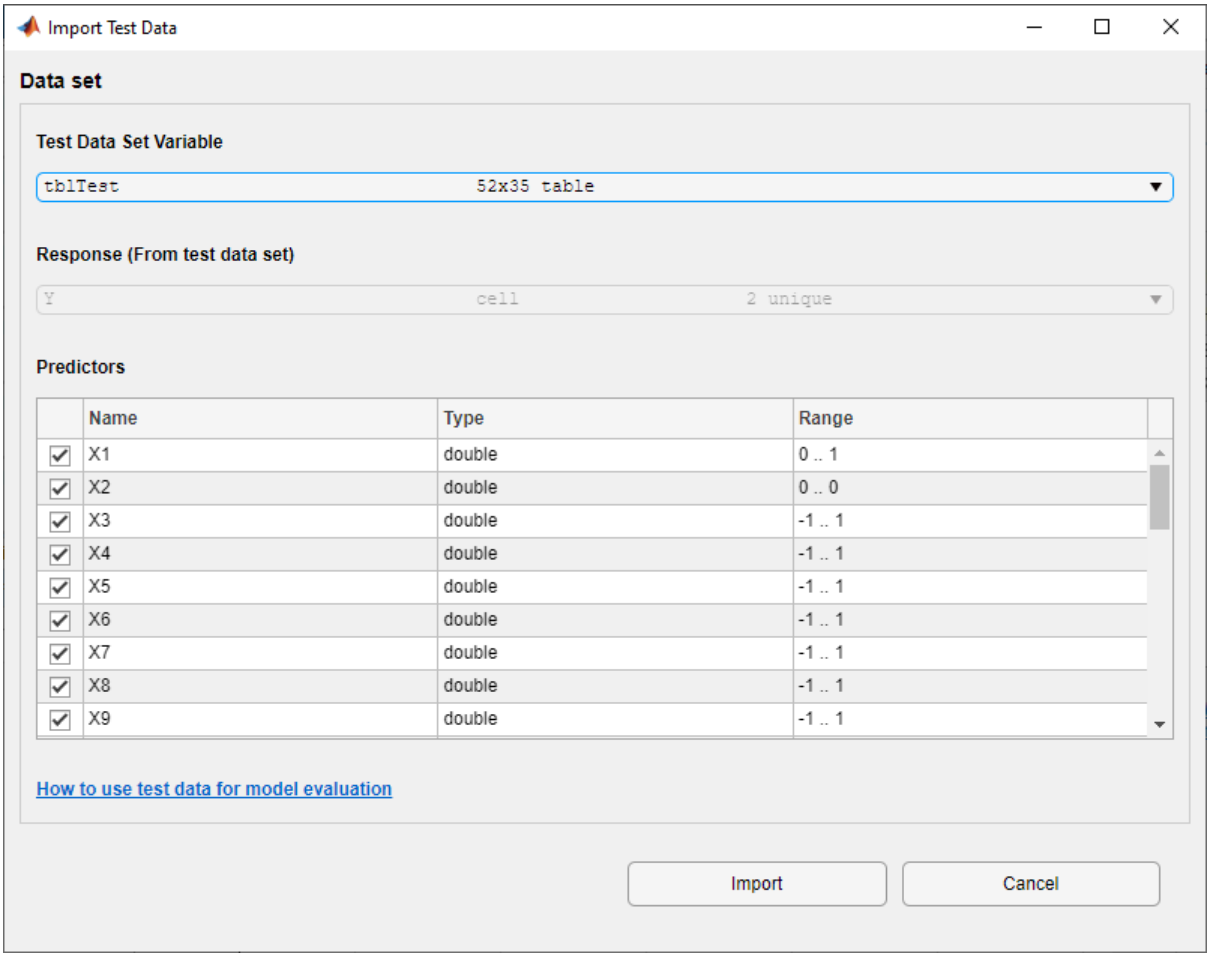
A trained optimizable model does not always have a higher accuracy than the trained preset models. If a trained optimizable model does not perform well, you can try to get better results by running the optimization for longer. In the **Model Type** section, select **Advanced > Optimizer Options**. In the dialog box, increase the **Iterations** value. For example, you can double-click the default value of `30` and enter a value of `60`.

12 Because hyperparameter tuning often leads to overfitted models, check the performance of the optimizable SVM model on a test set and compare it to the performance of the best preset SVM model. Begin by importing test data into the app.

On the **Classification Learner** tab, in the **Testing** section, select **Test Data > From Workspace**.

13 In the Import Test Data dialog box, select the `tblTest` table from the **Test Data Set Variable** list.

As shown in the dialog box, the app identifies the response and predictor variables.



14 Click **Import**.

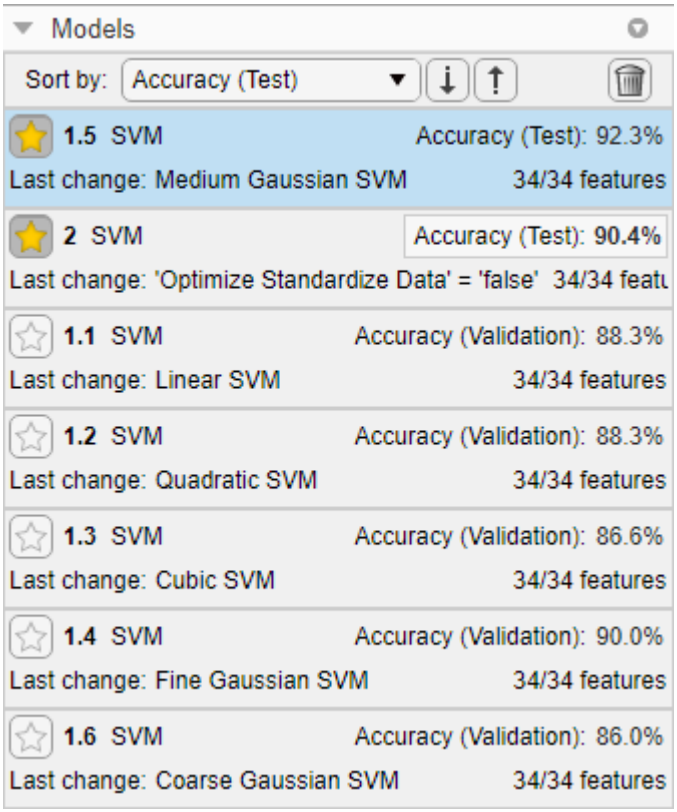
15 Compute the accuracy of the best preset model and the optimizable model on the `tblTest` data.

First, in the **Models** pane, click the star icons next to the **Medium Gaussian SVM** model and the **Optimizable SVM** model.

16 For each model, select the model in the **Models** pane, and then select **Test All > Test Selected** in the **Testing** section. The app computes the test set performance of the model trained on the full data set, including training and validation data.

17 Sort the models based on the test set accuracy. In the **Models** pane, open the **Sort by** list and select `Accuracy (Test)`.

In this example, the trained optimizable model does not perform as well as the trained preset model on the test set data.



18 In the **Plots** section on the **Classification Learner** tab, select **Confusion Matrix > Test Data**. Toggle between the medium Gaussian SVM model and the optimizable SVM model, and visually compare the two confusion matrices.

Check Classifier Performance Using Test Set in Classification Learner App

This example shows how to train multiple models in Classification Learner, and determine the best-performing models based on their validation accuracy. Check the test accuracy for the best-performing models trained on the full data set, including training and validation data.

1. In the MATLAB Command Window, load the `ionosphere` data set, and create a table containing the data. Separate the table into training and test sets.

   ```
   load ionosphere
   tbl = array2table(X);
   tbl.Y = Y;

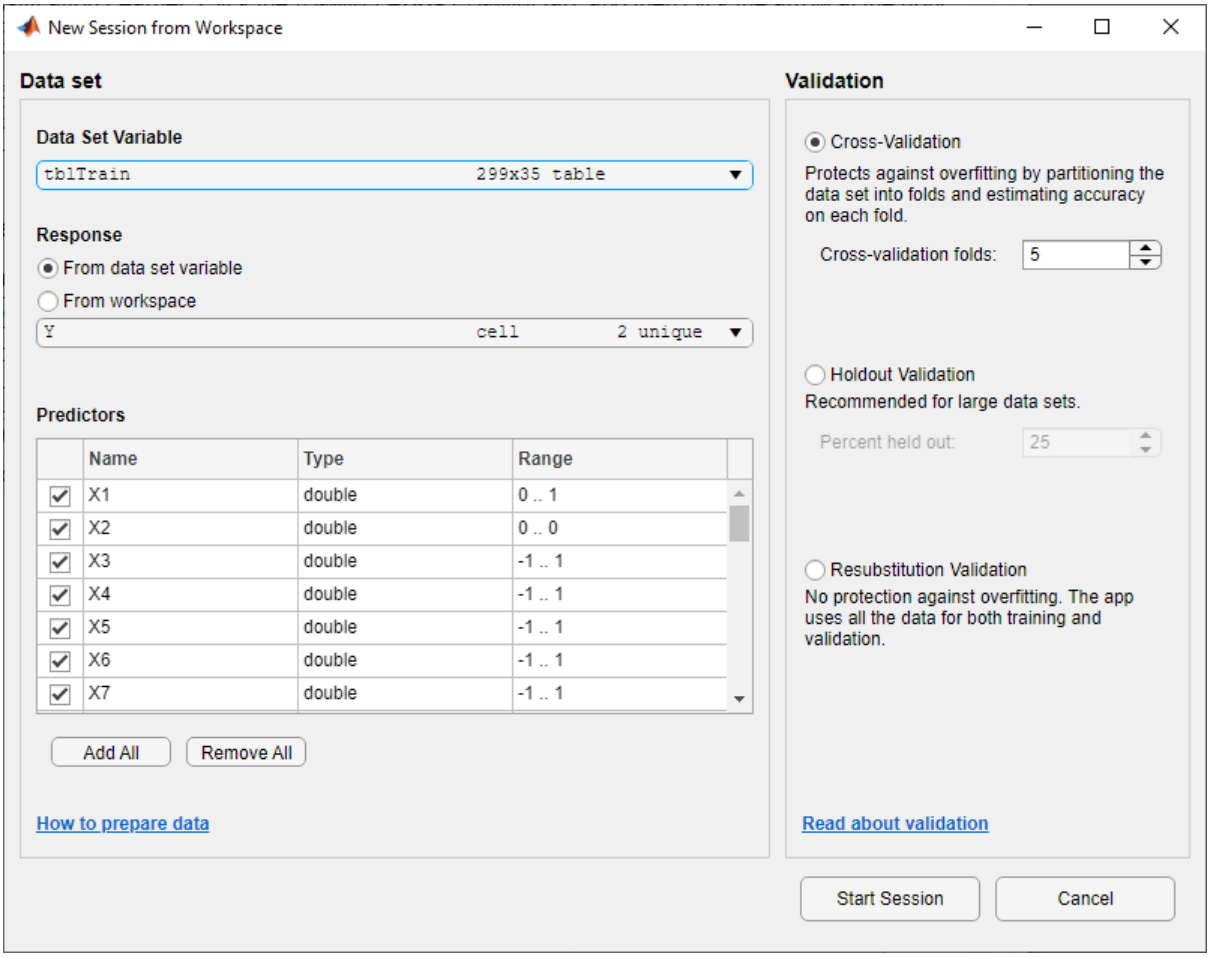
   rng('default') % For reproducibility of the data split
   partition = cvpartition(Y,'Holdout',0.15);
   idxTrain = training(partition); % Indices for the training set
   tblTrain = tbl(idxTrain,:);
   tblTest = tbl(~idxTrain,:);
   ```

2. Open Classification Learner. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.

3. On the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

4. In the New Session from Workspace dialog box, select the `tblTrain` table from the **Data Set Variable** list.

   As shown in the dialog box, the app selects the response and predictor variables. The default response variable is `Y`. To protect against overfitting, the default validation option is 5-fold cross-validation. For this example, do not change the default settings.



5 To accept the default options and continue, click **Start Session**.

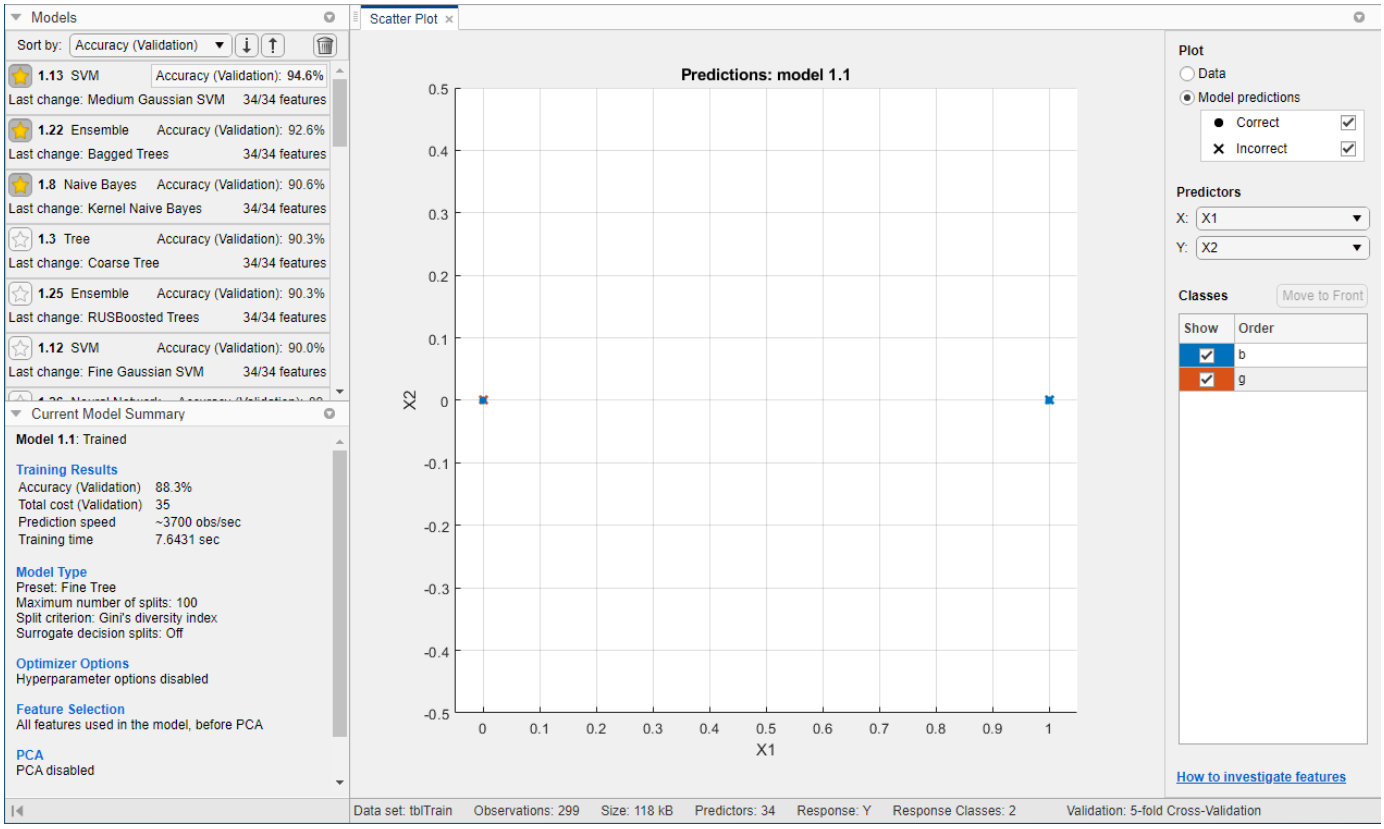
6 Train all preset models. On the **Classification Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Get Started** group, click **All**. In the **Training** section, click **Train**. The app trains one of each preset model type and displays the models in the **Models** pane.

Tip If you have Parallel Computing Toolbox, you can train all the models (**All**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.

---

7 Sort the trained models based on the validation accuracy. In the **Models** pane, open the **Sort by** list and select `Accuracy (Validation)`.

8 In the **Models** pane, click the star icons next to the three models with the highest validation accuracy. The app highlights the highest validation accuracy by outlining it in a box. In this example, the trained **Medium Gaussian SVM** model has the highest validation accuracy.



The app displays a scatter plot of the `ionosphere` data. Correctly classified points are marked with an O, and incorrectly classified points are marked with an X. The **Models** pane on the left shows the validation accuracy for each model.

Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

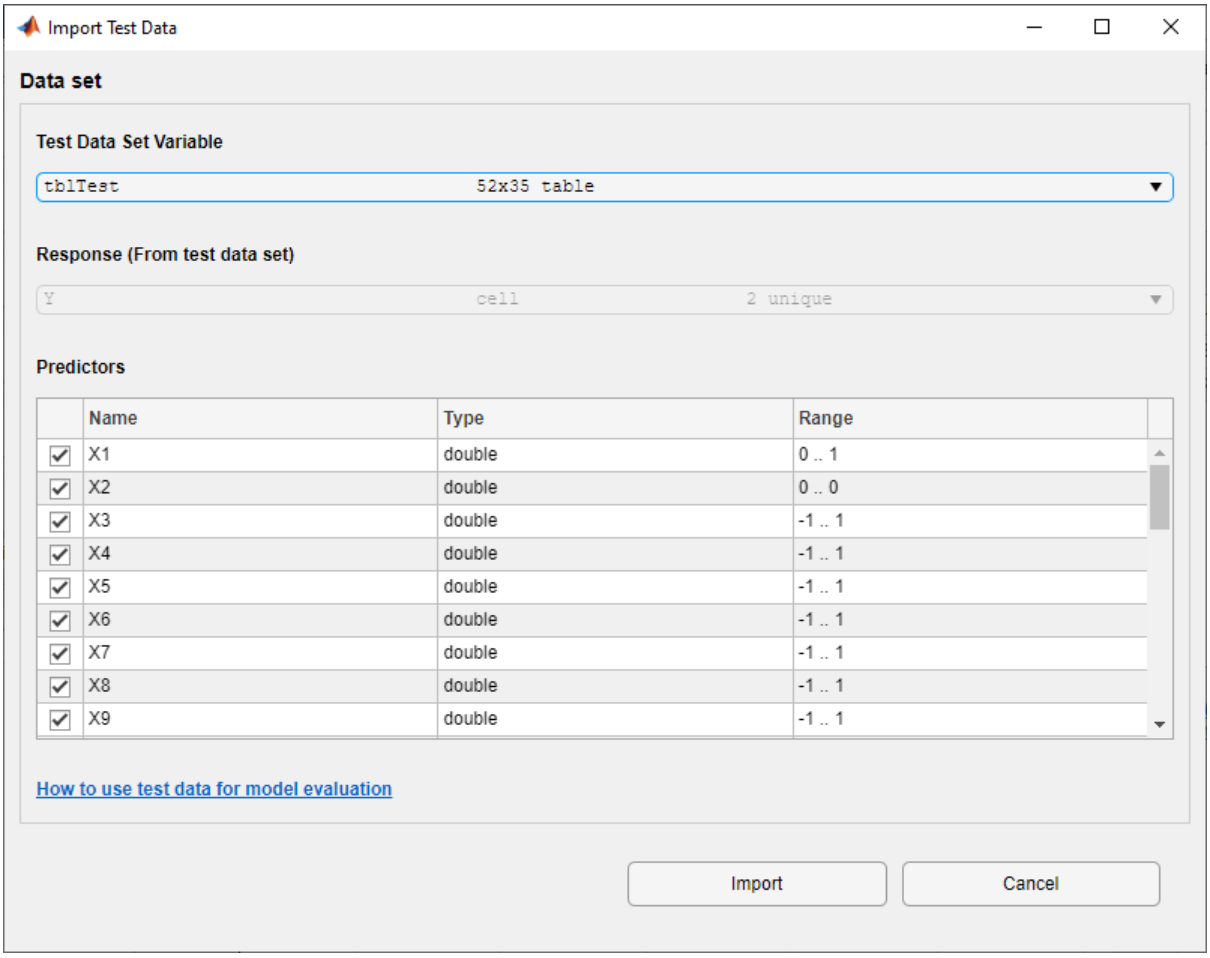
---

9 Check the test set performance of the best-performing models. Begin by importing test data into the app.

On the **Classification Learner** tab, in the **Testing** section, click **Test Data** and select **From Workspace**.

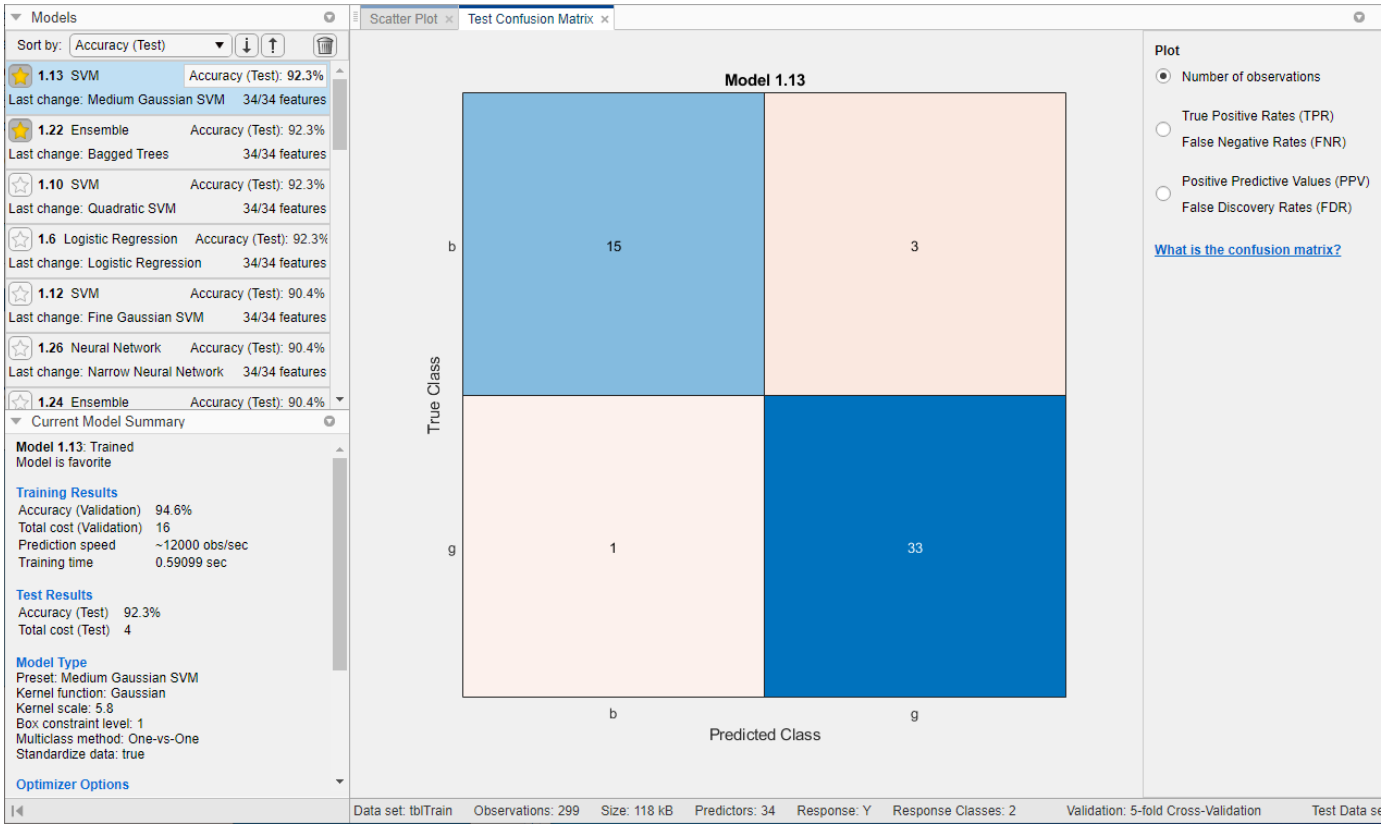
10 In the Import Test Data dialog box, select the `tblTest` table from the **Test Data Set Variable** list.

As shown in the dialog box, the app identifies the response and predictor variables.



11. Click **Import**.
12. Compute the accuracy of the best preset models on the `tblTest` data. For convenience, compute the test set accuracy for all models at once. On the **Classification Learner** tab, in the **Testing** section, click **Test All** and select **Test All**. The app computes the test set performance of the model trained on the full data set, including training and validation data.
13. Sort the models based on the test set accuracy. In the **Models** pane, open the **Sort by** list and select `Accuracy (Test)`. The app still outlines the metric for the model with the highest validation accuracy, despite displaying the test accuracy.
14. Visually check the test set performance of the models. On the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Test Data**. You can toggle between models to compare their performance.

    In this example, the trained **Medium Gaussian SVM** remains one of the best-performing models on the test set data.



15 Compare the validation and test accuracy for the trained **Medium Gaussian SVM** model. In the **Current Model Summary** pane, compare the **Accuracy (Validation)** value under **Training Results** to the **Accuracy (Test)** value under **Test Results**. In this example, the two values are close, which indicates that the validation accuracy is a good estimate of the test accuracy for this model.

Regression Learner

Train Regression Models in Regression Learner App

In this section...

You can use Regression Learner to train regression models including linear regression models, regression trees, Gaussian process regression models, support vector machines, ensembles of regression trees, and neural network regression models. In addition to training models, you can explore your data, select features, specify validation schemes, and evaluate results. You can export a model to the workspace to use the model with new data or generate MATLAB code to learn about programmatic classification.

Training a model in Regression Learner consists of two parts:

- Validated Model: Training a model with a validation scheme. By default, the app protects against overfitting by applying cross-validation. Alternatively, you can choose holdout validation. The validated model is visible in the app.
- Full Model: Training a model on full data without validation. The app trains this model simultaneously with the validated model. However, the model trained on full data is not visible in the app. When you choose a regression model to export to the workspace, Regression Learner exports the full model.

The app displays the results of the validated model. Diagnostic measures, such as model accuracy, and plots, such as response plot or residuals plot reflect the validated model results. You can automatically train one or more regression models, compare validation results, and choose the best model that works for your regression problem. When you choose a model to export to the workspace, Regression Learner exports the full model. Because Regression Learner creates a model object of the full model during training, you experience no lag time when you export the model. You can use the exported model to make predictions on new data.

To get started by training a selection of model types, see “Automated Regression Model Training” on page 24-2. If you already know which regression model you want to train, see “Manual Regression Model Training” on page 24-4.

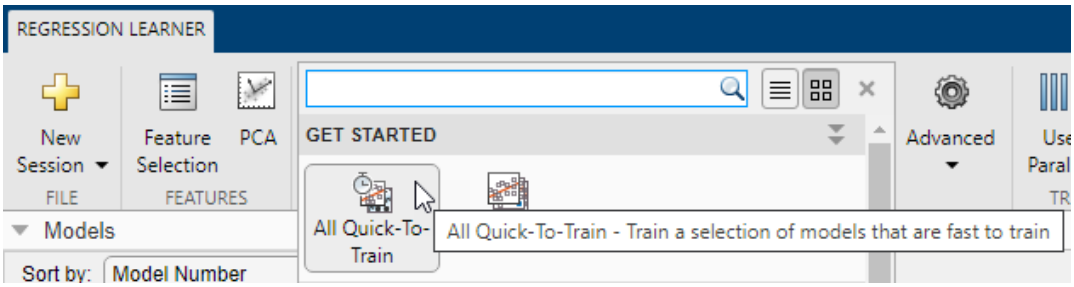
Automated Regression Model Training

You can use Regression Learner to automatically train a selection of different regression models on your data.

- Get started by automatically training multiple models simultaneously. You can quickly try a selection of models, and then explore promising models interactively.
- If you already know what model type you want, then you can train individual models instead. See “Manual Regression Model Training” on page 24-4.

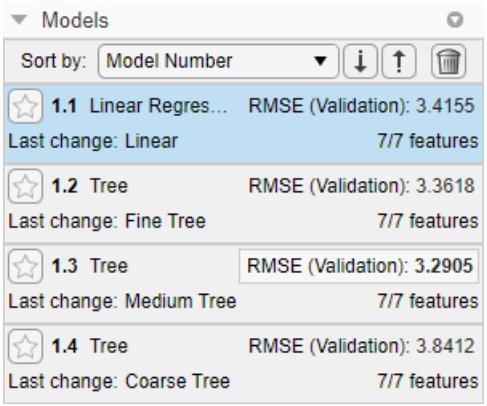
1. On the **Apps** tab, in the **Machine Learning** group, click **Regression Learner**.
2. Click **New Session** and select data from the workspace or from file. Specify a response variable and variables to use as predictors. See “Select Data and Validation for Regression Problem” on page 24-8.

3 On the **Regression Learner** tab, in the **Model Type** section, click the arrow to expand the list of regression models. Select **All Quick-To-Train**  . This option trains all the model presets that are fast to fit.



4 Click **Train**. 
Note If you have Parallel Computing Toolbox, you can train the models in parallel. See “Parallel Regression Model Training” on page 24-5.

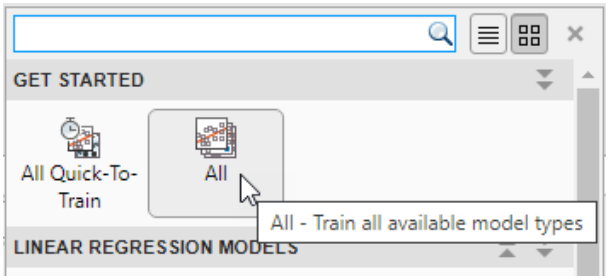
A selection of model types appears in the **Models** pane. When the models finish training, the best **RMSE (Validation)** score is highlighted in a box.



5 Click models in the **Models** pane to explore results in the plots.

For the next steps, see “Manual Regression Model Training” on page 24-4 or “Compare and Improve Regression Models” on page 24-5.

6 To try all the nonoptimizable model presets available, click **All**  , and then click **Train**.

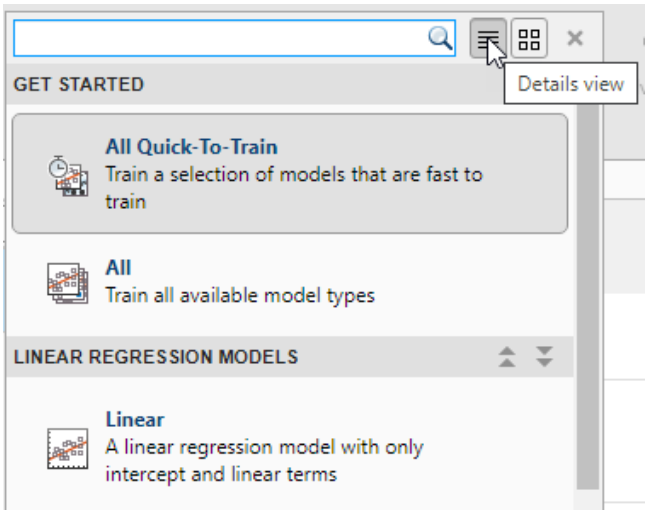


Manual Regression Model Training

To explore individual model types, you can train models one at a time or train a group of models of the same type.

1 Choose a model type. On the **Regression Learner** tab, in the **Model Type** section, click a model type. To see all available model options, click the arrow in the **Model Type** section to expand the list of regression models. The nonoptimizable model options in the gallery are preset starting points with different settings, suitable for a range of different regression problems.

To read descriptions of the models, switch to the details view or hover the mouse over a button to display its tooltip.



For more information on each option, see “Choose Regression Model Options” on page 24-12.

2 After selecting a model, click **Train**. 
Repeat to explore different models.

Tip Select regression trees first. If your trained models do not predict the response accurately enough, then try other models with higher flexibility. To avoid overfitting, look for a less flexible model that provides sufficient accuracy.

3 If you want to try all nonoptimizable models of the same or different types, then select one of the **All** options in the gallery.

   Alternatively, if you want to automatically tune hyperparameters of a specific model type, select the corresponding **Optimizable** model and perform hyperparameter optimization. For more information, see “Hyperparameter Optimization in Regression Learner App” on page 24-30.

For next steps, see “Compare and Improve Regression Models” on page 24-5.

Parallel Regression Model Training

You can train models in parallel using Regression Learner if you have Parallel Computing Toolbox. Parallel training allows you to train multiple models simultaneously and continue working.

To control parallel training, toggle the **Use Parallel** button on the app toolstrip. The **Use Parallel** button is only available if you have Parallel Computing Toolbox.

1 The first time you click **Train** after clicking the **Use Parallel** button, you see a dialog box while the app opens a parallel pool of workers. After the pool opens, you can train multiple models at once.

2 When models are training in parallel, you see progress indicators on each training and queued model in the **Models** pane. If you want, you can cancel individual models. During training, you can examine results and plots from models, and initiate training of more models.

If you have Parallel Computing Toolbox, then parallel training is available in Regression Learner, and you do not need to set the `UseParallel` option of the `statset` function.

Note You cannot perform hyperparameter optimization in parallel. The app disables the **Use Parallel** button when you select an optimizable model. If you then select a nonoptimizable model, the button is off by default.

Compare and Improve Regression Models

1 Click models in the **Models** pane to explore the results in the plots. Compare model performance by inspecting results in the plots. Examine the **RMSE (Validation)** score reported in the **Models** pane for each model.

   Additionally, you can compare the models by using the **Sort by** options in the **Models** pane. Delete any unwanted model by selecting the model and clicking the **Delete selected model** button in the upper right of the pane, or right-clicking the model and selecting **Delete model**.

   See “Assess Model Performance in Regression Learner” on page 24-42.

2. Select the best model in the **Models** pane and then try including and excluding different features in the model. Click **Feature Selection**. 
   Try the response plot to help you identify features to remove. See if you can improve the model by removing features with low predictive power. Specify predictors to include in the model, and train new models using the new options. Compare results among the models in the **Models** pane.

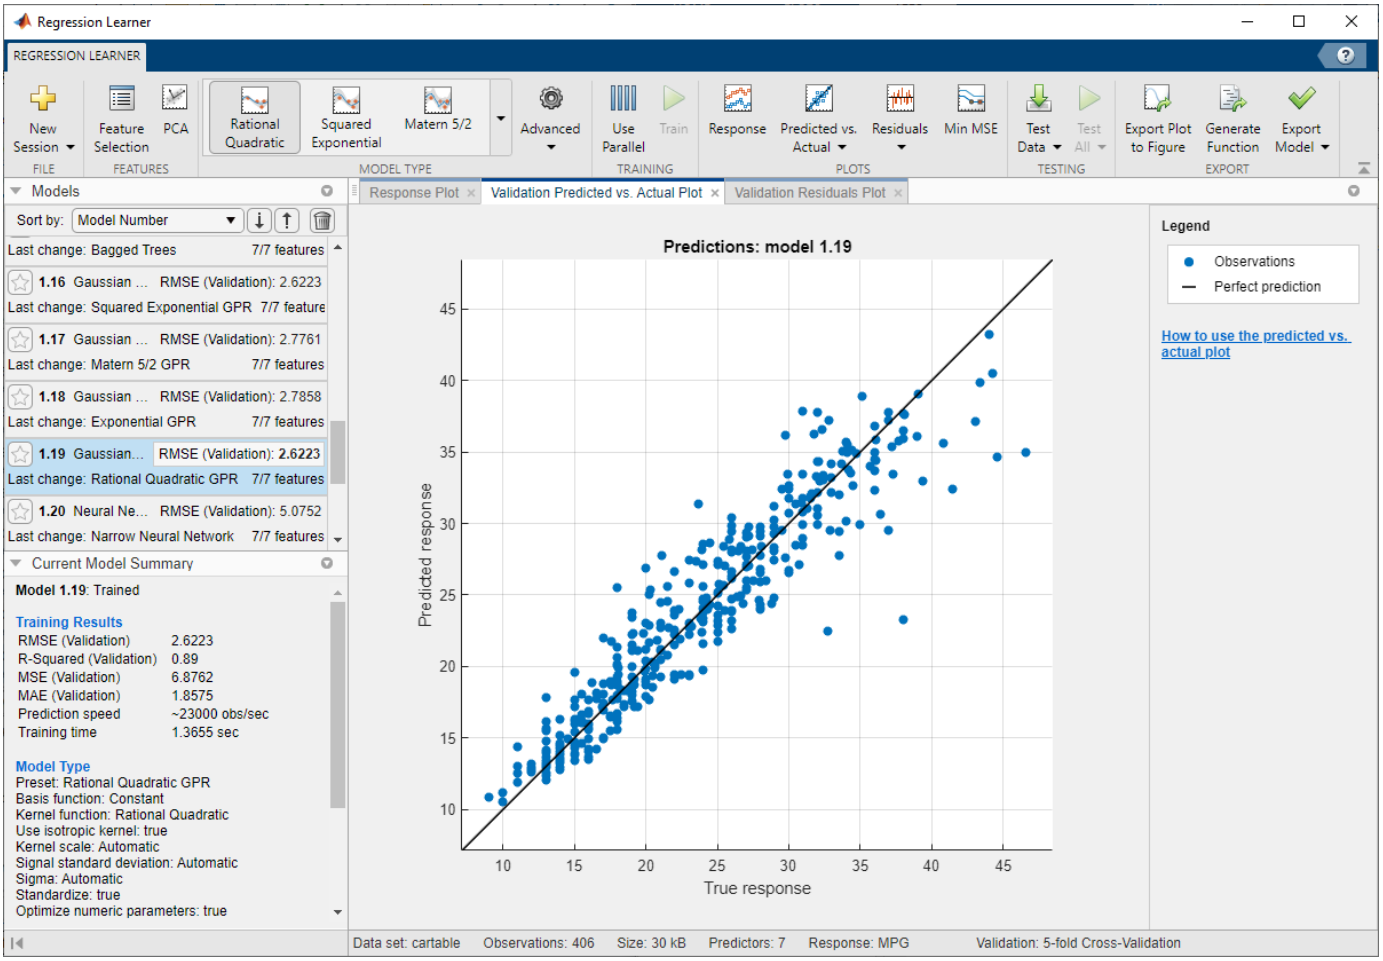
   You also can try transforming features with PCA to reduce dimensionality. 
   See “Feature Selection and Feature Transformation Using Regression Learner App” on page 24-26.

3. Improve the model further by changing model parameter settings in the Advanced dialog box. Then, train using the new options. To learn how to control model flexibility, see “Choose Regression Model Options” on page 24-12. For information on how to tune model parameter settings automatically, see “Hyperparameter Optimization in Regression Learner App” on page 24-30.

   If feature selection, PCA, or new parameter settings improve your model, try training **All**  model types with the new settings. See if another model type does better with the new settings.

Tip To avoid overfitting, look for a less flexible model that provides sufficient accuracy. For example, look for simple models, such as regression trees that are fast and easy to interpret. If your models are not accurate enough, then try other models with higher flexibility, such as ensembles. To learn about the model flexibility, see “Choose Regression Model Options” on page 24-12.

This figure shows the app with a **Models** pane containing various regression model types.



Tip For a step-by-step example comparing different regression models, see “Train Regression Trees Using Regression Learner App” on page 24-60.

Next, you can generate code to train the model with different data or export trained models to the workspace to make predictions using new data. See “Export Regression Model to Predict New Data” on page 24-54.

Select Data and Validation for Regression Problem

In this section...

Select Data from Workspace

Tip In Regression Learner, tables are the easiest way to work with your data, because they can contain numeric and label data. Use the Import Tool to bring your data into the MATLAB workspace as a table, or use the table functions to create a `table` from workspace variables. See “Tables”.

1. Load your data into the MATLAB workspace.

   Predictor variables can be numeric, categorical, string, or logical vectors, cell arrays of character vectors, or character arrays. The response variable must be a floating-point vector (single or double precision).

   Combine the predictor data into one variable, either a table or a matrix. You can additionally combine your predictor data and response variable, or you can keep them separate.

   For example data sets, see “Example Data for Regression” on page 24-9.
2. On the **Apps** tab, click **Regression Learner** to open the app.
3. On the **Regression Learner** tab, in the **File** section, click **New Session > From Workspace**.
4. In the New Session from Workspace dialog box, under **Data Set Variable**, select a table or matrix from the workspace variables.

   If you select a matrix, choose whether to use rows or columns for observations by clicking the option buttons.
5. Under **Response**, observe the default response variable. The app tries to select a suitable response variable from the data set variable and treats all other variables as predictors.

   If you want to use a different response variable, you can:

   - Use the list to select another variable from the data set variable.
   - Select a separate workspace variable by clicking the **From workspace** option button and then selecting a variable from the list.
6. Under **Predictors**, add or remove predictors using the check boxes. Add or remove all predictors by clicking **Add All** or **Remove All**. You can also add or remove multiple predictors by selecting them in the table, and then clicking **Add N** or **Remove N**, where **N** is the number of selected predictors. The **Add All** and **Remove All** buttons change to **Add N** and **Remove N** when you select multiple predictors.
7. Click **Start Session** to accept the default validation scheme and continue. The default validation option is 5-fold cross-validation, which protects against overfitting.

Tip If you have a large data set, you might want to switch to holdout validation. To learn more, see “Choose Validation Scheme” on page 24-10.

Note If you prefer loading data into the app directly from the command line, you can specify the predictor data, response variable, and validation type to use in Regression Learner in the command line call to `regressionLearner`. For more information, see **Regression Learner**.

For next steps, see “Train Regression Models in Regression Learner App” on page 24-2.

Import Data from File

1. On the **Regression Learner** tab, in the **File** section, select **New Session** > **From File**.
2. Select a file type in the list, such as spreadsheets, text files, or comma-separated values (`.csv`) files, or select **All Files** to browse for other file types such as `.dat`.

Example Data for Regression

To get started using Regression Learner, try these example data sets.

Name	Size	Description
Cars	Number of predictors: 7 Number of observations: 406 Response: `MPG` (miles per gallon)	Data on different car models, 1970–1982. Predict the fuel economy (in miles per gallon), or one of the other characteristics. For a step-by-step example, see “Train Regression Trees Using Regression Learner App” on page 24-60.

	Create a table from variables in the `carbig.mat` file:
	
	`load carbig`
	`cartable = table(Acceleration, Cylinders, Displacement,...`
	`Horsepower, Model_Year, Weight, Origin, MPG);`	

Abalone	Number of predictors: 8 Number of observations: 4177 Response: `Rings`	Measurements of abalone (a group of sea snails). Predict the age of abalones, which is closely related to the number of rings in their shells.

	Download the data from the UCI Machine Learning Repository and save it in your current folder. Read the data into a table and specify the variable names.
	
	`url = 'https://archive.ics.uci.edu/ml/machine-learning-databases/abalone/abalone.`
	`websave('abalone.csv',url);`
	`varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight';...`
	`'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};`
	`abalonetable = readtable('abalone.csv');`
	`abalonetable.Properties.VariableNames = varnames;`	

Hospital	Number of predictors: 5 Number of observations: 100 Response: `BloodPressure_2`	Simulated hospital data. Predict the blood pressure of patients.

Name	Size	Description

	Create a table from the `hospital` variable in the `hospital.mat` file:
	
	`load hospital.mat`
	`hospitaltable = dataset2table(hospital(:,2:end-1));`	

Choose Validation Scheme

Choose a validation method to examine the predictive accuracy of the fitted models. Validation estimates model performance on new data, and helps you choose the best model. Validation protects against overfitting. A model that is too flexible and suffers from overfitting has a worse validation accuracy. Choose a validation scheme before training any models so that you can compare all the models in your session using the same validation scheme.

Tip Try the default validation scheme and click **Start Session** to continue. The default option is 5-fold cross-validation, which protects against overfitting.

If you have a large data set and training the models takes too long using cross-validation, reimport your data and try the faster holdout validation instead.

- **Cross-Validation**: Select the number of folds (or divisions) to partition the data set.

  If you choose *k* folds, then the app:

  1. Partitions the data into *k* disjoint sets or folds
  2. For each validation fold:
     a. Trains a model using the training-fold observations (observations not in the validation fold)
     b. Assesses model performance using validation-fold data
  3. Calculates the average validation error over all folds

  This method gives a good estimate of the predictive accuracy of the final model trained using the full data set. The method requires multiple fits, but makes efficient use of all the data, so it works well for small data sets.
- **Holdout Validation**: Select a percentage of the data to use as a validation set. The app trains a model on the training set and assesses its performance with the validation set. The model used for validation is based on only a portion of the data, so holdout validation is appropriate only for large data sets. The final model is trained using the full data set.
- **Resubstitution Validation**: No protection against overfitting. The app uses all the data for training and computes the error rate on the same data. Without any separate validation data, you get an unrealistic estimate of the model's performance on new data. That is, the training sample accuracy is likely to be unrealistically high, and the predictive accuracy is likely to be lower.

  To help you avoid overfitting to the training data, choose another validation scheme instead.

Note The validation scheme only affects the way that Regression Learner computes validation metrics. The final model is always trained using the full data set.

All the models you train after selecting data use the same validation scheme that you select in this dialog box. You can compare all the models in your session using the same validation scheme.

To change the validation selection and train new models, you can select data again, but you lose any trained models. The app warns you that importing data starts a new session. Save any trained models you want to keep to the workspace, and then import the data.

For next steps training models, see “Train Regression Models in Regression Learner App” on page 24-2.

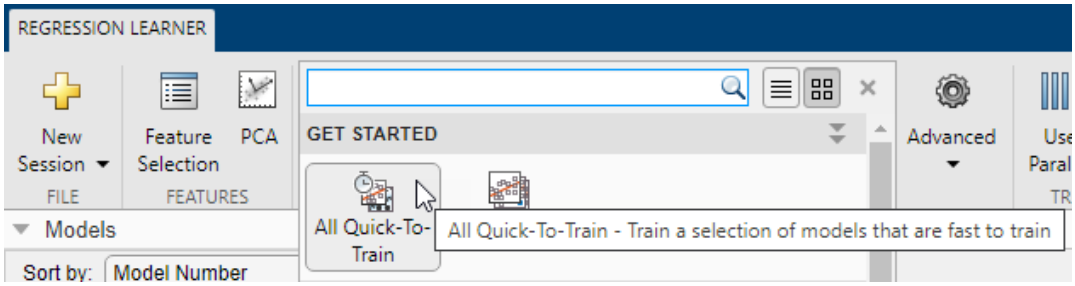
Choose Regression Model Options

In this section...

Choose Regression Model Type

You can use the Regression Learner app to automatically train a selection of different models on your data. Use automated training to quickly try a selection of model types, and then explore promising models interactively. To get started, try these options first:



Get Started Regression Model Buttons	Description
All Quick-To-Train	Try the **All Quick-To-Train** button first. The app trains all model types that are typically quick to train.
All	Use the **All** button to train all available nonoptimizable model types. Trains every type regardless of any prior trained models. Can be time-consuming.

To learn more about automated model training, see “Automated Regression Model Training” on page 24-2.

If you want to explore models one at a time, or if you already know what model type you want, you can select individual models or train a group of the same type. To see all available regression model options, on the **Regression Learner** tab, click the arrow in the **Model Type** section to expand the list of regression models. The nonoptimizable model options in the gallery are preset starting points with different settings, suitable for a range of different regression problems. To use optimizable model options and tune model hyperparameters automatically, see “Hyperparameter Optimization in Regression Learner App” on page 24-30.

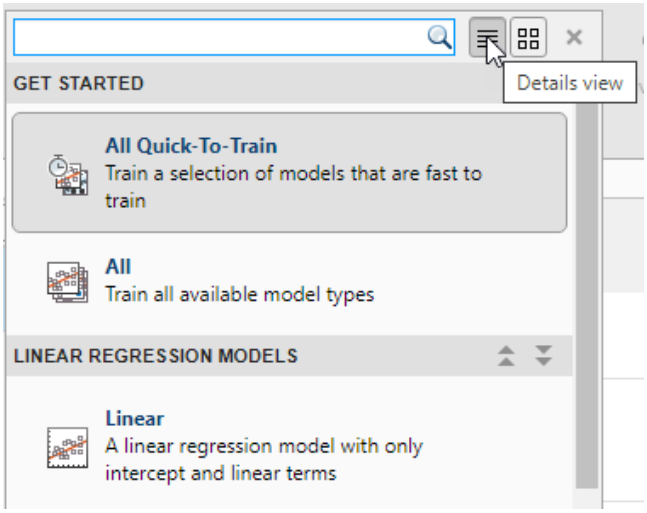
For help choosing the best model type for your problem, see the tables showing typical characteristics of different regression model types. Decide on the tradeoff you want in speed, flexibility, and interpretability. The best model type depends on your data.

Tip To avoid overfitting, look for a less flexible model that provides sufficient accuracy. For example, look for simple models such as regression trees that are fast and easy to interpret. If the models are not accurate enough predicting the response, choose other models with higher flexibility, such as ensembles. To control flexibility, see the details for each model type.

Characteristics of Regression Model Types

Regression Model Type	Interpretability
“Linear Regression Models” on page 24-14 	Easy
“Regression Trees” on page 24-16 	Easy
“Support Vector Machines” on page 24-18 	Easy for linear SVMs. Hard for other kernels.
“Gaussian Process Regression Models” on page 24-20 	Hard
“Ensembles of Trees” on page 24-22 	Hard
“Neural Networks” on page 24-24 	Hard

To read a description of each model in Regression Learner, switch to the details view in the list of all model presets.



Tip The nonoptimizable models in the **Model Type** gallery are preset starting points with different settings. After you choose a model type, such as regression trees, try training all the nonoptimizable presets to see which one produces the best model with your data.

For workflow instructions, see “Train Regression Models in Regression Learner App” on page 24-2.

Categorical Predictor Support

In Regression Learner, all model types support categorical predictors.

Tip If you have categorical predictors with many unique values, training linear models with interaction or quadratic terms and stepwise linear models can use a lot of memory. If the model fails to train, try removing these categorical predictors.

Linear Regression Models

Linear regression models have predictors that are linear in the model parameters, are easy to interpret, and are fast for making predictions. These characteristics make linear regression models popular models to try first. However, the highly constrained form of these models means that they often have low predictive accuracy. After fitting a linear regression model, try creating more flexible models, such as regression trees, and compare the results.

Tip In the **Model Type** gallery, click **All Linear** to try each of the linear regression options and see which settings produce the best model with your data. Select the best model in the **Models** pane and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Linear 	Easy	Very low
Interactions Linear 	Easy	Medium
Robust Linear 	Easy	Very low. Less sensitive to outliers, but can be slow to train.
Stepwise Linear 	Easy	Medium

Tip For a workflow example, see “Train Regression Trees Using Regression Learner App” on page 24-60.

Advanced Linear Regression Options

Regression Learner uses the `fitlm` function to train Linear, Interactions Linear, and Robust Linear models. The app uses the `stepwiselm` function to train Stepwise Linear models.

For Linear, Interactions Linear, and Robust Linear models you can set these options:

- **Terms**

  Specify which terms to use in the linear model. You can choose from:

  - `Linear`. A constant term and linear terms in the predictors
  - `Interactions`. A constant term, linear terms, and interaction terms between the predictors
  - `Pure Quadratic`. A constant term, linear terms, and terms that are purely quadratic in each of the predictors
  - `Quadratic`. A constant term, linear terms, and quadratic terms (including interactions)
- **Robust option**

  Specify whether to use a robust objective function and make your model less sensitive to outliers. With this option, the fitting method automatically assigns lower weights to data points that are more likely to be outliers.

Stepwise linear regression starts with an initial model and systematically adds and removes terms to the model based on the explanatory power of these incrementally larger and smaller models. For Stepwise Linear models, you can set these options:

- **Initial terms**

  Specify the terms that are included in the initial model of the stepwise procedure. You can choose from `Constant`, `Linear`, `Interactions`, `Pure Quadratic`, and `Quadratic`.
- **Upper bound on terms**

Specify the highest order of the terms that the stepwise procedure can add to the model. You can choose from `Linear`, `Interactions`, `Pure Quadratic`, and `Quadratic`.

- **Maximum number of steps**

  Specify the maximum number of different linear models that can be tried in the stepwise procedure. To speed up training, try reducing the maximum number of steps. Selecting a small maximum number of steps decreases your chances of finding a good model.

Tip If you have categorical predictors with many unique values, training linear models with interaction or quadratic terms and stepwise linear models can use a lot of memory. If the model fails to train, try removing these categorical predictors.

Regression Trees

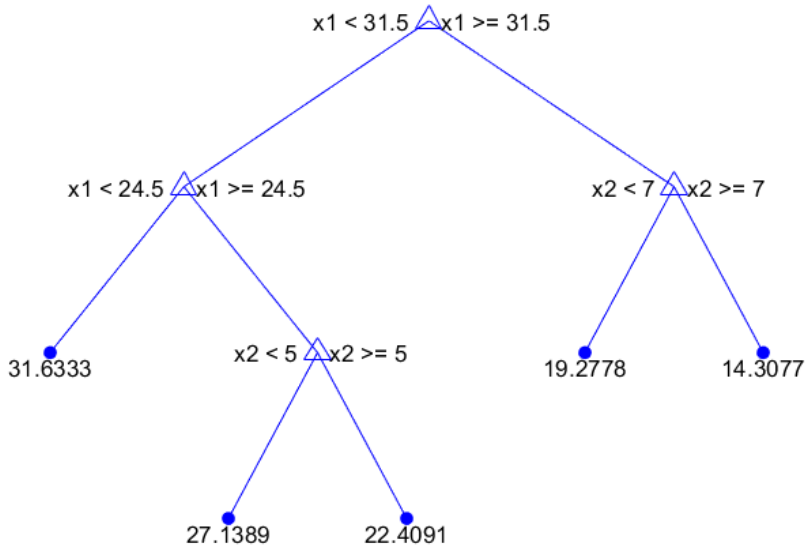
Regression trees are easy to interpret, fast for fitting and prediction, and low on memory usage. Try to grow smaller trees with fewer larger leaves to prevent overfitting. Control the leaf size with the **Minimum leaf size** setting.

Tip In the **Model Type** gallery, click **All Trees**  to try each of the nonoptimizable regression tree options and see which settings produce the best model with your data. Select the best model in the **Models** pane, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Fine Tree 	Easy	High Many small leaves for a highly flexible response function (Minimum leaf size is 4.)
Medium Tree 	Easy	Medium Medium-sized leaves for a less flexible response function (Minimum leaf size is 12.)
Coarse Tree 	Easy	Low Few large leaves for a coarse response function (Minimum leaf size is 36.)

To predict a response of a regression tree, follow the tree from the root (beginning) node down to a leaf node. The leaf node contains the value of the response.

Statistics and Machine Learning Toolbox trees are binary. Each step in a prediction involves checking the value of one predictor variable. For example, here is a simple regression tree



This tree predicts the response based on two predictors, `x1` and `x2`. To make a prediction, start at the top node. At each node, check the values of the predictors to decide which branch to follow. When the branches reach a leaf node, the response is set to the value corresponding to that node.

You can visualize your regression tree model by exporting the model from the app, and then entering:

```
view(trainedModel.RegressionTree,'Mode','graph')
```

Tip For a workflow example, see “Train Regression Trees Using Regression Learner App” on page 24-60.

Advanced Regression Tree Options

The Regression Learner app uses the `fitrtree` function to train regression trees. You can set these options:

- **Minimum leaf size**

  Specify the minimum number of training samples used to calculate the response of each leaf node. When you grow a regression tree, consider its simplicity and predictive power. To change the minimum leaf size, click the buttons or enter a positive integer value in the **Minimum leaf size** box.

  - A fine tree with many small leaves is usually highly accurate on the training data. However, the tree might not show comparable accuracy on an independent test set. A very leafy tree tends to overfit, and its validation accuracy is often far lower than its training (or resubstitution) accuracy.
  - In contrast, a coarse tree with fewer large leaves does not attain high training accuracy. But a coarse tree can be more robust in that its training accuracy can be near that of a representative test set.

Tip Decrease the **Minimum leaf size** to create a more flexible model.

- **Surrogate decision splits** — For missing data only.

  Specify surrogate use for decision splits. If you have data with missing values, use surrogate splits to improve the accuracy of predictions.

  When you set **Surrogate decision splits** to `On`, the regression tree finds at most 10 surrogate splits at each branch node. To change the number of surrogate splits, click the buttons or enter a positive integer value in the **Maximum surrogates per node** box.

  When you set **Surrogate decision splits** to `Find All`, the regression tree finds all surrogate splits at each branch node. The `Find All` setting can use considerable time and memory.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Regression Learner App” on page 24-30.

Support Vector Machines

You can train regression support vector machines (SVMs) in Regression Learner. Linear SVMs are easy to interpret, but can have low predictive accuracy. Nonlinear SVMs are more difficult to interpret, but can be more accurate.

Tip In the **Model Type** gallery, click **All SVMs**  to try each of the nonoptimizable SVM options and see which settings produce the best model with your data. Select the best model in the **Models** pane, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Linear SVM 	Easy	Low
Quadratic SVM 	Hard	Medium
Cubic SVM 	Hard	Medium
Fine Gaussian SVM 	Hard	High Allows rapid variations in the response function. Kernel scale is set to `sqrt(P)/4`, where `P` is the number of predictors.
Medium Gaussian SVM 	Hard	Medium Gives a less flexible response function. Kernel scale is set to `sqrt(P)`.

Regression Model Type	Interpretability	Model Flexibility
Coarse Gaussian SVM 	Hard	Low Gives a rigid response function. Kernel scale is set to `sqrt(P)*4`.

Statistics and Machine Learning Toolbox implements linear epsilon-insensitive SVM regression. This SVM ignores prediction errors that are less than some fixed number ε. The support vectors are the data points that have errors larger than ε. The function the SVM uses to predict new values depends only on the support vectors. To learn more about SVM regression, see Understanding Support Vector Machine Regression on page 25-2.

Tip For a workflow example, see "Train Regression Trees Using Regression Learner App" on page 24-60.

Advanced SVM Options

Regression Learner uses the `fitrsvm` function to train SVM regression models.

You can set these options in the app:

- **Kernel function**

  The kernel function determines the nonlinear transformation applied to the data before the SVM is trained. You can choose from:

  - `Gaussian` or Radial Basis Function (RBF) kernel
  - `Linear` kernel, easiest to interpret
  - `Quadratic` kernel
  - `Cubic` kernel
- **Box constraint mode**

  The box constraint controls the penalty imposed on observations with large residuals. A larger box constraint gives a more flexible model. A smaller value gives a more rigid model, less sensitive to overfitting.

  When **Box constraint mode** is set to `Auto`, the app uses a heuristic procedure to select the box constraint.

  Try to fine-tune your model by specifying the box constraint manually. Set **Box constraint mode** to `Manual` and specify a value. Change the value by clicking the buttons or entering a positive scalar value in the **Manual box constraint** box. The app automatically preselects a reasonable value for you. Try to increase or decrease this value slightly and see if this improves your model.

  Tip Increase the box constraint value to create a more flexible model.
- **Epsilon mode**

  Prediction errors that are smaller than the epsilon (ε) value are ignored and treated as equal to zero. A smaller epsilon value gives a more flexible model.

When **Epsilon mode** is set to `Auto`, the app uses a heuristic procedure to select the kernel scale.

Try to fine-tune your model by specifying the epsilon value manually. Set **Epsilon mode** to `Manual` and specify a value. Change the value by clicking the buttons or entering a positive scalar value in the **Manual epsilon** box. The app automatically preselects a reasonable value for you. Try to increase or decrease this value slightly and see if this improves your model.

Tip Decrease the epsilon value to create a more flexible model.

- **Kernel scale mode**

  The kernel scale controls the scale of the predictors on which the kernel varies significantly. A smaller kernel scale gives a more flexible model.

  When **Kernel scale mode** is set to `Auto`, the app uses a heuristic procedure to select the kernel scale.

  Try to fine-tune your model by specifying the kernel scale manually. Set **Kernel scale mode** to `Manual` and specify a value. Change the value by clicking the buttons or entering a positive scalar value in the **Manual kernel scale** box. The app automatically preselects a reasonable value for you. Try to increase or decrease this value slightly and see if this improves your model.

  Tip Decrease the kernel scale value to create a more flexible model.

- **Standardize**

  Standardizing the predictors transforms them so that they have mean 0 and standard deviation 1. Standardizing removes the dependence on arbitrary scales in the predictors and generally improves performance.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Regression Learner App” on page 24-30.

Gaussian Process Regression Models

You can train Gaussian process regression (GPR) models in Regression Learner. GPR models are often highly accurate, but can be difficult to interpret.

Tip In the **Model Type** gallery, click **All GPR Models**  to try each of the nonoptimizable GPR model options and see which settings produce the best model with your data. Select the best model in the **Models** pane, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Rational Quadratic 	Hard	Automatic

Regression Model Type	Interpretability	Model Flexibility
Squared Exponential 	Hard	Automatic
Matern 5/2 	Hard	Automatic
Exponential 	Hard	Automatic

In Gaussian process regression, the response is modeled using a probability distribution over a space of functions. The flexibility of the presets in the **Model Type** gallery is automatically chosen to give a small training error and, simultaneously, protection against overfitting. To learn more about Gaussian process regression, see Gaussian Process Regression Models on page 6-2.

Tip For a workflow example, see "Train Regression Trees Using Regression Learner App" on page 24-60.

Advanced Gaussian Process Regression Options

Regression Learner uses the `fitrgp` function to train GPR models.

You can set these options in the app:

- **Basis function**

  The basis function specifies the form of the prior mean function of the Gaussian process regression model. You can choose from `Zero`, `Constant`, and `Linear`. Try to choose a different basis function and see if this improves your model.

- **Kernel function**

  The kernel function determines the correlation in the response as a function of the distance between the predictor values. You can choose from `Rational Quadratic`, `Squared Exponential`, `Matern 5/2`, `Matern 3/2`, and `Exponential`.

  To learn more about kernel functions, see Kernel (Covariance) Function Options on page 6-6.

- **Use isotropic kernel**

  If you use an isotropic kernel, the correlation length scales are the same for all the predictors. With a nonisotropic kernel, each predictor variable has its own separate correlation length scale.

  Using a nonisotropic kernel can improve the accuracy of your model, but can make the model slow to fit.

  To learn more about nonisotropic kernels, see Kernel (Covariance) Function Options. on page 6-6

- **Kernel mode**

  You can manually specify *initial* values of the kernel parameters **Kernel scale** and **Signal standard deviation**. The signal standard deviation is the prior standard deviation of the response

values. By default the app locally optimizes the kernel parameters starting from the initial values. To use fixed kernel parameters, clear the **Optimize numeric parameters** check box in the advanced options.

When **Kernel scale mode** is set to `Auto`, the app uses a heuristic procedure to select the initial kernel parameters.

If you set **Kernel scale mode** to `Manual`, you can specify the initial values. Click the buttons or enter a positive scalar value in the **Kernel scale** box and the **Signal standard deviation** box.

If you clear the **Use isotropic kernel** check box, you cannot set initial kernel parameters manually.

- **Sigma mode**

  You can specify manually the *initial* value of the observation noise standard deviation **Sigma**. By default the app optimizes the observation noise standard deviation, starting from the initial value. To use fixed kernel parameters, clear the **Optimize numeric parameters** check box in the advanced options.

  When **Sigma mode** is set to `Auto`, the app uses a heuristic procedure to select the initial observation noise standard deviation.

  If you set **Sigma mode** to `Manual`, you can specify the initial values. Click the buttons or enter a positive scalar value in the **Sigma** box.

- **Standardize**

  Standardizing the predictors transforms them so that they have mean 0 and standard deviation 1. Standardizing removes the dependence on arbitrary scales in the predictors and generally improves performance.

- **Optimize numeric parameters**

  With this option, the app automatically optimizes numeric parameters of the GPR model. The optimized parameters are the coefficients of the **Basis function**, the kernel parameters **Kernel scale** and **Signal standard deviation**, and the observation noise standard deviation **Sigma**.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Regression Learner App” on page 24-30.

Ensembles of Trees

You can train ensembles of regression trees in Regression Learner. Ensemble models combine results from many weak learners into one high-quality ensemble model.

Tip In the **Model Type** gallery, click **All Ensembles**  to try each of the nonoptimizable ensemble options and see which settings produce the best model with your data. Select the best model in the **Models** pane, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Ensemble Method	Model Flexibility
Boosted Trees 	Hard	Least-squares boosting (`LSBoost`) with regression tree learners.	Medium to high
Bagged Trees 	Hard	Bootstrap aggregating or bagging, with regression tree learners.	High

Tip For a workflow example, see “Train Regression Trees Using Regression Learner App” on page 24-60.

Advanced Ensemble Options

Regression Learner uses the `fitrensemble` function to train ensemble models. You can set these options:

- **Minimum leaf size**

  Specify the minimum number of training samples used to calculate the response of each leaf node. When you grow a regression tree, consider its simplicity and predictive power. To change the minimum leaf size, click the buttons or enter a positive integer value in the **Minimum leaf size** box.

  - A fine tree with many small leaves is usually highly accurate on the training data. However, the tree might not show comparable accuracy on an independent test set. A very leafy tree tends to overfit, and its validation accuracy is often far lower than its training (or resubstitution) accuracy.
  - In contrast, a coarse tree with fewer large leaves does not attain high training accuracy. But a coarse tree can be more robust in that its training accuracy can be near that of a representative test set.

  Tip Decrease the **Minimum leaf size** to create a more flexible model.

- **Number of learners**

  Try changing the number of learners to see if you can improve the model. Many learners can produce high accuracy, but can be time consuming to fit.

  Tip Increase the **Number of learners** to create a more flexible model.

- **Learning rate**

  For boosted trees, specify the learning rate for shrinkage. If you set the learning rate to less than 1, the ensemble requires more learning iterations but often achieves better accuracy. 0.1 is a popular initial choice.

Alternatively, you can let the app choose some of these model options automatically by using hyperparameter optimization. See “Hyperparameter Optimization in Regression Learner App” on page 24-30.

Neural Networks

Neural network models typically have good predictive accuracy; however, they are not easy to interpret.

Model flexibility increases with the size and number of fully connected layers in the neural network.

Tip In the **Model Type** gallery, click **All Neural Networks**  to try each of the preset neural network options and see which settings produce the best model with your data. Select the best model in the **Models** pane, and try to improve that model by using feature selection and changing some advanced options.

Regression Model Type	Interpretability	Model Flexibility
Narrow Neural Network 	Hard	Medium — increases with **Size of each fully connected layer** setting
Medium Neural Network 	Hard	Medium — increases with **Size of each fully connected layer** setting
Wide Neural Network 	Hard	Medium — increases with **Size of each fully connected layer** setting
Bilayered Neural Network 	Hard	High — increases with **Size of each fully connected layer** setting
Trilayered Neural Network 	Hard	High — increases with **Size of each fully connected layer** setting

Each model is a feedforward, fully connected neural network for regression. The first fully connected layer of the neural network has a connection from the network input (predictor data), and each subsequent layer has a connection from the previous layer. Each fully connected layer multiplies the input by a weight matrix and then adds a bias vector. An activation function follows each fully connected layer, excluding the last. The final fully connected layer produces the network's output, namely predicted response values. For more information, see “Neural Network Structure” on page 33-2239.

For an example, see “Train Regression Neural Networks Using Regression Learner App” on page 24-69.

Advanced Neural Network Options

Regression Learner uses the `fitrnet` function to train neural network models. You can set these options:

- **Number of fully connected layers** — Specify the number of fully connected layers in the neural network, excluding the final fully connected layer for regression. You can choose a maximum of three fully connected layers.
- **Size of each fully connected layer** — Specify the size of each fully connected layer, excluding the final fully connected layer. If you choose to create a neural network with multiple fully connected layers, consider specifying layers with decreasing sizes.
- **Activation** — Specify the activation function for all fully connected layers, excluding the final fully connected layer. Choose from the following activation functions: `ReLU`, `Tanh`, `Sigmoid`, and `None`.
- **Iteration limit** — Specify the maximum number of training iterations.
- **Regularization term strength** — Specify the ridge (L2) regularization penalty term.
- **Standardize data** — Specify whether to standardize the numeric predictors. If predictors have widely different scales, standardizing can improve the fit. Standardizing the data is highly recommended.

Feature Selection and Feature Transformation Using Regression Learner App

In this section...

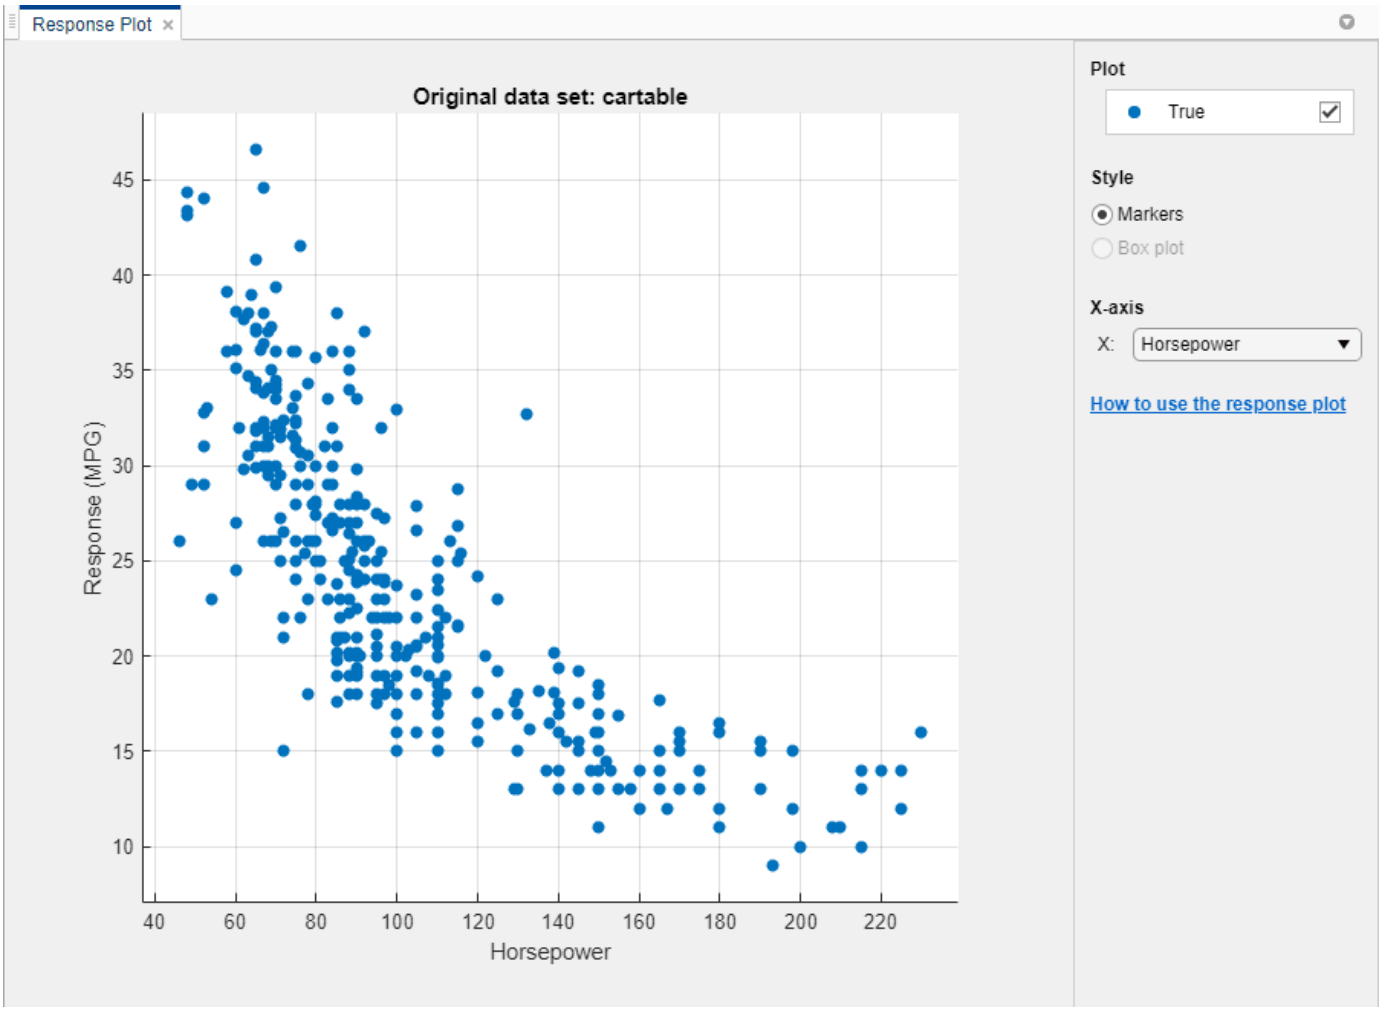
Investigate Features in the Response Plot

In Regression Learner, use the response plot to try to identify predictors that are useful for predicting the response. To visualize the relation between different predictors and the response, under **X-axis**, select different variables in the **X** list.

Before you train a regression model, the response plot shows the training data. If you have trained a regression model, then the response plot also shows the model predictions.

Observe which variables are associated most clearly with the response. When you plot the `carbig` data set, the predictor `Horsepower` shows a clear negative association with the response.

Look for features that do not seem to have any association with the response and use **Feature Selection** 
to remove those features from the set of used predictors.



You can export the response plots you create in the app to figures. See “Export Plots in Regression Learner App” on page 24-50.

Select Features to Include

In Regression Learner, you can specify different features (or predictors) to include in the model. See if you can improve models by removing features with low predictive power. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily with fewer predictors.

1. On the **Regression Learner** tab, in the **Features** section, click **Feature Selection** 
.
2. In the Feature Selection dialog box, clear the check boxes for the predictors you want to exclude.

Tip You can close the Feature Selection dialog box, or move it. The choices you make in the dialog box remain.

3. Click **Train** to train a new model using the new predictor options.
4. Observe the new model in the **Models** pane. The **Current Model Summary** pane displays how many predictors are excluded.
5. Check which predictors are included in a trained model. Click the model in the **Models** pane and look at the check boxes in the Feature Selection window.
6. Try to improve the model by including different features.

For an example using feature selection, see “Train Regression Trees Using Regression Learner App” on page 24-60.

Transform Features with PCA in Regression Learner

Use principal component analysis (PCA) to reduce the dimensionality of the predictor space. Reducing the dimensionality can create regression models in Regression Learner that help prevent overfitting. PCA linearly transforms predictors to remove redundant dimensions, and generates a new set of variables called principal components.

1. On the **Regression Learner** tab, in the **Features** section, select **PCA**.
2. In the Advanced PCA Options dialog box, select the **Enable PCA** check box.

   You can close the PCA dialog box, or move it. The choices you make in the dialog box remain.
3. Click **Train** again. The `pca` function transforms your selected features before training the model.

   By default, PCA keeps only the components that explain 95% of the variance. In the PCA dialog box, you can change the percentage of variance to explain by selecting the **Explained variance** value. A higher value risks overfitting, while a lower value risks removing useful dimensions.
4. Manually limit the number of PCA components. In the **Component reduction criterion** list, select `Specify number of components`. Select the **Number of numeric components** value. The number of components cannot be larger than the number of numeric predictors. PCA is not applied to categorical predictors.

You can check PCA Options for trained models in the **Current Model Summary** pane. For example:

```
PCA is keeping enough components to explain 95% variance.
After training, 2 components were kept.
Explained variance per component (in order): 92.5%, 5.3%, 1.7%, 0.5%
```

Check the explained variance percentages to decide whether to change the number of components.

To learn more about how Regression Learner applies PCA to your data, generate code for your trained regression model. For more information on PCA, see the `pca` function.

Hyperparameter Optimization in Regression Learner App

In this section...

After you choose a particular type of model to train, for example a decision tree or a support vector machine (SVM), you can tune your model by selecting different advanced options. For example, you can change the minimum leaf size of a decision tree or the box constraint of an SVM. Some of these options are internal parameters of the model, or hyperparameters, that can strongly affect its performance. Instead of manually selecting these options, you can use hyperparameter optimization within the Regression Learner app to automate the selection of hyperparameter values. For a given model type, the app tries different combinations of hyperparameter values by using an optimization scheme that seeks to minimize the model mean squared error (MSE), and returns a model with the optimized hyperparameters. You can use the resulting model as you would any other trained model.

Note Because hyperparameter optimization can lead to an overfitted model, the recommended approach is to create a separate test set before importing your data into the Regression Learner app. After you train your optimizable model, you can see how it performs on your test set. For an example, see “Train Regression Model Using Hyperparameter Optimization in Regression Learner App” on page 24-76.

To perform hyperparameter optimization in Regression Learner, follow these steps:

1. Choose a model type and decide which hyperparameters to optimize. See “Select Hyperparameters to Optimize” on page 24-30.

   Note Hyperparameter optimization is not supported for linear regression models and neural networks.

2. (Optional) Specify how the optimization is performed. For more information, see “Optimization Options” on page 24-36.
3. Train your model. Use the “Minimum MSE Plot” on page 24-37 to track the optimization results.
4. Inspect your trained model. See “Optimization Results” on page 24-39.

Select Hyperparameters to Optimize

In the Regression Learner app, in the **Model Type** section of the **Regression Learner** tab, click the arrow to open the gallery. The gallery includes optimizable models that you can train using hyperparameter optimization.

After you select an optimizable model, you can choose which of its hyperparameters you want to optimize. In the **Model Type** section, select **Advanced > Advanced**. The app opens a dialog box in which you can select **Optimize** check boxes for the hyperparameters that you want to optimize. Under **Values**, specify the fixed values for the hyperparameters that you do not want to optimize or that are not optimizable.

This table describes the hyperparameters that you can optimize for each type of model and the search range of each hyperparameter. It also includes the additional hyperparameters for which you can specify fixed values.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
Optimizable Tree 	• **Minimum leaf size** – The software searches among integers log-scaled in the range `[1,max(2,floor(n/2))]`, where `n` is the number of observations.	• **Surrogate decision splits** • **Maximum surrogates per node**	For more information, see “Advanced Regression Tree Options” on page 24-17.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
Optimizable SVM 	• **Kernel function** – The software searches among `Gaussian`, `Linear`, `Quadratic`, and `Cubic`. • **Box constraint** – The software searches among positive values log-scaled in the range `[0.001,1000]`. • **Kernel scale** – The software searches among positive values log-scaled in the range `[0.001,1000]`. • **Epsilon** – The software searches among positive values log-scaled in the range `[0.001,100]*iqr(Y)/1.349`, where `Y` is the response variable. • **Standardize data** – The software searches between `true` and `false`.		• The **Box constraint** optimizable hyperparameter combines the **Box constraint mode** and **Manual box constraint** advanced options of the preset SVM models. • The **Kernel scale** optimizable hyperparameter combines the **Kernel scale mode** and **Manual kernel scale** advanced options of the preset SVM models. • You can optimize the **Kernel scale** optimizable hyperparameter only when the **Kernel function** value is `Gaussian`. Unless you specify a value for **Kernel scale** by clearing the **Optimize** check box, the app uses the **Manual** value of `1` by default when the **Kernel function** has a value other than `Gaussian`. • The **Epsilon** optimizable hyperparameter combines the **Epsilon mode** and **Manual epsilon** advanced options of the preset SVM models.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
			For more information, see “Advanced SVM Options” on page 24-19.

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes

Optimizable GPR 	• **Basis function** – The software searches among `Zero`, `Constant`, and `Linear`.
	• **Kernel function** – The software searches among:
	  • `Nonisotropic Rational Quadratic`
	  • `Isotropic Rational Quadratic`
	  • `Nonisotropic Squared Exponential`
	  • `Isotropic Squared Exponential`
	  • `Nonisotropic Matern 5/2`
	  • `Isotropic Matern 5/2`
	  • `Nonisotropic Matern 3/2`
	  • `Isotropic Matern 3/2`
	  • `Nonisotropic Exponential`
	  • `Isotropic Exponential`
	• **Kernel scale** – The software searches among real values in the range `[0.001,1]*XMaxRange`, where `XMaxRange = max(max(X) – min(X))` and `X` is the predictor data.
	• **Sigma** – The software searches among real values in
		• **Signal standard deviation**
		• **Optimize numeric parameters**
			• The **Kernel function** optimizable hyperparameter combines the **Kernel function** and **Use isotropic kernel** advanced options of the preset Gaussian process models.
			• The **Kernel scale** optimizable hyperparameter combines the **Kernel mode** and **Kernel scale** advanced options of the preset Gaussian process models.
			• The **Sigma** optimizable hyperparameter combines the **Sigma mode** and **Sigma** advanced options of the preset Gaussian process models.
			• When you optimize the **Kernel scale** of isotropic kernel functions, only the kernel scale is optimized, not the signal standard deviation. You can either specify a **Signal standard deviation** value or use its default value.
			
			You cannot optimize the **Kernel scale** of nonisotropic kernel functions.
			
			For more information, see “Advanced Gaussian

Model	Optimizable Hyperparameters	Additional Hyperparameters	Notes
	the range `[0.0001,max(0.001,10*std(Y))]`, where `Y` is the response variable. • **Standardize** – The software searches between `true` and `false`.		Process Regression Options” on page 24-21.
Optimizable Ensemble 	• **Ensemble method** – The software searches among `Bag` and `LSBoost`. • **Minimum leaf size** – The software searches among integers log-scaled in the range `[1,max(2,floor(n/2))]`, where `n` is the number of observations. • **Number of learners** – The software searches among integers log-scaled in the range `[10,500]`. • **Learning rate** – The software searches among real values log-scaled in the range `[0.001,1]`. • **Number of predictors to sample** – The software searches among integers in the range `[1,max(2,p)]`, where `p` is the number of predictor variables.		• The `Bag` value of the **Ensemble method** optimizable hyperparameter specifies a **Bagged Trees** model. Similarly, the `LSBoost` **Ensemble method** value specifies a **Boosted Trees** model. • The **Number of predictors to sample** optimizable hyperparameter is not available in the advanced options of the preset ensemble models. For more information, see “Advanced Ensemble Options” on page 24-23.

Optimization Options

By default, the Regression Learner app performs hyperparameter tuning by using Bayesian optimization. The goal of Bayesian optimization, and optimization in general, is to find a point that minimizes an objective function. In the context of hyperparameter tuning in the app, a point is a set of hyperparameter values, and the objective function is the loss function, or the mean squared error (MSE). For more information on the basics of Bayesian optimization, see “Bayesian Optimization Workflow” on page 10-25.

You can specify how the hyperparameter tuning is performed. For example, you can change the optimization method to grid search or limit the training time. On the **Regression Learner** tab, in the **Model Type** section, select **Advanced > Optimizer Options**. The app opens a dialog box in which you can select optimization options.

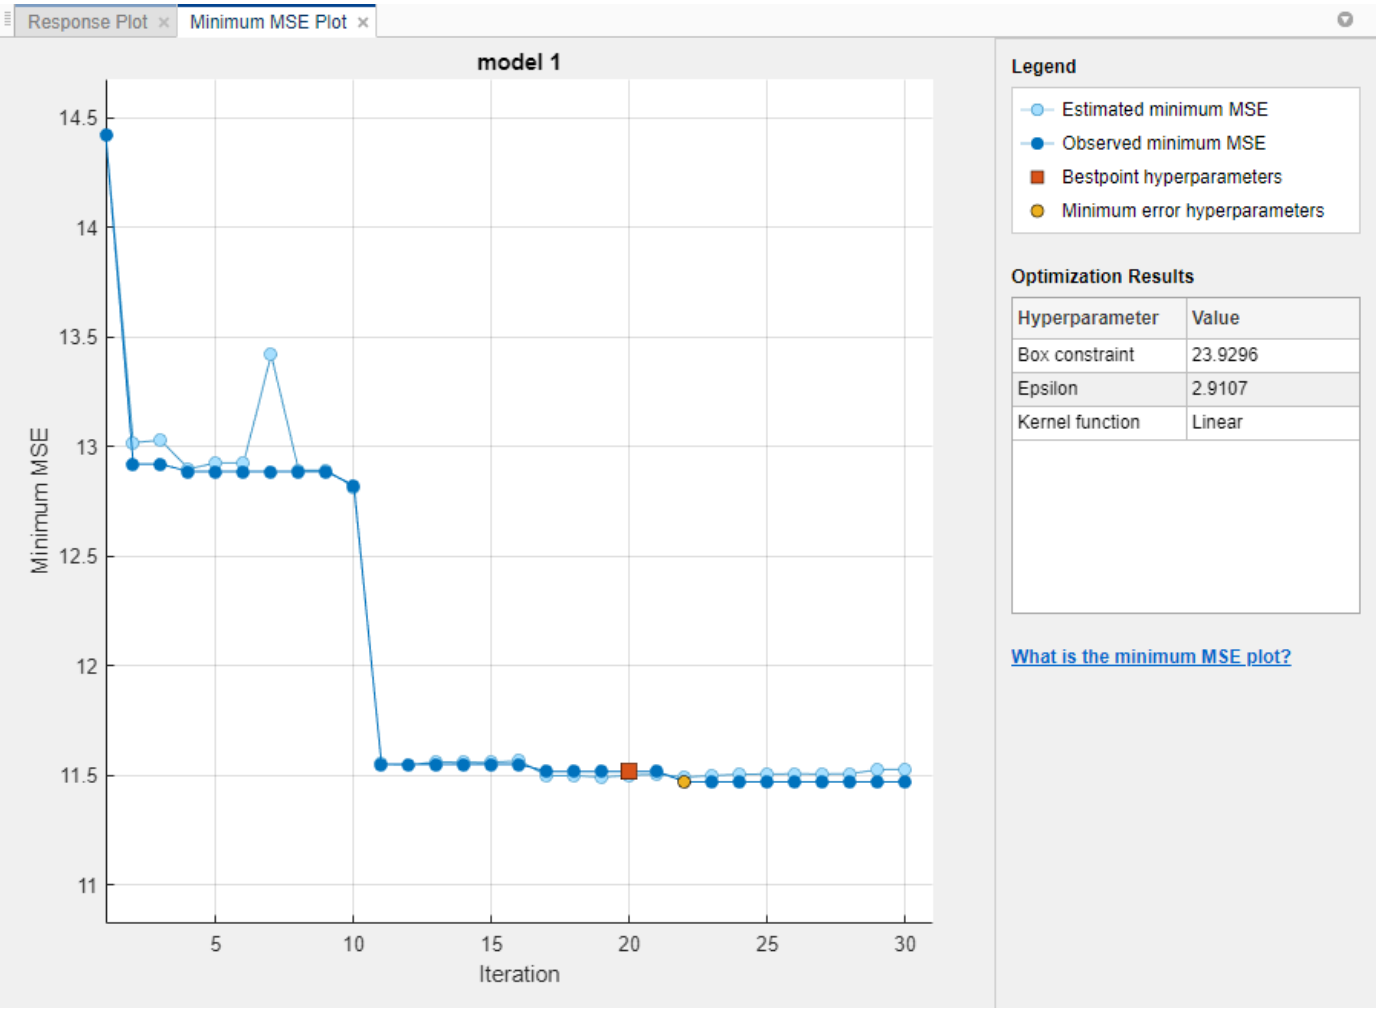
This table describes the available optimization options and their default values.

Option	Description
Optimizer	The optimizer values are: • `Bayesopt` (default) – Use Bayesian optimization. Internally, the app calls the `bayesopt` function. • `Grid search` – Use grid search with the number of values per dimension determined by the **Number of grid divisions** value. The app searches in a random order, using uniform sampling without replacement from the grid. • `Random search` – Search at random among points, where the number of points corresponds to the **Iterations** value.
Acquisition function	When the app performs Bayesian optimization for hyperparameter tuning, it uses the acquisition function to determine the next set of hyperparameter values to try. The acquisition function values are: • `Expected improvement per second plus` (default) • `Expected improvement` • `Expected improvement plus` • `Expected improvement per second` • `Lower confidence bound` • `Probability of improvement` For details on how these acquisition functions work in the context of Bayesian optimization, see “Acquisition Function Types” on page 10-3.

Option	Description
Iterations	Each iteration corresponds to a combination of hyperparameter values that the app tries. When you use Bayesian optimization or random search, specify a positive integer that sets the number of iterations. The default value is `30`. When you use grid search, the app ignores the **Iterations** value and evaluates the loss at every point in the entire grid. You can set a training time limit to stop the optimization process prematurely.
Training time limit	To set a training time limit, select this option and set the **Maximum training time in seconds** option. By default, the app does not have a training time limit.
Maximum training time in seconds	Set the training time limit in seconds as a positive real number. The default value is `300`. The run time can exceed the training time limit because this limit does not interrupt an iteration evaluation.
Number of grid divisions	When you use grid search, set a positive integer as the number of values the app tries for each numeric hyperparameter. The app ignores this value for categorical hyperparameters. The default value is `10`.

Minimum MSE Plot

After specifying which model hyperparameters to optimize and setting any additional optimization options (optional), train your optimizable model. On the **Regression Learner** tab, in the **Training** section, click **Train**. The app creates a **Minimum MSE Plot** that it updates as the optimization runs.



Note When you train an optimizable model, the app disables the **Use Parallel** button. After the training is complete, the app makes the button available again when you select a nonoptimizable model. The button is off by default.

The minimum mean squared error (MSE) plot displays the following information:

- **Estimated minimum MSE** – Each light blue point corresponds to an estimate of the minimum MSE computed by the optimization process when considering all the sets of hyperparameter values tried so far, including the current iteration.

  The estimate is based on an upper confidence interval of the current MSE objective model, as mentioned in the **Bestpoint hyperparameters** description.

  If you use grid search or random search to perform hyperparameter optimization, the app does not display these light blue points.
- **Observed minimum MSE** – Each dark blue point corresponds to the observed minimum MSE computed so far by the optimization process. For example, at the third iteration, the blue point corresponds to the minimum of the MSE observed in the first, second, and third iterations.

- **Bestpoint hyperparameters** – The red square indicates the iteration that corresponds to the optimized hyperparameters. You can find the values of the optimized hyperparameters listed in the upper right of the plot under **Optimization Results**.

  The optimized hyperparameters do not always provide the observed minimum MSE. When the app performs hyperparameter tuning by using Bayesian optimization (see “Optimization Options” on page 24-36 for a brief introduction), it chooses the set of hyperparameter values that minimizes an upper confidence interval of the MSE objective model, rather than the set that minimizes the MSE. For more information, see the `'Criterion','min-visited-upper-confidence-interval'` name-value pair argument of `bestPoint`.
- **Minimum error hyperparameters** – The yellow point indicates the iteration that corresponds to the hyperparameters that yield the observed minimum MSE.

  For more information, see the `'Criterion','min-observed'` name-value pair argument of `bestPoint`.

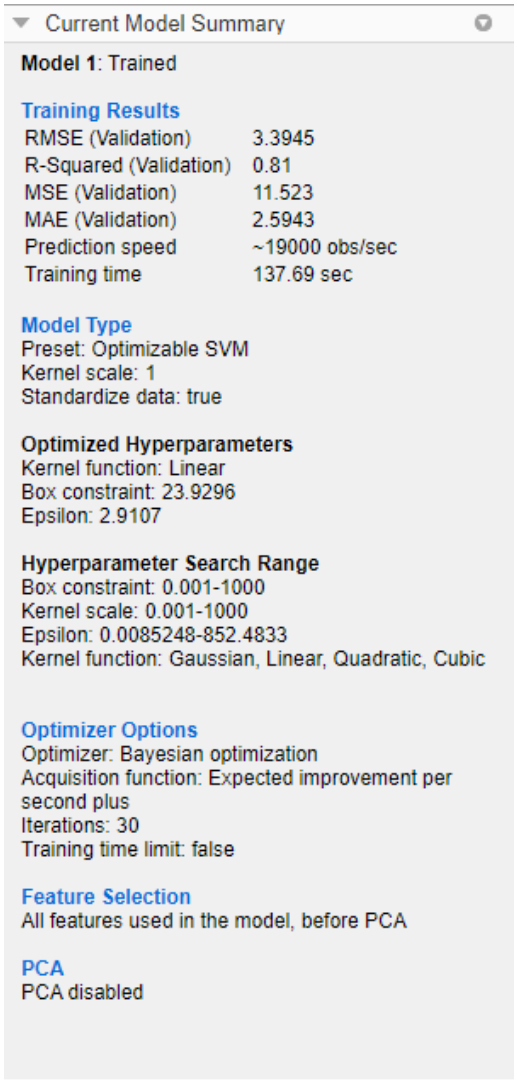
  If you use grid search to perform hyperparameter optimization, the **Bestpoint hyperparameters** and the **Minimum error hyperparameters** are the same.

Missing points in the plot correspond to `NaN` minimum MSE values.

Optimization Results

When the app finishes tuning model hyperparameters, it returns a model trained with the optimized hyperparameter values (**Bestpoint hyperparameters**). The model metrics, displayed plots, and exported model correspond to this trained model with fixed hyperparameter values.

To inspect the optimization results of a trained optimizable model, select the model in the **Models** pane and look at the **Current Model Summary** pane.



The **Current Model Summary** pane includes these sections:

- **Training Results** – Shows the performance of the optimizable model. See “View and Compare Model Statistics” on page 24-43
- **Model Type** – Displays the type of optimizable model and lists any fixed hyperparameter values
- **Optimized Hyperparameters** – Lists the values of the optimized hyperparameters
- **Hyperparameter Search Range** – Displays the search ranges for the optimized hyperparameters
- **Optimizer Options** – Shows the selected optimizer options

When you perform hyperparameter tuning using Bayesian optimization and you export a trained optimizable model to the workspace as a structure, the structure includes a `BayesianOptimization` object in the `HyperParameterOptimizationResult` field. The object contains the results of the optimization performed in the app.

When you generate MATLAB code from a trained optimizable model, the generated code uses the fixed and optimized hyperparameter values of the model to train on new data. The generated code

does not include the optimization process. For information on how to perform Bayesian optimization when you use a fit function, see “Bayesian Optimization Using a Fit Function” on page 10-26.

Assess Model Performance in Regression Learner

In this section...

After training regression models in Regression Learner, you can compare models based on model statistics, visualize results in response plot, or by plotting actual versus predicted response, and evaluate models using the residual plot.

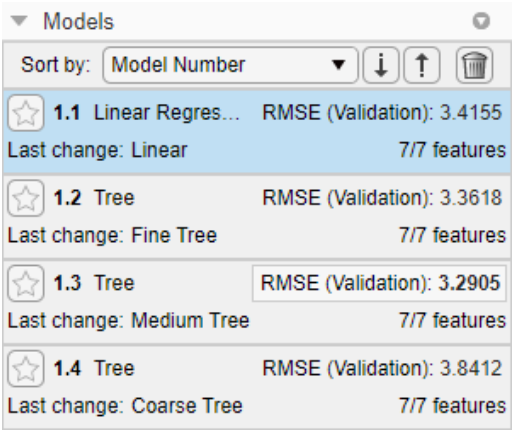
- If you use *k*-fold cross-validation, then the app computes the model statistics using the observations in the *k* validation folds and reports the average values. It makes predictions on the observations in the validation folds and the plots show these predictions. It also computes the residuals on the observations in the validation folds.

  Note When you import data into the app, if you accept the defaults, the app automatically uses cross-validation. To learn more, see “Choose Validation Scheme” on page 23-20.

- If you use holdout validation, the app computes the model statistics using the observations in the validation fold and makes predictions on these observations. The app uses these predictions in the plots and also computes the residuals based on the predictions.
- If you use resubstitution validation, the scores are resubstitution models statistics based on all the training data, and the predictions are resubstitution predictions.

Check Performance in Models Pane

After training a model in Regression Learner, check the **Models** pane to see which model has the best overall score. The best **RMSE (Validation)** is highlighted in a box. This score is the root mean square error (RMSE) on the validation set. The score estimates the performance of the trained model on new data. Use the score to help you choose the best model.

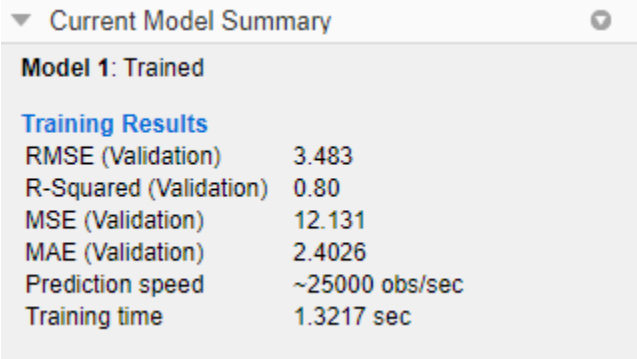


- For cross-validation, the score is the RMSE on all observations, counting each observation when it was in a held-out (validation) fold.
- For holdout validation, the score is the RMSE on the held-out observations.
- For resubstitution validation, the score is the resubstitution RMSE on all the training data.

The best overall score might not be the best model for your goal. Sometimes a model with slightly lower overall score is the better model for your goal. You want to avoid overfitting, and you might want to exclude some predictors where data collection is expensive or difficult.

View and Compare Model Statistics

You can view model statistics in the **Current Model Summary** pane and use these statistics to assess and compare models. The **Training Results** statistics are calculated on the validation set. The **Test Results** statistics, if displayed, are calculated on an imported test set. For more information, see “Evaluate Test Set Model Performance” on page 24-48.



To copy the information in the **Current Model Summary** pane, you can right-click into the pane and select **Copy text**.

Model Statistics

Statistic	Description	Tip
RMSE	Root mean square error. The RMSE is always positive and its units match the units of your response.	Look for smaller values of the RMSE.
R-Squared	Coefficient of determination. R-squared is always smaller than 1 and usually larger than 0. It compares the trained model with the model where the response is constant and equals the mean of the training response. If your model is worse than this constant model, then R-Squared is negative.	Look for an R-Squared close to 1.
MSE	Mean squared error. The MSE is the square of the RMSE.	Look for smaller values of the MSE.
MAE	Mean absolute error. The MAE is always positive and similar to the RMSE, but less sensitive to outliers.	Look for smaller values of the MAE.

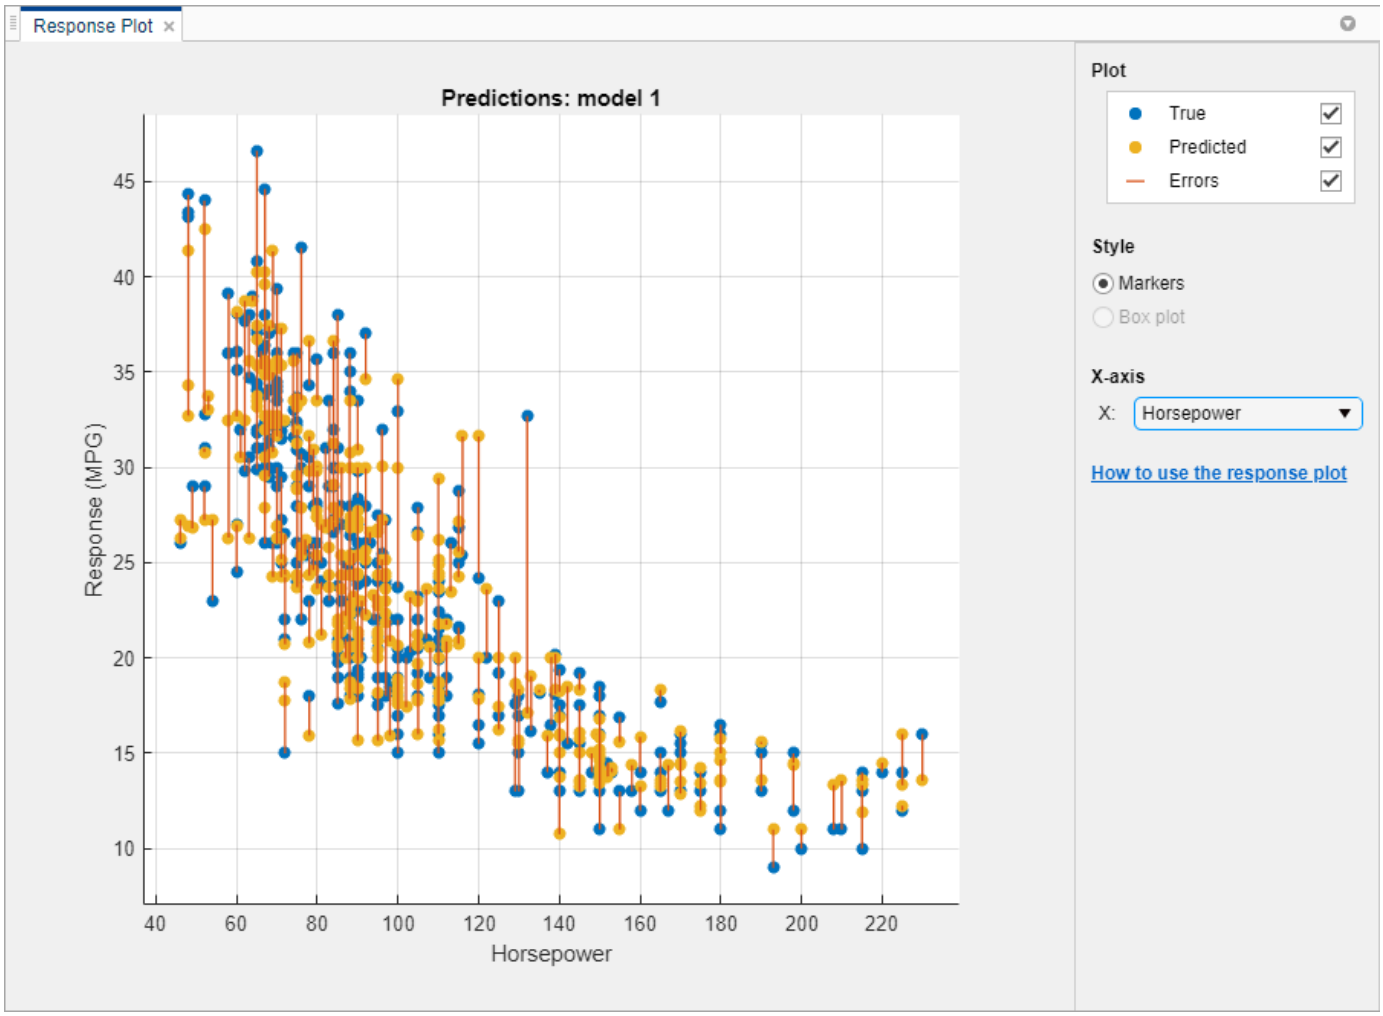
You can sort the models based on the different model statistics. To select a statistic for model sorting, use the **Sort by** list at the top of the **Models** pane.

You can also delete unwanted models listed in the **Models** pane. Select the model you want to delete and click the **Delete selected model** button in the upper right of the pane, or right-click the model and select **Delete model**. You cannot delete the last remaining model in the **Models** pane.

Explore Data and Results in Response Plot

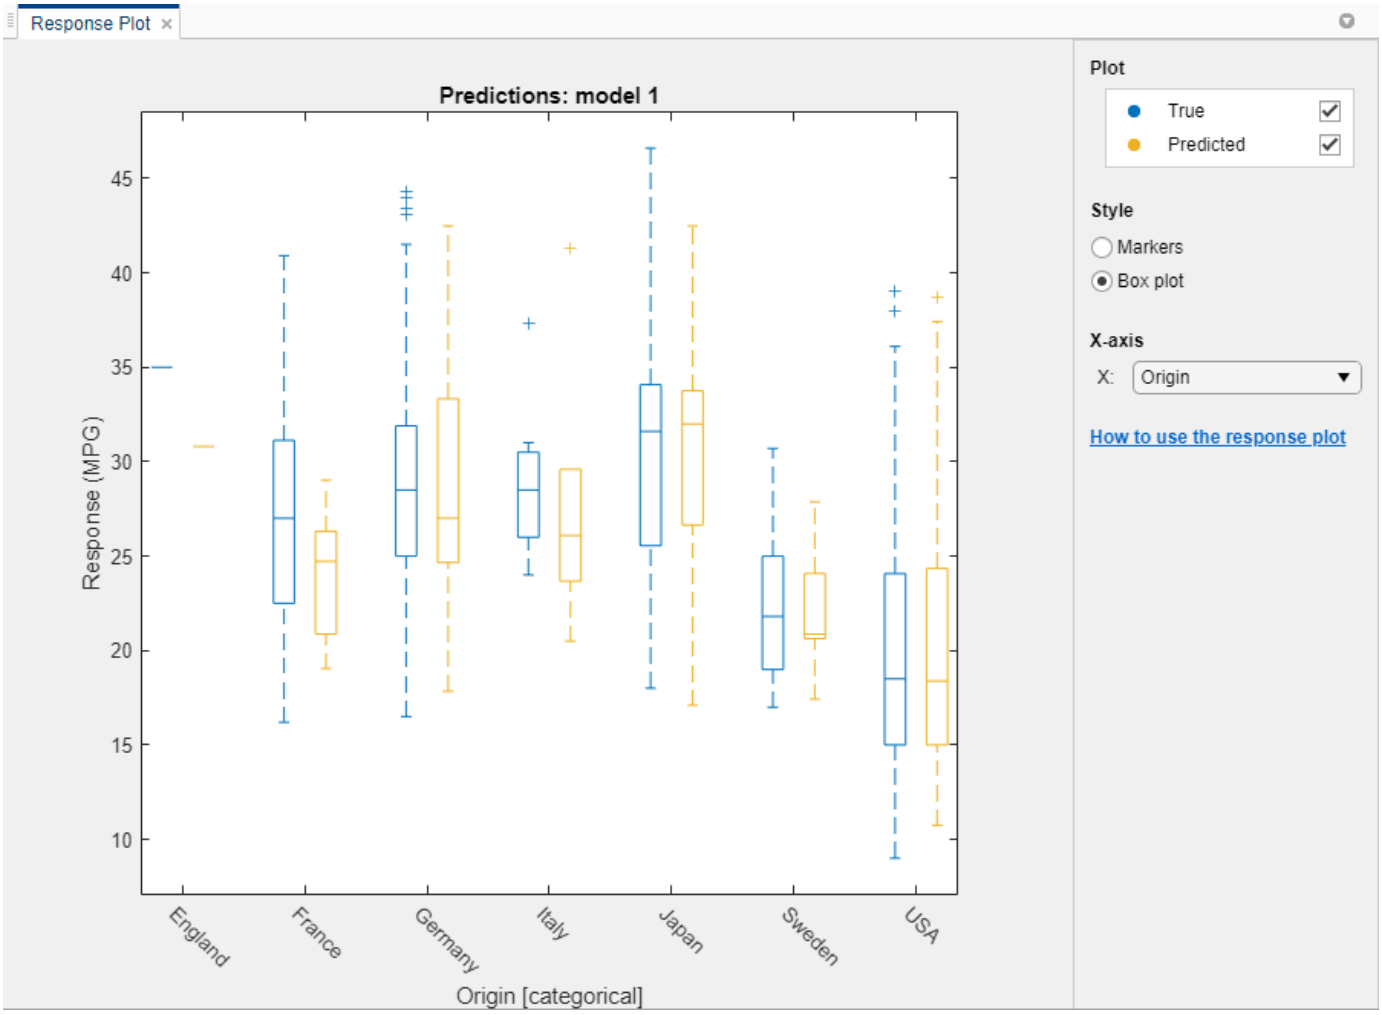
In the response plot, view the regression model results. After you train a regression model, the response plot displays the predicted response versus record number. If you are using holdout or cross-validation, then these predictions are the predictions on the held-out (validation) observations. In other words, each prediction is obtained using a model that was trained without using the corresponding observation. To investigate your results, use the controls on the right. You can:

- Plot predicted and/or true responses. Use the check boxes under **Plot** to make your selection.
- Show prediction errors, drawn as vertical lines between the predicted and true responses, by selecting the **Errors** check box.
- Choose the variable to plot on the *x*-axis under **X-axis**. You can choose either the record number or one of your predictor variables.



- Plot the response as markers, or as a box plot under **Style**. You can only select **Box plot** when the variable on the *x*-axis has few unique values.

A box plot displays the typical values of the response and any possible outliers. The central mark indicates the median, and the bottom and top edges of the box are the 25th and 75th percentiles, respectively. Vertical lines, called whiskers, extend from the boxes to the most extreme data points that are not considered outliers. The outliers are plotted individually using the `'+'` symbol. For more information about box plots, see `boxplot`.



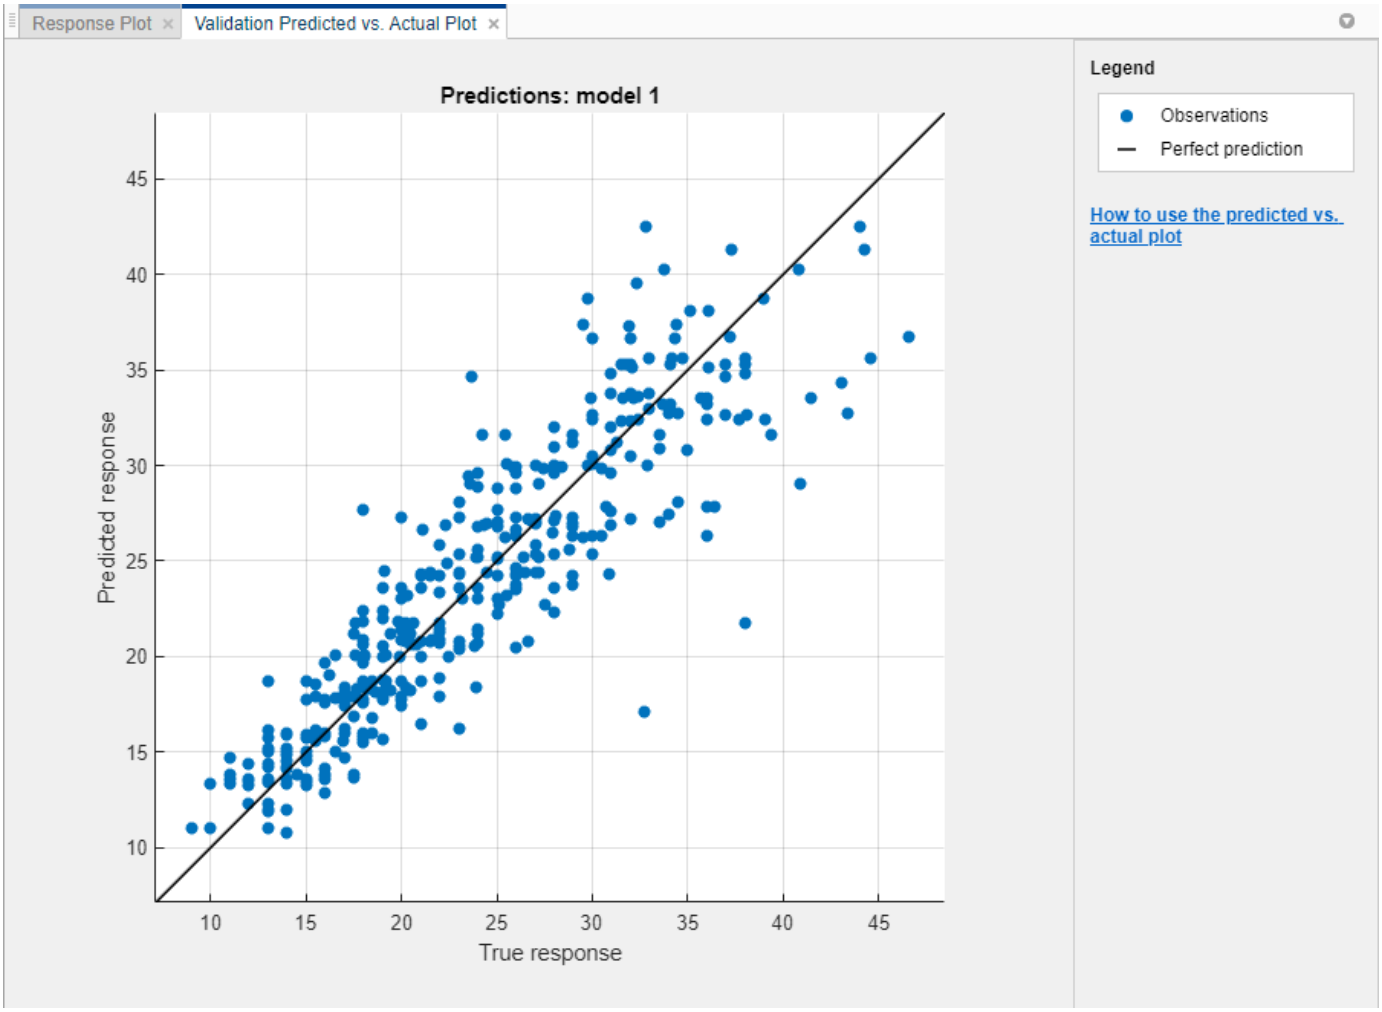
To export the response plots you create in the app to figures, see “Export Plots in Regression Learner App” on page 24-50.

Plot Predicted vs. Actual Response

Use the Predicted vs. Actual plot to check model performance. Use this plot to understand how well the regression model makes predictions for different response values. To view the Predicted vs. Actual plot after training a model, on the **Regression Learner** tab, in the **Plots** section, click **Predicted vs. Actual** and select **Validation Data**.

When you open the plot, the predicted response of your model is plotted against the actual, true response. A perfect regression model has a predicted response equal to the true response, so all the points lie on a diagonal line. The vertical distance from the line to any point is the error of the

prediction for that point. A good model has small errors, and so the predictions are scattered near the line.

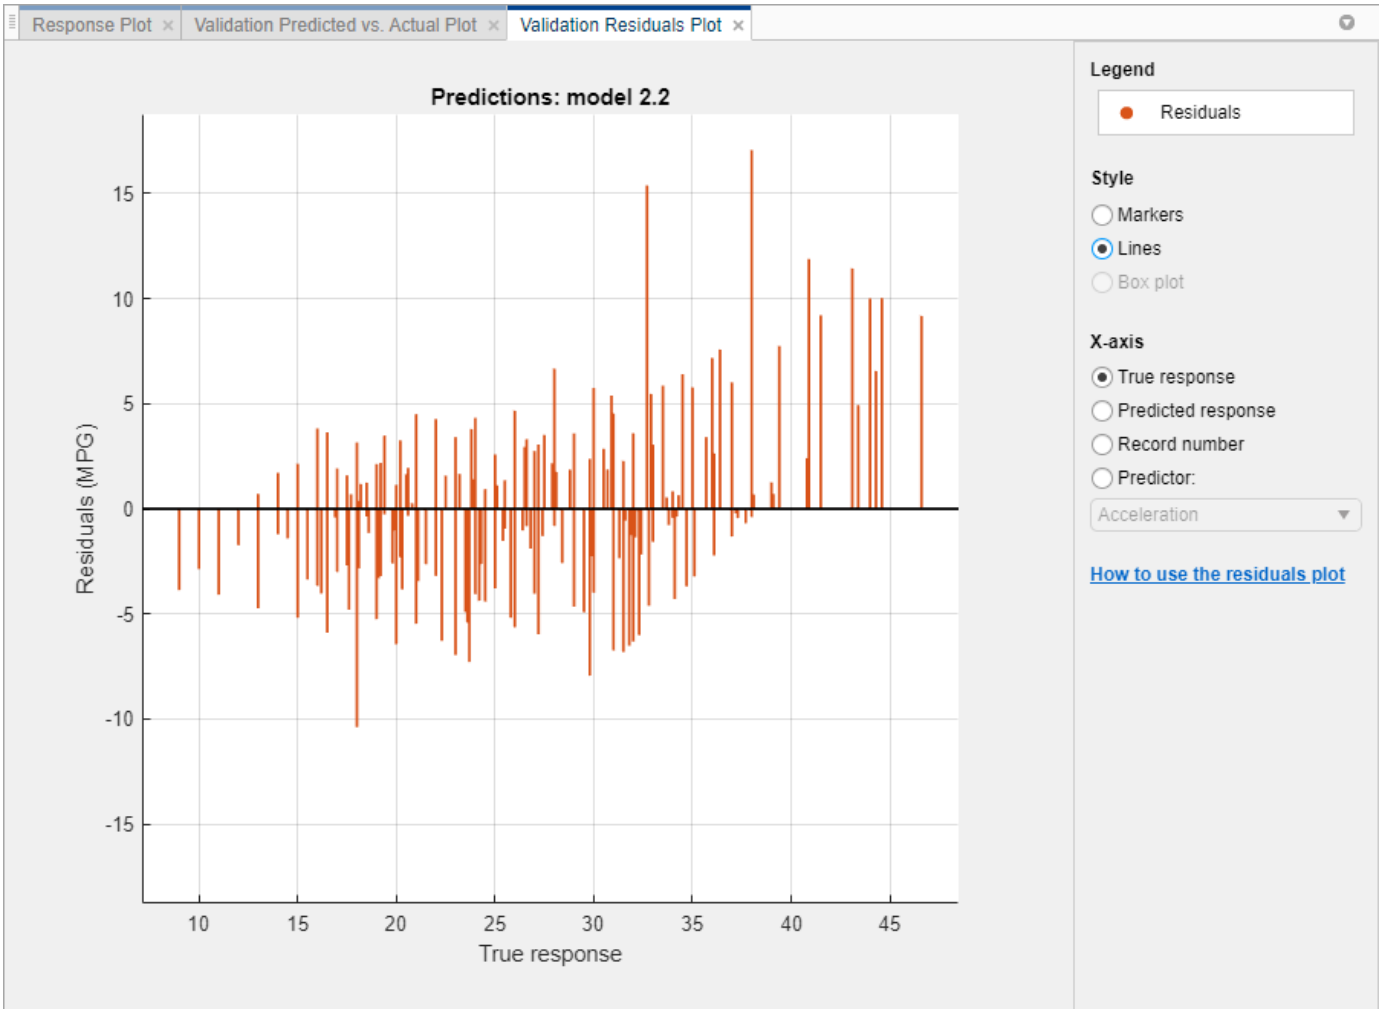


Usually a good model has points scattered roughly symmetrically around the diagonal line. If you can see any clear patterns in the plot, it is likely that you can improve your model. Try training a different model type or making your current model type more flexible using the **Advanced** options in the **Model Type** section. If you are unable to improve your model, it is possible that you need more data, or that you are missing an important predictor.

To export the Predicted vs. Actual plots you create in the app to figures, see “Export Plots in Regression Learner App” on page 24-50.

Evaluate Model Using Residuals Plot

Use the residuals plot to check model performance. To view the residuals plot after training a model, on the **Regression Learner** tab, in the **Plots** section, click **Residuals** and select **Validation Data**. The residuals plot displays the difference between the predicted and true responses. Choose the variable to plot on the *x*-axis under **X-axis**. Choose either the true response, predicted response, record number, or one of your predictors.



Usually a good model has residuals scattered roughly symmetrically around 0. If you can see any clear patterns in the residuals, it is likely that you can improve your model. Look for these patterns:

- Residuals are not symmetrically distributed around 0.
- Residuals change significantly in size from left to right in the plot.
- Outliers occur, that is, residuals that are much larger than the rest of the residuals.
- Clear, nonlinear pattern appears in the residuals.

Try training a different model type, or making your current model type more flexible using the **Advanced** options in the **Model Type** section. If you are unable to improve your model, it is possible that you need more data, or that you are missing an important predictor.

To export the residuals plots you create in the app to figures, see “Export Plots in Regression Learner App” on page 24-50.

Evaluate Test Set Model Performance

After training a model in Regression Learner, you can evaluate the model performance on a test set in the app. This process allows you to check whether the validation metrics provide good estimates for the model performance on new data.

1. Import a test data set into Regression Learner.

   - If the test data set is in the MATLAB workspace, then in the **Testing** section on the **Regression Learner** tab, click **Test Data** and select **From Workspace**.
   - If the test data set is in a file, then in the **Testing** section, click **Test Data** and select **From File**. Select a file type in the list, such as a spreadsheet, text file, or comma-separated values (`.csv`) file, or select **All Files** to browse for other file types such as `.dat`.

   In the Import Test Data dialog box, select the test data set from the **Test Data Set Variable** list. The test set must have the same variables as the predictors imported for training and validation.

2. Compute the test set metrics.

   - To compute test metrics for a single model, select the trained model in the **Models** pane. On the **Regression Learner** tab, in the **Testing** section, click **Test All** and select **Test Selected**.
   - To compute test metrics for all trained models, click **Test All** and select **Test All** in the **Testing** section.

   The app computes the test set performance of each model trained on the full data set, including training and validation data.

3. Compare the validation metrics with the test metrics.

   In the **Current Model Summary** pane, the app displays the validation metrics and test metrics under the **Training Results** section and **Test Results** section, respectively. You can check if the validation metrics give good estimates for the test metrics.

   You can also visualize the test results using plots.

   - Display a predicted vs. actual plot. In the **Plots** section on the **Regression Learner** tab, click **Predicted vs. Actual Plot** and select **Test Data**.
   - Display a residuals plot. In the **Plots** section, click **Residuals Plot** and select **Test Data**.

For an example, see “Check Model Performance Using Test Set in Regression Learner App” on page 24-83. For an example that uses test set metrics in a hyperparameter optimization workflow, see “Train Regression Model Using Hyperparameter Optimization in Regression Learner App” on page 24-76.

Export Plots in Regression Learner App

After you create plots interactively in the Regression Learner app, you can export your app plots to MATLAB figures. You can then copy, save, or customize the new figures. Choose among the available plots: response plot on page 24-26, Predicted vs. Actual plot on page 24-45, residuals plot on page 24-46, and minimum MSE plot on page 24-37.

- Before exporting a plot, make sure the plot in the app displays the same data that you want in the new figure.
- On the **Regression Learner** tab, in the **Export** section, click **Export Plot to Figure**. The app creates a figure from the selected plot.
  - The new figure might not have the same interactivity options as the plot in the Regression Learner app.
  - Additionally, the figure might have a different axes toolbar than the one in the app plot. For plots in Regression Learner, an axes toolbar appears above the top right of the plot. The buttons available on the toolbar depend on the contents of the plot. The toolbar can include buttons to export the plot as an image, add data tips, pan or zoom the data, and restore the view.

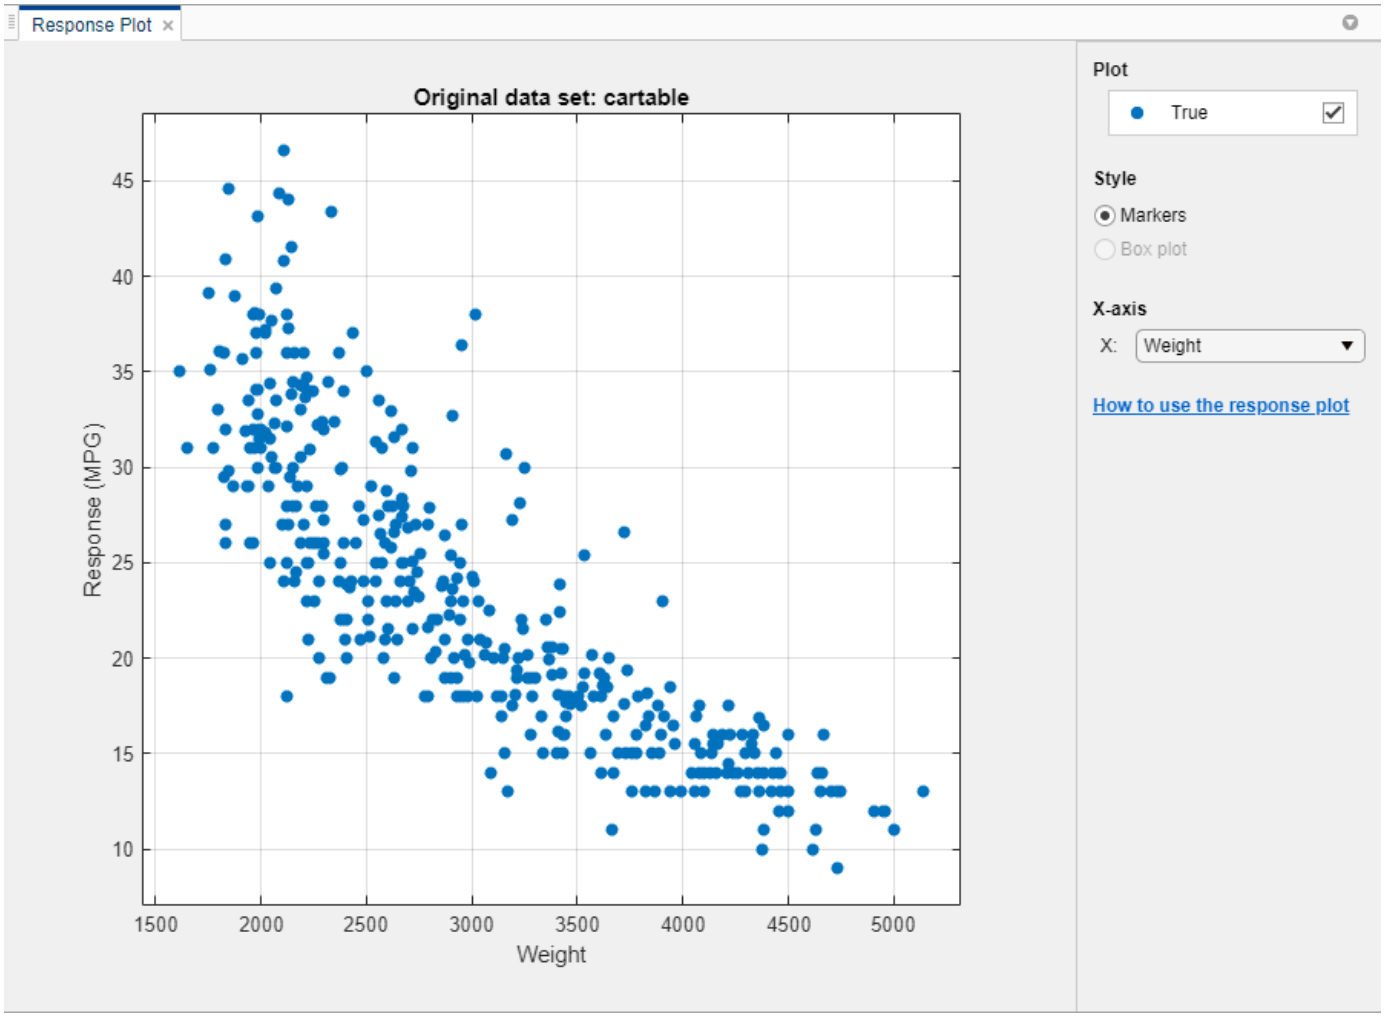
    
- Copy, save, or customize the new figure, which is displayed in the figure window.
  - To copy the figure, select **Edit > Copy Figure**. For more information, see “Copy Figure to Clipboard from Edit Menu”.
  - To save the figure, select **File > Save As**. Alternatively, you can follow the workflow described in “Customize Figure Before Saving”.
  - To customize the figure, click the Edit Plot button  on the figure toolbar. Right-click the section of the plot that you want to edit. You can change the listed properties, which might include **Color**, **Font**, **Line Style**, and other properties. Or, you can use the **Property Inspector** to change the figure properties.

As an example, export a response plot in the app to a figure, customize the figure, and save the modified figure.

1. In the MATLAB Command Window, load the `carbig` data set.

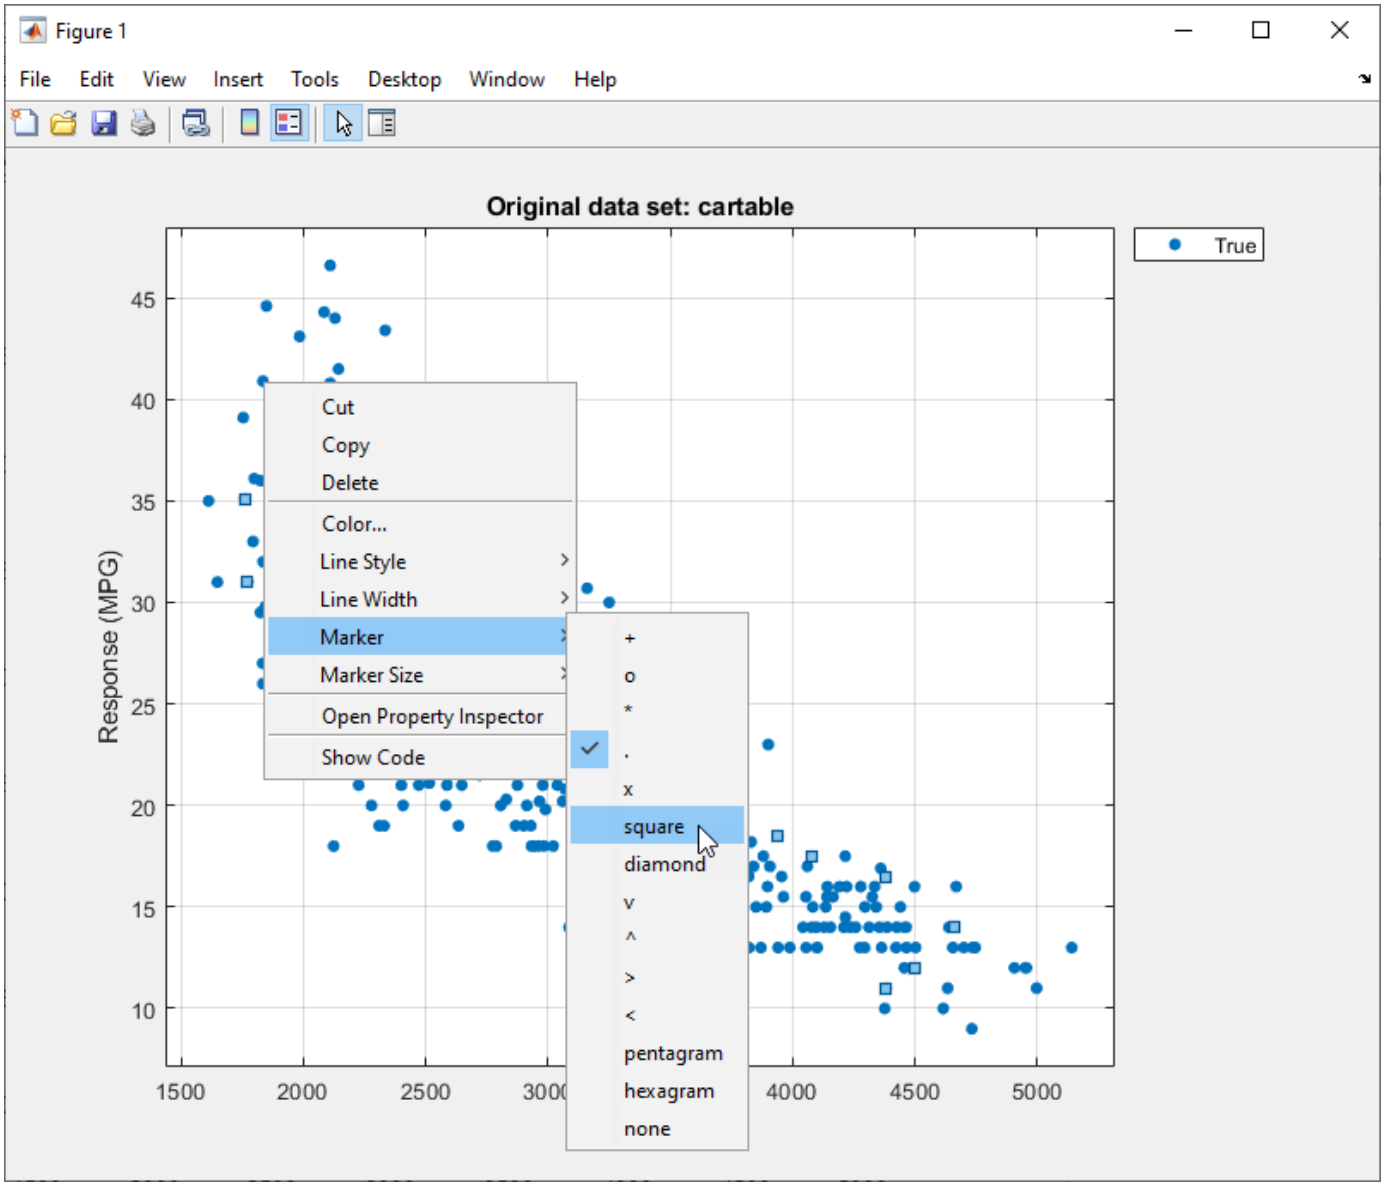
   ```
   load carbig
   cartable = table(Acceleration,Cylinders,Displacement, ...
       Horsepower,Model_Year,Weight,Origin,MPG);
   ```
2. Click the **Apps** tab.
3. In the **Apps** section, click the arrow to open the gallery. Under **Machine Learning and Deep Learning**, click **Regression Learner**.
4. On the **Regression Learner** tab, in the **File** section, click  .
5. In the New Session from Workspace dialog box, select the table `cartable` from the **Workspace Variable** list.
6. Click **Start Session**. Regression Learner creates a response plot of the data by default.

7 Change the x-axis data in the response plot to `Weight`.



8 On the **Regression Learner** tab, in the **Export** section, click **Export Plot to Figure**.

9 In the new figure, click the Edit Plot button on the figure toolbar. Right-click the points in the plot. In the context menu, select **Marker > square**.



10 To save the figure, select **File** > **Save As**. Specify the saved file location, name, and type.

Export Regression Model to Predict New Data

In this section...

Export Model to Workspace

After you create regression models interactively in the Regression Learner app, you can export your best model to the workspace. Then you can use that trained model to make predictions using new data.

Note The final model Regression Learner exports is always trained using the full data set. The validation scheme that you use only affects the way that the app computes validation metrics. You can use the validation metrics and various plots that visualize results to pick the best model for your regression problem.

Here are the steps for exporting a model to the MATLAB workspace:

1. In the app, select the model you want to export in the **Models** pane.
2. On the **Regression Learner** tab, in the **Export** section, click one of the export options:
   - To include the data used for training the model, select **Export Model**.

     You export the trained model to the workspace as a structure containing a regression model object.
   - To exclude the training data, select **Export Compact Model**. This option exports the model with unnecessary data removed where possible. For some models this is a compact object that does not include the training data, but you can still use it for making predictions on new data.
3. In the Export Model dialog box, check the name of your exported variable, and edit it if you want. Then, click **OK**. The default name for your exported model, `trainedModel`, increments every time you export to avoid overwriting your models (for example, `trainedModel1`).

   The new variable (for example, `trainedModel`) appears in your workspace.

   The app displays information about the exported model in the command window. Read the message to learn how to make predictions with new data.

Make Predictions for New Data

After you export a model to the workspace from Regression Learner, or run the code generated from the app, you get a `trainedModel` structure that you can use to make predictions using new data. The structure contains a model object and a function for prediction. The structure enables you to make predictions for models that include principal component analysis (PCA).

1. Use the exported model to make predictions for new data, `T`:

   ```
   yfit = trainedModel.predictFcn(T)
   ```

   where `trainedModel` is the name of your exported variable.

   Supply the data `T` with the same format and data type as the training data used in the app (table or matrix).

   - If you supply a table, then ensure that it contains the same predictor names as your training data. The `predictFcn` ignores additional variables in tables. Variable formats and types must match the original training data.
   - If you supply a matrix, it must contain the same predictor columns or rows as your training data, in the same order and format. Do not include a response variable, any variables that you did not import in the app, or other unused variables.

   The output `yfit` contains a prediction for each data point.

2. Examine the fields of the exported structure. For help making predictions, enter:

   ```
   trainedModel.HowToPredict
   ```

You also can extract the model object from the exported structure for further analysis. If you use feature transformation such as PCA in the app, you must take into account this transformation by using the information in the PCA fields of the structure.

Generate MATLAB Code to Train Model with New Data

After you create regression models interactively in the Regression Learner app, you can generate MATLAB code for your best model. Then you can use the code to train the model with new data.

Generate MATLAB code to:

- Train on huge data sets. Explore models in the app trained on a subset of your data, and then generate code to train a selected model on a larger data set.
- Create scripts for training models without needing to learn syntax of the different functions.
- Examine the code to learn how to train models programmatically.
- Modify the code for further analysis, for example to set options that you cannot change in the app.
- Repeat your analysis on different data and automate training.

To generate code and use it to train a model with new data:

1. In the app, from the **Models** pane, select the model you want to generate code for.
2. On the **Regression Learner** tab, in the **Export** section, click **Generate Function**.

   The app generates code from your session and displays the file in the MATLAB Editor. The file includes the predictors and response, the model training methods, and the validation methods. Save the file.
3. To retrain your model, call the function from the command line with your original data or new data as the input argument or arguments. New data must have the same shape as the original data.

Copy the first line of the generated code, excluding the word `function`, and edit the `trainingData` input argument to reflect the variable name of your training data or new data. Similarly, edit the `responseData` input argument (if applicable).

For example, to retrain a regression model trained with the `cartable` data set, enter:

```
[trainedModel,validationRMSE] = trainRegressionModel(cartable)
```

The generated code returns a `trainedModel` structure that contains the same fields as the structure you create when you export a model from Regression Learner to the workspace.

If you want to automate training the same model with new data, or learn how to programmatically train models, examine the generated code. The code shows you how to:

- Process the data into the right shape.
- Train a model and specify all the model options.
- Perform cross-validation.
- Compute statistics.
- Compute validation predictions and scores.

Note If you generate MATLAB code from a trained optimizable model, the generated code does not include the optimization process.

Generate C Code for Prediction

If you train one of the models in this table using Regression Learner, you can generate C code for prediction.

Model Type	Underlying Model Object
Linear Regression	`LinearModel` or `CompactLinearModel`
Decision Tree	`RegressionTree` or `CompactRegressionTree`
Support Vector Machine	`RegressionSVM` or `CompactRegressionSVM`
Gaussian Process Regression	`RegressionGP` or `CompactRegressionGP`
Ensemble	`RegressionEnsemble`, `CompactRegressionEnsemble`, or `RegressionBaggedEnsemble`

C code generation requires:

- MATLAB Coder license
- Appropriate model

1 For example, train a tree model in Regression Learner, and then export the model to the workspace.

Find the underlying regression model object in the exported structure. Examine the fields of the structure to find the model object, for example, `S.RegressionTree`, where `S` is the name of your structure.

The underlying model object depends on whether you exported a compact model. The model object can be a `RegressionTree` or `CompactRegressionTree` object.

2. Use the function `saveLearnerForCoder` to prepare the model for code generation: `saveLearnerForCoder(Mdl,filename)`. For example:

```
saveLearnerForCoder(S.RegressionTree,'myTree')
```

3. Create a function that loads the saved model and makes predictions on new data. For example:

```
function yfit = predictY (X) %#codegen
%PREDICTY Predict responses using tree model
%  PREDICTY uses the measurements in X
%  and the tree model in the file myTree.mat, and then
%  returns predicted responses in yfit.

CompactMdl = loadLearnerForCoder('myTree');
yfit = predict(CompactMdl,X);
end
```

4. Generate a MEX function from your function. For example:

```
codegen predictY.m -args {data}
```

The `%#codegen` compilation directive indicates that the MATLAB code is intended for code generation. To ensure that the MEX function can use the same input, specify the data in the workspace as arguments to the function using the `-args` option. Specify `data` as a matrix containing only the predictor columns used to train the model.

5. Use the MEX function to make predictions. For example:

```
yfit = predictY_mex(data);
```

If you used feature selection or PCA feature transformation in the app, then you need to take additional steps. If you used manual feature selection, supply the same columns in `X`. The `X` argument is the input to your function.

If you used PCA in the app, use the information in the PCA fields of the exported structure to take account of this transformation. It does not matter whether you imported a table or a matrix into the app, as long as `X` contains the matrix columns in the same order. Before generating code, follow these steps:

1. Save the PCACenters and PCACoefficients fields of the trained regression structure, `S`, to file using the following command:

```
save('pcaInfo.mat','-struct','S','PCACenters','PCACoefficients');
```

2. In your function file, include additional lines to perform the PCA transformation. Create a function that loads the saved model, performs PCA, and makes predictions on new data. For example:

```
function yfit = predictY (X) %#codegen
%PREDICTY Predict responses using tree model
%  PREDICTY uses the measurements in X
%  and the tree model in the file myTree.mat,
%  and then returns predicted responses in yfit.
% If you used manual feature selection in the app, ensure that X
% contains only the columns you included in the model.

CompactMdl = loadLearnerForCoder('myTree');
```

```
pcaInfo = coder.load('pcaInfo.mat','PCACenters','PCACoefficients');
PCACenters = pcaInfo.PCACenters;
PCACoefficients = pcaInfo.PCACoefficients;

% Performs PCA transformation
pcaTransformedX = bsxfun(@minus,X,PCACenters)*PCACoefficients;

yfit = predict(CompactMdl,pcaTransformedX);
end
```

For more information on the C code generation workflow and limitations, see “Code Generation”. For examples, see `saveLearnerForCoder` and `loadLearnerForCoder`.

Deploy Predictions Using MATLAB Compiler

After you export a model to the workspace from Regression Learner, you can deploy it using MATLAB Compiler.

Suppose you export the trained model to MATLAB Workspace based on the instructions in “Export Model to Workspace” on page 24-54, with the name `trainedModel`. To deploy predictions, follow these steps.

- Save the `trainedModel` structure in a .mat file.

  ```
  save mymodel trainedModel
  ```

- Write the code to be compiled. This code must load the trained model and use it to make a prediction. It must also have a pragma, so the compiler recognizes that Statistics and Machine Learning Toolbox code is needed in the compiled application. This pragma could be any function in the toolbox.

  ```
  function ypred = mypredict(tbl)
  %#function fitrtree
  load('mymodel.mat');
  ypred = trainedModel.predictFcn(tbl);
  end
  ```

- Compile as a standalone application.

  ```
  mcc -m mypredict.m
  ```

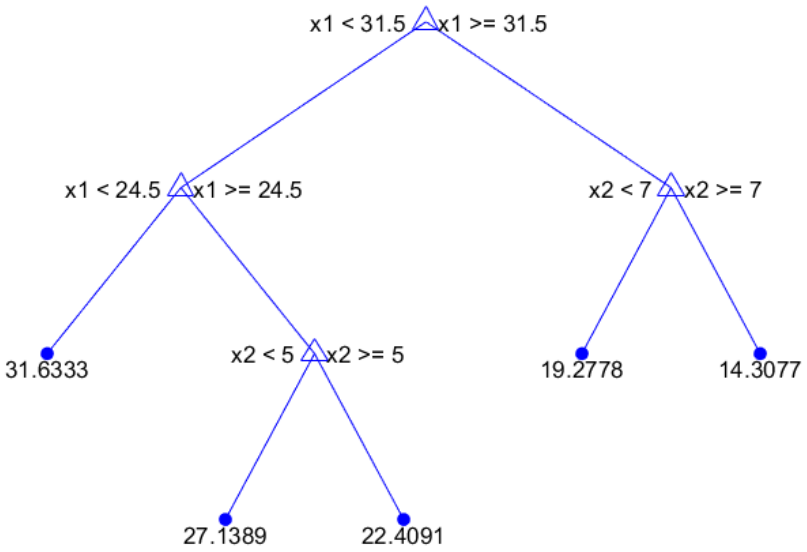
Train Regression Trees Using Regression Learner App

This example shows how to create and compare various regression trees using the Regression Learner app, and export trained models to the workspace to make predictions for new data.

You can train regression trees to predict responses to given input data. To predict the response of a regression tree, follow the tree from the root (beginning) node down to a leaf node. At each node, decide which branch to follow using the rule associated to that node. Continue until you arrive at a leaf node. The predicted response is the value associated to that leaf node.

Statistics and Machine Learning Toolbox trees are binary. Each step in a prediction involves checking the value of one predictor variable. For example, here is a simple regression tree:



This tree predicts the response based on two predictors, `x1` and `x2`. To predict, start at the top node. At each node, check the values of the predictors to decide which branch to follow. When the branches reach a leaf node, the response is set to the value corresponding to that node.

This example uses the `carbig` data set. This data set contains characteristics of different car models produced from 1970 through 1982, including:

- Acceleration
- Number of cylinders
- Engine displacement
- Engine power (Horsepower)
- Model year
- Weight
- Country of origin
- Miles per gallon (MPG)

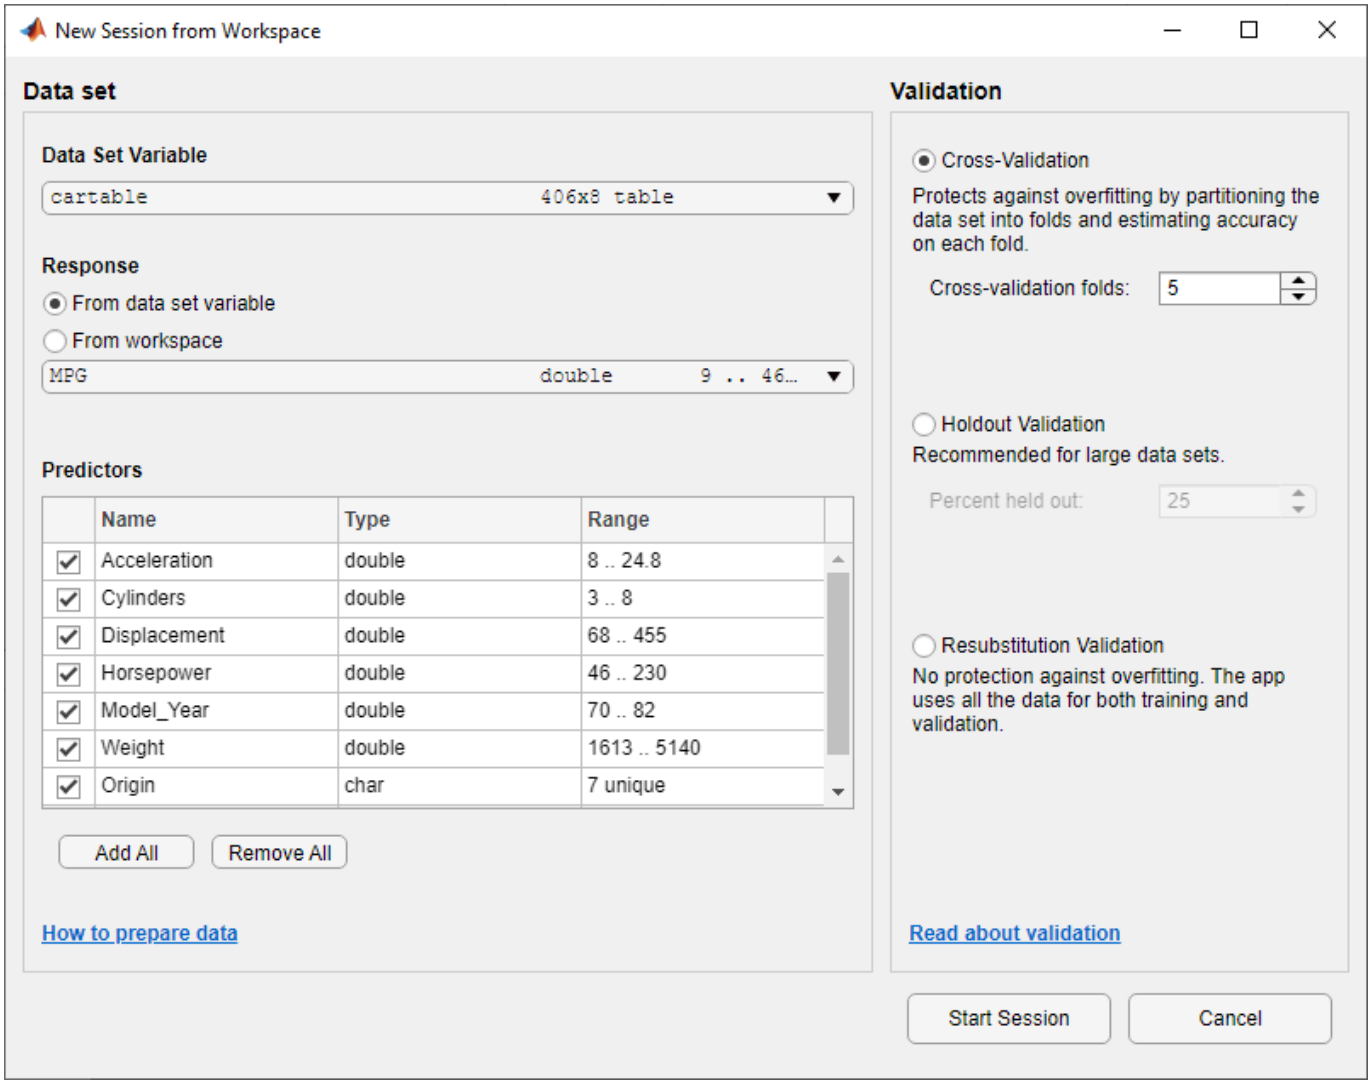
Train regression trees to predict the fuel economy in miles per gallon of a car model, given the other variables as inputs.

1. In MATLAB, load the `carbig` data set and create a table containing the different variables:

   ```
   load carbig
   cartable = table(Acceleration, Cylinders, Displacement,...
   Horsepower, Model_Year, Weight, Origin, MPG);
   ```

2. On the **Apps** tab, in the **Machine Learning and Deep Learning** group, click **Regression Learner**.
3. On the **Regression Learner** tab, in the **File** section, select **New Session > From Workspace**.
4. Under **Data Set Variable** in the New Session from Workspace dialog box, select `cartable` from the list of tables and matrices in your workspace.

   Observe that the app has preselected response and predictor variables. `MPG` is chosen as the response, and all the other variables as predictors. For this example, do not change the selections.

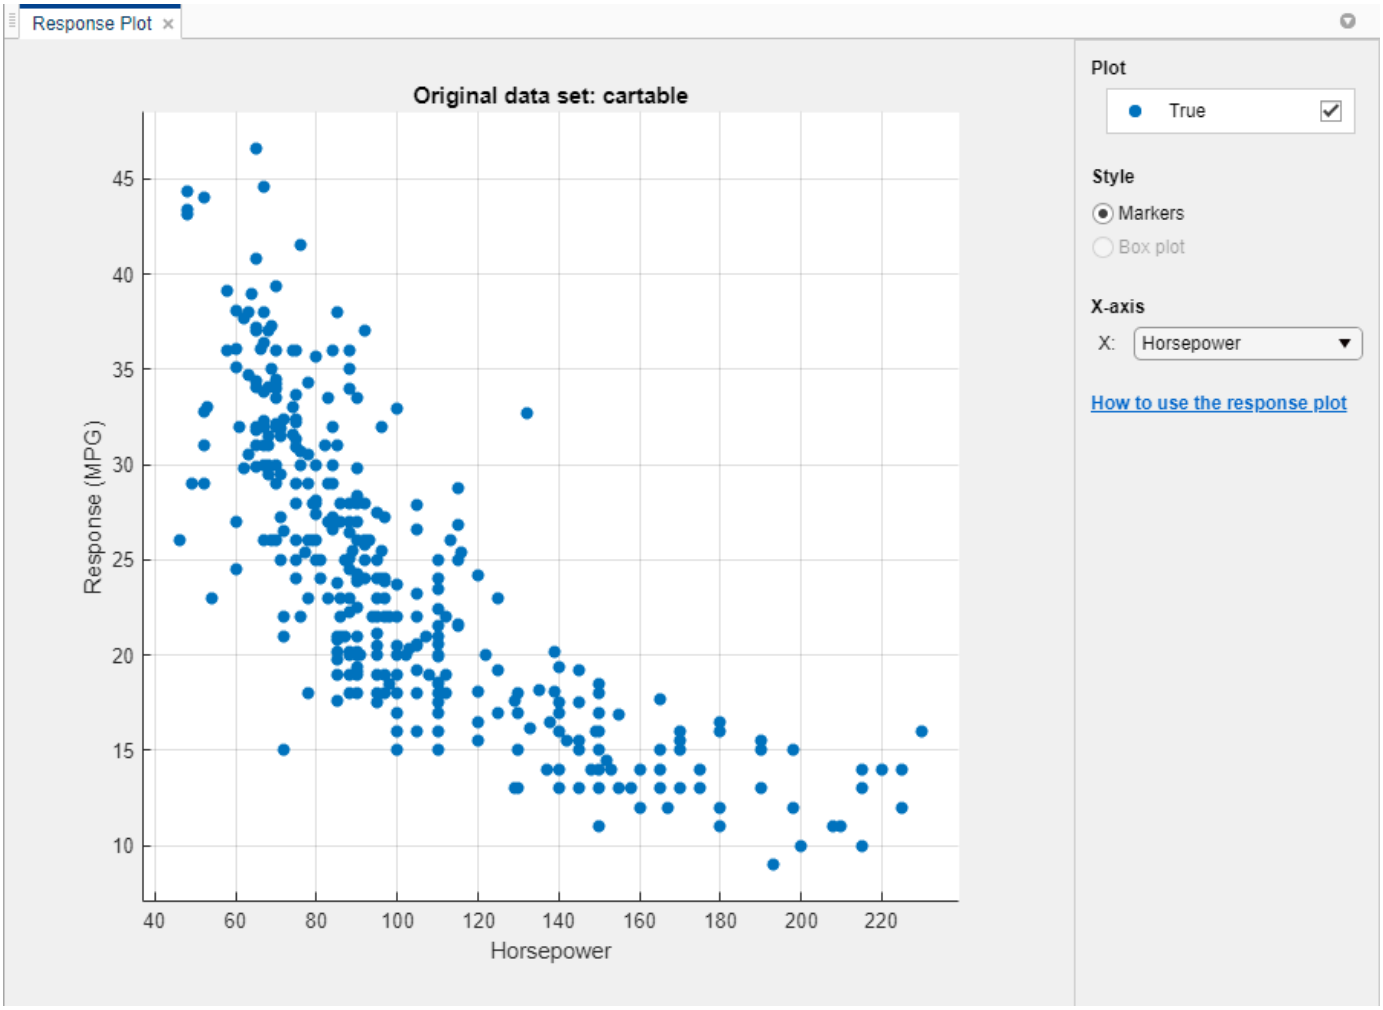


5 To accept the default validation scheme and continue, click **Start Session**. The default validation option is cross-validation, to protect against overfitting.

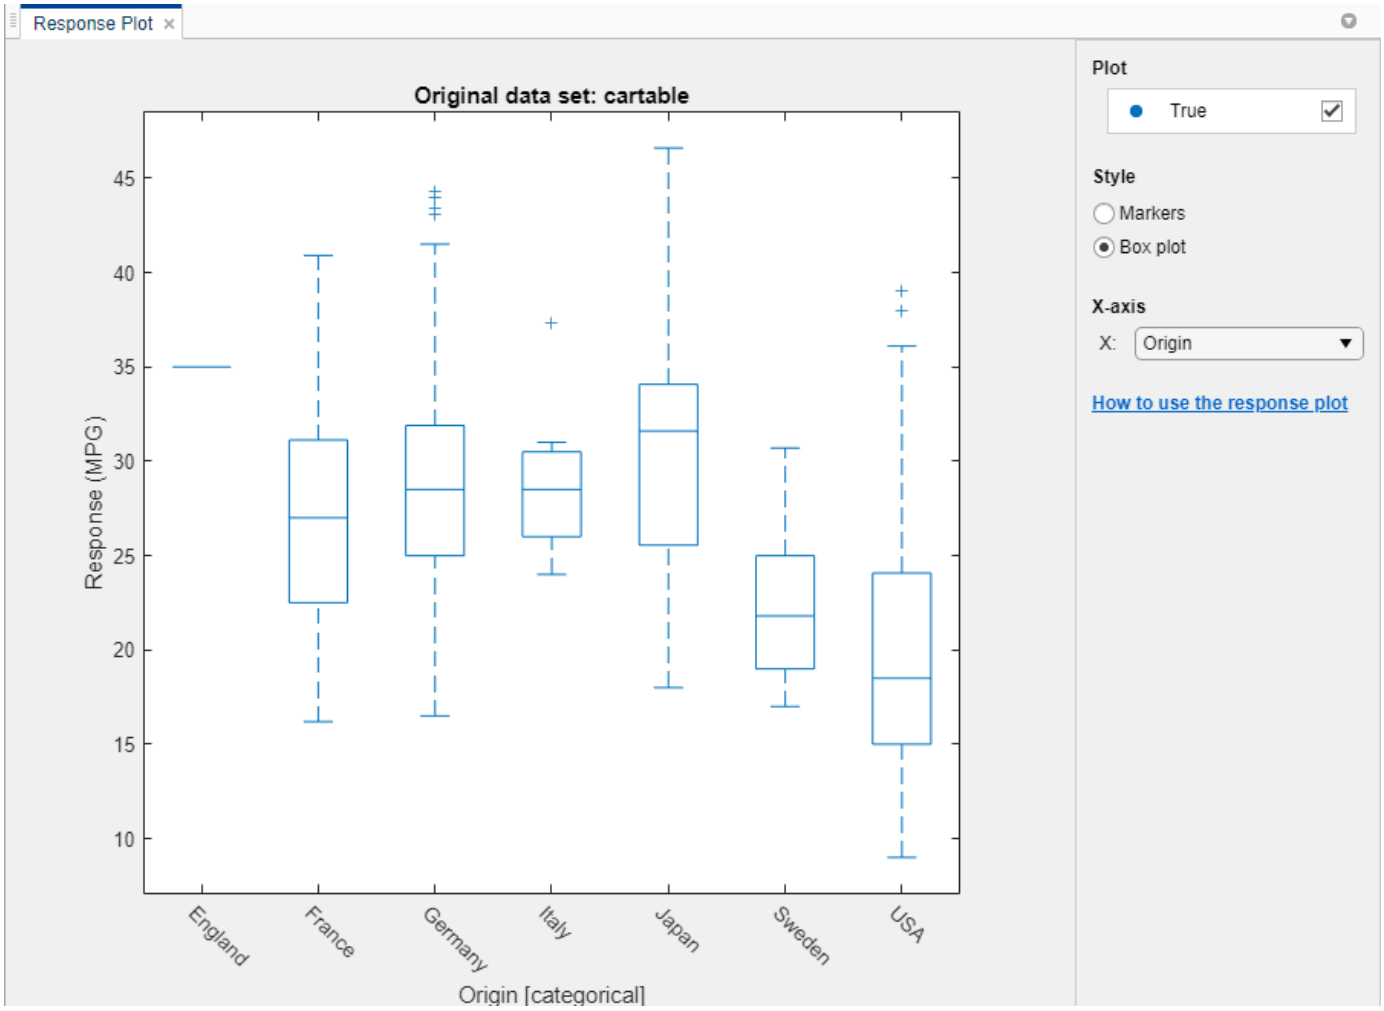
Regression Learner creates a plot of the response with the record number on the *x*-axis.

6 Use the response plot to investigate which variables are useful for predicting the response. To visualize the relation between different predictors and the response, select different variables in the **X** list under **X-axis**.

Observe which variables are correlated most clearly with the response. `Displacement`, `Horsepower`, and `Weight` all have a clearly visible impact on the response and all show a negative association with the response.



7 Select the variable `Origin` under **X-axis**. A box plot is automatically displayed. A box plot shows the typical values of the response and any possible outliers. The box plot is useful when plotting markers results in many points overlapping. To show a box plot when the variable on the *x*-axis has few unique values, under **Style**, select **Box plot**.



8 Create a selection of regression trees. On the **Regression Learner** tab, in the **Model Type** section, click **All Trees**  .

Then click **Train** 
.

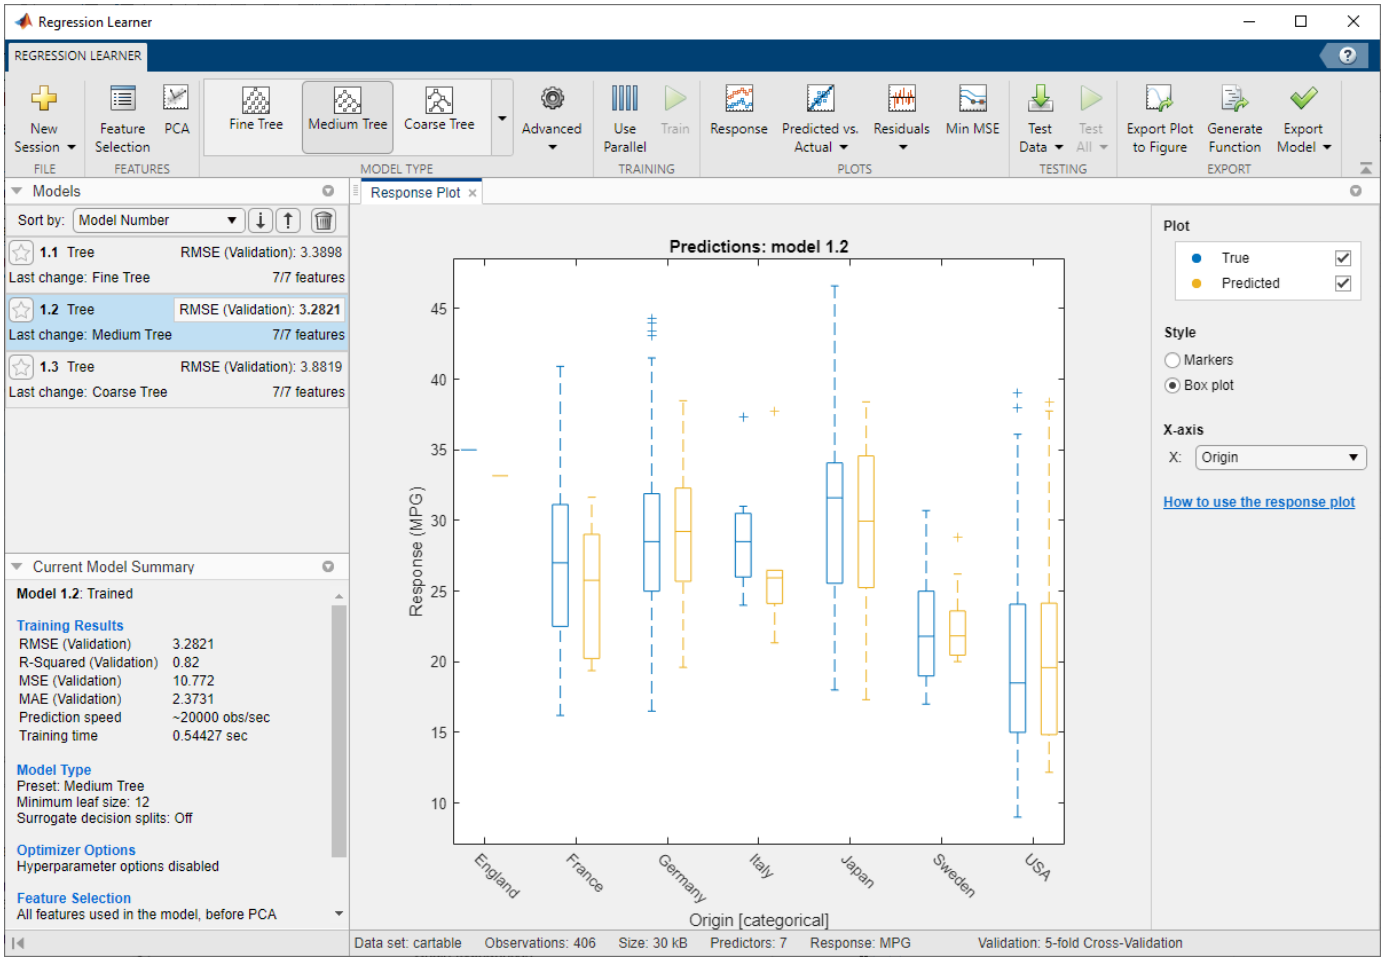
Tip If you have Parallel Computing Toolbox, you can train all the models (**All Trees**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.

Regression Learner creates and trains three regression trees: a **Fine Tree**, a **Medium Tree**, and a **Coarse Tree**.

The three models appear in the **Models** pane. Check the **RMSE (Validation)** (validation root mean square error) of the models. The best score is highlighted in a box.

The **Fine Tree** and the **Medium Tree** have similar RMSEs, while the **Coarse Tree** is less accurate.

Regression Learner plots both the true training response and the predicted response of the currently selected model.

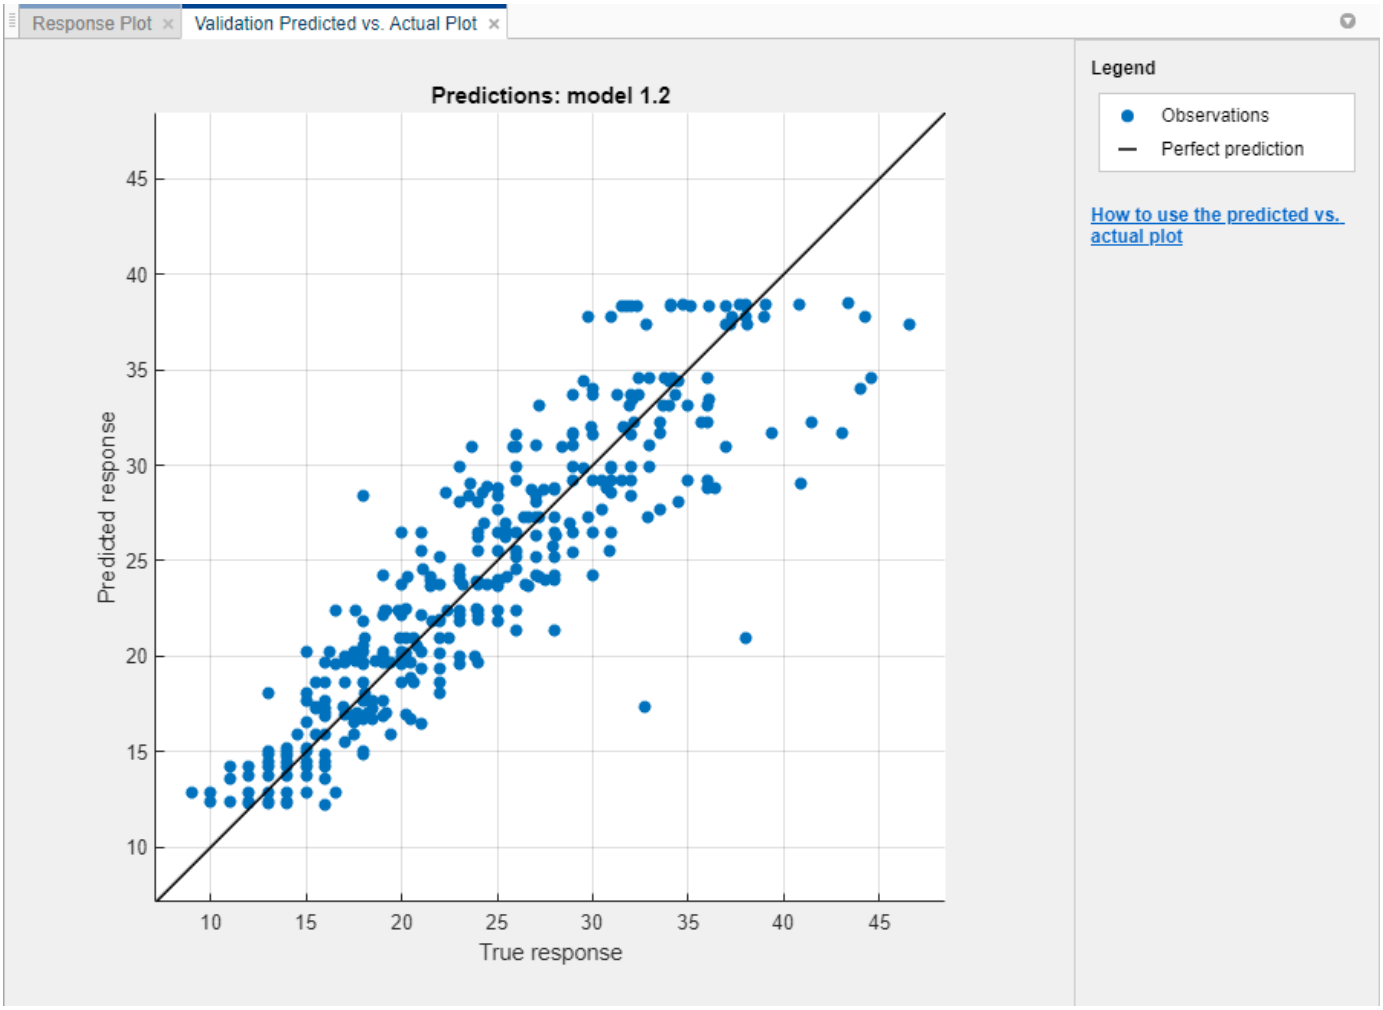


Note If you are using validation, there is some randomness in the results and so your model validation score can differ from the results shown.

9 Choose a model in the **Models** pane to view the results of that model. Under **X-axis**, select `Horsepower` and examine the response plot. Both the true and predicted responses are now plotted. Show the prediction errors, drawn as vertical lines between the predicted and true responses, by selecting the **Errors** check box.

10 See more details on the currently selected model in the **Current Model Summary** pane. Check and compare additional model characteristics, such as R-squared (coefficient of determination), MAE (mean absolute error), and prediction speed. To learn more, see “View and Compare Model Statistics” on page 24-43. In the **Current Model Summary** pane, you also can find details on the currently selected model type, such as options used for training the model.

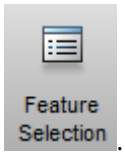
11 Plot the predicted response versus true response. On the **Regression Learner** tab, in the **Plots** section, click **Predicted vs. Actual** and select **Validation Data**. Use this plot to understand how well the regression model makes predictions for different response values.



A perfect regression model has predicted response equal to true response, so all the points lie on a diagonal line. The vertical distance from the line to any point is the error of the prediction for that point. A good model has small errors, so the predictions are scattered near the line. Usually a good model has points scattered roughly symmetrically around the diagonal line. If you can see any clear patterns in the plot, it is likely that you can improve your model.

12 Select the other models in the **Models** pane and compare the predicted versus actual plots.

13 In the **Model Type** gallery, select **All Trees** again. To try to improve the model, try including different features in the model. See if you can improve the model by removing features with low predictive power. On the **Regression Learner** tab, in the **Features** section, click **Feature Selection**.



In the Feature Selection dialog box, clear the check boxes for **Acceleration** and **Cylinders** to exclude them from the predictors.

Click **Train** 
to train new regression trees using the new predictor settings.

14 Observe the new models in the **Models** pane. These models are the same regression trees as before, but trained using only five of seven predictors. The app displays how many predictors are used. To check which predictors are used, click a model in the **Models** pane and observe the check boxes in the Feature Selection dialog box.

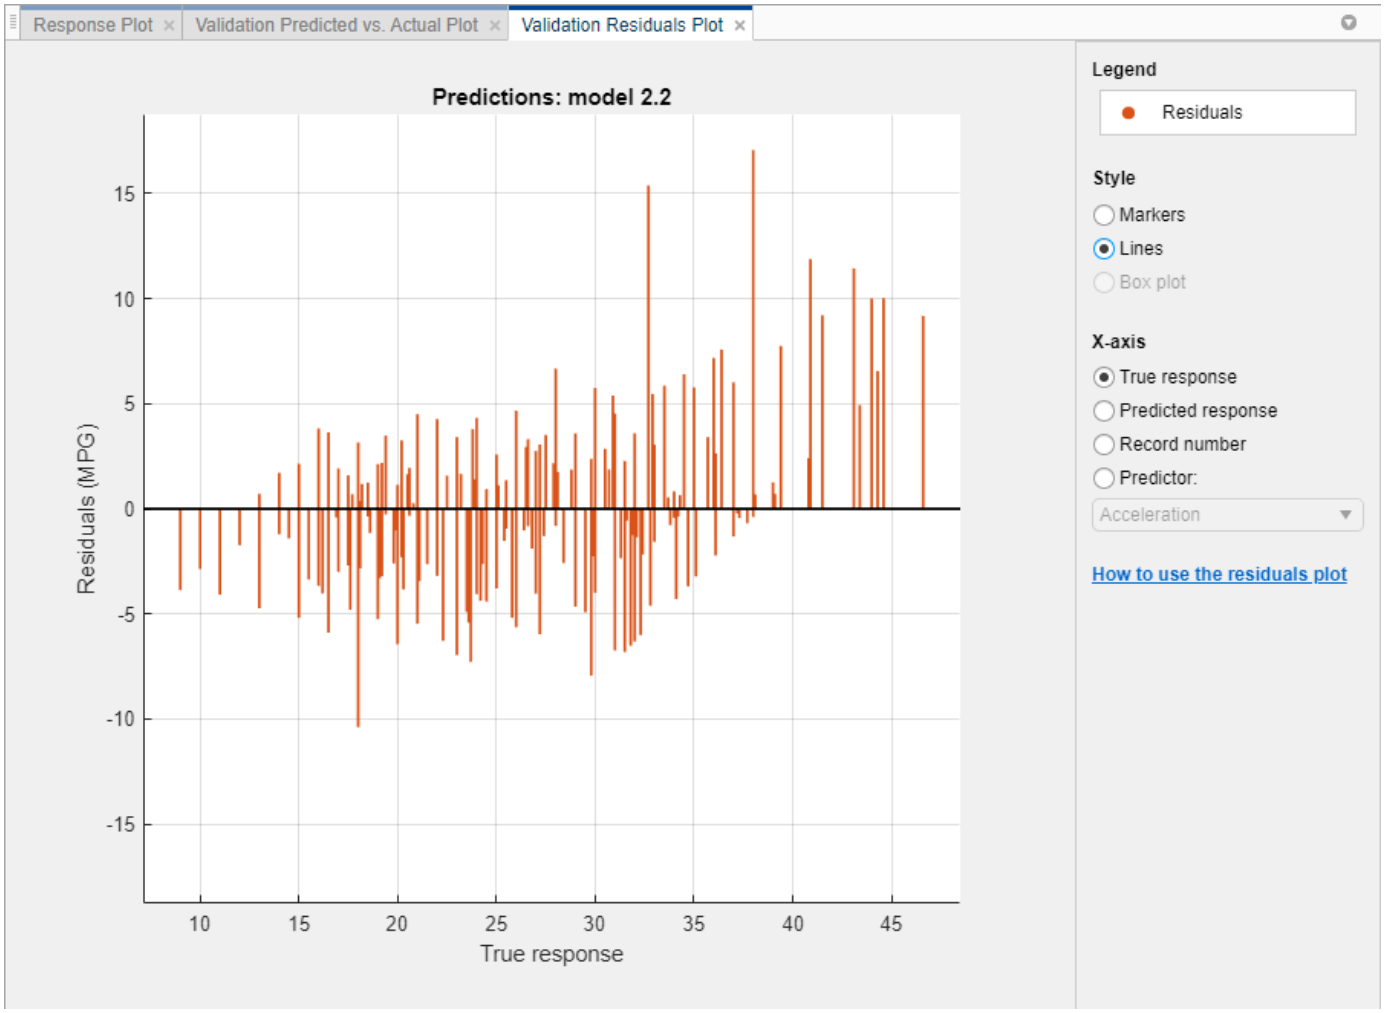
The models with the two features removed perform comparably to the models using all predictors. The models predict no better using all the predictors compared to using only a subset of the predictors. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily without some predictors.

15 Train the three regression tree presets using only `Horsepower` as predictor. Change the selections in the Feature Selection dialog box and click **Train**.

Using only the engine power as predictor results in models with lower accuracy. However, the models perform well given that they are using only a single predictor. With this simple one-dimensional predictor space, the coarse tree now performs as well as the medium and fine trees.

16 Select the best model in the **Models** pane and view the residuals plot. On the **Regression Learner** tab, in the **Plots** section, click **Residuals** and select **Validation Data**. The residuals plot displays the difference between the predicted and true responses. To display the residuals as a line graph, in the **Style** section, choose **Lines**.

Under **X-axis**, select the variable to plot on the *x*-axis. Choose either the true response, predicted response, record number, or one of your predictors.



Usually a good model has residuals scattered roughly symmetrically around 0. If you can see any clear patterns in the residuals, it is likely that you can improve your model.

17 To learn about model settings, choose the best model in the **Models** pane and view the advanced settings. The nonoptimizable model options in the **Model Type** gallery are preset starting points, and you can change additional settings. On the **Regression Learner** tab, in the **Model Type** section, click **Advanced**. Compare the different regression tree models in the **Models** pane, and observe the differences in the Advanced Regression Tree Options dialog box. The **Minimum leaf size** setting controls the size of the tree leaves, and through that the size and depth of the regression tree.

To try to improve the model further, change the **Minimum leaf size** setting to 8, and then train a new model by clicking **Train**.

View the settings for the selected trained model in the **Current Model Summary** pane or in the Advanced Regression Tree Options dialog box.

To learn more about regression tree settings, see “Regression Trees” on page 24-16.

18 Export the selected model to the workspace. On the **Regression Learner** tab, in the **Export** section, click **Export Model**. In the Export Model dialog box, click **OK** to accept the default variable name `trainedModel`.

To see information about the results, look in the command window.

19 Use the exported model to make predictions on new data. For example, to make predictions for the `cartable` data in your workspace, enter:

```
yfit = trainedModel.predictFcn(cartable)
```

The output `yfit` contains the predicted response for each data point.

20 If you want to automate training the same model with new data or learn how to programmatically train regression models, you can generate code from the app. To generate code for the best trained model, on the **Regression Learner** tab, in the **Export** section, click **Generate Function**.

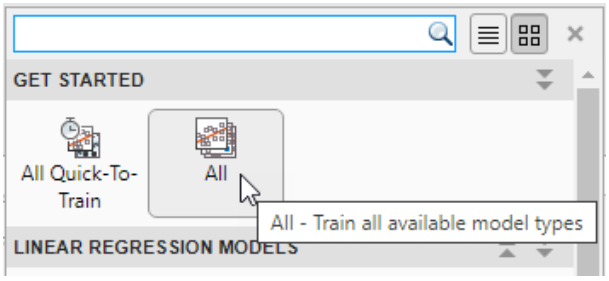
The app generates code from your model and displays the file in the MATLAB Editor. To learn more, see “Generate MATLAB Code to Train Model with New Data” on page 24-55.

Tip Use the same workflow as in this example to evaluate and compare the other regression model types you can train in Regression Learner.

Train all the nonoptimizable regression model presets available:

1 On the far right of the **Model Type** section, click the arrow to expand the list of regression models.

2 Click **All**  , and then click **Train**.



To learn about other regression model types, see “Train Regression Models in Regression Learner App” on page 24-2.

Train Regression Neural Networks Using Regression Learner App

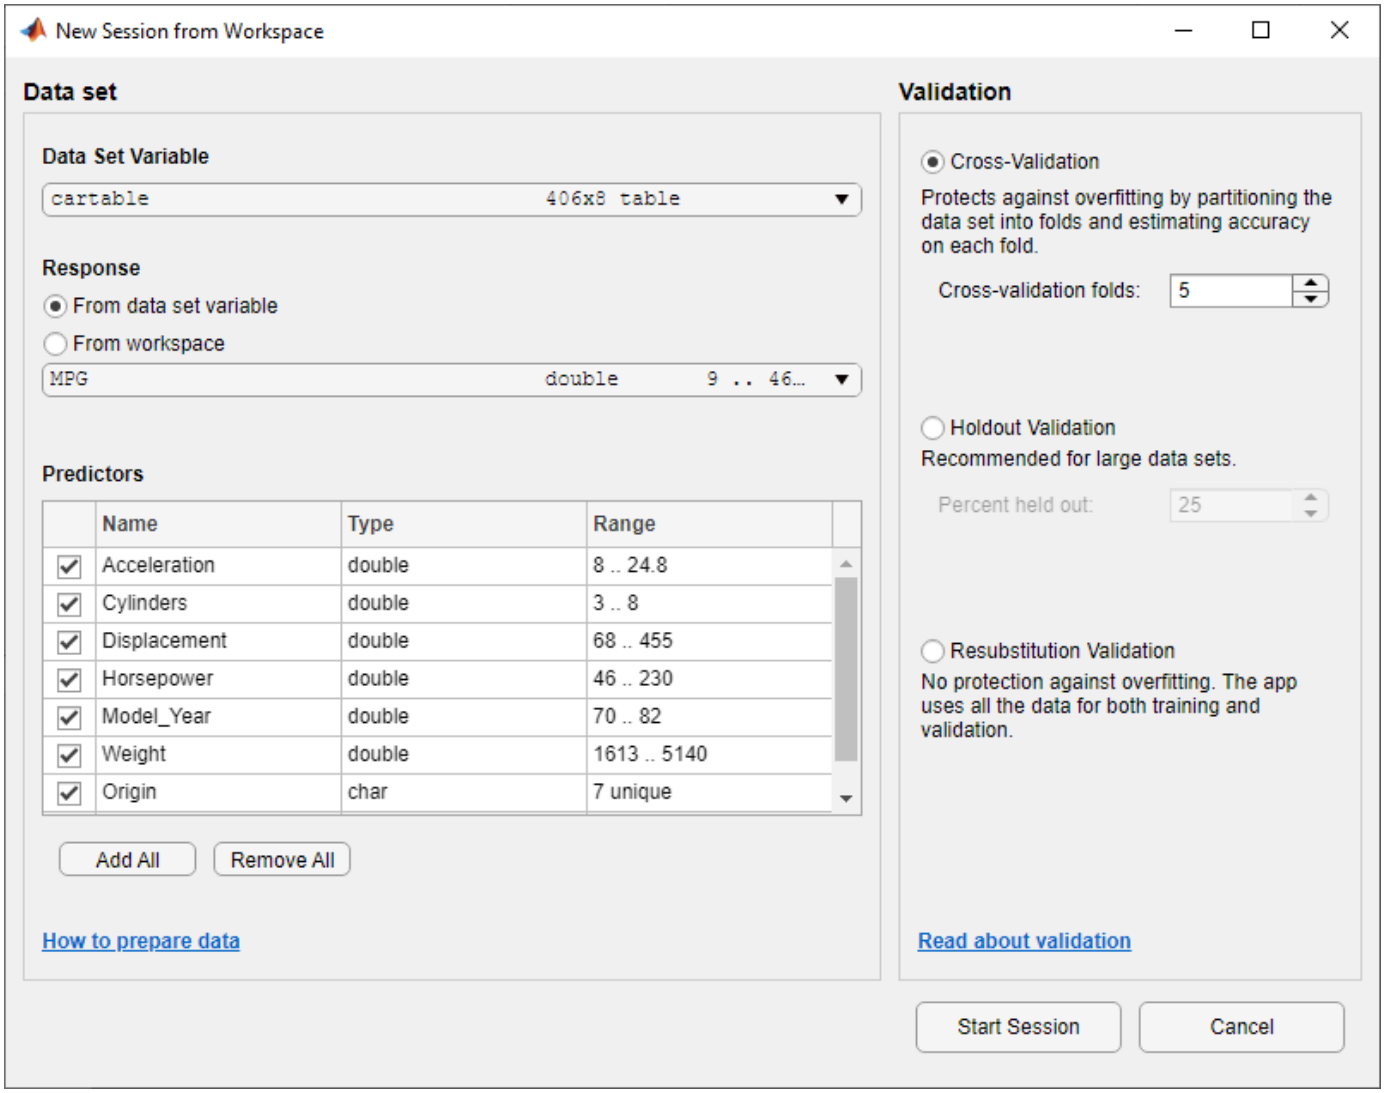
This example shows how to create and compare various regression neural network models using the Regression Learner app, and export trained models to the workspace to make predictions for new data.

1. In the MATLAB Command Window, load the `carbig` data set, and create a table containing the different variables.

   ```
   load carbig
   cartable = table(Acceleration,Cylinders,Displacement, ...
       Horsepower,Model_Year,Weight,Origin,MPG);
   ```

2. Click the **Apps** tab, and then click the **Show more** arrow on the right to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Regression Learner**.
3. On the **Regression Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.
4. In the New Session from Workspace dialog box, select the table `cartable` from the **Data Set Variable** list (if necessary).

   As shown in the dialog box, the app selects `MPG` as the response and the other variables as predictors. For this example, do not change the selections.



5 To accept the default validation scheme and continue, click **Start Session**. The default validation option is 5-fold cross-validation, to protect against overfitting.

   Regression Learner creates a plot of the response with the record number on the *x*-axis.

6 Use the response plot to investigate which variables are useful for predicting the response. To visualize the relation between different predictors and the response, select different variables in the **X** list under **X-axis**. Note which variables are correlated most clearly with the response.

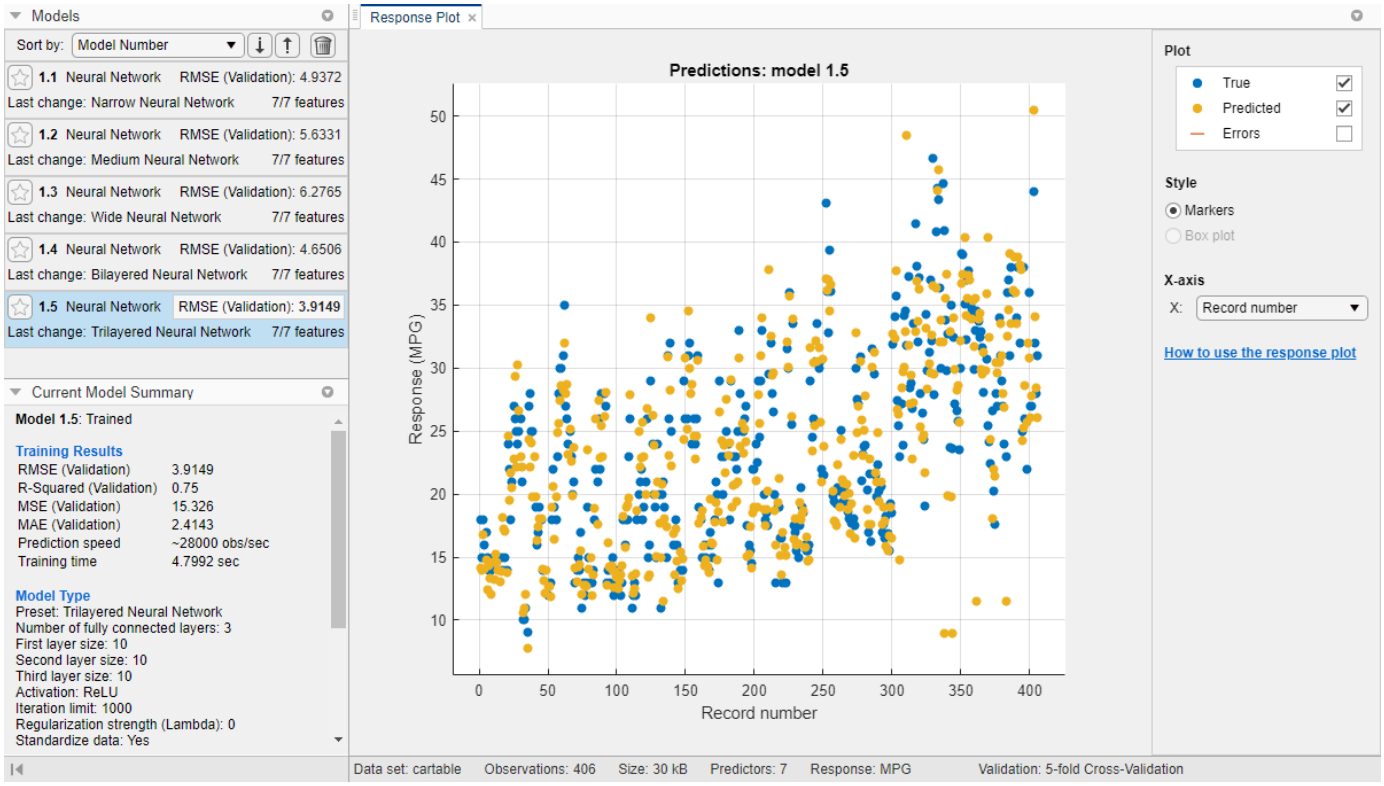
7 Create a selection of neural network models. On the **Regression Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Neural Networks** group, click **All Neural Networks**.

8 In the **Training** section, click **Train**. Regression Learner trains one of each neural network option in the gallery. In the **Models** pane, the app outlines the **RMSE (Validation)** (root mean squared error) of the best model.

   Tip If you have Parallel Computing Toolbox, you can train all the models (**All Neural Networks**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking

Train. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.

9 Select a model in the **Models** pane to view the results. Examine the response plot for the trained model. True responses are in blue, and predicted responses are in yellow.

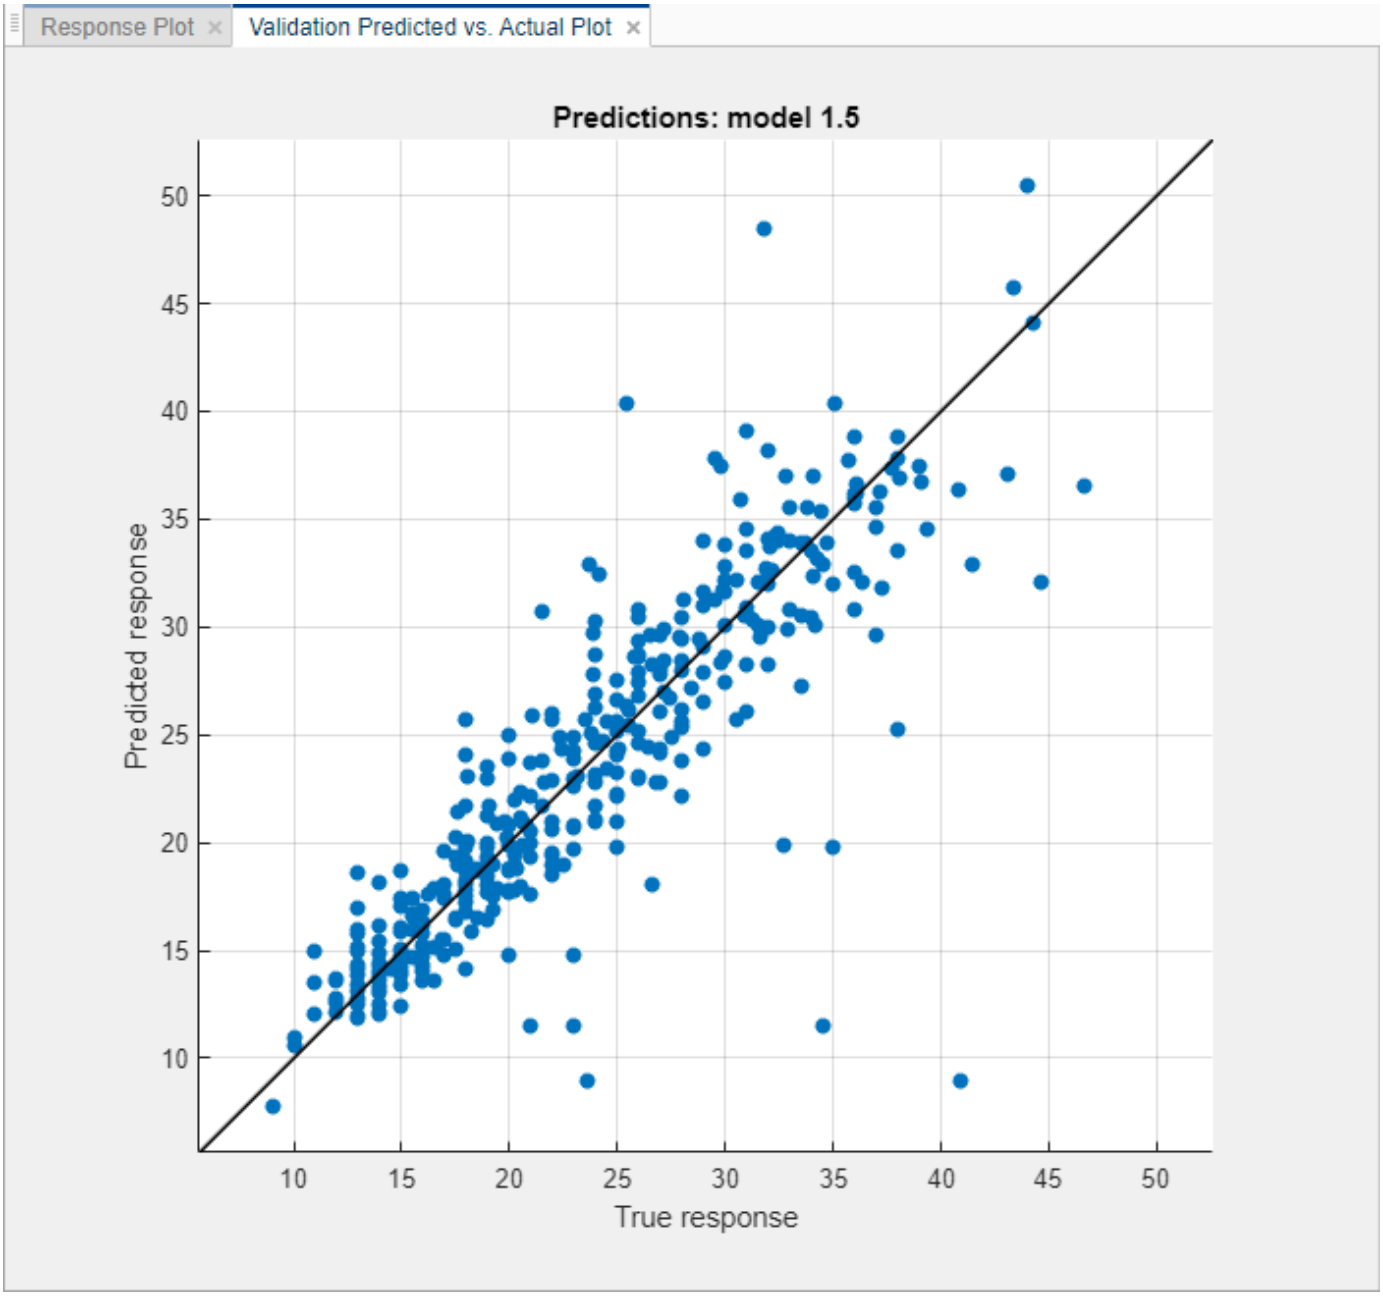


Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

10 Under **X-axis**, select `Horsepower` and examine the response plot. Both the true and predicted responses are now plotted. Show the prediction errors, drawn as vertical lines between the predicted and true responses, by selecting the **Errors** check box.

11 For more information on the currently selected model, consult the **Current Model Summary** pane. Check and compare additional model characteristics, such as R-squared (coefficient of determination), MAE (mean absolute error), and prediction speed. To learn more, see “View and Compare Model Statistics” on page 24-43. In the **Current Model Summary** pane, you can also find details on the currently selected model type, such as options used for training the model.

12 Plot the predicted response versus the true response. On the **Regression Learner** tab, in the **Plots** section, click **Predicted vs. Actual** and select **Validation Data**. Use this plot to determine how well the regression model makes predictions for different response values.



A perfect regression model has predicted responses equal to the true responses, so all the points lie on a diagonal line. The vertical distance from the line to any point is the error of the prediction for that point. A good model has small errors, so the predictions are scattered near the line. Typically, a good model has points scattered roughly symmetrically around the diagonal line. If you can see any clear patterns in the plot, you can most likely improve your model.

13 Select the other models in the **Models** pane and compare the predicted versus actual plots.

14 In the **Model Type** gallery, select **All Neural Networks** again. To try to improve the models, include different features. See if you can improve the models by removing features with low predictive power. On the **Regression Learner** tab, in the **Features** section, click **Feature Selection**.

In the Feature Selection dialog box, clear the check boxes for **Acceleration** and **Cylinders** to exclude them from the predictors.

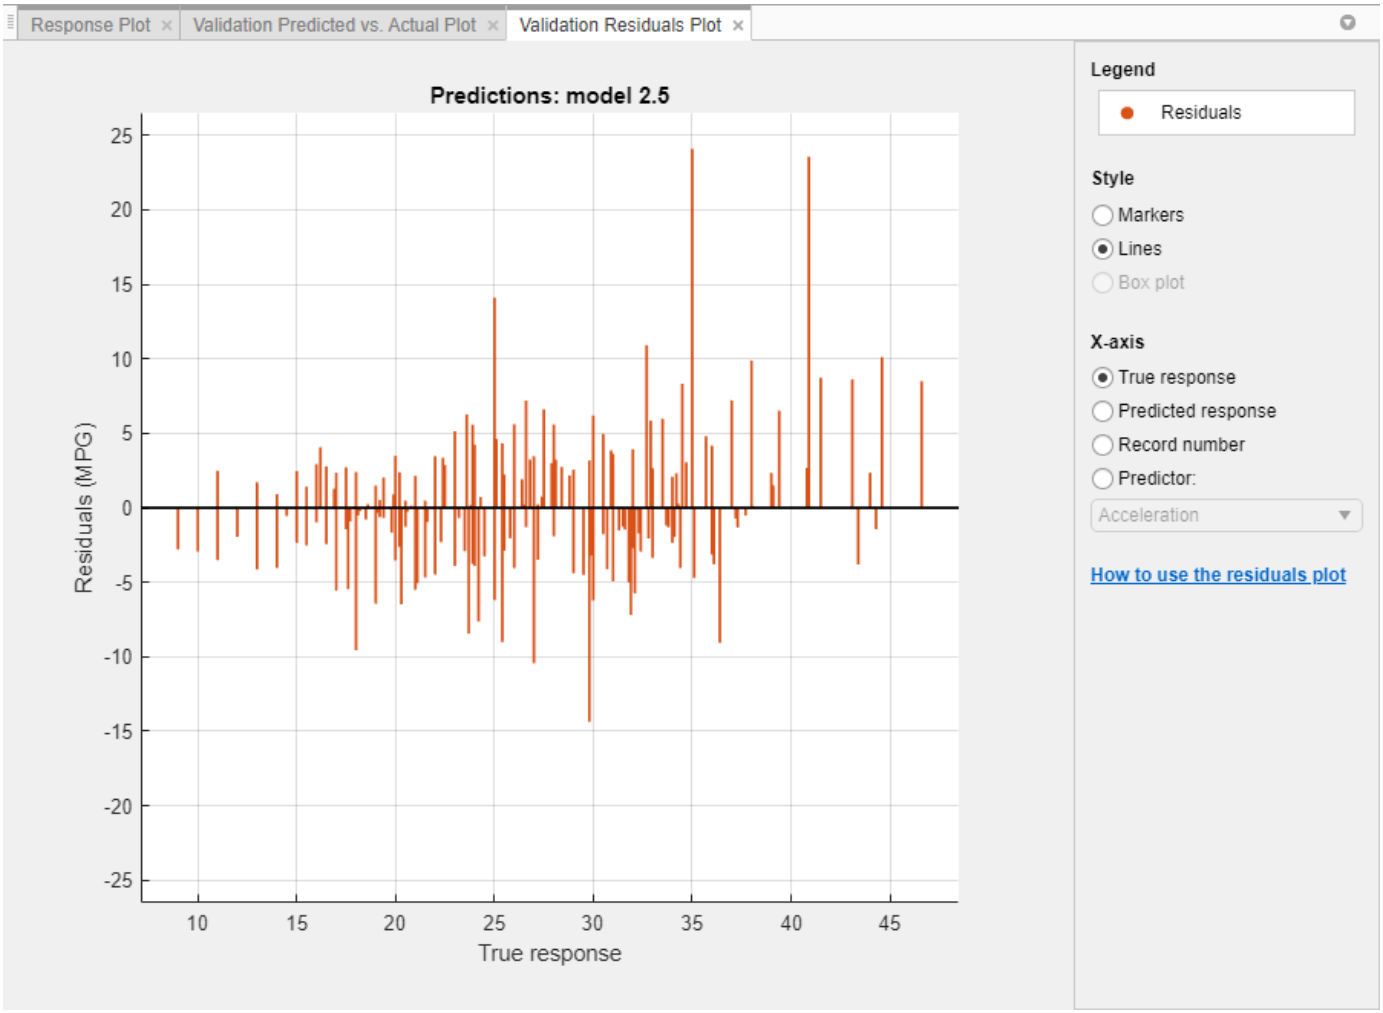
In the **Training** section, click **Train** to train the neural network models using the new predictor settings.

15 Observe the new models in the **Models** pane. These models are the same neural network models as before, but trained using only five of the seven predictors. For each model, the app displays how many predictors are used. To check which predictors are used, click a model in the **Models** pane and consult the **Feature Selection** section of the **Current Model Summary** pane.

The models with the two features removed perform comparably to the models with all predictors. The models predict no better using all the predictors compared to using only a subset of them. If data collection is expensive or difficult, you might prefer a model that performs satisfactorily without some predictors.

16 Select the best model in the **Models** pane and view the residuals plot. On the **Regression Learner** tab, in the **Plots** section, click **Residuals** and select **Validation Data**. The residuals plot displays the difference between the predicted and true responses. To display the residuals as a line graph, in the **Style** section, choose **Lines**.

Under **X-axis**, select the variable to plot on the *x*-axis. Choose the true response, predicted response, record number, or one of your predictors.



Typically, a good model has residuals scattered roughly symmetrically around 0. If you can see any clear patterns in the residuals, you can most likely improve your model.

17 You can try to further improve the best model in the **Models** pane by changing its advanced settings. On the **Regression Learner** tab, in the **Model Type** section, click **Advanced** and select **Advanced**. Try changing some of the settings, like the sizes of the fully connected layers or the regularization strength, and then train the new model by clicking **Train**.

To learn more about neural network model settings, see “Neural Networks” on page 24-24.

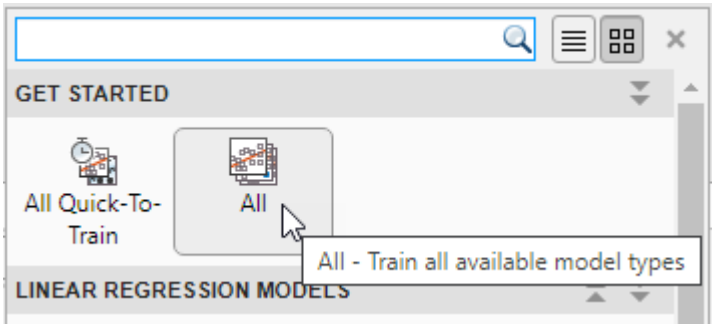
18 You can export a full or compact version of the trained model to the workspace. On the **Regression Learner** tab, in the **Export** section, click **Export Model** and select either **Export Model** or **Export Compact Model**. See “Export Regression Model to Predict New Data” on page 24-54.

19 To examine the code for training this model, click **Generate Function** in the **Export** section.

Tip Use the same workflow to evaluate and compare the other regression model types you can train in Regression Learner.

To train all the nonoptimizable regression model presets available for your data set:

1. On **Regression Learner** tab, in the **Model Type** section, click the arrow to open the gallery of regression models.
2. In the **Get Started** group, click **All**. Then, in the **Training** section, click **Train**.



To learn about other regression model types, see “Train Regression Models in Regression Learner App” on page 24-2.

Train Regression Model Using Hyperparameter Optimization in Regression Learner App

This example shows how to tune hyperparameters of a regression ensemble by using hyperparameter optimization in the Regression Learner app. Compare the test set performance of the trained optimizable ensemble to that of the best-performing preset ensemble model.

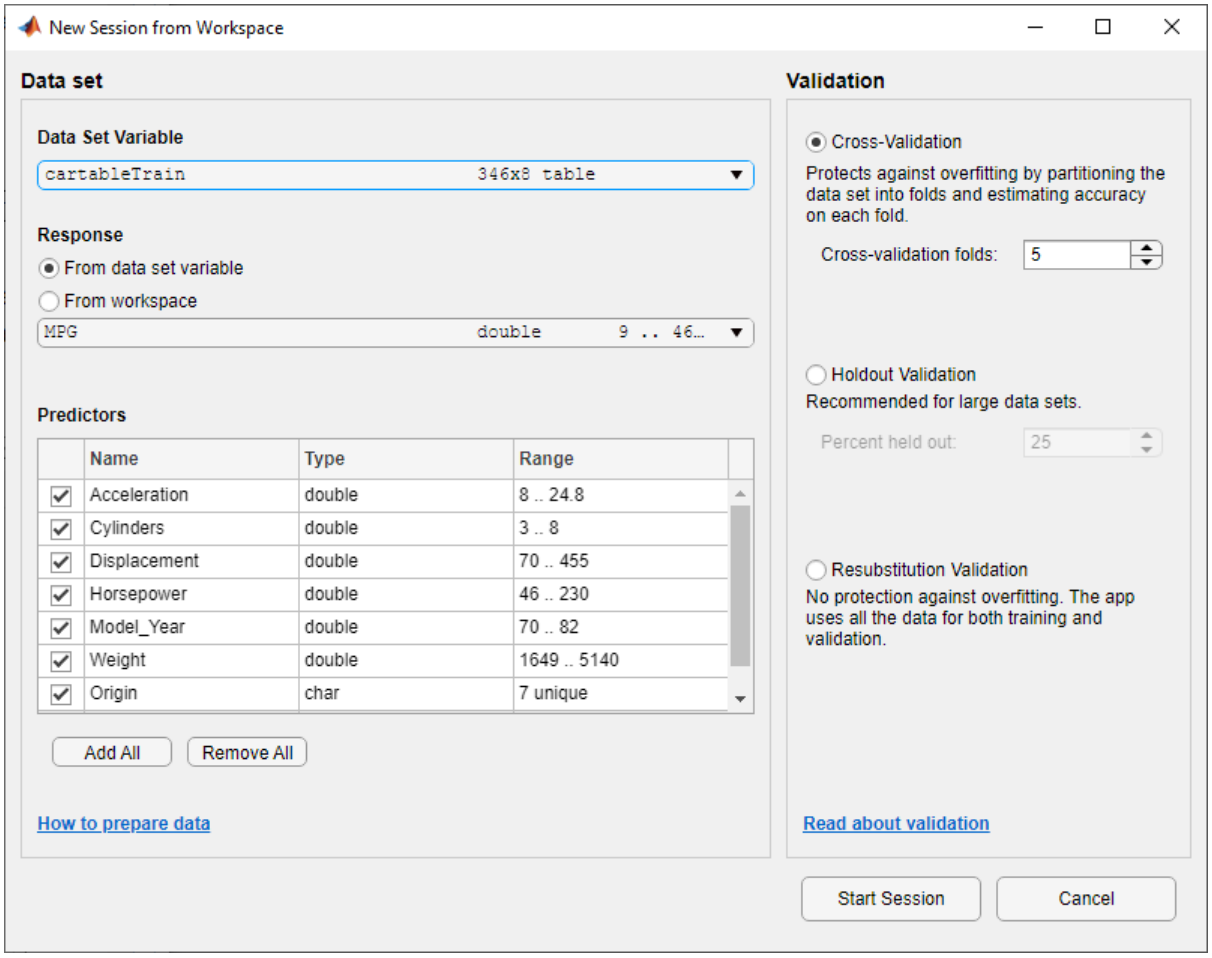
1. In the MATLAB Command Window, load the `carbig` data set, and create a table containing most of the variables. Separate the table into training and test sets.

   ```
   load carbig
   cartable = table(Acceleration,Cylinders,Displacement, ...
       Horsepower,Model_Year,Weight,Origin,MPG);

   rng('default') % For reproducibility of the data split
   n = length(MPG);
   partition = cvpartition(n,'Holdout',0.15);
   idxTrain = training(partition); % Indices for the training set
   cartableTrain = cartable(idxTrain,:);
   cartableTest = cartable(~idxTrain,:);
   ```

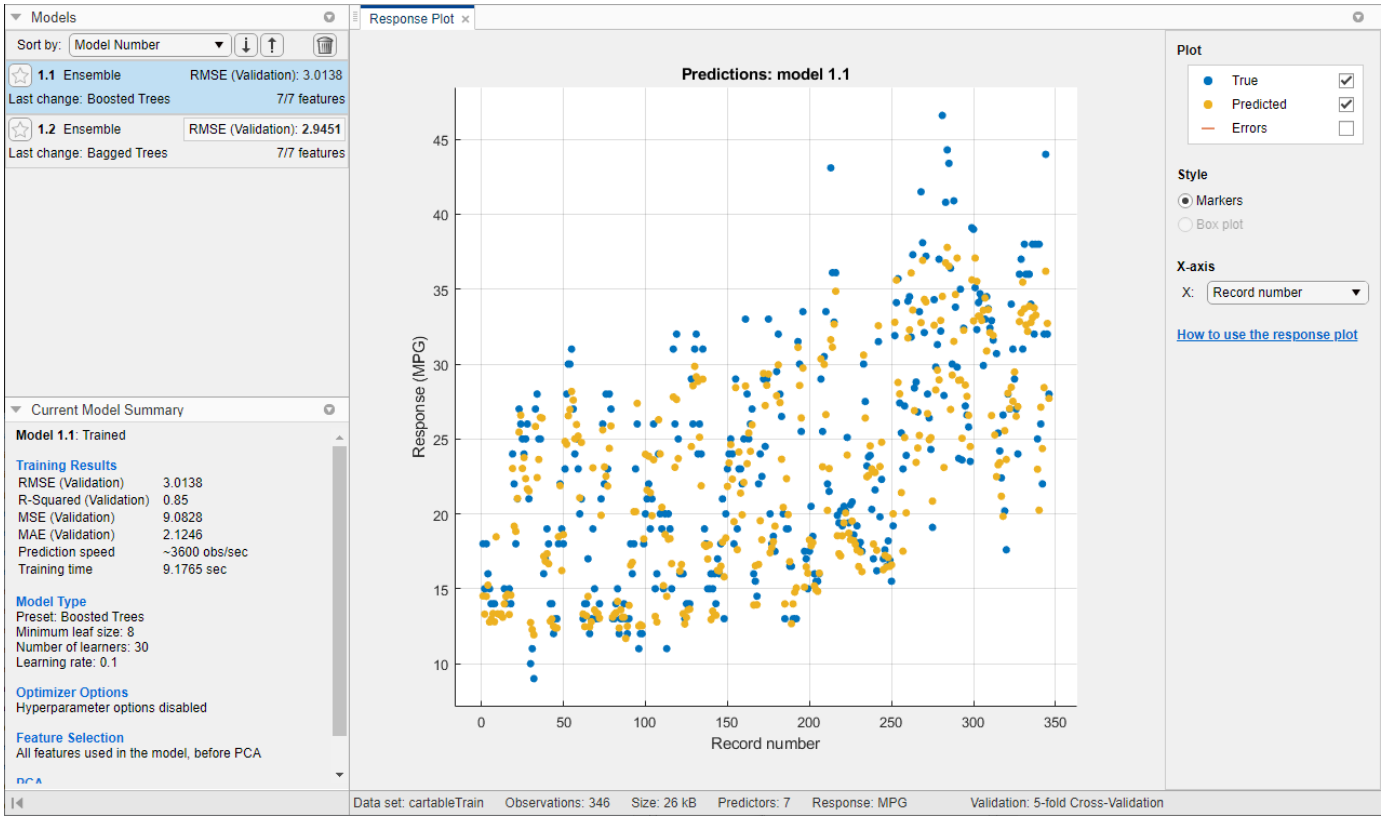
2. Open Regression Learner. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Regression Learner**.
3. On the **Regression Learner** tab, in the **File** section, select **New Session > From Workspace**.
4. In the New Session from Workspace dialog box, select the `cartableTrain` table from the **Data Set Variable** list.

   As shown in the dialog box, the app selects the response and predictor variables. The default response variable is `MPG`. The default validation option is 5-fold cross-validation, to protect against overfitting. For this example, do not change the default settings.



5. To accept the default options and continue, click **Start Session**.
6. Train all preset ensemble models. On the **Regression Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Ensembles of Trees** group, click **All Ensembles**. In the **Training** section, click **Train**. The app trains one of each ensemble model type and displays the models in the **Models** pane.

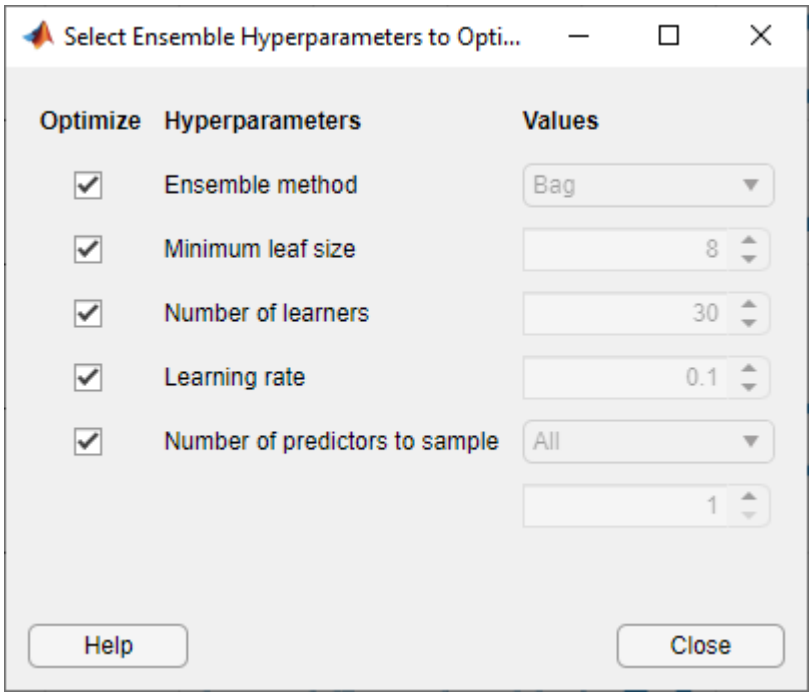
> **Tip** If you have Parallel Computing Toolbox, you can train all the ensemble models (**All Ensembles**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the ensemble models simultaneously.



The app displays a response plot of the car data. Blue points are true values, and yellow points are predicted values. The **Models** pane on the left shows the validation RMSE for each model.

Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

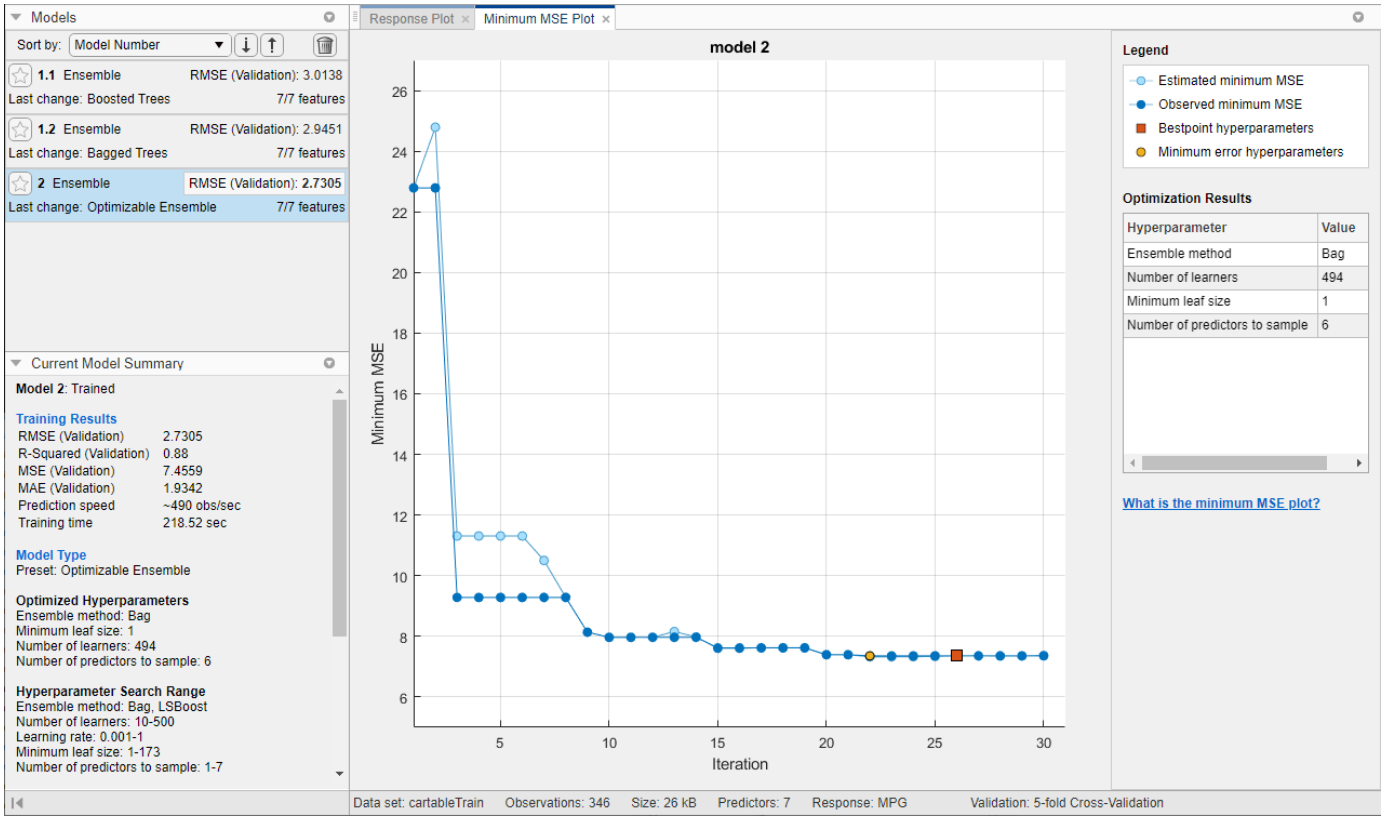
7. Select an optimizable ensemble model to train. On the **Regression Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Ensembles of Trees** group, click **Optimizable Ensemble**. The app disables the **Use Parallel** button when you select an optimizable model.
8. Select the model hyperparameters to optimize. In the **Model Type** section, select **Advanced > Advanced**. The app opens a dialog box in which you can select **Optimize** check boxes for the hyperparameters that you want to optimize. By default, all the check boxes are selected. For this example, accept the default selections, and close the dialog box.



9 In the **Training** section, click **Train**.

10 The app displays a **Minimum MSE Plot** as it runs the optimization process. At each iteration, the app tries a different combination of hyperparameter values and updates the plot with the minimum validation mean squared error (MSE) observed up to that iteration, indicated in dark blue. When the app completes the optimization process, it selects the set of optimized hyperparameters, indicated by a red square. For more information, see “Minimum MSE Plot” on page 24-37.

The app lists the optimized hyperparameters in both the **Optimization Results** section to the right of the plot and the **Optimized Hyperparameters** section of the **Current Model Summary** pane.



Note In general, the optimization results are not reproducible.

11 Compare the trained preset ensemble models to the trained optimizable model. In the **Models** pane, the app highlights the lowest **RMSE (Validation)** (validation root mean squared error) by outlining it in a box. In this example, the trained optimizable ensemble outperforms the two preset models.

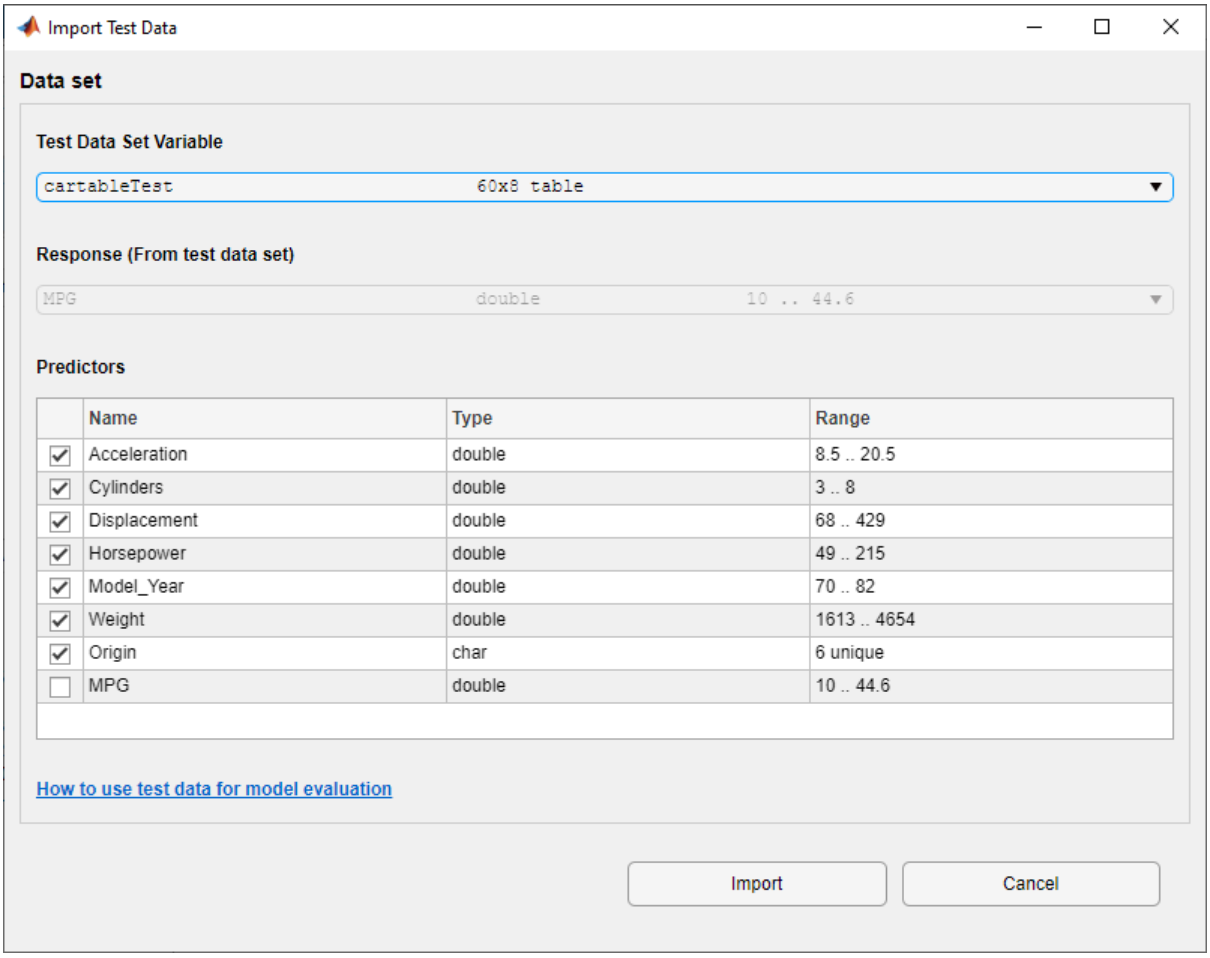
A trained optimizable model does not always have a lower RMSE than the trained preset models. If a trained optimizable model does not perform well, you can try to get better results by running the optimization for longer. In the **Model Type** section, select **Advanced > Optimizer Options**. In the dialog box, increase the **Iterations** value. For example, you can double-click the default value of `30` and enter a value of `60`.

12 Because hyperparameter tuning often leads to overfitted models, check the performance of the optimizable ensemble model on a test set and compare it to the performance of the best preset ensemble model. Begin by importing test data into the app.

On the **Regression Learner** tab, in the **Testing** section, select **Test Data > From Workspace**.

13 In the Import Test Data dialog box, select the `cartableTest` table from the **Test Data Set Variable** list.

As shown in the dialog box, the app identifies the response and predictor variables.



14 Click **Import**.

15 Compute the RMSE of the best preset model and the optimizable model on the `cartableTest` data.

First, in the **Models** pane, click the star icons next to the **Bagged Trees** model and the **Optimizable Ensemble** model.

16 For each model, select the model in the **Models** pane, and then select **Test All > Test Selected** in the **Testing** section. The app computes the test set performance of the model trained on the full data set, including training and validation data.

17 Sort the models based on the test set RMSE. In the **Models** pane, open the **Sort by** list and select `RMSE (Test)`.

In this example, the trained optimizable ensemble still outperforms the trained preset model on the test set data.

Check Model Performance Using Test Set in Regression Learner App

This example shows how to train multiple models in Regression Learner, and determine the best-performing models based on their validation metrics. Check the test metrics for the best-performing models trained on the full data set, including training and validation data.

1. In the MATLAB Command Window, load the `carbig` data set, and create a table containing most of the variables. Separate the table into training and test sets.

   ```
   load carbig
   cartable = table(Acceleration,Cylinders,Displacement, ...
       Horsepower,Model_Year,Weight,Origin,MPG);

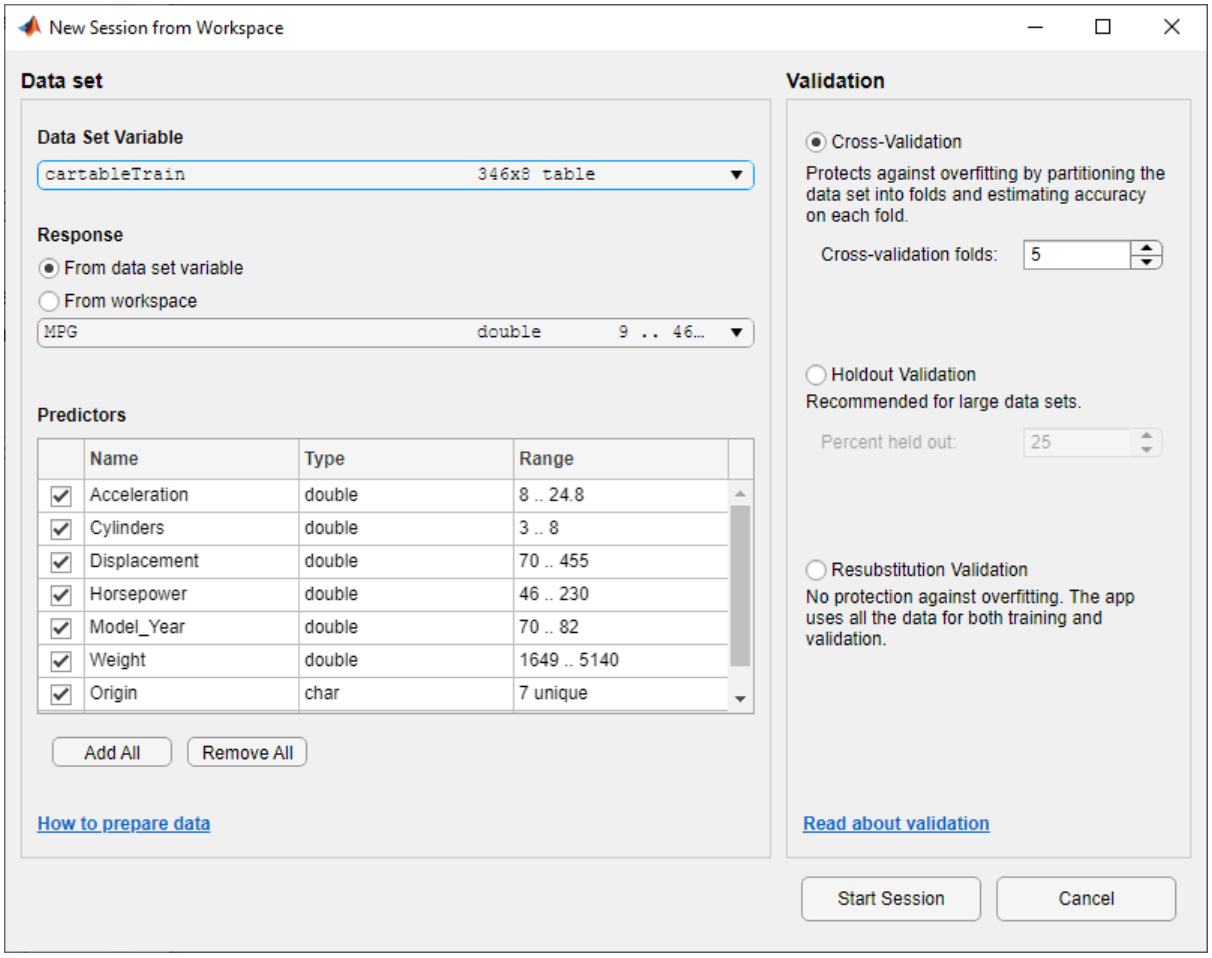
   rng('default') % For reproducibility of the data split
   n = length(MPG);
   partition = cvpartition(n,'Holdout',0.15);
   idxTrain = training(partition); % Indices for the training set
   cartableTrain = cartable(idxTrain,:);
   cartableTest = cartable(~idxTrain,:);
   ```

2. Open Regression Learner. Click the **Apps** tab, and then click the arrow at the right of the **Apps** section to open the apps gallery. In the **Machine Learning and Deep Learning** group, click **Regression Learner**.

3. On the **Regression Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

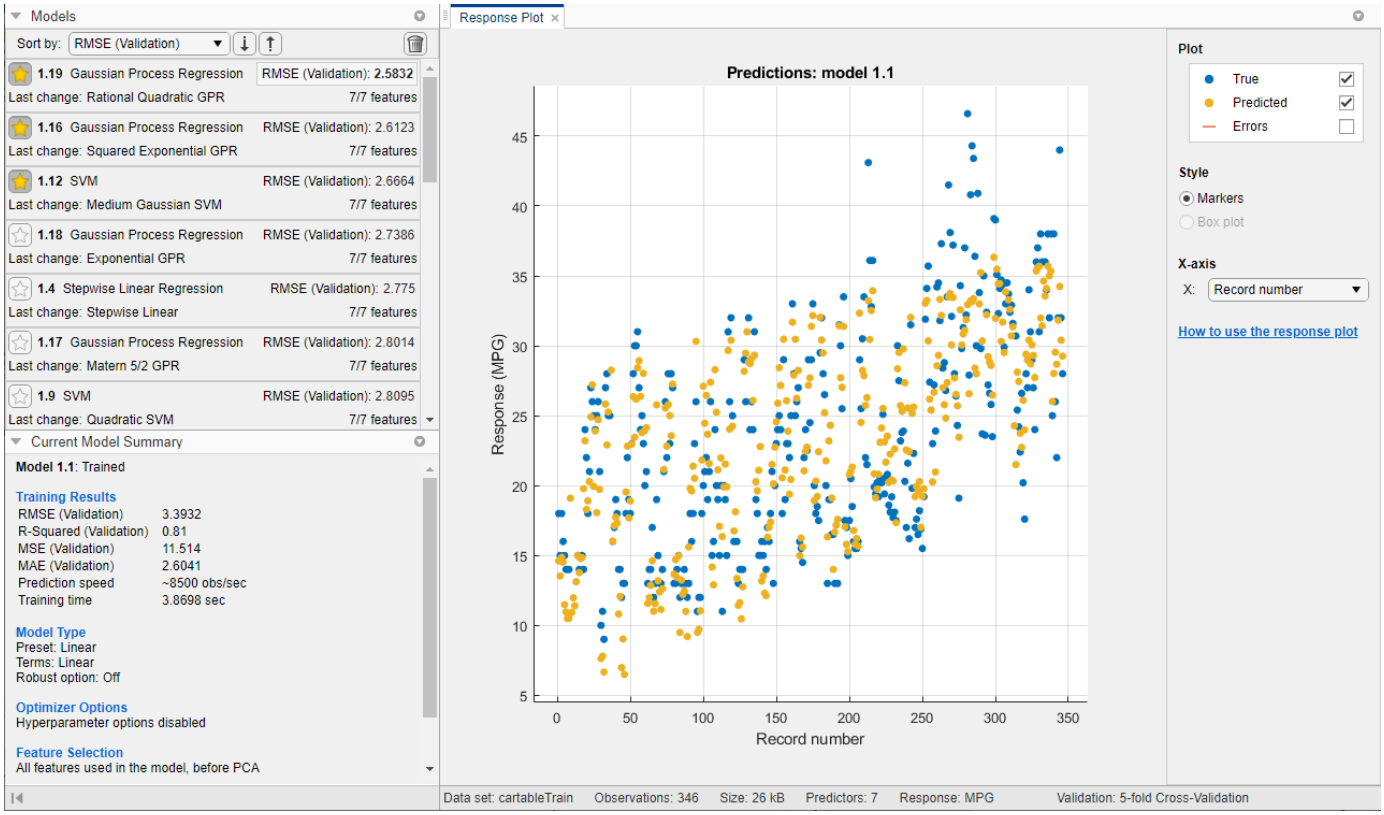
4. In the New Session from Workspace dialog box, select the `cartableTrain` table from the **Data Set Variable** list.

   As shown in the dialog box, the app selects the response and predictor variables. The default response variable is `MPG`. To protect against overfitting, the default validation option is 5-fold cross-validation. For this example, do not change the default settings.



5. To accept the default options and continue, click **Start Session**.
6. Train all preset models. On the **Regression Learner** tab, in the **Model Type** section, click the arrow to open the gallery. In the **Get Started** group, click **All**. In the **Training** section, click **Train**. The app trains one of each preset model type and displays the models in the **Models** pane.

   Tip If you have Parallel Computing Toolbox, you can train all the models (**All**) simultaneously by selecting the **Use Parallel** button in the **Training** section before clicking **Train**. After you click **Train**, the Opening Parallel Pool dialog box opens and remains open while the app opens a parallel pool of workers. During this time, you cannot interact with the software. After the pool opens, the app trains the models simultaneously.
7. Sort the trained models based on the validation root mean squared error (RMSE). In the **Models** pane, open the **Sort by** list and select `RMSE (Validation)`.
8. In the **Models** pane, click the star icons next to the three models with the lowest validation RMSE. The app highlights the lowest validation RMSE by outlining it in a box. In this example, the trained **Rational Quadratic GPR** model has the lowest validation RMSE.



The app displays a response plot of the car data. Blue points are true values, and yellow points are predicted values. The **Models** pane on the left shows the validation RMSE for each model.

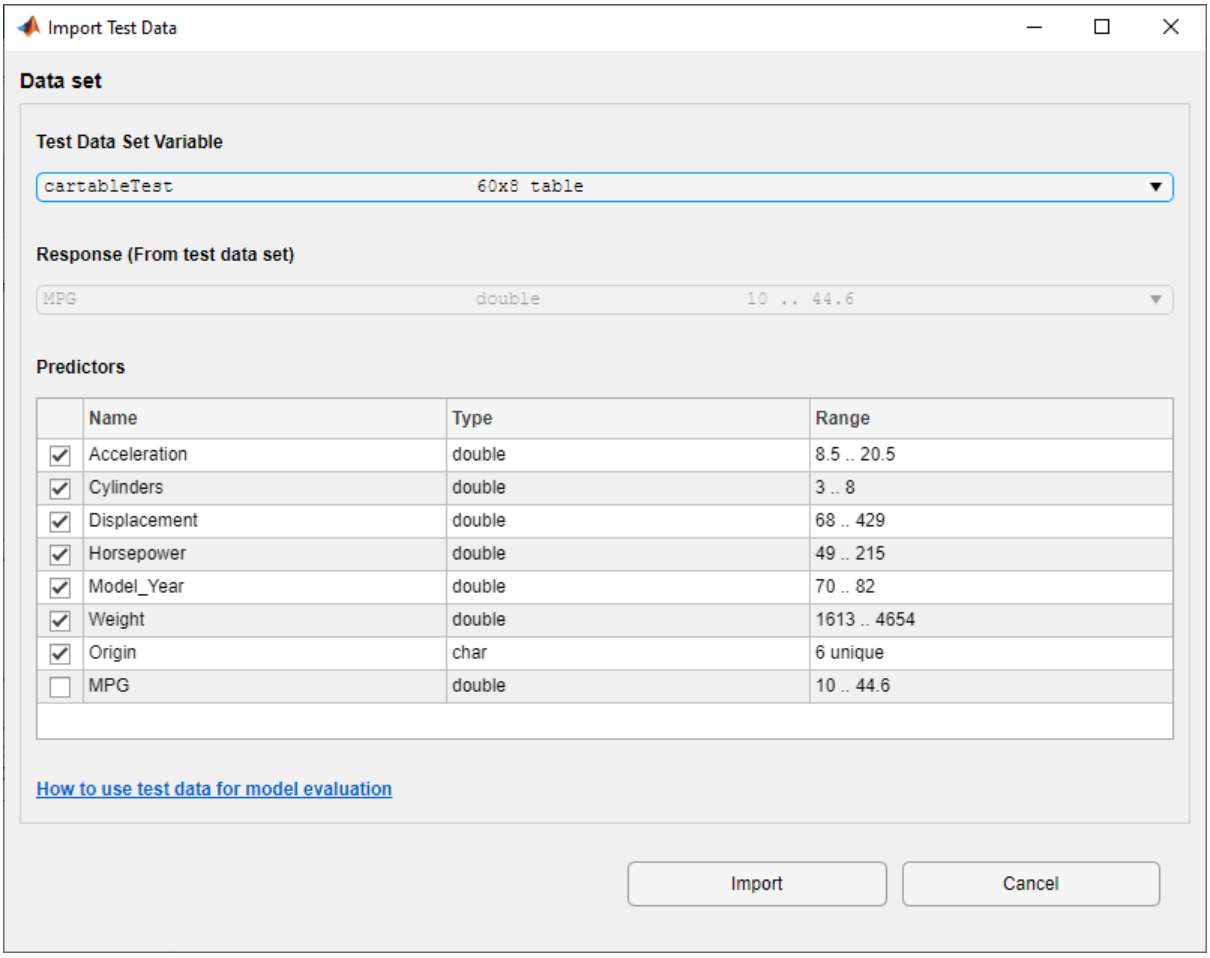
Note Validation introduces some randomness into the results. Your model validation results can vary from the results shown in this example.

9 Check the test set performance of the best-performing models. Begin by importing test data into the app.

On the **Regression Learner** tab, in the **Testing** section, click **Test Data** and select **From Workspace**.

10 In the Import Test Data dialog box, select the `cartableTest` table from the **Test Data Set Variable** list.

As shown in the dialog box, the app identifies the response and predictor variables.



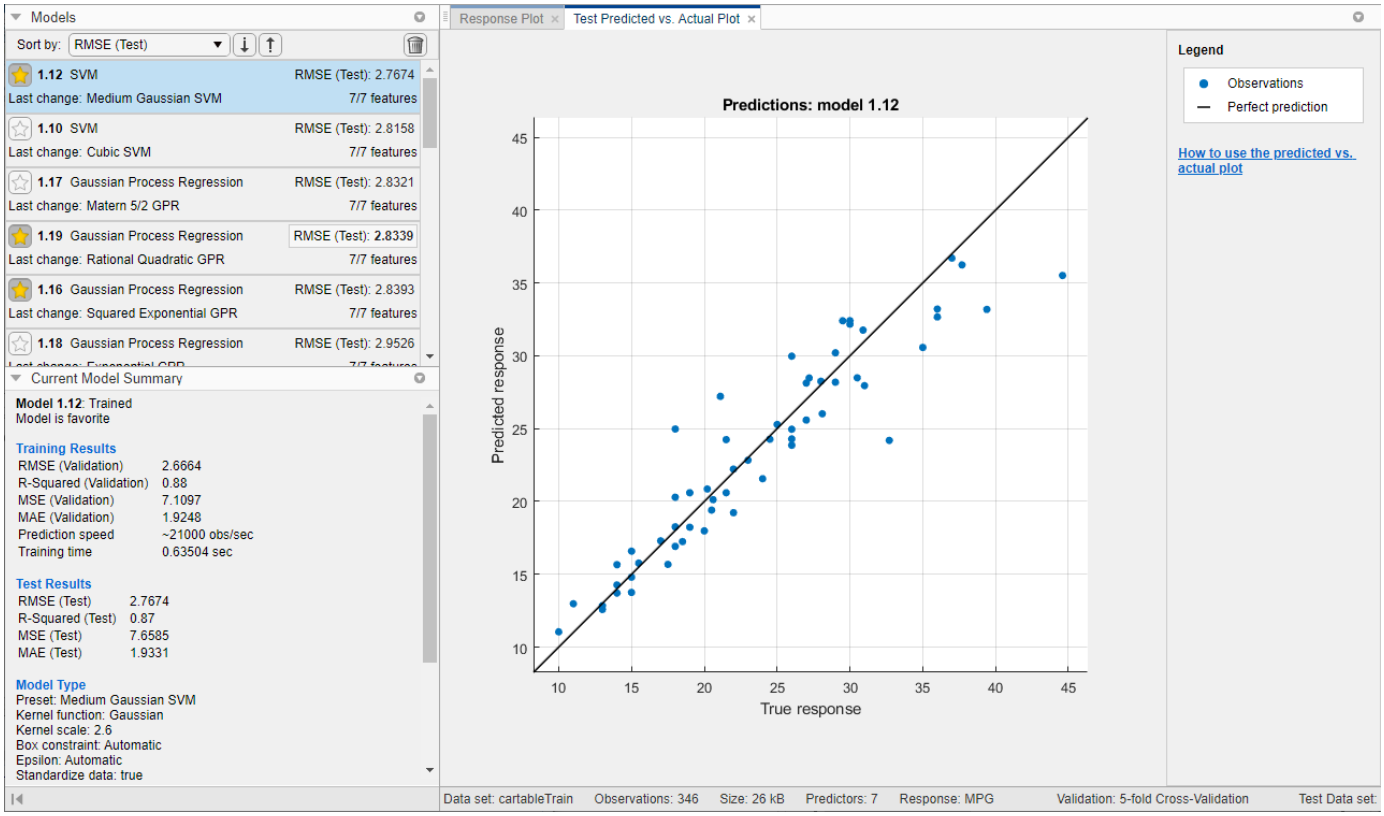
11 Click **Import**.

12 Compute the RMSE of the best preset models on the `cartableTest` data. For convenience, compute the test set RMSE for all models at once. On the **Regression Learner** tab, in the **Testing** section, click **Test All** and select **Test All**. The app computes the test set performance of the model trained on the full data set, including training and validation data.

13 Sort the models based on the test set RMSE. In the **Models** pane, open the **Sort by** list and select `RMSE (Test)`. The app still outlines the metric for the model with the lowest validation RMSE, despite displaying the test RMSE.

14 Visually check the test set performance of the models. On the **Regression Learner** tab, in the **Plots** section, click **Predicted vs. Actual** and select **Test Data**. You can toggle between models to compare their performance.

In this example, the trained **Medium Gaussian SVM** performs better on the test set data than the other two starred models.



15 Compare the validation and test RMSE for the trained **Medium Gaussian SVM** model. In the **Current Model Summary** pane, compare the **RMSE (Validation)** value under **Training Results** to the **RMSE (Test)** value under **Test Results**. In this example, the two values are close, which indicates that the validation RMSE is a good estimate of the test RMSE for this model.

Support Vector Machines

Understanding Support Vector Machine Regression

In this section...

Mathematical Formulation of SVM Regression

Overview

Support vector machine (SVM) analysis is a popular machine learning tool for classification and regression, first identified by Vladimir Vapnik and his colleagues in 1992[5]. SVM regression is considered a nonparametric technique because it relies on kernel functions.

Statistics and Machine Learning Toolbox implements linear epsilon-insensitive SVM (ε-SVM) regression, which is also known as $L1$ loss. In ε-SVM regression, the set of training data includes predictor variables and observed response values. The goal is to find a function $f(x)$ that deviates from y_n by a value no greater than ε for each training point x, and at the same time is as flat as possible.

Linear SVM Regression: Primal Formula

Suppose we have a set of training data where x_n is a multivariate set of N observations with observed response values y_n.

To find the linear function

$$f(x) = x'\beta + b,$$

and ensure that it is as flat as possible, find $f(x)$ with the minimal norm value ($\beta'\beta$). This is formulated as a convex optimization problem to minimize

$$J(\beta) = \frac{1}{2}\beta'\beta$$

subject to all residuals having a value less than ε; or, in equation form:

$$\forall n: |y_n - (x_n'\beta + b)| \le \varepsilon \ .$$

It is possible that no such function $f(x)$ exists to satisfy these constraints for all points. To deal with otherwise infeasible constraints, introduce slack variables ξ_n and ξ^*_n for each point. This approach is similar to the “soft margin” concept in SVM classification, because the slack variables allow regression errors to exist up to the value of ξ_n and ξ^*_n, yet still satisfy the required conditions.

Including slack variables leads to the objective function, also known as the primal formula[5]:

$$J(\beta) = \frac{1}{2}\beta'\beta + C\sum_{n=1}^{N}(\xi_n + \xi_n^*),$$

subject to:

$$\forall n: y_n - (x_n'\beta + b) \le \varepsilon + \xi_n$$
$$\forall n: (x_n'\beta + b) - y_n \le \varepsilon + \xi_n^*$$
$$\forall n: \xi_n^* \ge 0$$
$$\forall n: \xi_n \ge 0 \ .$$

The constant C is the box constraint, a positive numeric value that controls the penalty imposed on observations that lie outside the epsilon margin (ε) and helps to prevent overfitting (regularization). This value determines the trade-off between the flatness of $f(x)$ and the amount up to which deviations larger than ε are tolerated.

The linear ε-insensitive loss function ignores errors that are within ε distance of the observed value by treating them as equal to zero. The loss is measured based on the distance between observed value y and the ε boundary. This is formally described by

$$L_\varepsilon = \begin{cases} 0 & \text{if } |y - f(x)| \le \varepsilon \\ |y - f(x)| - \varepsilon & \text{otherwise} \end{cases}$$

Linear SVM Regression: Dual Formula

The optimization problem previously described is computationally simpler to solve in its Lagrange dual formulation. The solution to the dual problem provides a lower bound to the solution of the primal (minimization) problem. The optimal values of the primal and dual problems need not be equal, and the difference is called the “duality gap.” But when the problem is convex and satisfies a constraint qualification condition, the value of the optimal solution to the primal problem is given by the solution of the dual problem.

To obtain the dual formula, construct a Lagrangian function from the primal function by introducing nonnegative multipliers α_n and α^*_n for each observation x_n. This leads to the dual formula, where we minimize

$$L(\alpha) = \frac{1}{2}\sum_{i=1}^{N}\sum_{j=1}^{N}(\alpha_i - \alpha_i^*)\left(\alpha_j - \alpha_j^*\right)x_i'x_j + \varepsilon\sum_{i=1}^{N}(\alpha_i + \alpha_i^*) + \sum_{i=1}^{N} y_i(\alpha_i^* - \alpha_i)$$

subject to the constraints

$$\sum_{n=1}^{N}(\alpha_n - \alpha_n^*) = 0$$
$$\forall n: 0 \le \alpha_n \le C$$
$$\forall n: 0 \le \alpha_n^* \le C \ .$$

The β parameter can be completely described as a linear combination of the training observations using the equation

$$\beta = \sum_{n=1}^{N}(\alpha_n - \alpha_n^*)x_n \ .$$

The function used to predict new values depends only on the support vectors:

$$f(x) = \sum_{n=1}^{N}(\alpha_n - \alpha_n^*)(x_n'x) + b \ . \qquad (25\text{-}1)$$

The Karush-Kuhn-Tucker (KKT) complementarity conditions are optimization constraints required to obtain optimal solutions. For linear SVM regression, these conditions are

$$\forall n: \alpha_n(\varepsilon + \xi_n - y_n + x_n'\beta + b) = 0$$
$$\forall n: \alpha_n^*(\varepsilon + \xi_n^* + y_n - x_n'\beta - b) = 0$$
$$\forall n: \xi_n(C - \alpha_n) = 0$$
$$\forall n: \xi_n^*(C - \alpha_n^*) = 0 \ .$$

These conditions indicate that all observations strictly inside the epsilon tube have Lagrange multipliers $\alpha_n = 0$ and $\alpha_n^* = 0$. If either α_n or α_n^* is not zero, then the corresponding observation is called a *support vector*.

The property Alpha of a trained SVM model stores the difference between two Lagrange multipliers of support vectors, $\alpha_n - \alpha_n^*$. The properties SupportVectors and Bias store x_n and b, respectively.

Nonlinear SVM Regression: Primal Formula

Some regression problems cannot adequately be described using a linear model. In such a case, the Lagrange dual formulation allows the previously-described technique to be extended to nonlinear functions.

Obtain a nonlinear SVM regression model by replacing the dot product $x_1'x_2$ with a nonlinear kernel function $G(x_1,x_2) = <\varphi(x_1),\varphi(x_2)>$, where $\varphi(x)$ is a transformation that maps x to a high-dimensional space. Statistics and Machine Learning Toolbox provides the following built-in positive semidefinite kernel functions.

Kernel Name	Kernel Function
Linear (dot product)	$G(x_j, x_k) = x_j'x_k$
Gaussian	$G(x_j, x_k) = \exp\left(-\|x_j - x_k\|^2\right)$
Polynomial	$G(x_j, x_k) = (1 + x_j'x_k)^q$, where q is in the set {2,3,...}.

The *Gram matrix* is an n-by-n matrix that contains elements $g_{i,j} = G(x_i,x_j)$. Each element $g_{i,j}$ is equal to the inner product of the predictors as transformed by φ. However, we do not need to know φ, because we can use the kernel function to generate Gram matrix directly. Using this method, nonlinear SVM finds the optimal function $f(x)$ in the transformed predictor space.

Nonlinear SVM Regression: Dual Formula

The dual formula for nonlinear SVM regression replaces the inner product of the predictors ($x_i'x_j$) with the corresponding element of the Gram matrix ($g_{i,j}$).

Nonlinear SVM regression finds the coefficients that minimize

$$L(\alpha) = \frac{1}{2}\sum_{i=1}^{N}\sum_{j=1}^{N}(\alpha_i - \alpha_i^*)\left(\alpha_j - \alpha_j^*\right)G\left(x_i, x_j\right) + \varepsilon\sum_{i=1}^{N}(\alpha_i + \alpha_i^*) - \sum_{i=1}^{N} y_i(\alpha_i - \alpha_i^*)$$

subject to

$$\sum_{n=1}^{N}(\alpha_n - \alpha_n^*) = 0$$
$$\forall n: 0 \le \alpha_n \le C$$
$$\forall n: 0 \le \alpha_n^* \le C \ .$$

The function used to predict new values is equal to

$$f(x) = \sum_{n=1}^{N}(\alpha_n - \alpha_n^*)G(x_n, x) + b \ . \tag{25-2}$$

The KKT complementarity conditions are

$$\forall n: \alpha_n(\varepsilon + \xi_n - y_n + f(x_n)) = 0$$
$$\forall n: \alpha_n^*(\varepsilon + \xi_n^* + y_n - f(x_n)) = 0$$
$$\forall n: \xi_n(C - \alpha_n) = 0$$
$$\forall n: \xi_n^*(C - \alpha_n^*) = 0 \ .$$

Solving the SVM Regression Optimization Problem

Solver Algorithms

The minimization problem can be expressed in standard quadratic programming form and solved using common quadratic programming techniques. However, it can be computationally expensive to use quadratic programming algorithms, especially since the Gram matrix may be too large to be stored in memory. Using a decomposition method instead can speed up the computation and avoid running out of memory.

Decomposition methods (also called *chunking and working set methods*) separate all observations into two disjoint sets: the working set and the remaining set. A decomposition method modifies only the elements in the working set in each iteration. Therefore, only some columns of the Gram matrix are needed in each iteration, which reduces the amount of storage needed for each iteration.

Sequential minimal optimization (SMO) is the most popular approach for solving SVM problems[4]. SMO performs a series of two-point optimizations. In each iteration, a working set of two points are chosen based on a selection rule that uses second-order information. Then the Lagrange multipliers for this working set are solved analytically using the approach described in [2] and [1].

In SVM regression, the gradient vector ∇L for the active set is updated after each iteration. The decomposed equation for the gradient vector is

$$(\nabla L)_n = \begin{cases} \sum_{i=1}^{N}(\alpha_i - \alpha_i^*)G(x_i, x_n) + \varepsilon - y_n \ , & n \le N \\ -\sum_{i=1}^{N}(\alpha_i - \alpha_i^*)G(x_i, x_n) + \varepsilon + y_n \ , & n > N \end{cases} .$$

Iterative single data algorithm (ISDA) updates one Lagrange multiplier with each iteration[3]. ISDA is often conducted without the bias term b by adding a small positive constant a to the kernel function. Dropping b drops the sum constraint

$$\sum_{n=1}^{N}(\alpha_i - \alpha^*) = 0$$

in the dual equation. This allows us to update one Lagrange multiplier in each iteration, which makes it easier than SMO to remove outliers. ISDA selects the worst KKT violator among all the α_n and α_n^* values as the working set to be updated.

Convergence Criteria

Each of these solver algorithms iteratively computes until the specified convergence criterion is met. There are several options for convergence criteria:

- *Feasibility gap* — The feasibility gap is expressed as

  $$\Delta = \frac{J(\beta) + L(\alpha)}{J(\beta) + 1},$$

  where $J(\beta)$ is the primal objective and $L(\alpha)$ is the dual objective. After each iteration, the software evaluates the feasibility gap. If the feasibility gap is less than the value specified by `GapTolerance`, then the algorithm met the convergence criterion and the software returns a solution.
- *Gradient difference* — After each iteration, the software evaluates the gradient vector, ∇L. If the difference in gradient vector values for the current iteration and the previous iteration is less than the value specified by `DeltaGradientTolerance`, then the algorithm met the convergence criterion and the software returns a solution.
- *Largest KKT violation* — After each iteration, the software evaluates the KKT violation for all the α_n and α_n^* values. If the largest violation is less than the value specified by `KKTTolerance`, then the algorithm met the convergence criterion and the software returns a solution.

Incremental Learning

Incremental Learning Overview

In this section...

What Is Incremental Learning?

Incremental learning, or online learning, is a branch of machine learning that involves processing incoming data from a data stream—continuously and in real time—possibly given little to no knowledge of the distribution of the predictor variables, sample size, aspects of the prediction or objective function (including adequate tuning parameter values), and whether the observations have labels.

Incremental learning algorithms are flexible, efficient, and adaptive. The following characteristics distinguish incremental learning from traditional machine learning:

- An incremental model is fit to data quickly and efficiently, which means it can adapt, in real time, to changes (or drifts) in the data distribution.
- Because observation labels can be missing when corresponding predictor data is available, the algorithm must be able to generate predictions from the latest version of the model quickly, and defer training the model.
- Little information might be known about the population before incremental learning starts. Therefore, the algorithm can be run with a cold start. For example, for classification problems, the class names might not be known until after the model processes observations. When enough information is known before learning begins (for example, you have good estimates of linear model coefficients), you can specify such information to provide the model with a warm start.
- Because observations can arrive in a stream, the sample size is likely unknown and possibly large, which makes data storage inefficient or impossible. Therefore, the algorithm must process observations when they are available and before the system discards them. This incremental learning characteristic makes hyperparameter tuning difficult or impossible.

In traditional machine learning, a batch of labeled data is available to perform cross-validation to estimate the generalization error and tune hyperparameters, infer the predictor variable distribution, and fit the model. However, the resulting model must be retrained from the beginning if underlying distributions drift or the model degrades. Although performing cross-validation to tune hyperparameters is difficult in an incremental learning environment, incremental learning methods are flexible because they can adapt to distribution drift in real time, with predictive accuracy approaching that of a traditionally trained model as the model trains more data.

Suppose an incremental model is prepared to generate predictions and have its predictive performance measured. Given incoming chunks of observations, an incremental learning scheme processes data in real time and in any of the following ways, but usually in the specified order:

1. **Evaluate model**: Track the predictive performance of the model when true labels are available, either on the incoming data only, over a sliding window of observations, or over the entire history of the model used for incremental learning.
2. **Detect drift**: Check for structural breaks or distribution drift. For example, determine whether the distribution of any predictor variable has sufficiently changed.

3. **Train model**: Update the model by training it on the incoming observations, when true labels are available or when the current model has sufficiently degraded.
4. **Generate predictions**: Predict labels from the latest model.

This procedure is a special case of incremental learning, in which all incoming chunks are treated as test (holdout) sets. The procedure is called interleaved test-then-train or prequential evaluation [1].

If insufficient information exists for an incremental model to generate predictions, or you do not want to track the predictive performance of the model because it has not been trained enough, you can include an optional initial step to find adequate values for hyperparameters, for models that support one (estimation period), or an initial training period before model evaluation (metrics warm-up period).

As an example of an incremental learning problem, consider a smart thermostat that automatically sets a temperature given the ambient temperature, relative humidity, time of day, and other measurements, and can learn the user's indoor temperature preferences. Suppose the manufacturer prepared the device by embedding a known model that describes the average person's preferences given the measurements. After installation, the device collects data every minute, and adjusts the temperature to its presets. The thermostat adjusts the embedded model, or retrains itself, based on the user's actions or inactions with the device. This cycle can continue indefinitely. If the thermostat has limited disk space to store historical data, it needs to retrain itself in real time. If the manufacturer did not prepare the device with a known model, the device retrains itself more often.

Incremental Learning with MATLAB

Statistics and Machine Learning Toolbox functionalities enable you to implement incremental learning for classification or regression. Like other Statistics and Machine Learning Toolbox machine learning functionalities, the entry point into incremental learning is an incremental learning object, which you pass to functions with data to implement incremental learning. Unlike other machine learning functions, data is not required to create an incremental learning object. However, the incremental learning object specifies how to process incoming data, such as when to fit the model, measure performance metrics, or perform both actions, in addition to the parametric form of the model and problem-specific options.

Incremental Learning Model Objects

This table contains the available entry-point model objects for incremental learning with their supported machine learning objective, model type, and any information required upon creation.

Model Object	Objective	Model Type	Required Information
`incrementalClassificationLinear`	Binary classification	Linear SVM and logistic regression	None
`incrementalClassificationNaiveBayes`	Mutliclass classification	Naive Bayes with normal predictor conditional distributions	Maximum number of classes expected in the data during incremental learning or names of all expected classes
`incrementalRegressionLinear`	Regression	Linear	None

Properties of a incremental learning model object specify:

- Data characteristics, such as the number of predictor variables `NumPredictors` and their first and second moments.
- Model characteristics, such as, for linear models, the learner type `Learner`, linear coefficients `Beta`, and intercept `Bias`
- Training options, such as, for linear models, the objective solver `Solver` and solver-specific hyperparameters such as the ridge penalty `Lambda` for standard and average stochastic gradient descent (SGD and ASGD)
- Model performance evaluation characteristics and options, such as whether the model is warm `IsWarm`, which performance metrics to track `Metrics`, and the latest values of the performance metrics

Unlike when working with other machine learning model objects, you can create either model by directly calling the object and specifying property values of options using name-value arguments; you do not need to fit a model to data to create one. This feature is convenient when you have little information about the data or model before training it. Depending on your specifications, the software can enforce estimation and metrics warm-up periods, during which incremental fitting functions infer data characteristics and then train the model for performance evaluation. By default, for linear models, the software solves the objective function using the adaptive scale-invariant solver, which does not require tuning and is insensitive to the predictor variable scales [2].

Alternatively, you can convert a traditionally trained model to either model by using the `incrementalLearner` function. Convertible models include support vector machines (SVM) for binary classification and regression, naive Bayes classification, and linear regression models. For example, `incrementalLearner` converts a trained linear classification model of type `ClassificationLinear` to an `incrementalClassificationLinear` object. By default, the software considers converted models to be prepared for all aspects of incremental learning (converted models are warm). `incrementalLearner` carries over data characteristics (such as class names), fitted parameters, and options available for incremental learning from the traditionally trained model being converted. For example:

- For naive Bayes classification, `incrementalLearner` carries over all class names in the data expected during incremental learning, and the fitted moments of the conditional predictor distributions (`DistributionParameters`).
- For linear models, if the objective solver of the traditionally trained model is SGD, `incrementalLearner` sets the incremental learning solver to SGD.

Incremental Learning Functions

The incremental learning model object specifies all aspects of the incremental learning algorithm, from training and model evaluation preparation through training and model evaluation. To implement incremental learning, you pass the configured incremental learning model to an incremental fitting function or model evaluation function. Statistics and Machine Learning Toolbox incremental learning functions offer two workflows that are well suited for prequential learning. For simplicity, the following workflow descriptions assume that the model is prepared to evaluate the model performance (in other words, the model is warm).

- **Flexible workflow** — When a data chunk is available:

  1. Compute cumulative and window model performance metrics by passing the data and current model to the `updateMetrics` function. The data is treated as test (holdout) data because the model has not been trained on it yet. `updateMetrics` overwrites the model performance stored in the model with the new values. For linear models, see `updateMetrics` and, for naive Bayes classification models, see `updateMetrics`.

2. Optionally detect distribution drift or whether the model has degraded.
3. Train the model by passing the incoming data chunk and current model to the `fit` function. The `fit` function uses the specified solver to fit the model to the incoming data chunk, and overwrites the current coefficients and bias with the new estimates. For linear models, see `fit` and, for naive Bayes classification models, see `fit`.

The flexible workflow enables you to perform custom model and data quality assessments before deciding whether to train the model. All steps are optional, but call `updateMetrics` before `fit` when you plan to call both functions.

- **Succinct workflow** — When a data chunk is available, supply the incoming chunk and a configured incremental model to the `updateMetricsAndFit` function. `updateMetricsAndFit` calls `updateMetrics` immediately followed by `fit`. The succinct workflow enables you to implement incremental learning with prequential evaluation easily when you plan to track the model performance and train the model on all incoming data chunks. For linear models, see `updateMetricsAndFit` and, for naive Bayes classification models, see `updateMetricsAndFit`.

Once you create an incremental model object and choose a workflow to use, write a loop that implements incremental learning:

1. Read a chunk of observations from a data stream, when the chunk is available.
2. Implement the flexible or succinct workflow. To perform incremental learning properly, overwrite the input model with the output model. For example:

```
% Flexible workflow
Mdl = updateMetrics(Mdl,X,Y);
% Insert optional code
Mdl = fit(Mdl,X,Y);

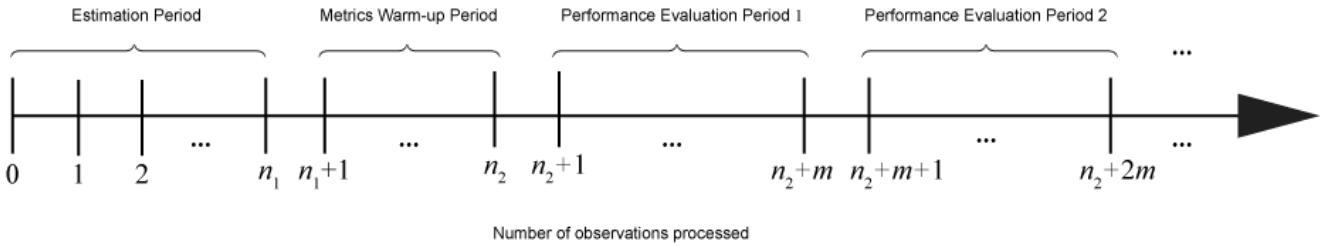
% Succinct workflow
Mdl = updateMetricsAndFit(Mdl,X,Y);
```

   The model tracks its performance on incoming data incrementally using metrics measured since the beginning of training (cumulative) and over a specified window of consecutive observations (window). However, you can optionally compute the model loss on the incoming chunk, and then pass the incoming chunk and current model to the `loss` function. `loss` returns the scalar loss; it does not adjust the model. For linear models, see `loss` and, for naive Bayes classification models, see `loss`.

   Model configurations determine whether incremental learning functions train or evaluate model performance during each iteration. Configurations can change as the functions process data. For more details, see “Incremental Learning Periods” on page 26-6.
3. Optionally:
   - Generate predictions by passing the chunk and latest model to `predict`. For linear models, see `predict` and, for naive Bayes classification models, see `predict`.
   - If the model was fit to data, compute the resubstitution loss by passing the chunk and latest model to `loss`.
   - For naive Bayes classification models, the `logp` function enables you to detect outliers in real-time. The function returns the log unconditional probability density of the predictor variables at each observation in the chunk.

Incremental Learning Periods

Given incoming chunks of data, the actions performed by incremental learning functions depend on the current configuration or state of the model. This figure shows the periods (consecutive groups of observations) during which incremental learning functions perform particular actions.



This table describes the actions performed by incremental learning functions during each period.

Period	Associated Model Properties	Size (Number of Observations)	Actions
Estimation	`EstimationPeriod`, applies to linear classification and regression models only	n_1	When required, fitting functions choose values for hyperparameters based on estimation period observations. Actions include the following: • Estimate predictor moments `Mu` and `Sigma` for data standardization. • Adjust the learning rate `LearnRate` for SGD solvers according to the learning rate schedule `LearnRateSchedule`. • Estimate the SVM regression parameter ε `Epsilon`. • Store information buffers required for estimation. • Update corresponding properties at the end of the period.
Metrics Warm-up	`MetricsWarmupPeriod`	$n_2 - n_1$	When the property `IsWarm` is `false`, fitting functions perform the following actions: • Fit the model to the incoming chunk of data. • Update corresponding model properties, such as `Beta` or `DistributionParameters`, after fitting the model. • At the end of the period, the model is warm (the `IsWarm` property becomes `true`).

Period	Associated Model Properties	Size (Number of Observations)	Actions
Performance Evaluation *j*	`Metrics` and `MetricsWindowSize`	*m*	• At the start of Performance Evaluation Period 1, functions begin to track cumulative `Cumulative` and window `Window` metrics. `Window` is a vector of `NaN`s throughout this period. • Functions overwrite `Cumulative` metrics with the updated cumulative metric at each iteration. At the end of each Performance Evaluation Period, functions compute and overwrite `Window` metrics based on the last *m* observations. • Functions store information buffers required for computing model performance.

Configure Incremental Learning Model

An incremental learning model object completely specifies how functions implement incremental fitting and model performance evaluation. To configure (or prepare) an incremental learning model, create one by calling the object directly, or by converting a traditionally trained model to one of the objects. The following table lists the available objects, conversion functions, and supported learners for the corresponding machine learning objective.

Objective	Creation Approach	Function	Supported Learners
Binary classification	Call object	`incrementalClassificationLinear`	Linear SVM Logistic regression
	Convert model	`incrementalLearner` converts a linear SVM model (`ClassificationSVM` or `CompactClassificationSVM`) `incrementalLearner` converts a linear classification model (`ClassificationLinear`)	
Mutlicl ass classific ation	Call object	`incrementalClassificationNaiveBayes`	Naive Bayes classification with normally distributed predictor variables, conditioned on the class
	Convert model	`incrementalLearner` converts a full naive Bayes classification model (`ClassificationNaiveBayes`)	
Regress ion	Call object	`incrementalRegressionLinear`	Linear SVM regression Least squares
	Convert model	`incrementalLearner` converts a linear SVM regression model (`RegressionSVM` or `CompactRegressionSVM`) `incrementalLearner` converts a linear regression model (`RegressionLinear`)	

The creation approach you choose depends on the information you have and your preferences.

- **Call object**: Create an incremental model to your specifications by calling the object directly. This approach is flexible, enabling you to specify most options to suit your preferences, and the resulting model provides reasonable default values. However:

  - For linear classification or regression models, an estimation period might be required for your specifications.
  - For naive Bayes classification models, you must specify the maximum number of classes or all class names expected in the data during incremental learning.

  For more details, see “Call Object Directly” on page 26-9.
- **Convert model**: Convert a traditionally trained model to an incremental learner to initialize a model for incremental learning. `incrementalLearner` passes information that the traditionally trained model learned from the data. For linear models, passed information includes including optimized coefficient estimates, data characteristics, and applicable hyperparameter values. For naive Bayes classification models, passed information includes data characteristics, such as all

expected class names and fitted moments of the conditional predictor distributions. However, to convert a traditionally trained model, you must have a set of labeled data to which you can fit a model.

When you use `incrementalLearner`, you can specify all performance evaluation options and only training, model, and data options that are unknown during conversion. For more details, see "Convert Traditionally Trained Model" on page 26-12.

Regardless of the incremental model creation approach you use, consider these configurations:

- Model performance evaluation settings, such as the performance metrics to measure
- For linear models:
  - Model type, such as SVM
  - Coefficient initial values
  - Objective function solver, such as standard stochastic gradient descent (SGD)
  - Solver hyperparameter values, such as the learning rate of SGD solvers

Call Object Directly

Unlike when working with other machine learning model objects, you can create an incremental learning model by calling the corresponding object directly, without any knowledge about the data. For linear models, the only information required to create a model directly is the machine learning problem, either classification or regression, whereas naive Bayes classification models require the maximum number of classes expected in the data or all class names. For example, the following code creates a default incremental model for linear regression and a naive Bayes classification model for a data stream containing 5 classes.

```
MdlLR = incrementalRegressionLinear();
MdlNB = incrementalClassificationNaiveBayes('MaxNumClasses',5)
```

If you have information about the data to specify, or you want to configure model options or performance evaluation settings, use name-value arguments when you call the object. (All model properties are read-only; you cannot adjust them using dot notation.) For example, the following pseudocode creates an incremental logistic regression model for binary classification, initializes the linear model coefficients `Beta` and bias `Bias` (obtained from prior knowledge of the problem), and sets the performance metrics warm-up period to `500` observations.

```
Mdl = incrementalClassificationLinear('Learner','logistic',...
    'Beta',Beta,'Bias',Bias,'MetricsWarmupPeriod',500);
```

The following tables briefly describe notable options for the major aspects of incremental learning. For more details on all options, see `incrementalRegressionLinear`, `incrementalClassificationLinear`, or `incrementalClassificationNaiveBayes`.

Model Options and Data Properties

This table contains notable model options and data characteristics.

Model Type	Model Options and Data Properties	Description
Linear classification or regression	`'Beta'`	Linear coefficients that also serve as initial values for incremental fitting
	`'Bias'`	Model intercept that also serve as an initial value for incremental fitting
	`'Learner'`	Model type, such as linear SVM or least squares
Naive Bayes classification	`'Cost'`	Misclassification cost matrix
Classification	`'ClassNames'`	For classification, the expected class names in the observation labels

Training and Solver Options and Properties

This table contains notable training and solver options and properties.

Model Type	Training and Solver Options and Properties	Description
Linear classification or regression	`'EstimationPeriod'`	Pretraining estimation period
	`'Solver'`	Objective function optimization algorithm
	`'Standardize'`	Flag to standardize predictor data
	`'Lambda'`	Ridge penalty, a model hyperparameter that requires tuning for SGD optimization
	`'BatchSize'`	Mini-batch size, an SGD hyperparameter
	`'LearnRate'`	Learning rate, an SGD hyperparameter
	`'Mu'`	Read-only property containing predictor variable means
	`'Sigma'`	Read-only property containing predictor variable standard deviations
Naive Bayes classification	`'DistributionParameters'`	Fitted moments of each conditional predictor distribution given each class

For linear classification and regression models:

- The estimation period, specified by the number of observations in `EstimationPeriod`, occurs before training begins (see Incremental Learning Periods on page 26-6). During the estimation period, the incremental fitting function `fit` or `updateMetricsAndFit` computes quantities required for training when they are unknown. For example, if you set `'Standardize',true`, incremental learning functions require predictor means and standard deviations to standardize

the predictor data. Consequently, the incremental model requires a positive estimation period (the default is `1000`).

- The default solver is the adaptive scale-invariant solver `'scale-invariant'` [2], which is hyperparameter free and insensitive to the predictor variable scales; therefore, predictor data standardization is not required. You can specify standard or average SGD instead, `'sgd'` or `'asgd'`. However, SGD is sensitive to predictor variable scales and requires hyperparameter tuning, which can be difficult or impossible to do during incremental learning. If you plan to use an SGD solver, complete these steps:

  1. Obtain labeled data.
  2. Traditionally train a linear classification or regression model by calling `fitclinear` or `fitrlinear`, respectively. Specify the SGD solver you plan to use for incremental learning, cross-validate to determine an appropriate set of hyperparameters, and standardize the predictor data.
  3. Train the model on the entire sample using the specified hyperparameter set.
  4. Convert the resulting model to an incremental learner by using `incrementalLearner`.

Performance Evaluation Options and Properties

Performance evaluation properties and options enable you to configure how and when model performance is measured by the incremental learning function `updateMetrics` or `updateMetricsAndFit`. Regardless of the options you choose, first familiarize yourself with the incremental learning periods on page 26-6.

This table contains all performance evaluation options and properties.

Performance Evaluation Options and Properties	Description
`'Metrics'`	List of performance metrics or loss functions to measure incrementally
`'MetricsWarmupPeiod'`	Number of observations to which the incremental model must be fit before it tracks performance metrics
`'MetricsWindowSize'`	Number of observations to use to compute window performance metrics
`'IsWarm'`	Read-only property indicating whether the model is warm (measures performance metrics)
`'Metrics'`	Read-only property containing a table of tracked cumulative and window metrics

The metrics specified by the `'Metrics'` name-value form a table stored in the `Metrics` property of the model. For example, if you specify `'Metrics',["Metric1" "Metric2"]` when you create an incremental model `Mdl`, the `Metrics` property is

```
>> Mdl.Metrics

ans =

  2×2 table
                Cumulative    Window
                __________    ______
```

```
    Metric1        NaN         NaN
    Metric2        NaN         NaN
```

Specify a positive metrics warm-up period when you believe the model is of low quality and needs to be trained before the function `updateMetrics` or `updateMetricsAndFit` tracks performance metrics in the `Metrics` property. In this case, the `IsWarm` property is `false`, and you must pass the incoming data and model to the incremental fitting function `fit` or `updateMetricsAndFit`.

When the incremental fitting function processes enough data to satisfy the estimation (for linear models) and metrics warm-up periods, the `IsWarm` property becomes `true`, and you can measure the model performance on incoming data and optionally train the model. For naive Bayes classification models, incremental fitting functions must additionally fit the model to all expected classes to become warm.

When the model is warm, `updateMetrics` or `updateMetricsAndFit` tracks all specified metrics cumulatively (from the start of the evaluation) and within a window of observations specified by the `MetricsWindowSize` property. Cumulative metrics reflect the model performance over the entire incremental learning history; after Performance Evaluation Period 1 starts, cumulative metrics are independent of the evaluation period. Window metrics reflect the model performance only over the specified window size for each performance evaluation period.

Convert Traditionally Trained Model

`incrementalLearner` enables you to initialize an incremental model using information learned from a traditionally trained model. The converted model can generate predictions and it is warm, which means that incremental learning functions can measure model performance metrics from the start of the data stream. In other words, estimation and performance metrics warm-up periods are not required for incremental learning.

To convert a traditionally trained model to an incremental learner, pass the model and any options specified by name-value arguments to `incrementalLearner`. For example, the following pseudocode initializes an incremental classification model by using all information that a linear SVM model for binary classification has learned from a batch of data.

```
Mdl = fitcsvm(X,Y);
IncrementalMdl = incrementalLearner(Mdl,Name,Value);
```

`IncrementalMdl` is an incremental learner object associated with the machine learning objective.

Ease of incremental model creation and initialization is offset by decreased flexibility. The software assumes that fitted parameters, hyperparameter values, and data characteristics learned during traditional training are appropriate for incremental learning. Therefore, you cannot set corresponding learned or tuned options when you call `incrementalLearner`. This table lists notable read-only properties of `IncrementalMdl` that `incrementalLearner` transfers from `Mdl`, or that the function infers from other values.

Model Type	Property	Description
All	`NumPredictors`	Number of predictor variables. For models that dummy-code categorical predictor variables, `NumPredictors` is `numel(Mdl.ExpandedPredictorNames)`, and predictor variables expected during incremental learning correspond to the names. For more details, see “Dummy Variables” on page 2-48.
Classification	`ClassNames`	All class labels expected during incremental learning
	`Prior`	Prior class distribution
	`ScoreTransform`	A function to apply to classification scores. For example, if you configure an SVM model to compute posterior class probabilities, `ScoreTransform` (containing the score-to-posterior-probability function learned from the data) is transferred.
Regression	`Epsilon`	For an SVM learner, half the width of the epsilon-insensitive band
	`ResponseTransform`	A function to apply to predicted responses
Linear classification or regression	`Beta`	Linear model coefficients
	`Bias`	Model intercept
	`Learner`	Linear model type
	`Mu`	For an SVM model object, the predictor variable means
	`Sigma`	For an SVM model object, the predictor variable standard deviations
Naive Bayes classification	`DistributionNames`	A `NumPredictors` length cell vector with `'normal'` in each cell. If you convert a naive Bayes classification model containing at least one non-normal predictor, `incrementalLearner` issues an error.
	`DistributionParameters`	Fitted moments of each conditional predictor distribution given each class

Note

- The `NumTrainingObservations` property of `IncrementalMdl` does not include the observations used to train `Mdl`.
- If you specify `'Standardize',true` when you train `Mdl`, `IncrementalMdl` is configured to standardize predictors during incremental learning by default.

The following conditions apply when you convert a linear classification or regression model (`ClassificationLinear` and `RegressionLinear`, respectively):

- Incremental fitting functions support ridge (L2) regularization only.
- Incremental fitting functions support the specification of only one regularization value. Therefore, if you specify a regularization path (vector of regularization values) when you call `fitclinear` or `fitrlinear`, choose the model associated with one penalty by passing it to `selectModels`.
- If you solve the objective function by using standard or average SGD (`'sgd'` or `'asgd'` for the `'Solver'` name-value argument), these conditions apply when you call `incrementalLearner`:
  - `incrementalLearner` transfers the solver used to optimize `Mdl` to `IncrementalMdl`.
  - You can specify the adaptive scale-invariant solver `'scale-invariant'` instead, but you cannot specify a different SGD solver.
  - If you do not specify the adaptive scale-invariant solver, `incrementalLearner` transfers model and solver hyperparameter values to the incremental model object, such as the learning rate `LearnRate`, mini-batch size `BatchSize`, and ridge penalty `Lambda`. You cannot modify the transferred properties.

If you require more flexibility when you create an incremental model, you can call the object directly on page 26-9 and initialize the model by individually setting learned information using name-value arguments. The following pseudocode show two examples:

- Initialize an incremental classification model from the coefficients and class names learned by fitting a linear SVM model for binary classification to a batch of data `Xc` and `Yc`.
- Initialize an incremental regression model from the coefficients learned by fitting a linear model to a batch of data `Xr` and `Yr`.

```
% Linear Classification
Mdl = fitcsvm(Xc,Yc);
IncrementalMdl = incrementalClassificationLinear('Beta',Mdl.Beta,...
    'Bias',Mdl.Bias,'ClassNames',Mdl.ClassNames);

% Linear Regression
Mdl = fitlm(Xr,Yr);
Bias = Mdl.Coefficients.Estimate(1);
Beta = Mdl.Coefficients.Estimate(2:end);
IncrementalMdl = incrementalRegressionLinear('Learner','leastsquares',...
    'Bias',Bias,'Beta',Beta);
```

For naive Bayes classification models, you cannot specify the moments of the conditional probability distribution of each predictor variable `DistributionParameters`; they must be fitted to data, by `fit` or `fitcnb`

Implement Incremental Learning for Linear Regression Using Succinct Workflow

This example shows how to use the succinct workflow to implement incremental learning for linear regression with prequential evaluation. Specifically, this example does the following:

1. Create a default incremental learning model for linear regression.
2. Simulate a data stream using a for loop, which feeds small chunks of observations to the incremental learning algorithm.
3. For each chunk, use `updateMetricsAndFit` to measure the model performance given the incoming data, and then fit the model to that data.

Create Default Model Object

Create a default incremental learning model for linear regression.

```
Mdl = incrementalRegressionLinear()
```

```
Mdl =
  incrementalRegressionLinear

               IsWarm: 0
              Metrics: [1x2 table]
    ResponseTransform: 'none'
                 Beta: [0x1 double]
                 Bias: 0
              Learner: 'svm'

  Properties, Methods
```

```
Mdl.EstimationPeriod
```

```
ans = 1000
```

`Mdl` is an `incrementalRegressionLinear` model object. All its properties are read-only.

`Mdl` must be fit to data before you can use it to perform any other operations. The software sets the estimation period to 1000 because half the width of the epsilon insensitive band `Epsilon` is unknown. You can set `Epsilon` to a positive floating point scalar by using the `'Epsilon'` name-value pair argument. This action results in a default estimation period of 0.

Load Data

Load the robot arm data set.

```
load robotarm
```

For details on the data set, enter `Description` at the command line.

Implement Incremental Learning

Use the succinct workflow to update model performance metrics and fit the incremental model to the training data by calling the `updateMetricsAndFit` function. At each iteration:

- Process 50 observations to simulate a data stream.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the cumulative metrics, window metrics, and the first coefficient β_1 to see how they evolve during incremental learning.

```
% Preallocation
n = numel(ytrain);
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ei = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = zeros(nchunk,1);

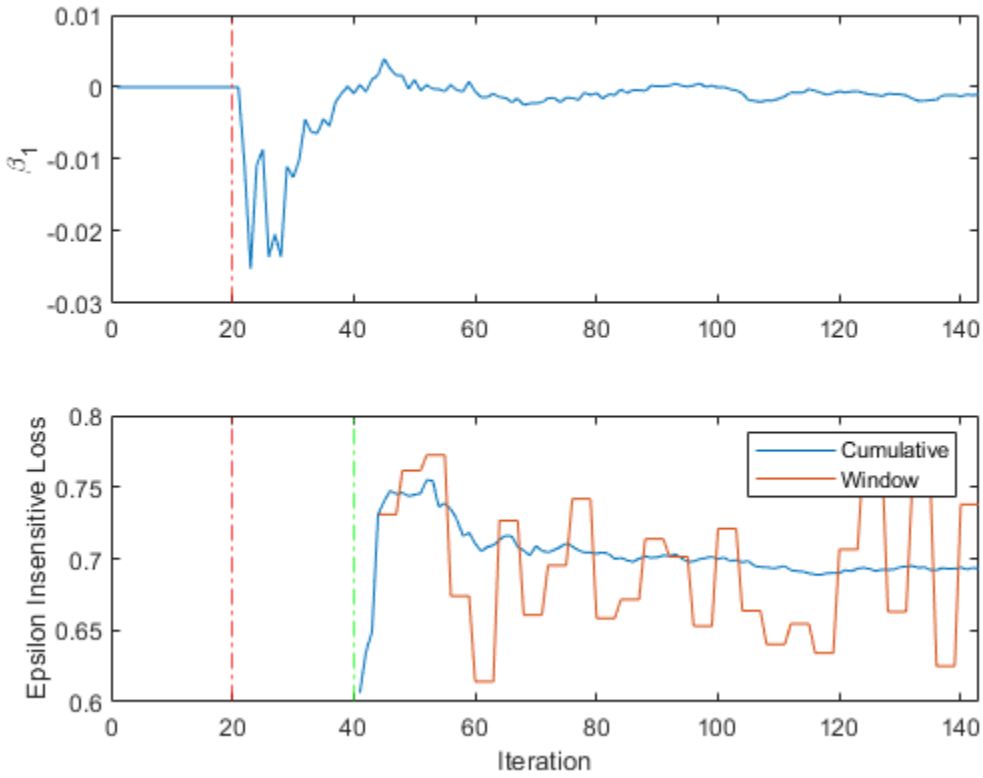
% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetricsAndFit(Mdl,Xtrain(idx,:),ytrain(idx));
    ei{j,:} = Mdl.Metrics{"EpsilonInsensitiveLoss",:};
    beta1(j + 1) = Mdl.Beta(1);
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

Inspect Model Evolution

To see how the performance metrics and β_1 evolved during training, plot them on separate subplots.

```
figure;
subplot(2,1,1)
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xline(Mdl.EstimationPeriod/numObsPerChunk,'r-.');
subplot(2,1,2)
h = plot(ei.Variables);
xlim([0 nchunk]);
ylabel('Epsilon Insensitive Loss')
xline(Mdl.EstimationPeriod/numObsPerChunk,'r-.');
xline((Mdl.EstimationPeriod + Mdl.MetricsWarmupPeriod)/numObsPerChunk,'g-.');
legend(h,ei.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- After the estimation period (first 20 iterations), fit β_1 during all incremental learning iterations.
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 200 observations (4 iterations).

Implement Incremental Learning for Classification Using Succinct Workflow

This example shows how to use the succinct workflow to implement incremental learning for binary classification with prequential evaluation. Specifically, this example does the following:

1. Create a default incremental learning model for binary classification.
2. Simulate a data stream using a for loop, which feeds small chunks of observations to the incremental learning algorithm.
3. For each chunk, use `updateMetricsAndFit` to measure the model performance given the incoming data, and then fit the model to that data.

Although this example treats the application as a binary classification problem, you can implement multiclass incremental learning using the naive Bayes algorithm instead by following this same workflow. See the `incrementalClassificationNaiveBayes` object.

Create Default Model Object

Create a default incremental learning model for binary classification.

```
Mdl = incrementalClassificationLinear()
```

```
Mdl =
  incrementalClassificationLinear

            IsWarm: 0
           Metrics: [1x2 table]
        ClassNames: [1x0 double]
    ScoreTransform: 'none'
              Beta: [0x1 double]
              Bias: 0
           Learner: 'svm'

  Properties, Methods
```

`Mdl` is an `incrementalClassificationLinear` model object. All its properties are read-only.

`Mdl` must be fit to data before you can use it to perform any other operations.

Load and Preprocess Data

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
n = numel(actid);
rng(1); % For reproducibility
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Walking, Running, or Dancing. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = Y > 2;
```

Implement Incremental Learning

Use the succinct workflow to update model performance metrics and fit the incremental model to the training data by calling the `updateMetricsAndFit` function. At each iteration:

- Process 50 observations to simulate a data stream.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the cumulative metrics, the window metrics, and the first coefficient β_1 to see how they evolve during incremental learning.

```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = zeros(nchunk,1);

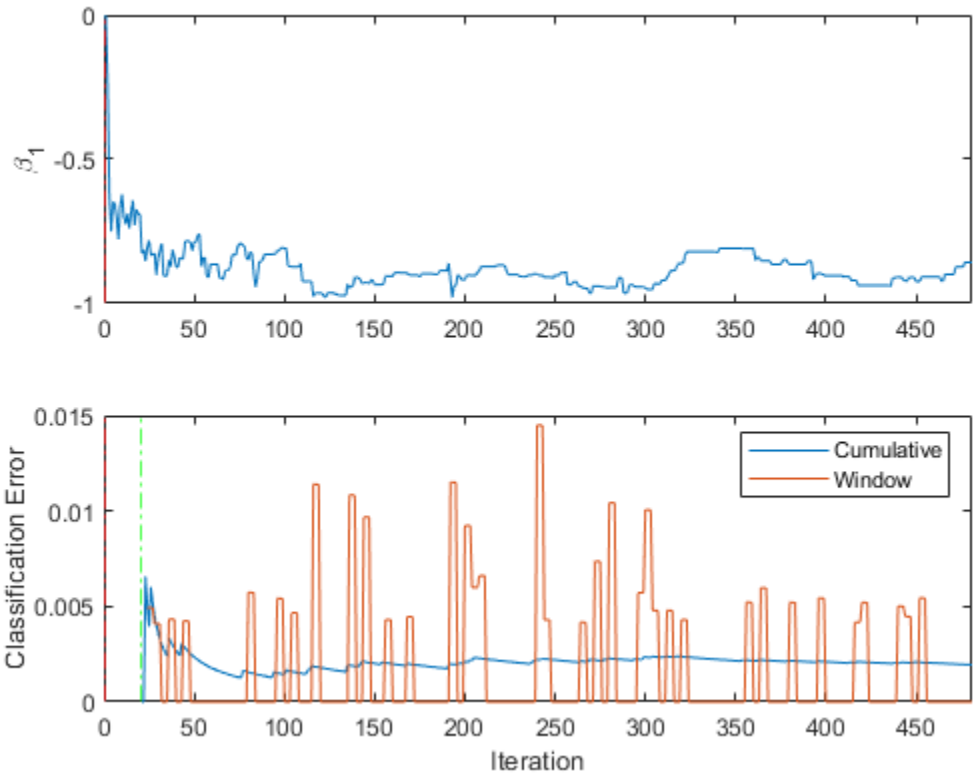
% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetricsAndFit(Mdl,X(idx,:),Y(idx));
    ce{j,:} = Mdl.Metrics{"ClassificationError",:};
    beta1(j + 1) = Mdl.Beta(1);
end
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

Inspect Model Evolution

To see how the performance metrics and β_1 evolved during training, plot them on separate subplots.

```
figure;
subplot(2,1,1)
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xline(Mdl.EstimationPeriod/numObsPerChunk,'r-.');
subplot(2,1,2)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
xline(Mdl.EstimationPeriod/numObsPerChunk,'r-.');
xline((Mdl.EstimationPeriod + Mdl.MetricsWarmupPeriod)/numObsPerChunk,'g-.');
legend(h,ce.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit β_1 during all incremental learning iterations.
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 200 observations (4 iterations).

Implement Incremental Learning for Linear Regression Using Flexible Workflow

This example shows how to use the flexible workflow to implement incremental learning for linear regression with prequential evaluation. A traditionally trained model initializes the incremental model. Specifically, this example does the following:

1. Train a linear regression model on a subset of data.
2. Convert the traditionally trained model to an incremental learning model for linear regression.
3. Simulate a data stream using a for loop, which feeds small chunks of observations to the incremental learning algorithm.
4. For each chunk, use `updateMetrics` to measure the model performance given the incoming data, and then use `fit` to fit the model to that data.

Load and Preprocess Data

Load the 2015 NYC housing data set, and shuffle the data. For more details on the data, see NYC Open Data.

```
load NYCHousing2015
rng(1); % For reproducibility
n = size(NYCHousing2015,1);
idxshuff = randsample(n,n);
NYCHousing2015 = NYCHousing2015(idxshuff,:);
```

Suppose that the data collected from Manhattan (`BOROUGH = 1`) was collected using a new method that doubles its quality. Create a weight variable that attributes `2` to observations collected from Manhattan, and `1` to all other observations.

```
NYCHousing2015.W = ones(n,1) + (NYCHousing2015.BOROUGH == 1);
```

Extract the response variable `SALEPRICE` from the table. For numerical stability, scale `SALEPRICE` by `1e6`.

```
Y = NYCHousing2015.SALEPRICE/1e6;
NYCHousing2015.SALEPRICE = [];
```

Create dummy variable matrices from the categorical predictors.

```
catvars = ["BOROUGH" "BUILDINGCLASSCATEGORY" "NEIGHBORHOOD"];
dumvarstbl = varfun(@(x)dummyvar(categorical(x)),NYCHousing2015,...
    'InputVariables',catvars);
dumvarmat = table2array(dumvarstbl);
NYCHousing2015(:,catvars) = [];
```

Treat all other numeric variables in the table as linear predictors of sales price. Concatenate the matrix of dummy variables to the rest of the predictor data. Transpose the data.

```
idxnum = varfun(@isnumeric,NYCHousing2015,'OutputFormat','uniform');
X = [dumvarmat NYCHousing2015{:,idxnum}]';
```

Train Linear Regression Model

Fit a linear regression model to a random sample of half the data. Specify that observations are oriented along the columns of the data.

```
idxtt = randsample([true false],n,true);
TTMdl = fitrlinear(X(:,idxtt),Y(idxtt),'ObservationsIn','columns')
```

```
TTMdl =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [313x1 double]
                 Bias: 0.1889
               Lambda: 2.1977e-05
              Learner: 'svm'

  Properties, Methods
```

`TTMdl` is a `RegressionLinear` model object representing a traditionally trained linear regression model.

Convert Trained Model

Convert the traditionally trained linear regression model to a linear regression model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalRegressionLinear

               IsWarm: 1
              Metrics: [1x2 table]
    ResponseTransform: 'none'
                 Beta: [313x1 double]
                 Bias: 0.1889
              Learner: 'svm'

  Properties, Methods
```

Implement Incremental Learning

Use the flexible workflow to update model performance metrics and fit the incremental model to the training data by calling the `updateMetrics` and `fit` functions separately. Simulate a data stream by processing 500 observations at a time. At each iteration:

1. Call `updateMetrics` to update the cumulative and window epsilon insensitive loss of the model given the incoming chunk of observations. Overwrite the previous incremental model to update the losses in the `Metrics` property. Note that the function does not fit the model to the chunk of data—the chunk is "new" data for the model. Specify that observations are oriented along the columns of the data.
2. Call `fit` to fit the model to the incoming chunk of observations. Overwrite the previous incremental model to update the model parameters. Specify that observations are oriented along the columns of the data.
3. Store the losses and last estimated coefficient β_{313}.

```
% Preallocation
numObsPerChunk = 500;
nchunk = floor(n/numObsPerChunk);
ei = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta313 = zeros(nchunk,1);

% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetrics(IncrementalMdl,X(:,idx),Y(idx),'ObservationsIn','columns');
    ei{j,:} = IncrementalMdl.Metrics{"EpsilonInsensitiveLoss",:};
    IncrementalMdl = fit(IncrementalMdl,X(:,idx),Y(idx),'ObservationsIn','columns');
    beta313(j) = IncrementalMdl.Beta(end);
end
```

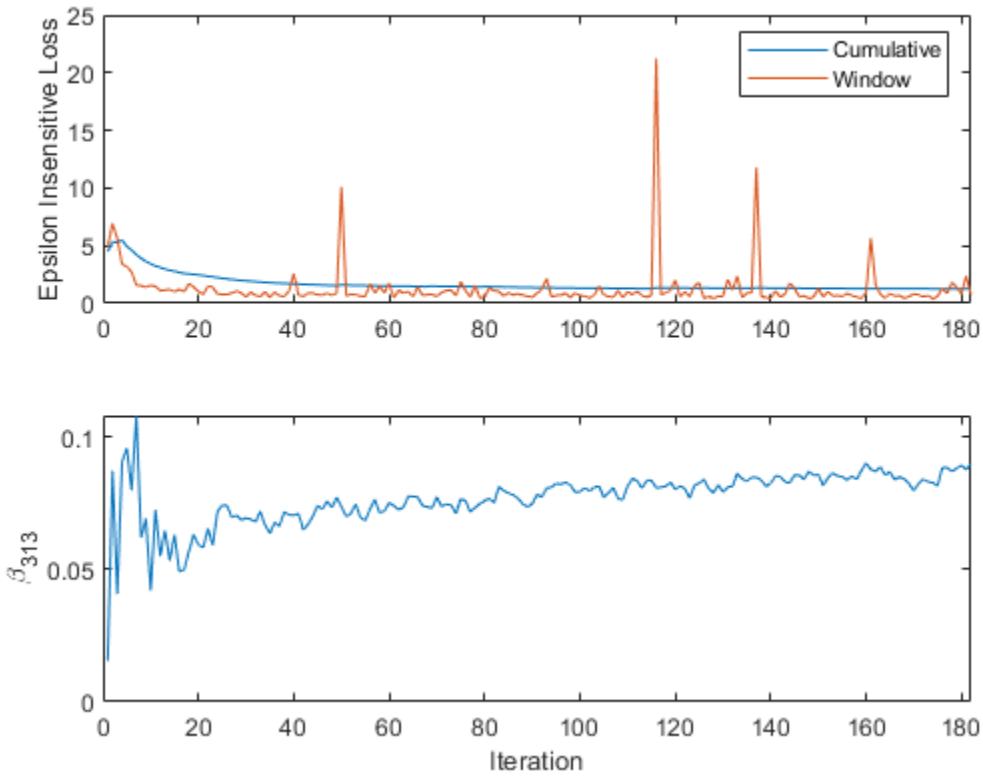
`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream.

Alternatively, you can use `updateMetricsAndFit` to update performance metrics of the model given a new chunk of data, and then fit the model to the data.

Inspect Model Evolution

Plot a trace plot of the performance metrics and estimated coefficient β_{313}.

```
figure;
subplot(2,1,1)
h = plot(ei.Variables);
xlim([0 nchunk]);
ylabel('Epsilon Insensitive Loss')
legend(h,ei.Properties.VariableNames)
subplot(2,1,2)
plot(beta313)
ylabel('\beta_{313}')
xlim([0 nchunk]);
xlabel('Iteration')
```



The cumulative loss gradually changes with each iteration (chunk of 500 observations), whereas the window loss jumps. Because the metrics window is 200 by default, `updateMetrics` measures the performance based on the latest 200 observations in each 500 observation chunk.

β_{313} changes abruptly at first and then just slightly as `fit` processes chunks of observations.

Implement Incremental Learning for Classification Using Flexible Workflow

This example shows how to use the flexible workflow to implement incremental learning for binary classification with prequential evaluation. A traditionally trained model initializes the incremental model. Specifically, this example does the following:

1. Train a linear model for binary classification on a subset of data.
2. Convert the traditionally trained model to an incremental learning model for binary classification.
3. Simulate a data stream using a for loop, which feeds small chunks of observations to the incremental learning algorithm.
4. For each chunk, use `updateMetrics` to measure the model performance given the incoming data, and then use `fit` to fit the model to that data.

Although this example treats the application as a binary classification problem, you can implement multiclass incremental learning using the naive Bayes algorithm instead by following this same workflow. See the `incrementalClassificationNaiveBayes` object.

Load and Preprocess Data

Load the human activity data set. Randomly shuffle the data. Orient the observations of the predictor data in columns.

```
load humanactivity
rng(1); % For reproducibility
n = numel(actid);
idx = randsample(n,n);
X = feat(idx,:)';
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Walking, Running, or Dancing. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = Y > 2;
```

Train Linear Model for Binary Classification

Fit a linear model for binary classification to a random sample of half the data. Specify that the observations are oriented along the columns of the data.

```
idxtt = randsample([true false],n,true);
TTMdl = fitclinear(X(:,idxtt),Y(idxtt),'ObservationsIn','columns')
```

```
TTMdl =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [60x1 double]
              Bias: -0.2999
            Lambda: 8.2967e-05
           Learner: 'svm'
```

```
  Properties, Methods
```

`TTMdl` is a `ClassificationLinear` model object representing a traditionally trained linear model for binary classification.

Convert Trained Model

Convert the traditionally trained classification model to a binary classification linear model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalClassificationLinear

            IsWarm: 1
           Metrics: [1x2 table]
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [60x1 double]
              Bias: -0.2999
           Learner: 'svm'

  Properties, Methods
```

Implement Incremental Learning

Use the flexible workflow to update model performance metrics and fit the incremental model to the training data by calling the `updateMetrics` and `fit` functions separately. Simulate a data stream by processing 50 observations at a time. At each iteration:

1. Call `updateMetrics` to update the cumulative and window classification error of the model given the incoming chunk of observations. Overwrite the previous incremental model to update the losses in the `Metrics` property. Note that the function does not fit the model to the chunk of data—the chunk is "new" data for the model. Specify that the observations are oriented in columns.
2. Call `fit` to fit the model to the incoming chunk of observations. Overwrite the previous incremental model to update the model parameters. Specify that the observations are oriented in columns.
3. Store the classification error and first estimated coefficient β_1.

```
% Preallocation
idxil = ~idxtt;
nil = sum(idxil);
numObsPerChunk = 50;
nchunk = floor(nil/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = [IncrementalMdl.Beta(1); zeros(nchunk,1)];
Xil = X(:,idxil);
Yil = Y(idxil);

% Incremental fitting
```

```
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetrics(IncrementalMdl,Xil(:,idx),Yil(idx),...
        'ObservationsIn','columns');
    ce{j,:} = IncrementalMdl.Metrics{"ClassificationError",:};
    IncrementalMdl = fit(IncrementalMdl,Xil(:,idx),Yil(idx),'ObservationsIn','columns');
    beta1(j + 1) = IncrementalMdl.Beta(end);
end
```

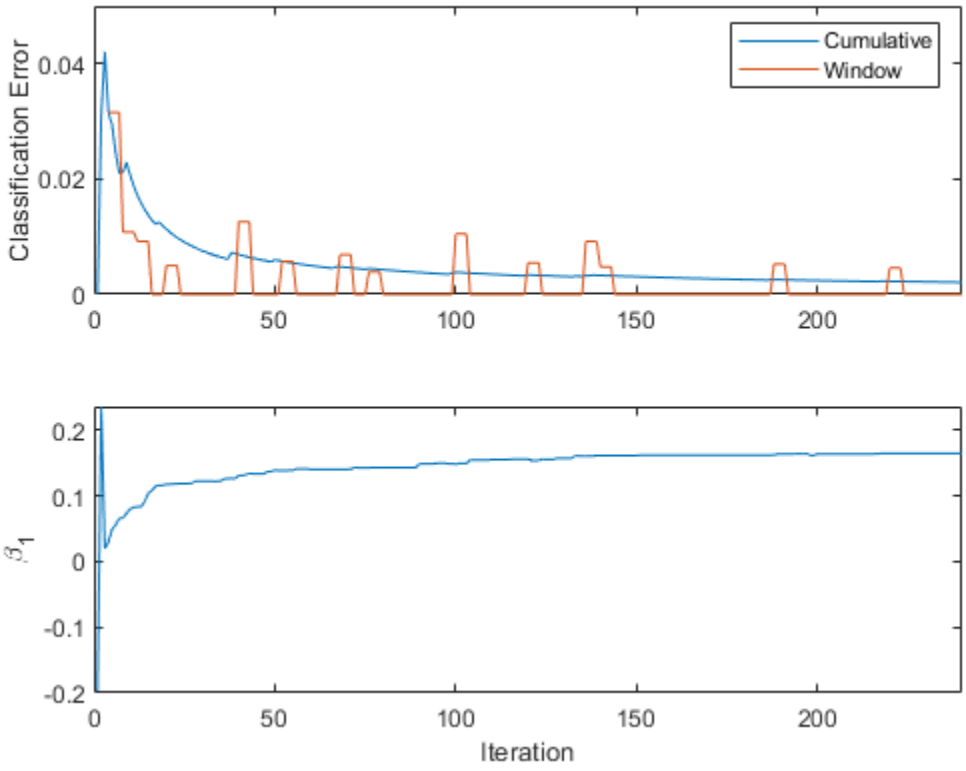
`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream.

Alternatively, you can use `updateMetricsAndFit` to update performance metrics of the model given a new chunk of data, and then fit the model to the data.

Inspect Model Evolution

Plot a trace plot of the performance metrics and estimated coefficient β_1.

```
figure;
subplot(2,1,1)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
legend(h,ce.Properties.VariableNames)
subplot(2,1,2)
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xlabel('Iteration')
```



The cumulative loss is stable and decreases gradually, whereas the window loss jumps.

β_1 changes abruptly at first, and then gradually levels off as `fit` processes more chunks of observations.

Initialize Incremental Learning Model from SVM Regression Model Trained in Regression Learner

This example shows how to tune and train a linear SVM regression model using the **Regression Learner** app. Then, at the command line, initialize and train an incremental model for linear SVM regression using the information gained from training in the app.

Load and Preprocess Data

Load the 2015 NYC housing data set, and shuffle the data. For more details on the data, see NYC Open Data.

```
load NYCHousing2015
rng(1); % For reproducibility
n = size(NYCHousing2015,1);
idxshuff = randsample(n,n);
NYCHousing2015 = NYCHousing2015(idxshuff,:);
```

For numerical stability, scale `SALEPRICE` by `1e6`.

```
NYCHousing2015.SALEPRICE = NYCHousing2015.SALEPRICE/1e6;
```

Consider training a linear SVM regression model to about 1% of the data, and reserving the remaining data for incremental learning.

Regression Learner supports categorical variables. However, because SVM models require dummy-coded categorical variables, and the `BUILDINGCLASSCATEGORY` and `NEIGHBORHOOD` variables contain many levels (some with low representation), the probability that a partition does not have all categories is high. Therefore, dummy-code all categorical variables. Concatenate the matrix of dummy variables to the rest of the numeric variables.

```
catvars = ["BOROUGH" "BUILDINGCLASSCATEGORY" "NEIGHBORHOOD"];
dumvars = splitvars(varfun(@(x)dummyvar(categorical(x)),NYCHousing2015,...
      'InputVariables',catvars));
NYCHousing2015(:,catvars) = [];
idxnum = varfun(@isnumeric,NYCHousing2015,'OutputFormat','uniform');
NYCHousing2015 = [dumvars NYCHousing2015(:,idxnum)];
```

Randomly partition the data into 1% and 99% subsets by calling `cvpartition` and specifying a holdout (test) sample proportion of `0.99`. Create tables for the 1% and 99% partitions.

```
cvp = cvpartition(n,'HoldOut',0.99);
idxtt = cvp.training;
idxil = cvp.test;
NYCHousing2015tt = NYCHousing2015(idxtt,:);
NYCHousing2015il = NYCHousing2015(idxil,:);
```

Tune and Train Model Using Regression Learner

Open **Regression Learner** by entering `regressionLearner` at the command line.

```
regressionLearner
```

Alternatively, on the **Apps** tab, click the **Show more** arrow to open the apps gallery. Under **Machine Learning and Deep Learning**, click the app icon.

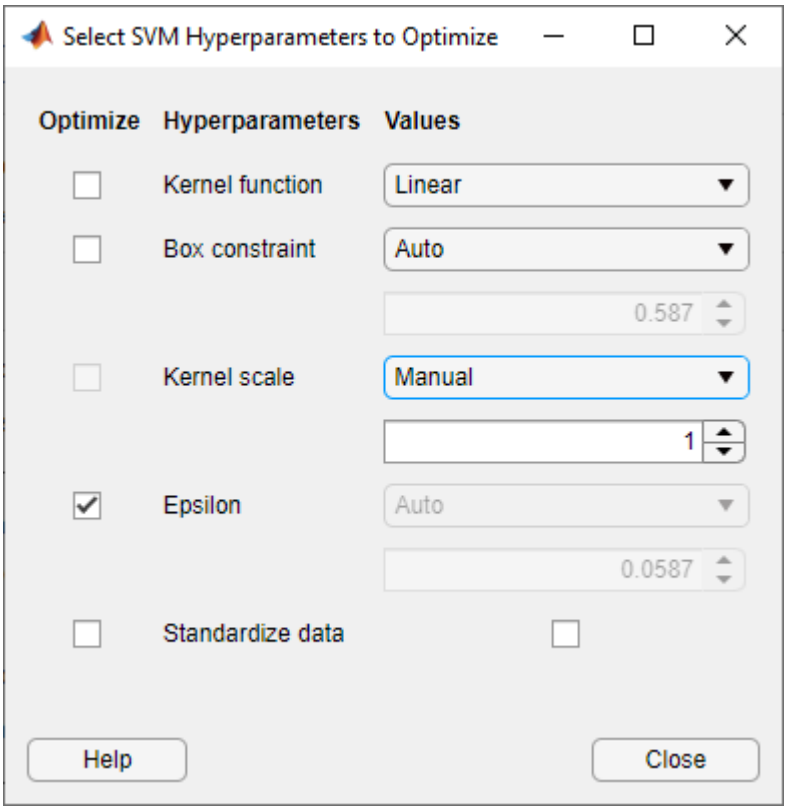
Choose the training data set and variables.

1. On the **Regression Learner** tab, in the **File** section, select **New Session**, and then select **From Workspace**.
2. In the **New Session from Workspace** dialog box, under **Data Set Variable**, select the data set **NYCHousing2015tt**.
3. Under **Response**, ensure the response variable **SALEPRICE** is selected.
4. Click **Start Session**.

The app implements 5-fold cross-validation by default.

Train a linear SVM regression model. Tune only the **Epsilon** hyperparameter by using Bayesian optimization.

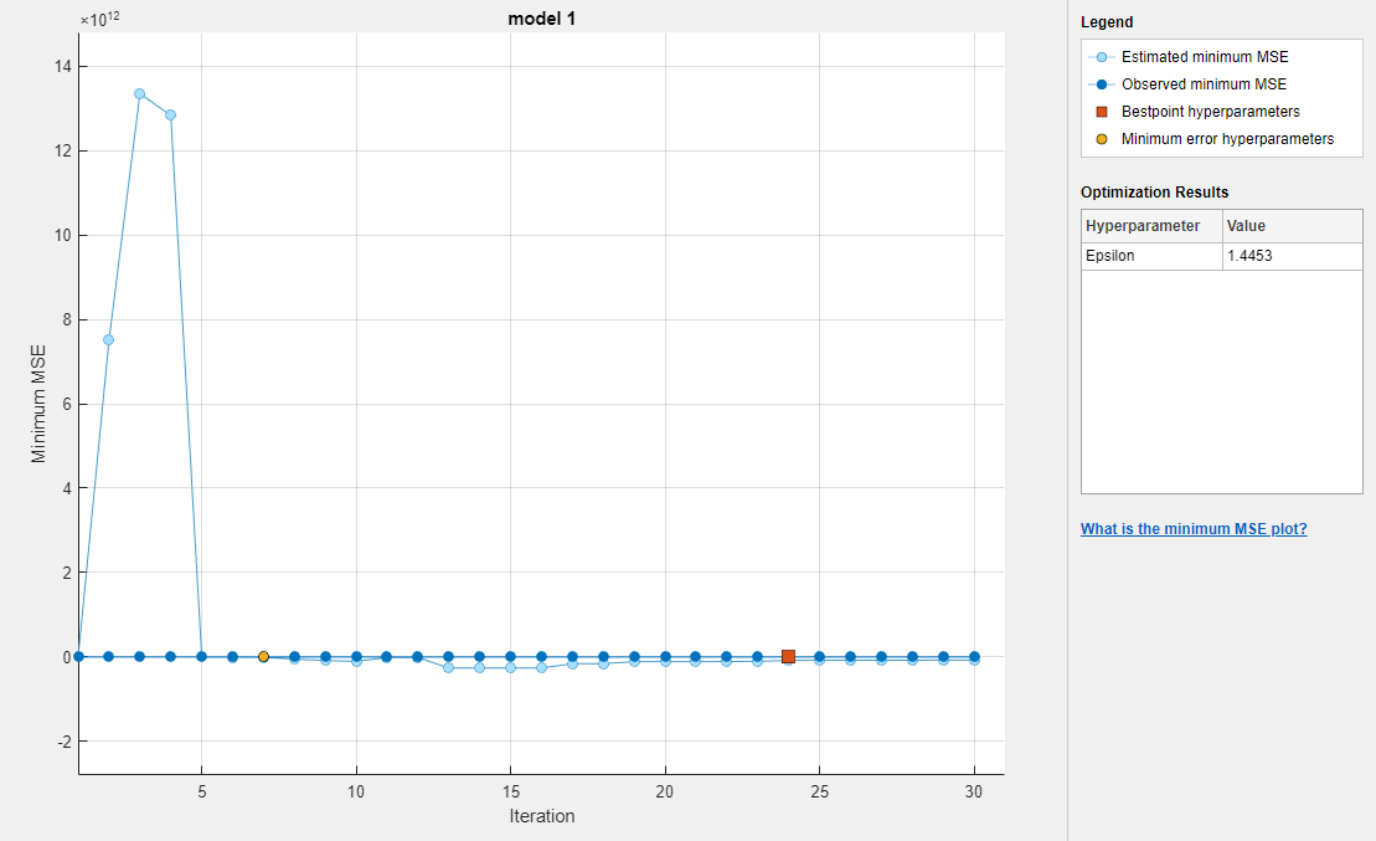
1. On the **Regression Learner** tab, in the **Model Type** section, click the **Show more** arrow to open the apps gallery. In the **Support Vector Machines** section, click **Optimizable SVM**.
2. On the **Regression Learner** tab, in the **Model Type** section, select **Advanced**, and then select **Advanced**.
3. In the **Select SVM Hyperparameters to Optimize** dialog box:
   a. Deselect the **Optimize** boxes for all options except **Epsilon**.
   b. Set the value of **Kernel scale** to `Manual` and `1`.
   c. Deselect the **Value** box **Standardize data**.



4. Close the dialog box.

5 On the **Regression Learner** tab, in the **Training** section, click **Train**.

The app shows a plot of the generalization minimum MSE of the model as optimization progresses. The app can take some time to optimize the algorithm.



Export the trained, optimized linear SVM regression model.

1 On the **Regression Learner** tab, in the **Export** section, select **Export Model**, and select **Export Model**.

2 In the **Export Model** dialog box, click **OK**.

The app passes the trained model, among other variables, in the structure array `trainedModel` to the workspace. Close **Regression Learner** .

Convert Exported Model to Incremental Model

At the command line, extract the trained SVM regression model from `trainedModel`.

```
Mdl = trainedModel.RegressionSVM;
```

Convert the model to an incremental model.

```
IncrementalMdl = incrementalLearner(Mdl)
IncrementalMdl.Epsilon
```

```
IncrementalMdl =
```

```
  incrementalRegressionLinear

              IsWarm: 1
             Metrics: [1×2 table]
    ResponseTransform: 'none'
                Beta: [312×1 double]
                Bias: 10.1437
             Learner: 'svm'

  Properties, Methods

ans =

    1.4453
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object for incremental learning using a linear SVM regression model. `incrementalLearner` initializes `IncrementalMdl` using the coefficients and the optimized value of the `Epsilon` hyperparameter learned from `Mdl`. Therefore, you can predict responses by passing `IncrementalMdl` and data to `predict`. Also, the `IsWarm` property is `true`, which means that the incremental learning functions measure the model performance from the start of incremental learning.

Implement Incremental Learning

Because incremental learning functions accept floating-point matrices only, create matrices for the predictor and response data.

```
Xil = NYCHousing2015il{:,1:(end-1)};
Yil = NYCHousing2015il{:,end};
```

Perform incremental learning on the 99% data partition by using the `updateMetricsAndFit` function. Simulate a data stream by processing 500 observations at a time. At each iteration:

1. Call `updateMetricsAndFit` to update the cumulative and window epsilon insensitive loss of the model given the incoming chunk of observations. Overwrite the previous incremental model to update the losses in the `Metrics` property. Note that the function does not fit the model to the chunk of data—the chunk is "new" data for the model.
2. Store the losses and last estimated coefficient β_{313}.

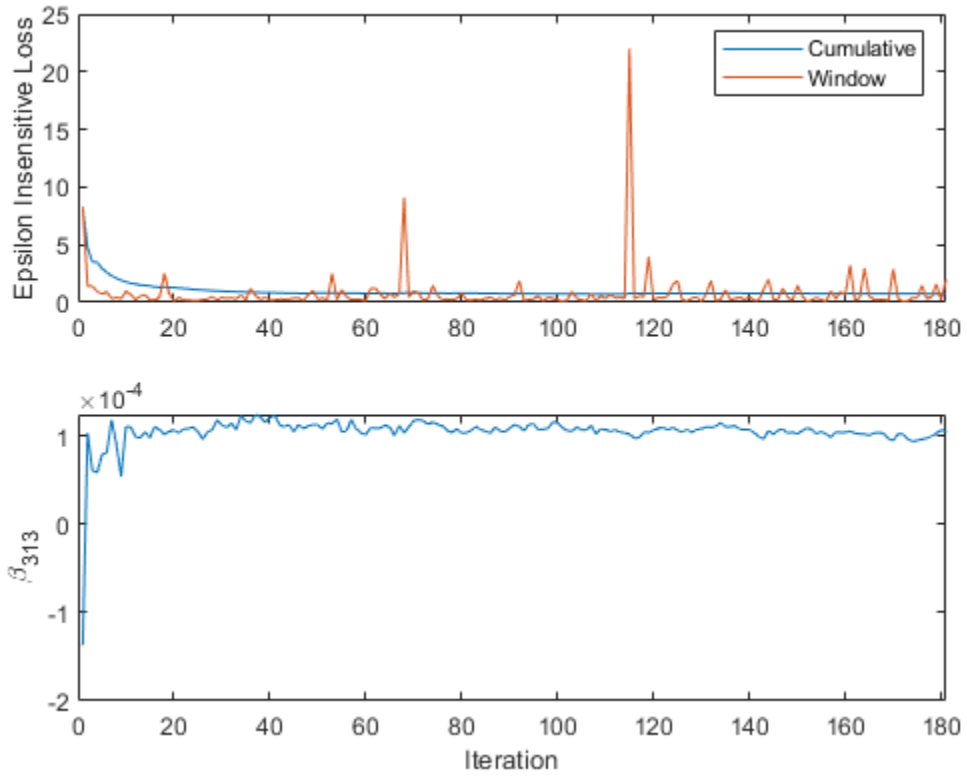
```
% Preallocation
nil = sum(idxil);
numObsPerChunk = 500;
nchunk = floor(nil/numObsPerChunk);
ei = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta313 = [IncrementalMdl.Beta(end); zeros(nchunk,1)];

% Incremental learning
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetricsAndFit(IncrementalMdl,Xil(idx,:),Yil(idx));
    ei{j,:} = IncrementalMdl.Metrics{"EpsilonInsensitiveLoss",:};
    beta313(j + 1) = IncrementalMdl.Beta(end);
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream.

Plot a trace plot of the performance metrics and estimated coefficient β_{313}.

```
figure;
subplot(2,1,1)
h = plot(ei.Variables);
xlim([0 nchunk]);
ylabel('Epsilon Insensitive Loss')
legend(h,ei.Properties.VariableNames)
subplot(2,1,2)
plot(beta313)
ylabel('\beta_{313}')
xlim([0 nchunk]);
xlabel('Iteration')
```



The cumulative loss gradually changes with each iteration (chunk of 500 observations), whereas the window loss jumps. Because the metrics window is 200 by default, `updateMetricsAndFit` measures the performance based on the latest 200 observations in each 500 observation chunk.

β_{313} changes abruptly and then levels off as `updateMetricsAndFit` processes chunks of observations.

Initialize Incremental Learning Model from Logistic Regression Model Trained in Classification Learner

This example shows how to train a logistic regression model using the **Classification Learner** app. Then, at the command line, initialize and train an incremental model for binary classification using the information gained from training in the app.

Load and Preprocess Data

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
rng(1); % For reproducibility
n = numel(actid);
idx = randsample(n,n);
X = feat(idx,:);
actid = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Walking, Running, or Dancing. Dichotomize the response by creating a categorical array that identifies whether the subject is moving (`actid > 2`).

```
moveidx = actid > 2;
Y = repmat("NotMoving",n,1);
Y(moveidx) = "Moving";
Y = categorical(Y);
```

Consider training a logistic regression model to about 1% of the data, and reserving the remaining data for incremental learning.

Randomly partition the data into 1% and 99% subsets by calling `cvpartition` and specifying a holdout (test) sample proportion of `0.99`. Create variables for the 1% and 99% partitions.

```
cvp = cvpartition(n,'HoldOut',0.99);
idxtt = cvp.training;
idxil = cvp.test;

Xtt = X(idxtt,:);
Xil = X(idxil,:);
Ytt = Y(idxtt);
Yil = Y(idxil);
```

Train Model Using Classification Learner

Open **Classification Learner** by entering `classificationLearner` at the command line.

```
classificationLearner
```

Alternatively, on the **Apps** tab, click the **Show more** arrow to open the apps gallery. Under **Machine Learning and Deep Learning**, click the app icon.

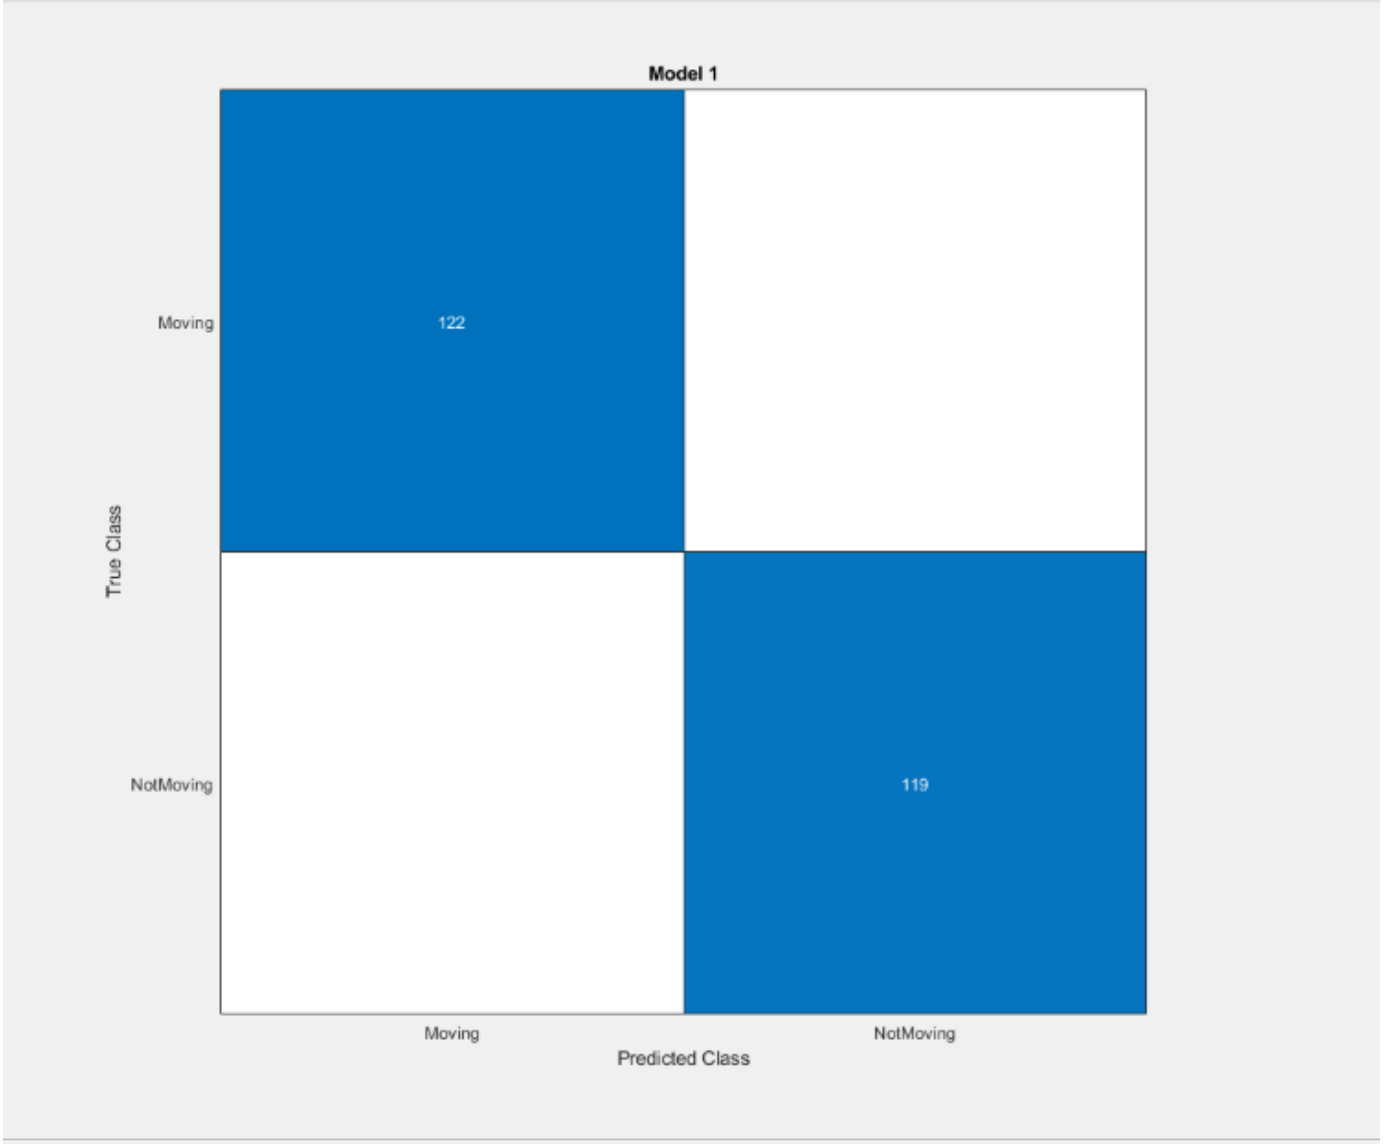
Choose the training data set and variables.

1. On the **Classification Learner** tab, in the **File** section, select **New Session > From Workspace**.

2. In the **New Session from Workspace** dialog box, under **Data Set Variable**, select the predictor variable **Xtt**.
3. Under **Response**, click **From workspace**; note that **Ytt** is selected automatically.
4. Under **Validation**, click **Resubstitution Validation**.
5. Click **Start Session**.

Train a logistic regression model.

1. On the **Classification Learner** tab, in the **Model Type** section, click the **Show more** arrow to open the gallery of models. In the **Logistic Regression Classifiers** section, click **Logistic Regression**.
2. On the **Classification Learner** tab, in the **Training** section, click **Train**.
3. When the app finishes training the model, plot a confusion matrix. On the **Classification Learner** tab, in the **Plots** section, click **Confusion Matrix** and select **Validation Data**.



The confusion matrix suggests that the model classifies in-sample observations well.

Export the trained logistic regression model.

1. On the **Classification Learner** tab, in the **Export** section, select **Export Model > Export Model**.
2. In the **Export Model** dialog box, click **OK**.

The app passes the trained model, among other variables, in the structure array `trainedModel` to the workspace. Close **Classification Learner** .

Initialize Incremental Model Using Exported Model

At the command line, extract the trained logistic regression model and the class names from `trainedModel`. The model is a `GeneralizedLinearModel` object. Because class names must match the data type of the response variable, convert the stored value to `categorical`.

```
Mdl = trainedModel.GeneralizedLinearModel;
ClassNames = categorical(trainedModel.ClassNames);
```

Extract the intercept and the coefficients from the model. The intercept is the first coefficient.

```
Bias = Mdl.Coefficients.Estimate(1);
Beta = Mdl.Coefficients.Estimate(2:end);
```

You cannot convert a `GeneralizedLinearModel` object to an incremental model directly. However, you can initialize an incremental model for binary classification by passing information learned from the app, such as estimated coefficients and class names.

Create an incremental model for binary classification directly. Specify the learner, intercept, coefficient estimates, and class names learned from **Classification Learner**. Because good initial values of coefficients exist and all class names are known, specify a metrics warm-up period of length `0`.

```
IncrementalMdl = incrementalClassificationLinear('Learner','logistic',...
    'Beta',Beta,'Bias',Bias,'ClassNames',ClassNames,...
    'MetricsWarmupPeriod',0)
```

```
IncrementalMdl =

  incrementalClassificationLinear

            IsWarm: 0
           Metrics: [1×2 table]
        ClassNames: [Moving    NotMoving]
    ScoreTransform: 'logit'
              Beta: [60×1 double]
              Bias: -471.7873
           Learner: 'logistic'

  Properties, Methods
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object for incremental learning using a logistic regression model. Because coefficients and all class names are specified, you can predict responses by passing `IncrementalMdl` and data to `predict`.

Implement Incremental Learning

Perform incremental learning on the 99% data partition by using the `updateMetricsAndFit` function. Simulate a data stream by processing 50 observations at a time. At each iteration:

1. Call `updateMetricsAndFit` to update the cumulative and window classification error of the model given the incoming chunk of observations. Overwrite the previous incremental model to update the losses in the `Metrics` property. Note that the function does not fit the model to the chunk of data—the chunk is "new" data for the model.
2. Store the losses and the estimated coefficient β_{14}.

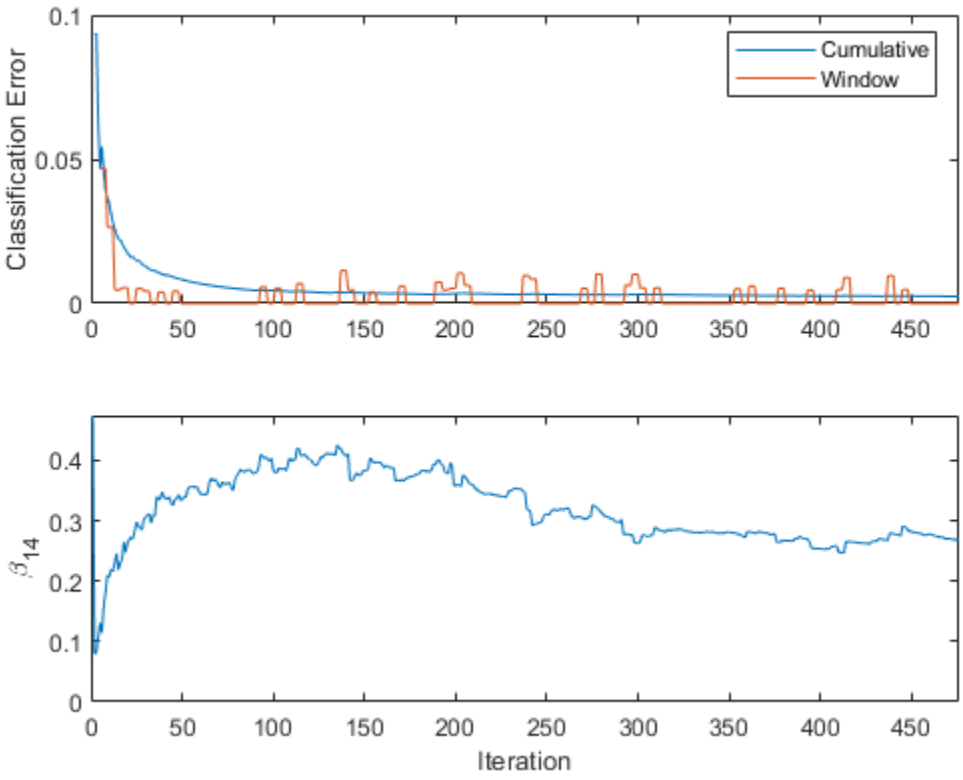
```
% Preallocation
nil = sum(idxil);
numObsPerChunk = 50;
nchunk = floor(nil/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta14 = [IncrementalMdl.Beta(14); zeros(nchunk,1)];

% Incremental learning
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetricsAndFit(IncrementalMdl,Xil(idx,:),Yil(idx));
    ce{j,:} = IncrementalMdl.Metrics{"ClassificationError",:};
    beta14(j + 1) = IncrementalMdl.Beta(14);
end
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream.

Plot a trace plot of the performance metrics and β_{14}.

```
figure;
subplot(2,1,1)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
legend(h,ce.Properties.VariableNames)
subplot(2,1,2)
plot(beta14)
ylabel('\beta_{14}')
xlim([0 nchunk]);
xlabel('Iteration')
```



The cumulative loss gradually changes with each iteration (chunk of 50 observations), whereas the window loss jumps. Because the metrics window is 200 by default and `updateMetricsAndFit` measures the performance every four iterations.

β_{14} adapts to the data as `updateMetricsAndFit` processes chunks of observations.

More About

- “Configure Incremental Learning Model” on page 26-8
- “Implement Incremental Learning for Classification Using Flexible Workflow” on page 26-26

Perform Conditional Training during Incremental Learning

This example shows how to train a naive Bayes mutliclass classification model for incremental learning only when the model performance is unsatisfactory.

The flexible incremental learning workflow enables you to train an incremental model on an incoming batch of data only when it is necessary (see “What Is Incremental Learning?” on page 26-2). For example, if the performance metrics of a model are satisfactory, then, to increase efficiency, you can skip training on incoming batches until the metrics become unsatisfactory.

Load Data

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
n = numel(actid);
rng(1) % For reproducibility
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Train Naive Bayes Classification Model

Configure a naive Bayes classification model for incremental learning by setting all the following:

- The maximum number of expected classes to 5
- The tracked performance metric to the misclassification error rate, which also includes minimal cost
- The metrics window size to 1000
- The metrics warmup period to 50

```
initobs = 50;
Mdl = incrementalClassificationNaiveBayes('MaxNumClasses',5,'MetricsWindowSize',1000,...
    'Metrics','classiferror','MetricsWarmupPeriod',initobs);
```

Fit the configured model to the first 50 observations.

```
Mdl = fit(Mdl,X(1:initobs,:),Y(1:initobs))
```

```
Mdl =
  incrementalClassificationNaiveBayes

                   IsWarm: 1
                  Metrics: [2×2 table]
               ClassNames: [1 2 3 4 5]
           ScoreTransform: 'none'
        DistributionNames: {1×60 cell}
    DistributionParameters: {5×60 cell}

  Properties, Methods
```

```
haveTrainedAllClasses = numel(unique(Y(1:initobs))) == 5
```

```
haveTrainedAllClasses = logical
   1
```

`Mdl` is an `incrementalClassificationNaiveBayes` model object. The model is warm (`IsWarm` is `1`) because all the following conditions apply:

- The initial training data contains all expected classes (`haveTrainedAllClasses` is `true`).
- `Mdl` was fit to `Mdl.MetricsWarmupPeriod` observations.

Therefore, the model is prepared to generate predictions, and incremental learning functions measure performance metrics within the model.

Perform Incremetnal Learning with Conditional Training

Suppose that you want to train the model only when the most recent 1000 observations have a misclassification error greater than 5%.

Perform incremental learning, with conditional training, by following this procedure for each iteration:

1. Simulate a data stream by processing a chunk of 100 observations at a time.
2. Update the model performance by passing the model and current chunk of data to `updateMetrics`. Overwrite the input model with the output model.
3. Fit the model to the chunk of data only when the misclassification error rate is greater than 0.05. Overwrite the input model with the output model when training occurs.
4. Store the misclassification error rate and the mean of the first predictor in the second class μ_{21} to see how they evolve during training.
5. Track when `fit` trains the model.

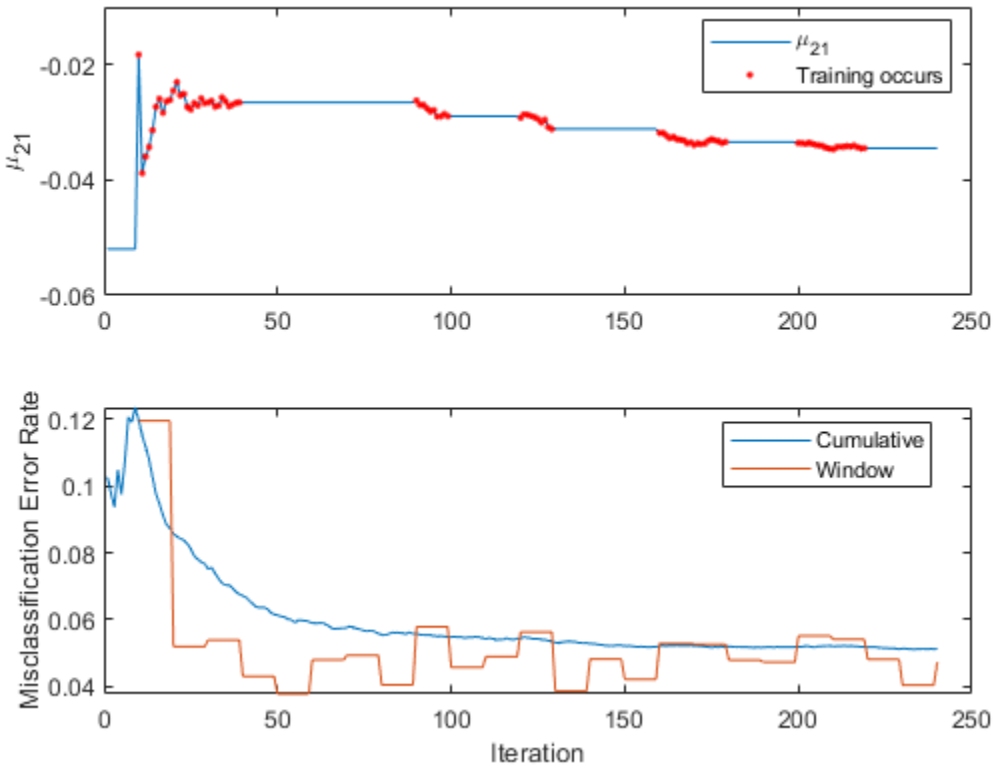
```
% Preallocation
numObsPerChunk = 100;
nchunk = floor((n - initobs)/numObsPerChunk);
mu21 = zeros(nchunk,1);
ce = array2table(nan(nchunk,2),'VariableNames',["Cumulative" "Window"]);
trained = false(nchunk,1);

% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1 + initobs);
    iend   = min(n,numObsPerChunk*j + initobs);
    idx = ibegin:iend;
    Mdl = updateMetrics(Mdl,X(idx,:),Y(idx));
    ce{j,:} = Mdl.Metrics{"ClassificationError",:};
    if ce{j,"Window"} > 0.05
        Mdl = fit(Mdl,X(idx,:),Y(idx));
        trained(j) = true;
    end
    mu21(j) = Mdl.DistributionParameters{2,1}(1);
end
```

`Mdl` is an `incrementalClassificationNaiveBayes` model object trained on all the data in the stream.

To see how the model performance and μ_{21} evolved during training, plot them on separate subplots. Identify periods during which the model was trained.

```
subplot(2,1,1)
plot(mu21)
hold on
plot(find(trained),mu21(trained),'r.')
ylabel('\mu_{21}')
legend('\mu_{21}','Training occurs','Location','best')
hold off
subplot(2,1,2)
plot(ce.Variables)
ylabel('Misclassification Error Rate')
xlabel('Iteration')
legend(ce.Properties.VariableNames,'Location','best')
```



The trace plot of μ_{21} shows periods of constant values, during which the model performance within the previous 1000 observation window is at most 0.05.

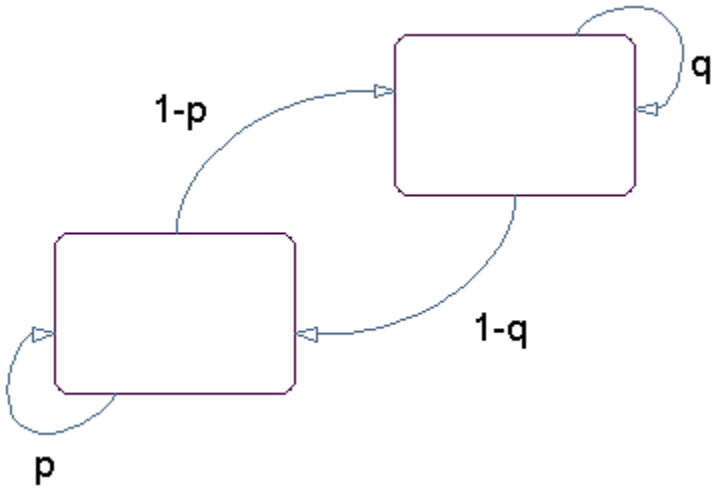
Markov Models

Markov Chains

Markov processes are examples of stochastic processes—processes that generate random sequences of outcomes or states according to certain probabilities. Markov processes are distinguished by being memoryless—their next state depends only on their current state, not on the history that led them there. Models of Markov processes are used in a wide variety of applications, from daily stock prices to the positions of genes in a chromosome.

A Markov model is given visual representation with a *state diagram*, such as the one below.



State Diagram for a Markov Model

The rectangles in the diagram represent the possible states of the process you are trying to model, and the arrows represent transitions between states. The label on each arrow represents the probability of that transition. At each step of the process, the model may generate an output, or emission, depending on which state it is in, and then make a transition to another state. An important characteristic of Markov models is that the next state depends only on the current state, and not on the history of transitions that lead to the current state.

For example, for a sequence of coin tosses the two states are heads and tails. The most recent coin toss determines the current state of the model and each subsequent toss determines the transition to the next state. If the coin is fair, the transition probabilities are all 1/2. The emission might simply be the current state. In more complicated models, random processes at each state will generate emissions. You could, for example, roll a die to determine the emission at any step.

Markov chains are mathematical descriptions of Markov models with a discrete set of states. Markov chains are characterized by:

- A set of states $\{1, 2, ..., M\}$
- An M-by-M transition matrix T whose i,j entry is the probability of a transition from state i to state j. The sum of the entries in each row of T must be 1, because this is the sum of the probabilities of making a transition from a given state to each of the other states.
- A set of possible outputs, or *emissions*, $\{s_1, s_2, ... , s_N\}$. By default, the set of emissions is $\{1, 2, ... , N\}$, where N is the number of possible emissions, but you can choose a different set of numbers or symbols.

- An M-by-N emission matrix E whose i,k entry gives the probability of emitting symbol s_k given that the model is in state i.

Markov chains begin in an initial state i_0 at step 0. The chain then transitions to state i_1 with probability T_{1i_1}, and emits an output s_{k_1} with probability $E_{i_1k_1}$. Consequently, the probability of observing the sequence of states $i_1i_2...i_r$ and the sequence of emissions $s_{k_1}s_{k_2}...s_{k_r}$ in the first r steps, is

$$T_{1i_1}E_{i_1k_1}T_{i_1i_2}E_{i_2k_2}...T_{i_{r-1}i_r}E_{i_rk}$$

Hidden Markov Models (HMM)

In this section...

Introduction to Hidden Markov Models (HMM)

A hidden Markov model (HMM) is one in which you observe a sequence of emissions, but do not know the sequence of states the model went through to generate the emissions. Analyses of hidden Markov models seek to recover the sequence of states from the observed data.

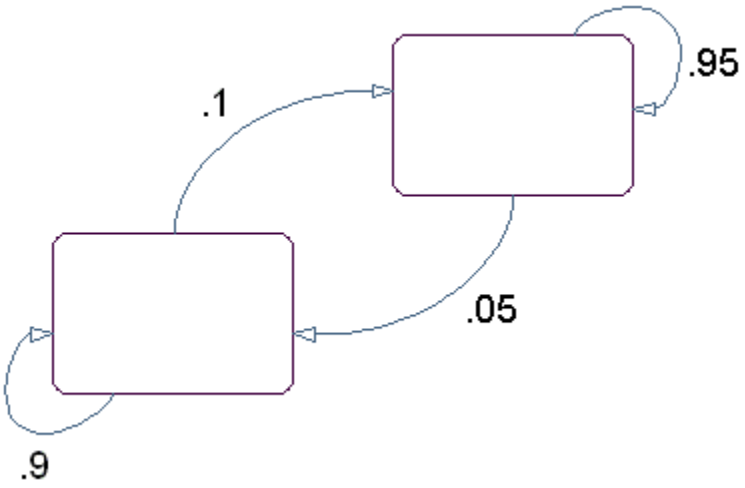
As an example, consider a Markov model with two states and six possible emissions. The model uses:

- A red die, having six sides, labeled 1 through 6.
- A green die, having twelve sides, five of which are labeled 2 through 6, while the remaining seven sides are labeled 1.
- A weighted red coin, for which the probability of heads is .9 and the probability of tails is .1.
- A weighted green coin, for which the probability of heads is .95 and the probability of tails is .05.

The model creates a sequence of numbers from the set {1, 2, 3, 4, 5, 6} with the following rules:

- Begin by rolling the red die and writing down the number that comes up, which is the emission.
- Toss the red coin and do one of the following:
  - If the result is heads, roll the red die and write down the result.
  - If the result is tails, roll the green die and write down the result.
- At each subsequent step, you flip the coin that has the same color as the die you rolled in the previous step. If the coin comes up heads, roll the same die as in the previous step. If the coin comes up tails, switch to the other die.

The state diagram for this model has two states, red and green, as shown in the following figure.



You determine the emission from a state by rolling the die with the same color as the state. You determine the transition to the next state by flipping the coin with the same color as the state.

The transition matrix is:

$$T = \begin{bmatrix} 0.9 & 0.1 \\ 0.05 & 0.95 \end{bmatrix}$$

The emissions matrix is:

$$E = \begin{bmatrix} \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} & \frac{1}{6} \\ \frac{7}{12} & \frac{1}{12} & \frac{1}{12} & \frac{1}{12} & \frac{1}{12} & \frac{1}{12} \end{bmatrix}$$

The model is not hidden because you know the sequence of states from the colors of the coins and dice. Suppose, however, that someone else is generating the emissions without showing you the dice or the coins. All you see is the sequence of emissions. If you start seeing more 1s than other numbers, you might suspect that the model is in the green state, but you cannot be sure because you cannot see the color of the die being rolled.

Hidden Markov models raise the following questions:

- Given a sequence of emissions, what is the most likely state path?
- Given a sequence of emissions, how can you estimate transition and emission probabilities of the model?
- What is the *forward probability* that the model generates a given sequence?
- What is the *posterior probability* that the model is in a particular state at any point in the sequence?

Analyzing Hidden Markov Models

Statistics and Machine Learning Toolbox functions related to hidden Markov models are:

- `hmmgenerate` — Generates a sequence of states and emissions from a Markov model
- `hmmestimate` — Calculates maximum likelihood estimates of transition and emission probabilities from a sequence of emissions and a known sequence of states
- `hmmtrain` — Calculates maximum likelihood estimates of transition and emission probabilities from a sequence of emissions
- `hmmviterbi` — Calculates the most probable state path for a hidden Markov model
- `hmmdecode` — Calculates the posterior state probabilities of a sequence of emissions

This section shows how to use these functions to analyze hidden Markov models.

Generating a Test Sequence

The following commands create the transition and emission matrices for the model described in the “Introduction to Hidden Markov Models (HMM)” on page 27-4:

```
TRANS = [.9 .1; .05 .95];

EMIS = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;...
7/12, 1/12, 1/12, 1/12, 1/12, 1/12];
```

To generate a random sequence of states and emissions from the model, use `hmmgenerate`:

```
[seq,states] = hmmgenerate(1000,TRANS,EMIS);
```

The output `seq` is the sequence of emissions and the output `states` is the sequence of states.

`hmmgenerate` begins in state 1 at step 0, makes the transition to state i_1 at step 1, and returns i_1 as the first entry in `states`. To change the initial state, see “Changing the Initial State Distribution” on page 27-8.

Estimating the State Sequence

Given the transition and emission matrices `TRANS` and `EMIS`, the function `hmmviterbi` uses the Viterbi algorithm to compute the most likely sequence of states the model would go through to generate a given sequence `seq` of emissions:

```
likelystates = hmmviterbi(seq, TRANS, EMIS);
```

`likelystates` is a sequence the same length as `seq`.

To test the accuracy of `hmmviterbi`, compute the percentage of the actual sequence `states` that agrees with the sequence `likelystates`.

```
sum(states==likelystates)/1000
ans =
   0.8200
```

In this case, the most likely sequence of states agrees with the random sequence 82% of the time.

Estimating Transition and Emission Matrices

The functions `hmmestimate` and `hmmtrain` estimate the transition and emission matrices `TRANS` and `EMIS` given a sequence `seq` of emissions.

Using hmmestimate

The function `hmmestimate` requires that you know the sequence of states `states` that the model went through to generate `seq`.

The following takes the emission and state sequences and returns estimates of the transition and emission matrices:

```
[TRANS_EST, EMIS_EST] = hmmestimate(seq, states)
```

```
TRANS_EST =
0.8989    0.1011
0.0585    0.9415

EMIS_EST =
0.1721    0.1721    0.1749    0.1612    0.1803    0.1393
0.5836    0.0741    0.0804    0.0789    0.0726    0.1104
```

You can compare the outputs with the original transition and emission matrices, `TRANS` and `EMIS`:

```
TRANS
TRANS =
0.9000    0.1000
0.0500    0.9500

EMIS
EMIS =
0.1667    0.1667    0.1667    0.1667    0.1667    0.1667
0.5833    0.0833    0.0833    0.0833    0.0833    0.0833
```

Using hmmtrain

If you do not know the sequence of states `states`, but you have initial guesses for `TRANS` and `EMIS`, you can still estimate `TRANS` and `EMIS` using `hmmtrain`.

Suppose you have the following initial guesses for `TRANS` and `EMIS`.

```
TRANS_GUESS = [.85 .15; .1 .9];
EMIS_GUESS = [.17 .16 .17 .16 .17 .17;.6 .08 .08 .08 .08 08];
```

You estimate `TRANS` and `EMIS` as follows:

```
[TRANS_EST2, EMIS_EST2] = hmmtrain(seq, TRANS_GUESS, EMIS_GUESS)

TRANS_EST2 =
0.2286    0.7714
0.0032    0.9968

EMIS_EST2 =
0.1436    0.2348    0.1837    0.1963    0.2350    0.0066
0.4355    0.1089    0.1144    0.1082    0.1109    0.1220
```

`hmmtrain` uses an iterative algorithm that alters the matrices `TRANS_GUESS` and `EMIS_GUESS` so that at each step the adjusted matrices are more likely to generate the observed sequence, `seq`. The algorithm halts when the matrices in two successive iterations are within a small tolerance of each other.

If the algorithm fails to reach this tolerance within a maximum number of iterations, whose default value is `100`, the algorithm halts. In this case, `hmmtrain` returns the last values of `TRANS_EST` and `EMIS_EST` and issues a warning that the tolerance was not reached.

If the algorithm fails to reach the desired tolerance, increase the default value of the maximum number of iterations with the command:

```
hmmtrain(seq,TRANS_GUESS,EMIS_GUESS,'maxiterations',maxiter)
```

where `maxiter` is the maximum number of steps the algorithm executes.

Change the default value of the tolerance with the command:

```
hmmtrain(seq, TRANS_GUESS, EMIS_GUESS, 'tolerance', tol)
```

where `tol` is the desired value of the tolerance. Increasing the value of `tol` makes the algorithm halt sooner, but the results are less accurate.

Two factors reduce the reliability of the output matrices of `hmmtrain`:

- The algorithm converges to a local maximum that does not represent the true transition and emission matrices. If you suspect this, use different initial guesses for the matrices `TRANS_EST` and `EMIS_EST`.
- The sequence `seq` may be too short to properly train the matrices. If you suspect this, use a longer sequence for `seq`.

Estimating Posterior State Probabilities

The posterior state probabilities of an emission sequence `seq` are the conditional probabilities that the model is in a particular state when it generates a symbol in `seq`, given that `seq` is emitted. You compute the posterior state probabilities with `hmmdecode`:

```
PSTATES = hmmdecode(seq,TRANS,EMIS)
```

The output `PSTATES` is an M-by-L matrix, where M is the number of states and L is the length of `seq`. `PSTATES(i,j)` is the conditional probability that the model is in state `i` when it generates the `j`th symbol of `seq`, given that `seq` is emitted.

`hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `PSTATES(i,1)` is the probability that the model is in state i at the following step 1. To change the initial state, see “Changing the Initial State Distribution” on page 27-8.

To return the logarithm of the probability of the sequence `seq`, use the second output argument of `hmmdecode`:

```
[PSTATES,logpseq] = hmmdecode(seq,TRANS,EMIS)
```

The probability of a sequence tends to 0 as the length of the sequence increases, and the probability of a sufficiently long sequence becomes less than the smallest positive number your computer can represent. `hmmdecode` returns the logarithm of the probability to avoid this problem.

Changing the Initial State Distribution

By default, Statistics and Machine Learning Toolbox hidden Markov model functions begin in state 1. In other words, the distribution of initial states has all of its probability mass concentrated at state 1. To assign a different distribution of probabilities, $p = [p_1, p_2, ..., p_M]$, to the M initial states, do the following:

1. Create an M+1-by-M+1 augmented transition matrix, $\widehat{T}$ of the following form:

   $$\widehat{T} = \begin{bmatrix} 0 & p \\ 0 & T \end{bmatrix}$$

   where T is the true transition matrix. The first column of $\widehat{T}$ contains M+1 zeros. p must sum to 1.

2. Create an M+1-by-N augmented emission matrix, $\widehat{E}$, that has the following form:

$$\widehat{E} = \begin{bmatrix} 0 \\ E \end{bmatrix}$$

If the transition and emission matrices are `TRANS` and `EMIS`, respectively, you create the augmented matrices with the following commands:

```
TRANS_HAT = [0 p; zeros(size(TRANS,1),1) TRANS];

EMIS_HAT = [zeros(1,size(EMIS,2)); EMIS];
```

Design of Experiments

Design of Experiments

Passive data collection leads to a number of problems in statistical modeling. Observed changes in a response variable may be correlated with, but not caused by, observed changes in individual factors (process variables). Simultaneous changes in multiple factors may produce interactions that are difficult to separate into individual effects. Observations may be dependent, while a model of the data considers them to be independent.

Designed experiments address these problems. In a designed experiment, the data-producing process is actively manipulated to improve the quality of information and to eliminate redundant data. A common goal of all experimental designs is to collect data as parsimoniously as possible while providing sufficient information to accurately estimate model parameters.

For example, a simple model of a response y in an experiment with two controlled factors x_1 and x_2 might look like this:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_1 x_2 + \varepsilon$$

Here ε includes both experimental error and the effects of any uncontrolled factors in the experiment. The terms $\beta_1 x_1$ and $\beta_2 x_2$ are main effects and the term $\beta_3 x_1 x_2$ is a two-way interaction effect. A designed experiment would systematically manipulate x_1 and x_2 while measuring y, with the objective of accurately estimating β_0, β_1, β_2, and β_3.

Full Factorial Designs

In this section...

Multilevel Designs

To systematically vary experimental factors, assign each factor a discrete set of levels. Full factorial designs measure response variables using every treatment (combination of the factor levels). A full factorial design for n factors with N_1, ..., N_n levels requires $N_1 \times ... \times N_n$ experimental runs—one for each treatment. While advantageous for separating individual effects, full factorial designs can make large demands on data collection.

As an example, suppose a machine shop has three machines and four operators. If the same operator always uses the same machine, it is impossible to determine if a machine or an operator is the cause of variation in production. By allowing every operator to use every machine, effects are separated. A full factorial list of treatments is generated by the function `fullfact`:

```
dFF = fullfact([3,4])
dFF =
     1     1
     2     1
     3     1
     1     2
     2     2
     3     2
     1     3
     2     3
     3     3
     1     4
     2     4
     3     4
```

Each of the 3×4 = 12 rows of `dFF` represent one machine/operator combination.

Two-Level Designs

Many experiments can be conducted with two-level factors, using two-level designs. For example, suppose the machine shop in the previous example always keeps the same operator on the same machine, but wants to measure production effects that depend on the composition of the day and night shifts. The function `ff2n` generates a full factorial list of treatments:

```
dFF2 = ff2n(4)
dFF2 =
     0     0     0     0
     0     0     0     1
     0     0     1     0
     0     0     1     1
     0     1     0     0
     0     1     0     1
     0     1     1     0
     0     1     1     1
```

```
1     0     0     0
1     0     0     1
1     0     1     0
1     0     1     1
1     1     0     0
1     1     0     1
1     1     1     0
1     1     1     1
```

Each of the $2^4 = 16$ rows of `dFF2` represent one schedule of operators for the day (`0`) and night (`1`) shifts.

Fractional Factorial Designs

In this section...

Introduction to Fractional Factorial Designs

Two-level designs are sufficient for evaluating many production processes. Factor levels of ±1 can indicate categorical factors, normalized factor extremes, or simply “up” and “down” from current factor settings. Experimenters evaluating process *changes* are interested primarily in the factor directions that lead to process improvement.

For experiments with many factors, two-level full factorial designs can lead to large amounts of data. For example, a two-level full factorial design with 10 factors requires $2^{10} = 1024$ runs. Often, however, individual factors or their interactions have no distinguishable effects on a response. This is especially true of higher order interactions. As a result, a well-designed experiment can use fewer runs for estimating model parameters.

Fractional factorial designs use a fraction of the runs required by full factorial designs. A subset of experimental treatments is selected based on an evaluation (or assumption) of which factors and interactions have the most significant effects. Once this selection is made, the experimental design must separate these effects. In particular, significant effects should not be confounded, that is, the measurement of one should not depend on the measurement of another.

Plackett-Burman Designs

Plackett-Burman designs are used when only main effects are considered significant. Two-level Plackett-Burman designs require a number of experimental runs that are a multiple of 4 rather than a power of 2. The function `hadamard` generates these designs:

```
dPB = hadamard(8)
dPB =
     1    1    1    1    1    1    1    1
     1   -1    1   -1    1   -1    1   -1
     1    1   -1   -1    1    1   -1   -1
     1   -1   -1    1    1   -1   -1    1
     1    1    1    1   -1   -1   -1   -1
     1   -1    1   -1   -1    1   -1    1
     1    1   -1   -1   -1   -1    1    1
     1   -1   -1    1   -1    1    1   -1
```

Binary factor levels are indicated by ±1. The design is for eight runs (the rows of `dPB`) manipulating seven two-level factors (the last seven columns of `dPB`). The number of runs is a fraction $8/2^7 = 0.0625$ of the runs required by a full factorial design. Economy is achieved at the expense of confounding main effects with any two-way interactions.

General Fractional Designs

At the cost of a larger fractional design, you can specify which interactions you wish to consider significant. A design of resolution *R* is one in which no *n*-factor interaction is confounded with any

other effect containing less than $R - n$ factors. Thus, a resolution III design does not confound main effects with one another but may confound them with two-way interactions (as in “Plackett-Burman Designs” on page 28-5), while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

Specify general fractional factorial designs using a full factorial design for a selected subset of basic factors and generators for the remaining factors. Generators are products of the basic factors, giving the levels for the remaining factors. Use the function `fracfact` to generate these designs:

```
dfF = fracfact('a b c d bcd acd')
dfF =
    -1    -1    -1    -1    -1    -1
    -1    -1    -1     1     1     1
    -1    -1     1    -1     1     1
    -1    -1     1     1    -1    -1
    -1     1    -1    -1     1    -1
    -1     1    -1     1    -1     1
    -1     1     1    -1    -1     1
    -1     1     1     1     1    -1
     1    -1    -1    -1    -1     1
     1    -1    -1     1     1    -1
     1    -1     1    -1     1    -1
     1    -1     1     1    -1     1
     1     1    -1    -1     1     1
     1     1    -1     1    -1    -1
     1     1     1    -1    -1    -1
     1     1     1     1     1     1
```

This is a six-factor design in which four two-level basic factors (`a`, `b`, `c`, and `d` in the first four columns of `dfF`) are measured in every combination of levels, while the two remaining factors (in the last three columns of `dfF`) are measured only at levels defined by the generators `bcd` and `acd`, respectively. Levels in the generated columns are products of corresponding levels in the columns that make up the generator.

The challenge of creating a fractional factorial design is to choose basic factors and generators so that the design achieves a specified resolution in a specified number of runs. Use the function `fracfactgen` to find appropriate generators:

```
generators = fracfactgen('a b c d e f',4,4)
generators =
    'a'
    'b'
    'c'
    'd'
    'bcd'
    'acd'
```

These are generators for a six-factor design with factors `a` through `f`, using $2^4 = 16$ runs to achieve resolution IV. The `fracfactgen` function uses an efficient search algorithm to find generators that meet the requirements.

An optional output from `fracfact` displays the confounding pattern of the design:

```
[dfF,confounding] = fracfact(generators);
confounding
confounding =
    'Term'     'Generator'    'Confounding'
```

```
'X1'       'a'            'X1'
'X2'       'b'            'X2'
'X3'       'c'            'X3'
'X4'       'd'            'X4'
'X5'       'bcd'          'X5'
'X6'       'acd'          'X6'
'X1*X2'    'ab'           'X1*X2 + X5*X6'
'X1*X3'    'ac'           'X1*X3 + X4*X6'
'X1*X4'    'ad'           'X1*X4 + X3*X6'
'X1*X5'    'abcd'         'X1*X5 + X2*X6'
'X1*X6'    'cd'           'X1*X6 + X2*X5 + X3*X4'
'X2*X3'    'bc'           'X2*X3 + X4*X5'
'X2*X4'    'bd'           'X2*X4 + X3*X5'
'X2*X5'    'cd'           'X1*X6 + X2*X5 + X3*X4'
'X2*X6'    'abcd'         'X1*X5 + X2*X6'
'X3*X4'    'cd'           'X1*X6 + X2*X5 + X3*X4'
'X3*X5'    'bd'           'X2*X4 + X3*X5'
'X3*X6'    'ad'           'X1*X4 + X3*X6'
'X4*X5'    'bc'           'X2*X3 + X4*X5'
'X4*X6'    'ac'           'X1*X3 + X4*X6'
'X5*X6'    'ab'           'X1*X2 + X5*X6'
```

The confounding pattern shows that main effects are effectively separated by the design, but two-way interactions are confounded with various other two-way interactions.

Response Surface Designs

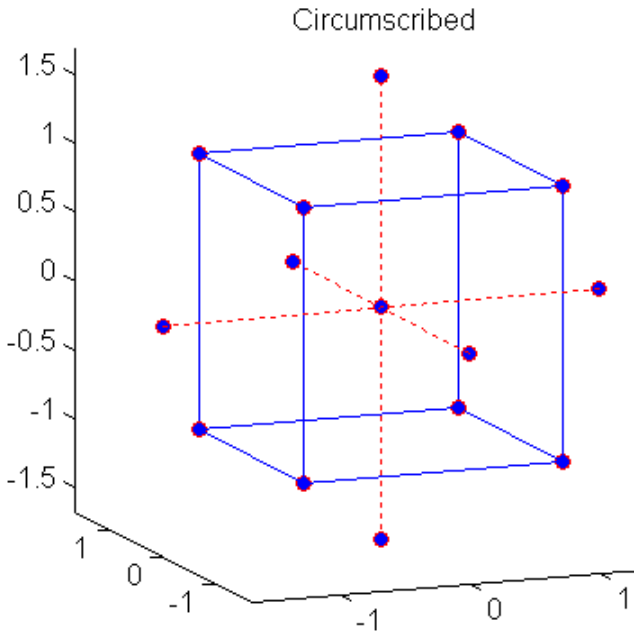
In this section...

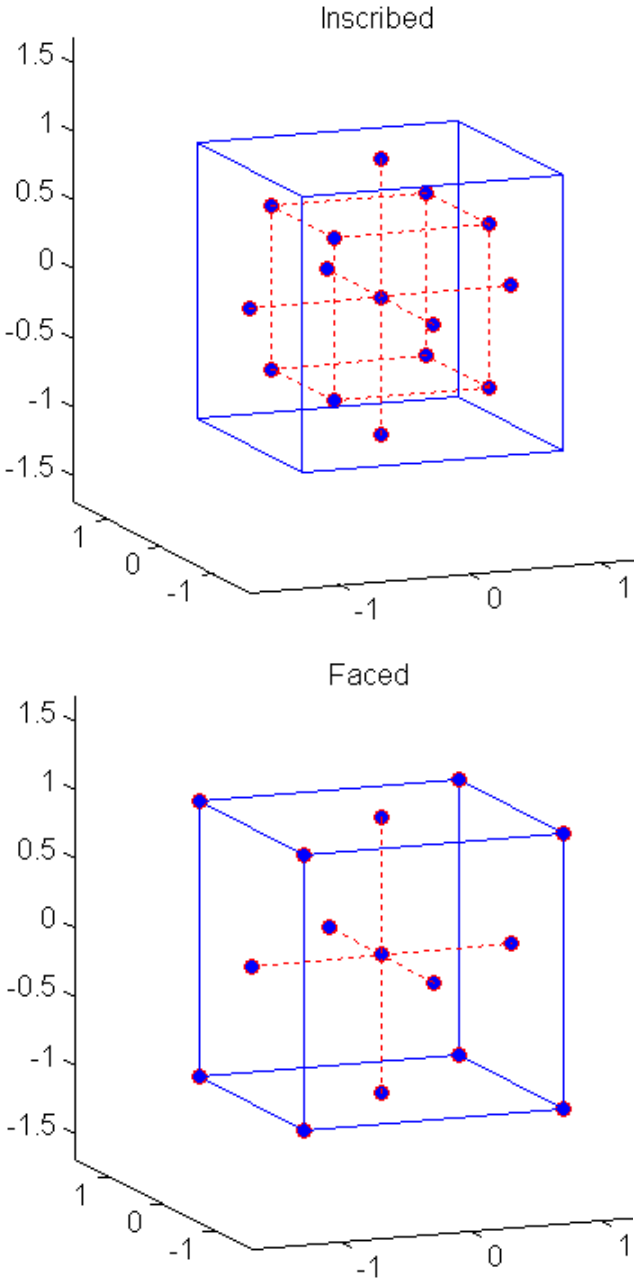
Introduction to Response Surface Designs

Quadratic response surfaces are simple models that provide a maximum or minimum without making additional assumptions about the form of the response. Quadratic models can be calibrated using full factorial designs with three or more levels for each factor, but these designs generally require more runs than necessary to accurately estimate model parameters. This section discusses designs for calibrating quadratic models that are much more efficient, using three or five levels for each factor, but not using all combinations of levels.

Central Composite Designs

Central composite designs (CCDs), also known as Box-Wilson designs, are appropriate for calibrating full quadratic models. There are three types of CCDs—circumscribed, inscribed, and faced—pictured below:





Each design consists of a factorial design (the corners of a cube) together with center and star points that allow for estimation of second-order effects. For a full quadratic model with n factors, CCDs have enough design points to estimate the $(n+2)(n+1)/2$ coefficients in a full quadratic model with n factors.

The type of CCD used (the position of the factorial and star points) is determined by the number of factors and by the desired properties of the design. The following table summarizes some important properties. A design is rotatable if the prediction variance depends only on the distance of the design point from the center of the design.

Design	Rotatable	Factor Levels	Uses Points Outside ±1	Accuracy of Estimates
Circumscribed (CCC)	Yes	5	Yes	Good over entire design space
Inscribed (CCI)	Yes	5	No	Good over central subset of design space
Faced (CCF)	No	3	No	Fair over entire design space; poor for pure quadratic coefficients

Generate CCDs with the function `ccdesign`:

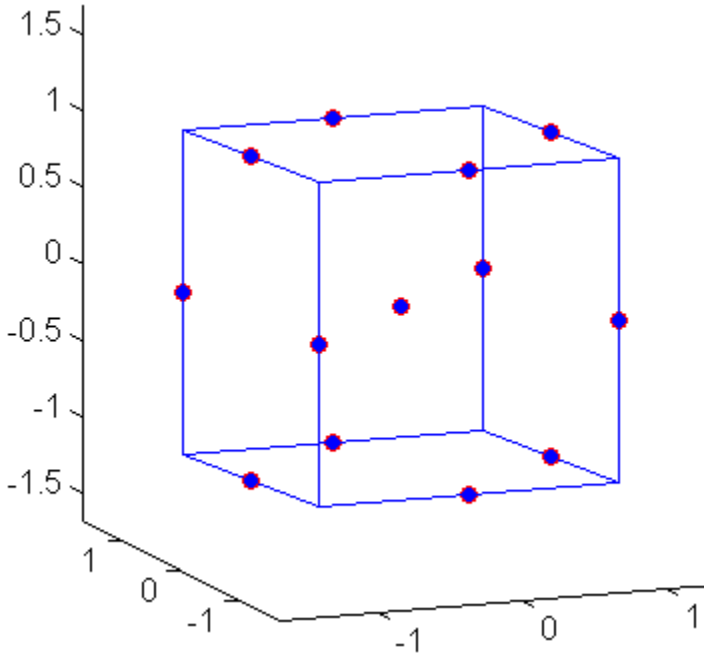
```
dCC = ccdesign(3,'type','circumscribed')
dCC =
   -1.0000   -1.0000   -1.0000
   -1.0000   -1.0000    1.0000
   -1.0000    1.0000   -1.0000
   -1.0000    1.0000    1.0000
    1.0000   -1.0000   -1.0000
    1.0000   -1.0000    1.0000
    1.0000    1.0000   -1.0000
    1.0000    1.0000    1.0000
   -1.6818         0         0
    1.6818         0         0
         0   -1.6818         0
         0    1.6818         0
         0         0   -1.6818
         0         0    1.6818
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
         0         0         0
```

The repeated center point runs allow for a more uniform estimate of the prediction variance over the entire design space.

Box-Behnken Designs

Like the designs described in “Central Composite Designs” on page 28-8, Box-Behnken designs are used to calibrate full quadratic models. Box-Behnken designs are rotatable and, for a small number of factors (four or less), require fewer runs than CCDs. By avoiding the corners of the design space, they allow experimenters to work around extreme factor combinations. Like an inscribed CCD, however, extremes are then poorly estimated.

The geometry of a Box-Behnken design is pictured in the following figure.



Design points are at the midpoints of edges of the design space and at the center, and do not contain an embedded factorial design.

Generate Box-Behnken designs with the function `bbdesign`:

```
dBB = bbdesign(3)
dBB =
    -1    -1     0
    -1     1     0
     1    -1     0
     1     1     0
    -1     0    -1
    -1     0     1
     1     0    -1
     1     0     1
     0    -1    -1
     0    -1     1
     0     1    -1
     0     1     1
     0     0     0
     0     0     0
     0     0     0
```

Again, the repeated center point runs allow for a more uniform estimate of the prediction variance over the entire design space.

D-Optimal Designs

In this section...

Introduction to D-Optimal Designs

Traditional experimental designs (“Full Factorial Designs” on page 28-3, “Fractional Factorial Designs” on page 28-5, and “Response Surface Designs” on page 28-8) are appropriate for calibrating linear models in experimental settings where factors are relatively unconstrained in the region of interest. In some cases, however, models are necessarily nonlinear. In other cases, certain treatments (combinations of factor levels) may be expensive or infeasible to measure. D-optimal designs are model-specific designs that address these limitations of traditional designs.

A D-optimal design is generated by an iterative search algorithm and seeks to minimize the covariance of the parameter estimates for a specified model. This is equivalent to maximizing the determinant $D = |X^TX|$, where X is the design matrix of model terms (the columns) evaluated at specific treatments in the design space (the rows). Unlike traditional designs, D-optimal designs do not require orthogonal design matrices, and as a result, parameter estimates may be correlated. Parameter estimates may also be locally, but not globally, D-optimal.

There are several Statistics and Machine Learning Toolbox functions for generating D-optimal designs:

Function	Description
`candexch`	Uses a row-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model and a specified candidate set. This is the second component of the algorithm used by `rowexch`.
`candgen`	Generates a candidate set for a specified model. This is the first component of the algorithm used by `rowexch`.
`cordexch`	Uses a coordinate-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model.
`daugment`	Uses a coordinate-exchange algorithm to augment an existing D-optimal design with additional runs to estimate additional model terms.
`dcovary`	Uses a coordinate-exchange algorithm to generate a D-optimal design with fixed covariate factors.
`rowexch`	Uses a row-exchange algorithm to generate a D-optimal design with a specified number of runs for a specified model. The algorithm calls `candgen` and then `candexch`. (Call `candexch` separately to specify a candidate set.)

The following sections explain how to use these functions to generate D-optimal designs.

Note The function `rsmdemo` generates simulated data for experimental settings specified by either the user or by a D-optimal design generated by `cordexch`. It uses the `rstool` interface to visualize response surface models fit to the data, and it uses the `nlintool` interface to visualize a nonlinear model fit to the data.

Generate D-Optimal Designs

Two Statistics and Machine Learning Toolbox algorithms generate D-optimal designs:

- The `cordexch` function uses a coordinate-exchange algorithm
- The `rowexch` function uses a row-exchange algorithm

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^TX|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D-optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a `'tries'` parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of X with a row from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly. In either case, if C is large, its static presence in memory can affect computation.

The coordinate-exchange algorithm, by contrast, does not use a candidate set. (Or rather, the candidate set is the entire design space.) At each step, the coordinate-exchange algorithm exchanges a single element of X with a new element evaluated at a neighboring point in design space. The absence of a candidate set reduces demands on memory, but the smaller scale of the search means that the coordinate-exchange algorithm is more likely to become trapped in a local minimum than the row-exchange algorithm.

For example, suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_{12} x_1 x_2 + \beta_{13} x_1 x_3 + \beta_{23} x_2 x_3 + \varepsilon$$

Use `cordexch` to generate a D-optimal design with seven runs:

```
nfactors = 3;
nruns = 7;
[dCE,X] = cordexch(nfactors,nruns,'interaction','tries',10)
dCE =
    -1     1     1
    -1    -1    -1
     1     1     1
    -1     1    -1
     1    -1     1
     1    -1    -1
    -1    -1     1
X =
     1    -1     1     1    -1    -1     1
     1    -1    -1    -1     1     1     1
     1     1     1     1     1     1     1
```

```
     1    -1     1    -1    -1     1    -1
     1     1    -1     1    -1     1    -1
     1     1    -1    -1    -1    -1     1
     1    -1    -1     1     1    -1    -1
```

Columns of the design matrix `X` are the model terms evaluated at each row of the design `dCE`. The terms appear in order from left to right:

1. Constant term
2. Linear terms (1, 2, 3)
3. Interaction terms (12, 13, 23)

Use `X` in a linear regression model fit to response data measured at the design points in `dCE`.

Use `rowexch` in a similar fashion to generate an equivalent design:

```
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
dRE =
    -1    -1     1
     1    -1     1
     1    -1    -1
     1     1     1
    -1    -1    -1
    -1     1    -1
    -1     1     1
X =
     1    -1    -1     1     1    -1    -1
     1     1    -1     1    -1     1    -1
     1     1    -1    -1    -1    -1     1
     1     1     1     1     1     1     1
     1    -1    -1    -1     1     1     1
     1    -1     1    -1    -1     1    -1
     1    -1     1     1    -1    -1     1
```

Augment D-Optimal Designs

In practice, you may want to add runs to a completed experiment to learn more about a process and estimate additional model coefficients. The `daugment` function uses a coordinate-exchange algorithm to augment an existing D-optimal design.

For example, the following eight-run design is adequate for estimating main effects in a four-factor model:

```
dCEmain = cordexch(4,8)
dCEmain =
     1    -1    -1     1
    -1    -1     1     1
    -1     1    -1     1
     1     1     1    -1
     1     1     1     1
    -1     1    -1    -1
     1    -1    -1    -1
    -1    -1     1    -1
```

To estimate the six interaction terms in the model, augment the design with eight additional runs:

```
dCEinteraction = daugment(dCEmain,8,'interaction')
dCEinteraction =
     1    -1    -1     1
    -1    -1     1     1
    -1     1    -1     1
     1     1     1    -1
     1     1     1     1
    -1     1    -1    -1
     1    -1    -1    -1
    -1    -1     1    -1
    -1     1     1     1
    -1    -1    -1    -1
     1    -1     1    -1
     1     1    -1     1
    -1     1     1    -1
     1     1    -1    -1
     1    -1     1     1
     1     1     1    -1
```

The augmented design is full factorial, with the original eight runs in the first eight rows.

The `'start'` parameter of the `candexch` function provides the same functionality as `daugment`, but uses a row exchange algorithm rather than a coordinate-exchange algorithm.

Specify Fixed Covariate Factors

In many experimental settings, certain factors and their covariates are constrained to a fixed set of levels or combinations of levels. These cannot be varied when searching for an optimal design. The `dcovary` function allows you to specify fixed covariate factors in the coordinate exchange algorithm.

For example, suppose you want a design to estimate the parameters in a three-factor linear additive model, with eight runs that necessarily occur at different times. If the process experiences temporal linear drift, you may want to include the run time as a variable in the model. Produce the design as follows:

```
time = linspace(-1,1,8)';
[dCV,X] = dcovary(3,time,'linear')
dCV =
   -1.0000    1.0000    1.0000   -1.0000
    1.0000   -1.0000   -1.0000   -0.7143
   -1.0000   -1.0000   -1.0000   -0.4286
    1.0000   -1.0000    1.0000   -0.1429
    1.0000    1.0000   -1.0000    0.1429
   -1.0000    1.0000   -1.0000    0.4286
    1.0000    1.0000    1.0000    0.7143
   -1.0000   -1.0000    1.0000    1.0000
X =
    1.0000   -1.0000    1.0000    1.0000   -1.0000
    1.0000    1.0000   -1.0000   -1.0000   -0.7143
    1.0000   -1.0000   -1.0000   -1.0000   -0.4286
    1.0000    1.0000   -1.0000    1.0000   -0.1429
    1.0000    1.0000    1.0000   -1.0000    0.1429
    1.0000   -1.0000    1.0000   -1.0000    0.4286
    1.0000    1.0000    1.0000    1.0000    0.7143
    1.0000   -1.0000   -1.0000    1.0000    1.0000
```

The column vector `time` is a fixed factor, normalized to values between ±1. The number of rows in the fixed factor specifies the number of runs in the design. The resulting design `dCV` gives factor settings for the three controlled model factors at each time.

Specify Categorical Factors

Categorical factors take values in a discrete set of levels. Both `cordexch` and `rowexch` have a `'categorical'` parameter that allows you to specify the indices of categorical factors and a `'levels'` parameter that allows you to specify a number of levels for each factor.

For example, the following eight-run design is for a linear additive model with five factors in which the final factor is categorical with three levels:

```
dCEcat = cordexch(5,8,'linear','categorical',5,'levels',3)
dCEcat =
    -1    -1     1     1     2
    -1    -1    -1    -1     3
     1     1     1     1     3
     1     1    -1    -1     2
     1    -1    -1     1     3
    -1     1    -1     1     1
    -1     1     1    -1     3
     1    -1     1    -1     1
```

Specify Candidate Sets

The row-exchange algorithm exchanges rows of an initial design matrix X with rows from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly.

For example, the following uses `rowexch` to generate a five-run design for a two-factor pure quadratic model using a candidate set that is produced internally:

```
dRE1 = rowexch(2,5,'purequadratic','tries',10)
dRE1 =
    -1     1
     0     0
     1    -1
     1     0
     1     1
```

The same thing can be done using `candgen` and `candexch` in sequence:

```
[dC,C] = candgen(2,'purequadratic') % Candidate set, C
dC =
    -1    -1
     0    -1
     1    -1
    -1     0
     0     0
     1     0
    -1     1
     0     1
     1     1
```

```
C =
     1    -1    -1     1     1
     1     0    -1     0     1
     1     1    -1     1     1
     1    -1     0     1     0
     1     0     0     0     0
     1     1     0     1     0
     1    -1     1     1     1
     1     0     1     0     1
     1     1     1     1     1
treatments = candexch(C,5,'tries',10) % D-opt subset
treatments =
     2
     1
     7
     3
     4
dRE2 = dC(treatments,:) % Display design
dRE2 =
     0    -1
    -1    -1
    -1     1
     1    -1
    -1     0
```

You can replace `C` in this example with a design matrix evaluated at your own candidate set. For example, suppose your experiment is constrained so that the two factors cannot have extreme settings simultaneously. The following produces a restricted candidate set:

```
constraint = sum(abs(dC),2) < 2; % Feasible treatments
my_dC = dC(constraint,:)
my_dC =
     0    -1
    -1     0
     0     0
     1     0
     0     1
```

Use the `x2fx` function to convert the candidate set to a design matrix:

```
my_C = x2fx(my_dC,'purequadratic')
my_C =
     1     0    -1     0     1
     1    -1     0     1     0
     1     0     0     0     0
     1     1     0     1     0
     1     0     1     0     1
```

Find the required design in the same manner:

```
my_treatments = candexch(my_C,5,'tries',10) % D-opt subset
my_treatments =
     2
     4
     5
     1
     3
my_dRE = my_dC(my_treatments,:) % Display design
```

```
my_dRE =
    -1     0
     1     0
     0     1
     0    -1
     0     0
```

Improve an Engine Cooling Fan Using Design for Six Sigma Techniques

This example shows how to improve the performance of an engine cooling fan through a Design for Six Sigma approach using Define, Measure, Analyze, Improve, and Control (DMAIC). The initial fan does not circulate enough air through the radiator to keep the engine cool during difficult conditions. First the example shows how to design an experiment to investigate the effect of three performance factors: fan distance from the radiator, blade-tip clearance, and blade pitch angle. It then shows how to estimate optimum values for each factor, resulting in a design that produces airflows beyond the goal of 875 ft^3 per minute using test data. Finally it shows how to use simulations to verify that the new design produces airflow according to the specifications in more than 99.999% of the fans manufactured. This example uses MATLAB, Statistics and Machine Learning Toolbox, and Optimization Toolbox.

Define the Problem

This example addresses an engine cooling fan design that is unable to pull enough air through the radiator to keep the engine cool during difficult conditions, such as stop-and-go traffic or hot weather). Suppose you estimate that you need airflow of at least 875 ft^3/min to keep the engine cool during difficult conditions. You need to evaluate the current design and develop an alternative design that can achieve the target airflow.

Assess Cooling Fan Performance

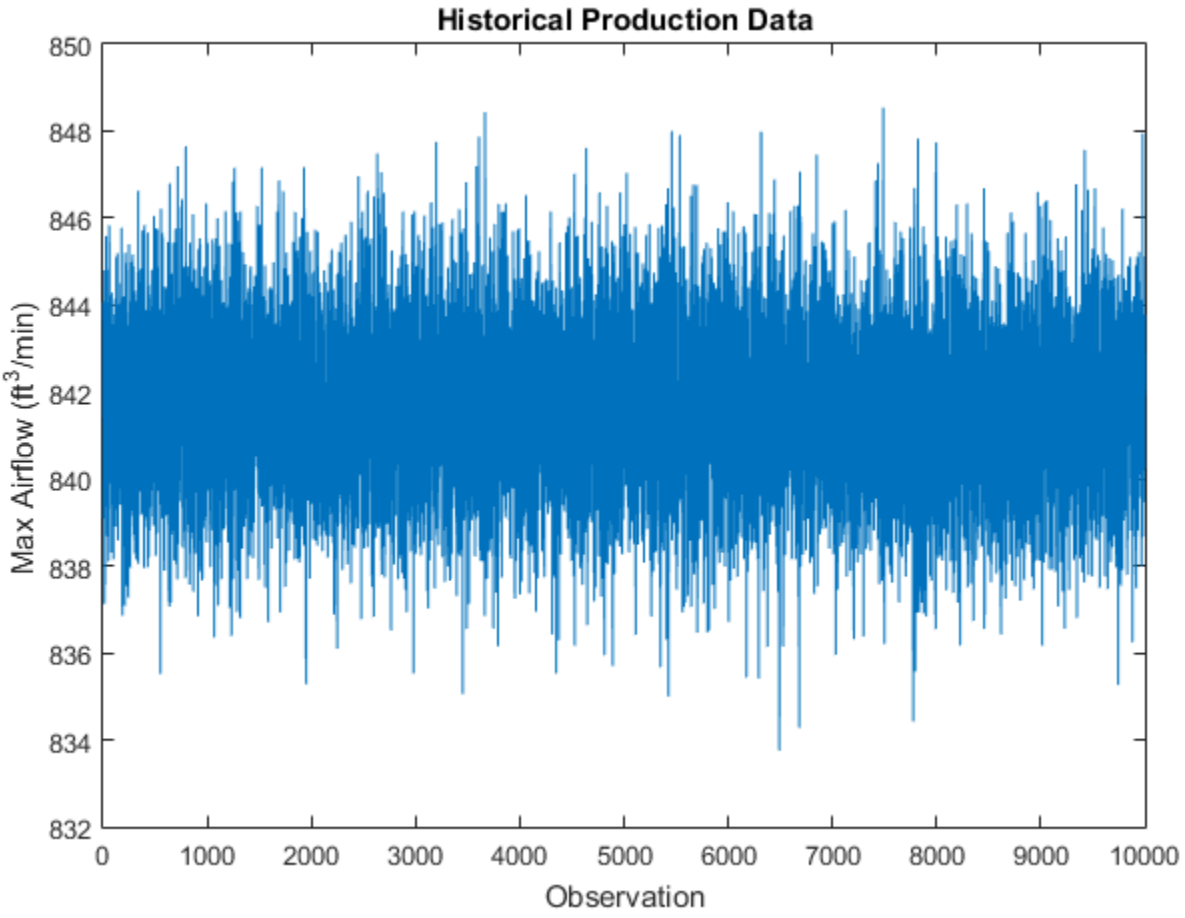
Load the sample data.

```
load(fullfile(matlabroot,'help/toolbox/stats/examples','OriginalFan.mat'))
```

The data consists of 10,000 measurements (historical production data) of the existing cooling fan performance.

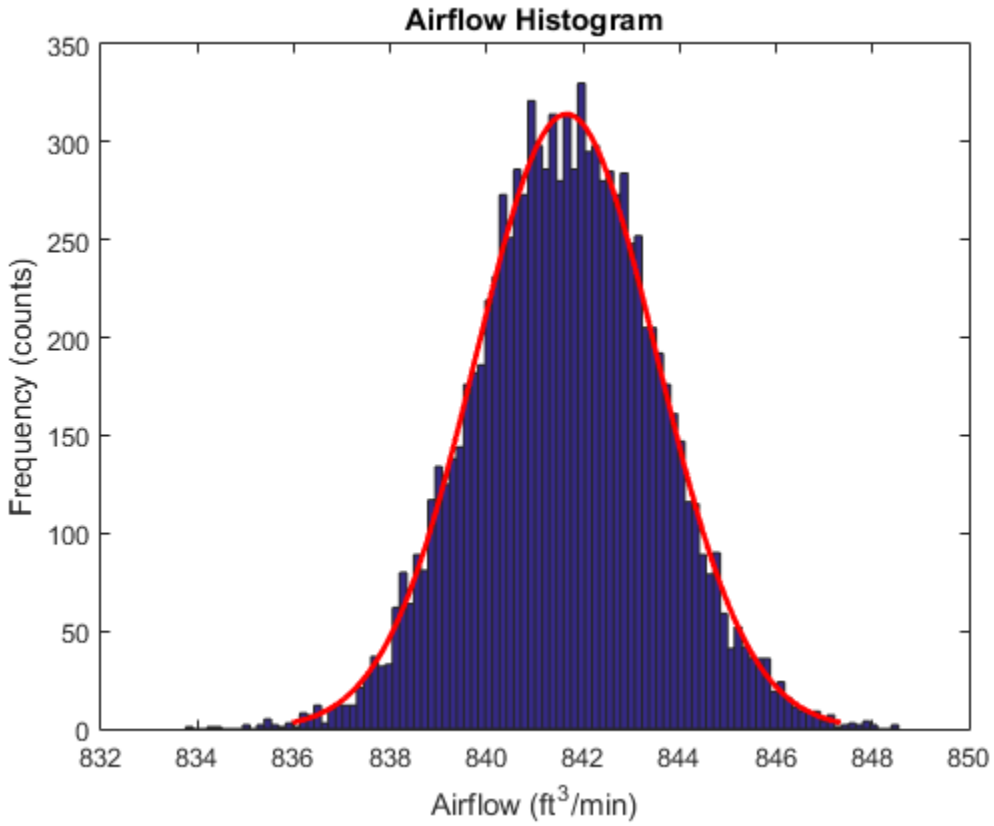
Plot the data to analyze the current fan's performance.

```
plot(originalfan)
xlabel('Observation')
ylabel('Max Airflow (ft^3/min)')
title('Historical Production Data')
```



The data is centered around 842 ft^3/min and most values fall within the range of about 8 ft^3/min. The plot does not tell much about the underlying distribution of data, however. Plot the histogram and fit a normal distribution to the data.

```
figure()
histfit(originalfan) % Plot histogram with normal distribution fit
format shortg
xlabel('Airflow (ft^3/min)')
ylabel('Frequency (counts)')
title('Airflow Histogram')
```



```
pd = fitdist(originalfan,'normal') % Fit normal distribution to data
```

```
pd =

  NormalDistribution

  Normal distribution
       mu = 841.652   [841.616, 841.689]
    sigma =  1.8768   [1.85114, 1.90318]
```

`fitdist` fits a normal distribution to data and estimates the parameters from data. The estimate for the mean airflow speed is 841.652 ft^3/min, and the 95% confidence interval for the mean airflow speed is (841.616, 841.689). This estimate makes it clear that the current fan is not close to the required 875 ft^3/min. There is need to improve the fan design to achieve the target airflow.

Determine Factors That Affect Fan Performance

Evaluate the factors that affect cooling fan performance using design of experiments (DOE). The response is the cooling fan airflow rate (ft^3/min). Suppose that the factors that you can modify and control are:

- Distance from radiator
- Pitch angle
- Blade tip clearance

In general, fluid systems have nonlinear behavior. Therefore, use a response surface design to estimate any nonlinear interactions among the factors. Generate the experimental runs for a Box-Behnken design on page 28-10 in coded (normalized) variables [-1, 0, +1].

```
CodedValue = bbdesign(3)
```

```
CodedValue =

    -1    -1     0
    -1     1     0
     1    -1     0
     1     1     0
    -1     0    -1
    -1     0     1
     1     0    -1
     1     0     1
     0    -1    -1
     0    -1     1
     0     1    -1
     0     1     1
     0     0     0
     0     0     0
     0     0     0
```

The first column is for the distance from radiator, the second column is for the pitch angle, and the third column is for the blade tip clearance. Suppose you want to test the effects of the variables at the following minimum and maximum values.

Distance from radiator: 1 to 1.5 inches
Pitch angle: 15 to 35 degrees
Blade tip clearance: 1 to 2 inches

Randomize the order of the runs, convert the coded design values to real-world units, and perform the experiment in the order specified.

```
runorder = randperm(15);     % Random permutation of the runs
bounds = [1 1.5;15 35;1 2];  % Min and max values for each factor

RealValue = zeros(size(CodedValue));
for i = 1:size(CodedValue,2) % Convert coded values to real-world units
    zmax = max(CodedValue(:,i));
    zmin = min(CodedValue(:,i));
    RealValue(:,i) = interp1([zmin zmax],bounds(i,:),CodedValue(:,i));
end
```

Suppose that at the end of the experiments, you collect the following response values in the variable `TestResult`.

```
TestResult = [837 864 829 856 880 879 872 874 834 833 860 859 874 876 875]';
```

Display the design values and the response.

```
disp({'Run Number','Distance','Pitch','Clearance','Airflow'})
disp(sortrows([runorder' RealValue TestResult]))
```

```
'Run Number'    'Distance'    'Pitch'    'Clearance'    'Airflow'

            1          1.5          35          1.5          856
```

```
 2         1.25          25          1.5          876
 3          1.5          25            1          872
 4         1.25          25          1.5          875
 5            1          35          1.5          864
 6         1.25          25          1.5          874
 7         1.25          15            2          833
 8          1.5          15          1.5          829
 9         1.25          15            1          834
10            1          15          1.5          837
11          1.5          25            2          874
12            1          25            1          880
13         1.25          35            1          860
14            1          25            2          879
15         1.25          35            2          859
```

Save the design values and the response in a `table`.

```
Expmt = table(runorder', CodedValue(:,1), CodedValue(:,2), CodedValue(:,3), ...
    TestResult,'VariableNames',{'RunNumber','D','P','C','Airflow'});
```

`D` stands for `Distance`, `P` stands for `Pitch`, and C stands for `Clearance`. Based on the experimental test results, the airflow rate is sensitive to the changing factors values. Also, four experimental runs meet or exceed the target airflow rate of 875 ft^3/min (runs 2, 4,12, and 14). However, it is not clear which, if any, of these runs is the optimal one. In addition, it is not obvious how robust the design is to variation in the factors. Create a model based on the current experimental data and use the model to estimate the optimal factor settings.

Improve the Cooling Fan Performance

The Box-Behnken design enables you to test for nonlinear (quadratic) effects. The form of the quadratic model is:

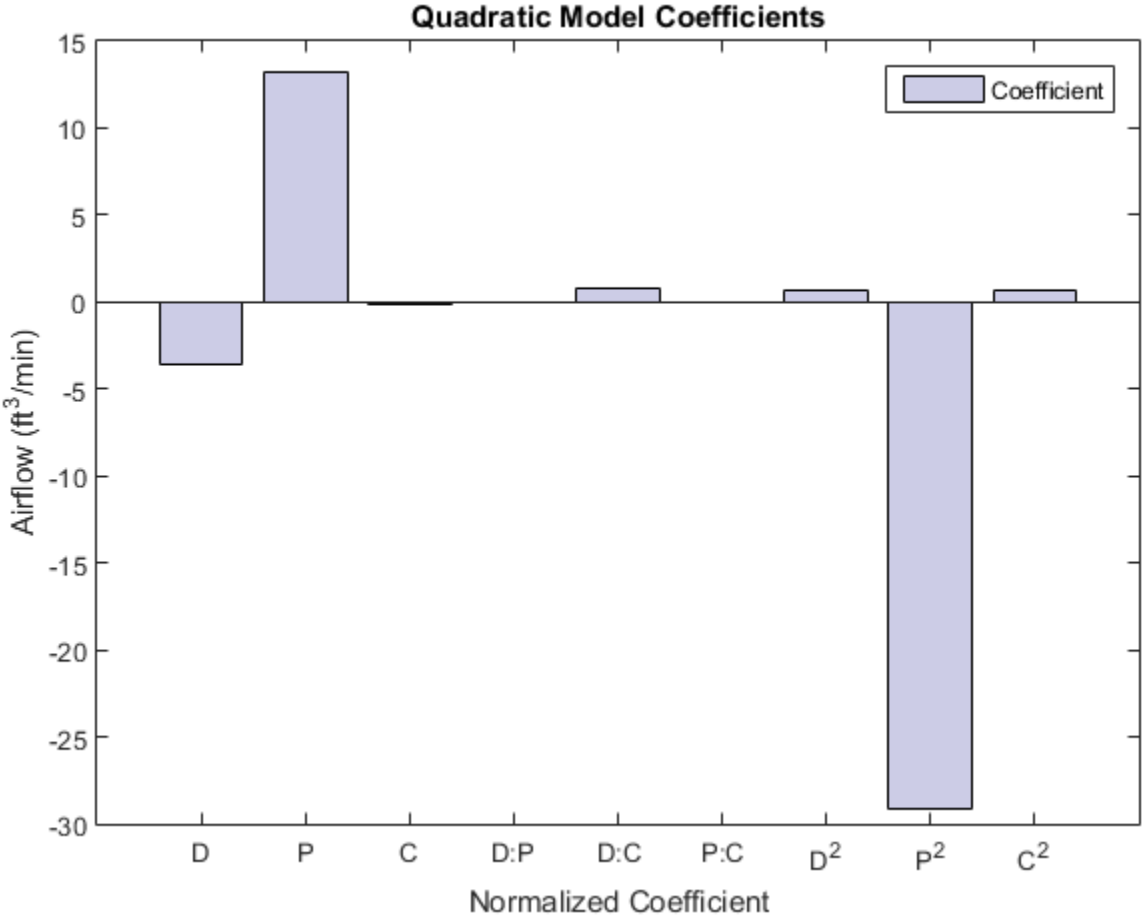
$$AF = \beta_0+\beta_1*Distance+\beta_2*Pitch+\beta_3*Clearance+\beta_4*Distance*Pitch$$
$$+\beta_5*Distance*Clearance+\beta_6*Pitch*Clearance+\beta_7*Distance^2$$
$$+\beta_8*Pitch^2+\beta_9*Clearance^2,$$

where AF is the airflow rate and B_i is the coefficient for the term i. Estimate the coefficients of this model using the `fitlm` function from Statistics and Machine Learning Toolbox.

```
mdl = fitlm(Expmt,'Airflow~D*P*C-D:P:C+D^2+P^2+C^2');
```

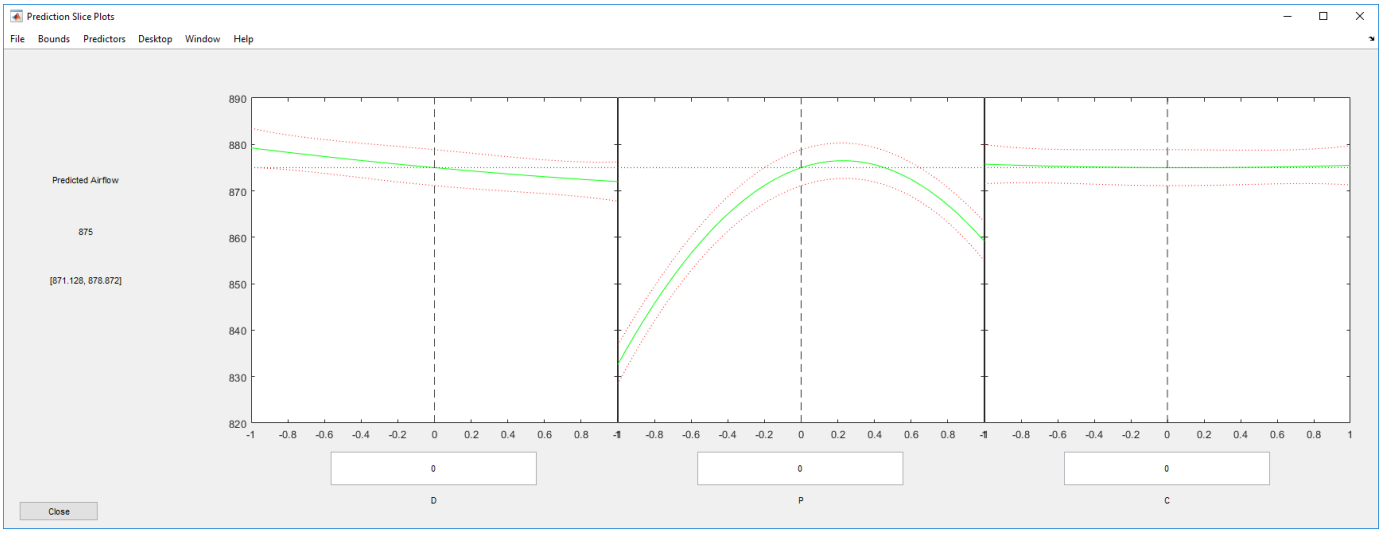
Display the magnitudes of the coefficients (for normalized values) in a bar chart.

```
figure()
h = bar(mdl.Coefficients.Estimate(2:10));
set(h,'facecolor',[0.8 0.8 0.9])
legend('Coefficient')
set(gcf,'units','normalized','position',[0.05 0.4 0.35 0.4])
set(gca,'xticklabel',mdl.CoefficientNames(2:10))
ylabel('Airflow (ft^3/min)')
xlabel('Normalized Coefficient')
title('Quadratic Model Coefficients')
```



The bar chart shows that *Pitch* and $Pitch^2$ are dominant factors. You can look at the relationship between multiple input variables and one output variable by generating a response surface plot. Use `plotSlice` to generate response surface plots for the model `mdl` interactively.

```
plotSlice(mdl)
```



The plot shows the nonlinear relationship of airflow with pitch. Move the blue dashed lines around and see the effect the different factors have on airflow. Although you can use `plotSlice` to determine the optimum factor settings, you can also use Optimization Toolbox to automate the task.

Find the optimal factor settings using the constrained optimization function `fmincon`.

Write the objective function.

```
f = @(x) -x2fx(x,'quadratic')*mdl.Coefficients.Estimate;
```

The objective function is a quadratic response surface fit to the data. Minimizing the negative airflow using `fmincon` is the same as maximizing the original objective function. The constraints are the upper and lower limits tested (in coded values). Set the initial starting point to be the center of the design of the experimental test matrix.

```
lb = [-1 -1 -1]; % Lower bound
ub = [1 1 1];    % Upper bound
x0 = [0 0 0];    % Starting point
[optfactors,fval] = fmincon(f,x0,[],[],[],[],lb,ub,[]); % Invoke the solver

Local minimum found that satisfies the constraints.

Optimization completed because the objective function is non-decreasing in
feasible directions, to within the default value of the function tolerance,
and constraints are satisfied to within the default value of the constraint tolerance.
```

Convert the results to a maximization problem and real-world units.

```
maxval = -fval;
maxloc = (optfactors + 1)';
bounds = [1 1.5;15 35;1 2];
maxloc=bounds(:,1)+maxloc .* ((bounds(:,2) - bounds(:,1))/2);
disp('Optimal Values:')
disp({'Distance','Pitch','Clearance','Airflow'})
disp([maxloc' maxval])

Optimal Values:
    'Distance'    'Pitch'    'Clearance'    'Airflow'
```

```
            1       27.275            1       882.26
```

The optimization result suggests placing the new fan one inch from the radiator, with a one-inch clearance between the tips of the fan blades and the shroud.

Because pitch angle has such a significant effect on airflow, perform additional analysis to verify that a 27.3 degree pitch angle is optimal.

```
load(fullfile(matlabroot,'help/toolbox/stats/examples','AirflowData.mat'))
tbl = table(pitch,airflow);
mdl2 = fitlm(tbl,'airflow~pitch^2');
mdl2.Rsquared.Ordinary
```

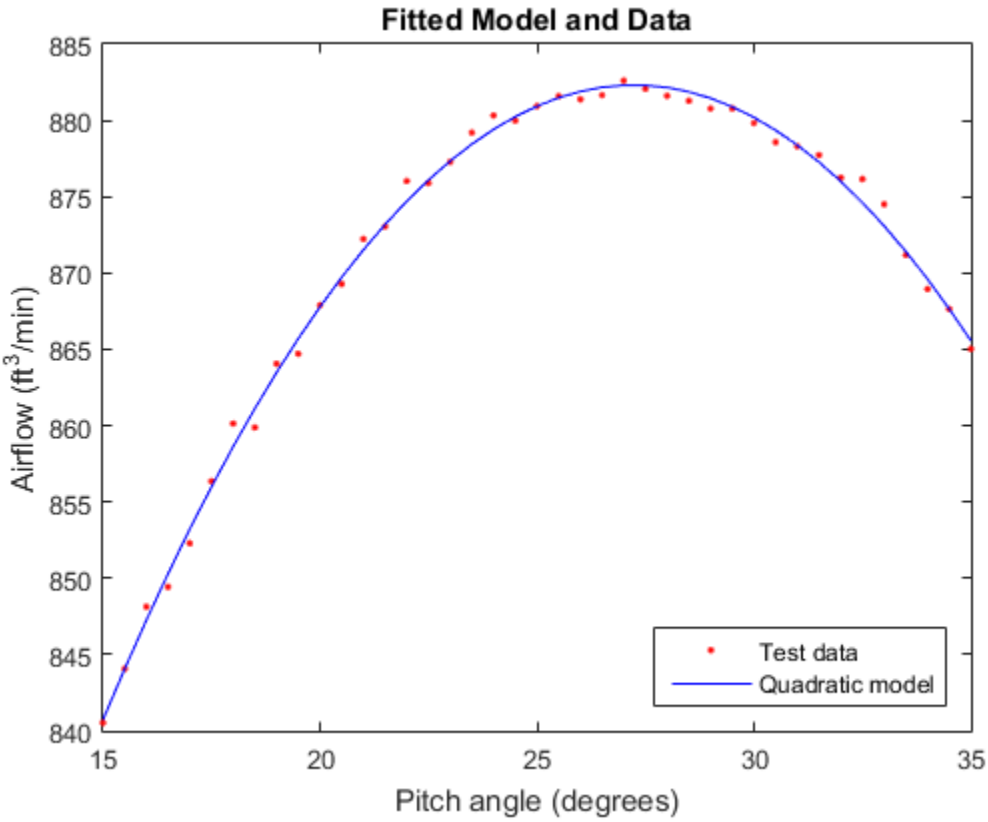
```
ans =

      0.99632
```

The results show that a quadratic model explains the effect of pitch on the airflow well.

Plot the pitch angle against airflow and impose the fitted model.

```
figure()
plot(pitch,airflow,'.r')
hold on
ylim([840 885])
line(pitch,mdl2.Fitted,'color','b')
title('Fitted Model and Data')
xlabel('Pitch angle (degrees)')
ylabel('Airflow (ft^3/min)')
legend('Test data','Quadratic model','Location','se')
hold off
```



Find the pitch value that corresponds to the maximum airflow.

```
pitch(find(airflow==max(airflow)))
```

```
ans =

    27
```

The additional analysis confirms that a 27.3 degree pitch angle is optimal.

The improved cooling fan design meets the airflow requirements. You also have a model that approximates the fan performance well based on the factors you can modify in the design. Ensure that the fan performance is robust to variability in manufacturing and installation by performing a sensitivity analysis.

Sensitivity Analysis

Suppose that, based on historical experience, the manufacturing uncertainty is as follows.

Factor	Real Values	Coded Values
Distance from radiator	1.00 +/- 0.05 inch	1.00 +/- 0.20 inch
Blade pitch angle	27.3 +/- 0.25 degrees	0.227 +/- 0.028 degrees
Blade tip clearance	1.00 +/- 0.125 inch	-1.00 +/- 0.25 inch

Verify that these variations in factors will enable to maintain a robust design around the target airflow. The philosophy of Six Sigma targets a defect rate of no more than 3.4 per 1,000,000 fans. That is, the fans must hit the 875 ft^3/min target 99.999% of the time.

You can verify the design using Monte Carlo simulation. Generate 10,000 random numbers for three factors with the specified tolerance. First, set the state of the random number generators so results are consistent across different runs.

```
rng('default')
```

Perform the Monte Carlo simulation. Include a noise variable that is proportional to the noise in the fitted model, `mdl` (that is, the RMS error of the model). Because the model coefficients are in coded variables, you must generate `dist`, `pitch`, and `clearance` using the coded definition.

```
dist = random('normal',optfactors(1),0.20,[10000 1]);
pitch = random('normal',optfactors(2),0.028,[10000 1]);
clearance = random('normal',optfactors(3),0.25,[10000 1]);
noise = random('normal',0,mdl2.RMSE,[10000 1]);
```

Calculate airflow for 10,000 random factor combinations using the model.

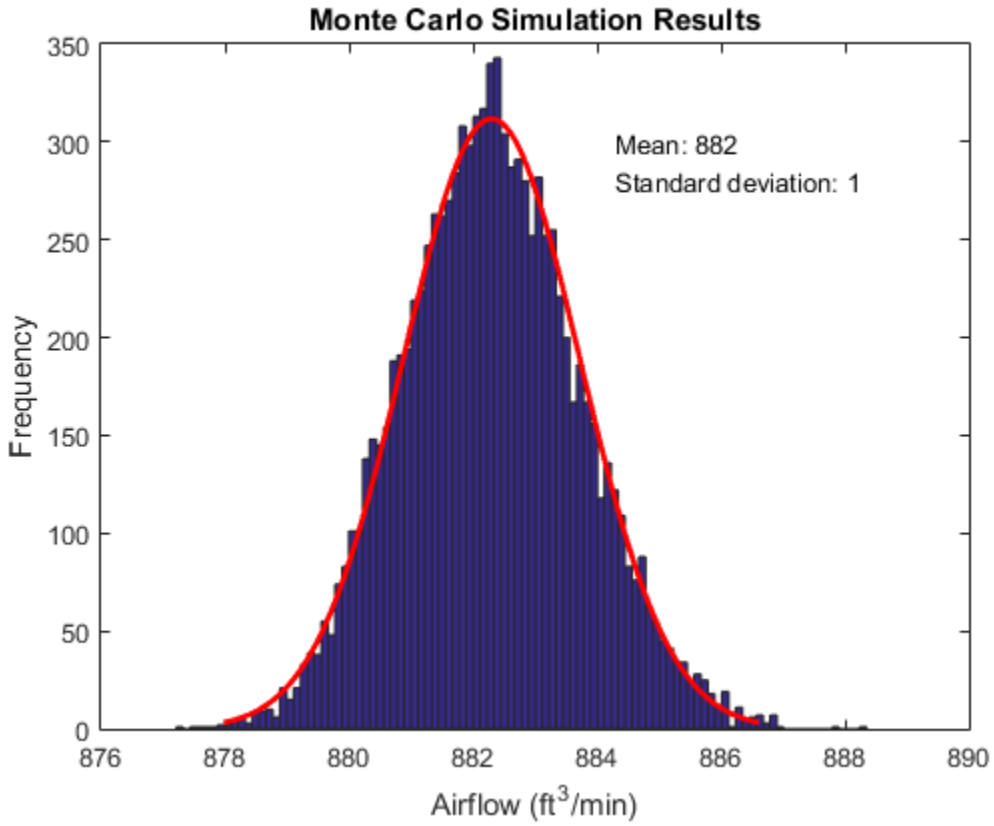
```
simfactor = [dist pitch clearance];
X = x2fx(simfactor,'quadratic');
```

Add noise to the model (the variation in the data that the model did not account for).

```
simflow = X*mdl.Coefficients.Estimate+noise;
```

Evaluate the variation in the model's predicted airflow using a histogram. To estimate the mean and standard deviation, fit a normal distribution to data.

```
pd = fitdist(simflow,'normal');
histfit(simflow)
hold on
text(pd.mu+2,300,['Mean: ' num2str(round(pd.mu))])
text(pd.mu+2,280,['Standard deviation: ' num2str(round(pd.sigma))])
hold off
xlabel('Airflow (ft^3/min)')
ylabel('Frequency')
title('Monte Carlo Simulation Results')
```



The results look promising. The average airflow is 882 ft^3/min and appears to be better than 875 ft^3/min for most of the data.

Determine the probability that the airflow is at 875 ft^3/min or below.

```
format long
pfail = cdf(pd,875)
pass = (1-pfail)*100
```

```
pfail =

     1.509289008603141e-07

pass =

  99.999984907109919
```

The design appears to achieve at least 875 ft^3/min of airflow 99.999% of the time.

Use the simulation results to estimate the process capability.

```
S = capability(simflow,[875.0 890])
pass = (1-S.Pl)*100
```

```
S =

       mu: 8.822982645666709e+02
```

```
    sigma: 1.424806876923940
        P: 0.999999816749816
       Pl: 1.509289008603141e-07
       Pu: 3.232128339675335e-08
       Cp: 1.754623760237126
      Cpl: 1.707427788957002
      Cpu: 1.801819731517250
      Cpk: 1.707427788957002

pass =

  99.9999849071099
```

The `Cp` value is 1.75. A process is considered high quality when `Cp` is greater than or equal to 1.6. The `Cpk` is similar to the `Cp` value, which indicates that the process is centered. Now implement this design. Monitor it to verify the design process and to ensure that the cooling fan delivers high-quality performance.

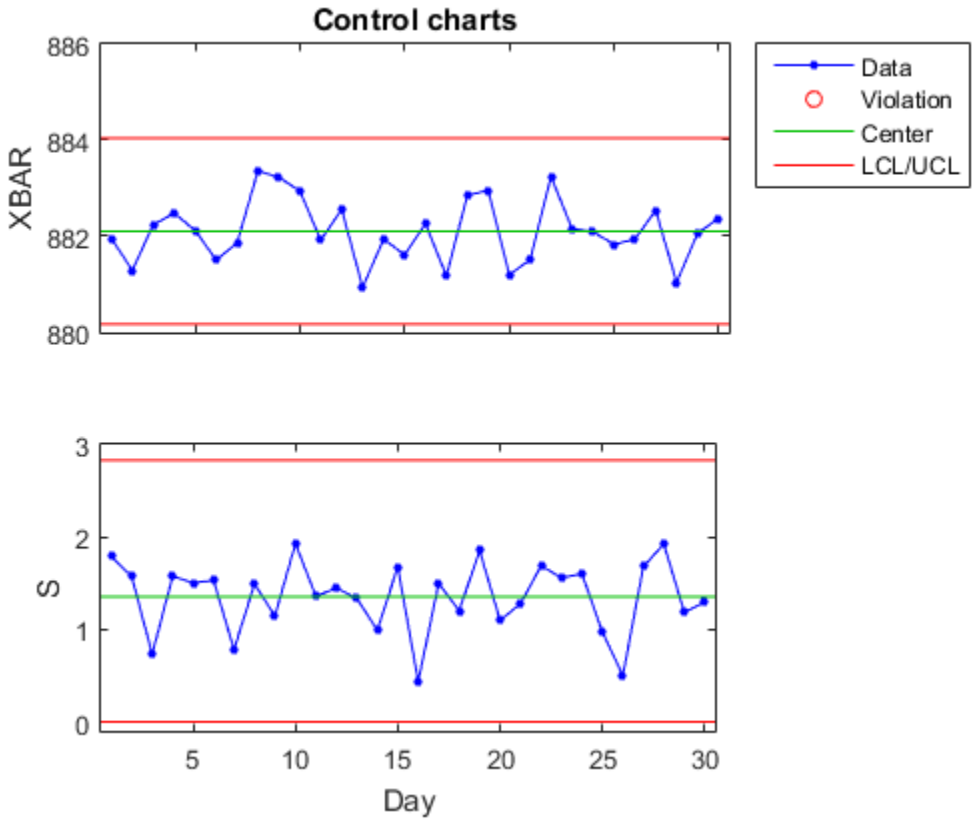
Control Manufacturing of the Improved Cooling Fan

You can monitor and evaluate the manufacturing and installation process of the new fan using control charts. Evaluate the first 30 days of production of the new cooling fan. Initially, five cooling fans per day were produced. First, load the sample data from the new process.

```
load(fullfile(matlabroot,'help/toolbox/stats/examples','spcdata.mat'))
```

Plot the *X*-bar and *S* charts.

```
figure()
controlchart(spcflow,'chart',{'xbar','s'}) % Reshape the data into daily sets
xlabel('Day')
```



According to the results, the manufacturing process is in statistical control, as indicated by the absence of violations of control limits or nonrandom patterns in the data over time. You can also run a capability analysis on the data to evaluate the process.

```
[row,col] = size(spcflow);
S2 = capability(reshape(spcflow,row*col,1),[875.0 890])
pass = (1-S.Pl)*100
```

```
S2 =

       mu: 8.821061141685465e+02
    sigma: 1.423887508874697
        P: 0.999999684316149
       Pl: 3.008932155898586e-07
       Pu: 1.479063578225176e-08
       Cp: 1.755756676295137
      Cpl: 1.663547652525458
      Cpu: 1.847965700064817
      Cpk: 1.663547652525458

pass =

  99.9999699106784
```

The `Cp` value of 1.755 is very similar to the estimated value of 1.73. The `Cpk` value of 1.66 is smaller than the `Cp` value. However, only a `Cpk` value less than 1.33, which indicates that the process shifted

significantly toward one of the process limits, is a concern. The process is well within the limits and it achieves the target airflow (875 ft^3/min) more than 99.999% of the time.

Statistical Process Control

Control Charts

A control chart displays measurements of process samples over time. The measurements are plotted together with user-defined *specification limits* and process-defined *control limits*. The process can then be compared with its specifications—to see if it is *in control* or *out of control*.

The chart is just a monitoring tool. Control activity might occur if the chart indicates an undesirable, systematic change in the process. The control chart is used to discover the variation, so that the process can be adjusted to reduce it.

Control charts are created with the `controlchart` function. Any of the following chart types may be specified:

- Xbar or mean
- Standard deviation
- Range
- Exponentially weighted moving average
- Individual observation
- Moving range of individual observations
- Moving average of individual observations
- Proportion defective
- Number of defectives
- Defects per unit
- Count of defects

Control rules are specified with the `controlrules` function. The following example illustrates how to use Western Electric rules to mark out of control measurements on an Xbar chart.

First load the sample data.

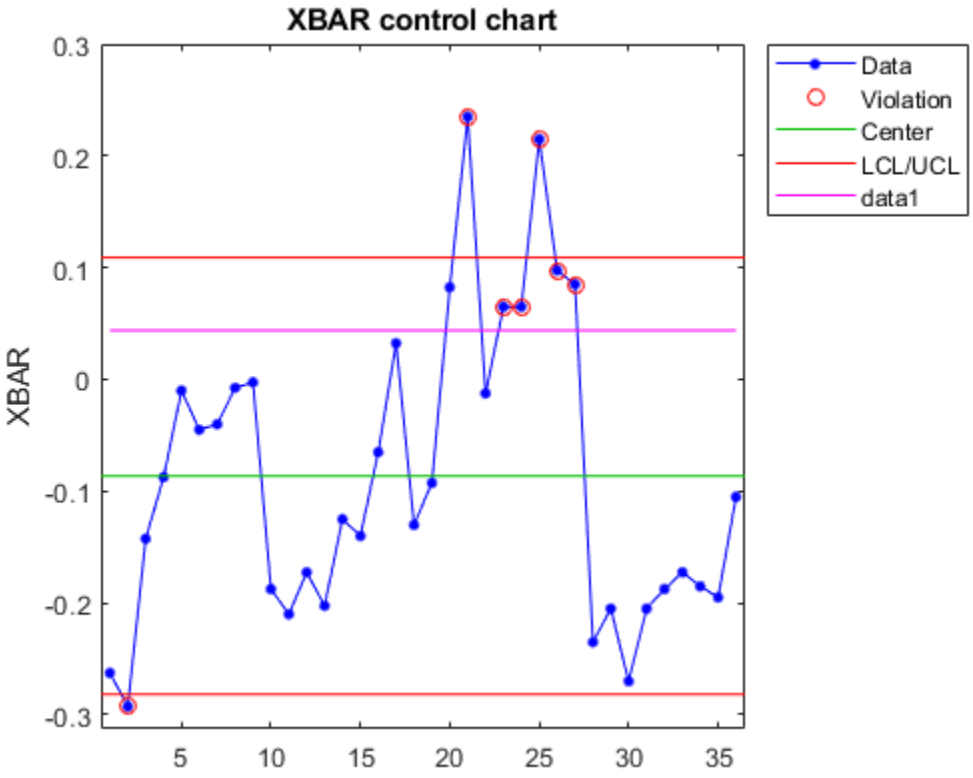
```
load parts
```

Construct the Xbar control chart using the Western Electric 2 rule (2 of 3 points at least 2 standard errors above the center line) to mark the out of control measurements.

```
st = controlchart(runout,'rules','we2');
```

For a better understanding of the Western Electric 2 rule, calculate and plot the 2 standard errors line on the chart.

```
x = st.mean;
cl = st.mu;
se = st.sigma./sqrt(st.n);
hold on
plot(cl+2*se,'m')
```



Identify the measurements that violate the control rule.

```
R = controlrules('we2',x,cl,se);
I = find(R)
```

```
I = 6×1

    21
    23
    24
    25
    26
    27
```

Capability Studies

Before going into production, many manufacturers run a *capability study* to determine if their process will run within specifications enough of the time. *Capability indices* produced by such a study are used to estimate expected percentages of defective parts.

Capability studies are conducted with the `capability` function. The following capability indices are produced:

- `mu` — Sample mean
- `sigma` — Sample standard deviation
- `P` — Estimated probability of being within the lower (`L`) and upper (`U`) specification limits
- `Pl` — Estimated probability of being below `L`
- `Pu` — Estimated probability of being above `U`
- `Cp` — `(U-L)/(6*sigma)`
- `Cpl` — `(mu-L)./(3.*sigma)`
- `Cpu` — `(U-mu)./(3.*sigma)`
- `Cpk` — `min(Cpl,Cpu)`

As an example, simulate a sample from a process with a mean of 3 and a standard deviation of 0.005:

```
rng default; % For reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99:

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
       mu: 3.0006
    sigma: 0.0058
        P: 0.9129
       Pl: 0.0339
       Pu: 0.0532
       Cp: 0.5735
      Cpl: 0.6088
      Cpu: 0.5382
      Cpk: 0.5382
```

Visualize the specification and process widths:

```
capaplot(data,[2.99 3.01]);
grid on
```

Tall Arrays

Logistic Regression with Tall Arrays

This example shows how to use logistic regression and other techniques to perform data analysis on tall arrays. Tall arrays represent data that is too large to fit into computer memory.

Define Execution Environment

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)
```

Get Data into MATLAB

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat `'NA'` values as missing data so that `datastore` replaces them with `NaN` values. Select a subset of the variables to work with, and include the name of the airline (`UniqueCarrier`) as a categorical variable. Create a tall table on top of the datastore.

```
ds = datastore('airlinesmall.csv');
ds.TreatAsMissing = 'NA';
ds.SelectedVariableNames = {'DayOfWeek','UniqueCarrier',...
    'ArrDelay','DepDelay','Distance'};
ds.SelectedFormats{2} = '%C';
tt = tall(ds);
tt.DayOfWeek = categorical(tt.DayOfWeek,1:7,...
    {'Sun','Mon','Tues','Wed','Thu','Fri','Sat'},'Ordinal',true)
```

```
tt =

  Mx5 tall table

    DayOfWeek    UniqueCarrier    ArrDelay    DepDelay    Distance
    _________    _____________    ________    ________    ________

        ?              ?              ?           ?           ?
        ?              ?              ?           ?           ?
        ?              ?              ?           ?           ?
        :              :              :           :           :
        :              :              :           :           :
```

Late Flights

Determine the flights that are late by 20 minutes or more by defining a logical variable that is true for a late flight. Add this variable to the tall table of data, noting that it is not yet evaluated. A preview of this variable includes the first few rows.

```
tt.LateFlight = tt.ArrDelay>=20
```

```
tt =

  Mx6 tall table

    DayOfWeek    UniqueCarrier    ArrDelay    DepDelay    Distance    LateFlight
```

```
    _________    ______________    ________    _________    ________    __________

        ?              ?             ?           ?           ?           ?
        ?              ?             ?           ?           ?           ?
        ?              ?             ?           ?           ?           ?
        :              :             :           :           :           :
        :              :             :           :           :           :
```

Calculate the mean of `LateFlight` to determine the overall proportion of late flights. Use `gather` to trigger evaluation of the tall array and bring the result into memory.

```
m = mean(tt.LateFlight)

m =

  tall double

    ?

m = gather(m)

Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 2: Completed in 1.4 sec
- Pass 2 of 2: Completed in 1.6 sec
Evaluation completed in 3.9 sec

m = 0.1580
```

Late Flights by Carrier

Examine whether certain types of flights tend to be late. First, check to see if certain carriers are more likely to have late flights.

```
tt.LateFlight = double(tt.LateFlight);
late_by_carrier = gather(grpstats(tt,'UniqueCarrier','mean','DataVar','LateFlight'))

Evaluating tall expression using the Local MATLAB Session:

     {'Wed' }       Wed          18240           0.18399
```

Wednesdays and Thursdays have the highest proportion of late flights, while Fridays have the lowest proportion.

Late Flights by Distance

Check to see if longer or shorter flights tend to be late. First, look at the density of the flight distance for flights that are late, and compare that with flights that are on time.

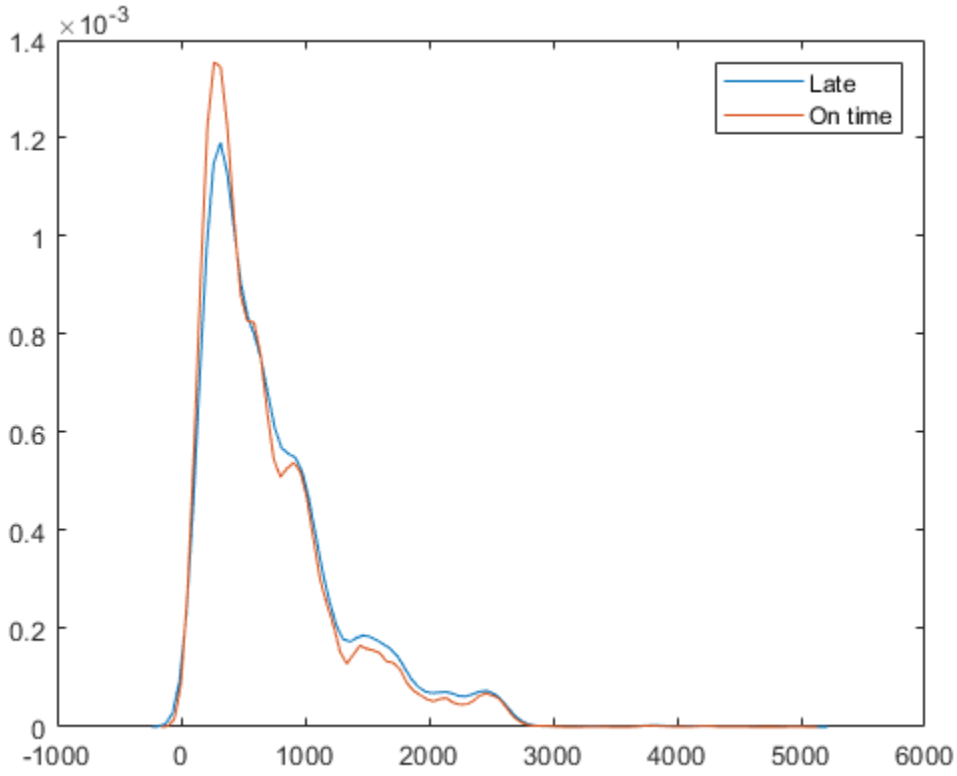
```
ksdensity(tt.Distance(tt.LateFlight==1))
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 2: Completed in 1.7 sec
- Pass 2 of 2: Completed in 1.6 sec
Evaluation completed in 4 sec
```

```
hold on
ksdensity(tt.Distance(tt.LateFlight==0))
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 2: Completed in 1.4 sec
- Pass 2 of 2: Completed in 1.7 sec
Evaluation completed in 3.5 sec
```

```
hold off
legend('Late','On time')
```



Flight distance does not make a dramatic difference in whether a flight is early or late. However, the density appears to be slightly higher for on-time flights at distances of about 400 miles. The density is also higher for late flights at distances of about 2000 miles. Calculate some simple descriptive statistics for the late and on-time flights.

```
late_by_distance = gather(grpstats(tt,'LateFlight',{'mean' 'std'},'DataVar','Distance'))
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 1.7 sec
Evaluation completed in 2.2 sec

late_by_distance=2×5 table
    GroupLabel    LateFlight    GroupCount    mean_Distance    std_Distance
    __________    __________    __________    _____________    ____________

      {'0'}           0          1.04e+05        693.14           544.75
      {'1'}           1             19519        750.24           574.12
```

Late flights are about 60 miles longer on average, although this value makes up only a small portion of the standard deviation of the distance values.

Logistic Regression Model

Build a model for the probability of a late flight, using both continuous variables (such as `Distance`) and categorical variables (such as `DayOfWeek`) to predict the probabilities. This model can help to determine if the previous results observed for each predictor individually also hold true when you consider them together.

```
glm = fitglm(tt,'LateFlight~Distance+DayOfWeek','Distribution','binomial')

    DayOfWeek_Mon      -0.072603      0.029798    -2.4365      0.01483
    DayOfWeek_Tues      0.026909      0.029239    0.92029      0.35742
    DayOfWeek_Wed         0.2359      0.028276      8.343    7.2452e-17
    DayOfWeek_Thu        0.23569      0.028282     8.3338    7.8286e-17
    DayOfWeek_Fri       -0.19285      0.031583     -6.106    1.0213e-09
    DayOfWeek_Sat       0.033542      0.029702     1.1293       0.25879
    Distance          0.00018373    1.3507e-05     13.602    3.8741e-42

123319 observations, 123311 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 504, p-value = 8.74e-105
```

The model confirms that the previously observed conclusions hold true here as well:

- The Wednesday and Thursday coefficients are positive, indicating a higher probability of a late flight on those days. The Friday coefficient is negative, indicating a lower probability.
- The Distance coefficient is positive, indicating that longer flights have a higher probability of being late.

All of these coefficients have very small p-values. This is common with data sets that have many observations, since one can reliably estimate small effects with large amounts of data. In fact, the uncertainty in the model is larger than the uncertainty in the estimates for the parameters in the model.

Prediction with Model

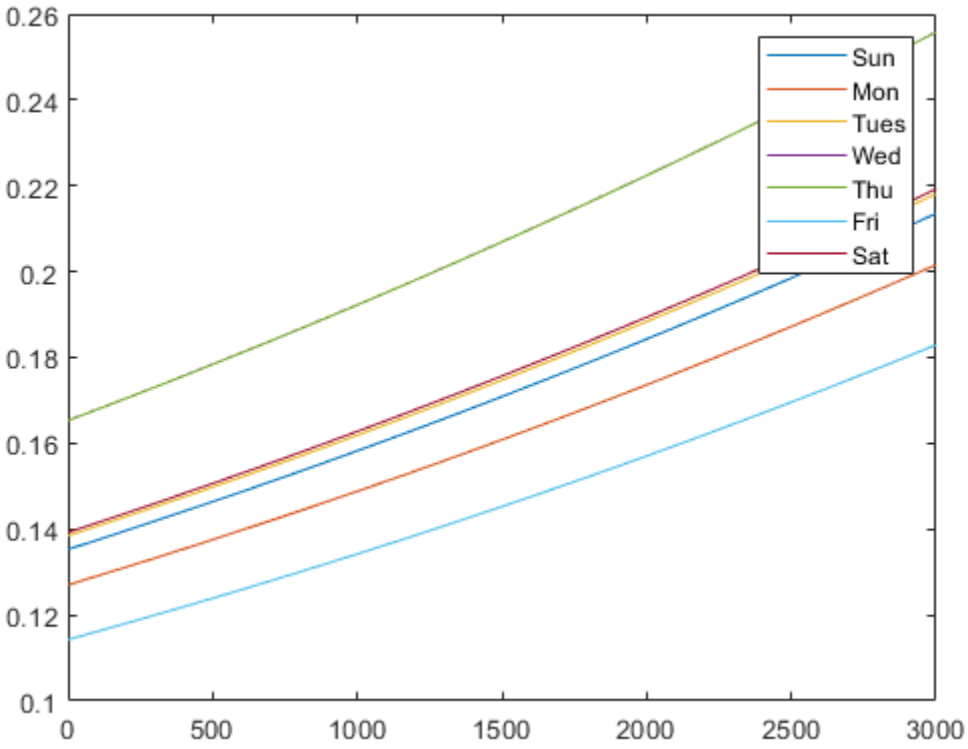
Predict the probability of a late flight for each day of the week, and for distances ranging from 0 to 3000 miles. Create a table to hold the predictor values by indexing the first 100 rows in the original table `tt`.

```
x = gather(tt(1:100,{'Distance' 'DayOfWeek'}));
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.35 sec
Evaluation completed in 0.59 sec

x.Distance = linspace(0,3000)';
x.DayOfWeek(:) = 'Sun';
plot(x.Distance,predict(glm,x));

days = {'Sun' 'Mon' 'Tues' 'Wed' 'Thu' 'Fri' 'Sat'};
hold on
for j=2:length(days)
    x.DayOfWeek(:) = days{j};
    plot(x.Distance,predict(glm,x));
end
legend(days)
```



According to this model, a Wednesday or Thursday flight of 500 miles has the same probability of being late, about 18%, as a Friday flight of about 3000 miles.

Since these probabilities are all much less than 50%, the model is unlikely to predict that any given flight will be late using this information. Investigate the model more by focusing on the flights for which the model predicts a probability of 20% or more of being late, and compare that to the actual results.

```
C = gather(crosstab(tt.LateFlight,predict(glm,tt)>.20))
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 1.3 sec
Evaluation completed in 1.4 sec

C = 2×2

       99613        4391
       18394        1125
```

Among the flights predicted to have a 20% or higher probability of being late, about 20% were late `1125/(1125 + 4391)`. Among the remainder, less than 16% were late `18394/(18394 + 99613)`.

Bayesian Optimization with Tall Arrays

This example shows how to use Bayesian optimization to select optimal parameters for training a kernel classifier by using the `'OptimizeHyperparameters'` name-value argument. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data, and extracts class labels and predictor data from the tall table to run the optimization procedure.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Get Data into MATLAB®

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. For folders that contain a collection of files, you can specify the entire folder location, or use the wildcard character, `'*.csv'`, to include multiple files with the same file extension in the datastore. Select a subset of the variables to work with, and treat `'NA'` values as missing data so that `datastore` replaces them with `NaN` values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek',...
                            'DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt  = tall(ds) % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

tt =

```

Remove rows in `X` and `Y` that contain missing data.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:end-1);
Y = R(:,end);
```

Perform Bayesian Optimization Using `OptimizeHyperparameters`

Optimize hyperparameters automatically using the `'OptimizeHyperparameters'` name-value argument.

Standardize the predictor variables.

```
Z = zscore(X);
```

Find the optimal values for the `'KernelScale'` and `'Lambda'` name-value arguments that minimize the loss on the holdout validation set. By default, the software selects and reserves 20% of the data as validation data, and trains the model using the rest of the data. You can change the holdout fraction by using the `'HyperparameterOptimizationOptions'` name-value argument. For reproducibility, use the `'expected-improvement-plus'` acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs”.

```
rng('default')
tallrng('default')
Mdl = fitckernel(Z,Y,'Verbose',0,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-p
```

  Properties, Methods
```

Perform Bayesian Optimization by Using bayesopt

Alternatively, you can use the `bayesopt` function to find the optimal values of hyperparameters.

Split the data set into training and test sets. Specify a 1/3 holdout sample for the test set.

```
rng('default') % For reproducibility
tallrng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',1/3);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition);         % Indices for the test set
```

Extract training and testing data and standardize the predictor data.

```
Ytrain = Y(trainingInds); % Training class labels
Xtrain = X(trainingInds,:);
[Ztrain,mu,stddev] = zscore(Xtrain); % Standardized training data

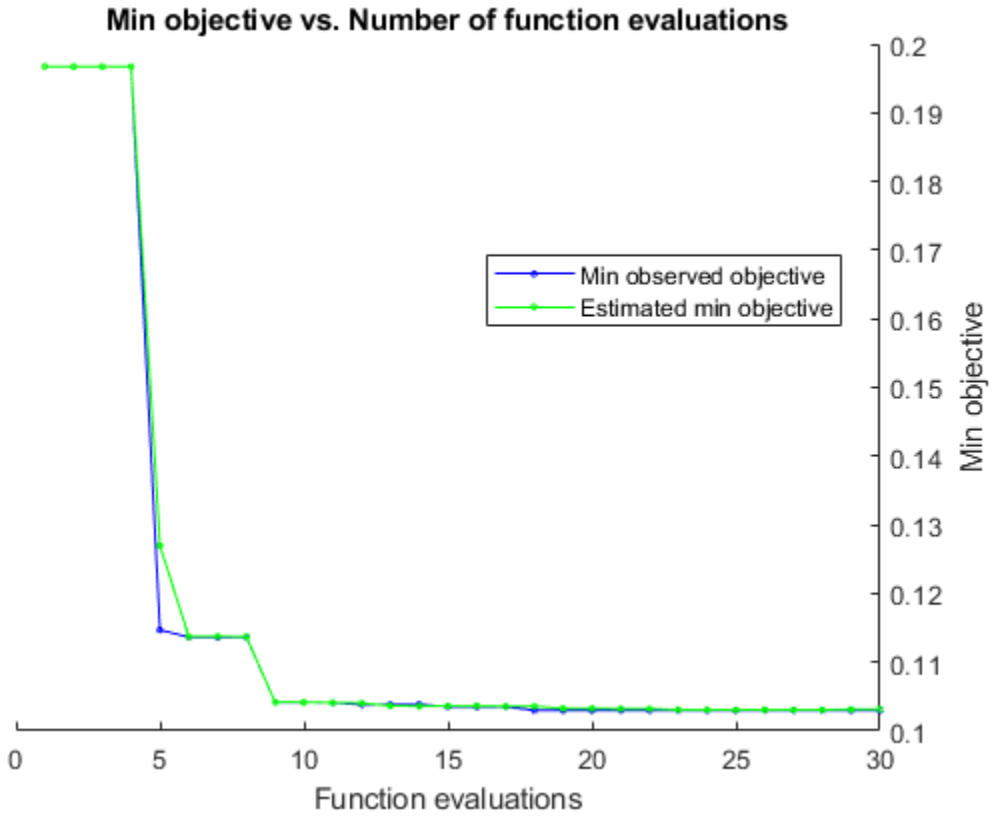
Ytest = Y(testInds); % Testing class labels
Xtest = X(testInds,:);
Ztest = (Xtest-mu)./stddev; % Standardized test data
```

Define the variables `sigma` and `lambda` to find the optimal values for the `'KernelScale'` and `'Lambda'` name-value arguments. Use `optimizableVariable` and specify a wide range for the variables because optimal values are unknown. Apply logarithmic transformation to the variables to search for the optimal values on a log scale.

```
N = gather(numel(Ytrain)); % Evaluate the length of the tall training array in memory
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: 0% complete
Evaluation 0% complete
```

```
- Pass 1 of 1: Completed in 0.95 sec
Evaluation 91% complete
```



```
Evaluation completed in 1.1 sec
```

```
sigma = optimizableVariable('sigma',[1e-3,1e3],'Transform','log');
lambda = optimizableVariable('lambda',[(1e-3)/N, (1e3)/N],'Transform','log');
```

Create the objective function for Bayesian optimization. The objective function takes in a table that contains the variables `sigma` and `lambda`, and then computes the classification loss value for the binary Gaussian kernel classification model trained using the `fitckernel` function. Set `'Verbose',0` within `fitckernel` to suppress the iterative display of diagnostic information.

```
minfn = @(z)gather(loss(fitckernel(Ztrain,Ytrain, ...
    'KernelScale',z.sigma,'Lambda',z.lambda,'Verbose',0), ...
    Ztest,Ytest));
```

Optimize the parameters `[sigma,lambda]` of the kernel classification model with respect to the classification loss by using `bayesopt`. By default, `bayesopt` displays iterative information about the optimization at the command line. For reproducibility, set the `AcquisitionFunctionName` option to `'expected-improvement-plus'`. The default acquisition function depends on run time and, therefore, can give varying results.

```
results = bayesopt(minfn,[sigma,lambda],'AcquisitionFunctionName','expected-improvement-plus')
```

```

```

Return the best feasible point in the Bayesian model `results` by using the `bestPoint` function. Use the default criterion `min-visited-upper-confidence-interval`, which determines the best feasible point as the visited point that minimizes an upper confidence interval on the objective function value.

```
zbest = bestPoint(results)
```

```
zbest=1×2 table
    sigma       lambda
    ______    __________

    1.5886    4.9128e-07
```

The table `zbest` contains the optimal estimated values for the `'KernelScale'` and `'Lambda'` name-value arguments. You can specify these values when training a new optimized kernel classifier by using

```
Mdl = fitckernel(Ztrain,Ytrain,'KernelScale',zbest.sigma,'Lambda',zbest.lambda)
```

For tall arrays, the optimization procedure can take a long time. If the data set is too large to run the optimization procedure, you can try to optimize the parameters by using only partial data. Use the `datasample` function and specify `'Replace','false'` to sample data without replacement.

Statistics and Machine Learning with Big Data Using Tall Arrays

This example shows how to perform statistical analysis and machine learning on out-of-memory data with MATLAB® and Statistics and Machine Learning Toolbox™.

Tall arrays and tables are designed for working with out-of-memory data. This type of data consists of a very large number of rows (observations) compared to a smaller number of columns (variables). Instead of writing specialized code that takes into account the huge size of the data, such as with MapReduce, you can use tall arrays to work with large data sets in a manner similar to in-memory MATLAB arrays. The fundamental difference is that tall arrays typically remain unevaluated until you request that the calculations be performed.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)
```

This example works with a subset of data on a single computer to develop a linear regression model, and then it scales up to analyze all of the data set. You can scale up this analysis even further to:

- Work with data that cannot be read into memory
- Work with data distributed across clusters using MATLAB Parallel Server™
- Integrate with big data systems like Hadoop® and Spark®

Introduction to Machine Learning with Tall Arrays

Several unsupervised and supervised learning algorithms in Statistics and Machine Learning Toolbox are available to work with tall arrays to perform data mining and predictive modeling with out-of-memory data. These algorithms are appropriate for out-of-memory data and can include slight variations from the in-memory algorithms. Capabilities include:

- k-Means clustering
- Linear regression
- Generalized linear regression
- Logistic regression
- Discriminant analysis

The machine learning workflow for out-of-memory data in MATLAB is similar to in-memory data:

1. Preprocess
2. Explore
3. Develop model
4. Validate model
5. Scale up to larger data

This example follows a similar structure in developing a predictive model for airline delays. The data includes a large file of airline flight information from 1987 through 2008. The example goal is to predict the departure delay based on a number of variables.

Details on the fundamental aspects of tall arrays are included in the example “Analyze Big Data in MATLAB Using Tall Arrays”. This example extends the analysis to include machine learning with tall arrays.

Create Tall Table of Airline Data

A datastore is a repository for collections of data that are too large to fit in memory. You can create a datastore from a number of different file formats as the first step to create a tall array from an external data source.

Create a datastore for the sample file `airlinesmall.csv`. Select the variables of interest, treat `'NA'` values as missing data, and generate a preview table of the data.

```
ds = datastore(fullfile(matlabroot,'toolbox','matlab','demos','airlinesmall.csv'));
ds.SelectedVariableNames = {'Year','Month','DayofMonth','DayOfWeek',...
    'DepTime','ArrDelay','DepDelay','Distance'};
ds.TreatAsMissing = 'NA';
pre = preview(ds)
```

```
pre=8×8 table
    Year    Month    DayofMonth    DayOfWeek    DepTime    ArrDelay    DepDelay    Distance
    ____    _____    __________    _________    _______    ________    ________    ________

    1987     10          21            3          642          8          12          308
    1987     10          26            1         1021          8           1          296
    1987     10          23            5         2055         21          20          480
    1987     10          23            5         1332         13          12          296
    1987     10          22            4          629          4          -1          373
    1987     10          28            3         1446         59          63          308
    1987     10           8            4          928          3          -2          447
    1987     10          10            6          859         11          -1          954
```

Create a tall table backed by the datastore to facilitate working with the data. The underlying data type of a tall array depends on the type of datastore. In this case, the datastore is tabular text and returns a tall table. The display includes a preview of the data, with indication that the size is unknown.

```
tt = tall(ds)
```

```
tt =

  Mx8 tall table

```

Preprocess Data

This example aims to explore the time of day and day of week in more detail. Convert the day of week to categorical data with labels and determine the hour of day from the numeric departure time variable.

```
tt.DayOfWeek = categorical(tt.DayOfWeek,1:7,{'Sun','Mon','Tues',...
    'Wed','Thu','Fri','Sat'});
tt.Hr = discretize(tt.DepTime,0:100:2400,0:23)
```

```
tt =

```

Include only years after 2000 and ignore rows with missing data. Identify data of interest by logical condition.

```
idx = tt.Year >= 2000 & ...
    ~any(ismissing(tt),2);
tt = tt(idx,:);
```

Explore Data by Group

A number of exploratory functions are available for tall arrays. For example, the `grpstats` function calculates grouped statistics of tall arrays. Explore the data by determining the centrality and spread of the data with summary statistics grouped by day of week. Also, explore the correlation between the departure delay and arrival delay.

```
g = grpstats(tt(:,{'ArrDelay','DepDelay','DayOfWeek'}),'DayOfWeek',...
    {'mean','std','skewness','kurtosis'})
```

```
g =

  Mx11 tall table

    GroupLabel    DayOfWeek    GroupCount    mean_ArrDelay    std_ArrDelay    skewness_ArrDelay
    __________    _________    __________    _____________    ____________    _________________

        ?             ?            ?              ?               ?                 ?
        ?             ?            ?              ?               ?                 ?
        ?             ?            ?              ?               ?                 ?
        :             :            :              :               :                 :
        :             :            :              :               :                 :
```

```
C = corr(tt.DepDelay,tt.ArrDelay)
```

```
C =

  MxNx... tall array

    :    :    :
```

These commands produce more tall arrays. The commands are not executed until you explicitly gather the results into the workspace. The `gather` command triggers execution and attempts to minimize the number of passes required through the data to perform the calculations. `gather` requires that the resulting variables fit into memory.

```
[statsByDay,C] = gather(g,C)
```

```
Evaluating tall expression using the Local MATLAB Session:

C = 0.8966
```

The variables containing the results are now in-memory variables in the Workspace. Based on these calculations, variation occurs in the data and there is correlation between the delays that you can investigate further.

Explore the effect of day of week and hour of day and gain additional statistical information such as the standard error of the mean and the 95% confidence interval for the mean. You can pass the entire tall table and specify which variables to perform calculations on.

```
byDayHr = grpstats(tt,{'Hr','DayOfWeek'},...
    {'mean','sem','meanci'},'DataVar','DepDelay');
byDayHr = gather(byDayHr);
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 3.2 sec
Evaluation completed in 4 sec
```

Due to the data partitioning of the tall array, the output might be unordered. Rearrange the data in memory for further exploration.

```
x = unstack(byDayHr(:,{'Hr','DayOfWeek','mean_DepDelay'}),...
    'mean_DepDelay','DayOfWeek');
x = sortrows(x)
```

```

Visualize Data in Tall Arrays

Currently, you can visualize tall array data using `histogram`, `histogram2`, `binScatterPlot`, and `ksdensity`. The visualizations all trigger execution, similar to calling the `gather` function.

Use `binScatterPlot` to examine the relationship between the `Hr` and `DepDelay` variables.

```
binScatterPlot(tt.Hr,tt.DepDelay,'Gamma',0.25)
```

```

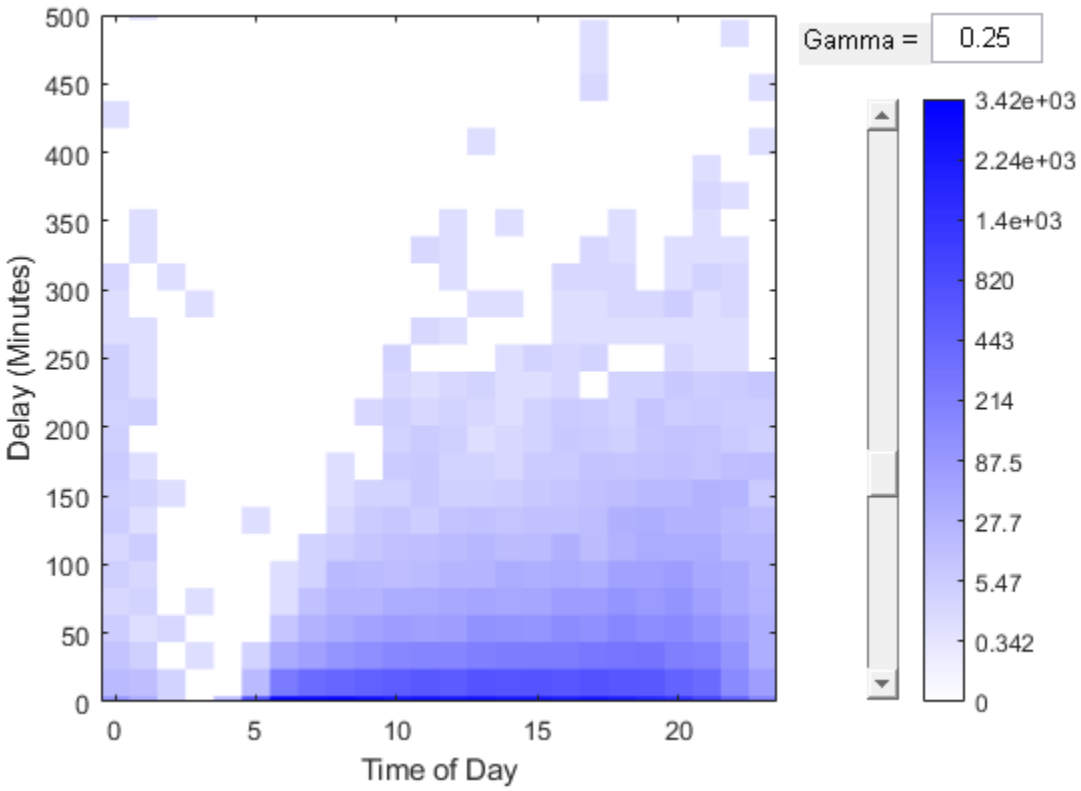
ylim([0 500])
xlabel('Time of Day')
ylabel('Delay (Minutes)')
```



As noted in the output display, the visualizations often take two passes through the data: one to perform the binning, and one to perform the binned calculation and produce the visualization.

Split Data into Training and Validation Sets

To develop a machine learning model, it is useful to reserve part of the data to train and develop the model and another part of the data to test the model. A number of ways exist for you to split the data into training and validation sets.

Use `datasample` to obtain a random sampling of the data. Then use `cvpartition` to partition the data into test and training sets. To obtain nonstratified partitions, set a uniform grouping variable by multiplying the data samples by zero.

For reproducibility, set the seed of the random number generator using `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs”.

```
tallrng('default')
data = datasample(tt,25000,'Replace',false);
groups = 0*data.DepDelay;
y = cvpartition(groups,'HoldOut',1/3);
dataTrain = data(training(y),:);
dataTest = data(test(y),:);
```

Fit Supervised Learning Model

Build a model to predict the departure delay based on several variables. The linear regression model function `fitlm` behaves similarly to the in-memory function. However, calculations with tall arrays result in a `CompactLinearModel`, which is more efficient for large data sets. Model fitting triggers execution because it is an iterative process.

```
model = fitlm(dataTrain,'ResponseVar','DepDelay')
```

```
Evaluating tall expression using the Local MATLAB Session:

Number of observations: 16667, Error degrees of freedom: 16653
Root Mean Squared Error: 12.4
R-squared: 0.834,  Adjusted R-Squared: 0.833
F-statistic vs. constant model: 6.41e+03, p-value = 0
```

Predict and Validate the Model

The display indicates fit information, as well as coefficients and associated coefficient statistics.

The `model` variable contains information about the fitted model as properties, which you can access using dot notation. Alternatively, double click the variable in the Workspace to explore the properties interactively.

```
model.Rsquared
```

```
ans = struct with fields:
    Ordinary: 0.8335
    Adjusted: 0.8334
```

Predict new values based on the model, calculate the residuals, and visualize using a histogram. The `predict` function predicts new values for both tall and in-memory data.

```
pred = predict(model,dataTest);
err = pred - dataTest.DepDelay;
figure
histogram(err,'BinLimits',[-100 100],'Normalization','pdf')
```

```
Evaluating tall expression using the Local MATLAB Session:

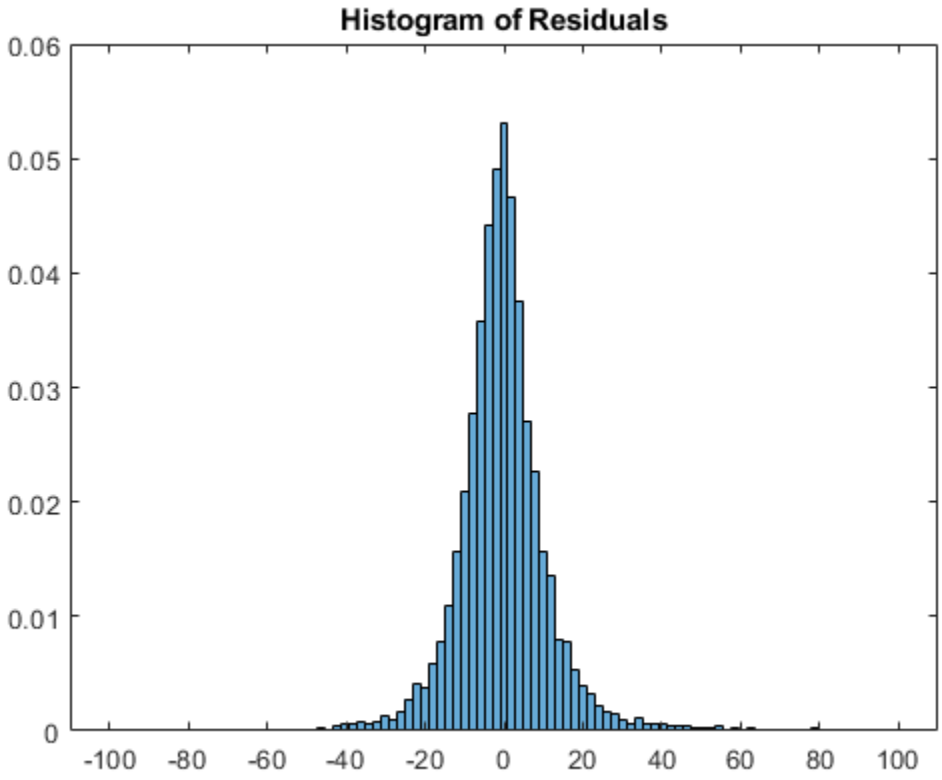
- Pass 2 of 2: Completed in 1.9 sec
Evaluation completed in 5.6 sec
```

```
title('Histogram of Residuals')
```



Assess and Adjust Model

Looking at the output p-values in the display, some variables might be unnecessary in the model. You can reduce the complexity of the model by removing these variables.

Examine the significance of the variables in the model more closely using `anova`.

```
a = anova(model)
```

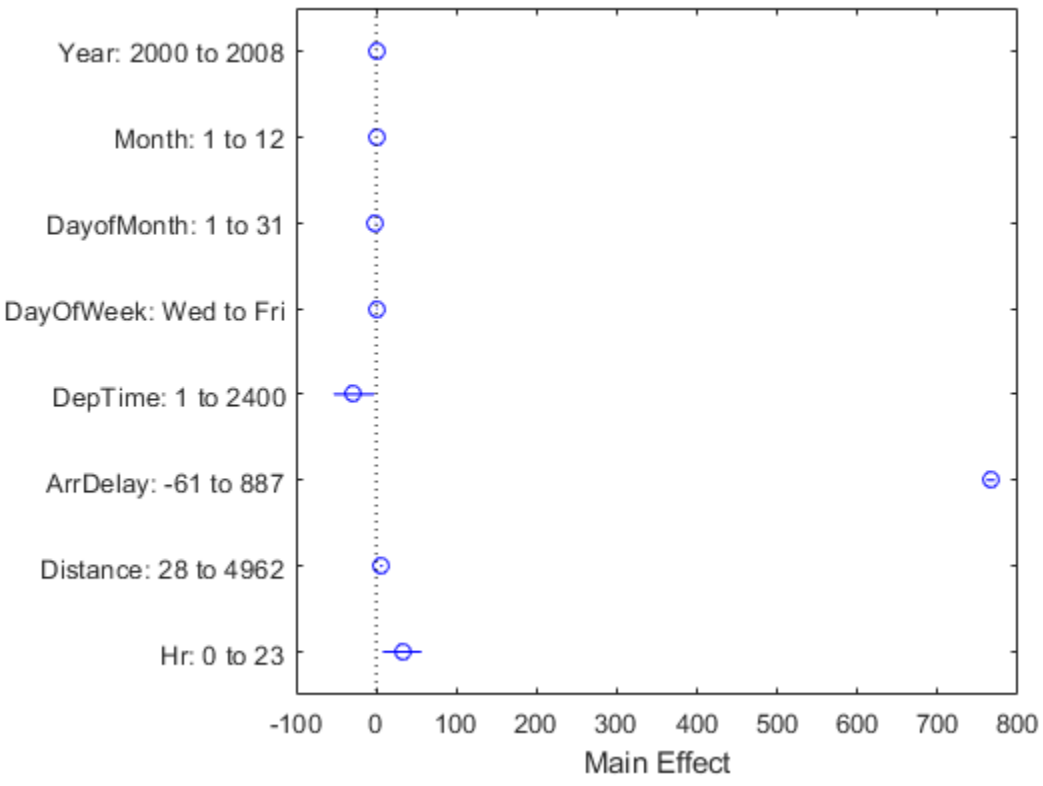
```
a=9×5 table
                SumSq        DF        MeanSq          F          pValue
              _________    _____    ___________    _______    ___________
```

```
Year              26.88        1         26.88    0.17533       0.67543
Month             175.84       1         175.84    1.1469       0.28421
DayofMonth        114.6        1         114.6    0.74749       0.38729
DayOfWeek         3691.4       6         615.23    4.0129     0.00050851
DepTime           705.42       1         705.42    4.6012       0.031964
ArrDelay       1.2112e+07      1      1.2112e+07    79004              0
Distance          8920.9       1         8920.9    58.188     2.5106e-14
Hr                1047.5       1         1047.5    6.8321      0.0089613
Error          2.5531e+06   16653        153.31
```

Based on the p-values, the variables `Year`, `Month`, and `DayOfMonth` are not significant to this model, so you can remove them without negatively affecting the model quality.

To explore these model parameters further, use interactive visualizations such as `plotSlice`, `plotInteractions`, and `plotEffects`. For example, use `plotEffects` to examine the estimated effect that each predictor variable has on the departure delay.

```
plotEffects(model)
```



Based on these calculations, `ArrDelay` is the main effect in the model (it is highly correlated to `DepDelay`). The other effects are observable, but have much less impact. In addition, `Hr` was determined from `DepTime`, so only one of these variables is necessary to the model.

Reduce the number of variables to exclude all date components, and then fit a new model.

```
model2 = fitlm(dataTrain,'DepDelay ~ DepTime + ArrDelay + Distance')
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 2.4 sec
Evaluation completed in 2.5 sec

model2 =
Compact linear regression model:
    DepDelay ~ 1 + DepTime + ArrDelay + Distance

Root Mean Squared Error: 12.4
R-squared: 0.833,  Adjusted R-Squared: 0.833
F-statistic vs. constant model: 2.77e+04, p-value = 0
```

Model Development

Even with the model simplified, it can be useful to further adjust the relationships between the variables and include specific interactions. To experiment further, repeat this workflow with smaller tall arrays. For performance while tuning the model, you can consider working with a small extraction of in-memory data before scaling up to the entire tall array.

In this example, you can use functionality like stepwise regression, which is suited for iterative, in-memory model development. After tuning the model, you can scale up to use tall arrays.

Gather a subset of the data into the workspace and use `stepwiselm` to iteratively develop the model in memory.

```
subset = gather(dataTest);
```

```
Evaluating tall expression using the Local MATLAB Session:

    ArrDelay:Distance         -2.4743e-05    4.6508e-06     -5.3203    1.0496e-07

Number of observations: 16667, Error degrees of freedom: 16643
Root Mean Squared Error: 12.3
R-squared: 0.837,  Adjusted R-Squared: 0.836
F-statistic vs. constant model: 3.7e+03, p-value = 0
```

You can repeat this process to continue to adjust the linear model. However, in this case, you should explore different types of regression that might be more appropriate for this data. For example, if you do not want to include the arrival delay, then this type of linear model is no longer appropriate. See “Logistic Regression with Tall Arrays” on page 30-2 for more information.

Scale to Spark

A key capability of tall arrays in MATLAB and Statistics and Machine Learning Toolbox is the connectivity to platforms such as Hadoop and Spark. You can even compile the code and run it on Spark using MATLAB Compiler™. See “Extend Tall Arrays with Other Products” for more information about using these products:

- Database Toolbox™
- Parallel Computing Toolbox™
- MATLAB® Parallel Server™
- MATLAB Compiler™

Parallel Statistics

Quick Start Parallel Computing for Statistics and Machine Learning Toolbox

Note To use parallel computing as described in this chapter, you must have a Parallel Computing Toolbox license.

What Is Parallel Statistics Functionality?

You can use any of the Statistics and Machine Learning Toolbox functions with Parallel Computing Toolbox constructs such as `parfor` and `spmd`. However, some functions, such as those with interactive displays, can lose functionality in parallel. In particular, displays and interactive usage are not effective on workers (see “Vocabulary for Parallel Computation” on page 31-8).

Additionally, the following functions are enhanced to use parallel computing internally. These functions use `parfor` internally to parallelize calculations.

- `bayesopt`
- `bootci`
- `bootstrp`
- `candexch`
- `compare` of `LinearMixedModel`
- `cordexch`
- `crossval`

- `fitrsvm`
- `fitrkernel`
- `fitckernel`

This chapter gives the simplest way to use these enhanced functions in parallel. For more advanced topics, including the issues of reproducibility and nested `parfor` loops, see the other sections in this chapter.

For information on parallel statistical computing at the command line, enter

```
help parallelstats
```

How To Compute in Parallel

To have a function compute in parallel:

1. “Set Up a Parallel Environment” on page 31-4
2. “Set the UseParallel Option to true” on page 31-4
3. “Call the Function Using the Options Structure” on page 31-4

Set Up a Parallel Environment

To run a statistical computation in parallel, first set up a parallel environment.

Note Setting up a parallel environment can take several seconds.

For a multicore machine, enter the following at the MATLAB command line:

```
parpool(n)
```

n is the number of workers you want to use.

You can also run parallel code in MATLAB Online™. For details, see “Use Parallel Computing Toolbox with Cloud Center Cluster in MATLAB Online” (Parallel Computing Toolbox).

Set the UseParallel Option to true

Create an options structure with the `statset` function. To run in parallel, set the `UseParallel` option to `true`:

```
paroptions = statset('UseParallel',true);
```

Call the Function Using the Options Structure

Call your function with syntax that uses the options structure. For example:

```
% Run crossval in parallel
cvMse = crossval('mse',x,y,'predfun',regf,'Options',paroptions);

% Run bootstrp in parallel
```

```
sts = bootstrp(100,@(x)[mean(x) std(x)],y,'Options',paroptions);

% Run TreeBagger in parallel
b = TreeBagger(50,meas,spec,'OOBPred','on','Options',paroptions);
```

For more complete examples of parallel statistical functions, see “Use Parallel Processing for Regression TreeBagger Workflow” on page 31-6, “Implement Jackknife Using Parallel Computing” on page 31-17, “Implement Cross-Validation Using Parallel Computing” on page 31-18, and “Implement Bootstrap Using Parallel Computing” on page 31-20.

After you have finished computing in parallel, close the parallel environment:

```
delete mypool
```

Tip To save time, keep the pool open if you expect to compute in parallel again soon.

Use Parallel Processing for Regression TreeBagger Workflow

This example shows you how to:

- Use an ensemble of bagged regression trees to estimate feature importance.
- Improve computation speed by using parallel computing.

The sample data is a database of 1985 car imports with 205 observations, 25 predictors, and 1 response, which is insurance risk rating, or "symboling." The first 15 variables are numeric and the last 10 are categorical. The symboling index takes integer values from -3 to 3.

Load the sample data and separate it into predictor and response arrays.

```
load imports-85;
Y = X(:,1);
X = X(:,2:end);
```

Set up the parallel environment to use the default number of workers. The computer that created this example has six cores.

```
mypool = parpool
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

mypool =

 ProcessPool with properties:

            Connected: true
           NumWorkers: 6
              Cluster: local
        AttachedFiles: {}
    AutoAddClientPath: true
          IdleTimeout: 30 minutes (30 minutes remaining)
          SpmdEnabled: true
```

Set the options to use parallel processing.

```
paroptions = statset('UseParallel',true);
```

Estimate feature importance using leaf size `1` and `5000` trees in parallel. Time the function for comparison purposes.

```
tic
b = TreeBagger(5000,X,Y,'Method','r','OOBVarImp','on', ...
    'cat',16:25,'MinLeafSize',1,'Options',paroptions);
toc
```

```
Elapsed time is 9.873065 seconds.
```

Perform the same computation in serial for timing comparison.

```
tic
b = TreeBagger(5000,X,Y,'Method','r','OOBVarImp','on', ...
    'cat',16:25,'MinLeafSize',1);
toc
```

```
Elapsed time is 28.092654 seconds.
```

The results show that computing in parallel takes a fraction of the time it takes to compute serially. Note that the elapsed time can vary depending on your operating system.

Concepts of Parallel Computing in Statistics and Machine Learning Toolbox

In this section...

Subtleties in Parallel Computing

There are two main subtleties in parallel computations:

- Nested parallel evaluations (see “No Nested parfor Loops” on page 31-11). Only the outermost `parfor` loop runs in parallel, the others run serially.
- Reproducible results when using random numbers (see “Reproducibility in Parallel Statistical Computations” on page 31-13). How can you get exactly the same results when repeatedly running a parallel computation that uses random numbers?

Vocabulary for Parallel Computation

- worker — An independent MATLAB session that runs code distributed by the client.
- client — The MATLAB session with which you interact, and that distributes jobs to workers.
- `parfor` — A Parallel Computing Toolbox function that distributes independent code segments to workers (see “Working with parfor” on page 31-11).
- random stream — A pseudorandom number generator, and the sequence of values it generates. MATLAB implements random streams with the `RandStream` class.
- reproducible computation — A computation that can be exactly replicated, even in the presence of random numbers (see “Reproducibility in Parallel Statistical Computations” on page 31-13).

When to Run Statistical Functions in Parallel

In this section...

Why Run in Parallel?

The main reason to run statistical computations in parallel is to gain speed, meaning to reduce the execution time of your program or functions. “Factors Affecting Speed” on page 31-9 discusses the main items affecting the speed of programs or functions. “Factors Affecting Results” on page 31-9 discusses details that can cause a parallel run to give different results than a serial run.

Note Some Statistics and Machine Learning Toolbox functions have built-in parallel computing capabilities. See Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 31-2. You can also use any Statistics and Machine Learning Toolbox functions with Parallel Computing Toolbox functions such as `parfor` loops. To decide when to call functions in parallel, consider the factors affecting speed and results.

Factors Affecting Speed

Some factors that can affect the speed of execution of parallel processing are:

- Parallel environment setup. It takes time to run `parpool` to begin computing in parallel. If your computation is fast, the setup time can exceed any time saved by computing in parallel.
- Parallel overhead. There is overhead in communication and coordination when running in parallel. If function evaluations are fast, this overhead could be an appreciable part of the total computation time. Thus, solving a problem in parallel can be slower than solving the problem serially. For an example, see Improving Optimization Performance with Parallel Computing in MATLAB Digest, March 2009.
- No nested `parfor` loops. This is described in “Working with parfor” on page 31-11. `parfor` does not work in parallel when called from within another `parfor` loop. If you have programmed your custom functions to take advantage of parallel processing, the limitation of no nested `parfor` loops can cause a parallel function to run slower than expected.
- When executing serially, `parfor` loops run slightly slower than `for` loops.
- Passing parameters. Parameters are automatically passed to worker sessions during the execution of parallel computations. If there are many parameters, or they take a large amount of memory, passing parameters can slow the execution of your computation.
- Contention for resources: network and computing. If the pool of workers has low bandwidth or high latency, parallel computation can be slow.

Factors Affecting Results

Some factors can affect results when using parallel processing. You might need to adjust your code to run in parallel, for example, you need independent loops and the workers must be able to access the variables. Some important factors are:

- Persistent or global variables. If any functions use persistent or global variables, these variables can take different values on different worker processors. The body of a `parfor` loop cannot contain global or persistent variable declarations.
- Accessing external files. The order of computations is not guaranteed during parallel processing, so external files can be accessed in unpredictable order, leading to unpredictable results. Furthermore, if multiple processors try to read an external file simultaneously, the file can become locked, leading to a read error, and halting function execution.
- Noncomputational functions, such as `input`, `plot`, and `keyboard`, can behave badly when used in your custom functions. Do not use these functions in a `parfor` loop, because they can cause a worker to become nonresponsive, since it is waiting for input.
- `parfor` does not allow `break` or `return` statements.
- The random numbers you use can affect the results of your computations. See “Reproducibility in Parallel Statistical Computations” on page 31-13.

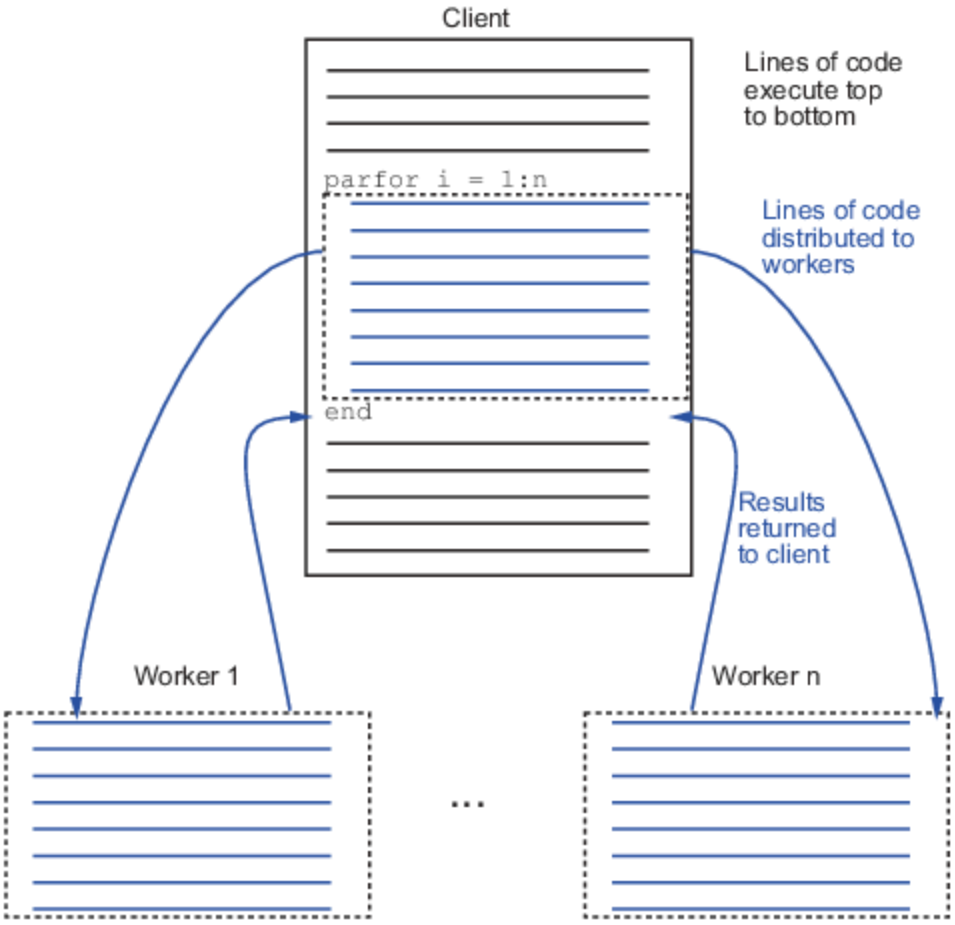
For advice on converting for loops to use `parfor`, see “Parallel for-Loops (parfor)” (Parallel Computing Toolbox).

Working with parfor

In this section...

How Statistical Functions Use parfor

`parfor` is a Parallel Computing Toolbox function similar to a `for` loop. Parallel statistical functions call `parfor` internally. `parfor` distributes computations to worker processors.



Characteristics of parfor

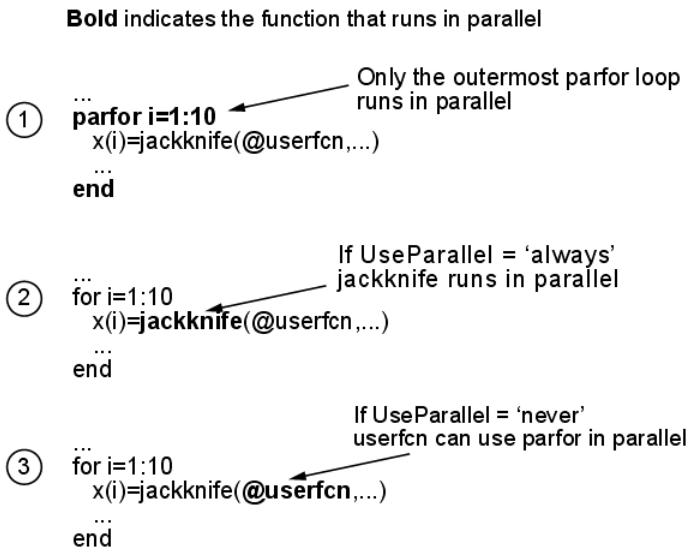
You might need to adjust your code to run in parallel, for example, you need independent loops and the workers must be able to access the variables. For advice on using `parfor`, see “Parallel for-Loops (parfor)” (Parallel Computing Toolbox).

No Nested parfor Loops

`parfor` does not work in parallel when called from within another `parfor` loop, or from an `spmd` block. Parallelization occurs only at the outermost level.

Suppose, for example, you want to apply `jackknife` to your function `userfcn`, which calls `parfor`, and you want to call `jackknife` in a loop. The following figure shows three cases:

1. The outermost loop is `parfor`. Only that loop runs in parallel.
2. The outermost `parfor` loop is in `jackknife`. Only `jackknife` runs in parallel.
3. The outermost `parfor` loop is in `userfcn`. `userfcn` uses `parfor` in parallel.



When `parfor` Runs in Parallel

For help converting nested loops to use `parfor`, see "Convert for-Loops Into parfor-Loops" (Parallel Computing Toolbox).

See also Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 31-2.

Reproducibility in Parallel Statistical Computations

In this section...

Issues and Considerations in Reproducing Parallel Computations

A reproducible computation is one that gives the same results every time it runs. Reproducibility is important for:

- Debugging — To correct an anomalous result, you need to reproduce the result.
- Confidence — When you can reproduce results, you can investigate and understand them.
- Modifying existing code — When you change existing code, you want to ensure that you do not break anything.

Generally, you do not need to ensure reproducibility for your computation. Often, when you want reproducibility, the simplest technique is to run in serial instead of in parallel. In serial computation you can simply call the `rng` function as follows:

```
s = rng % Obtain the current state of the random stream
% run the statistical function
rng(s) % Reset the stream to the previous state
% run the statistical function again, obtain identical results
```

This section addresses the case when your function uses random numbers, and you want reproducible results in parallel. This section also addresses the case when you want the same results in parallel as in serial.

Running Reproducible Parallel Computations

To run a Statistics and Machine Learning Toolbox function reproducibly:

1. Set the `UseSubstreams` option to `true` using `statset`.
2. Set the `Streams` option to a type that supports substreams: `'mlfg6331_64'` or `'mrg32k3a'`. For information on these streams, see `RandStream.list`.
3. To compute in parallel, set the `UseParallel` option to `true`.
4. To fit an ensemble in parallel using `fitcensemble` or `fitrensemble`, create a tree template with the `'Reproducible'` name-value pair set to `true`:

   ```
   t = templateTree('Reproducible',true);
   ens = fitcensemble(X,Y,'Method','bag','Learners',t,...
       'Options',options);
   ```
5. Call the function with the options structure.
6. To reproduce the computation, reset the stream, then call the function again.

To understand why this technique gives reproducibility, see “How Substreams Enable Reproducible Parallel Computations” on page 31-14.

For example, to use the 'mlfg6331_64' stream for reproducible computation:

1. Create an appropriate options structure:

```
s = RandStream('mlfg6331_64');
options = statset('UseParallel',true, ...
    'Streams',s,'UseSubstreams',true);
```

2. Run your parallel computation. For instructions, see Quick Start Parallel Computing for Statistics and Machine Learning Toolbox on page 31-2.
3. Reset the random stream:

```
reset(s);
```

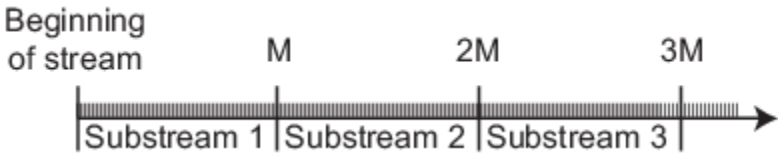
4. Rerun your parallel computation. You obtain identical results.

For examples of parallel computation run this reproducible way, see “Reproducible Parallel Bootstrap” on page 31-21 and “Train Classification Ensemble in Parallel” on page 18-109.

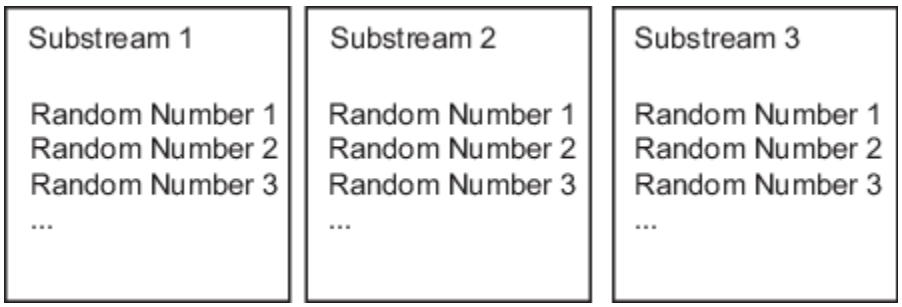
Parallel Statistical Computation Using Random Numbers

What Are Substreams?

A substream is a portion of a random stream that RandStream can access quickly. There is a number M such that for any positive integer k, RandStream can go to the kMth pseudorandom number in the stream. From that point, RandStream can generate the subsequent entries in the stream. Currently, RandStream has $M = 2^{72}$, about 5e21, or more.



The entries in different substreams have good statistical properties, similar to the properties of entries in a single stream: independence, and lack of *k*-way correlation at various lags. The substreams are so long that you can view the substreams as being independent streams, as in the following picture.



Two RandStream stream types support substreams: 'mlfg6331_64' and 'mrg32k3a'.

How Substreams Enable Reproducible Parallel Computations

When MATLAB performs computations in parallel with parfor, each worker receives loop iterations in an unpredictable order. Therefore, you cannot predict which worker gets which iteration, so cannot determine the random numbers associated with each iteration.

Substreams allow MATLAB to tie each iteration to a particular sequence of random numbers. `parfor` gives each iteration an index. The iteration uses the index as the substream number. Since the random numbers are associated with the iterations, not with the workers, the entire computation is reproducible.

To obtain reproducible results, simply reset the stream, and all the substreams generate identical random numbers when called again. This method succeeds when all the workers use the same stream, and the stream supports substreams. This concludes the discussion of how the procedure in “Running Reproducible Parallel Computations” on page 31-13 gives reproducible parallel results.

Random Numbers on the Client or Workers

A few functions generate random numbers on the client before distributing them to parallel workers. The workers do not use random numbers, so operate purely deterministically. For these functions, you can run a parallel computation reproducibly using any random stream type.

The functions that operate this way include:

- `crossval`
- `plsregress`
- `sequentialfs`

To obtain identical results, reset the random stream on the client, or the random stream you pass to the client. For example:

```
s = rng % Obtain the current state of the random stream
% run the statistical function
rng(s) % Reset the stream to the previous state
% run the statistical function again, obtain identical results
```

While this method enables you to run reproducibly in parallel, the results can differ from a serial computation. The reason for the difference is `parfor` loops run in reverse order from `for` loops. Therefore, a serial computation can generate random numbers in a different order than a parallel computation. For unequivocal reproducibility, use the technique in “Running Reproducible Parallel Computations” on page 31-13.

Distributing Streams Explicitly

For testing or comparison using particular random number algorithms, you must set the random number generators. How do you set these generators in parallel, or initialize streams on each worker in a particular way? Or you might want to run a computation using a different sequence of random numbers than any other you have run. How can you ensure the sequence you use is statistically independent?

Parallel Statistics and Machine Learning Toolbox functions allow you to set random streams on each worker explicitly. For information on *creating* multiple streams, enter `help RandStream/create` at the command line. To create four independent streams using the `'mrg32k3a'` generator:

```
s = RandStream.create('mrg32k3a','NumStreams',4,...
    'CellOutput',true);
```

Pass these streams to a statistical function using the `Streams` option. For example:

```
parpool(4) % if you have at least 4 cores
s = RandStream.create('mrg32k3a','NumStreams',4,...
```

```
    'CellOutput',true); % create 4 independent streams
paroptions = statset('UseParallel',true,...
    'Streams',s); % set the 4 different streams
x = [randn(700,1); 4 + 2*randn(300,1)];
latt = -4:0.01:12;
myfun = @(X) ksdensity(X,latt);
pdfestimate = myfun(x);
B = bootstrp(200,myfun,x,'Options',paroptions);
```

This method of distributing streams gives each worker a different stream for the computation. However, it does not allow for a reproducible computation, because the workers perform the 200 bootstraps in an unpredictable order. If you want to perform a reproducible computation, use substreams as described in “Running Reproducible Parallel Computations” on page 31-13.

If you set the `UseSubstreams` option to `true`, then set the `Streams` option to a single random stream of the type that supports substreams (`'mlfg6331_64'` or `'mrg32k3a'`). This setting gives reproducible computations.

Implement Jackknife Using Parallel Computing

This example is from the `jackknife` function reference page, but runs in parallel.

Generate a sample data of size 10000 from a normal distribution with mean 0 and standard deviation 5.

```
sigma = 5;
rng('default')
y = normrnd(0,sigma,10000,1);
```

Run `jackknife` in parallel to estimate the variance. To do this, use `statset` to create the options structure and set the `UseParallel` field to true.

```
opts = statset('UseParallel',true);
m = jackknife(@var,y,1,'Options',opts);
```

Compare the known bias formula with the jackknife bias estimate.

```
n = length(y);
bias = -sigma^2/n % Known bias formula
jbias = (n-1)*(mean(m)-var(y,1)) % jackknife bias estimate
```

```
Starting parallel pool (parpool) using the 'local' profile ...

Connected to the parallel pool (number of workers: 6).

bias =

   -0.0025

jbias =

   -0.0025
```

Compare how long it takes to compute in serial and in parallel.

```
tic;m = jackknife(@var,y,1);toc  % Serial computation
```

```
Elapsed time is 1.638026 seconds.
```

```
tic;m = jackknife(@var,y,1,'Options',opts);toc % Parallel computation
```

```
Elapsed time is 0.507961 seconds.
```

`jackknife` does not use random numbers, so gives the same results every time, whether run in parallel or serial.

Implement Cross-Validation Using Parallel Computing

In this section...

Simple Parallel Cross Validation

In this example, use `crossval` to compute a cross-validation estimate of mean-squared error for a regression model. Run the computations in parallel.

```
mypool = parpool()
Starting parpool using the 'local' profile ... connected to 2 workers.

mypool =

  Pool with properties:

    AttachedFiles: {0x1 cell}
       NumWorkers: 2
      IdleTimeout: 30
          Cluster: [1x1 parallel.cluster.Local]
     RequestQueue: [1x1 parallel.RequestQueue]
      SpmdEnabled: 1

opts = statset('UseParallel',true);

load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

    0.1028
```

This simple example is not a good candidate for parallel computation:

```
% How long to compute in serial?
tic;cvMse = crossval('mse',X,y,'Predfun',regf);toc
Elapsed time is 0.073438 seconds.

% How long to compute in parallel?
tic;cvMse = crossval('mse',X,y,'Predfun',regf,...
    'Options',opts);toc
Elapsed time is 0.289585 seconds.
```

Reproducible Parallel Cross Validation

To run `crossval` in parallel in a reproducible fashion, set the options and reset the random stream appropriately (see “Running Reproducible Parallel Computations” on page 31-13).

```
mypool = parpool()

Starting parpool using the 'local' profile ... connected to 2 workers.

mypool =

  Pool with properties:

    AttachedFiles: {0x1 cell}
       NumWorkers: 2
      IdleTimeout: 30
          Cluster: [1x1 parallel.cluster.Local]
     RequestQueue: [1x1 parallel.RequestQueue]
      SpmdEnabled: 1

s = RandStream('mlfg6331_64');
opts = statset('UseParallel',true,...
    'Streams',s,'UseSubstreams',true);

load('fisheriris');
y = meas(:,1);
X = [ones(size(y,1),1),meas(:,2:4)];
regf=@(XTRAIN,ytrain,XTEST)(XTEST*regress(ytrain,XTRAIN));

cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

    0.1020
```

Reset the stream:

```
reset(s)
cvMse = crossval('mse',X,y,'Predfun',regf,'Options',opts)

cvMse =

    0.1020
```

Implement Bootstrap Using Parallel Computing

In this section...

Bootstrap in Serial and Parallel

Here is an example timing a bootstrap in parallel versus in serial. The example generates data from a mixture of two Gaussians, constructs a nonparametric estimate of the resulting data, and uses a bootstrap to get a sense of the sampling variability.

1 Generate the data:

```
% Generate a random sample of size 1000,
% from a mixture of two Gaussian distributions
x = [randn(700,1); 4 + 2*randn(300,1)];
```

2 Construct a nonparametric estimate of the density from the data:

```
latt = -4:0.01:12;
myfun = @(X) ksdensity(X,latt);
pdfestimate = myfun(x);
```

3 Bootstrap the estimate to get a sense of its sampling variability. Run the bootstrap in serial for timing comparison.

```
tic;B = bootstrp(200,myfun,x);toc

Elapsed time is 10.878654 seconds.
```

4 Run the bootstrap in parallel for timing comparison:

```
mypool = parpool()
Starting parpool using the 'local' profile ... connected to 2 workers.

mypool =

  Pool with properties:

    AttachedFiles: {0x1 cell}
       NumWorkers: 2
      IdleTimeout: 30
          Cluster: [1x1 parallel.cluster.Local]
     RequestQueue: [1x1 parallel.RequestQueue]
      SpmdEnabled: 1

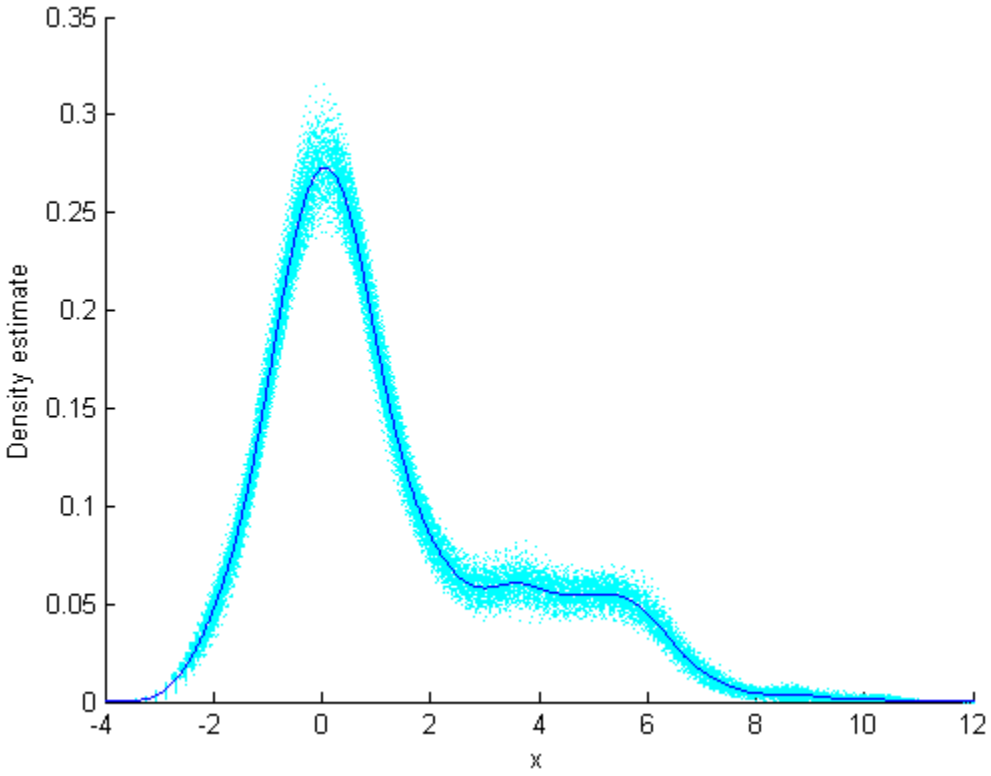
opt = statset('UseParallel',true);
tic;B = bootstrp(200,myfun,x,'Options',opt);toc

Elapsed time is 6.304077 seconds.
```

Computing in parallel is nearly twice as fast as computing in serial for this example.

Overlay the `ksdensity` density estimate with the 200 bootstrapped estimates obtained in the parallel bootstrap. You can get a sense of how to assess the accuracy of the density estimate from this plot.

```
hold on
for i=1:size(B,1),
    plot(latt,B(i,:),'c:')
end
plot(latt,pdfestimate);
xlabel('x');ylabel('Density estimate')
```



Reproducible Parallel Bootstrap

To run the example in parallel in a reproducible fashion, set the options appropriately (see “Running Reproducible Parallel Computations” on page 31-13). First set up the problem and parallel environment as in “Bootstrap in Serial and Parallel” on page 31-20. Then set the options to use substreams along with a stream that supports substreams.

```
s = RandStream('mlfg6331_64'); % has substreams
opts = statset('UseParallel',true,...
    'Streams',s,'UseSubstreams',true);
B2 = bootstrp(200,myfun,x,'Options',opts);
```

To rerun the bootstrap and get the same result:

```
reset(s) % set the stream to initial state
B3 = bootstrp(200,myfun,x,'Options',opts);
isequal(B2,B3) % check if same results
```

```
ans =
     1
```

Code Generation

Introduction to Code Generation

In this section...

MATLAB Coder generates readable and portable C and C++ code from Statistics and Machine Learning Toolbox functions that support code generation. You can integrate the generated code into your projects as source code, static libraries, or dynamic libraries. You can also use the generated code within the MATLAB environment to accelerate computationally intensive portions of your MATLAB code.

Generating C/C++ code requires MATLAB Coder and has the following limitations:

- You cannot call any function at the top level when generating code by using `codegen`. Instead, call the function within an *entry-point* function, and then generate code from the entry-point function. The entry-point function, also known as the *top-level* or *primary* function, is a function you define for code generation. All functions within the entry-point function must support code generation.
- The MATLAB Coder limitations also apply to Statistics and Machine Learning Toolbox for code generation. For details, see “MATLAB Language Features Supported for C/C++ Code Generation” (MATLAB Coder).
- Code generation in Statistics and Machine Learning Toolbox does not support sparse matrices.
- For the code generation usage notes and limitations for each function, see the Code Generation section on the function reference page.

For a list of Statistics and Machine Learning Toolbox functions that support code generation, see Function List (C/C++ Code Generation).

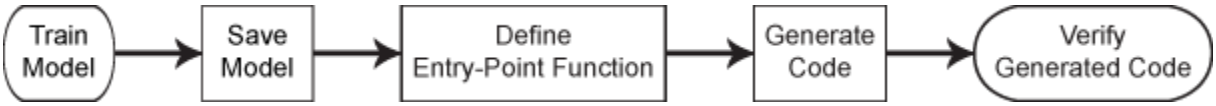
Code Generation Workflows

You can generate C/C++ code for the Statistics and Machine Learning Toolbox functions in several ways.

- General code generation workflow for functions that are not the object functions of machine learning models

  
  Define an *entry-point* function that calls the function that supports code generation, generate C/C++ code for the entry-point function by using `codegen`, and then verify the generated code. The entry-point function, also known as the *top-level* or *primary* function, is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function. All functions within the entry-point function must support code generation.

  For details, see “General Code Generation Workflow” on page 32-5.
- Code generation workflow for the object function of a machine learning model (including `predict`, `random`, `knnsearch`, `rangesearch`, and incremental learning object functions)



Save a trained model by using `saveLearnerForCoder`, and define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the object function. Then generate code for the entry-point function by using `codegen`, and verify the generated code. The input arguments of the entry-point function cannot be classification or regression model objects. Therefore, you need to work around this limitation by using `saveLearnerForCoder` and `loadLearnerForCoder`.

You can also generate single-precision C/C++ code for the prediction of machine learning models for classification and regression. For single-precision code generation, specify the name-value pair argument `'Datatype','single'` as an additional input to the `loadLearnerForCoder` function.

For details, see these examples

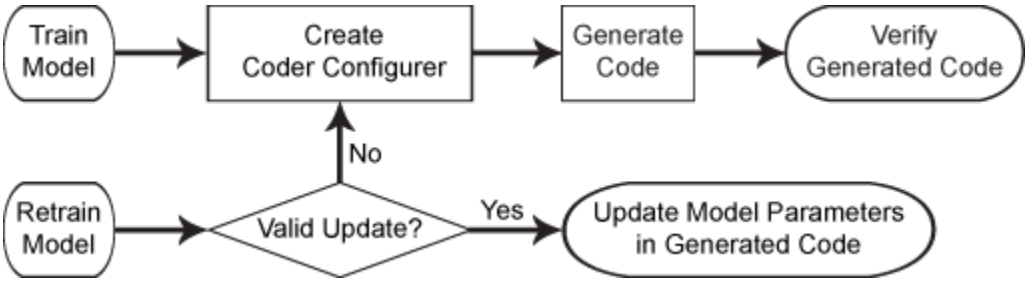
- “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9
- “Code Generation for Incremental Learning” on page 32-13
- “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22
- “Code Generation for Nearest Neighbor Searcher” on page 32-19
- “Code Generation and Classification Learner App” on page 32-31
- “Specify Variable-Size Arguments for Code Generation” on page 32-45

You can also generate fixed-point C/C++ code for the prediction of a support vector machine (SVM) model, a decision tree model, and an ensemble of decision trees for classification and regression. This type of code generation requires Fixed-Point Designer™.

Fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. You can also optimize the fixed-point data types before generating code.

For details, see “Fixed-Point Code Generation for Prediction of SVM” on page 32-87.

- Code generation workflow for the `predict` and `update` functions of a tree model, an SVM model, a linear model, or a multiclass error-correcting output codes (ECOC) classification model using SVM or linear binary learners



Create a coder configurer by using `learnerCoderConfigurer`, generate code by using `generateCode`, and then verify the generated code. You can configure code generation options and specify the coder attributes of the model parameters using object properties. After you retrain the model with new data or settings, you can update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code.

For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 32-80.

Code Generation Applications

To integrate the prediction of a machine learning model into Simulink®, use a MATLAB Function block or the Simulink blocks in the Statistics and Machine Learning Toolbox library. For details, see these examples:

- “Predict Class Labels Using MATLAB Function Block” on page 32-40
- “Predict Responses Using RegressionSVM Predict Block” on page 32-115
- “Predict Class Labels Using ClassificationSVM Predict Block” on page 32-111

Code generation for the Statistics and Machine Learning Toolbox functions also works with other toolboxes such as System object™ and Stateflow®, as described in these examples:

- “System Objects for Classification and Code Generation” on page 32-54
- “Predict Class Labels Using Stateflow” on page 32-62

For more applications of code generation, see these examples:

- “Code Generation for Image Classification” on page 32-103
- “Human Activity Recognition Simulink Model for Smartphone Deployment” on page 32-66

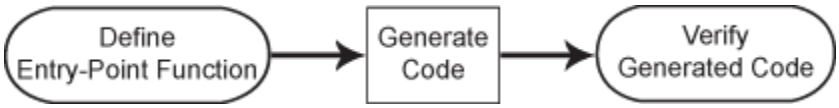
General Code Generation Workflow

The general code generation workflow for the Statistics and Machine Learning Toolbox functions that are not the object functions of machine learning models is the same as the workflow described in MATLAB Coder. For details, see “Get Started with MATLAB Coder” (MATLAB Coder). To learn how to generate code for the object functions of machine learning models, see “Introduction to Code Generation” on page 32-2.

This example briefly explains the general code generation workflow as summarized in this flow chart:



Define Entry-Point Function

An *entry-point* function, also known as the *top-level* or *primary* function, is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and generate C/C++ code for the entry-point function by using `codegen`. All functions within the entry-point function must support code generation.

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

For example, to generate code that estimates the interquartile range of a data set using `iqr`, define this function.

```
function r = iqrCodeGen(x) %#codegen
%IQRCODEGEN Estimate interquartile range
%   iqrCodeGen returns the interquartile range of the data x,
%   a single- or double-precision vector.
r = iqr(x);
end
```

You can allow for optional input arguments by specifying `varargin` as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder) and “Specify Variable-Size Arguments for Code Generation” on page 32-45.

Generate Code

Set Up Compiler

To generate C/C++ code, you must have access to a compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. To view and change the default C compiler, enter:

```
mex -setup
```

For more details, see “Change Default Compiler”.

Generate Code Using codegen

After setting up your compiler, generate code for the entry-point function by using `codegen` or the MATLAB Coder app. To learn how to generate code using the MATLAB Coder app, see “Generate MEX Functions by Using the MATLAB Coder App” (MATLAB Coder).

To generate code at the command line, use `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify the data types and sizes of all inputs of the entry-point function when you call `codegen` by using the `-args` option.

- To specify the data type and exact input array size, pass a MATLAB expression that represents the set of values with a certain data type and array size. For example, to specify that the generated code from `iqrCodeGen.m` must accept a double-precision numeric column vector with 100 elements, enter:

  ```
  testX = randn(100,1);
  codegen iqrCodeGen -args {testX} -report
  ```

  The `-report` flag generates a code generation report. See “Code Generation Reports” (MATLAB Coder).
- To specify that at least one of the dimensions can have any length, use the `-args` option with `coder.typeof` as follows.

  ```
  -args {coder.typeof(example_value, size_vector, variable_dims)}
  ```

  The values of *`example_value`*, *`size_vector`*, and *`variable_dims`* specify the properties of the input array that the generated code can accept.

  - An input array has the same data type as the example values in *`example_value`*.
  - *`size_vector`* is the array size of an input array if the corresponding *`variable_dims`* value is `false`.
  - *`size_vector`* is the upper bound of the array size if the corresponding *`variable_dims`* value is `true`.
  - *`variable_dims`* specifies whether each dimension of the array has a variable size or a fixed size. A value of `true` (logical 1) means that the corresponding dimension has a variable size; a value of `false` (logical 0) means that the corresponding dimension has a fixed size.

  Specifying a variable-size input is convenient when you have data with an unknown number of observations at compile time. For example, to specify that the generated code from `iqrCodeGen.m` can accept a double-precision numeric column vector of any length, enter:

  ```
  testX = coder.typeof(0,[Inf,1],[1,0]);
  codegen iqrCodeGen -args {testX} -report
  ```

  `0` for the *`example_value`* value implies that the data type is `double` because `double` is the default numeric data type of MATLAB. `[Inf,1]` for the *`size_vector`* value and `[1,0]` for the *`variable_dims`* value imply that the size of the first dimension is variable and unbounded, and the size of the second dimension is fixed to be 1.

Note Specification of variable size inputs can affect performance. For details, see “Control Memory Allocation for Variable-Size Arrays” (MATLAB Coder).

- To specify a character array, such as supported name-value pair arguments, specify the character array as a constant using `coder.Constant`. For example, suppose that `'Name'` is a valid name-value pair argument for `iqrCodeGen.m`, and the corresponding value `value` is numeric. Then enter:

  ```
  codegen iqrCodeGen -args {testX,coder.Constant('Name'),value} -report
  ```

For more details, see “Generate C Code at the Command Line” (MATLAB Coder) and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

Build Type

MATLAB Coder can generate code for these types:

- MEX (MATLAB Executable) function
- Standalone C/C++ code
- Standalone C/C++ code compiled to a static library
- Standalone C/C++ code compiled to a dynamically linked library
- Standalone C/C++ code compiled to an executable

You can specify the build type using the `-config` option of `codegen`. For more details on setting code generation options, see “Configure Build Settings” (MATLAB Coder).

By default, `codegen` generates a MEX function. A MEX function is a C/C++ program that is executable from MATLAB. You can use a MEX function to accelerate MATLAB algorithms and to test the generated code for functionality and run-time issues. For details, see “MATLAB Algorithm Acceleration” (MATLAB Coder) and “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Code Generation Report

You can use the `-report` flag to produce a code generation report. This report helps you debug code generation issues and view the generated C/C++ code. For details, see “Code Generation Reports” (MATLAB Coder).

Verify Generated Code

Test a MEX function to verify that the generated code provides the same functionality as the original MATLAB code. To perform this test, run the MEX function using the same inputs that you used to run the original MATLAB code, and then compare the results. Running the MEX function in MATLAB before generating standalone code also enables you to detect and fix run-time errors that are much harder to diagnose in the generated standalone code. For more details, see “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Pass some data to verify whether `iqr`, `iqrCodeGen`, and `iqrCodeGen_mex` return the same interquartile range.

```
testX = randn(100,1);
r = iqr(testX);
r_entrypoint = iqrCodeGen(testX);
r_mex = iqrCodeGen_mex(testX);
```

Compare the outputs by using `isequal`.

```
isequal(r,r_entrypoint,r_mex)
```

`isequal` returns logical 1 (true) if all the inputs are equal.

You can also verify the MEX function using a test file and `coder.runTest`. For details, see “Testing Code Generated from MATLAB Code” (MATLAB Coder).

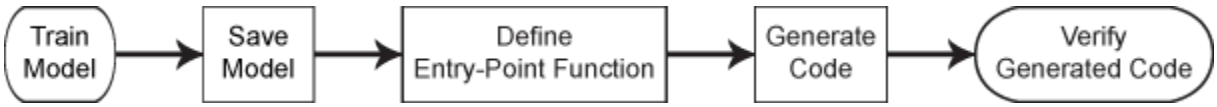
Code Generation for Prediction of Machine Learning Model at Command Line

This example shows how to generate code for the prediction of classification and regression model objects at the command line. You can also generate code using the MATLAB® Coder™ app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22 for details.

Certain classification and regression model objects have a `predict` or `random` function that supports code generation. Prediction using these object functions requires a trained classification or regression model object, but the `-args` option of `codegen` (MATLAB Coder) does not accept these objects. Work around this limitation by using `saveLearnerForCoder` and `loadLearnerForCoder` as described in this example.

This flow chart shows the code generation workflow for the object functions of classification and regression model objects.



After you train a model, save the trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the object function. Then generate code for the entry-point function by using `codegen`, and verify the generated code.

Train Classification Model

Train a classification model object equipped with a code-generation-enabled `predict` function. In this case, train a support vector machine (SVM) classification model.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
Y = species(inds);
Mdl = fitcsvm(X,Y);
```

This step can include data preprocessing, feature selection, and optimizing the model using cross-validation, for example.

Save Model Using `saveLearnerForCoder`

Save the classification model to the file `SVMModel.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'SVMModel');
```

`saveLearnerForCoder` saves the classification model to the MATLAB binary file `SVMModel.mat` as a structure array in the current folder.

Define Entry-Point Function

An *entry-point* function, also known as the *top-level* or *primary* function, is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and generate C/C++ code

for the entry-point function by using `codegen`. All functions within the entry-point function must support code generation.

Define an entry-point function that returns predicted labels for input predictor data. Within the function, load the trained classification model by using `loadLearnerForCoder`, and then pass the loaded model to `predict`. In this case, define the `predictLabelsSVM` function, which predicts labels using the SVM model `Mdl`.

```
type predictLabelsSVM.m % Display contents of predictLabelsSVM.m file
```

```
function label = predictLabelsSVM(x) %#codegen
%PREDICTLABELSSVM Label new observations using trained SVM model Mdl
%   predictLabelsSVM predicts the vector of labels label using
%   the saved SVM model Mdl and the predictor data x.
Mdl = loadLearnerForCoder('SVMModel');
label = predict(Mdl,x);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Set Up Compiler

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate Code Using `codegen`

Generate code for the entry-point function using `codegen` (MATLAB Coder). Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify the data types and sizes of all inputs of the entry-point function when you call `codegen` by using the `-args` option.

In this case, pass `X` as a value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`.

```
codegen predictLabelsSVM -args {X}
```

```
Code generation successful.
```

If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof` (MATLAB Coder). For details, see “Specify Variable-Size Arguments for Code Generation” on page 32-45 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder)

Build Type

MATLAB Coder can generate code for the following build types:

- MEX (MATLAB Executable) function
- Standalone C/C++ code
- Standalone C/C++ code compiled to a static library
- Standalone C/C++ code compiled to a dynamically linked library
- Standalone C/C++ code compiled to an executable

You can specify the build type using the `-config` option of `codegen` (MATLAB Coder). For more details on setting code generation options, see the `-config` option of `codegen` (MATLAB Coder) and "Configure Build Settings" (MATLAB Coder).

By default, `codegen` generates a MEX function. A MEX function is a C/C++ program that is executable from MATLAB. You can use a MEX function to accelerate MATLAB algorithms and to test the generated code for functionality and run-time issues. For details, see "MATLAB Algorithm Acceleration" (MATLAB Coder) and "Why Test MEX Functions in MATLAB?" (MATLAB Coder).

Code Generation Report

You can use the `-report` flag to produce a code generation report. This report helps you debug code generation issues and view the generated C/C++ code. For details, see "Code Generation Reports" (MATLAB Coder).

Verify Generated Code

Test a MEX function to verify that the generated code provides the same functionality as the original MATLAB code. To perform this test, run the MEX function using the same inputs that you used to run the original MATLAB code, and then compare the results. Running the MEX function in MATLAB before generating standalone code also enables you to detect and fix run-time errors that are much harder to diagnose in the generated standalone code. For more details, see "Why Test MEX Functions in MATLAB?" (MATLAB Coder).

Pass some predictor data to verify whether `predict`, `predictLabelsSVM`, and the MEX function return the same labels.

```
labels1 = predict(Mdl,X);
labels2 = predictLabelsSVM(X);
labels3 = predictLabelsSVM_mex(X);
```

Compare the predicted labels by using `isequal`.

```
verifyMEX = isequal(labels1,labels2,labels3)
```

```
verifyMEX = logical
   1
```

`isequal` returns logical 1 (`true`), which means all the inputs are equal. The comparison confirms that the `predict` function, `predictLabelsSVM` function, and MEX function return the same labels.

Code Generation for Incremental Learning

This example shows how to generate code that implements incremental learning for binary linear classification. To motivate its purpose, consider training a wearable device tasked to determine whether the wearer is idle or moving, based on sensory features the device reads.

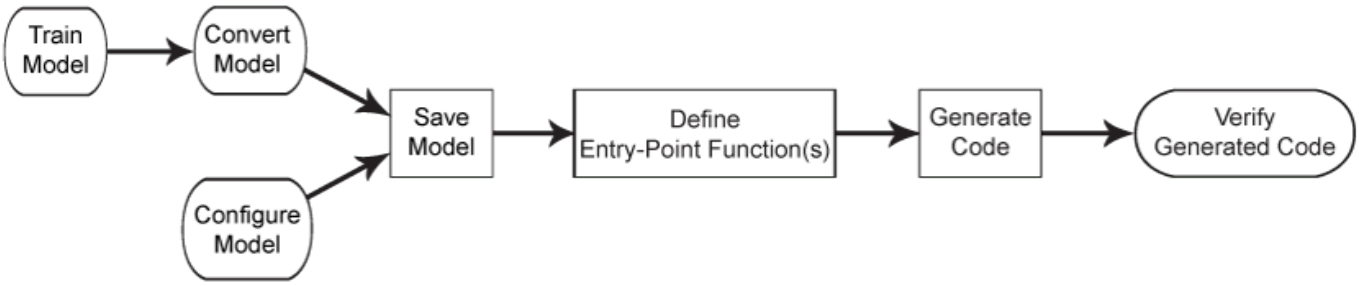
The generated code performs the following tasks, as defined in entry-point functions:

1. Load a configured incremental learning model template created at the command line.
2. Track performance metrics on the incoming batch of data from a data stream. This example tracks misclassification rate and hinge loss.
3. Update the model by fitting the incremental model to the batch of data.
4. Predicts labels for the batch of data.

This example generates code from the MATLAB® command line, but you can generate code using the MATLAB® Coder™ app instead. For more details, see “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22.

All incremental learning object functions for binary linear classification (and also linear regression) support code generation. To prepare code to generate for incremental learning, the object functions require an appropriately configured incremental learning model object, but the `-args` option of `codegen` (MATLAB Coder) does not accept these objects. To work around this limitation, use the `saveLearnerForCoder` and `loadLearnerForCoder` functions.

This flow chart shows the code generation workflows for the incremental learning object functions for linear models.



The flow chart suggests two distinct but merging workflows.

- The workflow beginning with **Train Model > Convert Model** requires data, in which case you can optionally perform feature selection or optimize the model by performing cross-validation before generating code for incremental learning.
- The workflow beginning with **Configure Model** does not require data. Instead, you must manually configure an incremental learning model object.

For details on the differences between the workflows, and for help deciding which one to use, see “Configure Incremental Learning Model” on page 26-8.

Regardless of the workflow you choose, the resulting incremental learning model must have all the following qualities:

- The `NumPredictors` property reflect the number of predictors in the predictor data during incremental learning.

- For classification, the `ClassNames` property must contain all class names expected during incremental learning.

If you choose the **Train Model > Convert Model** workflow and you fit the model to data containing all known classes, the model is configured for code generation.

After you prepare an incremental learning model, save the model object by using `saveLearnerForCoder`. Then, define an entry-point function that loads the saved model by using `loadLearnerForCoder`, and that performs incremental learning by calling the object functions. Alternatively, you can define multiple entry-point functions that perform the stages of incremental learning separately (this example uses this workflow). However, this workflow requires special treatment when an updated model object is an input to another entry-point function. For example, you write the following three entry-point functions:

- A function that accepts the current model and a batch of data, calls `updateMetrics`, and returns a model with updated performance metrics.
- A function that accepts the updated model and the batch of data, calls `fit`, and returns a model with updated coefficients.
- A function that accepts the further updated model and the batch of predictor data, calls `predict`, and returns predicted labels.

Finally, generate code for the entry-point functions by using `codegen`, and verify the generated code.

Load and Preprocess Data

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
rng(1); % For reproducibility
n = numel(actid);
p = size(feat,2);
idx = randsample(n,n);
X = feat(idx,:);
actid = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Walking, Running, or Dancing. Dichotomize the response by identifying whether the subject is idle (`actid` <= 2). Store the unique class names. Create categorical arrays.

```
classnames = categorical(["Idle" "NotIdle"]);
Y = repmat(classnames(1),n,1);
Y(actid > 2) = classnames(2);
```

Configure Incremental Learning Model

To generate code for incremental classification, you must appropriately configure a binary classification linear model for incremental learning `incrementalClassificationLinear`.

Create a binary classification (SVM) model for incremental learning. Fully configure the model for code generation by specify all expected class names and the number of predictor variables. Also, specify tracking the misclassification rate and hinge loss. For reproducibility, this example turns off observation shuffling for the scale-invariant solver.

```
metrics = ["classiferror" "hinge"];
IncrementalMdl = incrementalClassificationLinear('ClassNames',classnames,'NumPredictors',p,...
    'Shuffle',false,'Metrics',metrics)

IncrementalMdl =
  incrementalClassificationLinear

            IsWarm: 0
           Metrics: [2x2 table]
        ClassNames: [Idle    NotIdle]
    ScoreTransform: 'none'
              Beta: [60x1 double]
              Bias: 0
           Learner: 'svm'

  Properties, Methods
```

`Mdl` is an `incremenalClassificationLinear` model object configured for code generation. `Mdl` is *cold* (`Mdl.IsWarm` is `0`) because it has not processed data—the coefficients are `0`.

Alternatively, because the data is available, you can fit an SVM model to the data by using either `fitcsvm` or `fitclinear`, and then convert the resulting model to an incremental learning model by passing the model to `incrementalLearner`. The resulting model is *warm* because it has processed data—its coefficients are likely non-zero.

Save Model Using saveLearnerForCoder

Save the incremental learning model to the file `InitialMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(IncrementalMdl,'InitialMdl');
```

`saveLearnerForCoder` saves the incremental learning model to the MATLAB binary file `SVMClassIncrLearner.mat` as structure arrays in the current folder.

Define Entry-Point Functions

An *entry-point* function, also known as the *top-level* or *primary* function, is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and generate C/C++ code for the entry-point function by using `codegen`. All functions within the entry-point function must support code generation.

Define four separate entry-point functions in your current folder that perform the following actions:

- `myInitialModelIncrLearn.m` — Load the saved model by using `loadLearnerForCoder`, and return a model of the same form for code generation. This entry-point function facilitates the use of a model, returned by an entry-point function, as an input to another entry-point function.
- `myUpdateMetricsIncrLearn.m` — Measure the performance of the current model on an incoming batch of data, and store the performance metrics in the model. The function accepts the current model, and predictor and response data, and returns an updated model.
- `myFitIncrLearn.m` — Fit the current model to the incoming batch of data, and store the updated coefficients in the model. The function accepts the current model, and predictor and response data, and returns an updated model.

- `myPredictIncrLearn.m` — Predicted labels for the incoming batch of data using the current model. The function accepts the current model and predictor data, and returns labels and class scores.

For more details on generating code for multiple entry-point functions, see “Generate Code for Multiple Entry-Point Functions” (MATLAB Coder).

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

Alternatively, you can access the functions in `mlr/examples/stats/main`, where `mlr` is the value of `matlabroot`.

Display the body of each function.

```
type myInitialModelIncrLearn.m
```

```
function incrementalModel = myInitialModelIncrLearn() %#codegen
% MYINITIALMODELINCRLEARN Load and return configured linear model for
% binary classification InitialMdl
    incrementalModel = loadLearnerForCoder('InitialMdl');
end
```

```
type myUpdateMetricsIncrLearn.m
```

```
function incrementalModel = myUpdateMetricsIncrLearn(incrementalModel,X,Y) %#codegen
% MYUPDATEMETRICSINCRLEARN Measure model performance metrics on new data
      incrementalModel = updateMetrics(incrementalModel,X,Y);
end
```

```
type myFitIncrLearn.m
```

```
function incrementalModel = myFitIncrLearn(incrementalModel,X,Y) %#codegen
% MYFITINCRLEARN Fit model to new data
      incrementalModel = fit(incrementalModel,X,Y);
end
```

```
type myPredictIncrLearn.m
```

```
function [labels,scores] = myPredictIncrLearn(incrementalModel,X) %#codegen
% MYPREDICTINCRLEARN Predict labels and classification scores on new data
      [labels,scores] = predict(incrementalModel,X);
end
```

Generate Code

Set Up Compiler

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Build Type

MATLAB Coder can generate code for the following build types:

- MEX (MATLAB Executable) function
- Standalone C/C++ code
- Standalone C/C++ code compiled to a static library
- Standalone C/C++ code compiled to a dynamically linked library
- Standalone C/C++ code compiled to an executable

You can specify the build type using the `-config` option of `codegen` (MATLAB Coder). For more details on setting code generation options, see the `-config` option of `codegen` (MATLAB Coder) and "Configure Build Settings" (MATLAB Coder).

By default, `codegen` generates a MEX function. A MEX function is a C/C++ program that is executable from MATLAB. You can use a MEX function to accelerate MATLAB algorithms and to test the generated code for functionality and run-time issues. For details, see "MATLAB Algorithm Acceleration" (MATLAB Coder) and "Why Test MEX Functions in MATLAB?" (MATLAB Coder).

Generate Code Using codegen

Because C and C++ are statically typed languages, you must specify the properties of all variables in the entry-point function at compile time. Specify all of the following:

- The data types of the data inputs of the entry-point functions by using `coder.typeof` (MATLAB Coder). Also, because the number of observations can vary from batch to batch, specify that the number of observations (first dimension) has variable size. For details, see "Specify Variable-Size Arguments for Code Generation" on page 32-45 and "Specify Properties of Entry-Point Function Inputs" (MATLAB Coder).
- Because several entry-point functions accept an incremental model object as a input, and operate on it, create a representation of the model object for code generation by using `coder.OutputType` (MATLAB Coder). For more details, see "Pass an Entry-Point Function Output as an Input" (MATLAB Coder).

```
predictorData = coder.typeof(X,[],[true false]);
responseData = coder.typeof(Y,[],true);
IncrMdlOutputType = coder.OutputType('myInitialModelIncrLearn');
```

Generate code for the entry-point functions using `codegen` (MATLAB Coder). For each entry-point function argument, use the `-args` flags to specify the coder representations of the variables. Specify the output MEX function name `myIncrLearn_mex`.

```
codegen -o myIncrLearn_mex ...
myInitialModelIncrLearn ...
myUpdateMetricsIncrLearn -args {IncrMdlOutputType,predictorData,responseData} ...
myFitIncrLearn -args {IncrMdlOutputType,predictorData,responseData} ...
myPredictIncrLearn –args {IncrMdlOutputType,predictorData} -report

Code generation successful: To view the report, open('codegen\mex\myIncrLearn_mex\html\report.ml
```

For help debugging code generation issues, view the generated C/C++ code by clicking `View report` (see "Code Generation Reports" (MATLAB Coder)).

Verify Generated Code

Test the MEX function to verify that the generated code provides the same functionality as the original MATLAB code. To perform this test, run the MEX function using the same inputs that you used to run the original MATLAB code, and then compare the results. Running the MEX function in

MATLAB before generating standalone code also enables you to detect and fix run-time errors that are much harder to diagnose in the generated standalone code. For more details, see “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Perform incremental learning by using the generated MEX functions and directly by using the object functions. Specify a batch

```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
hinge = ce;
ceCG = ce;
hingeCG = ce;
IncrementalMdlCG = myIncrLearn_mex('myInitialModelIncrLearn');
scores = zeros(n,2);
scoresCG = zeros(n,2);

% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;

    IncrementalMdl = updateMetrics(IncrementalMdl,X(idx,:),Y(idx));
    ce{j,:} = IncrementalMdl.Metrics{"ClassificationError",:};
    hinge{j,:} = IncrementalMdl.Metrics{"HingeLoss",:};
    IncrementalMdlCG = myIncrLearn_mex('myUpdateMetricsIncrLearn',IncrementalMdlCG,...
        X(idx,:),Y(idx));
    ceCG{j,:} = IncrementalMdlCG.Metrics{"ClassificationError",:};
    hingeCG{j,:} = IncrementalMdlCG.Metrics{"HingeLoss",:};

    IncrementalMdl = fit(IncrementalMdl,X(idx,:),Y(idx));
    IncrementalMdlCG = myIncrLearn_mex('myFitIncrLearn',IncrementalMdlCG,X(idx,:),Y(idx));

    [~,scores(idx,:)] = predict(IncrementalMdl,X(idx,:));
    [~,scoresCG(idx,:)] = myIncrLearn_mex('myPredictIncrLearn',IncrementalMdlCG,X(idx,:));
end
```

Compare the cumulative metrics and scores for classifying `Idle` returned by the object functions and MEX functions.

```
idx = all(~isnan(ce.Variables),2);
areCEsEqual = norm(ce.Cumulative(idx) - ceCG.Cumulative(idx))

areCEsEqual = 8.9904e-18

idx = all(~isnan(hinge.Variables),2);
areHingeLossesEqual = norm(hinge.Cumulative(idx) - hingeCG.Cumulative(idx))

areHingeLossesEqual = 9.5220e-17

areScoresEqual = norm(scores(:,1) - scoresCG(:,1))

areScoresEqual = 8.7996e-13
```

The differences between the returned quantities are negligible.

Code Generation for Nearest Neighbor Searcher

The object functions `knnsearch` and `rangesearch` of the nearest neighbor searcher objects, `ExhaustiveSearcher` and `KDTreeSearcher`, support code generation. This example shows how to generate code for finding the nearest neighbor using an exhaustive searcher object at the command line. The example shows two different ways to generate code, depending on the way you use the object: load the object by using `loadLearnerForCoder` in an entry-point function, and pass a compile-time constant object to the generated code.

Train Exhaustive Nearest Neighbor Searcher

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng('default');              % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the `'Distance'` and `'P'` name-value pair arguments to use the Minkowski distance with an exponent of 1 for finding the nearest neighbor.

```
Mdl = ExhaustiveSearcher(X,'Distance','minkowski','P',1);
```

Find the index of the training data (`X`) that is the nearest neighbor of each point in the query data (`Y`).

```
Idx = knnsearch(Mdl,Y);
```

Generate Code Using `saveLearnerForCoder` and `loadLearnerForCoder`

Generate code that loads an exhaustive searcher, takes query data as an input argument, and then finds the nearest neighbor.

Save the exhaustive searcher to a file using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'searcherModel')
```

`saveLearnerForCoder` saves the model to the MATLAB binary file `searcherModel.mat` as a structure array in the current folder.

Define the entry-point function `myknnsearch1` that takes query data as an input argument. Within the function, load the searcher object by using `loadLearnerForCoder`, and then pass the loaded model to `knnsearch`.

```
type myknnsearch1.m % Display contents of myknnsearch1.m file
```

```
function idx = myknnsearch1(Y) %#codegen
Mdl = loadLearnerForCoder('searcherModel');
idx = knnsearch(Mdl,Y);
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function files, `myknnsearch1.m`, `myknnsearch2.m`, and `myknnsearch3.m`.

Generate code for `myknnsearch1` by using `codegen` (MATLAB Coder). Specify the data type and dimension of the input argument by using `coder.typeof` (MATLAB Coder) so that the generated code accepts a variable-size array.

```
codegen myknnsearch1 -args {coder.typeof(Y,[Inf,4],[1,0])}
```

```
Code generation successful.
```

For a more detailed code generation example that uses `saveLearnerForCoder` and `loadLearnerForCoder`, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9. For more details about specifying variable-size arguments, see “Specify Variable-Size Arguments for Code Generation” on page 32-45.

Pass the query data (`Y`) to verify that `myknnsearch1` and the MEX file return the same indices.

```
myIdx1 = myknnsearch1(Y);
myIdx1_mex = myknnsearch1_mex(Y);
```

Compare `myIdx1` and `myIdx1_mex` by using `isequal`.

```
verifyMEX1 = isequal(Idx,myIdx1,myIdx1_mex)
```

```
verifyMEX1 = logical
   1
```

`isequal` returns logical 1 (`true`) if all the inputs are equal. This comparison confirms that `myknnsearch1` and the MEX file return the same results.

Generate Code with Constant Folded Model Object

Nearest neighbor searcher objects can be an input argument of a function you define for code generation. The `-args` option of `codegen` (MATLAB Coder) accept a compile-time constant searcher object.

Define the entry-point function `myknnsearch2` that takes both an exhaustive searcher model and query data as input arguments instead of loading the model in the function.

```
type myknnsearch2.m % Display contents of myknnsearch2.m file
```

```
function idx = myknnsearch2(Mdl,Y) %#codegen
idx = knnsearch(Mdl,Y);
end
```

To generate code that takes the model object as well as the query data, designate the model object as a compile-time constant by using `coder.Constant` (MATLAB Coder) and include the constant folded model object in the `-args` value of `codegen`.

```
codegen myknnsearch2 -args {coder.Constant(Mdl),coder.typeof(Y,[Inf,4],[1,0])}
```

```
Code generation successful.
```

The code generation workflow with a constant folded model object follows general code generation workflow. For details, see “General Code Generation Workflow” on page 32-5.

Verify that `myknnsearch2` and the MEX file return the same results.

```
myIdx2 = myknnsearch2(Mdl,Y);
myIdx2_mex = myknnsearch2_mex(Mdl,Y);
verifyMEX2 = isequal(Idx,myIdx2,myIdx2_mex)

verifyMEX2 = logical
   1
```

Generate Code with Name-Value Pair Arguments

Define the entry-point function `myknnsearch3` that takes a model object, query data, and name-value pair arguments. You can allow for optional name-value arguments by specifying varargin as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```
type myknnsearch3.m % Display contents of myknnsearch3.m file

function idx = myknnsearch3(Mdl,Y,varargin) %#codegen
idx = knnsearch(Mdl,Y,varargin{:});
end
```

To generate code that allows a user-defined exponent for the Minkowski distance, include `{coder.Constant('P'),0}` in the `-args` value of `codegen`. Use `coder.Constant` (MATLAB Coder) because the name of a name-value pair argument must be a compile-time constant.

```
codegen myknnsearch3 -args {coder.Constant(Mdl),coder.typeof(Y,[Inf,4],[1,0]),coder.Constant('P'

Code generation successful.
```

Verify that `myknnsearch3` and the MEX file return the same results.

```
newIdx = knnsearch(Mdl,Y,'P',2);
myIdx3 = myknnsearch3(Mdl,Y,'P',2);
myIdx3_mex = myknnsearch3_mex(Mdl,Y,'P',2);
verifyMEX3 = isequal(newIdx,myIdx3,myIdx3_mex)

verifyMEX3 = logical
   1
```

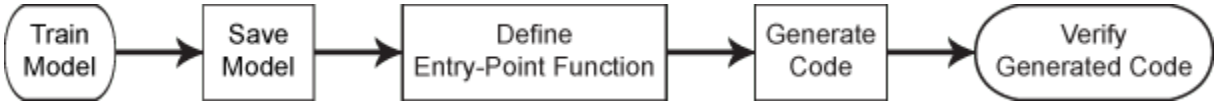
Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App

This example shows how to generate C/C++ code for the prediction of classification and regression model objects by using the MATLAB® Coder™ app. You can also generate code at the command line using `codegen` (MATLAB Coder). See “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9 for details.

Certain classification and regression model objects have a `predict` or `random` function that supports code generation. Prediction using these object functions requires a trained classification or regression model object, but an entry-point function for code generation cannot have these objects as input variables. Work around this limitation by using `saveLearnerForCoder` and `loadLearnerForCoder` as described in this example.

This flow chart shows the code generation workflow for the object functions of classification and regression model objects.



In this example, you train a classification ensemble model using *k*-nearest-neighbor weak learners and save the trained model by using `saveLearnerForCoder`. Then, define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the object function. Write a script to test the entry-point function. Finally, generate code by using the MATLAB Coder app and verify the generated code.

Train Classification Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a classification ensemble model with *k*-nearest-neighbor weak learners by using the random subspace method. For details of classifications that use a random subspace ensemble, see “Random Subspace Classification” on page 18-104.

```
rng('default')  % For reproducibility
learner = templateKNN('NumNeighbors',2);
Mdl = fitcensemble(X,Y,'Method','Subspace','NPredToSample',5, ...
    'Learners',learner,'NumLearningCycles',13);
```

Save Model Using `saveLearnerForCoder`

Save the trained ensemble model to a file named `knnEnsemble.mat` in your current folder.

```
saveLearnerForCoder(Mdl,'knnEnsemble')
```

`saveLearnerForCoder` makes the full classification model `Mdl` compact, and then saves it to the MATLAB binary file `knnEnsemble.mat` as a structure array in the current folder.

Define Entry-Point Function

An *entry-point* function, also known as the *top-level* or *primary* function, is a function you define for code generation. You must define an entry-point function that calls code-generation-enabled functions

and generate C/C++ code from the entry-point function. All functions within the entry-point function must support code generation.

In a new file in your current folder, define an entry-point function named `myknnEnsemblePredict` that does the following:

- Accept input data (`X`), the file name of the saved model (`fileName`), and valid name-value pair arguments of the `predict` function (`varargin`).
- Load a trained ensemble model by using `loadLearnerForCoder.`
- Predict labels and corresponding scores from the loaded model.

You can allow for optional name-value arguments by specifying varargin as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```
type myknnEnsemblePredict.m % Display the contents of myknnEnsemblePredict.m file.
```

```
function [label,score] = myknnEnsemblePredict(X,fileName,varargin) %#codegen
CompactMdl = loadLearnerForCoder(fileName);
[label,score] = predict(CompactMdl,X,varargin{:});
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation. See “Check Code with the Code Analyzer” (MATLAB Coder).

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB, then MATLAB opens the example folder. This folder includes the entry-point function file (`myknnEnsemblePredict.m`) and the test file (`test_myknnEnsemblePredict.m`, described later on).

Set Up Compiler

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Create Test File

Write a test script that calls the `myknnEnsemblePredict` function. In the test script, specify the input arguments and name-value pair arguments that you use in the generated code. You use this test script to define input types automatically when generating code using the MATLAB Coder app.

In this example, create the `test_myknnEnsemblePredict.m` file in your current folder, as shown.

```
type test_myknnEnsemblePredict.m % Display the contents of test_myknnEnsemblePredict.m file.
```

```
%% Load Sample data
load ionosphere

%% Test myknnEnsemblePredict
[label,score] = myknnEnsemblePredict(X,'knnEnsemble','Learners',1:13);
```

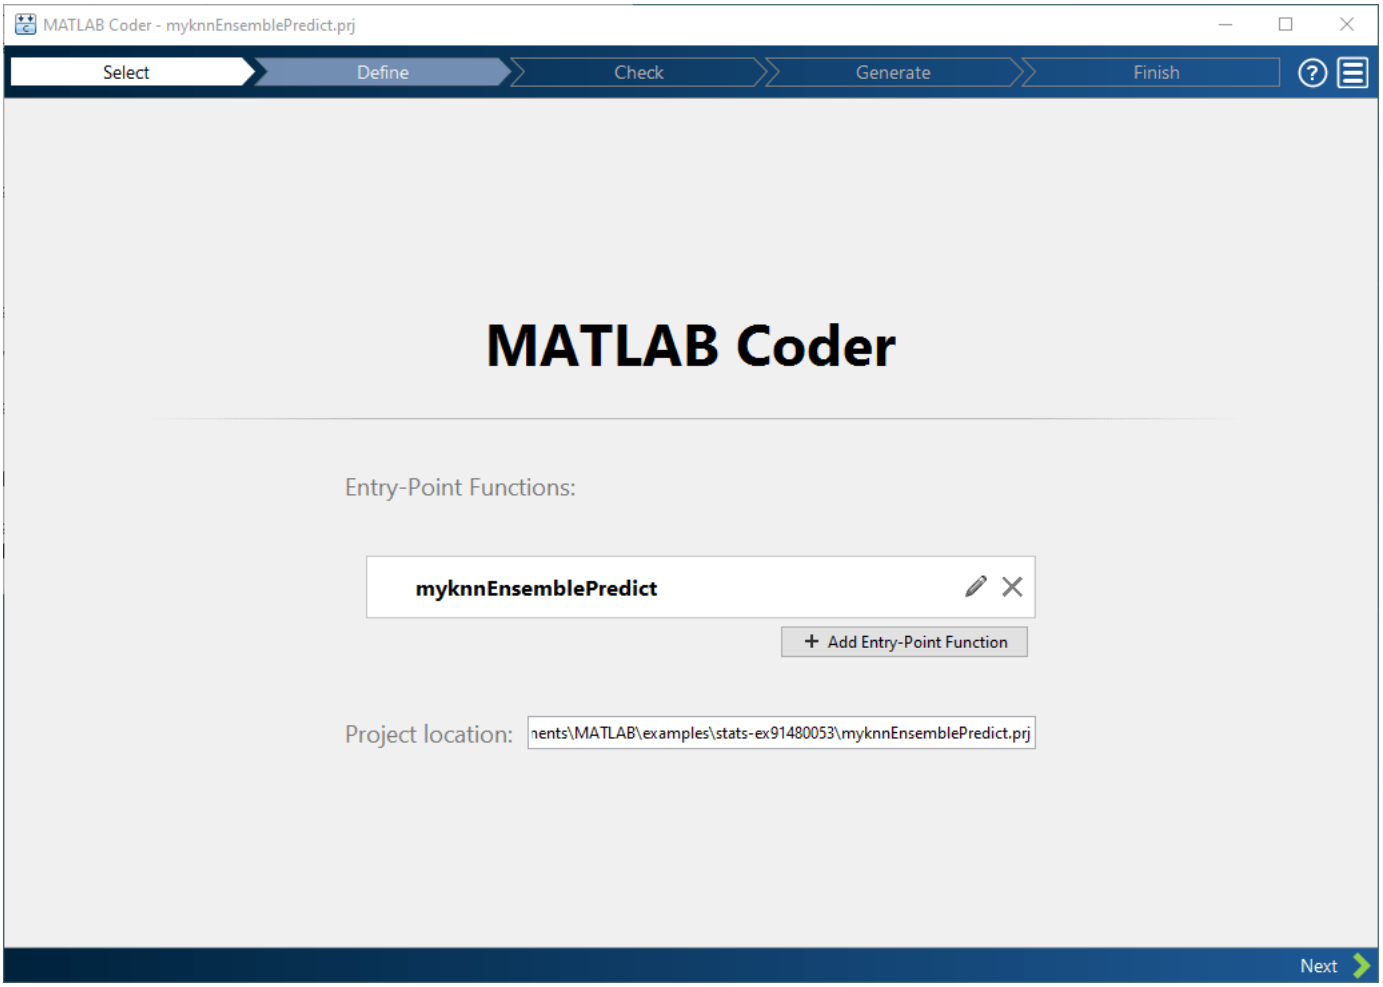
For details, see “Automatically Define Input Types by Using the App” (MATLAB Coder).

Generate Code Using MATLAB Coder App

The MATLAB Coder app generates C or C++ code from MATLAB code. The workflow-based user interface steps you through the code generation process. The following steps describe a brief workflow of the MATLAB Coder App. For more details, see MATLAB Coder (MATLAB Coder) and “Generate C Code by Using the MATLAB Coder App” (MATLAB Coder).

1. Open the MATLAB Coder App and Select the Entry-Point Function File.

On the **Apps** tab, in the **Apps** section, click the **Show more** arrow to open the apps gallery. Under **Code Generation**, click **MATLAB Coder**. The app opens the **Select Source Files** page. Enter or select the name of the entry-point function, `myknnEnsemblePredict`.

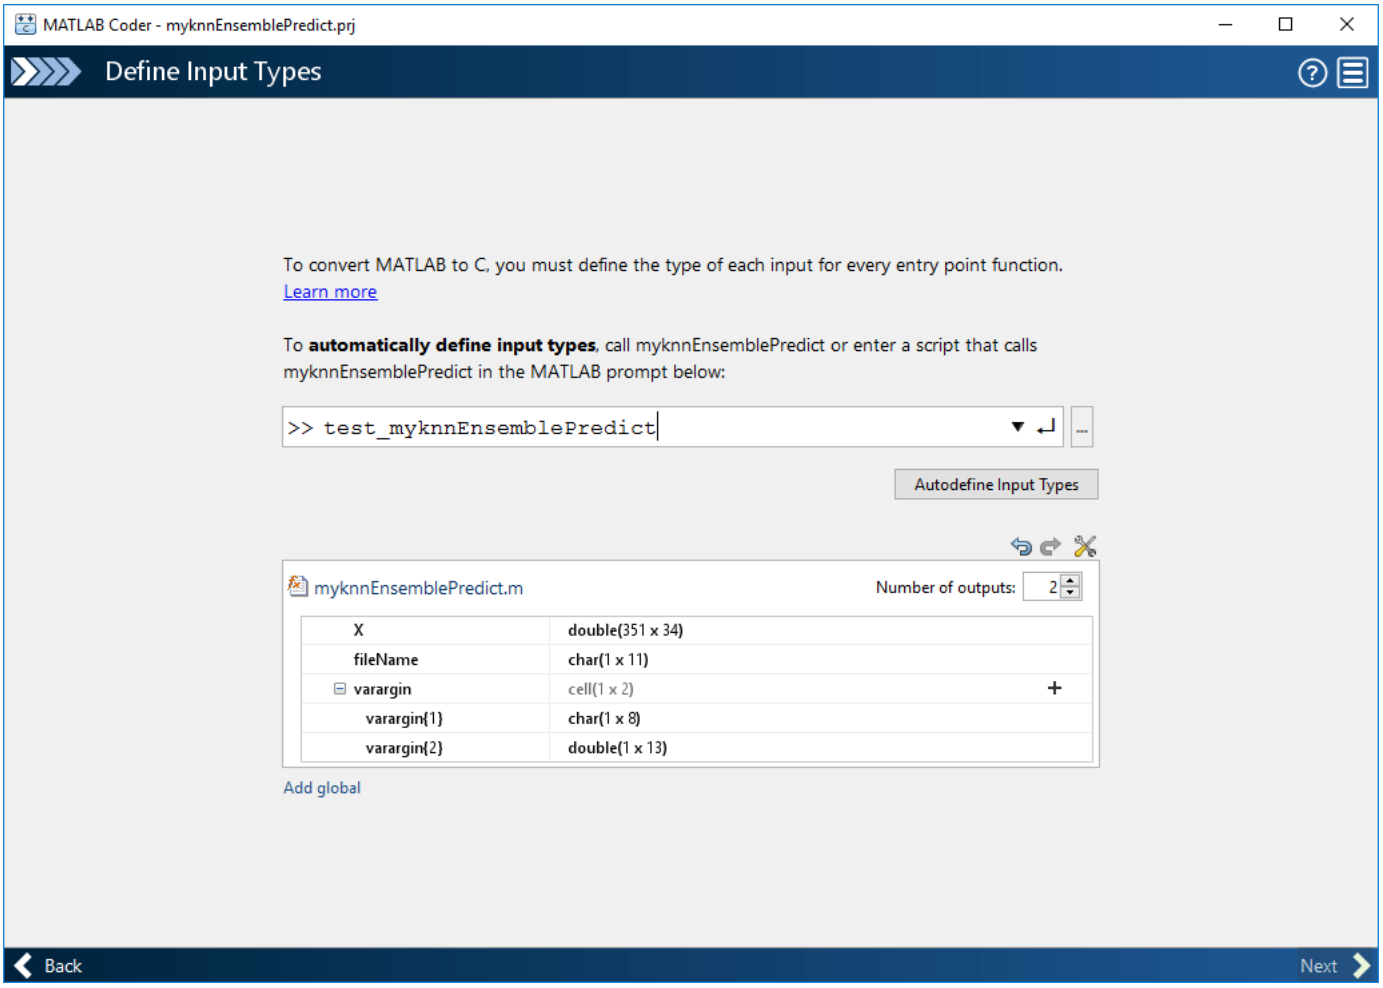


Click **Next** to go to the **Define Input Types** page.

2. Define Input Types

Because C uses static typing, MATLAB Coder must determine the properties of all variables in the MATLAB files at compile time. Therefore, you need to specify the properties of the entry-point function inputs.

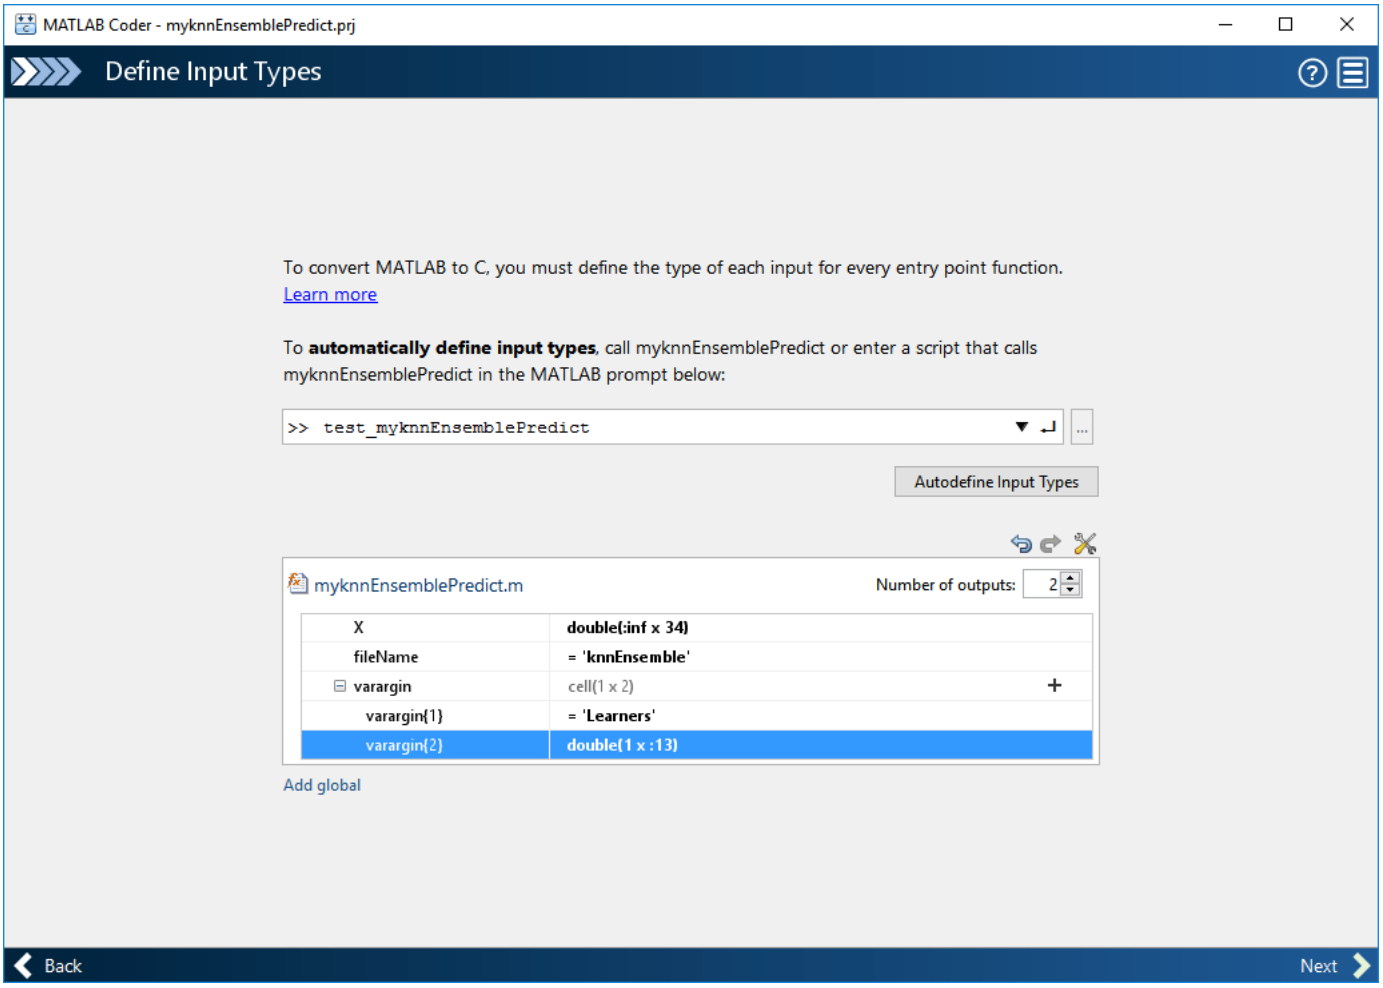
Enter or select the test script `test_myknnEnsemblePredict` and click **Autodefine Input Types**.



The MATLAB Coder app recognizes input types of the `myknnEnsemblePredict` function based on the test script.

Modify the input types:

- `X` — The app infers that input `X` is `double(351x34)`. The number of predictors must be fixed to be the same as the number of predictors in the trained model. However, you can have a different number of observations for prediction. If the number of observations is unknown, change `double(351x34)` to `double(:351x34)` or `double(:infx34)`. The setting `double(:351x34)` allows the number of observations up to 351, and the setting `double(:infx34)` allows an unbounded number of observations. In this example, specify `double(:infx34)` by clicking `351` and selecting `:inf`.
- `fileName` — Click **`char`**, select **Define Constant**, and type the file name with single quotes, `'knnEnsemble'`.
- `varargin{1}` — Names in name-value pair arguments must be compile-time constants. Click **`char`**, select **Define Constant**, and type `'Learners'`.
- `varargin{2}` — To allow user-defined indices up to 13 weak learners in the generated code, change `double(1x13)` to `double(1x:13)`.

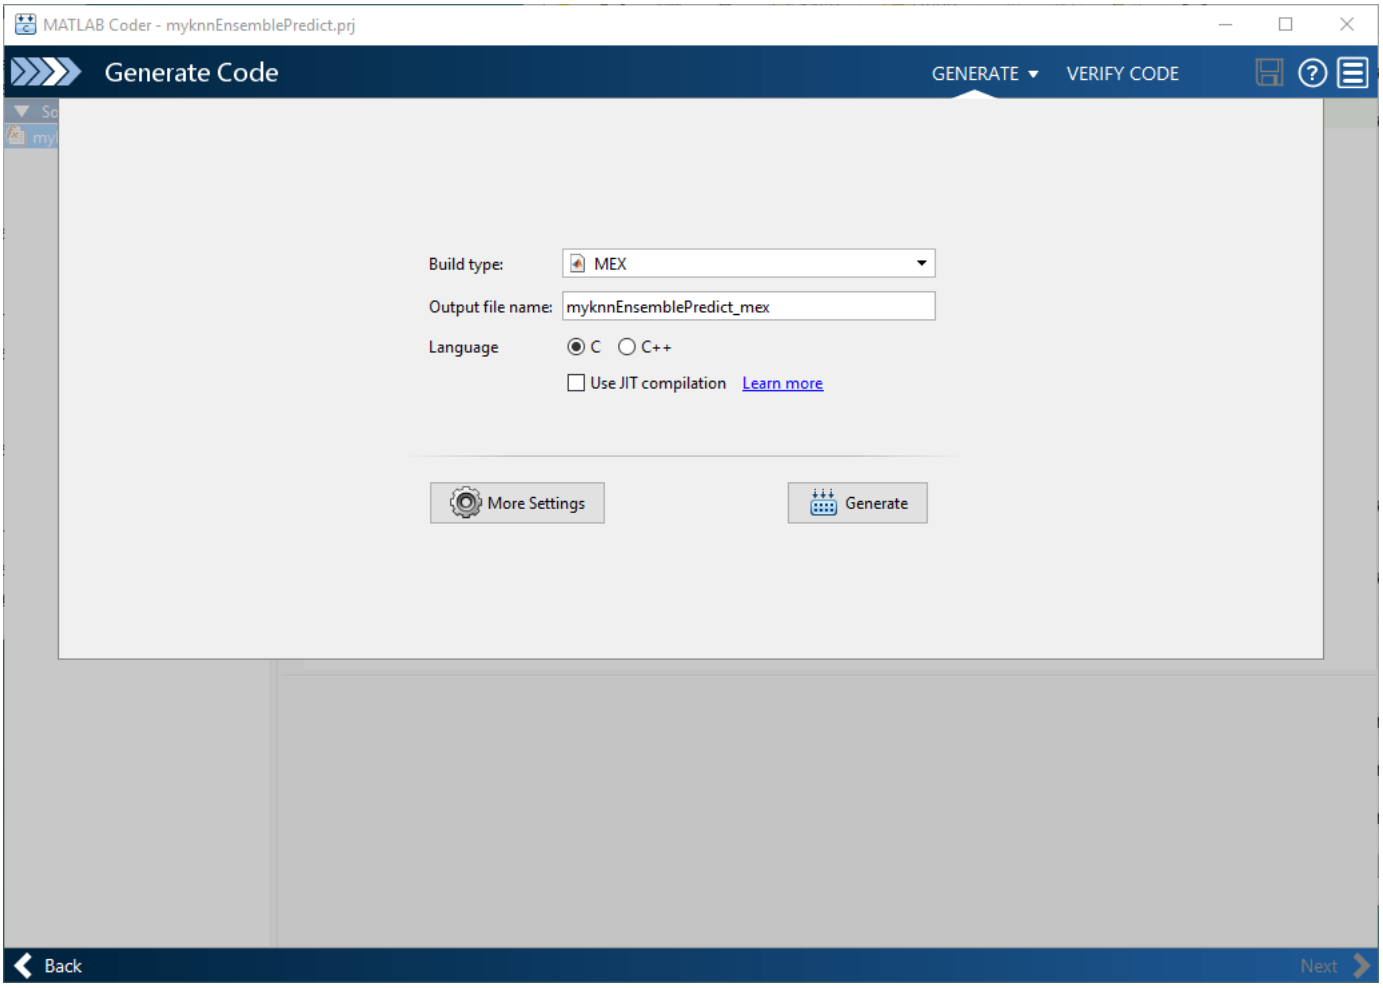


Click **Next** to go to the **Check for Run-Time Issues** page. This optional step generates a MEX file, runs the MEX function, and reports issues. Click **Next** to go to the **Generate Code** page.

3. Generate C Code

Set **Build type** to MEX and click **Generate**. The app generates a MEX function, `myknnEnsemblePredict_mex`. A MEX function is a C/C++ program that is executable from MATLAB. You can use a MEX function to accelerate MATLAB algorithms and to test the generated code for functionality and run-time issues. For details, see “MATLAB Algorithm Acceleration” (MATLAB Coder) and “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

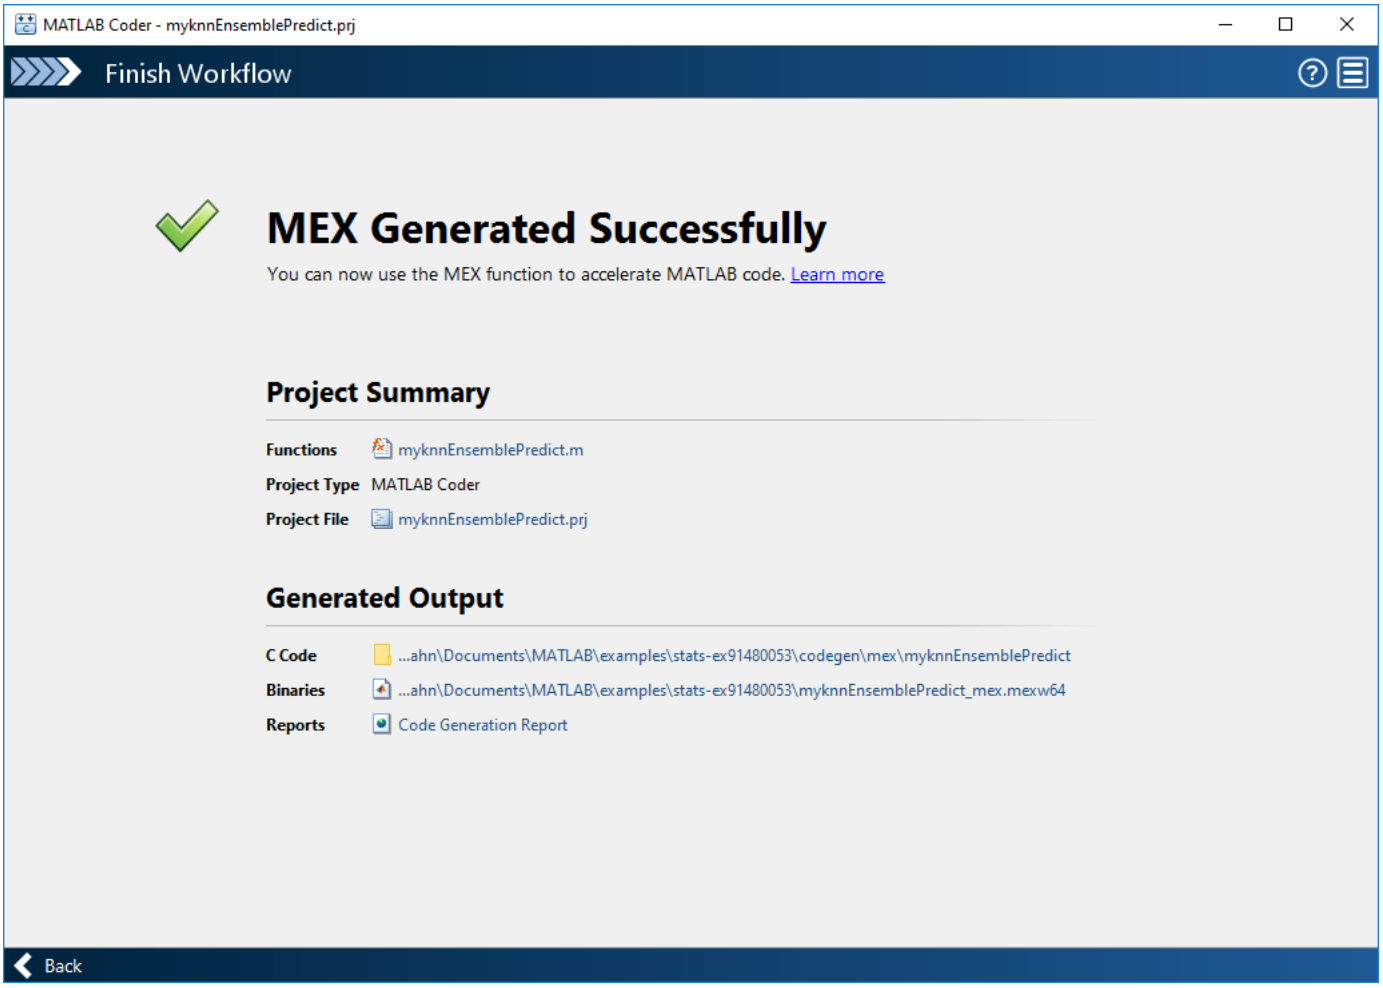
Depending on the specified build type, MATLAB Coder generates a MEX function or standalone C/C++ code compiled to a static library, dynamic linked library, or executable. For details on setting a build type, see “Configure Build Settings” (MATLAB Coder).



Click **Next** to go to the **Finish Workflow** page.

4. Review the Finish Workflow Page

The **Finish Workflow** page indicates that code generation succeeded. This page also provides a project summary and links to generated output.



Generate Code Using Script

You can convert a MATLAB Coder project to the equivalent script of MATLAB commands after you define input types. Then you run the script to generate code. For details, see “Convert MATLAB Coder Project to MATLAB Script” (MATLAB Coder).

On the MATLAB Coder app toolbar, click the **Open action menu** button: 

Select **Convert to script**, and then click **Save**. The app creates the file `myknnEnsemblePredict_script.m`, which reproduces the project in a configuration object and runs the `codegen` (MATLAB Coder) function.

Display the contents of the file `myknnEnsemblePredict_script.m`.

```
type myknnEnsemblePredict_script.m
```

```
% MYKNNENSEMBLEPREDICT_SCRIPT   Generate MEX-function myknnEnsemblePredict_mex
%  from myknnEnsemblePredict.
%
% Script generated from project 'myknnEnsemblePredict.prj' on 17-Nov-2017.
%
```

```
% See also CODER, CODER.CONFIG, CODER.TYPEOF, CODEGEN.

%% Create configuration object of class 'coder.MexCodeConfig'.
cfg = coder.config('mex');
cfg.GenerateReport = true;
cfg.ReportPotentialDifferences = false;

%% Define argument types for entry-point 'myknnEnsemblePredict'.
ARGS = cell(1,1);
ARGS{1} = cell(4,1);
ARGS{1}{1} = coder.typeof(0,[Inf  34],[1 0]);
ARGS{1}{2} = coder.Constant('knnEnsemble');
ARGS{1}{3} = coder.Constant('Learners');
ARGS{1}{4} = coder.typeof(0,[1 13],[0 1]);

%% Invoke MATLAB Coder.
codegen -config cfg myknnEnsemblePredict -args ARGS{1} -nargout 2
```

Run the script.

```
myknnEnsemblePredict_script
```

```
Code generation successful: To view the report, open('codegen\mex\myknnEnsemblePredict\html\repo
```

Verify Generated Code

Test a MEX function to verify that the generated code provides the same functionality as the original MATLAB code. To perform this test, run the MEX function using the same inputs that you used to run the original MATLAB code, and then compare the results. Running the MEX function in MATLAB before generating standalone code also enables you to detect and fix run-time errors that are much harder to diagnose in the generated standalone code. For more details, see “Why Test MEX Functions in MATLAB?” (MATLAB Coder).

Pass some predictor data to verify that `myknnEnsemblePredict` and the MEX function return the same results.

```
[label1,score1] = predict(Mdl,X,'Learners',1:10);
[label2,score2] = myknnEnsemblePredict(X,'knnEnsemble','Learners',1:10);
[label3,score3] = myknnEnsemblePredict_mex(X,'knnEnsemble','Learners',1:10);
```

Compare `label1`, `label2`, and `label3` by using `isequal`.

```
isequal(label1,label2,label3)
```

```
ans = logical
   1
```

`isequal` returns logical 1 (`true`), which means all the inputs are equal.

The `score3` output from the MEX function might include round-off differences compared with the output from the `predict` function. In this case, compare `score1` and `score3`, allowing a small tolerance.

```
find(abs(score1-score3) > 1e-12)
```

```
ans =

  0x1 empty double column vector
```

`find` returns an empty vector if the element-wise absolute difference between `score1` and `score3` is not larger than the specified tolerance `1e-12`. The comparisons confirm that `myknnEnsemblePredict` and the MEX function return the same results.

Code Generation and Classification Learner App

Classification Learner is well suited for choosing and training classification models interactively, but it does not generate C/C++ code that labels data based on a trained model. The **Generate Function** button in the **Export** section of the Classification Learner app generates MATLAB code for training a model but does not generate C/C++ code. This example shows how to generate C code from a function that predicts labels using an exported classification model. The example builds a model that predicts the credit rating of a business given various financial ratios, according to these steps:

1. Use the credit rating data set in the file `CreditRating_Historical.dat`, which is included with Statistics and Machine Learning Toolbox.
2. Reduce the data dimensionality using principal component analysis (PCA).
3. Train a set of models that support code generation for label prediction.
4. Export the model with the minimum 5-fold, cross-validated classification accuracy.
5. Generate C code from an entry-point function that transforms the new predictor data and then predicts corresponding labels using the exported model.

Load Sample Data

Load sample data and import the data into the Classification Learner app. Review the data using scatter plots and remove unnecessary predictors.

Use `readtable` to load the historical credit rating data set in the file `CreditRating_Historical.dat` into a table.

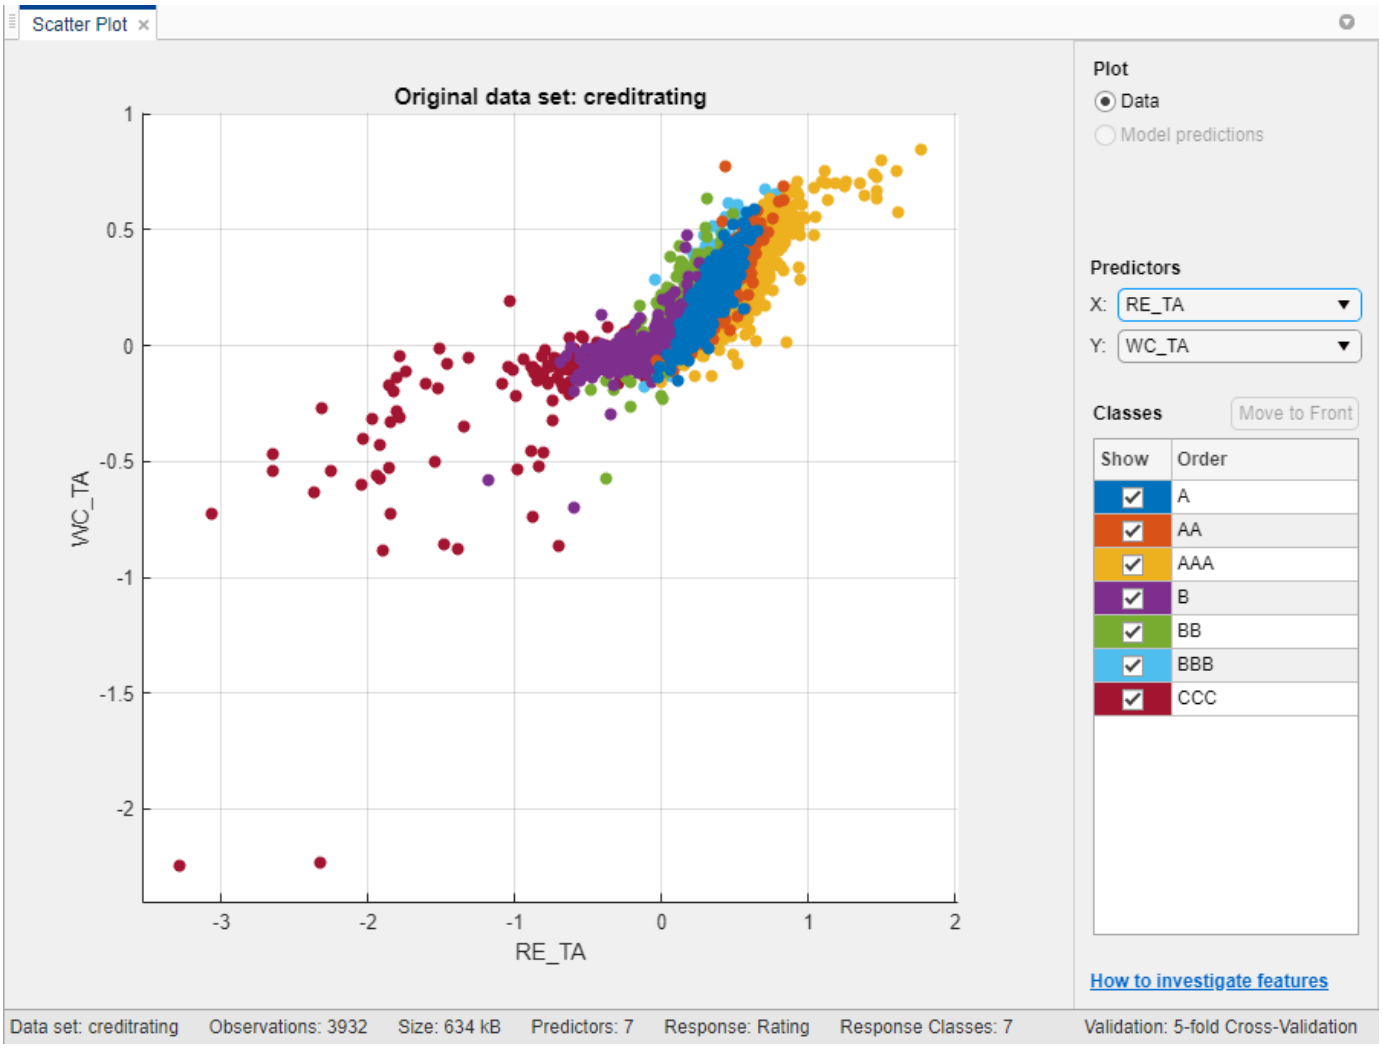
```
creditrating = readtable('CreditRating_Historical.dat');
```

On the **Apps** tab, click **Classification Learner**.

In Classification Learner, on the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

In the New Session from Workspace dialog box, select the table `creditrating`. All variables, except the one identified as the response, are double-precision numeric vectors. Click **Start Session** to compare classification models based on the 5-fold, cross-validated classification accuracy.

Classification Learner loads the data and plots a scatter plot of the variables `WC_TA` versus `ID`. Because identification numbers are not helpful to display in a plot, choose `RE_TA` for **X** under **Predictors**.



The scatter plot suggests that the two variables can separate the classes `AAA`, `BBB`, `BB`, and `CCC` fairly well. However, the observations corresponding to the remaining classes are mixed into these classes.

Identification numbers are not helpful for prediction. Therefore, in the **Features** section, click **Feature Selection** and then clear the **ID** check box. You can also remove unnecessary predictors from the beginning by using the check boxes in the New Session from Workspace dialog box. This example shows how to remove unused predictors for code generation when you have included all predictors.

Enable PCA

Enable PCA to reduce the data dimensionality.

In the **Features** section, click **PCA**, and then select **Enable PCA**. This action applies PCA to the predictor data, and then transforms the data before training the models. Classification Learner uses only components that collectively explain 95% of the variability.

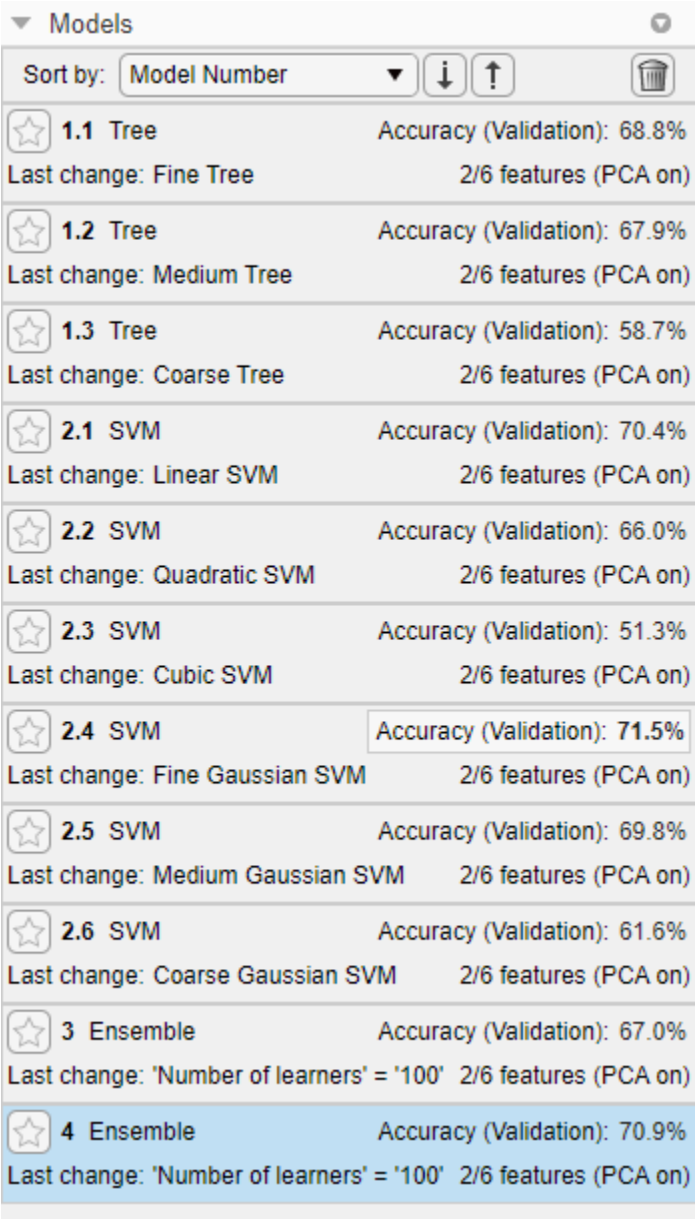
Train Models

Train a set of models that support code generation for label prediction. For a list of models in Classification Learner that support code generation, see “Generate C Code for Prediction” on page 23-79.

Select the following classification models and options, which support code generation for label prediction, and then perform cross-validation (for more details, see “Introduction to Code Generation” on page 32-2). To select each model, in the **Model Type** section, click the **Show more** arrow, and then click the model. After selecting a model and specifying any options, close any open menus, and then click **Train** in the **Training** section.

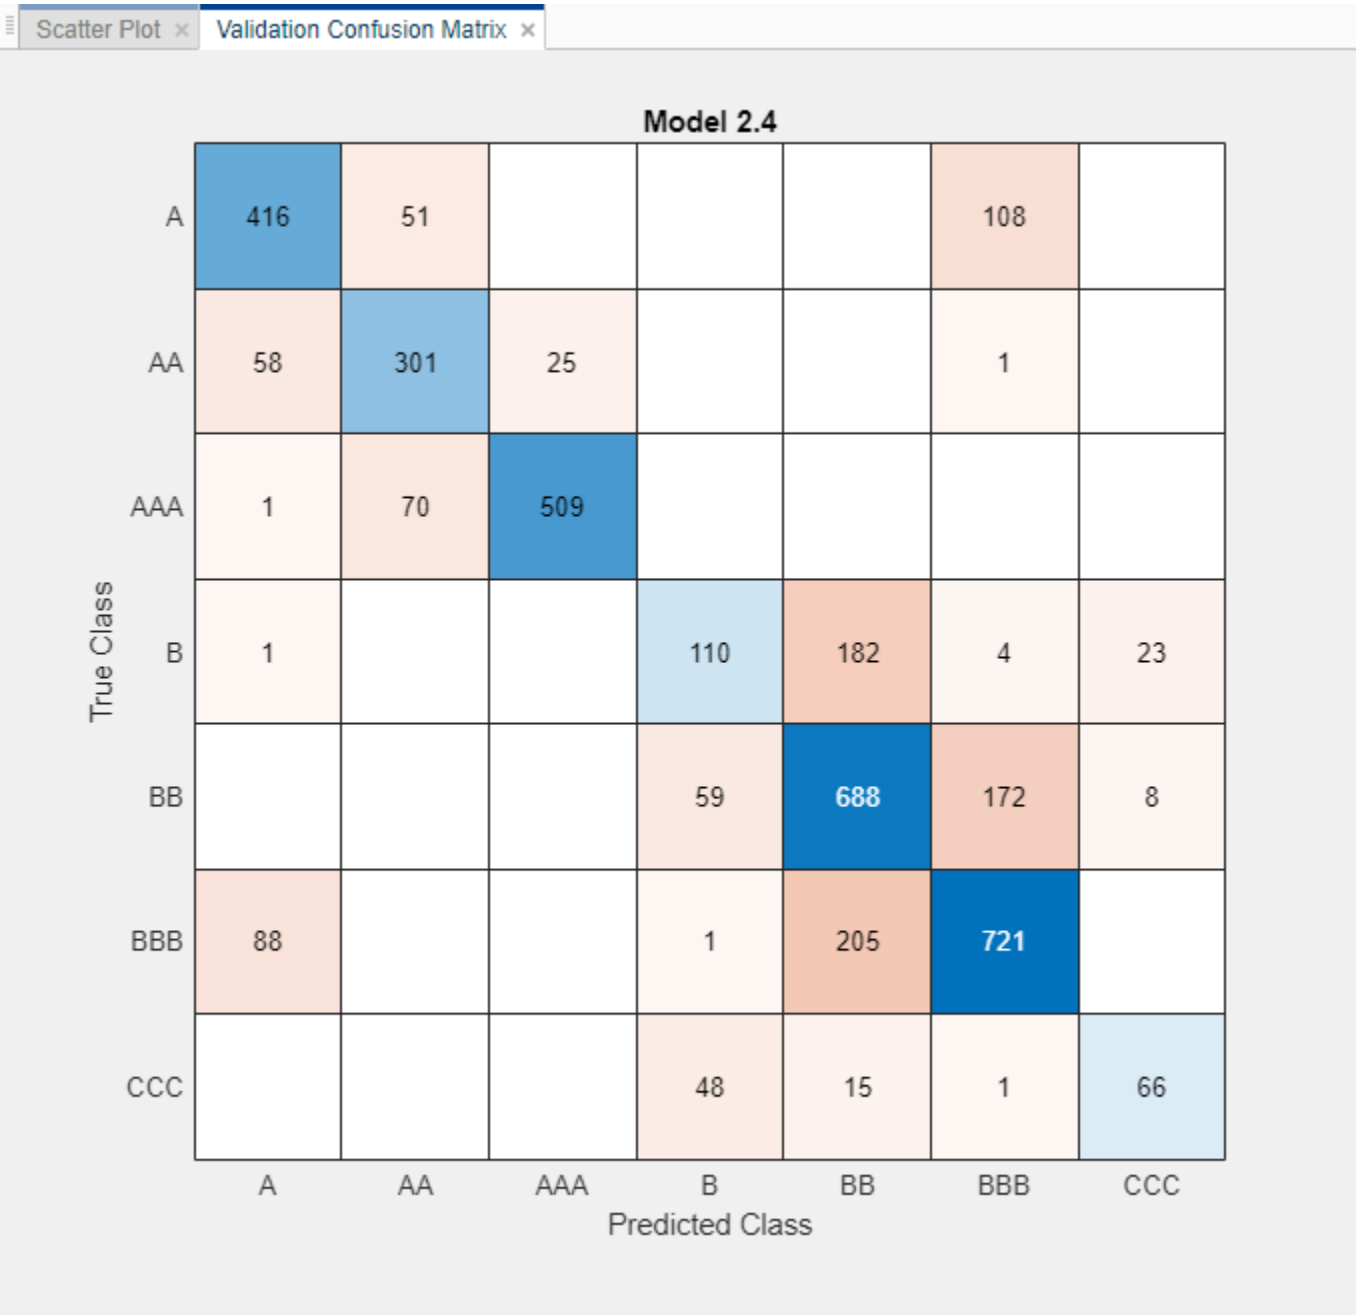
Models and Options to Select	Description
Under **Decision Trees**, select **All Trees**	Classification trees of various complexities
Under **Support Vector Machines**, select **All SVMs**	SVMs of various complexities and using various kernels. Complex SVMs require time to fit.
Under **Ensemble Classifiers**, select **Boosted Trees**. In the **Model Type** section, click **Advanced**. Reduce **Maximum number of splits** to **5** and increase **Number of learners** to **100**.	Boosted ensemble of classification trees
Under **Ensemble Classifiers**, select **Bagged Trees**. In the **Model Type** section, click **Advanced**. Increase **Maximum number of splits** to **50** and increase **Number of learners** to **100**.	Random forest of classification trees

After cross-validating each model type, the **Models** pane displays each model and its 5-fold, cross-validated classification accuracy, and highlights the model with the best accuracy.



Select the model that yields the maximum 5-fold, cross-validated classification accuracy, which is the error-correcting output codes (ECOC) model of Fine Gaussian SVM learners. With PCA enabled, Classification Learner uses two predictors out of six.

In the **Plots** section, click **Confusion Matrix** and select **Validation Data**.



The model does well distinguishing between A, B, and C classes. However, the model does not do as well distinguishing between particular levels within those groups, the lower B levels in particular.

Export Model to Workspace

Export the model to the MATLAB Workspace and save the model using `saveLearnerForCoder`.

In the **Export** section, click **Export Model**, and then select **Export Compact Model**. Click **OK** in the dialog box.

The structure `trainedModel` appears in the MATLAB Workspace. The field `ClassificationSVM` of `trainedModel` contains the compact model.

At the command line, save the compact model to a file called `ClassificationLearnerModel.mat` in your current folder.

```
saveLearnerForCoder(trainedModel.ClassificationSVM,'ClassificationLearnerModel')
```

Generate C Code for Prediction

Prediction using the object functions requires a trained model object, but the `-args` option of `codegen` does not accept such objects. Work around this limitation by using `saveLearnerForCoder` and `loadLearnerForCoder`. Save a trained model by using `saveLearnerForCoder`. Then, define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `predict` function. Finally, use `codegen` to generate code for the entry-point function.

Preprocess Data

Preprocess new data in the same way you preprocess the training data.

To preprocess, you need the following three model parameters:

- `removeVars` — Column vector of at most `p` elements identifying indices of variables to remove from the data, where `p` is the number of predictor variables in the raw data
- `pcaCenters` — Row vector of exactly `q` PCA centers
- `pcaCoefficients` — `q`-by-`r` matrix of PCA coefficients, where `r` is at most `q`

Specify the indices of predictor variables that you removed while selecting data using **Feature Selection** in Classification Learner. Extract the PCA statistics from `trainedModel`.

```
removeVars = 1;
pcaCenters = trainedModel.PCACenters;
pcaCoefficients = trainedModel.PCACoefficients;
```

Save the model parameters to a file named `ModelParameters.mat` in your current folder.

```
save('ModelParameters.mat','removeVars','pcaCenters','pcaCoefficients');
```

Define Entry-Point Function

An entry-point function is a function you define for code generation. Because you cannot call any function at the top level using `codegen`, you must define an entry-point function that calls code-generation-enabled functions, and then generate C/C++ code for the entry-point function by using `codegen`.

In your current folder, define a function named `mypredictCL.m` that:

- Accepts a numeric matrix (`X`) of raw observations containing the same predictor variables as the ones passed into Classification Learner
- Loads the classification model in `ClassificationLearnerModel.mat` and the model parameters in `ModelParameters.mat`
- Removes the predictor variables corresponding to the indices in `removeVars`
- Transforms the remaining predictor data using the PCA centers (`pcaCenters`) and coefficients (`pcaCoefficients`) estimated by Classification Learner

- Returns predicted labels using the model

```
function label = mypredictCL(X) %#codegen
%MYPREDICTCL Classify credit rating using model exported from
%Classification Learner
%   MYPREDICTCL loads trained classification model (SVM) and model
%   parameters (removeVars, pcaCenters, and pcaCoefficients), removes the
%   columns of the raw matrix of predictor data in X corresponding to the
%   indices in removeVars, transforms the resulting matrix using the PCA
%   centers in pcaCenters and PCA coefficients in pcaCoefficients, and then
%   uses the transformed data to classify credit ratings. X is a numeric
%   matrix with n rows and 7 columns. label is an n-by-1 cell array of
%   predicted labels.

% Load trained classification model and model parameters
SVM = loadLearnerForCoder('ClassificationLearnerModel');
data = coder.load('ModelParameters');
removeVars = data.removeVars;
pcaCenters = data.pcaCenters;
pcaCoefficients = data.pcaCoefficients;

% Remove unused predictor variables
keepvars = 1:size(X,2);
idx = ~ismember(keepvars,removeVars);
keepvars = keepvars(idx);
XwoID = X(:,keepvars);

% Transform predictors via PCA
Xpca = bsxfun(@minus,XwoID,pcaCenters)*pcaCoefficients;

% Generate label from SVM
label = predict(SVM,Xpca);
end
```

Generate Code

Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Specify variable-size arguments using `coder.typeof` and generate code using the arguments.

Create a double-precision matrix called `x` for code generation using `coder.typeof`. Specify that the number of rows of `x` is arbitrary, but that `x` must have `p` columns.

```
p = size(creditrating,2) - 1;
x = coder.typeof(0,[Inf,p],[1 0]);
```

For more details about specifying variable-size arguments, see “Specify Variable-Size Arguments for Code Generation” on page 32-45.

Generate a MEX function from `mypredictCL.m`. Use the `-args` option to specify `x` as an argument.

```
codegen mypredictCL -args x
```

`codegen` generates the MEX file `mypredictCL_mex.mexw64` in your current folder. The file extension depends on your platform.

Verify Generated Code

Verify that the MEX function returns the expected labels.

Remove the response variable from the original data set, and then randomly draw 15 observations.

```
rng('default'); % For reproducibility
m = 15;
testsampleT = datasample(creditrating(:,1:(end - 1)),m);
```

Predict corresponding labels by using `predictFcn` in the classification model trained by Classification Learner.

```
testLabels = trainedModel.predictFcn(testsampleT);
```

Convert the resulting table to a matrix.

```
testsample = table2array(testsampleT);
```

The columns of `testsample` correspond to the columns of the predictor data loaded by Classification Learner.

Pass the test data to `mypredictCL`. The function `mypredictCL` predicts corresponding labels by using `predict` and the classification model trained by Classification Learner.

```
testLabelsPredict = mypredictCL(testsample);
```

Predict corresponding labels by using the generated MEX function `mypredictCL_mex`.

```
testLabelsMEX = mypredictCL_mex(testsample);
```

Compare the sets of predictions.

```
isequal(testLabels,testLabelsMEX,testLabelsPredict)
```

```
ans =

  logical

   1
```

`isequal` returns logical 1 (true) if all the inputs are equal. `predictFcn`, `mypredictCL`, and the MEX function return the same values.

Predict Class Labels Using MATLAB Function Block

This example shows how to add a MATLAB® Function block to a Simulink® model for label prediction. The MATLAB Function block accepts streaming data, and predicts the label and classification score using a trained, support vector machine (SVM) classification model. For details on using the MATLAB Function block, see “Create Custom Functionality Using MATLAB Function Block” (Simulink).

Train Classification Model

This example uses the `ionosphere` data set, which contains radar-return qualities (`Y`) and predictor data (`X`). Radar returns are either of good quality (`'g'`) or of bad quality (`'b'`).

Load the `ionosphere` data set. Determine the sample size.

```
load ionosphere
n = numel(Y)
```

```
n = 351
```

The MATLAB Function block cannot return cell arrays. Convert the response variable to a logical vector whose elements are `1` if the radar returns are good, and `0` otherwise.

```
Y = strcmp(Y,'g');
```

Suppose that the radar returns are detected in sequence, and you have the first 300 observations, but you have not received the last 51 yet. Partition the data into present and future samples.

```
prsntX = X(1:300,:);
prsntY = Y(1:300);
ftrX = X(301:end,:);
ftrY = Y(301:end);
```

Train an SVM model using all, presently available data. Specify predictor data standardization.

```
Mdl = fitcsvm(prsntX,prsntY,'Standardize',true);
```

`Mdl` is a `ClassificationSVM` model.

Save Model Using `saveLearnerForCoder`

At the command line, you can use `Mdl` to make predictions for new observations. However, you cannot use `Mdl` as an input argument in a function meant for code generation.

Prepare `Mdl` to be loaded within the function using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'SVMIonosphere');
```

`saveLearnerForCoder` compacts `Mdl`, and then saves it in the MAT-file `SVMIonosphere.mat`.

Define MATLAB Function

Define a MATLAB function named `svmIonospherePredict.m` that predicts whether a radar return is of good quality. The function must:

- Include the code generation directive `%#codegen` somewhere in the function.

- Accept radar-return predictor data. The data must be commensurate with X except for the number of rows.
- Load `SVMIonosphere.mat` using `loadLearnerForCoder`.
- Return predicted labels and classification scores for predicting the quality of the radar return as good (that is, the positive-class score).

```
function [label,score] = svmIonospherePredict(X) %#codegen
%svmIonospherePredict Predict radar-return quality using SVM model
%   svmIonospherePredict predicts labels and estimates classification
%   scores of the radar returns in the numeric matrix of predictor data X
%   using the compact SVM model in the file SVMIonosphere.mat.  Rows of X
%   correspond to observations and columns to predictor variables.  label
%   is the predicted label and score is the confidence measure for
%   classifying the radar-return quality as good.
%
% Copyright 2016 The MathWorks Inc.
Mdl = loadLearnerForCoder('SVMIonosphere');
[label,bothscores] = predict(Mdl,X);
score = bothscores(:,2);
end
```

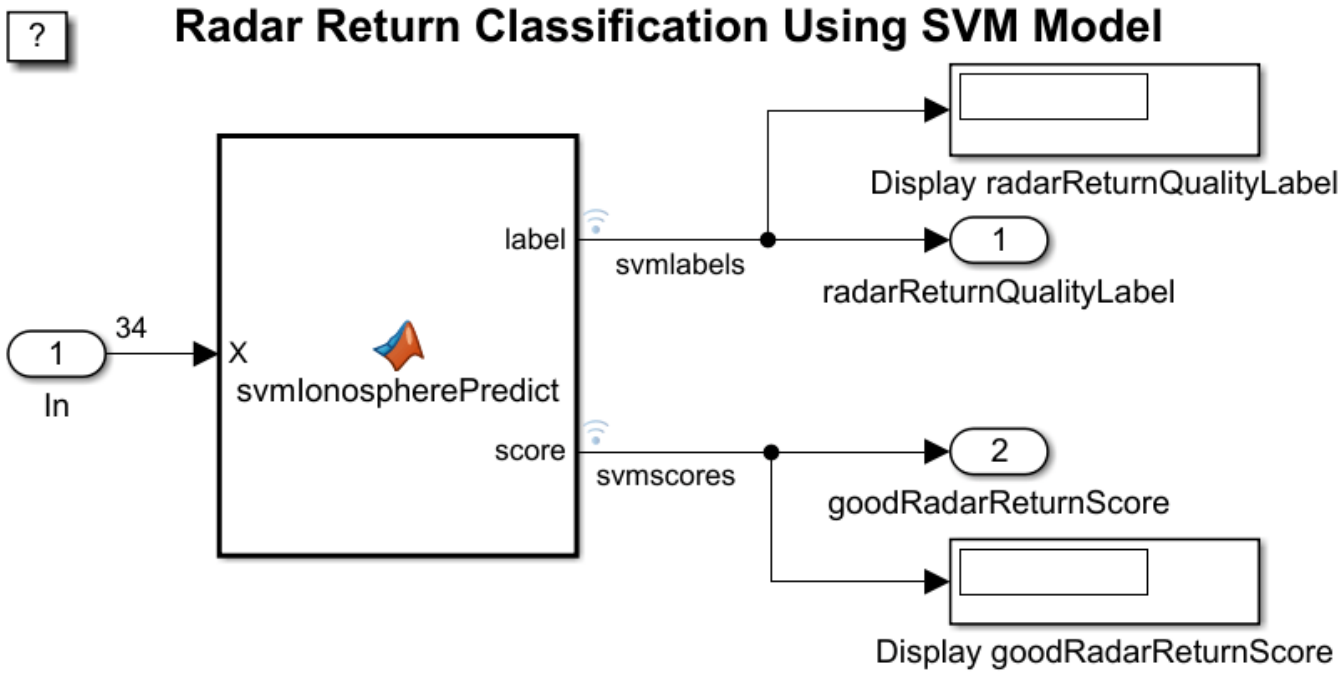
Note: If you click the button located in the upper-right section of this page and open this example in MATLAB, then MATLAB opens the example folder. This folder includes the entry-point function file.

Create Simulink Model

Create a Simulink model with the MATLAB Function block that dispatches to `svmIonospherePredict.m`.

This example provides the Simulink model `slexSVMIonospherePredictExample.slx`. Open the Simulink model.

```
SimMdlName = 'slexSVMIonospherePredictExample';
open_system(SimMdlName)
```



The figure displays the Simulink model. When the input node detects a radar return, it directs that observation into the MATLAB Function block that dispatches to `svmIonosphere Predict.m`. After predicting the label and score, the model returns these values to the workspace and displays the values within the model one at a time. When you load `slexSVMIonosphere PredictExample.slx`, MATLAB also loads the data set that it requires called `radarReturnInput`. However, this example shows how to construct the required data set.

The model expects to receive input data as a structure array called `radarReturnInput` containing these fields:

- `time` - The points in time at which the observations enter the model. In the example, the duration includes the integers from 0 though 50. The orientation must correspond to the observations in the predictor data. So, for this example, `time` must be a column vector.
- `signals` - A 1-by-1 structure array describing the input data, and containing the fields `values` and `dimensions`. `values` is a matrix of predictor data. `dimensions` is the number of predictor variables.

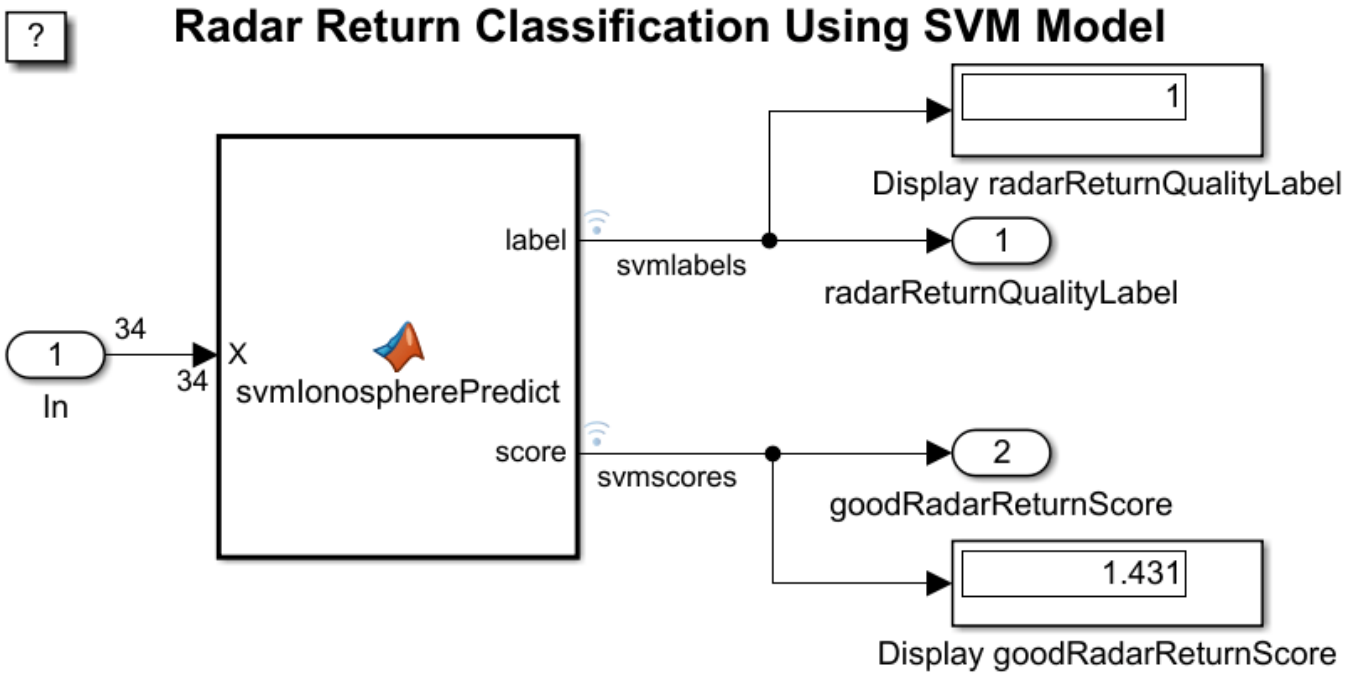
Create an appropriate structure array for future radar returns.

```
radarReturnInput.time = (0:50)';
radarReturnInput.signals(1).values = ftrX;
radarReturnInput.signals(1).dimensions = size(ftrX,2);
```

You can change the name from `radarReturnInput`, and then specify the new name in the model. However, Simulink expects the structure array to contain the described field names.

Simulate the model using the data held out of training, that is, the data in `radarReturnInput`.

```
sim(SimMdlName);
```



The figure shows the model after it processes all observations in `radarReturnInput` one at a time. The predicted label of `X(351,:)` is `1` and its positive-class score is `1.431`. The variables `tout`, `yout`, and `svmlogsout` appear in the workspace. `yout` and `svmlogsout` are `SimulinkData.Dataset` objects containing the predicted labels and scores. For more details, see "Data Format for Logged Simulation Data" (Simulink).

Extract the simulation data from the simulation log.

```
labelsSL = svmlogsout.getElement(1).Values.Data;
scoresSL = svmlogsout.getElement(2).Values.Data;
```

`labelsSL` is a 51-by-1 numeric vector of predicted labels. `labelsSL(j) = 1` means that the SVM model predicts that radar return `j` in the future sample is of good quality, and `0` means otherwise. `scoresSL` is a 51-by-1 numeric vector of positive-class scores, that is, signed distances from the decision boundary. Positive scores correspond to predicted labels of `1`, and negative scores correspond to predicted labels of `0`.

Predict labels and positive-class scores at the command line using `predict`.

```
[labelCMD,scoresCMD] = predict(Mdl,ftrX);
scoresCMD = scoresCMD(:,2);
```

`labelCMD` and `scoresCMD` are commensurate with `labelsSL` and `scoresSL`.

Compare the future-sample, positive-class scores returned by `slexSVMIonospherePredictExample` to those returned by calling `predict` at the command line.

```
err = sum((scoresCMD - scoresSL).^2);
err < eps
```

```
ans = logical
   1
```

The sum of squared deviations between the sets of scores is negligible.

If you also have a Simulink Coder™ license, then you can generate C code from `slexSVMIonospherePredictExample.slx` in Simulink or from the command line using `slbuild` (Simulink). For more details, see “Generate C Code for a Model” (Simulink Coder).

Specify Variable-Size Arguments for Code Generation

This example shows how to specify variable-size input arguments when you generate code for the object functions of classification and regression model objects. Variable-size data is data whose size might change at run time. Specifying variable-size input arguments is convenient when you have data with an unknown size at compile time. This example also describes how to include name-value pair arguments in an entry-point function and how to specify them when generating code.

For more detailed code generation workflow examples, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9 and “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22.

Train Classification Model

Load Fisher's iris data set. Convert the labels to a character matrix.

```
load fisheriris
species = char(species);
```

Train a classification tree using the entire data set.

```
Mdl = fitctree(meas,species);
```

`Mdl` is a `ClassificationTree` model.

Save Model Using `saveLearnerForCoder`

Save the trained classification tree to a file named `ClassTreeIris.mat` in your current folder by using `saveLearnerForCoder`.

```
MdlName = 'ClassTreeIris';
saveLearnerForCoder(Mdl,MdlName);
```

Define Entry-Point Function

In your current folder, define an entry-point function named `mypredictTree.m` that does the following:

- Accept measurements with columns corresponding to `meas` and accept valid name-value pair arguments.
- Load a trained classification tree by using `loadLearnerForCoder`.
- Predict labels and corresponding scores, node numbers, and class numbers from the loaded classification tree.

You can allow for optional name-value pair arguments by specifying varargin as an input argument. For details, see “Code Generation for Variable Length Argument Lists” (MATLAB Coder).

```
type mypredictTree.m  % Display contents of mypredictTree.m file
```

```
function [label,score,node,cnum] = mypredictTree(x,savedmdl,varargin) %#codegen
%MYPREDICTTREE Predict iris species using classification tree
%   MYPREDICTTREE predicts iris species for the n observations in the
%   n-by-4 matrix x using the classification tree stored in the MAT-file
%   whose name is in savedmdl, and then returns the predictions in the
%   array label. Each row of x contains the lengths and widths of the petal
%   and sepal of an iris (see the fisheriris data set). For other output
```

```
%   argument descriptions, see the predict reference page.
CompactMdl = loadLearnerForCoder(savedmdl);
[label,score,node,cnum] = predict(CompactMdl,x,varargin{:});
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Specify Variable-Size Arguments

Because C and C++ are statically typed languages, you must determine the properties of all variables in an entry-point function at compile time using the `-args` option of `codegen`.

Use `coder.Constant` (MATLAB Coder) to specify a compile-time constant input.

```
coder.Constant(v)
```

`coder.Constant(v)` creates a `coder.Constant` type variable whose values are constant, the same as `v`, during code generation.

Use `coder.typeof` (MATLAB Coder) to specify a variable-size input.

```
coder.typeof(example_value, size_vector, variable_dims)
```

The values of `example_value`, `size_vector`, and `variable_dims` specify the properties of the input array that the generated code can accept.

- An input array has the same data type as the example values in `example_value`.
- `size_vector` is the array size of an input array if the corresponding `variable_dims` value is `false`.
- `size_vector` is the upper bound of the array size if the corresponding `variable_dims` value is `true`.
- `variable_dims` specifies whether each dimension of the array has a variable size or a fixed size. A value of `true` (logical 1) means that the corresponding dimension has a variable size; a value of `false` (logical 0) means that the corresponding dimension has a fixed size.

The entry-point function `mypredictTree` accepts predictor data, the MAT-file name containing the trained model object, and optional name-value pair arguments. Suppose that you want to generate code that accepts a variable-size array for predictor data and the `'Subtrees'` name-value pair argument with a variable-size vector for its value. Then you have four input arguments: predictor data, the MAT-file name, and the name and value of the `'Subtrees'` name-value pair argument.

Define a 4-by-1 cell array and assign each input argument type of the entry-point function to each cell.

```
ARGS = cell(4,1);
```

For the first input, use `coder.typeof` to specify that the predictor data variable is double-precision with the same number of columns as the predictor data used in training the model, but that the number of observations (rows) is arbitrary.

```
p = numel(Mdl.PredictorNames);
ARGS{1} = coder.typeof(0,[Inf,p],[1,0]);
```

`0` for the `example_value` value implies that the data type is `double` because `double` is the default numeric data type of MATLAB. `[Inf,p]` for the `size_vector` value and `[1,0]` for the `variable_dims` value imply that the size of the first dimension is variable and unbounded, and the size of the second dimension is fixed to be `p`.

The second input is the MAT-file name, which must be a compile-time constant. Use `coder.Constant` to specify the type of the second input.

```
ARGS{2} = coder.Constant(MdlName);
```

The last two inputs are the name and value of the `'Subtrees'` name-value pair argument. Names of name-value pair arguments must be compile-time constants.

```
ARGS{3} = coder.Constant('Subtrees');
```

Use `coder.typeof` to specify that the value of `'Subtrees'` is a double-precision row vector and that the upper bound of the row vector size is `max(Mdl.PrunedList)`.

```
m = max(Mdl.PruneList);
ARGS{4} = coder.typeof(0,[1,m],[0,1]);
```

Again, `0` for the `example_value` value implies that the data type is `double` because `double` is the default numeric data type of MATLAB. `[1,m]` for the `size_vector` value and `[0,1]` for the `variable_dims` value imply that the size of the first dimension is fixed to be `1`, and the size of the second dimension is variable and its upper bound is `m`.

Generate Code Using `codegen`

Generate a MEX function from the entry-point function `mypredictTree` using the cell array `ARGS`, which includes input argument types for `mypredictTree`. Specify the input argument types using the `-args` option. Specify the number of output arguments in the generated entry-point function using the `-nargout` option. The generate code includes the specified number of output arguments in the order in which they occur in the entry-point function definition.

```
codegen mypredictTree -args ARGS -nargout 2
```

```
Code generation successful.
```

`codegen` generates the MEX function `mypredictTree_mex` with a platform-dependent extension in your current folder.

The `predict` function accepts single-precision values, double-precision values, and `'all'` for the `'SubTrees'` name-value pair argument. However, you can specify only double-precision values when you use the MEX function for prediction because the data type specified by `ARGS{4}` is double.

Verify Generated Code

Predict labels for a random selection of 15 values from the training data using the generated MEX function and the subtree at pruning level 1. Compare the labels from the MEX function with those predicted by `predict`.

```
rng('default'); % For reproducibility
Xnew = datasample(meas,15);
[labelMEX,scoreMEX] = mypredictTree_mex(Xnew,MdlName,'Subtrees',1);
[labelPREDICT,scorePREDICT] = predict(Mdl,Xnew,'Subtrees',1);
labelPREDICT
```

```
labelPREDICT = 15x10 char array
    'virginica '
    'virginica '
    'setosa    '
    'virginica '
    'versicolor'
    'setosa    '
    'setosa    '
    'versicolor'
    'virginica '
    'virginica '
    'setosa    '
    'virginica '
    'virginica '
    'versicolor'
    'virginica '
```

`labelMEX`

```
labelMEX = 15x1 cell
    {'virginica' }
    {'virginica' }
    {'setosa'    }
    {'virginica' }
    {'versicolor'}
    {'setosa'    }
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
    {'virginica' }
    {'setosa'    }
    {'virginica' }
    {'virginica' }
    {'versicolor'}
    {'virginica' }
```

The predicted labels are the same as the MEX function labels except for the data type. When the response data type is `char` and `codegen` cannot determine that the value of `Subtrees` is a scalar, then the output from the generated code is a cell array of character vectors.

For the comparison, you can convert `labelsPREDICT` to a cell array and use `isequal`.

```
cell_labelPREDICT = cellstr(labelPREDICT);
verifyLabel = isequal(labelMEX,cell_labelPREDICT)
```

```
verifyLabel = logical
   1
```

`isequal` returns logical 1 (`true`), which means all the inputs are equal.

Compare the second outputs as well. `scoreMex` might include round-off differences compared with `scorePREDICT`. In this case, compare `scoreMEX` and `scorePREDICT`, allowing a small tolerance.

```
find(abs(scorePREDICT-scoreMEX) > 1e-8)
```

```
ans =

  0x1 empty double column vector
```

`find` returns an empty vector if the element-wise absolute difference between `scorePREDICT` and `scoreMEX` is not larger than the specified tolerance `1e-8`. The comparison confirms that `scorePREDICT` and `scoreMEX` are equal within the tolerance `1e−8`.

Create Dummy Variables for Categorical Predictors and Generate C/C++ Code

This example shows how to generate code for classifying data using a support vector machine (SVM) model. Train the model using numeric and encoded categorical predictors. Use `dummyvar` to convert categorical predictors to numeric dummy variables before fitting an SVM classifier. When passing new data to your trained model, you must preprocess the data in a similar manner.

Alternatively, if a trained model identifies categorical predictors in the `CategoricalPredictors` property, then you do not need to create dummy variables manually to generate code. The software handles categorical predictors automatically. For an example, see “Generate Code to Classify Data in Table” on page 32-100.

Preprocess Data and Train SVM Classifier

Load the `patients` data set. Create a table using the `Diastolic` and `Systolic` numeric variables. Each row of the table corresponds to a different patient.

```
load patients
tbl = table(Diastolic,Systolic);
head(tbl)
```

```
ans=8×2 table
    Diastolic    Systolic
    _________    ________

       93           124
       77           109
       83           125
       75           117
       80           122
       70           121
       88           130
       82           115
```

Convert the `Gender` variable to a `categorical` variable. The order of the categories in `categoricalGender` is important because it determines the order of the columns in the predictor data. Use `dummyvar` to convert the categorical variable to a matrix of zeros and ones, where a `1` value in the `(i,j)`th entry indicates that the `i`th patient belongs to the `j`th category.

```
categoricalGender = categorical(Gender);
orderGender = categories(categoricalGender)
```

```
orderGender = 2x1 cell
    {'Female'}
    {'Male'  }
```

```
dummyGender = dummyvar(categoricalGender);
```

Note: The resulting `dummyGender` matrix is rank deficient. Depending on the type of model you train, this rank deficiency can be problematic. For example, when training linear models, remove the first column of the dummy variables.

Create a table that contains the dummy variable `dummyGender` with the corresponding variable headings. Combine this new table with `tbl`.

```
tblGender = array2table(dummyGender,'VariableNames',orderGender);
tbl = [tbl tblGender];
head(tbl)
```

```
ans=8×4 table
    Diastolic    Systolic    Female    Male
    _________    ________    ______    ____

       93           124         0        1
       77           109         0        1
       83           125         1        0
       75           117         1        0
       80           122         1        0
       70           121         1        0
       88           130         1        0
       82           115         0        1
```

Convert the `SelfAssessedHealthStatus` variable to a `categorical` variable. Note the order of the categories in `categoricalHealth`, and convert the variable to a numeric matrix using `dummyvar`.

```
categoricalHealth = categorical(SelfAssessedHealthStatus);
orderHealth = categories(categoricalHealth)
```

```
orderHealth = 4x1 cell
    {'Excellent'}
    {'Fair'     }
    {'Good'     }
    {'Poor'     }
```

```
dummyHealth = dummyvar(categoricalHealth);
```

Create a table that contains `dummyHealth` with the corresponding variable headings. Combine this new table with `tbl`.

```
tblHealth = array2table(dummyHealth,'VariableNames',orderHealth);
tbl = [tbl tblHealth];
head(tbl)
```

```
ans=8×8 table
    Diastolic    Systolic    Female    Male    Excellent    Fair    Good    Poor
    _________    ________    ______    ____    _________    ____    ____    ____

       93           124         0        1          1          0       0       0
       77           109         0        1          0          1       0       0
       83           125         1        0          0          0       1       0
       75           117         1        0          0          1       0       0
       80           122         1        0          0          0       1       0
       70           121         1        0          0          0       1       0
       88           130         1        0          0          0       1       0
       82           115         0        1          0          0       1       0
```

The third row of `tbl`, for example, corresponds to a patient with these characteristics: diastolic blood pressure of 83, systolic blood pressure of 125, female, and good self-assessed health status.

Because all the values in `tbl` are numeric, you can convert the table to a matrix `X`.

```
X = table2array(tbl);
```

Train an SVM classifier using `X`. Specify the `Smoker` variable as the response.

```
Y = Smoker;
Mdl = fitcsvm(X,Y);
```

Generate C/C++ Code

Generate code that loads the SVM classifier, takes new predictor data as an input argument, and then classifies the new data.

Save the SVM classifier to a file using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'SVMClassifier')
```

`saveLearnerForCoder` saves the classifier to the MATLAB® binary file `SVMClassifier.mat` as a structure array in the current folder.

Define the entry-point function `mySVMPredict`, which takes new predictor data as an input argument. Within the function, load the SVM classifier by using `loadLearnerForCoder`, and then pass the loaded classifier to `predict`.

```
function label = mySVMPredict(X) %#codegen
Mdl = loadLearnerForCoder('SVMClassifier');
label = predict(Mdl,X);
end
```

Generate code for `mySVMPredict` by using `codegen`. Specify the data type and dimensions of the new predictor data by using `coder.typeof` so that the generated code accepts a variable-size array.

```
codegen mySVMPredict -args {coder.typeof(X,[Inf 8],[1 0])}
```

```
Code generation successful.
```

Verify that `mySVMPredict` and the MEX file return the same results for the training data.

```
label = predict(Mdl,X);
mylabel = mySVMPredict(X);
mylabel_mex = mySVMPredict_mex(X);
verifyMEX = isequal(label,mylabel,mylabel_mex)
```

```
verifyMEX = logical
   1
```

Predict Labels for New Data

To predict labels for new data, you must first preprocess the new data. If you run the generated code in the MATLAB environment, you can follow the preprocessing steps described in this section. If you deploy the generated code outside the MATLAB environment, the preprocessing steps can differ. In either case, you must ensure that the new data has the same columns as the training data `X`.

In this example, take the third, fourth, and fifth patients in the `patients` data set. Preprocess the data for these patients so that the resulting numeric matrix matches the form of the training data.

Convert the categorical variables to dummy variables. Because the new observations might not include values from all categories, you need to specify the same categories as the ones used during training and maintain the same category order. In MATLAB, pass the ordered cell array of category names associated with the corresponding training data variable (in this example, `orderGender` for gender values and `orderHealth` for self-assessed health status values).

```
newcategoricalGender = categorical(Gender(3:5),orderGender);
newdummyGender = dummyvar(newcategoricalGender);

newcategoricalHealth = categorical(SelfAssessedHealthStatus(3:5),orderHealth);
newdummyHealth = dummyvar(newcategoricalHealth);
```

Combine all the new data into a numeric matrix.

```
newX = [Diastolic(3:5) Systolic(3:5) newdummyGender newdummyHealth]
```

```
newX = 3×8

    83   125     1     0     0     0     1     0
    75   117     1     0     0     1     0     0
    80   122     1     0     0     0     1     0
```

Note that `newX` corresponds exactly to the third, fourth, and fifth rows of the matrix `X`.

Verify that `mySVMPredict` and the MEX file return the same results for the new data.

```
newlabel = predict(Mdl,newX);
newmylabel = mySVMPredict(newX);
newmylabel_mex = mySVMPredict_mex(newX);
newverifyMEX = isequal(newlabel,newmylabel,newmylabel_mex)
```

```
newverifyMEX = logical
   1
```

System Objects for Classification and Code Generation

This example shows how to generate C code from a MATLAB® System object™ that classifies images of digits by using a trained classification model. This example also shows how to use the System object for classification in Simulink®. The benefit of using System objects over MATLAB function is that System objects are more appropriate for processing large amounts of streaming data. For more details, see “What Are System Objects?”.

This example is based on “Code Generation for Image Classification” on page 32-103, which is an alternative workflow to “Digit Classification Using HOG Features” (Computer Vision Toolbox).

Load Data

Load the `digitimages`.

```
load digitimages.mat
```

`images` is a 28-by-28-by-3000 array of `uint16` integers. Each page is a raster image of a digit. Each element is a pixel intensity. Corresponding labels are in the 3000-by-1 numeric vector `Y`. For more details, enter `Description` at the command line.

Store the number of observations and the number of predictor variables. Create a data partition that specifies to hold out 20% of the data. Extract training and test set indices from the data partition.

```
rng(1); % For reproducibility
n = size(images,3);
p = numel(images(:,:,1));
cvp = cvpartition(n,'Holdout',0.20);
idxTrn = training(cvp);
idxTest = test(cvp);
```

Rescale Data

Rescale the pixel intensities so that they range in the interval [0,1] within each image. Specifically, suppose p_{ij} is pixel intensity j within image i. For image i, rescale all of its pixel intensities by using this formula:

$$\hat{p}_{ij} = \frac{p_{ij} - \min_j(p_{ij})}{\max_j(p_{ij}) - \min_j(p_{ij})}.$$

```
X = double(images);

for i = 1:n
    minX = min(min(X(:,:,i)));
    maxX = max(max(X(:,:,i)));
    X(:,:,i) = (X(:,:,i) - minX)/(maxX - minX);
end
```

Reshape Data

For code generation, the predictor data for training must be in a table of numeric variables or a numeric matrix.

Reshape the data to a matrix such that predictor variables correspond to columns and images correspond to rows. Because `reshape` takes elements column-wise, transpose its result.

```
X = reshape(X,[p,n])';
```

Train and Optimize Classification Models

Cross-validate an ECOC model of SVM binary learners and a random forest based on the training observations. Use 5-fold cross-validation.

For the ECOC model, specify predictor standardization and optimize classification error over the ECOC coding design and the SVM box constraint. Explore all combinations of these values:

- For the ECOC coding design, use one-versus-one and one-versus-all.
- For the SVM box constraint, use three logarithmically spaced values from 0.1 to 100 each. For all models, store the 5-fold cross-validated misclassification rates.

```
coding = {'onevsone' 'onevsall'};
boxconstraint = logspace(-1,2,3);
cvLossECOC = nan(numel(coding),numel(boxconstraint)); % For preallocation

for i = 1:numel(coding)
    for j = 1:numel(boxconstraint)
        t = templateSVM('BoxConstraint',boxconstraint(j),'Standardize',true);
        CVMdl = fitcecoc(X(idxTrn,:),Y(idxTrn),'Learners',t,'KFold',5,...
            'Coding',coding{i});
        cvLossECOC(i,j) = kfoldLoss(CVMdl);
        fprintf('cvLossECOC = %f for model using %s coding and box constraint=%f\n',...
            cvLossECOC(i,j),coding{i},boxconstraint(j))
    end
end
```

```
cvLossECOC = 0.058333 for model using onevsone coding and box constraint=0.100000
cvLossECOC = 0.057083 for model using onevsone coding and box constraint=3.162278
cvLossECOC = 0.050000 for model using onevsone coding and box constraint=100.000000
cvLossECOC = 0.120417 for model using onevsall coding and box constraint=0.100000
cvLossECOC = 0.121667 for model using onevsall coding and box constraint=3.162278
cvLossECOC = 0.127917 for model using onevsall coding and box constraint=100.000000
```

For the random forest, vary the maximum number of splits by using the values in the sequence $\{3^2, 3^3, \ldots, 3^m\}$. m is such that 3^m is no greater than n - 1. To reproduce random predictor selections, specify `'Reproducible',true`.

```
n = size(X,1);
m = floor(log(n - 1)/log(3));
maxNumSplits = 3.^(2:m);
cvLossRF = nan(numel(maxNumSplits));
for i = 1:numel(maxNumSplits)
    t = templateTree('MaxNumSplits',maxNumSplits(i),'Reproducible',true);
    CVMdl = fitcensemble(X(idxTrn,:),Y(idxTrn),'Method','bag','Learners',t,...
        'KFold',5);
    cvLossRF(i) = kfoldLoss(CVMdl);
    fprintf('cvLossRF = %f for model using %d as the maximum number of splits\n',...
        cvLossRF(i),maxNumSplits(i))
end
```

```
cvLossRF = 0.319167 for model using 9 as the maximum number of splits
cvLossRF = 0.192917 for model using 27 as the maximum number of splits
cvLossRF = 0.066250 for model using 81 as the maximum number of splits
cvLossRF = 0.015000 for model using 243 as the maximum number of splits
```

```
cvLossRF = 0.013333 for model using 729 as the maximum number of splits
cvLossRF = 0.009583 for model using 2187 as the maximum number of splits
```

For each algorithm, determine the hyperparameter indices that yield the minimal misclassification rates.

```
minCVLossECOC = min(cvLossECOC(:))
```

```
minCVLossECOC = 0.0500
```

```
linIdx = find(cvLossECOC == minCVLossECOC,1);
[bestI,bestJ] = ind2sub(size(cvLossECOC),linIdx);
bestCoding = coding{bestI}
```

```
bestCoding =
'onevsone'
```

```
bestBoxConstraint = boxconstraint(bestJ)
```

```
bestBoxConstraint = 100
```

```
minCVLossRF = min(cvLossRF(:))
```

```
minCVLossRF = 0.0096
```

```
linIdx = find(cvLossRF == minCVLossRF,1);
[bestI,bestJ] = ind2sub(size(cvLossRF),linIdx);
bestMNS = maxNumSplits(bestI)
```

```
bestMNS = 2187
```

The random forest achieves a smaller cross-validated misclassification rate.

Train an ECOC model and a random forest using the training data. Supply the optimal hyperparameter combinations.

```
t = templateSVM('BoxConstraint',bestBoxConstraint,'Standardize',true);
MdlECOC = fitcecoc(X(idxTrn,:),Y(idxTrn),'Learners',t,'Coding',bestCoding);
t = templateTree('MaxNumSplits',bestMNS);
MdlRF = fitcensemble(X(idxTrn,:),Y(idxTrn),'Method','bag','Learners',t);
```

Create a variable for the test sample images and use the trained models to predict test sample labels.

```
testImages = X(idxTest,:);
testLabelsECOC = predict(MdlECOC,testImages);
testLabelsRF = predict(MdlRF,testImages);
```

Save Classification Model to Disk

`MdlECOC` and `MdlRF` are predictive classification models, but you must prepare them for code generation. Save `MdlECOC` and `MdlRF` to your present working folder using `saveLearnerForCoder`.

```
saveLearnerForCoder(MdlECOC,'DigitImagesECOC');
saveLearnerForCoder(MdlRF,'DigitImagesRF');
```

Create System Object for Prediction

Create two System objects, one for the ECOC model and the other for the random forest, that:

- Load the previously saved trained model by using `loadLearnerForCoder`.
- Make sequential predictions by the `step` method.
- Enforce no size changes to the input data.
- Enforce double-precision, scalar output.

        end
    end
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the files used in this example.

For System object basic requirements, see “Define Basic System Objects”.

Define Prediction Functions for Code Generation

Define two MATLAB functions called `predictDigitECOCSO.m` and `predictDigitRFSO.m`. The functions:

- Include the code generation directive `%#codegen`.
- Accept image data commensurate with `X`.
- Predict labels using the `ECOCClassifier` and `RFClassifier` System objects, respectively.
- Return predicted labels.

```
type predictDigitECOCSO.m % Display contents of predictDigitECOCSO.m file
```

```
function label = predictDigitECOCSO(X) %#codegen
%PREDICTDIGITECOCSO Classify digit in image using ECOC Model System object
%   PREDICTDIGITECOCSO classifies the 28-by-28 images in the rows of X
%   using the compact ECOC model in the System object ECOCClassifier, and
%   then returns class labels in label.
classifier = ECOCClassifier;
```

```
label = step(classifier,X);
end
```

```
type predictDigitRFSO.m % Display contents of predictDigitRFSO.m file
```

```
function label = predictDigitRFSO(X) %#codegen
%PREDICTDIGITRFSO Classify digit in image using RF Model System object
%   PREDICTDIGITRFSO classifies the 28-by-28 images in the rows of X
%   using the compact random forest in the System object RFClassifier, and
%   then returns class labels in label.
classifier = RFClassifier;
label = step(classifier,X);
end
```

Compile MATLAB Function to MEX File

Compile the prediction function that achieves better test-sample accuracy to a MEX file by using `codegen`. Specify the test set images by using the `-args` argument.

```
if(minCVLossECOC <= minCVLossRF)
    codegen predictDigitECOCSO -args testImages
else
    codegen predictDigitRFSO -args testImages
end
```

```
Code generation successful.
```

Verify that the generated MEX file produces the same predictions as the MATLAB function.

```
if(minCVLossECOC <= minCVLossRF)
    mexLabels = predictDigitECOCSO_mex(testImages);
    verifyMEX = sum(mexLabels == testLabelsECOC) == numel(testLabelsECOC)
else
    mexLabels = predictDigitRFSO_mex(testImages);
    verifyMEX = sum(mexLabels == testLabelsRF) == numel(testLabelsRF)
end
```

```
verifyMEX = logical
   1
```

`verifyMEX` is `1`, which indicates that the predictions made by the generated MEX file and the corresponding MATLAB function are the same.

Predict Labels by Using System Objects in Simulink

Create a video file that displays the test-set images frame-by-frame.

```
v = VideoWriter('testImages.avi','Uncompressed AVI');
v.FrameRate = 1;
open(v);
dim = sqrt(p)*[1 1];
for j = 1:size(testImages,1)
    writeVideo(v,reshape(testImages(j,:),dim));
end
close(v);
```

Define a function called `scalePixelIntensities.m` that converts RGB images to grayscale, and then scales the resulting pixel intensities so that their values are in the interval [0,1].

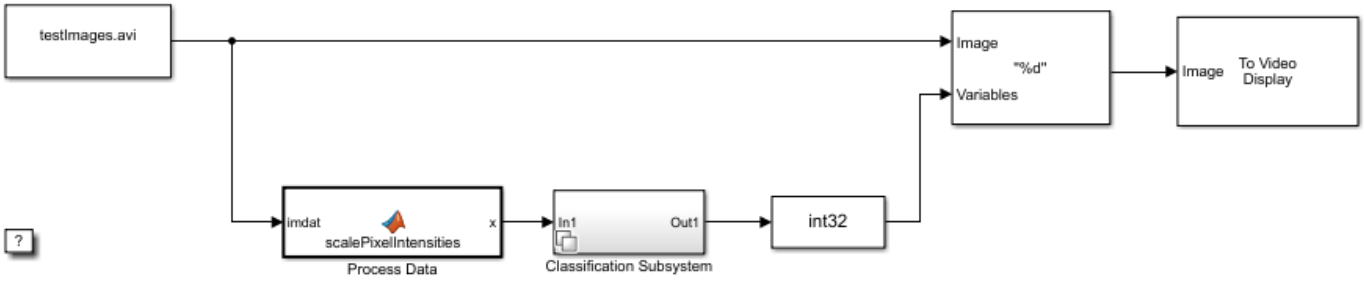
```
type scalePixelIntensities.m % Display contents of scalePixelIntensities.m file
```

```
function x = scalePixelIntensities(imdat)
%SCALEPIXELINTENSITIES Scales image pixel intensities
%   SCALEPIXELINTENSITIES scales the pixel intensities of the image such
%   that the result x is a row vector of values in the interval [0,1].
imdat = rgb2gray(imdat);

minimdat = min(min(imdat));
maximdat = max(max(imdat));
x = (imdat - minimdat)/(maximdat - minimdat);
end
```

Load the Simulink® model `slexClassifyAndDisplayDigitImages.slx`.

```
SimMdlName = 'slexClassifyAndDisplayDigitImages';
open_system(SimMdlName);
```



The figure displays the Simulink® model. At the beginning of simulation, the From Multimedia File block loads the video file of the test-set images. For each image in the video:

- The From Multimedia File block converts and outputs the image to a 28-by-28 matrix of pixel intensities.
- The Process Data block scales the pixel intensities by using `scalePixelIntensities.m`, and outputs a 1-by-784 vector of scaled intensities.
- The Classification Subsystem block predicts labels given the processed image data. The block chooses the System object that minimizes classification error. In this case, the block chooses the random forest. The block outputs a double-precision scalar label.
- The Data Type Conversion block converts the label to an `int32` scalar.
- The Insert Text block embeds the predicted label on the current frame.
- The To Video Display block displays the annotated frame.

Simulate the model.

```
sim(SimMdlName)
```

The model displays all 600 test-set images and its prediction quickly. The last image remains in the video display. You can generate predictions and display them with corresponding images one-by-one by clicking the **Step Forward** button instead.

If you also have a Simulink® Coder™ license, then you can generate C code from `slexClassifyAndDisplayDigitImages.slx` in Simulink® or from the command line using `slbuild` (Simulink). For more details, see “Generate C Code for a Model” (Simulink Coder).

Predict Class Labels Using Stateflow

This example shows how to use a Stateflow® chart for label prediction. The example trains a discriminant analysis model for the Fisher iris data set by using `fitcdiscr`, and defines a function for code generation that loads the trained model and predicts labels for new data. The Stateflow chart in this example accepts streaming data and predicts labels using the function you define.

Fisher's iris data set, which is included in Statistics and Machine Learning Toolbox™, contains species (`species`) and measurements (`meas`) on sepal length, sepal width, petal length, and petal width for 150 iris specimens. The data set contains 50 specimens from each of three species: setosa, versicolor, and virginica.

Load the Fisher iris data set.

```
load fisheriris
```

Convert `species` to an index vector where 1, 2, and 3 correspond to setosa, versicolor, and virginica, respectively.

```
species = grp2idx(species);
```

Partition the data into a training set and a test set.

```
rng('default') % For reproducibility
idx1 = randperm(150,75)';
idx2 = setdiff((1:150)',idx1);
X = meas(idx1,:);
Y = species(idx1,:);
trainX = meas(idx2,:);
trainY = species(idx2,:);
```

Use `trainX` and `trainY` to train a model, and use `X` and `Y` to test the trained model.

Train a quadratic discriminant analysis model.

```
Mdl = fitcdiscr(trainX,trainY,'DiscrimType','quadratic');
```

`Mdl` is a `ClassificationDiscriminant` model. At the command line, you can use `Mdl` to make predictions for new observations. However, you cannot use `Mdl` as an input argument in a function for code generation. Prepare `Mdl` to be loaded within the function by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'DiscrIris');
```

`saveLearnerForCoder` compacts `Mdl` and saves it in the MAT-file `DiscrIris.mat`.

To display the predicted species in the display box of the Stateflow model, define an enumeration class by using a `classdef` block in the MATLAB® file `IrisSpecies.m`.

```
classdef IrisSpecies < Simulink.IntEnumType
  enumeration
    Setosa(1)
    Versicolor(2)
    Virginica(3)
  end
end
```

For details about enumerated data, see “Define Enumerated Data Types” (Stateflow).

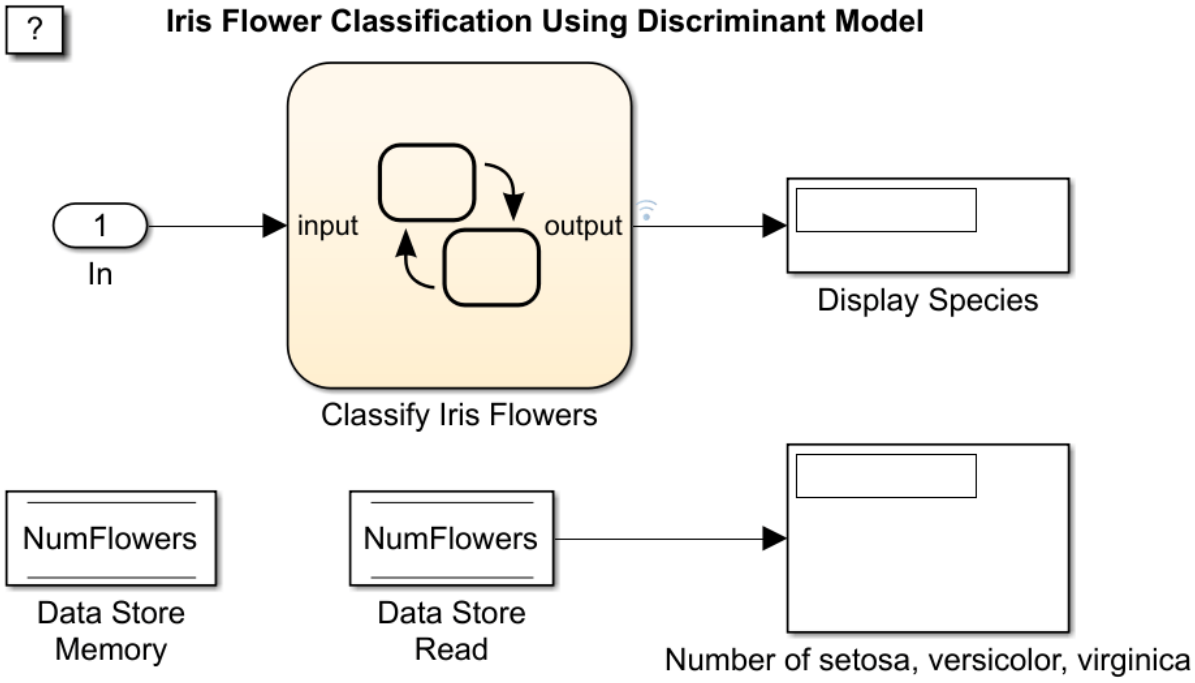
Define a function named `mypredict.m` that predicts the iris species from new measurement data by using the trained model. The function should:

- Include the code generation directive `%#codegen` somewhere in the function.
- Accept iris measurement data. The data must be consistent with X except for the number of rows.
- Load `DiscrIris.mat` using `loadLearnerForCoder`.
- Return predicted iris species.

```
function label  = mypredict(X) %#codegen
%MYPREDICT Predict species of iris flowers using discriminant model
%   mypredict predicts species of iris flowers using the compact
%   discriminant model in the file DiscrIris.mat. Rows of X correspond to
%   observations and columns correspond to predictor variables. label is
%   the predicted species.
mdl = loadLearnerForCoder('DiscrIris');
labelTemp = predict(mdl,X);
label = IrisSpecies(labelTemp);
end
```

Open the Simulink® model `sf_countflowers.slx`.

```
sfName = 'sf_countflowers';
open_system(sfName);
```



The figures display the Simulink model and the flow graph contained in the Stateflow chart. When the input node detects measurement data, it directs the data into the chart. The chart then predicts a species of iris flower and counts the number of flowers for each species. The chart returns the predicted species to the workspace and displays the species within the model, one at a time. The data store memory block `NumFlowers` stores the number of flowers for each species.

The chart expects to receive input data as a structure array called `fisheririsInput` containing these fields:

- `time` - The points in time at which the observations enter the model. In the example, the duration includes the integers from 0 through 74. The orientation of `time` must correspond to the observations in the predictor data. So, for this example, `time` must be a column vector.
- `signals` - A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`. The `values` field is a matrix of predictor data. The `dimensions` field is the number of predictor variables.

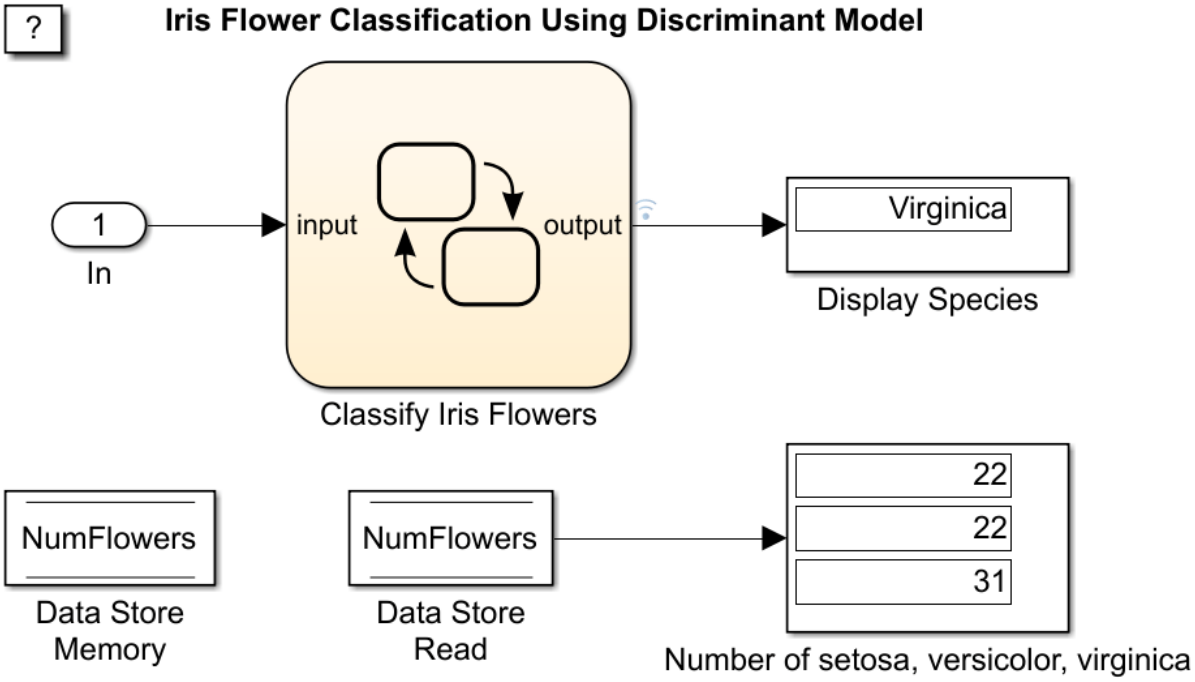
Create an appropriate structure array for iris flower measurements.

```
fisheririsInput.time = (0:74)';
fisheririsInput.signals.dimensions = 4;
fisheririsInput.signals.values = X;
```

You can change the name from `fisheririsInput`, and then specify the new name in the model. However, Stateflow expects the structure array to contain the described field names. For more details, see “Loading Data Structures to Root-Level Inputs” (Simulink).

Simulate the model.

```
sim(sfName)
```



The figure shows the model after it processes all observations in `fisheririsInput`, one at a time. The predicted species of `X(75,:)` is virginica. The number of setosa, versicolor, and virginica in `X` is 22, 22, and 31, respectively.

The variable `logsout` appears in the workspace. `logsout` is a `SimulinkData.Dataset` object containing the predicted species. Extract the predicted species data from the simulation log.

```
labelSF = logsout.getElement(1).Values.Data;
```

Predict species at the command line using `predict`.

```
labelCMD = predict(Mdl,X);
```

Compare the predicted species returned by `sf_countflowers` to those returned by calling `predict` at the command line.

```
isequal(labelCMD,labelSF)
```

```
ans = logical
   1
```

`isequal` returns logical 1 (`true`) if all the inputs are equal. This comparison confirms that `sf_countflowers` returns the expected results.

If you also have a Simulink Coder™ license, then you can generate C code from `sf_countflowers.slx` in Simulink or from the command line using `rtwbuild` (Simulink Coder). For more details, see “Generate C Code for a Model” (Simulink Coder).

Human Activity Recognition Simulink Model for Smartphone Deployment

This example shows how to prepare a Simulink® model that classifies human activity based on smartphone sensor signals for code generation and smartphone deployment. The example provides two Simulink models that are ready for deployment to an Android™ device and an iOS device. After you install the required support package for a target device, train the classification model and deploy the Simulink model to the device.

Load Sample Data Set

Load the `humanactivity` data set.

```
load humanactivity
```

The `humanactivity` data set contains 24,075 observations of five different physical human activities: Sitting, Standing, Walking, Running, and Dancing. Each observation has 60 features extracted from acceleration data measured by smartphone accelerometer sensors. The data set contains the following variables:

- `actid` — Response vector containing the activity IDs in integers: 1, 2, 3, 4, and 5 representing Sitting, Standing, Walking, Running, and Dancing, respectively
- `actnames` — Activity names corresponding to the integer activity IDs
- `feat` — Feature matrix of 60 features for 24,075 observations
- `featlabels` — Labels of the 60 features

The Sensor HAR (human activity recognition) App [1] on page 32-0 was used to create the `humanactivity` data set. When measuring the raw acceleration data with this app, a person placed a smartphone in a pocket so that the smartphone was upside down and the screen faced toward the person. The software then calibrated the measured raw data accordingly and extracted the 60 features from the calibrated data. For details about the calibration and feature extraction, see [2] on page 32-0 and [3] on page 32-0 , respectively. The Simulink models described later also use the raw acceleration data and include blocks for calibration and feature extraction.

Prepare Data

This example uses 90% of the observations to train a model that classifies the five types of human activities and 10% of the observations to validate the trained model. Use `cvpartition` to specify a 10% holdout for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(actid,'Holdout',0.10);
trainingInds = training(Partition); % Indices for the training set
XTrain = feat(trainingInds,:);
YTrain = actid(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = feat(testInds,:);
YTest = actid(testInds);
```

Convert the feature matrix `XTrain` and the response vector `YTrain` into a table to load the training data set in the Classification Learner app.

```
tTrain = array2table([XTrain YTrain]);
```

Specify the variable name for each column of the table.

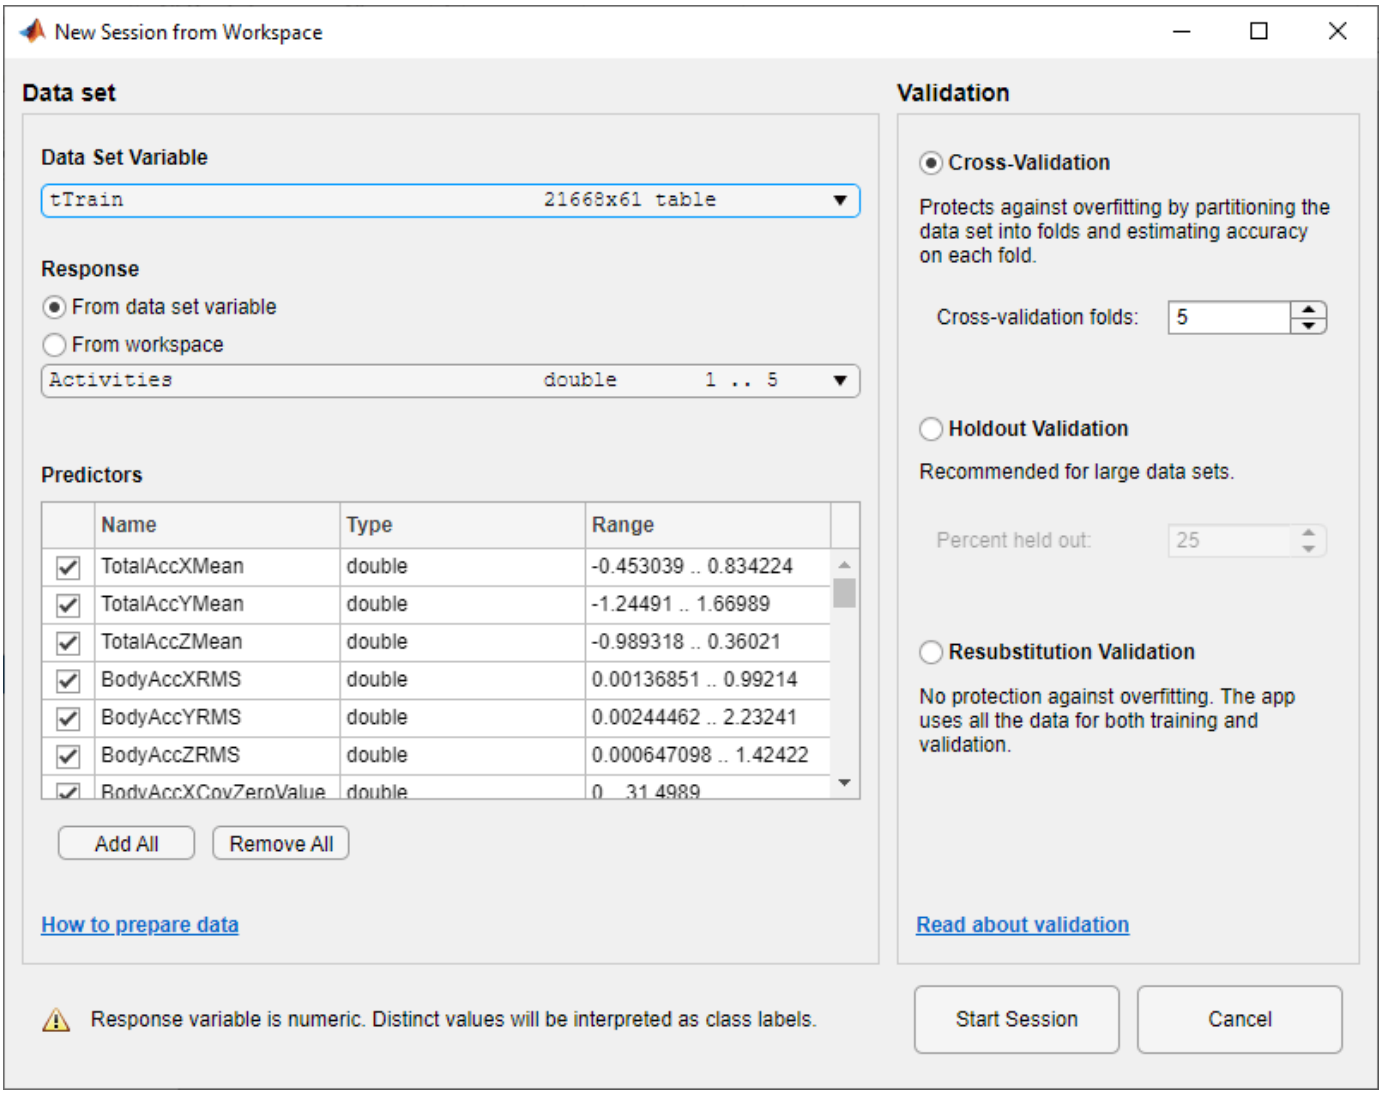
```
tTrain.Properties.VariableNames = [featlabels' 'Activities'];
```

Train Boosted Tree Ensemble Using Classification Learner App

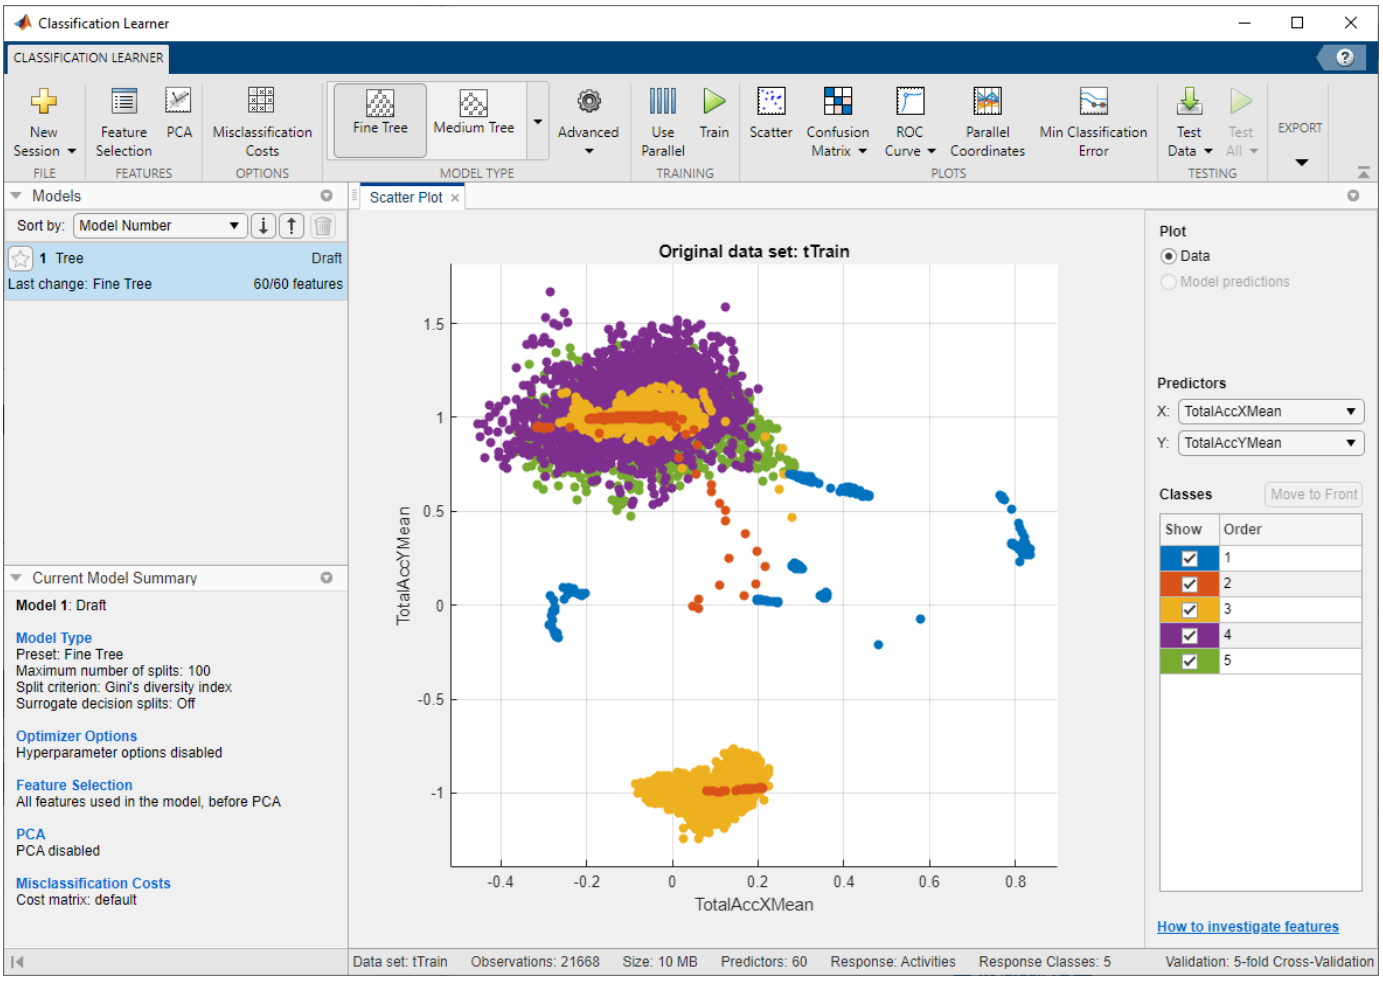
Train a classification model by using the Classification Learner app. To open the Classification Learner app, enter `classificationLearner` at the command line. Alternatively, click the **Apps** tab, and click the arrow at the right of the **Apps** section to open the gallery. Then, under **Machine Learning and Deep Learning**, click **Classification Learner**.

On the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

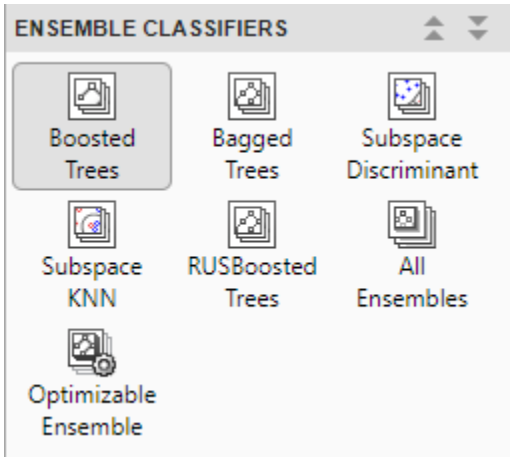
In the New Session from Workspace dialog box, click the arrow for **Data Set Variable**, and then select the table `tTrain`. Classification Learner detects the predictors and the response from the table.



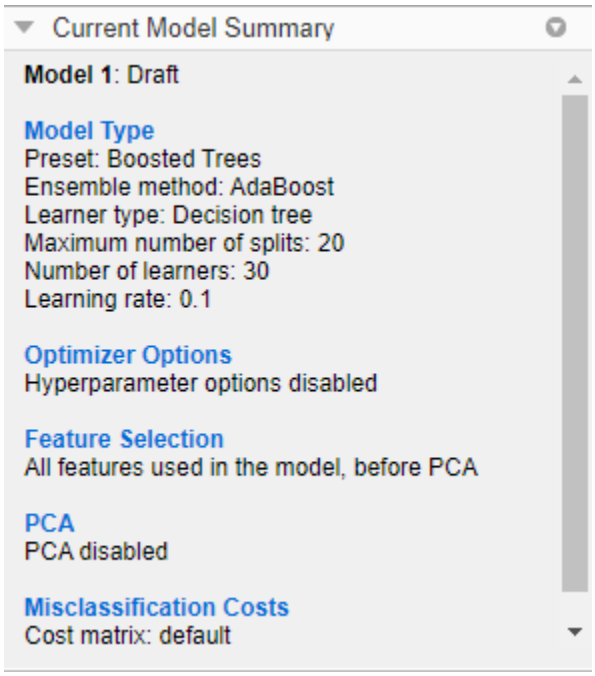
The default option is 5-fold cross-validation, which protects against overfitting. Click **Start Session**. Classification Learner loads the data set and plots a scatter plot of the first two features.



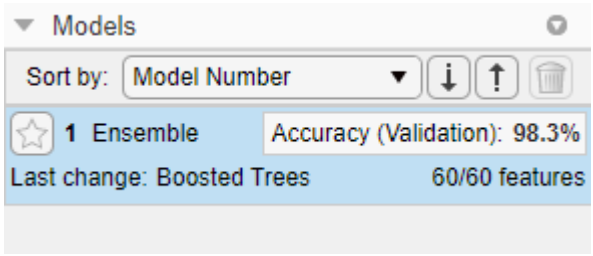
On the **Classification Learner** tab, click the arrow at the right of the **Model Type** section to open the gallery. Then, under **Ensemble Classifiers**, click **Boosted Trees**.



The **Current Model Summary** pane displays the default settings of the boosted tree ensemble model.



On the **Classification Learner** tab, in the **Training** section, click **Train**. When the training is complete, the **Models** pane displays the 5-fold, cross-validated classification accuracy.



On the **Classification Learner** tab, in the **Export** section, click **Export Model**, and then select **Export Compact Model**. Click **OK** in the dialog box. The structure `trainedModel` appears in the MATLAB® Workspace. The field `ClassificationEnsemble` of `trainedModel` contains the compact model. Extract the trained model from the structure.

```
classificationEnsemble = trainedModel.ClassificationEnsemble;
```

Train Boosted Tree Ensemble at Command Line

Alternatively, you can train the same classification model at the command line.

```
template = templateTree('MaxNumSplits',20,'Reproducible',true);
classificationEnsemble = fitcensemble(XTrain,YTrain, ...
    'Method','AdaBoostM2', ...
    'NumLearningCycles',30, ...
    'Learners',template, ...
    'LearnRate',0.1, ...
    'ClassNames',[1; 2; 3; 4; 5]);
```

Perform 5-fold cross-validation for `classificationEnsemble` and compute the validation accuracy.

```
partitionedModel = crossval(classificationEnsemble,'KFold',5);
validationAccuracy = 1-kfoldLoss(partitionedModel)
```

```
validationAccuracy = 0.9833
```

Evaluate Performance on Test Data

Evaluate performance on the test data set.

```
testAccuracy = 1-loss(classificationEnsemble,XTest,YTest)
```

```
testAccuracy = 0.9759
```

The trained model correctly classifies 97.59% of the human activities on the test data set. This result confirms that the trained model does not overfit to the training data set.

Note that the accuracy values can vary slightly depending on your operating system.

Save Trained Model

For code generation including a classification model object, use `saveLearnerForCoder` and `loadLearnerForCoder`.

Save the trained model by using `saveLearnerForCoder`.

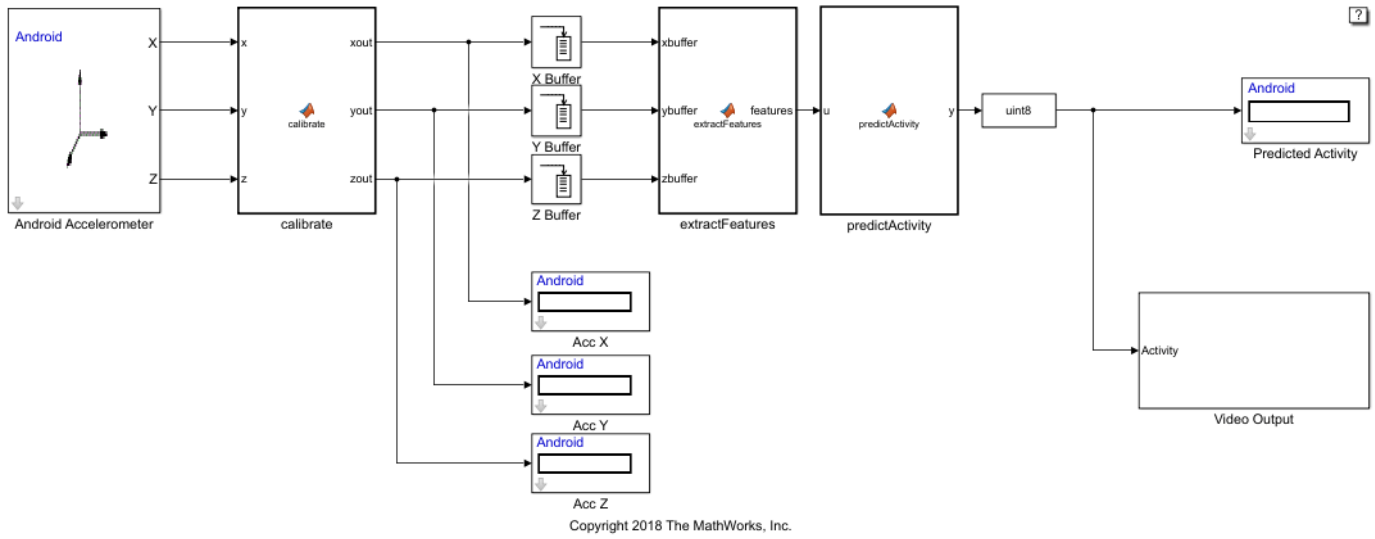
```
saveLearnerForCoder(classificationEnsemble,'EnsembleModel.mat');
```

The function block **predictActivity** in the Simulink models loads the trained model by using `loadLearnerForCoder` and uses the trained model to classify new data.

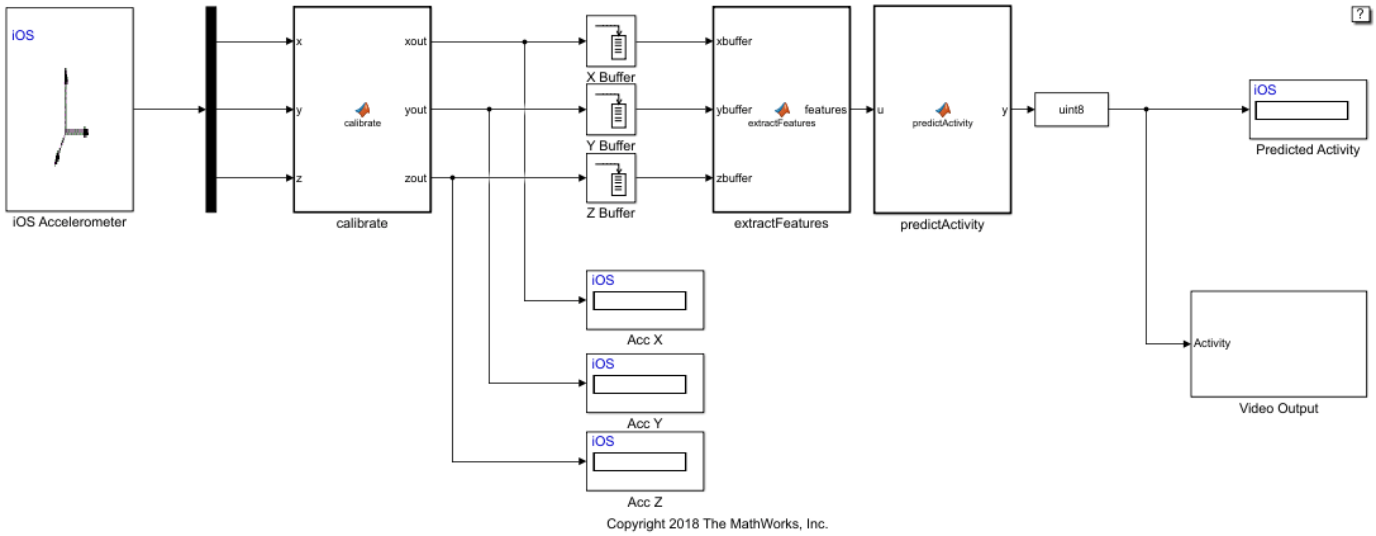
Deploy Simulink Model to Device

Now that you have prepared a classification model, you can open the Simulink model, depending on which type of smartphone you have, and deploy the model to your device. Note that the Simulink model requires the `EnsembleModel.mat` file and the calibration matrix file `slexHARAndroidCalibrationMatrix.mat` or `slexHARiOSCalibrationMatrix.mat`. If you click the button located in the upper-right section of this page and open this example in MATLAB, then MATLAB opens the example folder that includes these calibration matrix files.

Type `slexHARAndroidExample` to open the Simulink model for Android deployment.



Type `slexHARiOSExample` to open the Simulink model for iOS deployment. You can open the model on the Mac OS platform.



The two Simulink models classify human activity based on acceleration data measured by a smartphone sensor. The models include the following blocks:

- The **Accelerometer** block receives raw acceleration data from accelerometer sensors on the device.
- The **calibrate** block is a MATLAB Function block that calibrates the raw acceleration data. This block uses the calibration matrix in the `slexHARAndroidCalibrationMatrix.mat` file or the `slexHARiOSCalibrationMatrix.mat` file. If you click the button located in the upper-right section of this page and open this example in MATLAB, then MATLAB opens the example folder that includes these files.
- The display blocks **Acc X**, **Acc Y**, and **Acc Z** are connected to the **calibrate** block and display calibrated data points for each axis on the device.

- Each of the **Buffer** blocks, **X Buffer**, **Y Buffer**, and **Z Buffer**, buffers 32 samples of an accelerometer axis with 12 samples of overlap between buffered frames. After collecting 20 samples, each **Buffer** block joins the 20 samples with 12 samples from the previous frame and passes the total 32 samples to the **extractFeatures** block. Each **Buffer** block receives an input sample every 0.1 second and outputs a buffered frame including 32 samples every 2 seconds.
- The **extractFeatures** block is a MATLAB Function block that extracts 60 features from a buffered frame of 32 accelerometer samples. This function block uses DSP System Toolbox™ and Signal Processing Toolbox™.
- The **predictActivity** block is a MATLAB Function block that loads the trained model from the `EnsembleModel.mat` file by using `loadLearnerForCoder` and classifies the user activity using the extracted features. The output is an integer between 1 and 5, corresponding to Sitting, Standing, Walking, Running, and Dancing, respectively.
- The **Predicted Activity** block displays the classified user activity values on the device.
- The **Video Output** subsystem uses a multiport switch block to choose the corresponding user activity image data to display on the device. The **Convert to RGB** block decomposes the selected image into separate RGB vectors and passes the image to the **Activity Display** block.

To deploy the Simulink model to your device, follow the steps in “Run Model on Android Devices” (Simulink Support Package for Android Devices) or “Run Model on Apple iOS Devices” (Simulink Support Package for Apple iOS Devices). Run the model on your device, place the device in the same way as described earlier for collecting the training data, and try the five activities. The model displays the classified activity accordingly.

To ensure the accuracy of the model, you need to place your device in the same way as described for collecting the training data. If you want to place your device in a different location or orientation, then collect the data in your own way and use your data to train the classification model.

The accuracy of the model can be different from the accuracy of the test data set (`testaccuracy`), depending on the device. To improve the model, you can consider using additional sensors and updating the calibration matrix. Also, you can add another output block for audio feedback to the output subsystem using Audio Toolbox™. Use a ThingSpeak™ write block to publish classified

activities and acceleration data from your device to the Internet of Things. For details, see https://thingspeak.com/.

Human Activity Recognition Simulink Model for Fixed-Point Deployment

This example shows how to prepare a Simulink® model that classifies human activity based on sensor signals for code generation and deployment to low-power hardware. The example provides a Simulink classification model that is ready for deployment to a BBC micro:bit device. First, download and install Simulink Coder™ Support Package for BBC micro:bit from the Add-On Explorer. Then, train the classification model and deploy the Simulink model to the target device.

Load Sample Data Set

Load the `humanactivity` data set.

```
load humanactivity
```

The `humanactivity` data set contains 24,075 observations of five physical human activities: Sitting, Standing, Walking, Running, and Dancing. Each observation has 60 features extracted from acceleration data measured by smartphone accelerometer sensors. The data set contains the following variables:

- `actid` — Response vector containing the activity IDs in integers: 1, 2, 3, 4, and 5 representing Sitting, Standing, Walking, Running, and Dancing, respectively
- `actnames` — Activity names corresponding to the integer activity IDs
- `feat` — Feature matrix of 60 features for 24,075 observations
- `featlabels` — Labels of the 60 features

The Sensor HAR (human activity recognition) App [1] on page 32-0 was used to create the `humanactivity` data set. When measuring the raw acceleration data with this app, a person placed a smartphone in a pocket so that the smartphone was upside down and the screen faced toward the person. The software then calibrated the measured raw data accordingly and extracted the 60 features from the calibrated data. For details about the calibration and feature extraction, see [2] on page 32-0 and [3] on page 32-0 , respectively. The Simulink models described later also use the raw acceleration data and include blocks for calibration and feature extraction.

To reduce the memory footprint for fixed-point deployment, specify to use only the first 15 features of the data set in the trained classifier.

```
feat = feat(:,1:15);
featlabels = featlabels(1:15);
```

Prepare Data

This example uses 90% of the observations to train a model that classifies the five types of human activities, and 10% of the observations to validate the trained model. Use `cvpartition` to specify a 10% holdout for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(actid,'Holdout',0.10);
```

Extract the training and test indices.

```
trainInds = training(Partition);
testInds = test(Partition);
```

Specify the training and test data sets.

```
XTrain = feat(trainInds,:);
YTrain = actid(trainInds);
XTest = feat(testInds,:);
YTest = actid(testInds);
```

Train Decision Tree at Command Line

Train a fitted binary classification decision tree using the predictors `XTrain` and class labels `YTrain`. A recommended practice is to specify the class names. Also, specify a maximum of 20 branch nodes for the decision tree.

```
classificationTree = fitctree(XTrain,YTrain,...
    'ClassNames',[1;2;3;4;5],...
    'MaxNumSplits',20)
```

```
classificationTree =
  ClassificationTree
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: [1 2 3 4 5]
           ScoreTransform: 'none'
          NumObservations: 21668

  Properties, Methods
```

Perform 5-fold cross-validation for `classificationTree` and compute the validation accuracy.

```
partitionedModel = crossval(classificationTree,'KFold',5);
validationAccuracy = 1-kfoldLoss(partitionedModel)
```

```
validationAccuracy = 0.9700
```

Alternatively, you can train and cross-validate the same classification model using the Classification Learner app. For a similar example, see “Human Activity Recognition Simulink Model for Smartphone Deployment” on page 32-66.

Evaluate Performance on Test Data

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
testAccuracy = 1-loss(classificationTree,XTest,YTest)
```

```
testAccuracy = 0.9617
```

The trained model correctly classifies 96.17% of the human activities on the test data set. This result confirms that the trained model does not overfit to the training data set.

Note that the accuracy values can vary slightly depending on your operating system.

Predict in Simulink Model

Now that you have prepared a classification model, you can open the Simulink model. You can import the trained classification object containing the decision tree `classificationTree` into a ClassificationTree Predict block. You can add this block from the Statistics and Machine Learning

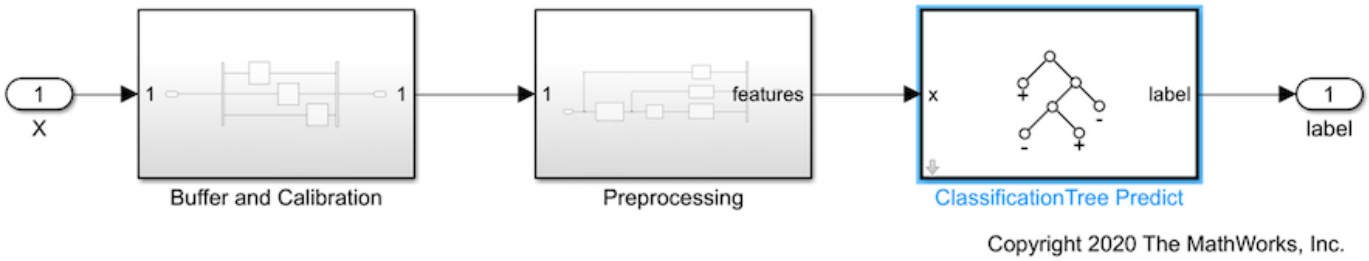
Toolbox™ library. For more information on how to create a model that includes a **ClassificationTree Predict** block, see “Predict Class Labels Using ClassificationTree Predict Block” on page 32-121. In this case, you will use the Simulink model `slexHARFixedPointExample` provided with this example.

Create a large set of accelerometer data `ts` to use as input to the Simulink model.

```
inData = load('rawAccData');
Xacc = inData.acc_data;
t = 0:size(Xacc,1)-1;
ts = timeseries(Xacc,t,'InterpretSingleRowDataAs3D',true);
numSteps = numel(t)-1;
```

Open the Simulink model `slexHARFixedPointExample` by entering the following at the command line. Note that the Simulink model includes callbacks that load necessary variables for the preprocessing subsystem into the base workspace.

```
slexHARFixedPointExample
```



The `slexHARFixedPointExample` model contains the following blocks:

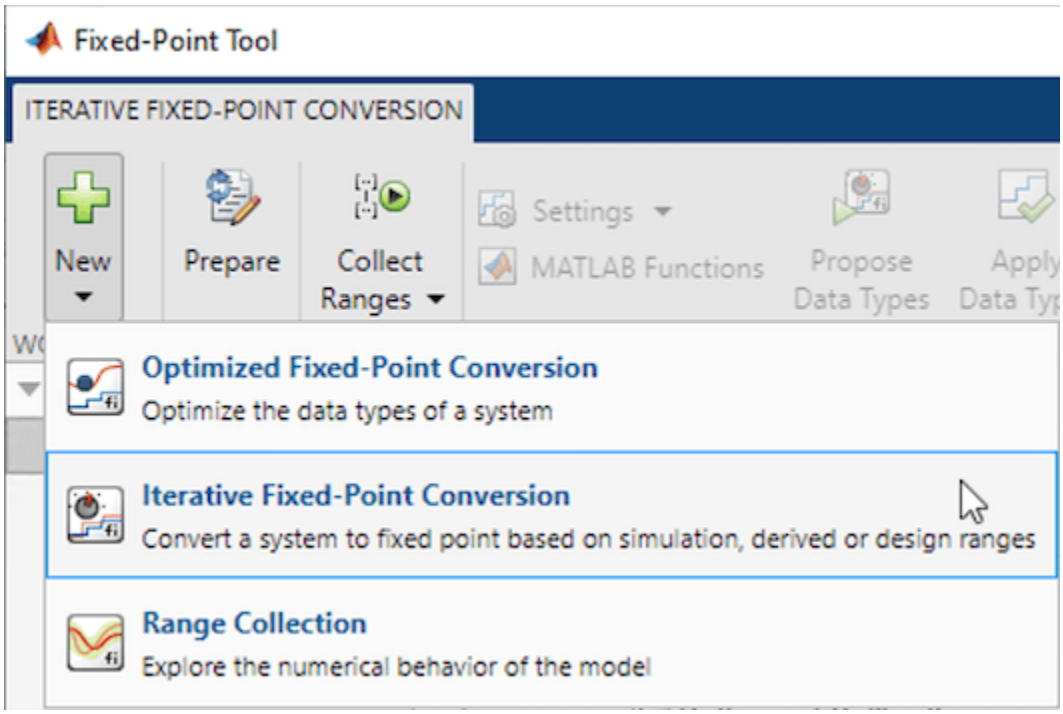
- The **X** block (input port) links the signal `ts` from the Workspace into the system.
- The **Buffer and Calibration** block contains three **Buffer** blocks: **X Buffer**, **Y Buffer**, and **Z Buffer**. Each of these blocks buffers 32 samples of an accelerometer axis with 12 samples of overlap between buffered frames. After collecting 20 samples, each **Buffer** block joins them with 12 samples from the previous frame and passes the total of 32 samples to the **Preprocessing** block. Each **Buffer** block receives an input sample every 0.1 second and outputs a buffered frame including 32 samples every 2 seconds.
- The **Preprocessing** block extracts 15 features from a buffered frame of 32 accelerometer samples. This subsystem block uses DSP System Toolbox™ and Signal Processing Toolbox™.
- The **ClassificationTree Predict** block is a library block from the Statistics and Machine Learning Toolbox library that classifies the human activities using the extracted features. The output is an integer between 1 and 5, corresponding to Sitting, Standing, Walking, Running, and Dancing, respectively.

Convert to Fixed-Point

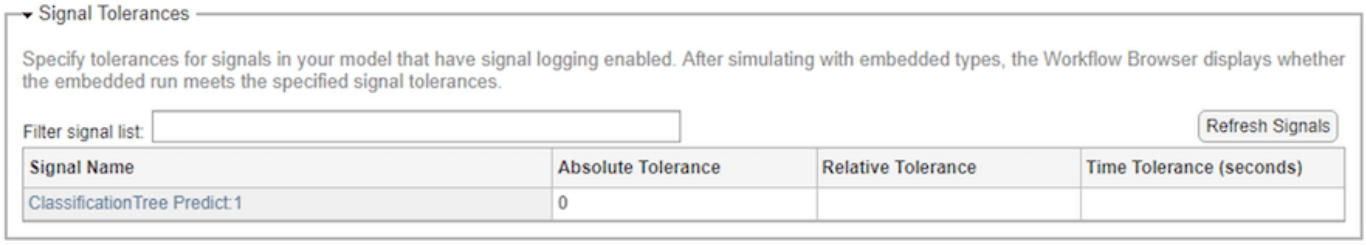
Convert the `slexHARFixedPointExample` model to the fixed-point model `slexHARFixedPointConvertedExample`. Then, deploy `slexHARFixedPointConvertedExample` to the BBC micro:bit board. The target device does not have a floating-point unit (FPU), and performs fixed-point calculations more efficiently than floating-point calculations.

In the `slexHARFixedPointExample` model, right-click the **Label** port and select **Log Selected Signals**. Then, open the **Fixed-Point Tool** app by selecting it from the apps gallery, available from

the **Apps** tab. In the Fixed-Point Tool, under **New** workflow, select `Iterative Fixed-Point Conversion`.



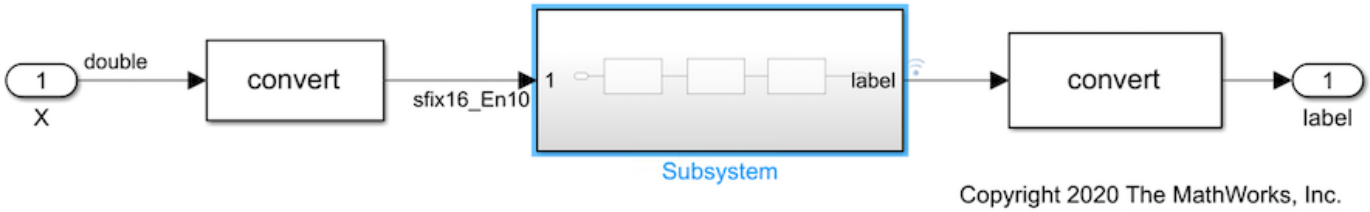
On the **Iterative Fixed-Point Conversion** tab, in the **Signal Tolerances** section, specify the acceptable level of tolerance (difference between the original value and the value of the new design) for the `label` signal. A recommended practice for classification models is to specify 0 absolute tolerance. With this setting, the labels returned by the fixed-point classification model must be the same as the labels returned by the floating-point model. (For regression models, the acceptable tolerance can be a nonzero user-specified number.)



Then, review the steps in the example “Convert Floating-Point Model to Fixed Point” (Fixed-Point Designer) to learn how to create a Simulink model that is converted to fixed-point.

Open the fixed-point Simulink model `slexHARFixedPointConvertedExample` by entering the following at the command line. The **Subsystem** block contains the **Buffer and Calibration**, **Preprocessing**, and **ClassificationTree Predict** blocks as shown earlier for the `slexHARFixedPointExample` model.

```
slexHARFixedPointConvertedExample
```

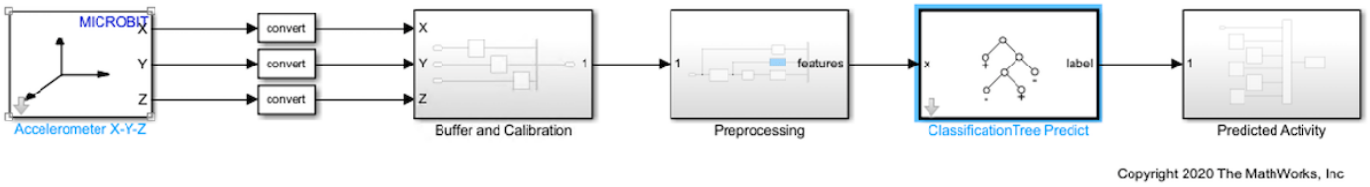


Alternatively, you can select the `Optimized Fixed-Point Conversion` workflow in the **Fixed-Point Tool** app or manually define the data type in the block dialog box. For more information, see "Configure Blocks with Fixed-Point Output" (Fixed-Point Designer).

Deploy to Hardware

Open the Simulink model for deployment to the BBC micro:bit device by entering the following at the command line. The `slexHARFixedPointDeployExample` model is converted to fixed-point, and has I/O blocks for the accelerometer and display ports on the target device.

```
slexHARFixedPointDeployExample
```



The Simulink model `slexHARFixedPointDeployExample` classifies the human activities based on acceleration data measured by a smartphone sensor. The model includes the following blocks:

- The **Accelerometer** block receives raw acceleration data from accelerometer sensors on the device.
- The **Buffer and Calibration**, **Preprocessing**, and **ClassificationTree Predict** blocks are the same as those shown earlier for the `slexHARFixedPointExample` model.
- The **Predicted Activity** block displays the classified human activity values on the 5x5 LED matrix of the BBC micro:bit device. The letters "S", "T", "W", "R", and "D" represent Sitting, Standing, Walking, Running, and Dancing, respectively.

To deploy the Simulink model to your device, follow the steps in "Getting Started with Simulink Coder Support Package for BBC micro:bit" (Simulink Coder Support Package for BBC micro:bit). Run the model on your device, place the device in the same way as described earlier for collecting the training data, and try the five activities. The model displays the classified activity accordingly.

To ensure the accuracy of the model, you must place your device in the same way as described for collecting the training data. If you want to place your device in a different location or at a different orientation, then collect the data in your own way and use your data to train the classification model.

The accuracy of the model can be different from the accuracy of the test data set (`testAccuracy`), depending on the device. To improve the model accuracy, consider using additional sensors, such as a gyroscope.

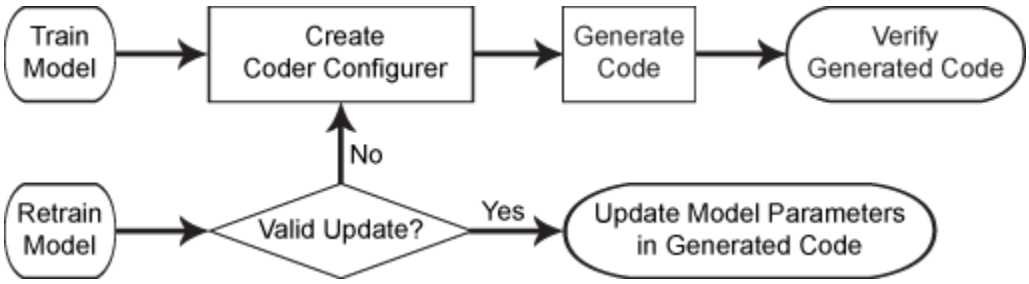
Code Generation for Prediction and Update Using Coder Configurer

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes of model parameters using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the model by using `generateCode`. This requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow for the `predict` and `update` functions using a coder configurer.



This table shows coder configurer objects corresponding to the supported machine learning models.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	`ClassificationTreeCoderConfigurer`
SVM for one-class and binary classification	`ClassificationSVMCoderConfigurer`
Linear model for binary classification	`ClassificationLinearCoderConfigurer`
Multiclass model for SVMs and linear models	`ClassificationECOCCoderConfigurer`
Binary decision tree for regression	`RegressionTreeCoderConfigurer`
Support vector machine (SVM) regression	`RegressionSVMCoderConfigurer`
Linear regression	`RegressionLinearCoderConfigurer`

For details and examples, see the reference pages for the coder configurer objects.

Code Generation for Probability Distribution Objects

This example shows how to generate code that fits a probability distribution to sample data and evaluates the fitted distribution.

First, define an entry-point function that uses `fitdist` to create a probability distribution object and uses its object functions to evaluate the fitted distribution. Then, generate code for the entry-point function by using `codegen` (MATLAB Coder). An entry-point function can have a probability distribution object as both an input argument and an output argument. Therefore, alternatively, you can define two entry-point functions, one for fitting a distribution and the other for evaluating the fitted distribution. The first entry-point function returns a fitted distribution, and the second entry-point function accepts the fitted distribution as an input argument. This example first describes the workflow with a single entry-point function, and then briefly describes the workflow with two entry-point functions.

`fitdist` supports code generation for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. The supported object functions of the fitted probability distribution objects, created by `fitdist`, are `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “General Code Generation Workflow” on page 32-5.

Define Entry-Point Function

Define an entry-point function named `myFitandEvaluate` that takes the sample data, distribution name, truncation limits of the distribution, and data values at which to evaluate the cumulative distribution function (cdf) and probability density function (pdf). Within the entry-point function, fit a probability distribution object to the sample data, truncate the distribution to the specified truncation limits, compute the mean of the truncated distribution, and compute the cdf and pdf values at the specified data values.

Display the contents of the `myFitandEvaluate.m` file.

```
type myFitandEvaluate.m
```

```
function [pd_truncated,st] = myFitandEvaluate(data,distname,truncation_limits,x) %#codegen
% Fit a probability distribution object to data.
pd = fitdist(data,distname);

% Truncate pd.
pd_truncated = truncate(pd,truncation_limits(1),truncation_limits(2));

% Compute the mean of the truncated pd.
mean_val = mean(pd_truncated);

% Compute the cdf and pdf, evaluated at x.
cdf_val = cdf(pd_truncated,x);
pdf_val = pdf(pd_truncated,x);

% Create a structure array containing the mean, cdf, and pdf values.
st = struct('mean', mean_val,'cdf',cdf_val,'pdf',pdf_val);
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function files for this example.

Generate Code

Specify the input argument types of `myFitandEvaluate` using a 4-by-1 cell array. Assign each input argument type of the entry-point function to each cell. Specify the data type and exact input array size by using an example value that represents the set of values with a certain data type and array size.

```
ARGS = cell(4,1);
ARGS{1} = ones(100,1);
ARGS{2} = coder.Constant('Exponential');
ARGS{3} = ones(1,2);
ARGS{4} = ones(10,1);
```

The second input of `myFitandEvaluate` is a distribution name, which is the second input argument of `fitdist`. This argument must be a compile-time constant. Therefore, you specify `ARGS{2}` by using `coder.Constant` (MATLAB Coder).

If you want to specify `ARGS{1}` and `ARGS{3}` as variable-size inputs, use `coder.typeof` (MATLAB Coder). For details, see “General Code Generation Workflow” on page 32-5.

Generate a MEX function from the entry-point function `myFitandEvaluate`. Specify the input argument types using the `-args` option and the cell array `ARGS`.

```
codegen myFitandEvaluate -args ARGS
```

```
Code generation successful.
```

`codegen` (MATLAB Coder) generates the MEX function `myFitandEvaluate_mex` with a platform-dependent extension in your current folder.

Verify Generated Code

Pass some data to verify whether `myFitandEvaluate` and `myFitandEvaluate_mex` return the same outputs.

```
rng('default') % For reproducibility
data = exprnd(1,[100,1]); % Exponential random numbers with mean parameter 1
distname = 'Exponential';
truncation_limits = [0,4];
x = (0:9)';
[pd_truncated,st] = myFitandEvaluate(data,distname,truncation_limits,x);
[pd_truncated_mex,st_mex] = myFitandEvaluate_mex(data,distname,truncation_limits,x);
```

Compare the probability distribution objects `pd_truncated` and `pd_truncated_mex`.

```
pd_truncated
```

```
pd_truncated =
  ExponentialDistribution

  Exponential distribution
    mu = 0.917049
  Truncated to the interval [0, 4]
```

```
pd_truncated_mex
```

```
pd_truncated_mex =
  ExponentialDistribution
```

```
  Exponential distribution
    mu = 0.917049
  Truncated to the interval [0, 4]
```

```
verifyMEX_pd = isequal(pd_truncated,pd_truncated_mex)
```

```
verifyMEX_pd = logical
   1
```

`isequal` returns logical 1 (`true`), which means `pd_truncated` and `pd_truncated_mex` are equal.

Compare the structure arrays that contain the mean, cdf, and pdf values.

```
verifyMEX_st = isequal(st,st_mex)
```

```
verifyMEX_st = logical
   1
```

The comparison confirms that `myFitandEvaluate` and `myFitandEvaluate_mex` return the same outputs. The generated code might not produce the same floating-point numerical results as MATLAB, as described in “Differences Between Generated Code and MATLAB Code” (MATLAB Coder). In that case, compare the values allowing a small tolerance.

Workflow with Two Entry-Point Functions

An entry-point function can have a probability distribution object as both an input argument and an output argument. Therefore, you can define two entry-point functions, one for fitting a distribution and the other for evaluating the fitted distribution. Then generate code for the two entry-point functions.

Define Entry-Point Functions

Define two entry-point functions. The first entry-point function `myFitDist` fits a probability distribution object to the sample data. The second entry-point function `myEvaluateDist` truncates the distribution, computes the mean of the truncated distribution, and computes the cdf and pdf values at the specified data values. `myEvaluateDist` takes the output of `myFitDist` as an input argument.

Display the contents of the `myFitDist.m` and `myEvaluateDist.m` files.

```
type myFitDist.m
```

```
function pd = myFitDist(data,dist) %#codegen
% Fit probability distribution object to data.
pd = fitdist(data,dist);
end
```

```
type myEvaluateDist.m
```

```
function [pd_truncated,st] = myEvaluateDist(pd,truncation_limits,x) %#codegen
% Truncate pd.
pd_truncated = truncate(pd,truncation_limits(1),truncation_limits(2));

% Compute the mean of the truncated pd.
```

```
mean_val = mean(pd_truncated);

% Compute the cdf and pdf, evaluated at x.
cdf_val = cdf(pd_truncated,x);
pdf_val = pdf(pd_truncated,x);

% Create a structure array containing the mean, cdf, and pdf values.
st = struct('mean', mean_val,'cdf',cdf_val,'pdf',pdf_val);
end
```

Generate Code

Specify the input argument types of `myFitDist` and `myEvaluateDist`.

```
ARGS_myFitDist = cell(2,1);
ARGS_myFitDist{1} = ones(100,1);
ARGS_myFitDist{2} = coder.Constant('Exponential');

ARGS_myEvaluateDist = cell(3,1);
ARGS_myEvaluateDist{1} = fitdist(exprnd(1,[100,1]),'Exponential');
ARGS_myEvaluateDist{2} = ones(1,2);
ARGS_myEvaluateDist{3} = ones(10,1);
```

If you do not need to generate a MEX function, then you can specify `ARGS_myEvaluateDist{1}` as `coder.OutputType('myFitdist')`, as described in "Pass an Entry-Point Function Output as an Input" (MATLAB Coder). You cannot use `coder.OutputType` (MATLAB Coder) when generating a MEX function, because the data type of the output from `myFitDist` does not match the data type of the input to `myEvaluateDist` in the generated MEX function.

Generate code for the two entry-point functions.

```
codegen -o myFitandEvaluate_mex2 myFitDist -args ARGS_myFitDist myEvaluateDist -args ARGS_myEvalu

Code generation successful.
```

`codegen` (MATLAB Coder) generates the MEX function `myFitandEvaluate_mex2`. For details about generating code for multiple entry-point functions, see "Generate Code for Multiple Entry-Point Functions" (MATLAB Coder).

Verify Generated Code

Verify the generated code.

```
rng('default')
data = exprnd(1,[100,1]);
distname = 'Exponential';
truncation_limits = [0,4];
x = (0:9)';
pd2 = myFitDist(data,distname);
[pd_truncated2,st2] = myEvaluateDist(pd2,truncation_limits,x);
pd_mex2 = myFitandEvaluate_mex2('myFitDist',data,distname);
[pd_truncated_mex2,st_mex2] = myFitandEvaluate_mex2('myEvaluateDist',pd_mex2,truncation_limits,x
verifyMEX_pd2 = isequal(pd2,pd_mex2)

verifyMEX_pd2 = logical
   1

verifyMEX_pd_truncated2 = isequal(pd_truncated2,pd_truncated_mex)
```

```
verifyMEX_pd_truncated2 = logical
   1
```

```
verifyMEX_st2 = isequal(st2,st_mex2)
```

```
verifyMEX_st2 = logical
   1
```

`isequal` returns logical 1 (`true`), which means that the entry-point functions and the corresponding MEX functions return the same outputs.

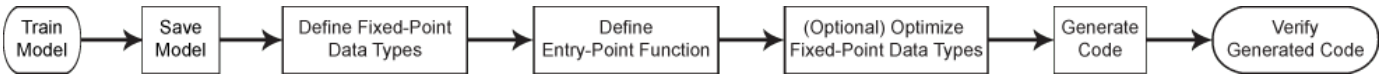
- Function List (C/C++ Code Generation)

Fixed-Point Code Generation for Prediction of SVM

This example shows how to generate fixed-point C/C++ code for the prediction of a support vector machine (SVM) model. Compared to the general C/C++ code generation workflow, fixed-point code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. You can also optimize the fixed-point data types before generating code.

This flow chart shows the fixed-point code generation workflow.



1. Train an SVM model.
2. Save the trained model by using `saveLearnerForCoder`.
3. Define the fixed-point data types of the variables required for prediction by using the data type function generated by `generateLearnerDataTypeFcn`.
4. Define an entry-point function that loads the model by using both `loadLearnerForCoder` and the structure, and then calls the `predict` function.
5. (Optional) Optimize the fixed-point data types.
6. Generate fixed-point C/C++ code.
7. Verify the generated code.

Step 5 is an optional step to improve the performance of the generated fixed-point code. To do so, repeat these two steps until you are satisfied with the code performance:

1. Record minimum and maximum values of the variables for prediction by using `buildInstrumentedMex` (Fixed-Point Designer).
2. View the instrumentation results using `showInstrumentationResults` (Fixed-Point Designer). Then, tune the fixed-point data types (if necessary) to prevent overflow and underflow, and to improve the precision of the fixed-point code.

In this workflow, you define the fixed-point data types by using the data type function generated from `generateLearnerDataTypeFcn`. Separating data types of the variables from the algorithm makes testing simpler. You can programmatically toggle data types between floating-point and fixed-point by using the input argument of the data type function. Also, this workflow is compatible with “Manual Fixed-Point Conversion Workflow” (Fixed-Point Designer).

Preprocess Data

Load the `census1994` data set. This data set consists of demographic data from the US Census Bureau used to predict whether an individual makes over $50,000 a year.

```
load census1994
```

Consider a model that predicts the salary category of employees given their age, working class, education level, capital gain and loss, and number of working hours per week. Extract the variables of interest and save them using a table.

```
tbl = adultdata(:,{'age','education_num','capital_gain','capital_loss','hours_per_week'});
```

Print a summary of the table.

```
summary(tbl)
```

```
Variables:

    age: 32561x1 double

        Values:

            Min          17
            Median       37
            Max          90

    education_num: 32561x1 double

        Values:

            Min           1
            Median       10
            Max          16

    capital_gain: 32561x1 double

        Values:

            Min            0
            Median         0
            Max        99999

    capital_loss: 32561x1 double

        Values:

            Min            0
            Median         0
            Max         4356

    hours_per_week: 32561x1 double

        Values:

            Min           1
            Median       40
            Max          99
```

The scales of the variables are not consistent. In this case, you can train a model using a standardized data set by specifying the `'Standardize'` name-value pair argument of `fitcsvm`. However, adding the operations for standardization to the fixed-point code can reduce precision and increase memory use. Instead, you can manually standardize the data set, as shown in this example. The example also describes how to check the memory use at the end.

Fixed-point code generation does not support tables or categorical arrays. So, define the predictor data `X` using a numeric matrix, and define the class labels `Y` using a logical vector. A logical vector uses memory most efficiently in a binary classification problem.

```
X = table2array(tbl);
Y = adultdata.salary == '<=50K';
```

Define the observation weights `w`.

```
w = adultdata.fnlwgt;
```

The memory use of a trained model increases as the number of support vectors in the model increases. To reduce the number of support vectors, you can increase the box constraint when training by using the `'BoxConstraint'` name-value pair argument or use a subsampled representative data set for training. Note that increasing the box constraint can lead to longer training times, and using a subsampled data set can reduce the accuracy of the trained model. In this example, you randomly sample 1000 observations from the data set and use the subsampled data for training.

```
rng('default') % For reproducibility
[X_sampled,idx] = datasample(X,1000,'Replace',false);
Y_sampled = Y(idx);
w_sampled = w(idx);
```

Find the weighted means and standard deviations by training the model using the `'Weight'` and `'Standardize'` name-value pair arguments.

```
tempMdl = fitcsvm(X_sampled,Y_sampled,'Weight',w_sampled,'KernelFunction','gaussian','Standardize
mu = tempMdl.Mu;
sigma = tempMdl.Sigma;
```

If you do not use the `'Cost'`, `'Prior'`, or `'Weight'` name-value pair argument for training, then you can find the mean and standard deviation values by using the `zscore` function.

```
[standardizedX_sampled,mu,sigma] = zscore(X_sampled);
```

Standardize the predictor data by using `mu` and `sigma`.

```
standardizedX = (X-mu)./sigma;
standardizedX_sampled = standardizedX(idx,:);
```

You can use a test data set to validate the trained model and to test an instrumented MEX function. Specify a test data set and standardize the test predictor data by using `mu` and `sigma`.

```
XTest = table2array(adulttest(:,{'age','education_num','capital_gain','capital_loss','hours_per_w
standardizedXTest = (XTest-mu)./sigma;
YTest = adulttest.salary == '<=50K';
```

Train Model

Train a binary SVM classification model.

```
Mdl = fitcsvm(standardizedX_sampled,Y_sampled,'Weight',w_sampled,'KernelFunction','gaussian');
```

`Mdl` is a `ClassificationSVM` model.

Compute the classification error for the training data set and the test data set.

```
loss(Mdl,standardizedX_sampled,Y_sampled)
```

```
ans = 0.1663
```

```
loss(Mdl,standardizedXTest,YTest)
```

```
ans = 0.1905
```

The SVM classifier misclassifies approximately 17% of the training data and 19% of the test data.

Save Model

Save the SVM classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'myMdl');
```

Define Fixed-Point Data Types

Use `generateLearnerDataTypeFcn` to generate a function that defines the fixed-point data types of the variables required for prediction of the SVM model. Use all available predictor data to obtain realistic ranges for the fixed-point data types.

```
generateLearnerDataTypeFcn('myMdl',[standardizedX; standardizedXTest])
```

`generateLearnerDataTypeFcn` generates the `myMdl_datatype` function. Display the contents of `myMdl_datatype.m` by using the `type` function.

```
type myMdl_datatype.m
```

```
function T = myMdl_datatype(dt)
%MYMDL_DATATYPE Define data types for fixed-point code generation
%
%   T = MYMDL_DATATYPE(DT) returns the data type structure T, which defines
%   data types for the variables required to generate fixed-point C/C++ code
%   for prediction of a machine learning model. Each field of T contains a
%   fixed-point object returned by fi. The input argument dt specifies the
%   DataType property of the fixed-point object. Specify dt as 'Fixed' (default)
%   for fixed-point code generation or specify dt as 'Double' to simulate
%   floating-point behavior of the fixed-point code.
%
%   Use the output structure T as both an input argument of an entry-point
%   function and the second input argument of loadLearnerForCoder within the
%   entry-point function. For more information, see loadLearnerForCoder.

%   File: myMdl_datatype.m
%   Statistics and Machine Learning Toolbox Version 12.1 (Release R2021a)
%   Generated by MATLAB, 25-Feb-2021 14:04:00

if nargin < 1
    dt = 'Fixed';
end

% Set fixed-point math settings
fm = fimath('RoundingMethod','Floor', ...
    'OverflowAction','Wrap', ...
    'ProductMode','FullPrecision', ...
    'MaxProductWordLength',128, ...
    'SumMode','FullPrecision', ...
    'MaxSumWordLength',128);

% Data type for predictor data
T.XDataType = fi([],true,16,11,fm,'DataType',dt);

% Data type for output score
T.ScoreDataType = fi([],true,16,14,fm,'DataType',dt);
```

```
% Internal variables
% Data type of the squared distance dist = (x-sv)^2 for the Gaussian kernel G(x,sv) = exp(-dist)
% where x is the predictor data for an observation and sv is a support vector
T.InnerProductDataType = fi([],true,16,6,fm,'DataType',dt);

end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

The `myMdl_datatype` function uses the default word length (16) and proposes the maximum fraction length to avoid overflows, based on the default word length (16) and safety margin (10%) for each variable.

Create a structure `T` that defines the fixed-point data types by using `myMdl_datatype`.

```
T = myMdl_datatype('Fixed')
```

```
T = struct with fields:
              XDataType: [0x0 embedded.fi]
           ScoreDataType: [0x0 embedded.fi]
    InnerProductDataType: [0x0 embedded.fi]
```

The structure `T` includes the fields for the named and internal variables required to run the `predict` function. Each field contains a fixed-point object, returned by `fi` (Fixed-Point Designer). For example, display the fixed-point data type properties of the predictor data.

```
T.XDataType
```

```
ans =

[]

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 11

        RoundingMethod: Floor
        OverflowAction: Wrap
           ProductMode: FullPrecision
  MaxProductWordLength: 128
               SumMode: FullPrecision
     MaxSumWordLength: 128
```

For more details about the generated function and the structure, see “Data Type Function” on page 33-2631.

Define Entry-Point Function

Define an entry-point function named `myFixedPointPredict` that does the following:

- Accept the predictor data `X` and the fixed-point data type structure `T`.
- Load a fixed-point version of a trained SVM classification model by using both `loadLearnerForCoder` and the structure `T`.

- Predict labels and scores using the loaded model.

```
function [label,score] = myFixedPointPredict(X,T) %#codegen
Mdl = loadLearnerForCoder('myMdl','DataType',T);
[label,score] = predict(Mdl,X);
end
```

(Optional) Optimize Fixed-Point Data Types

Optimize the fixed-point data types by using `buildInstrumentedMex` and `showInstrumentationResults`. Record minimum and maximum values of all named and internal variables for prediction by using `buildInstrumentedMex`. View the instrumentation results using `showInstrumentationResults`; then, based on the results, tune the fixed-point data type properties of the variables.

Specify Input Argument Types of Entry-Point Function

Specify the input argument types of `myFixedPointPredict` using a 2-by-1 cell array.

```
ARGS = cell(2,1);
```

The first input argument is the predictor data. The `XDataType` field of the structure `T` specifies the fixed-point data type of the predictor data. Convert `X` to the type specified in `T.XDataType` by using the `cast` (Fixed-Point Designer) function.

```
X_fx = cast(standardizedX,'like',T.XDataType);
```

The test data set does not have the same size as the training data set. Specify `ARGS{1}` by using `coder.typeof` (MATLAB Coder) so that the MEX function can take variable-size inputs.

```
ARGS{1} = coder.typeof(X_fx,size(standardizedX),[1,0]);
```

The second input argument is the structure `T`, which must be a compile-time constant. Use `coder.Constant` (MATLAB Coder) to specify `T` as a constant during code generation.

```
ARGS{2} = coder.Constant(T);
```

Create Instrumented MEX Function

Create an instrumented MEX function by using `buildInstrumentedMex` (Fixed-Point Designer).

- Specify the input argument types of the entry-point function by using the `-args` option.
- Specify the MEX function name by using the `-o` option.
- Compute a histogram by using the `-histogram` option.
- Allow full code generation support by using the `-coder` option.

```
buildInstrumentedMex myFixedPointPredict -args ARGS -o myFixedPointPredict_instrumented -histogra

Code generation successful.
```

Test Instrumented MEX Function

Run the instrumented MEX function to record instrumentation results.

```
[labels_fx1,scores_fx1] = myFixedPointPredict_instrumented(X_fx,T);
```

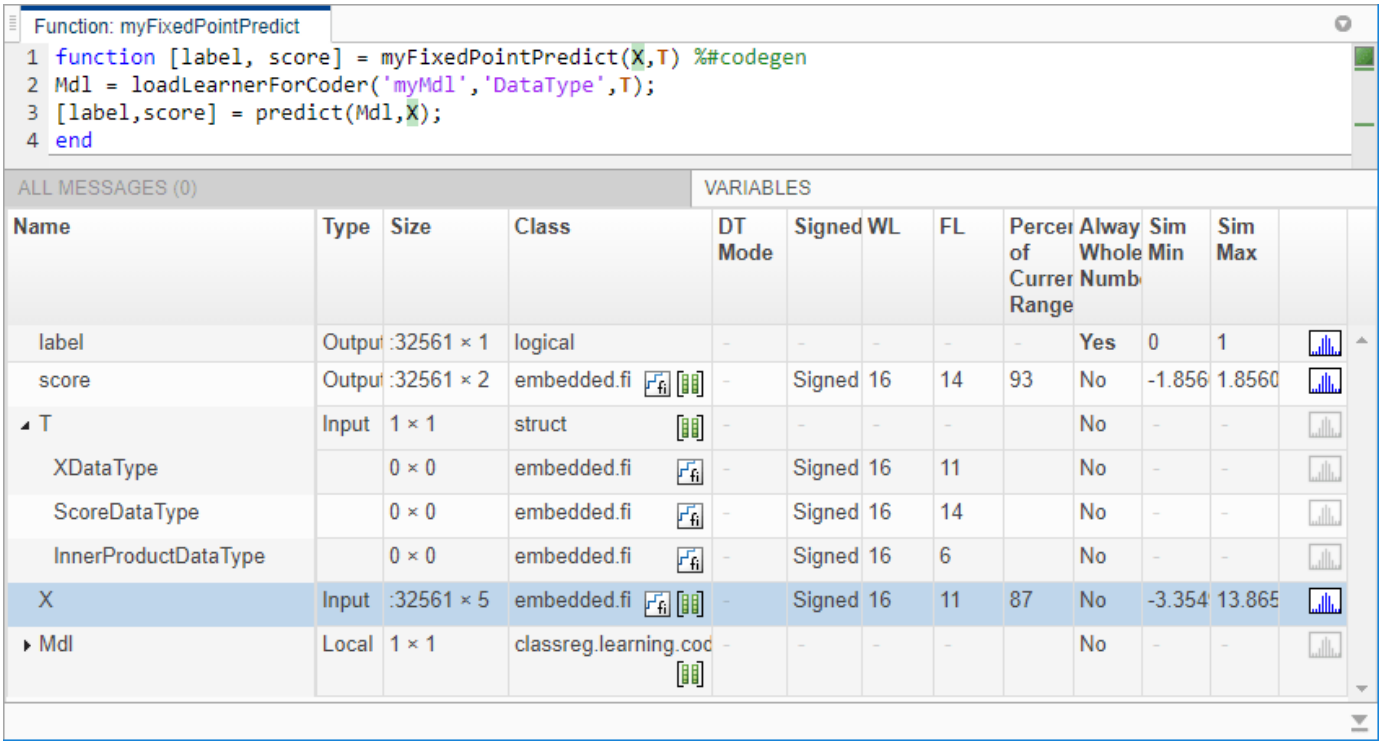
You can run the instrumented MEX function multiple times to record results from various test data sets. Run the instrumented MEX function using `standardizedXTest`.

```
Xtest_fx = cast(standardizedXTest,'like',T.XDataType);
[labels_fx1_test,scores_fx1_test] = myFixedPointPredict_instrumented(Xtest_fx,T);
```

View Results of Instrumented MEX Function

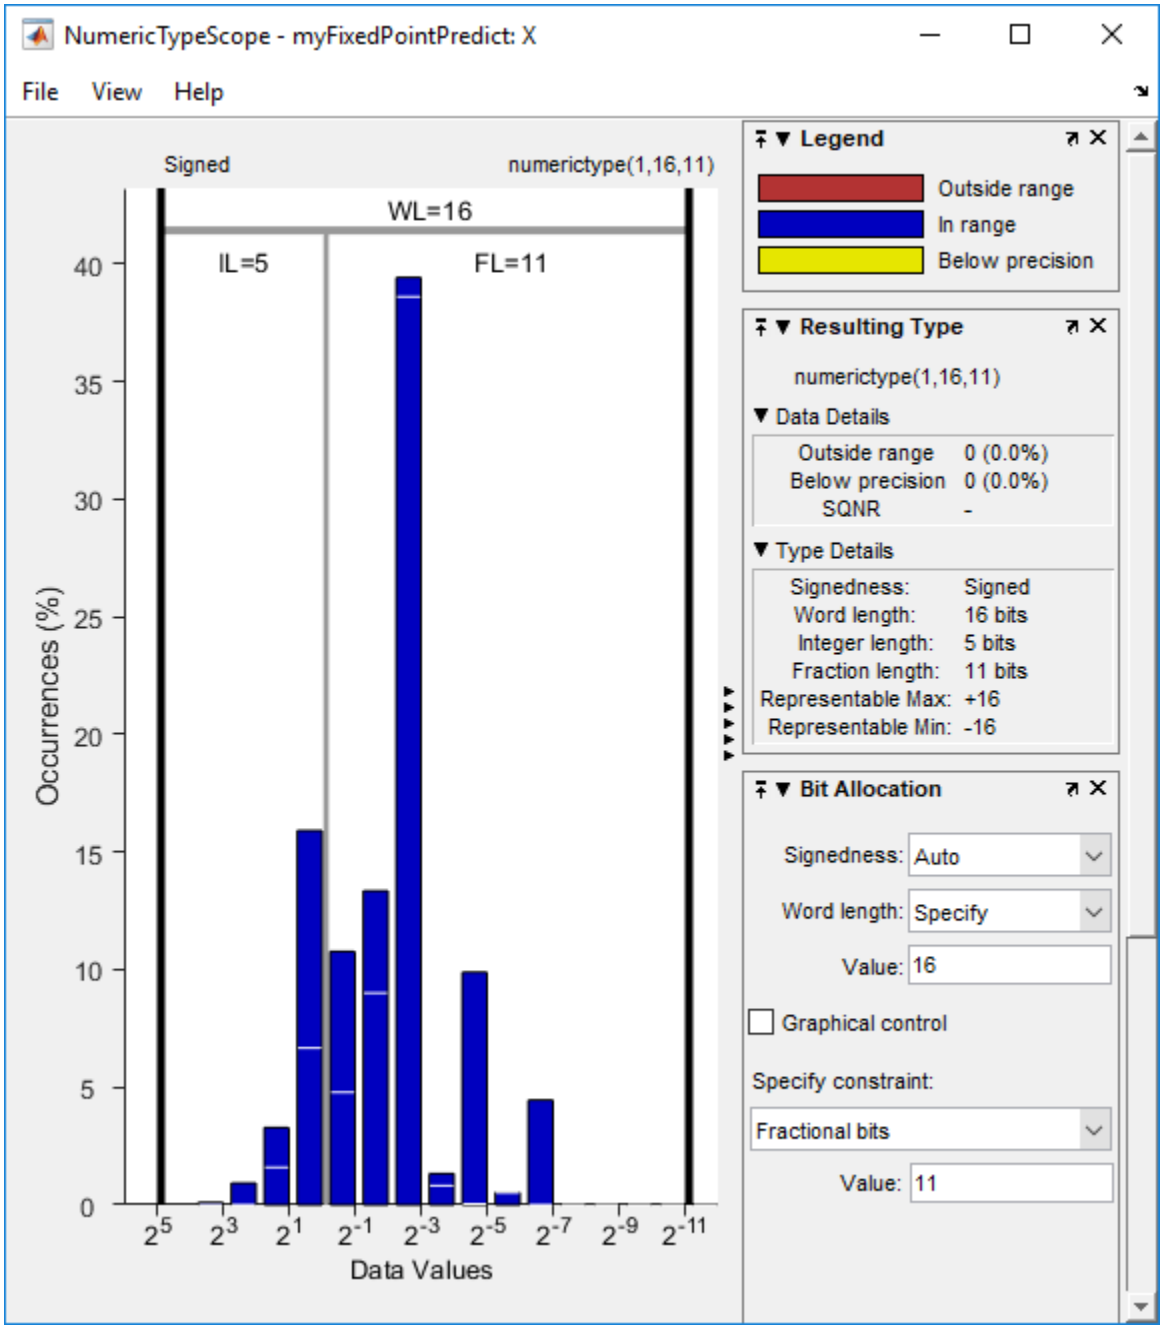
Call `showInstrumentationResults` (Fixed-Point Designer) to open a report containing the instrumentation results. View the simulation minimum and maximum values, proposed fraction length, percent of current range, and whole number status.

```
showInstrumentationResults('myFixedPointPredict_instrumented')
```



The proposed word lengths and fraction lengths in `X` are the same as those in `XDataType` in the structure `T`.

View the histogram for a variable by clicking  on the **Variables** tab.



The window contains the histogram and dialog panels with information about the variable. For information on this window, see the `NumericTypeScope` (Fixed-Point Designer) reference page.

Clear the results by using `clearInstrumentationResults` (Fixed-Point Designer).

```
clearInstrumentationResults('myFixedPointPredict_instrumented')
```

Verify Instrumented MEX Function

Compare the outputs from `predict` and `myFixedPointPredict_instrumented`.

```
[labels,scores] = predict(Mdl,standardizedX);
verify_labels1 = isequal(labels,labels_fx1)
```

```
verify_labels1 = logical
   0
```

`isequal` returns logical 1 (true) if `labels` and `labels_fx1` are equal. If the labels are not equal, you can compute the percentage of incorrectly classified labels as follows.

```
diff_labels1 = sum(strcmp(string(labels_fx1),string(labels))==0)/length(labels_fx1)*100
```

```
diff_labels1 = 0.1228
```

Find the maximum of the relative differences between the score outputs.

```
diff_scores1 = max(abs((scores_fx1.double(:,1)-scores(:,1))./scores(:,1)))
```

```
diff_scores1 = 174.0771
```

Tune Fixed-Point Data Types

You can tune the fixed-point data types if the recorded results show overflow or underflow, or if you want to improve the precision of the generated code. Modify the fixed-point data types by updating the `myMdl_datatype` function and creating a new structure, and then generate the code using the new structure. To update the `myMdl_datatype` function, you can manually modify the fixed-point data types in the function file (`myMdl_datatype.m`). Or, you can generate the function by using `generateLearnerDataTypeFcn` and specifying a longer word length, as shown in this example. For more details, see “Tips” on page 33-2632.

Generate a new data type function. Specify the word length 32 and the name `myMdl_datatype2` for the generated function.

```
generateLearnerDataTypeFcn('myMdl',[standardizedX; standardizedXTest],'WordLength',32,'OutputFun
```

Display the contents of `myMdl_datatype2.m`.

```
type myMdl_datatype2.m
```

```
function T = myMdl_datatype2(dt)
%MYMDL_DATATYPE2 Define data types for fixed-point code generation
%
%   T = MYMDL_DATATYPE2(DT) returns the data type structure T, which defines
%   data types for the variables required to generate fixed-point C/C++ code
%   for prediction of a machine learning model. Each field of T contains a
%   fixed-point object returned by fi. The input argument dt specifies the
%   DataType property of the fixed-point object. Specify dt as 'Fixed' (default)
%   for fixed-point code generation or specify dt as 'Double' to simulate
%   floating-point behavior of the fixed-point code.
%
%   Use the output structure T as both an input argument of an entry-point
%   function and the second input argument of loadLearnerForCoder within the
%   entry-point function. For more information, see loadLearnerForCoder.

%   File: myMdl_datatype2.m
%   Statistics and Machine Learning Toolbox Version 12.1 (Release R2021a)
%   Generated by MATLAB, 25-Feb-2021 14:05:34
```

```
if nargin < 1
    dt = 'Fixed';
end

% Set fixed-point math settings
fm = fimath('RoundingMethod','Floor', ...
    'OverflowAction','Wrap', ...
    'ProductMode','FullPrecision', ...
    'MaxProductWordLength',128, ...
    'SumMode','FullPrecision', ...
    'MaxSumWordLength',128);

% Data type for predictor data
T.XDataType = fi([],true,32,27,fm,'DataType',dt);

% Data type for output score
T.ScoreDataType = fi([],true,32,30,fm,'DataType',dt);

% Internal variables
% Data type of the squared distance dist = (x-sv)^2 for the Gaussian kernel G(x,sv) = exp(-dist)
% where x is the predictor data for an observation and sv is a support vector
T.InnerProductDataType = fi([],true,32,22,fm,'DataType',dt);

end
```

The `myMdl_datatype2` function specifies the word length 32 and proposes the maximum fraction length to avoid overflows.

Create a structure `T2` that defines the fixed-point data types by using `myMdl_datatype2`.

```
T2 = myMdl_datatype2('Fixed')
```

```
T2 = struct with fields:
               XDataType: [0x0 embedded.fi]
          ScoreDataType: [0x0 embedded.fi]
    InnerProductDataType: [0x0 embedded.fi]
```

Create a new instrumented MEX function, record the results, and view the results by using `buildInstrumentedMex` and `showInstrumentationResults`.

```
X_fx2 = cast(standardizedX,'like',T2.XDataType);
buildInstrumentedMex myFixedPointPredict -args {X_fx2,coder.Constant(T2)} -o myFixedPointPredict_
```

```
Code generation successful.
```

```
[labels_fx2,scores_fx2] = myFixedPointPredict_instrumented2(X_fx2,T2);
showInstrumentationResults('myFixedPointPredict_instrumented2')
```

Review the instrumentation report, and then clear the results.

```
clearInstrumentationResults('myFixedPointPredict_instrumented2')
```

Verify `myFixedPointPredict_instrumented2`.

```
verify_labels2 = isequal(labels,labels_fx2)
```

```
verify_labels2 = logical
   0

diff_labels2 = sum(strcmp(string(labels_fx2),string(labels))==0)/length(labels_fx2)*100

diff_labels2 = 0.0031

diff_scores2 = max(abs((scores_fx2.double(:,1)-scores(:,1))./scores(:,1)))

diff_scores2 = 4.5598
```

The percentage of incorrectly classified labels `diff_labels2` and the relative difference in score values `diff_scores2` are smaller than those from the previous MEX function generated using the default word length (16).

For more details about optimizing fixed-point data types by instrumenting MATLAB® code, see the reference pages `buildInstrumentedMex` (Fixed-Point Designer), `showInstrumentationResults` (Fixed-Point Designer), and `clearInstrumentationResults` (Fixed-Point Designer), and the example “Set Data Types Using Min/Max Instrumentation” (Fixed-Point Designer).

Generate Code

Generate code for the entry-point function using `codegen`. Instead of specifying a variable-size input for a predictor data set, specify a fixed-size input by using `coder.typeof`. If you know the size of the predictor data set that you pass to the generated code, then generating code for a fixed-size input is preferable for the simplicity of the code.

```
codegen myFixedPointPredict -args {coder.typeof(X_fx2,[1,5],[0,0]),coder.Constant(T2)}

Code generation successful.
```

`codegen` generates the MEX function `myFixedPointPredict_mex` with a platform-dependent extension.

Verify Generated Code

You can verify the `myFixedPointPredict_mex` function in the same way that you verify the instrumented MEX function. See the **Verify Instrumented MEX Function** section for details.

```
[labels_sampled,scores_sampled] = predict(Mdl,standardizedX_sampled);
n = size(standardizedX_sampled,1);
labels_fx = true(n,1);
scores_fx = zeros(n,2);
for i = 1:n
    [labels_fx(i),scores_fx(i,:)] = myFixedPointPredict_mex(X_fx2(idx(i),:),T2);
end
verify_labels = isequal(labels_sampled,labels_fx)

verify_labels = logical
   1

diff_labels = sum(strcmp(string(labels_fx),string(labels_sampled))==0)/length(labels_fx)*100

diff_labels = 0

diff_scores = max(abs((scores_fx(:,1)-scores_sampled(:,1))./scores_sampled(:,1)))
```

```
diff_scores = 0.0633
```

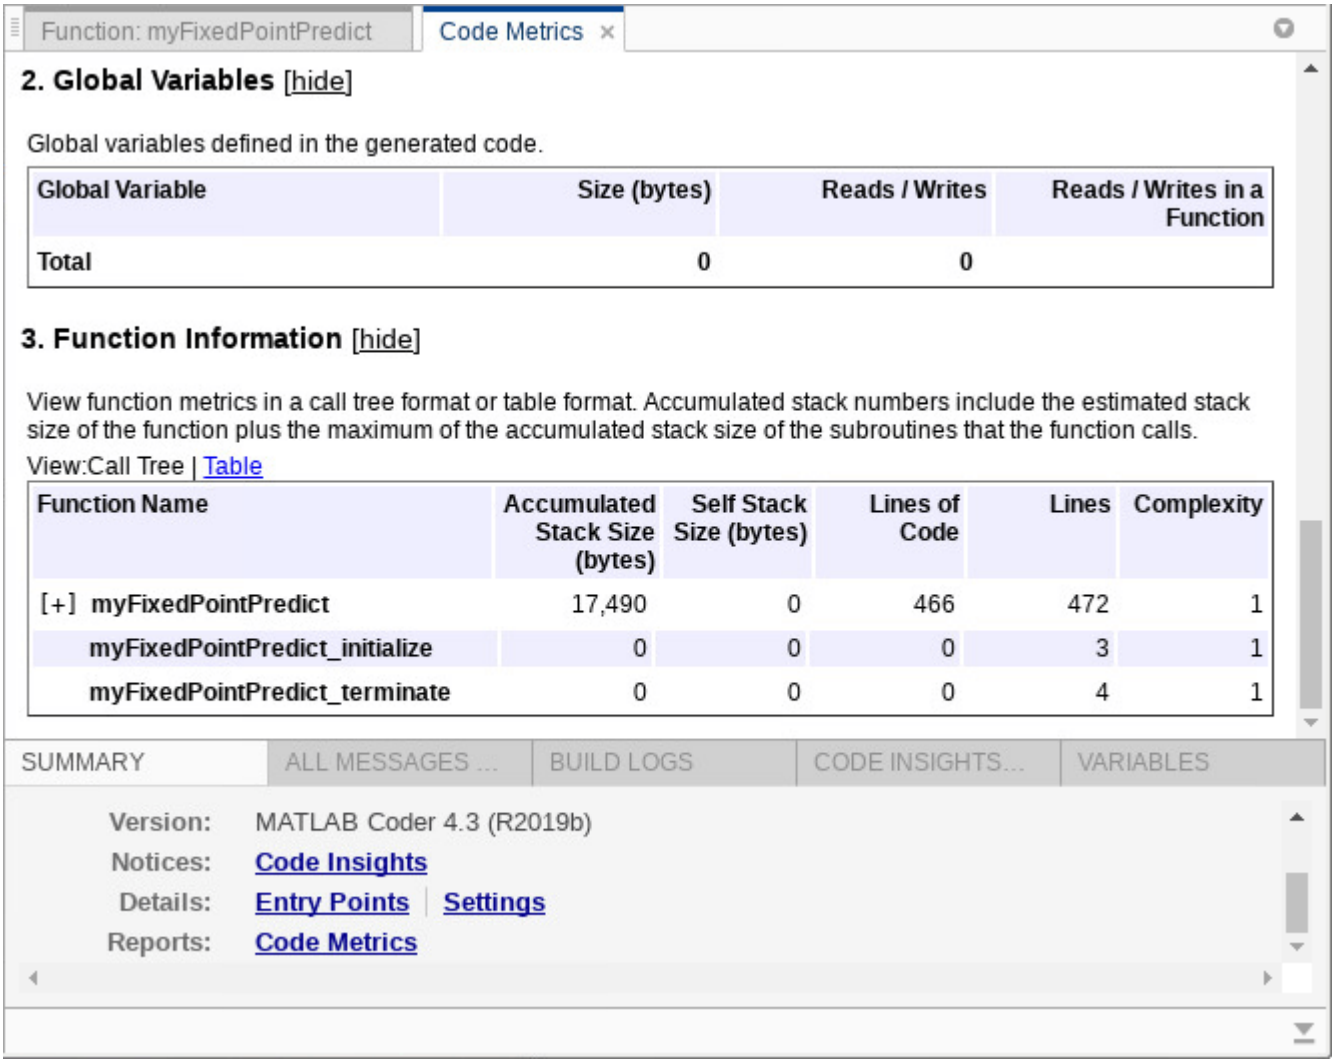
Memory Use

A good practice is to manually standardize predictor data before training a model. If you use the `'Standardize'` name-value pair argument instead, then the generated fixed-point code includes standardization operations, which can cause loss of precision and increased memory use.

If you generate a static library, you can find the memory use of the generated code by using a code generation report. Specify `-config:lib` to generate a static library, and use the `-report` option to generate a code generation report.

```
codegen myFixedPointPredict -args {coder.typeof(X_fx2,[1,5],[0,0]),coder.Constant(T2)} -o myFixed
```

On the **Summary** tab of the code generation report, click **Code Metrics**. The Function Information section shows the accumulated stack size.



To find the memory use of a model trained with `'Standardized','true'`, you can run the following code.

```
Mdl = fitcsvm(X_sampled,Y_sampled,'Weight',w_sampled,'KernelFunction','gaussian','Standardize',t
saveLearnerForCoder(Mdl,'myMdl');
generateLearnerDataTypeFcn('myMdl',[X; XTest],'WordLength',32,'OutputFunctionName','myMdl_standa
T3 = myMdl_standardize_datatype('Fixed');
X_fx3 = cast(X_sampled,'like',T3.XDataType);
codegen myFixedPointPredict -args {coder.typeof(X_fx3,[1,5],[0,0]),coder.Constant(T3)} -o myFixe
```

- “Set Data Types Using Min/Max Instrumentation” (Fixed-Point Designer)

Generate Code to Classify Data in Table

This example shows how to generate code for classifying numeric and categorical data in a table using a binary decision tree model. The trained model in this example identifies categorical predictors in the `CategoricalPredictors` property; therefore, the software handles categorical predictors automatically. You do not need to create dummy variables manually for categorical predictors to generate code.

In the general code generation workflow, you can train a classification or regression model on data in a table. You pass arrays (instead of a table) to your entry-point function for prediction, create a table inside the entry-point function, and then pass the table to `predict`. For more information on table support in code generation, see “Code Generation for Tables” (MATLAB Coder) and “Table Limitations for Code Generation” (MATLAB Coder).

Train Classification Model

Load the `patients` data set. Create a table that contains numeric predictors of type `single` and `double`, categorical predictors of type `categorical`, and the response variable `Smoker` of type `logical`. Each row of the table corresponds to a different patient.

```
load patients
Age = single(Age);
Weight = single(Weight);
Gender = categorical(Gender);
SelfAssessedHealthStatus = categorical(SelfAssessedHealthStatus);
Tbl = table(Age,Diastolic,Systolic,Weight,Gender,SelfAssessedHealthStatus,Smoker);
```

Train a classification tree using the data in `Tbl`.

```
Mdl = fitctree(Tbl,'Smoker')
```

```
Mdl =
  ClassificationTree
             PredictorNames: {1x6 cell}
               ResponseName: 'Smoker'
      CategoricalPredictors: [5 6]
                 ClassNames: [0 1]
             ScoreTransform: 'none'
            NumObservations: 100

  Properties, Methods
```

The `CategoricalPredictors` property value is `[5 6]`, which indicates that `Mdl` identifies the 5th and 6th predictors (`'Gender'` and `'SelfAssessedHealthStatus'`) as categorical predictors. To identify any other predictors as categorical predictors, you can specify them by using the `'CategoricalPredictors'` name-value argument.

Display the predictor names and their order in `Mdl`.

```
Mdl.PredictorNames
```

```
ans = 1x6 cell
  Columns 1 through 5
```

```
    {'Age'}    {'Diastolic'}    {'Systolic'}    {'Weight'}    {'Gender'}

  Column 6

    {'SelfAssessedHe...'}
```

Save Model

Save the tree classifier to a file using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'TreeModel');
```

`saveLearnerForCoder` saves the classifier to the MATLAB® binary file `TreeModel.mat` as a structure array in the current folder.

Define Entry-Point Function

Define the entry-point function `predictSmoker`, which takes predictor variables as input arguments. Within the function, load the tree classifier by using `loadLearnerForCoder`, create a table from the input arguments, and then pass the classifier and table to `predict`.

```
function [labels,scores] = predictSmoker(age,diastolic,systolic,weight,gender,selfAssessedHealthS
%PREDICTSMOKER Label new observations using a trained tree model
%   predictSmoker predicts whether patients are smokers (1) or nonsmokers
%   (0) based on their age, diastolic blood pressure, systolic blood
%   pressure, weight, gender, and self assessed health status. The function
%   also provides classification scores indicating the likelihood that a
%   predicted label comes from a particular class (smoker or nonsmoker).
mdl = loadLearnerForCoder('TreeModel');
varnames = mdl.PredictorNames;
tbl = table(age,diastolic,systolic,weight,gender,selfAssessedHealthStatus, ...
    'VariableNames',varnames);
[labels,scores] = predict(mdl,tbl);
end
```

When you create a table inside an entry-point function, you must specify the variable names (for example, by using the `'VariableNames'` name-value pair argument of `table`). If your table contains only predictor variables, and the predictors are in the same order as in the table used to train the model, then you can find the predictor variable names in `mdl.PredictorNames`.

Generate Code

Generate code for `predictSmoker` by using `codegen`. Specify the data type and dimensions of the predictor variable input arguments using `coder.typeof`.

- The first input argument of `coder.typeof` specifies the data type of the predictor.
- The second input argument specifies the upper bound on the number of rows (`Inf`) and columns (`1`) in the predictor.
- The third input argument specifies that the number of rows in the predictor can change at run time but the number of columns is fixed.

```
ARGS = cell(4,1);
ARGS{1} = coder.typeof(Age,[Inf 1],[1 0]);
ARGS{2} = coder.typeof(Diastolic,[Inf 1],[1 0]);
ARGS{3} = coder.typeof(Systolic,[Inf 1],[1 0]);
ARGS{4} = coder.typeof(Weight,[Inf 1],[1 0]);
```

```
ARGS{5} = coder.typeof(Gender,[Inf 1],[1 0]);
ARGS{6} = coder.typeof(SelfAssessedHealthStatus,[Inf 1],[1 0]);

codegen predictSmoker -args ARGS

Code generation successful.
```

`codegen` generates the MEX function `predictSmoker_mex` with a platform-dependent extension in your current folder.

Verify Generated Code

Verify that `predict`, `predictSmoker`, and the MEX file return the same results for a random sample of 20 patients.

```
rng('default') % For reproducibility
[newTbl,idx] = datasample(Tbl,20);

[labels1,scores1] = predict(Mdl,newTbl);
[labels2,scores2] = predictSmoker(Age(idx),Diastolic(idx),Systolic(idx),Weight(idx),Gender(idx),S
[labels3,scores3] = predictSmoker_mex(Age(idx),Diastolic(idx),Systolic(idx),Weight(idx),Gender(id

verifyMEXlabels = isequal(labels1,labels2,labels3)

verifyMEXlabels = logical
   1

verifyMEXscores = isequal(scores1,scores2,scores3)

verifyMEXscores = logical
   1
```

- “Code Generation for Tables” (MATLAB Coder)
- “Table Limitations for Code Generation” (MATLAB Coder)

Code Generation for Image Classification

This example shows how to generate C code from a MATLAB® function that classifies images of digits using a trained classification model. This example demonstrates an alternative workflow to “Digit Classification Using HOG Features” (Computer Vision Toolbox). However, to support code generation in that example, you can follow the code generation steps in this example.

Automated image classification is an ubiquitous tool. For example, a trained classifier can be deployed to a drone to automatically identify anomalies on land in captured footage, or to a machine that scans handwritten zip codes on letters. In the latter example, after the machine finds the ZIP code and stores individual images of digits, the deployed classifier must guess which digits are in the images to reconstruct the ZIP code.

This example shows how to train and optimize a multiclass error-correcting output codes (ECOC) classification model to classify digits based on pixel intensities in raster images. The ECOC model contains binary support vector machine (SVM) learners. Then, this example shows how to generate C code that uses the trained model to classify new images. The data are synthetic images of warped digits of various fonts, which simulates handwritten digits.

Set Up Your C Compiler

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder™ locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Assumptions and Limitations

To generate C code, MATLAB Coder:

- Requires a properly configured compiler.
- Requires supported functions to be in a MATLAB function that you define. For the basic workflow, see “Introduction to Code Generation” on page 32-2.
- Forbids objects as input arguments of the defined function.

Concerning the last limitation, consider that:

- Trained classification models are objects
- MATLAB Coder supports `predict` to classify observations using trained models, but does not support fitting the model

To work around the code generation limitations for classification, train the classification model using MATLAB, then pass the resulting model object to `saveLearnerForCoder`. The `saveLearnerForCoder` function removes some properties that are not required for prediction, and then saves the trained model to disk as a structure array. Like the model, the structure array contains the information used to classify new observations.

After saving the model to disk, load the model in the MATLAB function by using `loadLearnerForCoder`. The `loadLearnerForCoder` function loads the saved structure array, and then reconstructs the model object. In the MATLAB function, to classify the observations, you can pass the model and predictor data set, which can be an input argument of the function, to `predict`.

Code Generation for Classification Workflow

Before deploying an image classifier onto a device:

1. Obtain a sufficient amount of labeled images.
2. Decide which features to extract from the images.
3. Train and optimize a classification model. This step includes choosing an appropriate algorithm and tuning hyperparameters, that is, model parameters not fit during training.
4. Save the model to disk by using `saveLearnerForCoder`.
5. Define a function for classifying new images. The function must load the model by using `loadLearnerForCoder`, and can return labels, such as classification scores.
6. Set up your C compiler.
7. Decide the environment in which to execute the generated code.
8. Generate C code for the function.

Load Data

Load the `digitimages` data set.

```
load digitimages
```

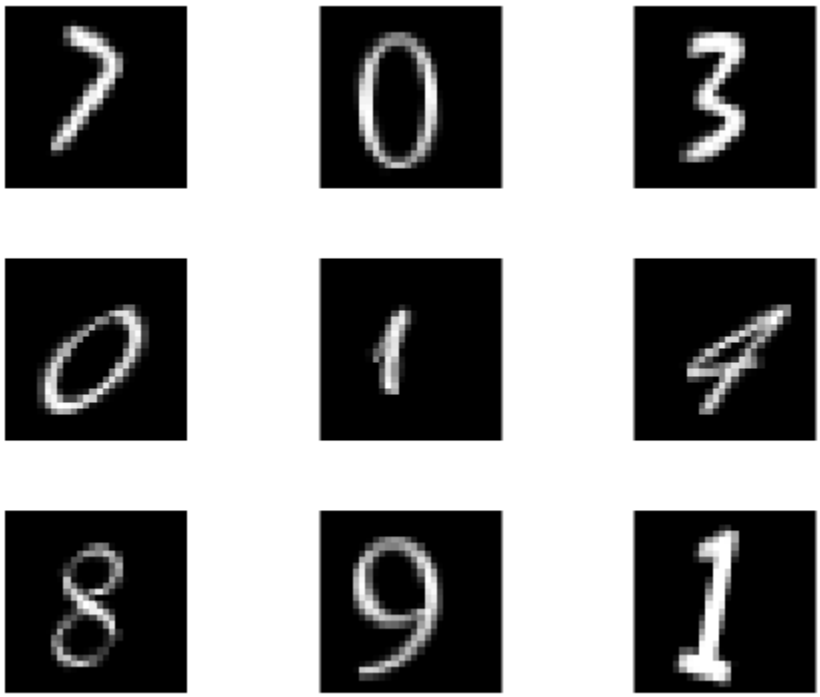
`images` is a 28-by-28-by-3000 array of `uint16` integers. Each page is a raster image of a digit. Each element is a pixel intensity. Corresponding labels are in the 3000-by-1 numeric vector `Y`. For more details, enter `Description` at the command line.

Store the number of observations and number of predictor variables. Create a data partition that specifies to hold out 20% of the data. Extract training and test set indices from the data partition.

```
rng(1) % For reproducibility
n = size(images,3);
p = numel(images(:,:,1));
cvp = cvpartition(n,'Holdout',0.20);
idxTrn = training(cvp);
idxTest = test(cvp);
```

Display nine random images from the data.

```
figure
for j = 1:9
    subplot(3,3,j)
    selectImage = datasample(images,1,3);
    imshow(selectImage,[])
end
```



Rescale Data

Because raw pixel intensities vary widely, you should normalize their values before training a classification model. Rescale the pixel intensities so that they range in the interval [0,1]. That is, suppose p_{ij} is pixel intensity j within image i. For image i, rescale all of its pixel intensities using this formula:

$$\widehat{p}_{ij} = \frac{p_{ij} - \min_j(p_{ij})}{\max_j(p_{ij}) - \min_j(p_{ij})}.$$

```
X = double(images);
for i = 1:n
    minX = min(min(X(:,:,i)));
    maxX = max(max(X(:,:,i)));
    X(:,:,i) = (X(:,:,i) - minX)/(maxX - minX);
end
```

Alternatively, if you have an Image Processing Toolbox™ license, then you can efficiently rescale pixel intensities of images to [0,1] by using `mat2gray`. For more details, see `mat2gray` (Image Processing Toolbox).

Reshape Data

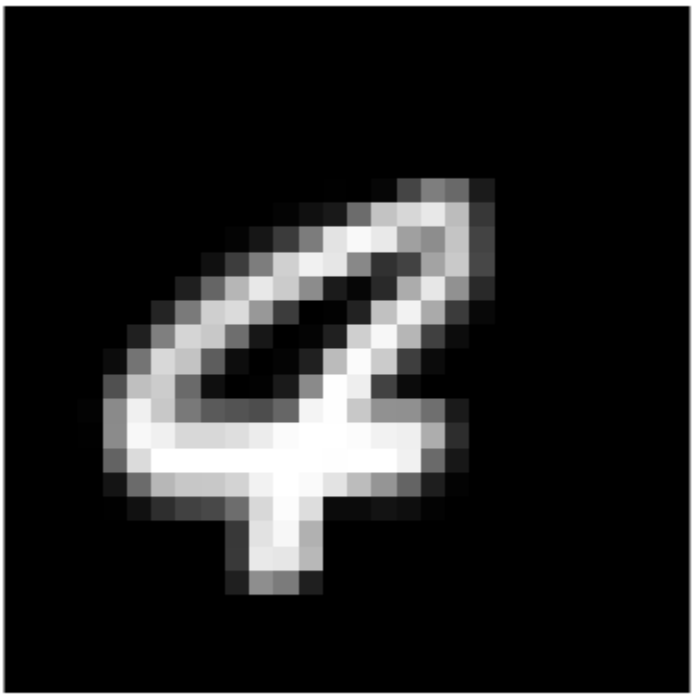
For code generation, the predictor data for training must be in a table of numeric variables or a numeric matrix.

Reshape the data to a matrix such that predictor variables (pixel intensities) correspond to columns, and images (observations) to rows. Because `reshape` takes elements column-wise, you must transpose its result.

```
X = reshape(X,[p,n])';
```

To ensure that preprocessing the data maintains the image, plot the first observation in X.

```
figure
imshow(reshape(X(1,:),sqrt(p)*[1 1]),[],'InitialMagnification','fit')
```



Extract Features

Computer Vision Toolbox™ offers several feature-extraction techniques for images. One such technique is the extraction of histogram of oriented gradient (HOG) features. To learn how to train an ECOC model using HOG features, see “Digit Classification Using HOG Features” (Computer Vision Toolbox). For details on other supported techniques, see “Local Feature Detection and Extraction” (Computer Vision Toolbox). This example uses the rescaled pixel intensities as predictor variables.

Train and Optimize Classification Model

Linear SVM models are often applied to image data sets for classification. However, SVM are binary classifiers, and there are 10 possible classes in the data set.

You can create a multiclass model of multiple binary SVM learners using `fitcecoc`. `fitcecoc` combines multiple binary learners using a coding design. By default, `fitcecoc` applies the one-versus-one design, which specifies training binary learners based on observations from all

combinations of pairs of classes. For example, in a problem with 10 classes, `fitcecoc` must train 45 binary SVM models.

In general, when you train a classification model, you should tune the hyperparameters until you achieve a satisfactory generalization error. That is, you should cross-validate models for particular sets of hyperparameters, and then compare the out-of-fold misclassification rates.

You can choose your own sets of hyperparameter values, or you can specify to implement Bayesian optimization. (For general details on Bayesian optimization, see “Bayesian Optimization Workflow” on page 10-25.) This example performs cross-validation over a chosen grid of values.

To cross-validate an ECOC model of SVM binary learners based on the training observations, use 5-fold cross-validation. Although the predictor values have the same range, to avoid numerical difficulties during training, standardize the predictors. Also, optimize the ECOC coding design and the SVM box constraint. Use all combinations of these values:

- For the ECOC coding design, use one-versus-one and one-versus-all.
- For the SVM box constraint, use three logarithmically-spaced values from 0.1 to 100 each.

For all models, store the 5-fold cross-validated misclassification rates.

```
coding = {'onevsone' 'onevsall'};
boxconstraint = logspace(-1,2,3);
cvLoss = nan(numel(coding),numel(boxconstraint)); % For preallocation

for i = 1:numel(coding)
    for j = 1:numel(boxconstraint)
        t = templateSVM('BoxConstraint',boxconstraint(j),'Standardize',true);
        CVMdl = fitcecoc(X(idxTrn,:),Y(idxTrn),'Learners',t,'KFold',5,...
            'Coding',coding{i});
        cvLoss(i,j) = kfoldLoss(CVMdl);
        fprintf('cvLoss = %f for model using %s coding and box constraint=%f\n',...
            cvLoss(i,j),coding{i},boxconstraint(j))
    end
end
```

```
cvLoss = 0.052083 for model using onevsone coding and box constraint=0.100000
cvLoss = 0.055000 for model using onevsone coding and box constraint=3.162278
cvLoss = 0.050000 for model using onevsone coding and box constraint=100.000000
cvLoss = 0.116667 for model using onevsall coding and box constraint=0.100000
cvLoss = 0.123750 for model using onevsall coding and box constraint=3.162278
cvLoss = 0.125000 for model using onevsall coding and box constraint=100.000000
```

Determine the hyperparameter indices that yield the minimal misclassification rate. Train an ECOC model using the training data. Standardize the training data and supply the observed, optimal hyperparameter combination.

```
minCVLoss = min(cvLoss(:))
```

```
minCVLoss = 0.0500
```

```
linIdx = find(cvLoss == minCVLoss);
[bestI,bestJ] = ind2sub(size(cvLoss),linIdx);
bestCoding = coding{bestI}
```

```
bestCoding =
'onevsone'
```

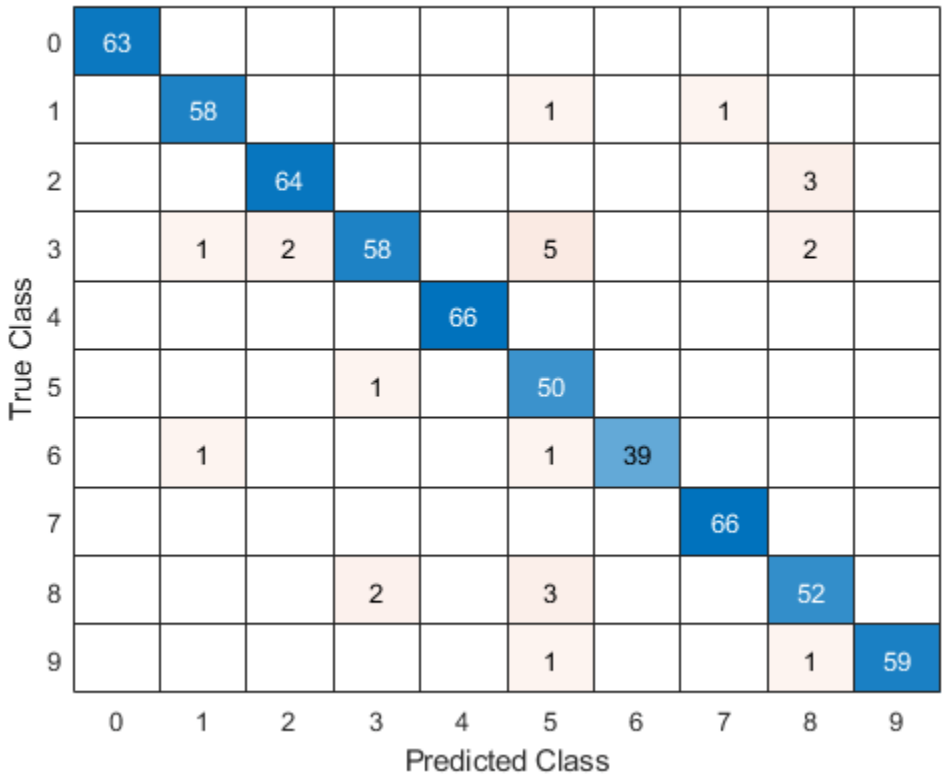
```
bestBoxConstraint = boxconstraint(bestJ)

bestBoxConstraint = 100

t = templateSVM('BoxConstraint',bestBoxConstraint,'Standardize',true);
Mdl = fitcecoc(X(idxTrn,:),Y(idxTrn),'Learners',t,'Coding',bestCoding);
```

Construct a confusion matrix for the test set images.

```
testImages = X(idxTest,:);
testLabels = predict(Mdl,testImages);
confusionMatrix = confusionchart(Y(idxTest),testLabels);
```



Diagonal and off-diagonal elements correspond to correctly and incorrectly classified observations, respectively. `Mdl` seems to correctly classify most images.

If you are satisfied with the performance of `Mdl`, then you can proceed to generate code for prediction. Otherwise, you can continue adjusting hyperparameters. For example, you can try training the SVM learners using different kernel functions.

Save Classification Model to Disk

`Mdl` is a predictive classification model, but you must prepare it for code generation. Save `Mdl` to your present working directory using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'DigitImagesECOC')
```

`saveLearnerForCoder` compacts `Mdl`, converts it to a structure array, and saves it in the MAT-file `DigitImagesECOC.mat`.

Define Prediction Function for Code Generation

Define an entry-point function named `predictDigitECOC.m` that does the following:

- Include the code generation directive `%#codegen` somewhere in the function.
- Accept image data commensurate with `X`.
- Load `DigitImagesECOC.mat` using `loadLearnerForCoder`.
- Return predicted labels.

```
type predictDigitECOC.m % Display contents of predictDigitECOC.m file
```

```
function label = predictDigitECOC(X) %#codegen
%PREDICTDIGITECOC Classify digit in image using ECOC Model
%   PREDICTDIGITECOC classifies the 28-by-28 images in the rows of X using
%   the compact ECOC model in the file DigitImagesECOC.mat, and then
%   returns class labels in label.
CompactMdl = loadLearnerForCoder('DigitImagesECOC.mat');
label = predict(CompactMdl,X);
end
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB, then MATLAB opens the example folder. This folder includes the entry-point function file.

Verify that the prediction function returns the same test set labels as `predict`.

```
pfLabels = predictDigitECOC(testImages);
verifyPF = isequal(pfLabels,testLabels)
```

```
verifyPF = logical
   1
```

`isequal` returns logical 1 (`true`), which means all the inputs are equal. The `predictDigitECOC` yields the expected results.

Decide Which Environment to Execute Generated Code

Generated code can run:

- Inside the MATLAB environment as a C-MEX file
- Outside the MATLAB environment as a standalone executable
- Outside the MATLAB environment as a shared utility linked to another standalone executable

This example generates a MEX file to be run in the MATLAB environment. Generating such a MEX file allows you to test the generated code using MATLAB tools before deploying the function outside the MATLAB environment. In the MEX function, you can include code for verification, but not for code generation, by declaring the commands as extrinsic using `coder.extrinsic` (MATLAB Coder). Extrinsic commands can include functions that do not have code generation support. All extrinsic commands in the MEX function run in MATLAB, but `codegen` does not generate code for them.

If you plan to deploy the code outside the MATLAB environment, then you must generate a standalone executable. One way to specify your compiler choice is by using the `-config` option of

`codegen`. For example, to generate a static C executable, specify `-config:exe` when you call `codegen`. For more details on setting code generation options, see the `-config` option of `codegen` (MATLAB Coder).

Compile MATLAB Function to MEX File

Compile `predictDigitECOC.m` to a MEX file using `codegen`. Specify these options:

- `-report` — Generates a compilation report that identifies the original MATLAB code and the associated files that `codegen` creates during code generation.
- `-args` — MATLAB Coder requires that you specify the properties of all the function input arguments. One way to do this is to provide `codegen` with an example of input values. Consequently, MATLAB Coder infers the properties from the example values. Specify the test set images commensurate with `X`.

```
codegen predictDigitECOC -report -args {testImages}
```

```
Code generation successful: View report
```

`codegen` successfully generated the code for the prediction function. You can view the report by clicking the `View report` link or by entering `open('codegen/mex/predictDigitECOC/html/report.mldatx')` in the Command Window. If code generation is unsuccessful, then the report can help you debug.

`codegen` creates the directory `pwd/codegen/mex/predictDigitECOC`, where `pwd` is your present working directory. In the child directory, `codegen` generates, among other things, the MEX-file `predictDigitECOC_mex.mexw64`.

Verify that the MEX file returns the same labels as `predict`.

```
mexLabels = predictDigitECOC_mex(testImages);
verifyMEX = isequal(mexLabels,testLabels)
```

```
verifyMEX = logical
   1
```

`isequal` returns logical 1 (`true`), meaning that the MEX-file yields the expected results.

Predict Class Labels Using ClassificationSVM Predict Block

This example shows how to use the ClassificationSVM Predict block for label prediction in Simulink®. The block accepts an observation (predictor data) and returns the predicted class label and class score for the observation using the trained support vector machine (SVM) classification model.

Train Classification Model

This example uses the `ionosphere` data set, which contains radar return qualities (`Y`) and predictor data (`X`) of 34 variables. Radar returns are either of good quality (`'g'`) or bad quality (`'b'`).

Load the `ionosphere` data set. Determine the sample size.

```
load ionosphere
n = numel(Y)
```

```
n = 351
```

Suppose that the radar returns are detected in sequence, and you have the first 300 observations, but you have not received the last 51 yet. Partition the data into present and future samples.

```
prsntX = X(1:300,:);
prsntY = Y(1:300);
ftrX = X(301:end,:);
ftrY = Y(301:end);
```

Train an SVM model using all presently available data. Specify predictor data standardization.

```
svmMdl = fitcsvm(prsntX,prsntY,'Standardize',true);
```

`svmMdl` is a `ClassificationSVM` model.

Check the negative and positive class names by using the `ClassNames` property of `svmMdl`.

```
svmMdl.ClassNames
```

```
ans = 2x1 cell
    {'b'}
    {'g'}
```

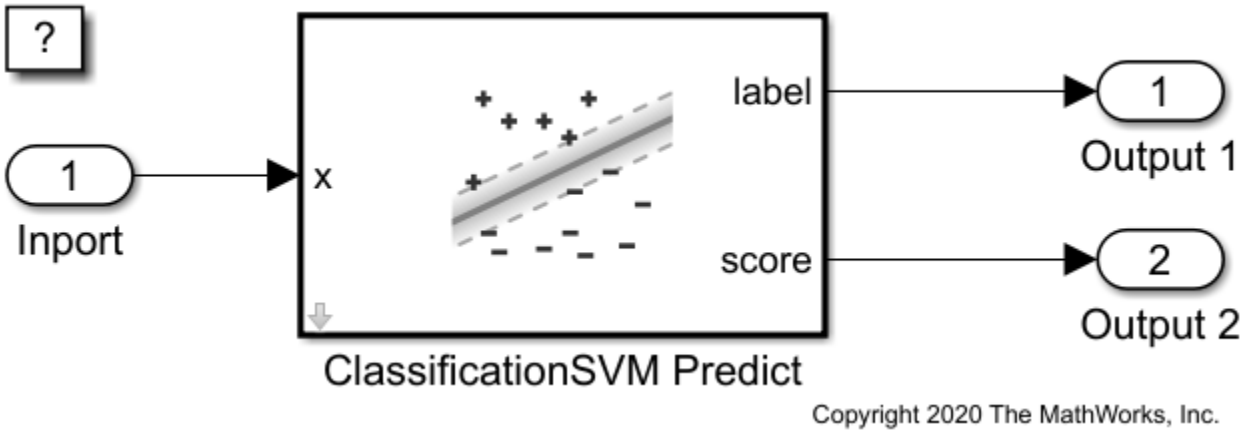
The negative class is `'b'`, and the positive class is `'g'`. The output values from the **score** port of the ClassificationSVM Predict block have the same order. The first and second elements correspond to the negative class and positive class scores, respectively.

Create Simulink Model

This example provides the Simulink model `slexIonosphereClassificationSVMPredictExample.slx`, which includes the ClassificationSVM Predict block. You can open the Simulink model or create a new model as described in this section.

Open the Simulink model `slexIonosphereClassificationSVMPredictExample.slx`.

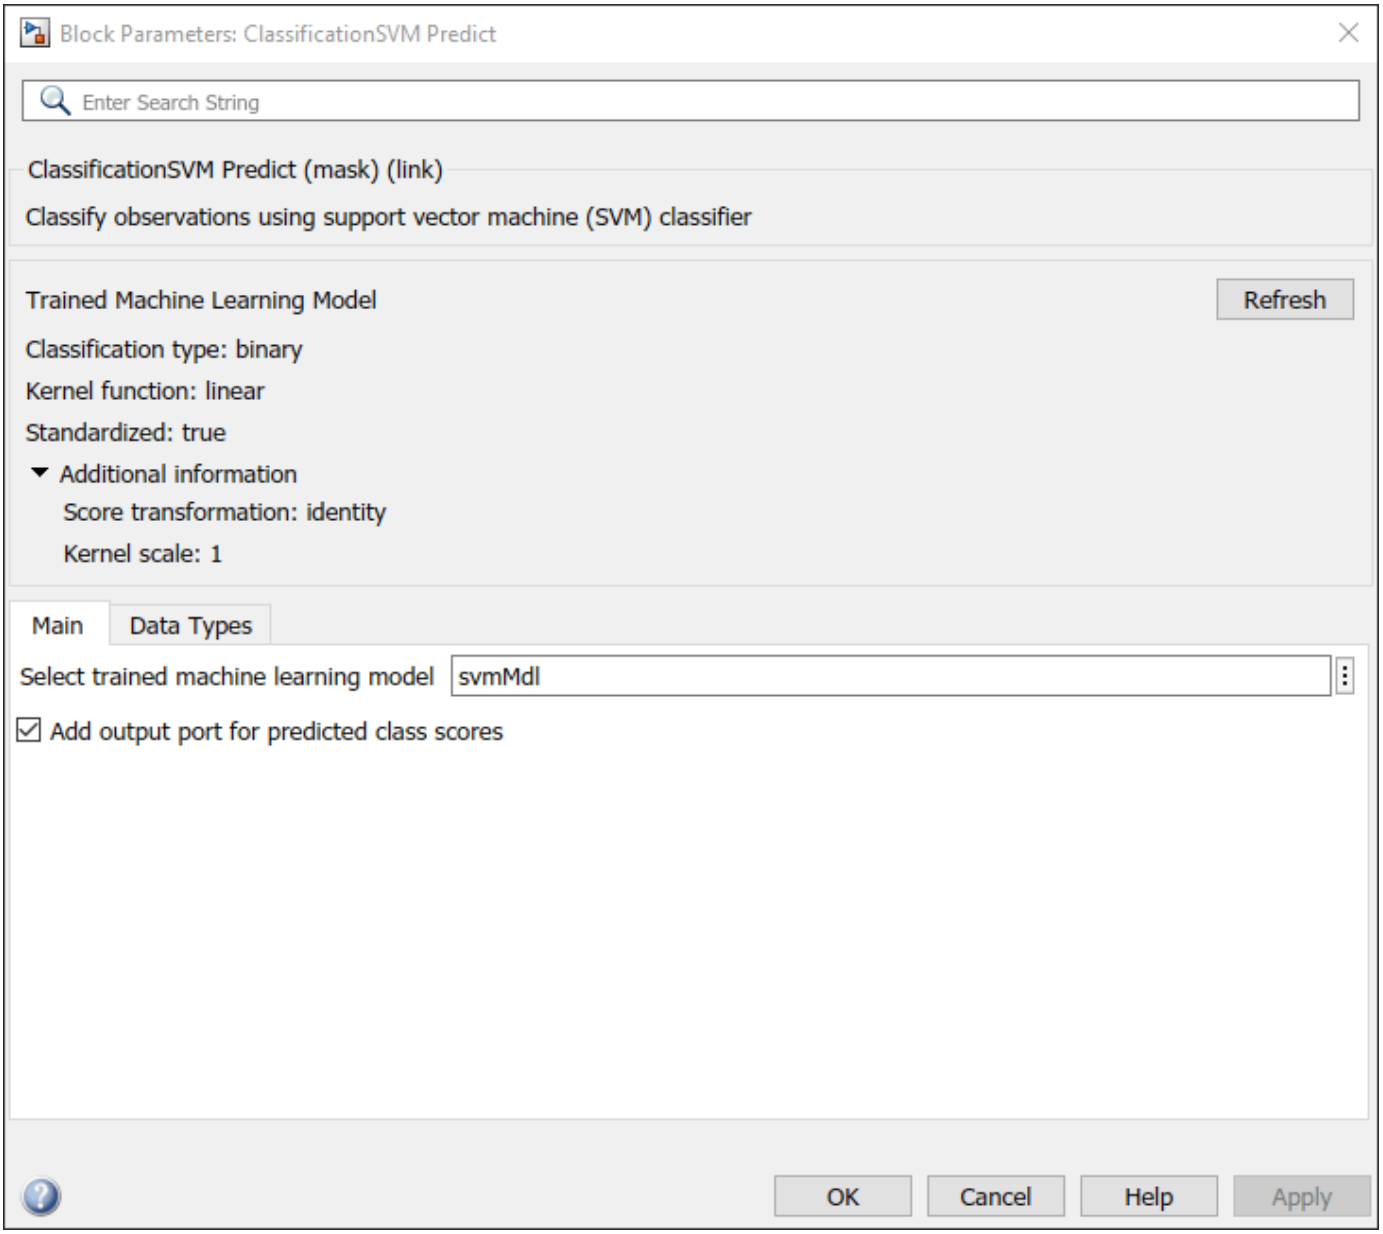
```
SimMdlName = 'slexIonosphereClassificationSVMPredictExample';
open_system(SimMdlName)
```



The `PreLoadFcn` callback function of `slexIonosphereClassificationSVMPredictExample` includes code to load the sample data, train the SVM model, and create an input signal for the Simulink model. If you open the Simulink model, then the software runs the code in `PreLoadFcn` before loading the Simulink model. To view the callback function, in the **Setup** section on the **Modeling** tab, click **Model Settings** and select **Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` callback function in the **Model callbacks** pane.

To create a new Simulink model, open the **Blank Model** template and add the ClassificationSVM Predict block. Add the Inport and Outport blocks and connect them to the ClassificationSVM Predict block.

Double-click the ClassificationSVM Predict block to open the Block Parameters dialog box. Specify the **Select trained machine learning model** parameter as `svmMdl`, which is the name of a workspace variable that contains the trained SVM model. Click the **Refresh** button. The dialog box displays the options used to train the SVM model `svmMdl` under **Trained Machine Learning Model**. Select the **Add output port for predicted class scores** check box to add the second output port **score**.



The ClassificationSVM Predict block expects an observation containing 34 predictor values. Double-click the Inport block, and set the **Port dimensions** to 34 on the **Signal Attributes** tab.

Create an input signal in the form of a structure array for the Simulink model. The structure array must contain these fields:

- `time` — The points in time at which the observations enter the model. In this example, the duration includes the integers from 0 through 50. The orientation must correspond to the observations in the predictor data. So, in this case, `time` must be a column vector.
- `signals` — A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`, where `values` is a matrix of predictor data, and `dimensions` is the number of predictor variables.

Create an appropriate structure array for future radar returns.

```
radarReturnInput.time = (0:50)';
radarReturnInput.signals(1).values = ftrX;
radarReturnInput.signals(1).dimensions = size(ftrX,2);
```

To import signal data from the workspace:

- Open the Configuration Parameters dialog box. On the **Modeling** tab, click **Model Settings**.
- In the **Data Import/Export** pane, select the **Input** check box and enter `carsmallInput` in the adjacent text box.
- In the **Solver** pane, under **Simulation time**, set **Stop time** to `radarReturnInput.time(end)`. Under **Solver selection**, set **Type** to `Fixed-step`, and set **Solver** to `discrete (no continuous states)`.

For more details, see “Load Signal Data for Simulation” (Simulink).

Simulate the model.

```
sim(SimMdlName);
```

When the Inport block detects an observation, it directs the observation into the ClassificationSVM Predict block. You can use the Simulation Data Inspector (Simulink) to view the logged data of the Outport blocks.

Predict Responses Using RegressionSVM Predict Block

This example shows how to train a support vector machine (SVM) regression model using the Regression Learner app, and then use the RegressionSVM Predict block for response prediction in Simulink®. The block accepts an observation (predictor data) and returns the predicted response for the observation using the trained SVM regression model.

Train Regression Model in Regression Learner App

Train an SVM regression model by using hyperparameter optimization in the Regression Learner App.

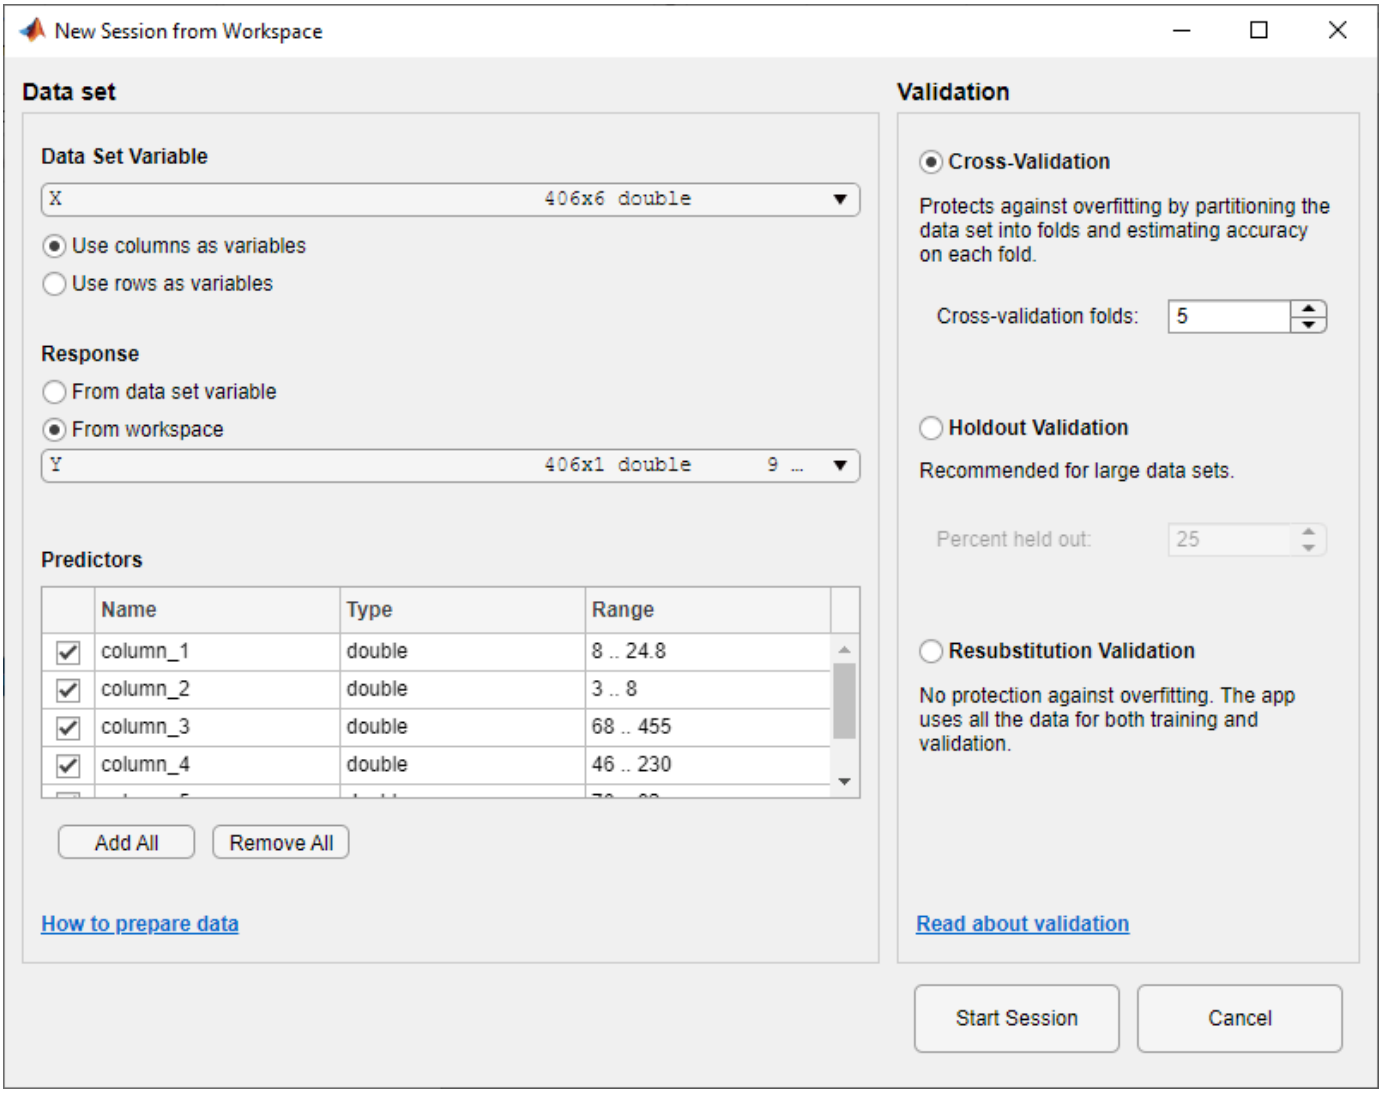
1. In the MATLAB® Command Window, load the `carbig` data set, and create a matrix containing most of the predictor variables and a vector of the response variable.

```
load carbig
X = [Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight];
Y = MPG;
```

2. Open Regression Learner. On the **Apps** tab, in the **Apps** section, click the **Show more** arrow to display the apps gallery. In the **Machine Learning and Deep Learning** group, click **Regression Learner**.

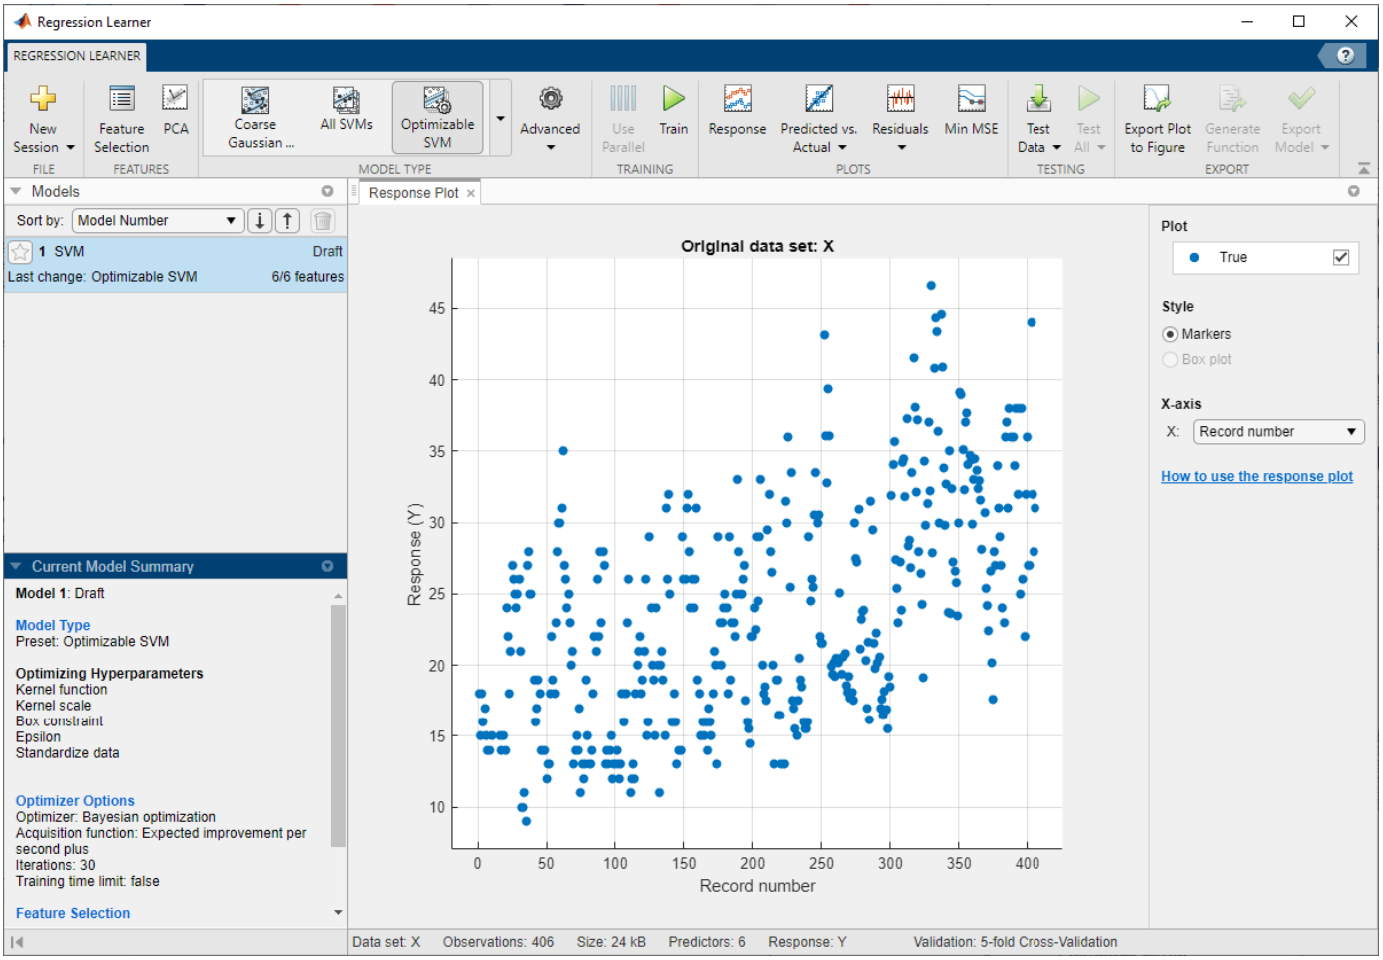
3. On the **Regression Learner** tab, in the **File** section, select **New Session** and select **From Workspace**..

4. In the New Session from Workspace dialog box, select the matrix X from the **Data Set Variable** list. Under **Response**, click the **From workspace** option button and select the vector Y from the workspace. The default validation option is 5-fold cross-validation, to protect against overfitting. For this example, do not change the default settings.



5. To accept the default options and continue, click **Start Session**.

6. Select an optimizable SVM model to train. On the **Regression Learner** tab, in the **Model Type** section, click the **Show more** arrow to open the gallery. In the **Support Vector Machines** group, click **Optimizable SVM**. The app disables the **Use Parallel** button when you select an optimizable model.



7. In the **Training** section, click **Train**. The app displays a **Minimum MSE Plot** as it runs the optimization process. At each iteration, the app tries a different combination of hyperparameter values and updates the plot with the minimum validation mean squared error (MSE) observed up to that iteration, indicated in dark blue. When the app completes the optimization process, it selects the set of optimized hyperparameters, indicated by a red square. For more information, see “Minimum MSE Plot” on page 24-37.

The app lists the optimized hyperparameters in both the **Optimization Results** section to the right of the plot and the **Optimized Hyperparameters** section of the **Current Model Summary** pane. In general, the optimization results are not reproducible.

8. Export the model to the MATLAB workspace. On the **Regression Learner** tab, in the **Export** section, click **Export Model** and select **Export Model**, then click **OK**. The default name for the exported model is `trainedModel`.

Alternatively, you can generate MATLAB code that trains a regression model with the same settings used to train the SVM model in the app. On the **Regression Learner** tab, in the **Export** section, click **Generate Function**. The app generates code from your session and displays the file in the MATLAB Editor. The file defines a function that accepts predictor and response variables, trains a regression model, and performs cross-validation. Change the function name to `trainRegressionSVMModel` and save the function file. Train an SVM model by using the `trainRegressionSVMModel` function.

```
trainedModel = trainRegressionSVMModel(X,Y);
```

9. Extract the trained SVM model from the `trainedModel` variable. `trainedModel` contains a `RegressionSVM` model object in the `RegressionSVM` field.

```
svmMdl = trainedModel.RegressionSVM;
```

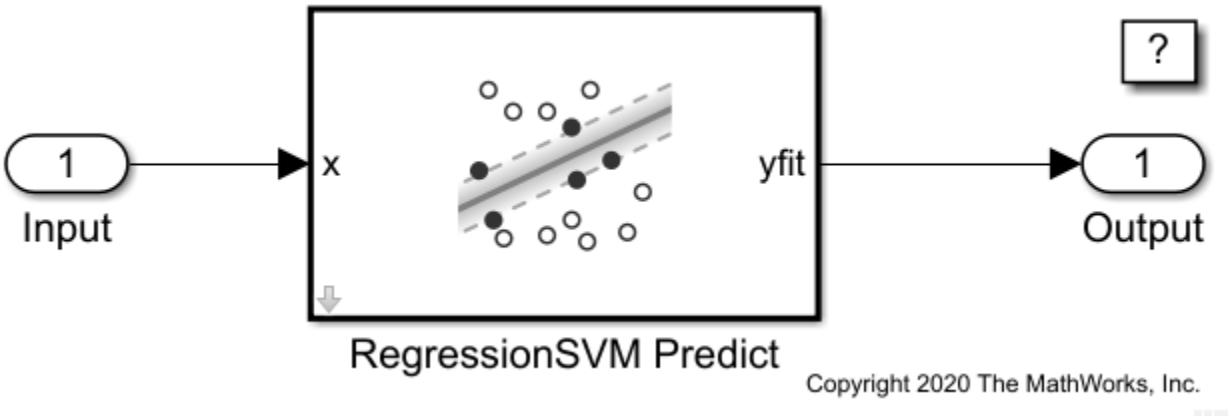
Because hyperparameter optimization can lead to an overfitted model, the recommended approach is to create a separate test set before importing your data into the Regression Learner app and see how the optimized model performs on your test set. For more details, see “Train Regression Model Using Hyperparameter Optimization in Regression Learner App” on page 24-76.

Create Simulink Model

This example provides the Simulink model `slexCarDataRegressionSVMPredictExample.slx`, which includes the RegressionSVM Predict block. You can open the Simulink model or create a new model as described in this section.

Open the Simulink model `slexCarDataRegressionSVMPredictExample.slx`.

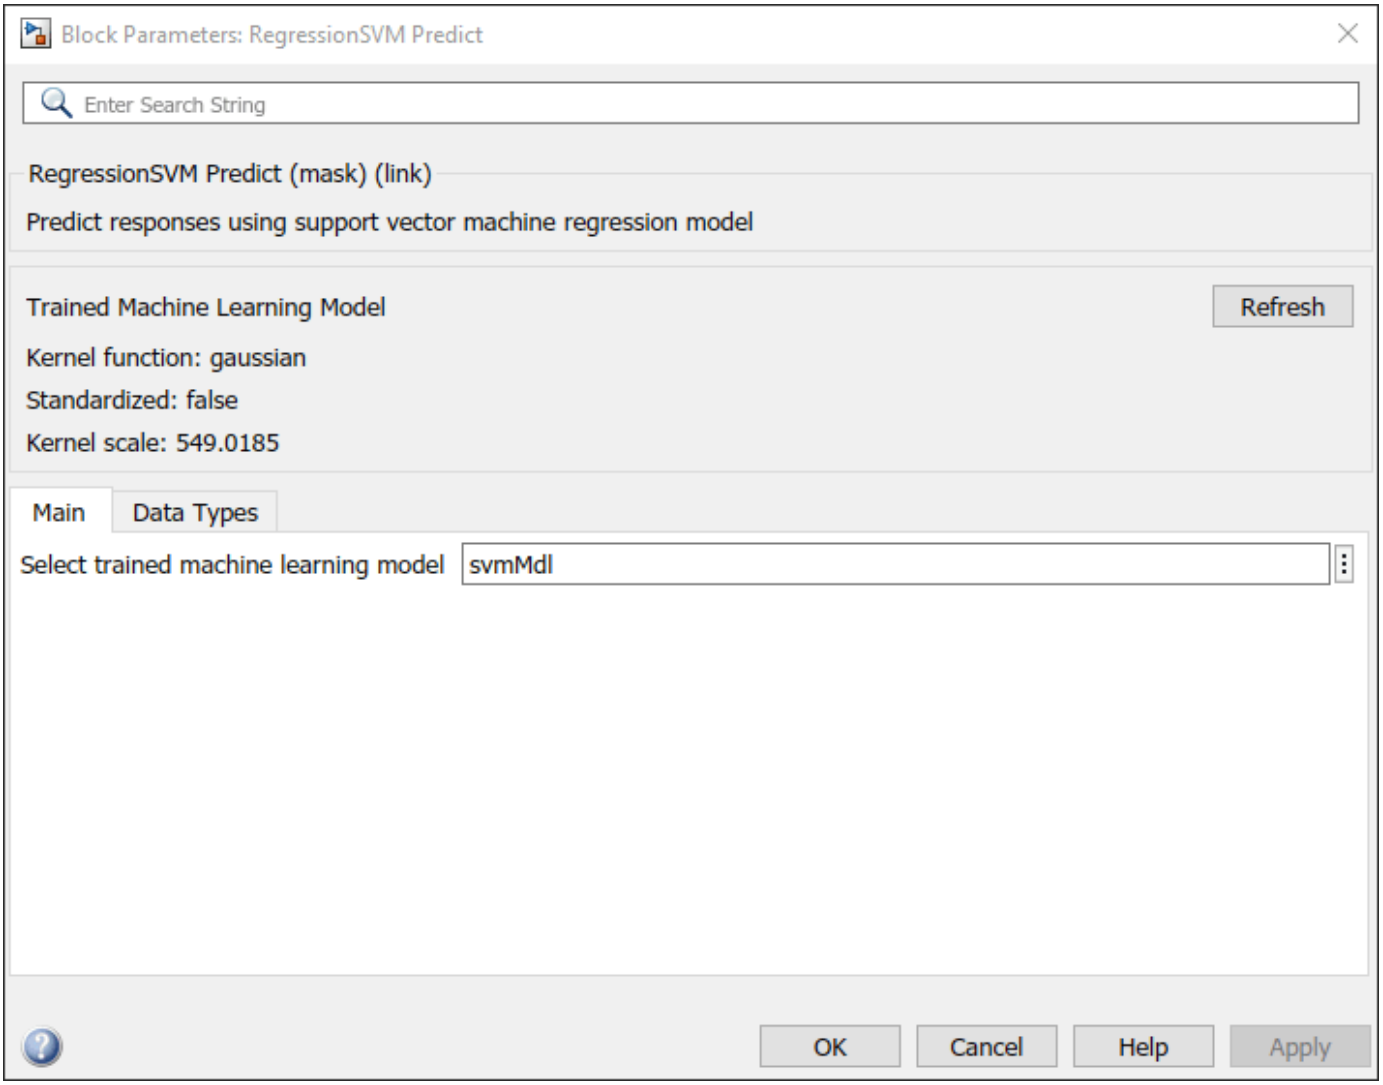
```
SimMdlName = 'slexCarDataRegressionSVMPredictExample';
open_system(SimMdlName)
```



The `PreLoadFcn` callback function of `slexCarDataRegressionSVMPredictExample` includes code to load the sample data, train the SVM model, and create an input signal for the Simulink model. If you open the Simulink model, then the software runs the code in `PreLoadFcn` before loading the Simulink model. To view the callback function, in the **Setup** section on the **Modeling** tab, click **Model Settings** and select **Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` callback function in the **Model callbacks** pane.

To create a new Simulink model, open the **Blank Model** template and add the RegressionSVM Predict block. Add the Inport and Outport blocks and connect them to the RegressionSVM Predict block.

Double-click the RegressionSVM Predict block to open the Block Parameters dialog box. You can specify the name of a workspace variable that contains the trained SVM model. The default variable name is `svmMdl`. Click the **Refresh** button. The dialog box displays the options used to train the SVM model `svmMdl` under **Trained Machine Learning Model**.



The RegressionSVM Predict block expects an observation containing 6 predictor values. Double-click the Inport block, and set the **Port dimensions** to 6 on the **Signal Attributes** tab.

Create an input signal in the form of a structure array for the Simulink model. The structure array must contain these fields:

- `time` — The points in time at which the observations enter the model. The orientation must correspond to the observations in the predictor data. So, in this example, `time` must be a column vector.
- `signals` — A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`, where `values` is a matrix of predictor data, and `dimensions` is the number of predictor variables.

Create an appropriate structure array for the `slexCarDataRegressionSVMPredictExample` model from the `carsmall` data set.

```
load carsmall
testX = [Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight];
```

```
testX = rmmissing(testX);
carsmallInput.time = (0:size(testX,1)-1)';
carsmallInput.signals(1).values = testX;
carsmallInput.signals(1).dimensions = size(testX,2);
```

To import signal data from the workspace:

- Open the Configuration Parameters dialog box. On the **Modeling** tab, click **Model Settings**.
- In the **Data Import/Export** pane, select the **Input** check box and enter `carsmallInput` in the adjacent text box.
- In the **Solver** pane, under **Simulation time**, set **Stop time** to `carsmallInput.time(end)`. Under **Solver selection**, set **Type** to `Fixed-step`, and set **Solver** to `discrete (no continuous states)`.

For more details, see “Load Signal Data for Simulation” (Simulink).

Simulate the model.

```
sim(SimMdlName);
```

When the Inport block detects an observation, it directs the observation into the RegressionSVM Predict block. You can use the Simulation Data Inspector (Simulink) to view the logged data of the Outport block.

Predict Class Labels Using ClassificationTree Predict Block

This example shows how to train a classification decision tree model using the Classification Learner app, and then use the ClassificationTree Predict block for label prediction in Simulink®. The block accepts an observation (predictor data) and returns the predicted class label and class score for the observation using the trained classification decision tree model.

Train Classification Model in Classification Learner App

Train a classification decision tree model by using hyperparameter optimization in the Classification Learner App.

1. In the MATLAB® Command Window, load the `ionosphere` data set, which contains radar return qualities (`Y`) and predictor data (`X`) of 34 variables. Radar returns are either of good quality (`'g'`) or bad quality (`'b'`).

Load the `ionosphere` data set. Determine the sample size.

```
load ionosphere
n = numel(Y)
```

```
n = 351
```

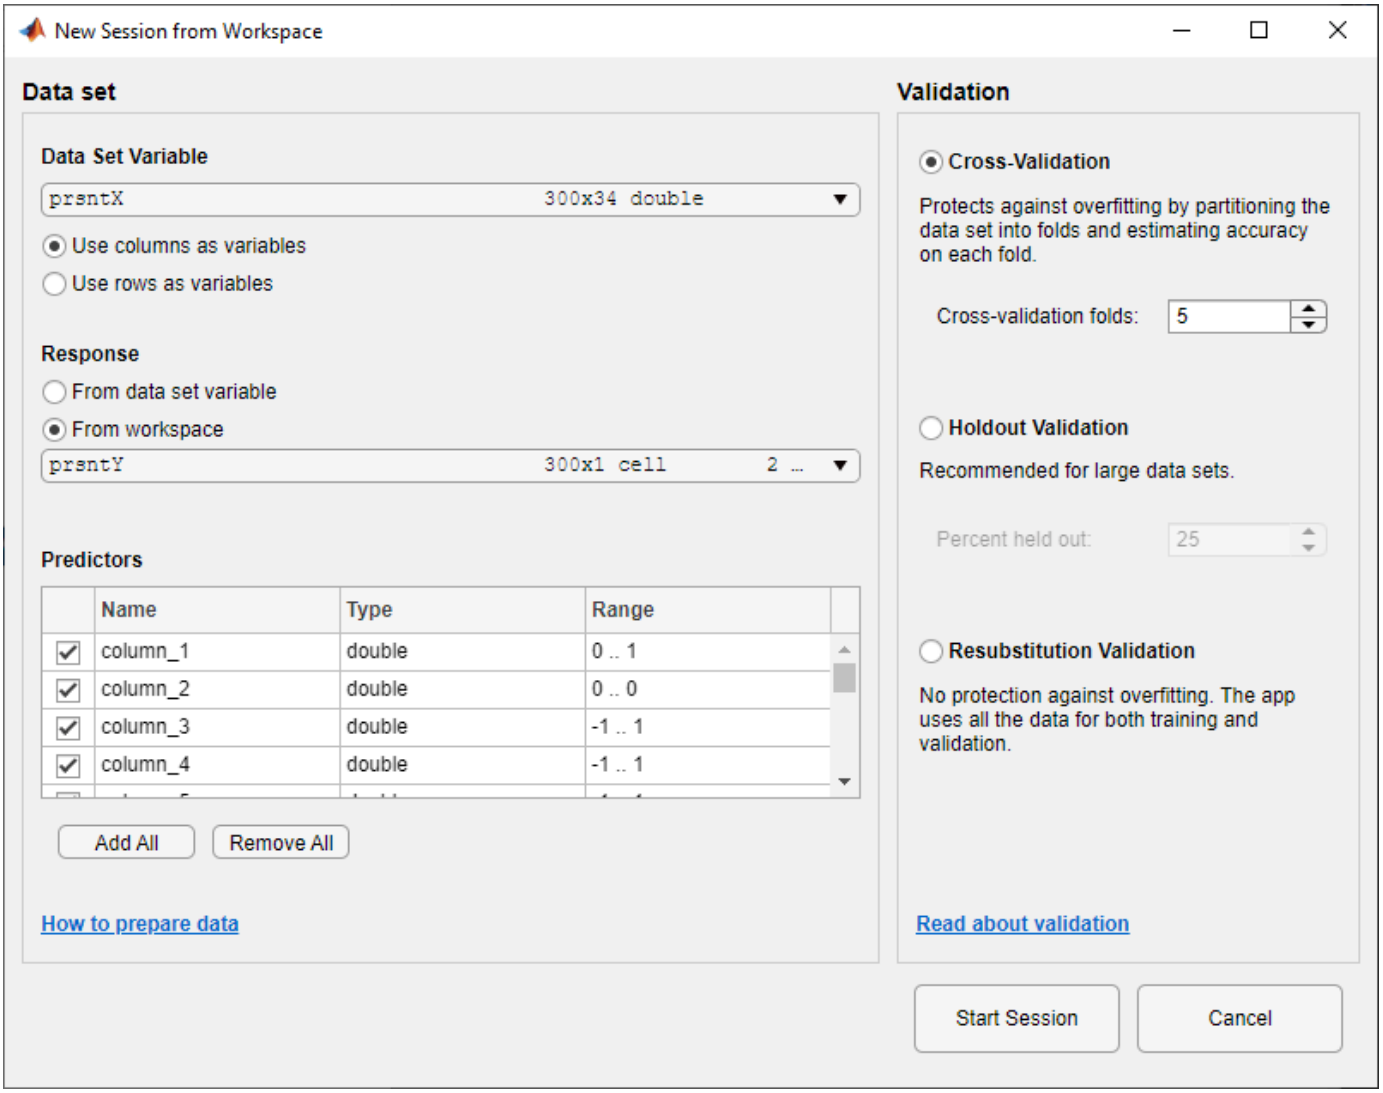
Suppose that the radar returns are detected in sequence, and you have the first 300 observations, but you have not received the last 51 yet. Partition the data into present and future samples.

```
prsntX = X(1:300,:);
prsntY = Y(1:300);
ftrX = X(301:end,:);
ftrY = Y(301:end);
```

2. Open Classification Learner. On the **Apps** tab, in the **Apps** section, click the **Show more** arrow to display the apps gallery. In the **Machine Learning and Deep Learning** group, click **Classification Learner**.

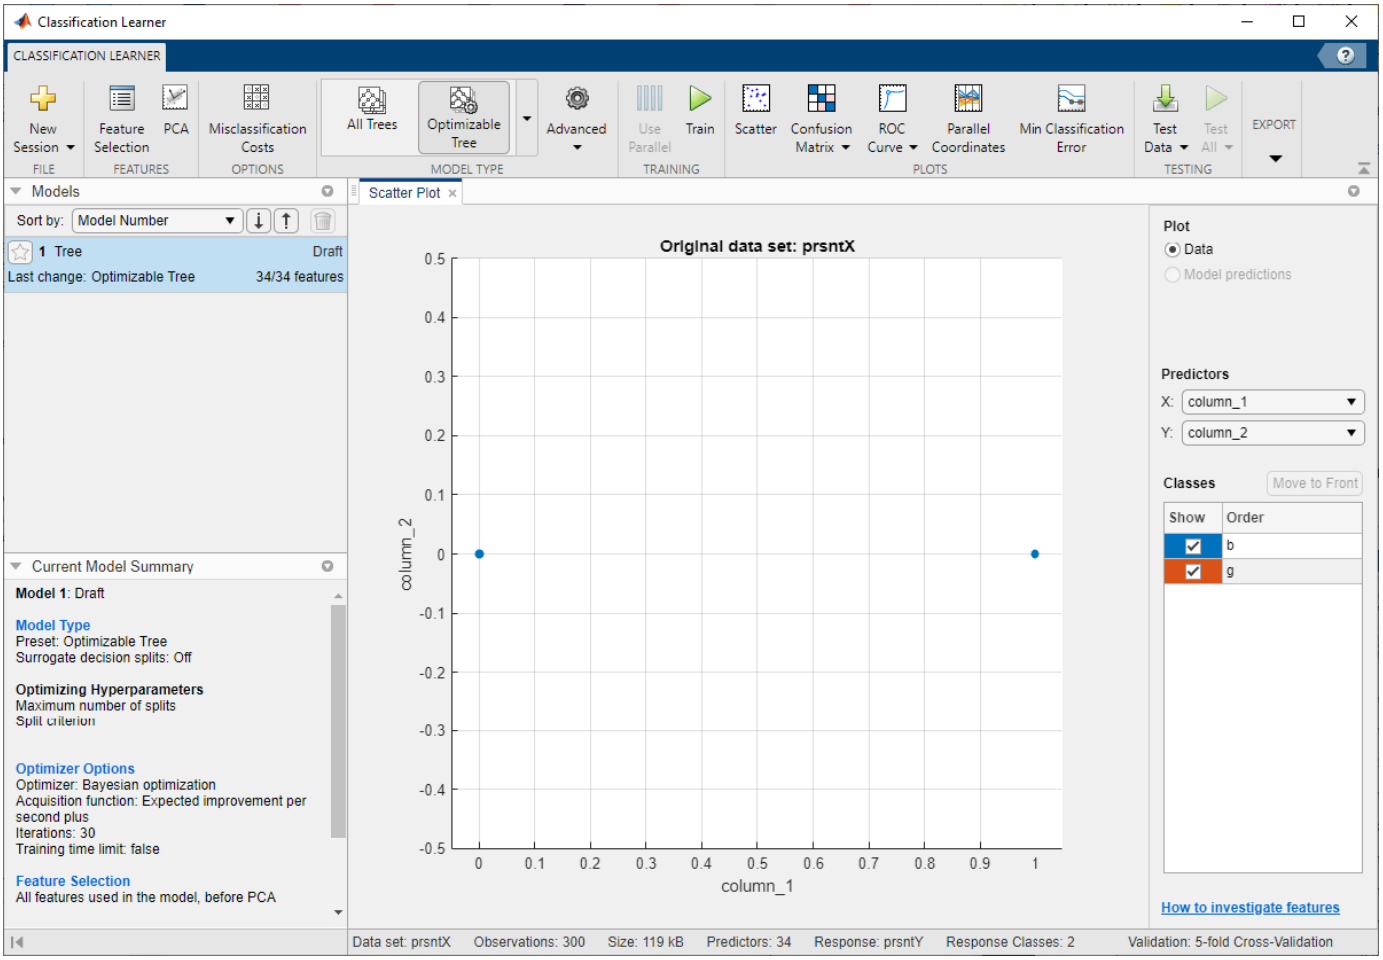
3. On the **Classification Learner** tab, in the **File** section, click **New Session** and select **From Workspace**.

4. In the New Session from Workspace dialog box, select the matrix `prsntX` from the **Data Set Variable** list. Under **Response**, click the **From workspace** option button and select the vector `prsntY` from the workspace. The default validation option is 5-fold cross-validation, to protect against overfitting. For this example, do not change the default settings.



5. To accept the default options and continue, click **Start Session**.

6. Select an optimizable tree model to train. On the **Classification Learner** tab, in the **Model Type** section, click the **Show more** arrow to open the gallery. In the **Decision Trees** group, click **Optimizable Tree**. The app disables the **Use Parallel** button when you select an optimizable model.



7. In the **Training** section, click **Train**. The app displays a **Minimum Classification Error Plot** as it runs the optimization process. At each iteration, the app tries a different combination of hyperparameter values and updates the plot with the minimum validation classification error observed up to that iteration, indicated in dark blue. When the app completes the optimization process, it selects the set of optimized hyperparameters, indicated by a red square. For more information, see “Minimum Classification Error Plot” on page 23-61.

The app lists the optimized hyperparameters in both the **Optimization Results** section to the right of the plot and the **Optimized Hyperparameters** section of the **Current Model Summary** pane. In general, the optimization results are not reproducible.

8. Export the model to the MATLAB workspace. On the **Classification Learner** tab, in the **Export** section, click **Export Model** and select **Export Model**, then click **OK**. The default name for the exported model is `trainedModel`.

Alternatively, you can generate MATLAB code that trains a classification model with the same settings used to train the model in the app. On the **Classification Learner** tab, in the **Export** section, click **Generate Function**. The app generates code from your session and displays the file in the MATLAB Editor. The file defines a function that accepts predictor and response variables, trains a classification model, and performs cross-validation. Change the function name to `trainClassificationTreeModel` and save the function file. Train a decision tree classification model by using the `trainClassificationTreeModel` function.

```
trainedModel = trainClassificationTreeModel(prsntX,prsntY);
```

9. Extract the trained model from the `trainedModel` variable. `trainedModel` contains a `ClassificationTree` model object in the `ClassificationTree` field.

```
treeMdl = trainedModel.ClassificationTree;
```

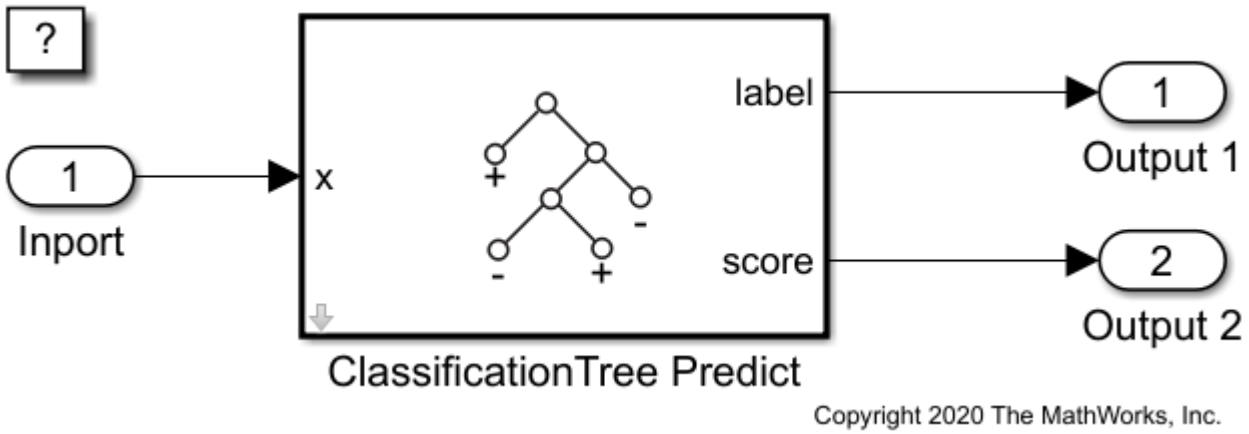
Because hyperparameter optimization can lead to an overfitted model, the recommended approach is to create a separate test set before importing your data into the Classification Learner app and see how the optimized model performs on your test set. For more details, see “Train Classifier Using Hyperparameter Optimization in Classification Learner App” on page 23-128.

Create Simulink Model

This example provides the Simulink model `slexIonosphereClassificationTreePredictExample.slx`, which includes the ClassificationTree Predict block. You can open the Simulink model or create a new model as described in this section.

Open the Simulink model `slexIonosphereClassificationTreePredictExample.slx`.

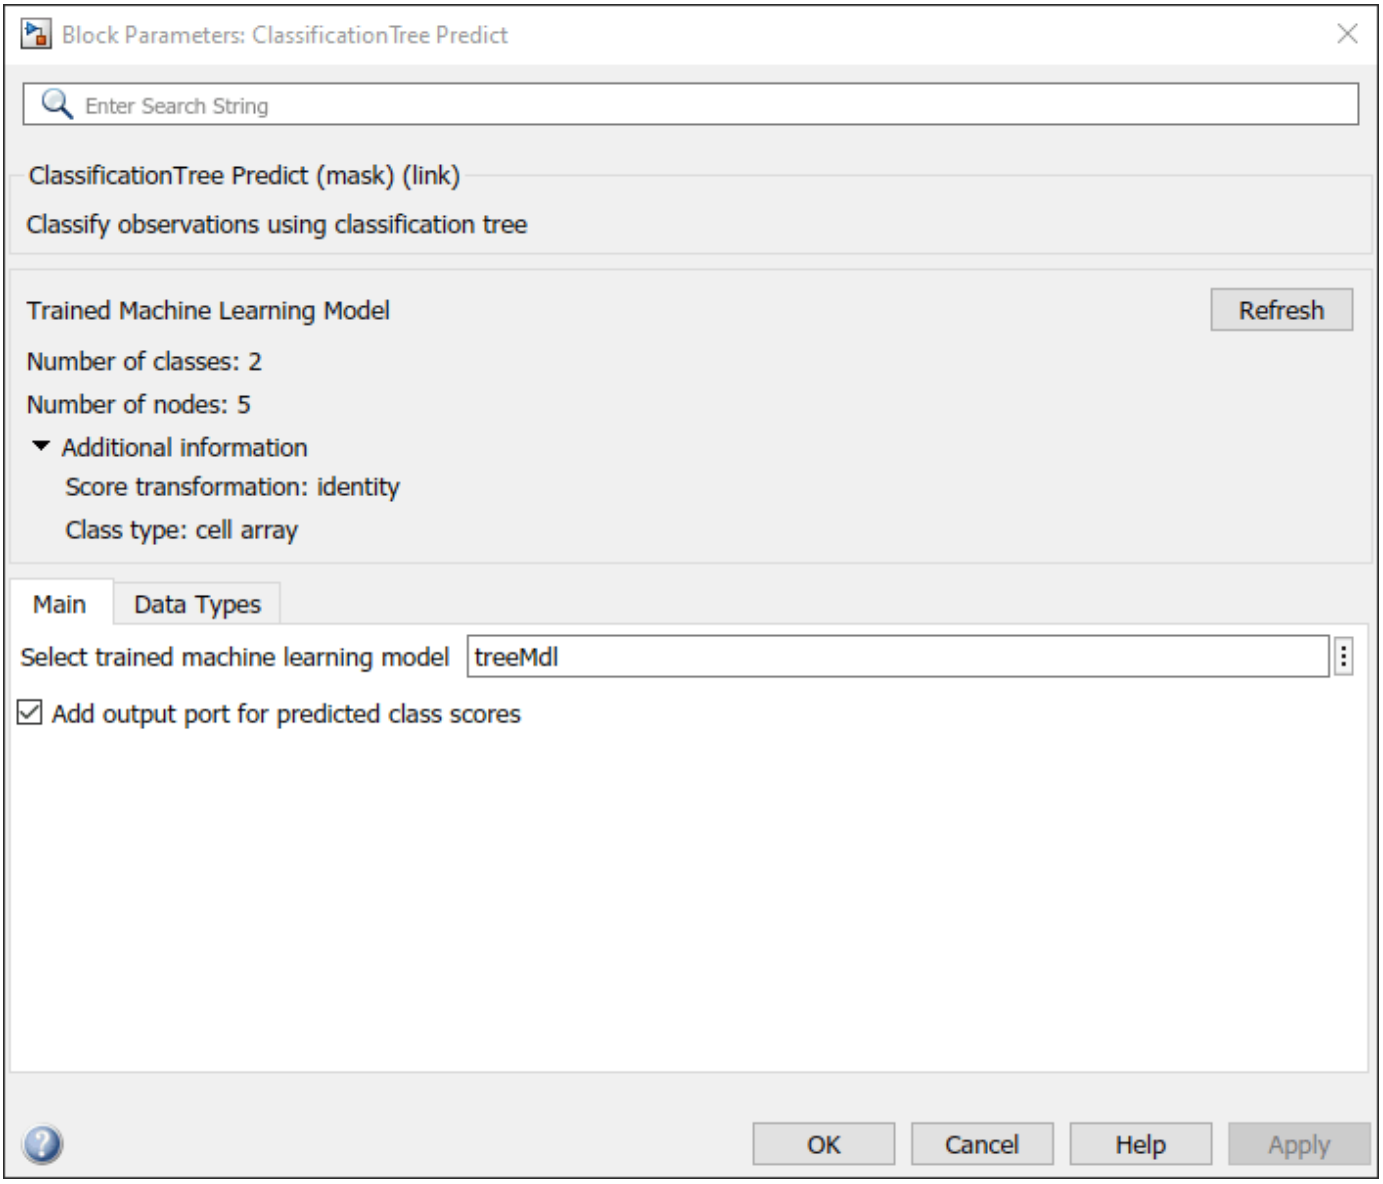
```
SimMdlName = 'slexIonosphereClassificationTreePredictExample';
open_system(SimMdlName)
```



The `PreLoadFcn` callback function of `slexIonosphereClassificationTreePredictExample` includes code to load the sample data, train the model, and create an input signal for the Simulink model. If you open the Simulink model, then the software runs the code in `PreLoadFcn` before loading the Simulink model. To view the callback function, in the **Setup** section on the **Modeling** tab, click **Model Settings** and select **Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` callback function in the **Model callbacks** pane.

To create a new Simulink model, open the **Blank Model** template and add the ClassificationTree Predict block. Add the Inport and Outport blocks and connect them to the ClassificationTree Predict block.

Double-click the ClassificationTree Predict block to open the Block Parameters dialog box. You can specify the name of a workspace variable that contains the trained model. The default variable name is `treeMdl`. Click the **Refresh** button. The dialog box displays the options used to train the model `treeMdl` under **Trained Machine Learning Model**. Select the **Add output port for predicted class scores** check box to add the second output port **score**.



The ClassificationTree Predict block expects an observation containing 34 predictor values. Double-click the Inport block, and set the **Port dimensions** to 34 on the **Signal Attributes** tab.

Create an input signal in the form of a structure array for the Simulink model. The structure array must contain these fields:

- `time` — The points in time at which the observations enter the model. In this example, the duration includes the integers from 0 through 50. The orientation must correspond to the observations in the predictor data. So, in this case, `time` must be a column vector.
- `signals` — A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`, where `values` is a matrix of predictor data, and `dimensions` is the number of predictor variables.

Create an appropriate structure array for future radar returns.

```
radarReturnInput.time = (0:50)';
radarReturnInput.signals(1).values = ftrX;
radarReturnInput.signals(1).dimensions = size(ftrX,2);
```

To import signal data from the workspace:

- Open the Configuration Parameters dialog box. On the **Modeling** tab, click **Model Settings**.
- In the **Data Import/Export** pane, select the **Input** check box and enter `radarReturnInput` in the adjacent text box.
- In the **Solver** pane, under **Simulation time**, set **Stop time** to `radarReturnInput.time(end)`. Under **Solver selection**, set **Type** to `Fixed-step`, and set **Solver** to `discrete (no continuous states)`.

For more details, see “Load Signal Data for Simulation” (Simulink).

Simulate the model.

```
sim(SimMdlName);
```

When the Inport block detects an observation, it directs the observation into the ClassificationTree Predict block. You can use the Simulation Data Inspector (Simulink) to view the logged data of the Outport blocks.

Predict Responses Using RegressionTree Predict Block

This example shows how to use the RegressionTree Predict block for response prediction in Simulink®. The block accepts an observation (predictor data) and returns the predicted response for the observation using the trained regression tree model.

Train Regression Model

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s. Create a matrix containing the predictor variables and a vector of the response variable.

```
load carbig
X = [Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight];
Y = MPG;
```

Train a regression tree model.

```
treeMdl = fitrtree(X,Y);
```

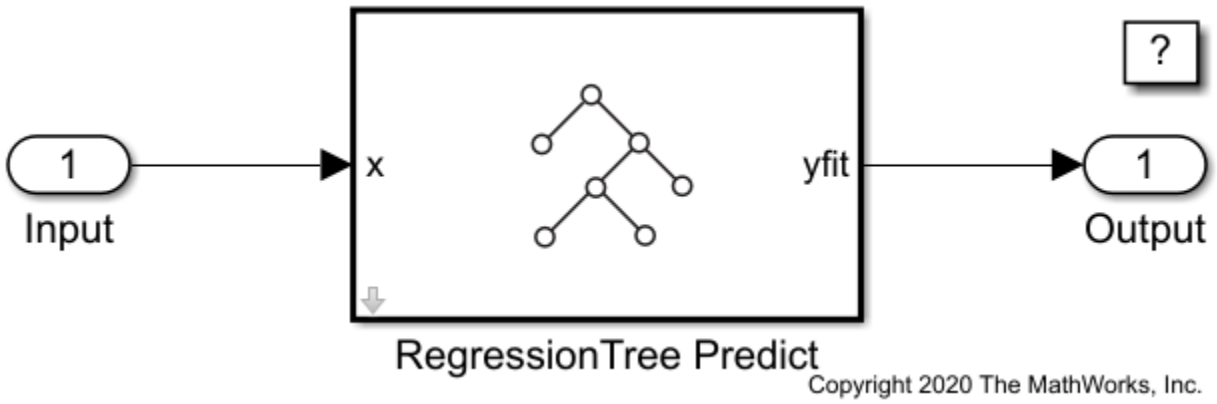
`treeMdl` is a `RegressionTree` model.

Create Simulink Model

This example provides the Simulink model `slexCarDataRegressionTreePredictExample.slx`, which includes the RegressionTree Predict block. You can open the Simulink model or create a new model as described in this section.

Open the Simulink model `slexCarDataRegressionTreePredictExample.slx`.

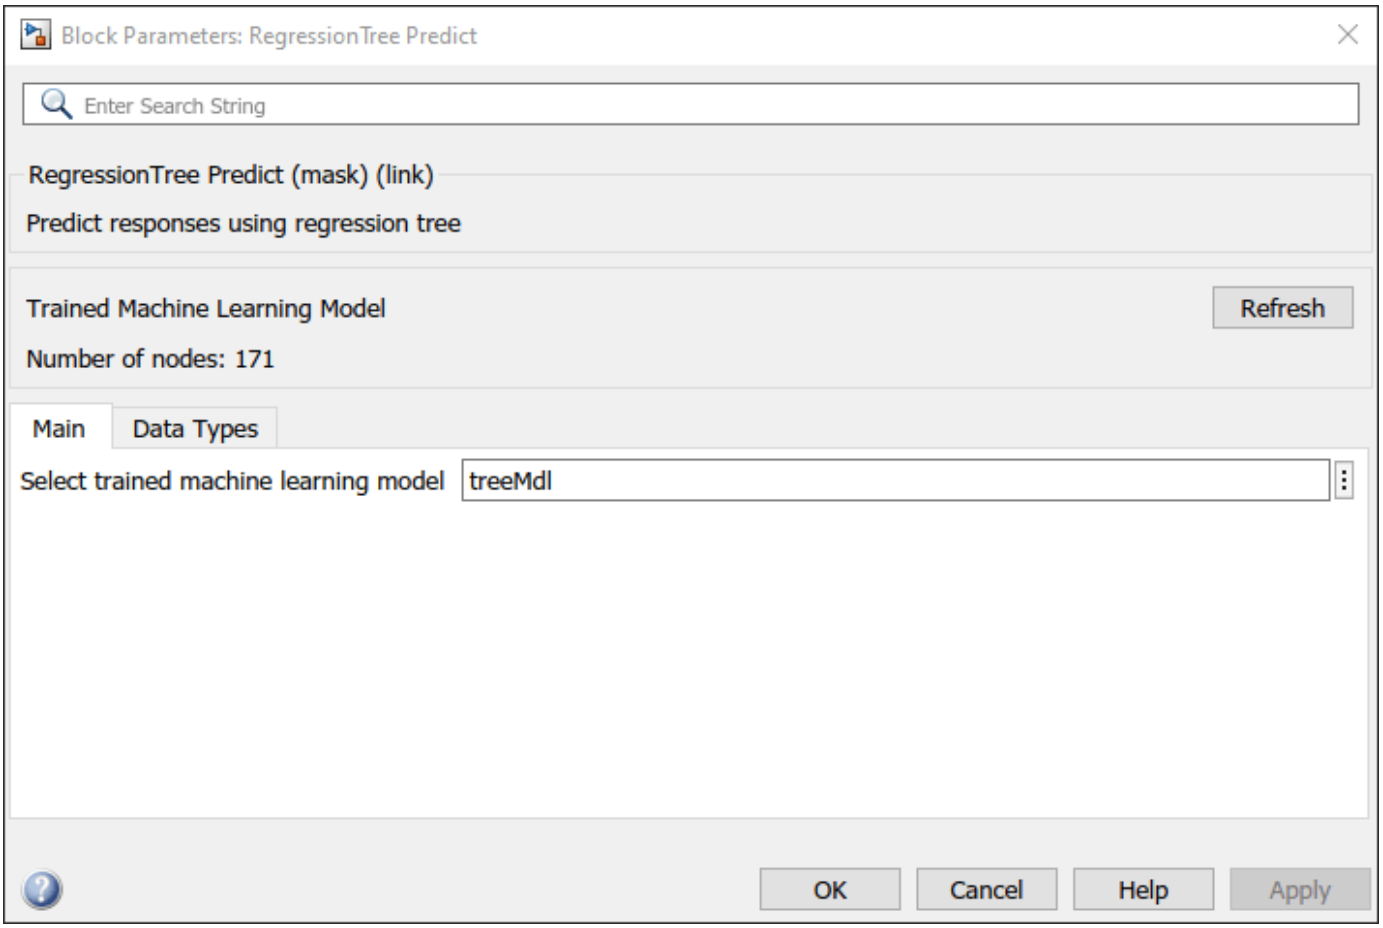
```
SimMdlName = 'slexCarDataRegressionTreePredictExample';
open_system(SimMdlName)
```



The `PreLoadFcn` callback function of `slexCarDataRegressionTreePredictExample` includes code to load the sample data, train the tree model, and create an input signal for the Simulink model. If you open the Simulink model, then the software runs the code in `PreLoadFcn` before loading the Simulink model. To view the callback function, in the **Setup** section on the **Modeling** tab, click **Model Settings** and select **Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` callback function in the **Model callbacks** pane.

To create a new Simulink model, open the **Blank Model** template and add the RegressionTree Predict block. Add the Inport and Outport blocks and connect them to the RegressionTree Predict block.

Double-click the RegressionTree Predict block to open the Block Parameters dialog box. You can specify the name of a workspace variable that contains the trained tree model. The default variable name is `treeMdl`. Click the **Refresh** button. The dialog box displays the options used to train the tree model `treeMdl` under **Trained Machine Learning Model**.



The RegressionTree Predict block expects an observation containing 6 predictor values. Double-click the Inport block, and set the **Port dimensions** to 6 on the **Signal Attributes** tab.

Create an input signal in the form of a structure array for the Simulink model. The structure array must contain these fields:

- `time` — The points in time at which the observations enter the model. The orientation must correspond to the observations in the predictor data. So, in this example, `time` must be a column vector.
- `signals` — A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`, where `values` is a matrix of predictor data, and `dimensions` is the number of predictor variables.

Create an appropriate structure array for the `slexCarDataRegressionTreePredictExample` model from the `carsmall` data set.

```
load carsmall
testX = [Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight];
testX = rmmissing(testX);
carsmallInput.time = (0:size(testX,1)-1)';
carsmallInput.signals(1).values = testX;
carsmallInput.signals(1).dimensions = size(testX,2);
```

To import signal data from the workspace:

- Open the Configuration Parameters dialog box. On the **Modeling** tab, click **Model Settings**.
- In the **Data Import/Export** pane, select the **Input** check box and enter `carsmallInput` in the adjacent text box.
- In the **Solver** pane, under **Simulation time**, set **Stop time** to `carsmallInput.time(end)`. Under **Solver selection**, set **Type** to `Fixed-step`, and set **Solver** to `discrete (no continuous states)`.

For more details, see “Load Signal Data for Simulation” (Simulink).

Simulate the model.

```
sim(SimMdlName);
```

When the Inport block detects an observation, it directs the observation into the RegressionTree Predict block. You can use the Simulation Data Inspector (Simulink) to view the logged data of the Outport block.

Predict Class Labels Using ClassificationEnsemble Predict Block

This example shows how to train an ensemble model with optimal hyperparameters, and then use the ClassificationEnsemble Predict block for label prediction in Simulink®. The block accepts an observation (predictor data) and returns the predicted class label and class score for the observation using the trained classification ensemble model.

Train Classification Model with Optimal Hyperparameters

Load the `CreditRating_Historical` data set. This data set contains customer IDs and their financial ratios, industry labels, and credit ratings. Determine the sample size.

```
tbl = readtable('CreditRating_Historical.dat');
n = numel(tbl)
```

```
n = 31456
```

Display the first three rows of the table.

```
head(tbl,3)
```

```
ans=3×8 table
     ID      WC_TA    RE_TA    EBIT_TA    MVE_BVTD    S_TA     Industry    Rating
    _____    _____    _____    _______    ________    _____    ________    ______

    62394    0.013    0.104     0.036      0.447      0.142       3        {'BB'}
    48608    0.232    0.335     0.062      1.969      0.281       8        {'A' }
    42444    0.311    0.367     0.074      1.935      0.366       1        {'A' }
```

`tbl.Industry` is a categorical variable for an industry label. When you train a model for the ClassificationEnsemble Predict block, you must preprocess categorical predictors by using the `dummyvar` function to include the categorical predictors in the model. You cannot use the `'CategoricalPredictors'` name-value argument. Create dummy variables for `tbl.Industry`.

```
d = dummyvar(tbl.Industry);
```

`dummyvar` creates dummy variables for each category of `tbl.Industry`. Determine the number of categories in `tbl.Industry` and the number of dummy variables in `d`.

```
unique(tbl.Industry)'
```

```
ans = 1×12

     1     2     3     4     5     6     7     8     9    10    11    12
```

```
size(d)
```

```
ans = 1×2

        3932          12
```

Create a numeric matrix for the predictor variables and a cell array for the response variable.

```
X = [table2array(tbl(:,2:6)) d];
Y = tbl.Rating;
```

X is a numeric matrix that contains 17 variables: the five financial ratios and the 12 dummy variables for the industry label. X does not use `tbl.ID` because the variable is not helpful in predicting credit ratings. Y is a cell array of character vectors that contains the corresponding credit ratings.

Suppose that you receive the data in sequence, and you have the first 3000 observations, but you have not received the last 932 yet. Partition the data into present and future samples.

```
prsntX = X(1:3000,:);
prsntY = Y(1:3000);
ftrX = X(3001:end,:);
ftrY = Y(3001:end);
```

Train an ensemble using all presently available data `prsntX` and `prsntY` with these options:

- Specify `'OptimizeHyperparameters'` as `'auto'` to train an ensemble with optimal hyperparameters. The `'auto'` option finds optimal values for `'Method'`,`'NumLearningCycles'`, and `'LearnRate'` (for applicable methods) of `fitcensemble` and `'MinLeafSize'` of tree learners.
- For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function. Also, for reproducibility of the random forest algorithm, specify `'Reproducible'` as `true` for tree learners.
- Specify the order of the classes by using the `'ClassNames'` name-value argument. The output values from the **score** port of the ClassificationEnsemble Predict block have the same order.

```
rng('default')
t = templateTree('Reproducible',true);
ensMdl = fitcensemble(prsntX,prsntY, ...
    'ClassNames',{'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC'}, ...
    'OptimizeHyperparameters','auto','Learners',t, ...
    'HyperparameterOptimizationOptions', ...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

```

  Properties, Methods
```

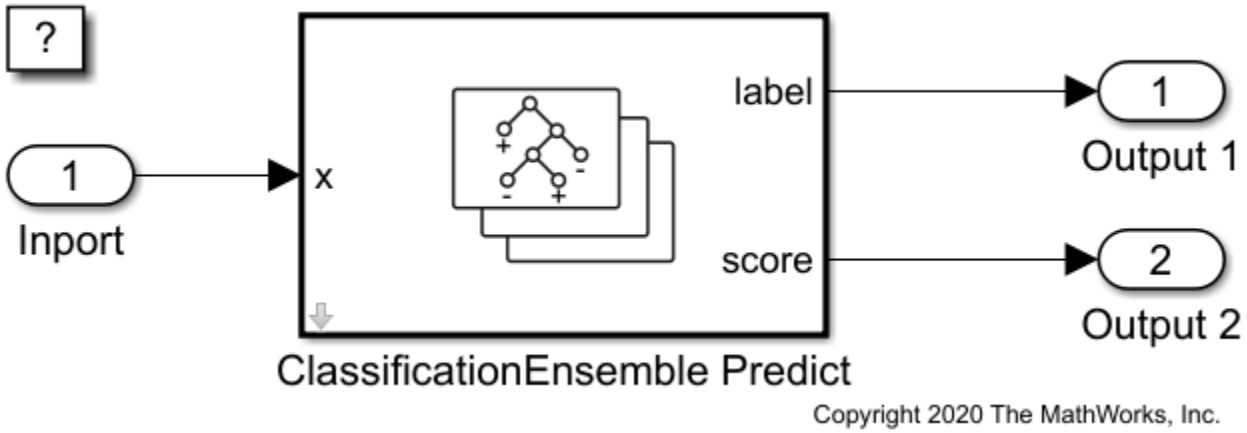
`fitcensemble` returns a `ClassificationBaggedEnsemble` object because the function finds the random forest algorithm (`'Bag'`) as the optimal method.

Create Simulink Model

This example provides the Simulink model `slexCreditRatingClassificationEnsemblePredictExample.slx`, which includes the ClassificationEnsemble Predict block. You can open the Simulink model or create a new model as described in this section.

Open the Simulink model `slexCreditRatingClassificationEnsemblePredictExample.slx`.

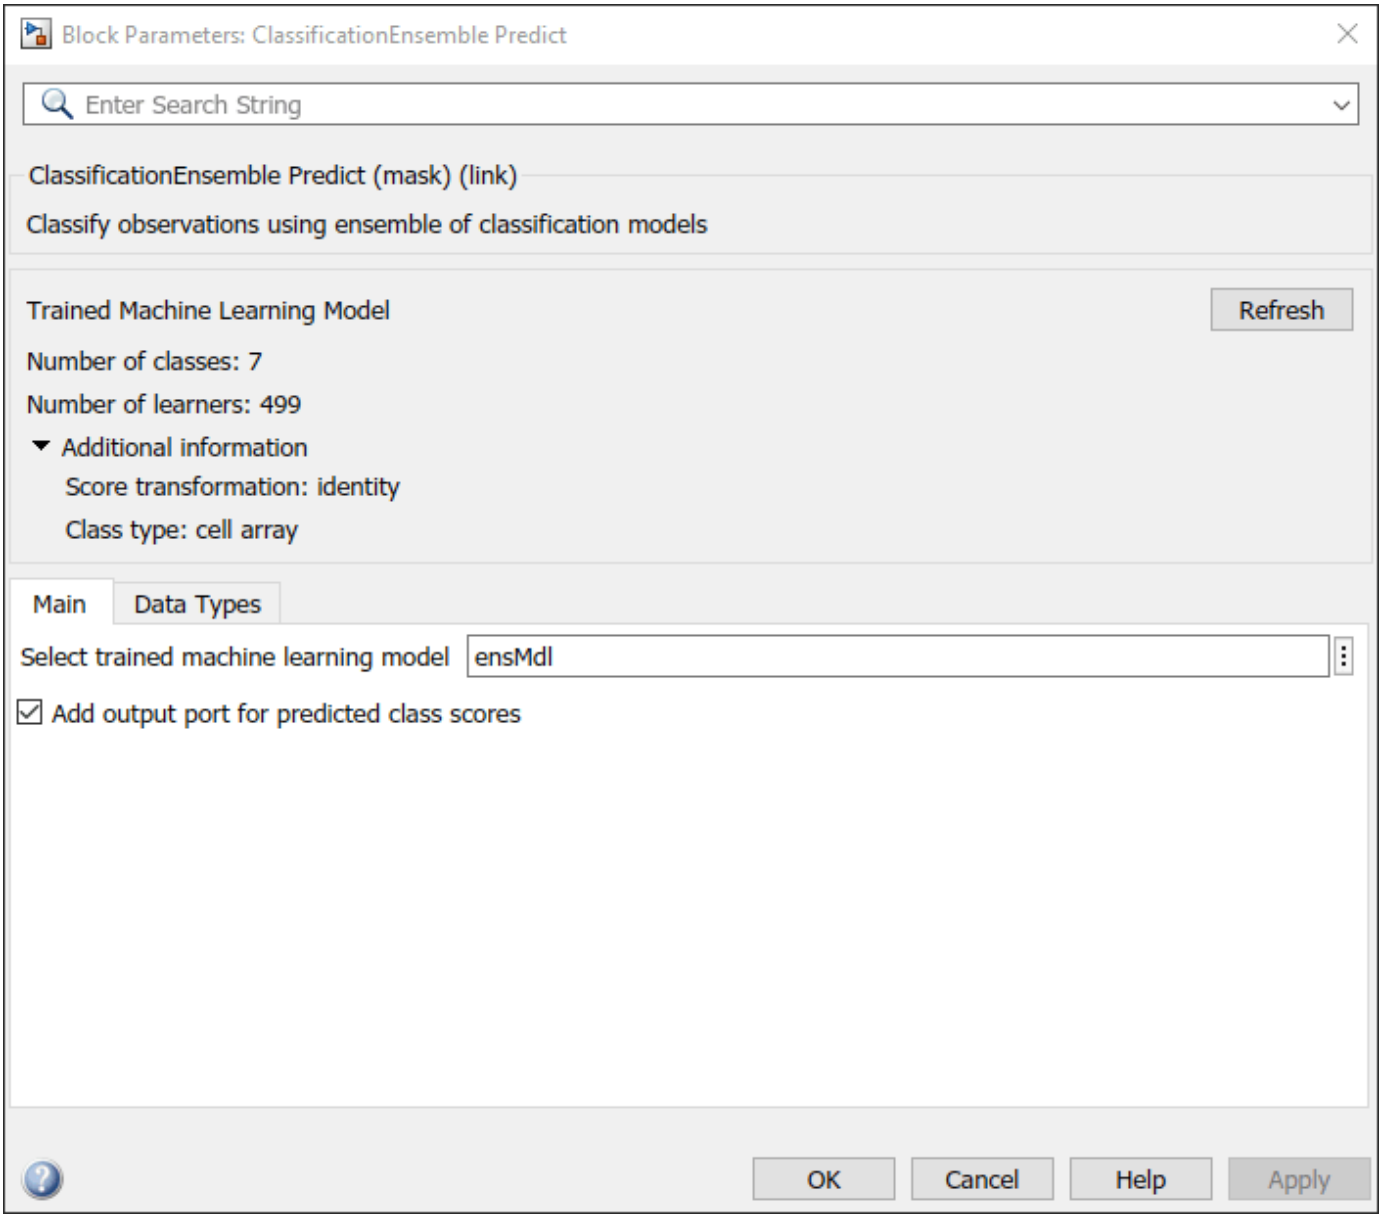
```
SimMdlName = 'slexCreditRatingClassificationEnsemblePredictExample';
open_system(SimMdlName)
```



The `PreLoadFcn` callback function of `slexCreditRatingClassificationEnsemblePredictExample` includes code to load the sample data, train the model using the optimal hyperparameters, and create an input signal for the Simulink model. If you open the Simulink model, then the software runs the code in `PreLoadFcn` before loading the Simulink model. To view the callback function, in the **Setup** section on the **Modeling** tab, click **Model Settings** and select **Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` callback function in the **Model callbacks** pane.

To create a new Simulink model, open the **Blank Model** template and add the ClassificationEnsemble Predict block. Add the Inport and Outport blocks and connect them to the ClassificationEnsemble Predict block.

Double-click the ClassificationEnsemble Predict block to open the Block Parameters dialog box. Specify the **Select trained machine learning model** parameter as `ensMdl`, which is the name of a workspace variable that contains the trained model. Click the **Refresh** button. The dialog box displays the options used to train the model `ensMdl` under **Trained Machine Learning Model**. Select the **Add output port for predicted class scores** check box to add the second output port **score**.



The ClassificationEnsemble Predict block expects an observation containing 17 predictor values. Double-click the Inport block, and set the **Port dimensions** to 17 on the **Signal Attributes** tab.

Create an input signal in the form of a structure array for the Simulink model. The structure array must contain these fields:

- `time` — The points in time at which the observations enter the model. In this example, the duration includes the integers from 0 through 931. The orientation must correspond to the observations in the predictor data. So, in this case, `time` must be a column vector.
- `signals` — A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`, where `values` is a matrix of predictor data, and `dimensions` is the number of predictor variables.

Create an appropriate structure array for future samples.

```
creditRatingInput.time = (0:931)';
creditRatingInput.signals(1).values = ftrX;
creditRatingInput.signals(1).dimensions = size(ftrX,2);
```

To import signal data from the workspace:

- Open the Configuration Parameters dialog box. On the **Modeling** tab, click **Model Settings**.
- In the **Data Import/Export** pane, select the **Input** check box and enter `creditRatingInput` in the adjacent text box.
- In the **Solver** pane, under **Simulation time**, set **Stop time** to `creditRatingInput.time(end)`. Under **Solver selection**, set **Type** to `Fixed-step`, and set **Solver** to `discrete (no continuous states)`.

For more details, see “Load Signal Data for Simulation” (Simulink).

Simulate the model.

```
sim(SimMdlName);
```

When the Inport block detects an observation, it directs the observation into the ClassificationEnsemble Predict block. You can use the Simulation Data Inspector (Simulink) to view the logged data of the Outport blocks.

Predict Responses Using RegressionEnsemble Predict Block

This example shows how to train an ensemble model with optimal hyperparameters, and then use the RegressionEnsemble Predict block for response prediction in Simulink®. The block accepts an observation (predictor data) and returns the predicted response for the observation using the trained regression ensemble model.

Train Regression Model with Optimal Hyperparameters

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
whos
```

```
  Name                Size            Bytes  Class     Attributes

  Acceleration      406x1              3248  double
  Cylinders         406x1              3248  double
  Displacement      406x1              3248  double
  Horsepower        406x1              3248  double
  MPG               406x1              3248  double
  Mfg               406x13            10556  char
  Model             406x36            29232  char
  Model_Year        406x1              3248  double
  Origin            406x7              5684  char
  Weight            406x1              3248  double
  cyl4              406x5              4060  char
  org               406x7              5684  char
  when              406x5              4060  char
```

`Origin` is a categorical variable. When you train a model for the RegressionEnsemble Predict block, you must preprocess categorical predictors by using the `dummyvar` function to include the categorical predictors in the model. You cannot use the `'CategoricalPredictors'` name-value argument. Create dummy variables for `Origin`.

```
c_Origin = categorical(cellstr(Origin));
d_Origin = dummyvar(c_Origin);
```

`dummyvar` creates dummy variables for each category of `c_Origin`. Determine the number of categories in `c_Origin` and the number of dummy variables in `d_Origin`.

```
unique(cellstr(Origin))
```

```
ans = 7x1 cell
    {'England'}
    {'France' }
    {'Germany'}
    {'Italy'  }
    {'Japan'  }
    {'Sweden' }
    {'USA'    }
```

```
size(d_Origin)
```

```
ans = 1×2
```

```
   406     7
```

`dummyvar` creates dummy variables for each category of `Origin`.

Create a matrix containing six numeric predictor variables and the seven dummy variables for `Origin`. Also, create a vector of the response variable.

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight,d_Origin];
Y = MPG;
```

Train an ensemble using `X` and `Y` with these options:

- Specify `'OptimizeHyperparameters'` as `'auto'` to train an ensemble with optimal hyperparameters. The `'auto'` option finds optimal values for `'Method'`,`'NumLearningCycles'`, and `'LearnRate'` (for applicable methods) of `fitrensemble` and `'MinLeafSize'` of tree learners.
- For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function. Also, for reproducibility of the random forest algorithm, specify `'Reproducible'` as `true` for tree learners.

```
rng('default')
t = templateTree('Reproducible',true);
ensMdl = fitrensemble(X,Y,'Learners',t, ...
    'OptimizeHyperparameters','auto', ...
    'HyperparameterOptimizationOptions', ...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

  Properties, Methods
```

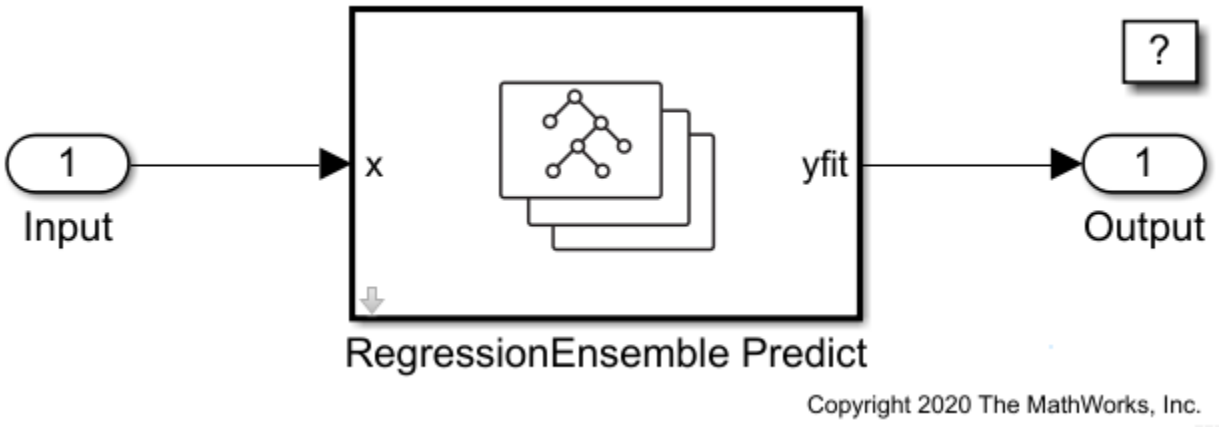
`fitrensemble` returns a `RegressionBaggedEnsemble` object because the function finds the random forest algorithm (`'Bag'`) as the optimal method.

Create Simulink Model

This example provides the Simulink model `slexCarDataRegressionEnsemblePredictExample.slx`, which includes the RegressionEnsemble Predict block. You can open the Simulink model or create a new model as described in this section.

Open the Simulink model `slexCarDataRegressionEnsemblePredictExample.slx`.

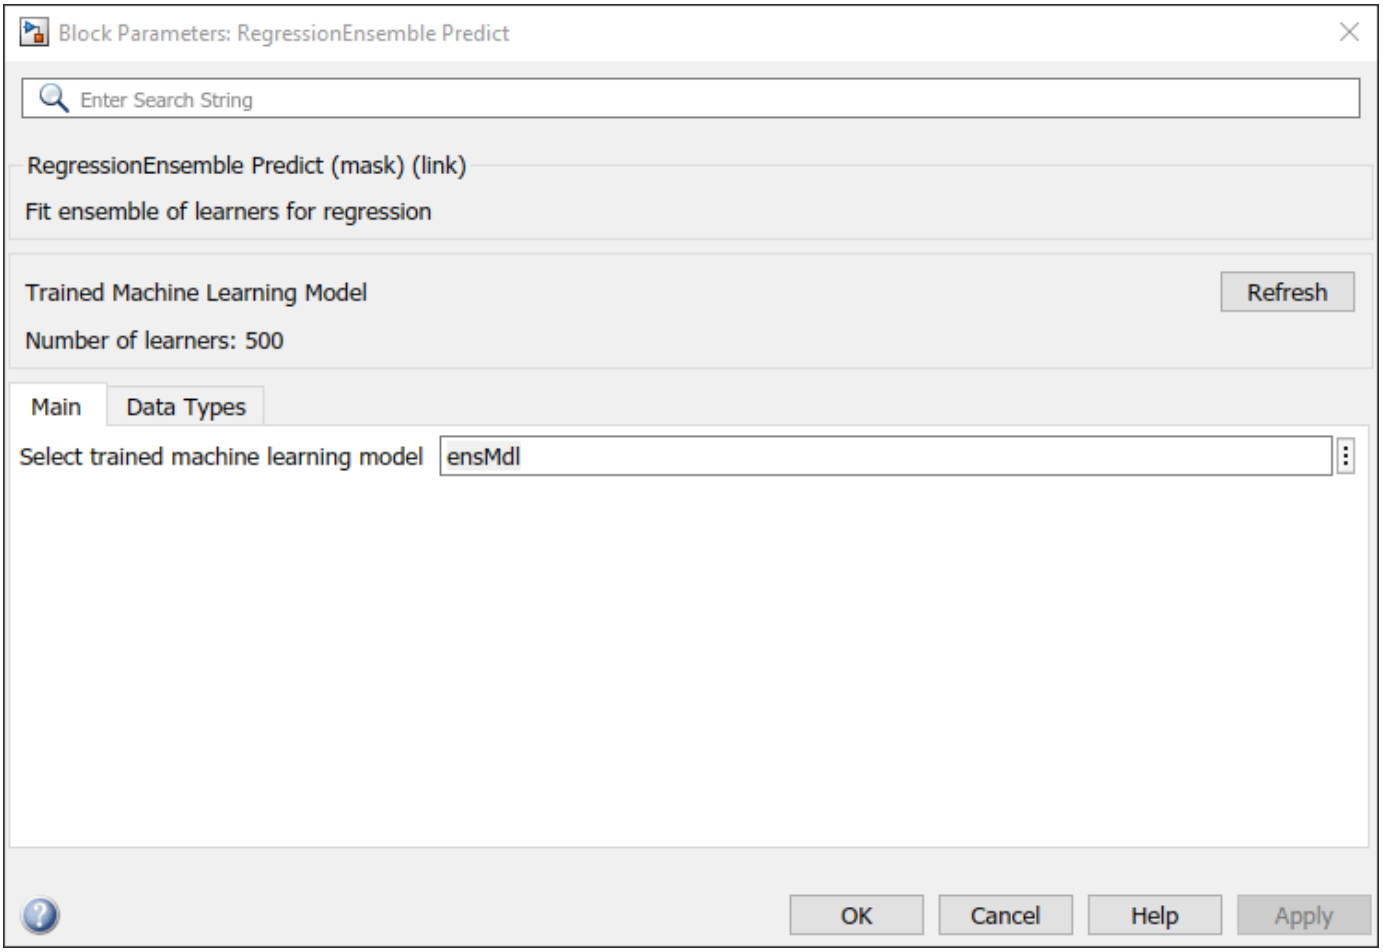
```
SimMdlName = 'slexCarDataRegressionEnsemblePredictExample';
open_system(SimMdlName)
```



The `PreLoadFcn` callback function of `slexCarDataRegressionEnsemblePredictExample` includes code to load the sample data, train the model using the optimal hyperparameters, and create an input signal for the Simulink model. If you open the Simulink model, then the software runs the code in `PreLoadFcn` before loading the Simulink model. To view the callback function, in the **Setup** section on the **Modeling** tab, click **Model Settings** and select **Model Properties**. Then, on the **Callbacks** tab, select the `PreLoadFcn` callback function in the **Model callbacks** pane.

To create a new Simulink model, open the **Blank Model** template and add the RegressionEnsemble Predict block. Add the Inport and Outport blocks and connect them to the RegressionEnsemble Predict block.

Double-click the RegressionEnsemble Predict block to open the Block Parameters dialog box. Specify the **Select trained machine learning model** parameter as `ensMdl`, which is the name of a workspace variable that contains the trained model. Click the **Refresh** button. The dialog box displays the options used to train the model `ensMdl` under **Trained Machine Learning Model**.



The RegressionEnsemble Predict block expects an observation containing 13 predictor values. Double-click the Inport block, and set the **Port dimensions** to 13 on the **Signal Attributes** tab.

Create an input signal in the form of a structure array for the Simulink model. The structure array must contain these fields:

- `time` — The points in time at which the observations enter the model. The orientation must correspond to the observations in the predictor data. So, in this example, `time` must be a column vector.
- `signals` — A 1-by-1 structure array describing the input data and containing the fields `values` and `dimensions`, where `values` is a matrix of predictor data, and `dimensions` is the number of predictor variables.

Create an appropriate structure array for the `slexCarDataRegressionEnsemblePredictExample` model from the `carsmall` data set. When you convert `Origin` in `carsmall` to the `categorical` data type array `c_Origin_small`, use `categories(c_Origin)` so that `c_Origin` and `c_Origin_small` have the same number of categories in the same order.

```
load carsmall
c_Origin_small = categorical(cellstr(Origin),categories(c_Origin));
d_Origin_small = dummyvar(c_Origin_small);
```

```
testX = [Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight,d_Origin_small];
testX = rmmissing(testX);
carsmallInput.time = (0:size(testX,1)-1)';
carsmallInput.signals(1).values = testX;
carsmallInput.signals(1).dimensions = size(testX,2);
```

To import signal data from the workspace:

- Open the Configuration Parameters dialog box. On the **Modeling** tab, click **Model Settings**.
- In the **Data Import/Export** pane, select the **Input** check box and enter `carsmallInput` in the adjacent text box.
- In the **Solver** pane, under **Simulation time**, set **Stop time** to `carsmallInput.time(end)`. Under **Solver selection**, set **Type** to `Fixed-step`, and set **Solver** to `discrete (no continuous states)`.

For more details, see “Load Signal Data for Simulation” (Simulink).

Simulate the model.

```
sim(SimMdlName);
```

When the Inport block detects an observation, it directs the observation into the RegressionTree Predict block. You can use the Simulation Data Inspector (Simulink) to view the logged data of the Outport block.

Code Generation for Logistic Regression Model Trained in Classification Learner

This example shows how to train a logistic regression model using Classification Learner, and then generate C code that predicts labels using the exported classification model.

Load Sample Data

Load sample data and import the data into the Classification Learner app.

Load the `patients` data set. Specify the predictor data `X`, consisting of `p` predictors, and the response variable `Y`.

```
load patients
X = [Age Diastolic Height Systolic Weight];
p = size(X,2);
Y = Gender;
```

On the **Apps** tab, click the **Show more** arrow at the right of the Apps section to display the gallery, and select **Classification Learner**. On the **Classification Learner** tab, in the **File** section, select **New Session > From Workspace**.

In the New Session from Workspace dialog box, under **Data Set Variable**, select `X` from the list of workspace variables. Under **Response**, click the **From workspace** option button and then select `Y` from the list. To accept the default validation scheme and continue, click **Start Session**. The default validation option is 5-fold cross-validation, to protect against overfitting.

By default, Classification Learner creates a scatter plot of the data.

Train Logistic Regression Model

Train a logistic regression model within the Classification Learner app.

On the **Classification Learner** tab, in the **Model Type** section, click the **Show more** arrow to display the gallery of classifiers. Under **Logistic Regression Classifiers**, click the **Logistic Regression** model. Click **Train** in the **Training** section. The app trains the model and displays its cross-validation accuracy score **Accuracy (Validation)**.

Export Model to Workspace

Export the model to the MATLAB® Workspace and save it using `saveLearnerForCoder`.

In the **Export** section, select **Export Model > Export Compact Model**. Click **OK** in the dialog box.

The structure `trainedModel` appears in the MATLAB Workspace. The field `GeneralizedLinearModel` of `trainedModel` contains the compact model.

Note: If you run this example with all supporting files, you can load the `trainedModel.mat` file at the command line rather than exporting the model. The `trainedModel` structure was created using the previous steps.

```
load('trainedModel.mat')
```

At the command line, save the compact model to a file named `myModel.mat` in your current folder.

```
saveLearnerForCoder(trainedModel.GeneralizedLinearModel,'myModel')
```

Additionally, save the names of the success, failure, and missing classes of the trained model.

```
classNames = {trainedModel.SuccessClass, ...
    trainedModel.FailureClass,trainedModel.MissingClass};
save('ModelParameters.mat','classNames');
```

Generate C Code for Prediction

Define the entry-point function for prediction, and generate code for the function by using `codegen`.

In your current folder, define a function named `classifyX.m` that does the following:

- Accepts a numeric matrix (`X`) of observations containing the same predictor variables as the ones used to train the logistic regression model
- Loads the classification model in `myModel.mat`
- Computes predicted probabilities using the model
- Converts the predicted probabilities to indices, where 1 indicates a success, 2 indicates a failure, and 3 indicates a missing value
- Loads the class names in `ModelParameters.mat`
- Returns predicted labels by indexing into the class names

```
function label = classifyX (X) %#codegen
%CLASSIFYX Classify using Logistic Regression Model
%  CLASSIFYX classifies the measurements in X
%  using the logistic regression model in the file myModel.mat,
%  and then returns class labels in label.

n = size(X,1);
label = coder.nullcopy(cell(n,1));

CompactMdl = loadLearnerForCoder('myModel');
probability = predict(CompactMdl,X);

index = ~isnan(probability).*((probability<0.5)+1) + isnan(probability)*3;

classInfo = coder.load('ModelParameters');
classNames = classInfo.classNames;

for i = 1:n
    label{i} = classNames{index(i)};
end
end
```

Note: If you create a logistic regression model in Classification Learner after using feature selection or principal component analysis (PCA), you must include additional lines of code in your entry-point function. For an example that shows these additional steps, see “Code Generation and Classification Learner App” on page 32-31.

Generate a MEX function from `classifyX.m`. Create a matrix `data` for code generation using `coder.typeof`. Specify that the number of rows in `data` is arbitrary, but that `data` must have `p` columns, where `p` is the number of predictors used to train the logistic regression model. Use the `-args` option to specify `data` as an argument.

```
data = coder.typeof(X,[Inf p],[1 0]);
codegen classifyX.m -args data
```

```
Code generation successful.
```

`codegen` generates the MEX file `classifyX_mex.mexw64` in your current folder. The file extension depends on your platform.

Verify that the MEX function returns the expected labels. Randomly draw 15 observations from `X`.

```
rng('default') % For reproducibility
testX = datasample(X,15);
```

Classify the observations by using the `predictFcn` function in the classification model trained in Classification Learner.

```
testLabels = trainedModel.predictFcn(testX);
```

Classify the observations by using the generated MEX function `classifyX_mex`.

```
testLabelsMEX = classifyX_mex(testX);
```

Compare the sets of predictions. `isequal` returns logical 1 (true) if `testLabels` and `testLabelsMEX` are equal.

```
isequal(testLabels,testLabelsMEX)
```

```
ans = logical
   1
```

`predictFcn` and the MEX function `classifyX_mex` return the same values.

addedvarplot(X,y,num,inmodel,stats)
addedvarplot(ax, ___ )
```

Description

`addedvarplot(X,y,num,inmodel)` displays an added variable plot using the predictive terms in `X`, the response values in `y`, the added term in column `num` of `X`, and the model with current terms specified by `inmodel`. `X` is an *n*-by-*p* matrix of *n* observations of *p* predictive terms. `y` is vector of *n* response values. `num` is a scalar index specifying the column of `X` with the term to be added. `inmodel` is a logical vector of *p* elements specifying the columns of `X` in the current model. By default, all elements of `inmodel` are `false`.

Note `addedvarplot` automatically includes a constant term in all models. Do not enter a column of 1s directly into `X`.

`addedvarplot(X,y,num,inmodel,stats)` uses the `stats` output from the `stepwisefit` function to improve the efficiency of repeated calls to `addedvarplot`. Otherwise, this syntax is equivalent to the previous syntax.

`addedvarplot(ax, ___ )` creates the plot in the axes specified by `ax` instead of the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes. For more information on creating an `Axes` object, see `axes` and `gca`.

Added variable plots are used to determine the unique effect of adding a new term to a multilinear model. The plot shows the relationship between the part of the response unexplained by terms already in the model and the part of the new term unexplained by terms already in the model. The "unexplained" parts are measured by the residuals of the respective regressions. A scatter of the residuals from the two regressions forms the added variable plot. In addition to the scatter of residuals, the plot produced by `addedvarplot` shows 95% confidence intervals on predictions from the fitted line. The slope of the fitted line is the coefficient that the new term would have if it were added to the model with terms `inmodel`. For more details, see "Added Variable Plot" on page 33-4579.

Added variable plots are sometimes known as partial regression leverage plots.

Examples

Create Added Variable Plot

Load the data in `hald.mat`, which contains observations of the reaction to heat for various cement mixtures.

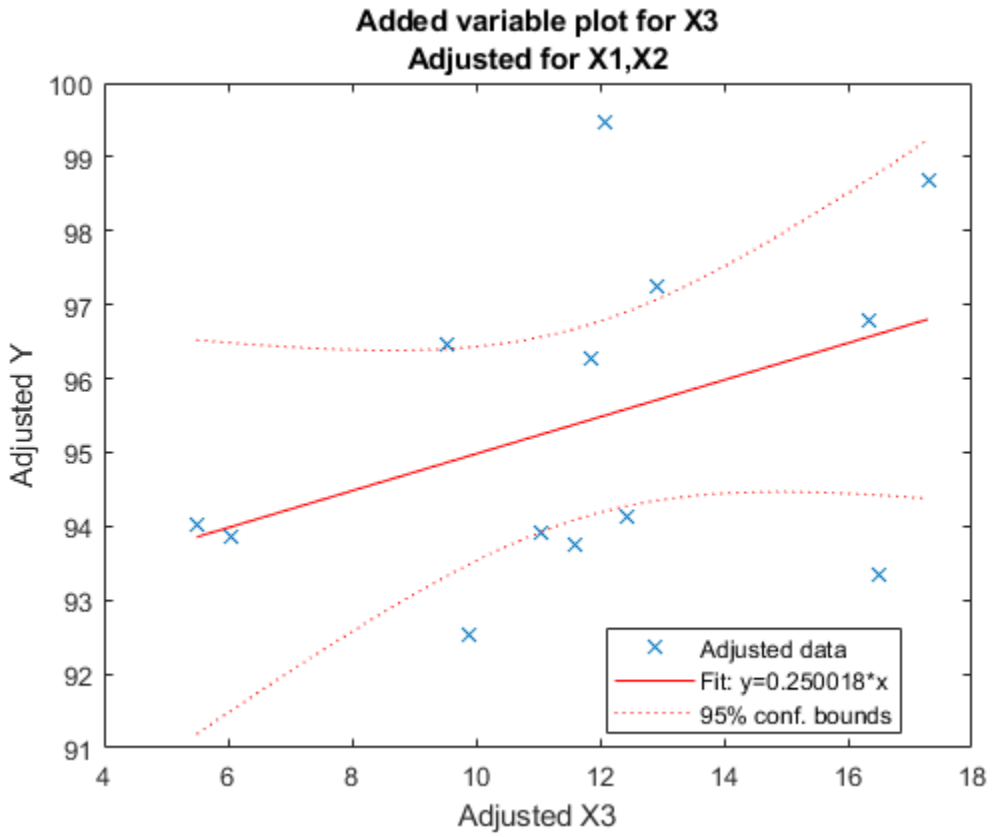
```
load hald
whos
```

```
  Name              Size            Bytes  Class     Attributes

  Description      22x58             2552  char
  hald             13x5               520  double
  heat             13x1               104  double
  ingredients      13x4               416  double
```

Create an added variable plot to investigate the effect of adding the third column of `ingredients` to a model that contains the first two columns.

```
inmodel = [true true false false];
addedvarplot(ingredients,heat,3,inmodel)
```



The wide scatter plot and the low slope of the fitted line are evidence against the statistical significance of adding the third column to the model.

Alternative Functionality

You can create a linear regression model object `LinearModel` by using `fitlm` or `stepwiselm` and use the object function `plotAdded` to create an added variable plot.

A `LinearModel` object provides the object properties and the object functions to investigate a fitted linear regression model. The object properties include information about coefficient estimates,

summary statistics, fitting method, and input data. Use the object functions to predict responses and to modify, evaluate, and visualize the linear regression model.

See Also

`plotAdded` | `stepwise` | `stepwisefit`

Introduced before R2006a

addK

Class: `clustering.evaluation.ClusterCriterion`
Package: `clustering.evaluation`

Evaluate additional numbers of clusters

Syntax

```
eva_out = addK(eva,klist)
```

Description

`eva_out = addK(eva,klist)` returns a clustering evaluation object `eva_out` that contains the evaluation data stored in the input object `eva`, plus additional evaluation data for the proposed number of clusters specified in `klist`.

Input Arguments

`eva` — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

`klist` — Additional numbers of clusters to evaluate

vector of positive integer values

Additional numbers of clusters to evaluate, specified as a vector of positive integer values. If any values in `klist` overlap with clustering solutions already evaluated in the input object `eva`, then `addK` ignores the overlapping values.

Output Arguments

`eva_out` — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a clustering evaluation object. `eva_out` contains data on the proposed clustering solutions included in the input clustering evaluation object `eva`, plus data on the additional proposed numbers of clusters specified in `klist`.

For all clustering evaluation object classes, `addK` updates the `InspectedK` and `CriterionValues` properties to include the proposed clustering solutions specified in `klist` and their corresponding criterion values. `addK` might also update the `OptimalK` and `OptimalY` properties to reflect the new optimal number of clusters and optimal clustering solution.

For certain cluster evaluation objects classes, `addK` might also update the following additional property values:

- For gap evaluation objects — `LogW`, `ExpectedLogW`, `StdLogW`, and `SE`

- For silhouette evaluation objects — `ClusterSilhouettes`

Examples

Evaluate Additional Numbers of Clusters

Create a clustering evaluation object using `evalclusters`, then use `addK` to evaluate additional numbers of clusters.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the Calinski-Harabasz criterion to evaluate proposed solutions of one through five clusters.

```
eva = evalclusters(meas,'kmeans','calinski','klist',1:5)
```

```
eva =
  CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
         InspectedK: [1 2 3 4 5]
    CriterionValues: [Inf 513.9245 561.6278 530.4871 456.1279]
           OptimalK: 1
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned value of `OptimalK` indicates that the optimal solution is three clusters.

Evaluate proposed solutions of 6 through 10 clusters using the same criteria. Add these evaluations to the original clustering evaluation object `eva`.

```
eva = addK(eva,6:10)
```

```
eva =
  CalinskiHarabaszEvaluation with properties:

    NumObservations: 150
         InspectedK: [1 2 3 4 5 6 7 8 9 10]
    CriterionValues: [1x10 double]
           OptimalK: 1
```

The updated values for `InspectedK` and `CriterionValues` show that `eva` now evaluates proposed solutions of 1 through 10 clusters. The `OptimalK` value still equals `3`, indicating that three clusters remain the optimal solution.

addlevels

(Not Recommended) Add levels to nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” data type instead.

Syntax

```
B = addlevels(A,newlevels)
```

Description

`B = addlevels(A,newlevels)` adds new levels specified by `newlevels` to the `nominal` or `ordinal` array `A`. `addlevels` adds the new levels at the end of the list of possible levels in `A`, but does not modify the value of any element. `B` does not contain elements at the new levels.

Examples

Add Levels To A Nominal Array

Add levels for additional species to Fisher's iris data.

Create a nominal array of the existing species in Fisher's iris data.

```
load fisheriris
species = nominal(species);
getlevels(species)
```

```
ans = 1x3 nominal
     setosa      versicolor      virginica
```

Add two additional species.

```
species = addlevels(species,{'spuria','ruthenica'});
getlevels(species)
```

```
ans = 1x5 nominal
     setosa      versicolor      virginica      spuria      ruthenica
```

Even though there are new levels, there are no elements in `species` that are in these new levels.

```
sum(species=='spuria')
```

```
ans = 0
```

```
sum(species=='ruthenica')
```

```
ans = 0
```

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

newlevels — Levels to add

string array | cell array of character vectors | 2-D character matrix

Levels to add to the input `nominal` or `ordinal` array, specified as a string array, a cell array of character vectors, or a 2-D character matrix.

Data Types: `char` | `string` | `cell`

Output Arguments

B — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

See Also

`droplevels` | `mergelevels` | `nominal` | `ordinal` | `reorderlevels`

Introduced in R2007a

addInteractions

Add interaction terms to univariate generalized additive model (GAM)

Syntax

```
UpdatedMdl = addInteractions(Mdl,Interactions)
UpdatedMdl = addInteractions(Mdl,Interactions,Name,Value)
```

Description

`UpdatedMdl = addInteractions(Mdl,Interactions)` returns an updated model `UpdatedMdl` by adding the interaction terms in `Interactions` to the univariate generalized additive model `Mdl`. The model `Mdl` must contain only linear terms for predictors.

If you want to resume training for the existing terms in `Mdl`, use the `resume` function.

`UpdatedMdl = addInteractions(Mdl,Interactions,Name,Value)` specifies additional options using one or more name-value arguments. For example, `'MaxPValue',0.05` specifies to include only the interaction terms whose *p*-values are not greater than 0.05.

Examples

Train GAM with Interaction Terms

Train a univariate GAM, which contains linear terms for predictors, and then add interaction terms to the trained model by using the `addInteractions` function.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table that contains the predictor variables (`Acceleration`, `Displacement`, `Horsepower`, and `Weight`) and the response variable (`MPG`).

```
tbl = table(Acceleration,Displacement,Horsepower,Weight,MPG);
```

Train a univariate GAM that contains linear terms for predictors in `tbl`.

```
Mdl = fitrgam(tbl,'MPG');
```

Add the five most important interaction terms to the trained model.

```
UpdatedMdl = addInteractions(Mdl,5);
```

`Mdl` is a univariate GAM, and `UpdatedMdl` is an updated GAM that contains all the terms in `Mdl` and five additional interaction terms. Display the interaction terms in `UpdatedMdl`.

```
UpdatedMdl.Interactions
```

```
ans = 5×2
```

```
     2     3
     1     2
     3     4
     1     4
     1     3
```

Each row of the `Interactions` property represents one interaction term and contains the column indexes of the predictor variables for the interaction term. You can use the `Interactions` property to check the interaction terms in the model and the order in which `fitrgam` adds them to the model.

Specify Options for Interaction Terms

Train a univariate GAM, which contains linear terms for predictors, and then add interaction terms to the trained model by using the `addInteractions` function. Specify the `'MaxPValue'` name-value argument to add interaction terms whose *p*-values are not greater than the `'MaxPValue'` value.

Load Fisher's iris data set. Create a table that contains observations for versicolor and virginica.

```
load fisheriris
inds = strcmp(species,'versicolor') | strcmp(species,'virginica');
Tbl = array2table(meas(inds,:),'VariableNames',["x1","x2","x3","x4"]);
Tbl.Y = species(inds,:);
```

Train a univariate GAM that contains linear terms for predictors in `Tbl`.

```
Mdl = fitcgam(Tbl,'Y');
```

Add important interaction terms to the trained model `Mdl`. Specify `'all'` for the `Interactions` argument, and set the `'MaxPValue'` name-value argument to 0.05. Among all available interaction terms, `addInteractions` identifies those whose *p*-values are not greater than the `'MaxPValue'` value and adds them to the model. The default `'MaxPValue'` is 1 so that the function adds all specified interaction terms to the model.

```
UpdatedMdl = addInteractions(Mdl,'all','MaxPValue',0.05);
UpdatedMdl.Interactions
```

```
ans = 5×2

     3     4
     2     4
     1     4
     2     3
     1     3
```

`Mdl` is a univariate GAM, and `UpdatedMdl` is an updated GAM that contains all the terms in `Mdl` and five additional interaction terms. `UpdatedMdl` includes five of the six available pairs of interaction terms.

Input Arguments

`Mdl` — Generalized additive model

`ClassificationGAM` model object | `RegressionGAM` model object

Generalized additive model, specified as a `ClassificationGAM` or `RegressionGAM` model object.

`Interactions` — Number of interaction terms or list of interaction terms

`0` | nonnegative integer | logical matrix | `'all'`

Number or list of interaction terms to include in the candidate set *S*, specified as a nonnegative integer scalar, a logical matrix, or `'all'`.

- Number of interaction terms, specified as a nonnegative integer — *S* includes the specified number of important interaction terms, selected based on the *p*-values of the terms.
- List of interaction terms, specified as a logical matrix — *S* includes the terms specified by a `t`-by-`p` logical matrix, where `t` is the number of interaction terms, and `p` is the number of predictors used to train the model. For example, `logical([1 1 0; 0 1 1])` represents two pairs of interaction terms: a pair of the first and second predictors, and a pair of the second and third predictors.

  If `addInteractions` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. That is, the column indexes of the logical matrix do not count the response and observation weight variables. The indexes also do not count any variables not used by the function.
- `'all'` — *S* includes all possible pairs of interaction terms, which is `p*(p − 1)/2` number of terms in total.

Among the interaction terms in *S*, the `addInteractions` function identifies those whose *p*-values are not greater than the `'MaxPValue'` value and uses them to build a set of interaction trees. Use the default value (`'MaxPValue'`,1) to build interaction trees using all terms in *S*.

Data Types: `single` | `double` | `logical` | `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `addInteractions(Mdl,'all','MaxPValue',0.05,'Verbose',1,'NumPrints',10)` specifies to include all available interaction terms whose *p*-values are not greater than 0.05 and to display diagnostic messages every 10 iterations.

`InitialLearnRateForInteractions` — Initial learning rate of gradient boosting for interaction terms

`1` (default) | numeric scalar in (0,1]

Initial learning rate of gradient boosting for interaction terms, specified as a numeric scalar in the interval (0,1].

For each boosting iteration for interaction trees, `addInteractions` starts fitting with the initial learning rate. The function halves the learning rate until it finds a rate that improves the model fit.

Training a model using a small learning rate requires more learning iterations, but often achieves better accuracy.

For more details about gradient boosting, see “Gradient Boosting Algorithm” on page 33-15.

Example: `'InitialLearnRateForInteractions',0.1`

Data Types: `single` | `double`

`MaxNumSplitsPerInteraction` — Maximum number of decision splits per interaction tree
4 (default) | positive integer scalar

Maximum number of decision splits (or branch nodes) for each interaction tree (boosted tree for an interaction term), specified as a positive integer scalar.

Example: `'MaxNumSplitsPerInteraction',5`

Data Types: `single` | `double`

`MaxPValue` — Maximum *p*-value for detecting interaction terms
1 (default) | numeric scalar in [0,1]

Maximum *p*-value for detecting interaction terms, specified as a numeric scalar in the interval [0,1].

`addInteractions` first finds the candidate set *S* of interaction terms from the `Interactions` value. Then the function identifies the interaction terms whose *p*-values are not greater than the `'MaxPValue'` value and uses them to build a set of interaction trees.

The default value (`'MaxPValue',1`) builds interaction trees for all interaction terms in the candidate set *S*.

For more details about detecting interaction terms, see “Interaction Term Detection” on page 33-15.

Example: `'MaxPValue',0.05`

Data Types: `single` | `double`

`NumPrint` — Number of iterations between diagnostic message printouts
`Mdl.ModelParameters.NumPrint` (default) | nonnegative integer scalar

Number of iterations between diagnostic message printouts, specified as a nonnegative integer scalar. This argument is valid only when you specify `'Verbose'` as 1.

If you specify `'Verbose',1` and `'NumPrint',numPrint`, then the software displays diagnostic messages every `numPrint` iterations in the Command Window.

The default value is `Mdl.ModelParameters.NumPrint`, which is the `NumPrint` value that you specify when creating the GAM object `Mdl`.

Example: `'NumPrint',500`

Data Types: `single` | `double`

`NumTreesPerInteraction` — Number of trees per interaction term
100 (default) | positive integer scalar

Number of trees per interaction term, specified as a positive integer scalar.

The `'NumTreesPerInteraction'` value is equivalent to the number of gradient boosting iterations for the interaction terms for predictors. For each iteration, `addInteractions` adds a set of interaction trees to the model, one tree for each interaction term. To learn about the gradient boosting algorithm, see “Gradient Boosting Algorithm” on page 33-15.

You can determine whether the fitted model has the specified number of trees by viewing the diagnostic message displayed when `'Verbose'` is 1 or 2, or by checking the `ReasonForTermination` property value of the model `Mdl`.

Example: `'NumTreesPerInteraction',500`

Data Types: `single` | `double`

`Verbose` — Verbosity level
`Mdl.ModelParameters.VerbosityLevel` (default) | `0` | `1` | `2`

Verbosity level, specified as `0`, `1`, or `2`. The `Verbose` value controls the amount of information that the software displays in the Command Window.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software displays no information.
`1`	The software displays diagnostic messages every `numPrint` iterations, where `numPrint` is the `'NumPrint'` value.
`2`	The software displays diagnostic messages at every iteration.

Each line of the diagnostic messages shows the information about each boosting iteration and includes the following columns:

- `Type` — Type of trained trees, `1D` (predictor trees, or boosted trees for linear terms for predictors) or `2D` (interaction trees, or boosted trees for interaction terms for predictors)
- `NumTrees` — Number of trees per linear term or interaction term that `addInteractions` added to the model so far
- `Deviance` — "Deviance" on page 33-15 of the model
- `RelTol` — Relative change of model predictions: $(\widehat{y}_k - \widehat{y}_{k-1})'(\widehat{y}_k - \widehat{y}_{k-1})/\widehat{y}_k'\widehat{y}_k$, where $\widehat{y}_k$ is a column vector of model predictions at iteration k
- `LearnRate` — Learning rate used for the current iteration

The default value is `Mdl.ModelParameters.VerbosityLevel`, which is the `Verbose` value that you specify when creating the GAM object `Mdl`.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`UpdatedMdl` — Updated generalized additive model
`ClassificationGAM` model object | `RegressionGAM` model object

Updated generalized additive model, returned as a `ClassificationGAM` or `RegressionGAM` model object. `UpdatedMdl` has the same object type as the input model `Mdl`.

To overwrite the input argument `Mdl`, assign the output of `addInteractions` to `Mdl`:

```
Mdl = addInteractions(Mdl,Interactions);
```

More About

Deviance

Deviance is a generalization of the residual sum of squares. It measures the goodness of fit compared to the saturated model.

The deviance of a fitted model is twice the difference between the loglikelihoods of the model and the saturated model:

$$-2(\log L - \log L_s),$$

where L and L_s are the likelihoods of the fitted model and the saturated model, respectively. The saturated model is the model with the maximum number of parameters that you can estimate.

`addInteractions` uses the deviance to measure the goodness of model fit and finds a learning rate that reduces the deviance at each iteration. Specify `'Verbose'` as 1 or 2 to display the deviance and learning rate in the Command Window.

Algorithms

Gradient Boosting Algorithm

`addInteractions` adds sets of interaction trees (boosted trees for interaction terms for predictors) to a univariate generalized additive model by using a gradient boosting algorithm (“Least-Squares Boosting” on page 18-50 for regression and “Adaptive Logistic Regression” on page 18-48 for classification). The algorithm iterates for at most `'NumTreesPerInteraction'` times for interaction trees.

For each boosting iteration, `addInteractions` builds a set of interaction trees with the initial learning rate `'InitialLearnRateForInteractions'`.

- When building a set of trees, the function trains one tree at a time. It fits a tree to the residual that is the difference between the response (observed response values for regression or scores of observed classes for classification) and the aggregated prediction from all trees grown previously. To control the boosting learning speed, the function shrinks the tree by the learning rate and then adds the tree to the model and updates the residual.
  - Updated model = current model + (learning rate)·(new tree)
  - Updated residual = current residual – (learning rate)·(response explained by new tree)
- If adding the set of trees improves the model fit (that is, reduces the deviance of the fit), then `addInteractions` moves to the next iteration.
- Otherwise, `addInteractions` halves the learning rate and uses it to update the model and residual. The function continues to halve the learning rate until it finds a rate that improves the model fit.

  If the function cannot find such a learning rate for interaction trees, then it terminates the model fitting. You can determine why training stopped by checking the `ReasonForTermination` property of the trained model.

Interaction Term Detection

For each pairwise interaction term $x_i x_j$ (specified by `Interactions`), the software performs an F-test to examine whether the term is statistically significant.

To speed up the process, `addInteractions` bins numeric predictors into at most 8 equiprobable bins. The number of bins can be less than 8 if a predictor has fewer than 8 unique values. The *F*-test examines the null hypothesis that the bins created by x_i and x_j have equal responses versus the alternative that at least one bin has a different response value from the others. A small *p*-value indicates that differences are significant, which implies that the corresponding interaction term is significant and, therefore, including the term can improve the model fit.

`addInteractions` builds a set of interaction trees using the terms whose *p*-values are not greater than the `'MaxPValue'` value. You can use the default `'MaxPValue'` value `1` to build interaction trees using all terms specified by `Interactions`.

`addInteractions` adds interaction terms to the model in the order of importance based on the *p*-values. Use the `Interactions` property of the returned model to check the order of the interaction terms added to the model.

“Train Generalized Additive Model for Regression” on page 12-91

Introduced in R2021a

addlistener

Class: `qrandstream`

Add listener for event

Syntax

```
el = addlistener(hsource,'eventname',callback)
el = addlistener(hsource,property,'eventname',callback)
```

Description

`el = addlistener(hsource,'eventname',callback)` creates a listener for the event named `eventname`, the source of which is handle object `hsource`. If `hsource` is an array of source handles, the listener responds to the named event on any handle in the array. `callback` is a function handle that is invoked when the event is triggered.

`el = addlistener(hsource,property,'eventname',callback)` adds a listener for a property event. `eventname` must be `'PreGet'`, `'PostGet'`, `'PreSet'`, or `'PostSet'`. `property` must be either a property name or cell array of property names, or a `meta.property` or array of `meta.property`. The properties must belong to the class of `hsource`. If `hsource` is scalar, `property` can include dynamic properties.

For all forms, `addlistener` returns an `event.listener`. To remove a listener, delete the object returned by `addlistener`. For example, `delete(el)` calls the handle class delete method to remove the listener and delete it from the workspace.

See Also

`delete` | `dynamicprops` | `event.listener` | `events` | `meta.property` | `notify` | `qrandstream` | `reset`

anova

Class: `GeneralizedLinearMixedModel`

Analysis of variance for generalized linear mixed-effects model

Syntax

```
stats = anova(glme)
stats = anova(glme,Name,Value)
```

Description

`stats = anova(glme)` returns a table, `stats`, that contains the results of *F*-tests to determine if all coefficients representing each fixed-effects term in the generalized linear mixed-effects model `glme` are equal to 0.

`stats = anova(glme,Name,Value)` returns a table, `stats`, using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the method used to compute the approximate denominator degrees of freedom for the *F*-tests.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`DFMethod` — Method for computing approximate denominator degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate denominator degrees of freedom to use in the *F*-test, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

Value	Description
`'residual'`	The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'none'`	All degrees of freedom are set to infinity.

The denominator degrees of freedom for the *F*-statistic correspond to the column `DF2` in the output structure `stats`.

Example: `'DFMethod','none'`

Output Arguments

`stats` — Results of *F*-tests for fixed-effects terms

table

Results of *F*-tests for fixed-effects terms, returned as a table with one row for each fixed-effects term in `glme` and the following columns.

Column Name	Description
`Term`	Name of the fixed-effects term
`FStat`	*F*-statistic for the term
`DF1`	Numerator degrees of freedom for the *F*-statistic
`DF2`	Denominator degrees of freedom for the *F*-statistic
`pValue`	*p*-value for the term

Each fixed-effects term is a continuous variable, a grouping variable, or an interaction between two or more continuous or grouping variables. For each fixed-effects term, `anova` performs an *F*-test (marginal test) to determine if all coefficients representing the fixed-effects term are equal to 0.

To perform tests for the type III hypothesis, when fitting the generalized linear mixed-effects model `fitglme`, you must use the `'effects'` contrasts for the `'DummyVarCoding'` name-value pair argument.

Examples

F-Tests for Fixed Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defect}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log\mu_{ij} = \beta_0 + \beta_1\text{newprocess}_{ij} + \beta_2\text{time\_dev}_{ij} + \beta_3\text{temp\_dev}_{ij} + \beta_4\text{supplier\_C}_{ij} + \beta_5\text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)',...
'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects')
```

```
glme =
Generalized linear mixed-effects model fit by ML

Model information:
    Number of observations             100
    Fixed effects coefficients           6

Random effects covariance parameters:
Group: factory (20 Levels)
    Name1                 Name2                 Type          Estimate
    {'(Intercept)'}       {'(Intercept)'}       {'std'}       0.31381

Group: Error
    Name                       Estimate
    {'sqrt(Dispersion)'}       1
```

Perform an *F*-test to determine if all fixed-effects coefficients are equal to 0.

```
stats = anova(glme)
```

```
stats =
    ANOVA marginal tests: DFMethod = 'residual'

    Term                  FStat       DF1    DF2    pValue
    {'(Intercept)'}          84.41    1      94     9.8194e-15
    {'newprocess' }        4.2881     1      94       0.041122
    {'time_dev'   }       0.013016    1      94        0.90941
    {'temp_dev'   }       0.086696    1      94        0.76907
    {'supplier'   }        0.59212    2      94         0.5552
```

The *p*-values for the intercept, `newprocess`, `time_dev`, and `temp_dev` are the same as in the coefficient table of the `glme` display. The small *p*-values for the intercept and `newprocess` indicate that these are significant predictors at the 5% significance level. The large *p*-values for `time_dev` and `temp_dev` indicate that these are not significant predictors at this level.

The *p*-value of 0.5552 for `supplier` measures the combined significance for both coefficients representing the categorical variable `supplier`. This includes the dummy variables `supplier_C` and `supplier_B` as shown in the coefficient table of the `glme` display. The large *p*-value indicates that `supplier` is not a significant predictor at the 5% significance level.

Tips

- For each fixed-effects term, `anova` performs an *F*-test (marginal test) to determine if all coefficients representing the fixed-effects term are equal to 0.

  When fitting a generalized linear mixed-effects (GLME) model using `fitglme` and one of the maximum likelihood fit methods (`'Laplace'` or `'ApproximateLaplace'`):

  - If you specify the `'CovarianceMethod'` name-value pair argument as `'conditional'`, then the *F*-tests are conditional on the estimated covariance parameters.
  - If you specify the `'CovarianceMethod'` name-value pair as `'JointHessian'`, then the *F*-tests account for the uncertainty in estimation of covariance parameters.

  When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods (`'MPL'` or `'REMPL'`), `anova` uses the fitted linear mixed effects model from the final pseudo likelihood iteration for inference on fixed effects.

addTerms

Add terms to generalized linear regression model

Syntax

```
NewMdl = addTerms(mdl,terms)
```

Description

`NewMdl = addTerms(mdl,terms)` returns a generalized linear regression model fitted using the input data and settings in `mdl` with the terms `terms` added.

Examples

Add Terms to Generalized Linear Regression Model

Create a generalized linear regression model using one predictor, and then add another predictor.

Generate sample data using Poisson random numbers with two underlying predictors `X(:,1)` and `X(:,2)`.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data. Include only the first predictor in the model.

```
mdl = fitglm(X,y,'y ~ x1','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
    log(y) ~ 1 + x1
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE        tStat     pValue
                   ________    _________    ______    ______

    (Intercept)     2.7784      0.014043    197.85      0
    x1              1.1732     0.0033653     348.6      0

100 observations, 98 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 1.25e+05, p-value = 0
```

Add the second predictor to the model.

```
mdl1 = addTerms(mdl,'x2')
```

```
mdl1 =
Generalized linear regression model:
    log(y) ~ 1 + x1 + x2
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE        tStat     pValue
                   ________    _________    ______    ______

    (Intercept)     1.0405      0.022122    47.034      0
    x1              0.9968      0.003362    296.49      0
    x2               1.987     0.0063433    313.24      0

100 observations, 97 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

Input Arguments

`mdl` — Generalized linear regression model

`GeneralizedLinearModel` object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

`terms` — Terms to add to regression model

character vector or string scalar formula in Wilkinson notation | *t*-by-*p* terms matrix

Terms to add to the regression model `mdl`, specified as one of the following:

- Character vector or string scalar formula in "Wilkinson Notation" on page 33-25 representing one or more terms. The variable names in the formula must be valid MATLAB identifiers.
- Terms matrix `T` of size *t*-by-*p*, where *t* is the number of terms and *p* is the number of predictor variables in `mdl`. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

  For example, suppose `mdl` has three variables `A`, `B`, and `C` in that order. Each row of `T` represents one term:

  - `[0 0 0]` — Constant term or intercept
  - `[0 1 0]` — `B`; equivalently, `A^0 * B^1 * C^0`
  - `[1 0 1]` — `A*C`
  - `[2 0 0]` — `A^2`
  - `[0 1 2]` — `B*(C^2)`

`addTerms` treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to add to the model. If you specify a categorical predictor to add to the model, `addTerms` adds a group of indicator variables for the predictor in one step.

Output Arguments

`NewMdl` — Generalized linear regression model with additional terms

`GeneralizedLinearModel` object

Generalized linear regression model with additional terms, returned as a `GeneralizedLinearModel` object. `NewMdl` is a newly fitted model that uses the input data and settings in `mdl` with additional terms specified in `terms`.

To overwrite the input argument `mdl`, assign the newly fitted model to `mdl`:

```
mdl = addTerms(mdl,terms);
```

More About

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- `+` means include the next variable.
- `−` means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- `*` defines an interaction and all lower-order terms.
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
`1`	Constant (intercept) term
`x1^k`, where `k` is a positive integer	`x1`, $x1^2$, ..., $x1^k$
`x1 + x2`	`x1`, `x2`
`x1*x2`	`x1`, `x2`, `x1*x2`
`x1:x2`	`x1*x2` only
`−x2`	Do not include `x2`
`x1*x2 + x3`	`x1`, `x2`, `x3`, `x1*x2`
`x1 + x2 + x3 + x1:x2`	`x1`, `x2`, `x3`, `x1*x2`
`x1*x2*x3 − x1:x2:x3`	`x1`, `x2`, `x3`, `x1*x2`, `x1*x3`, `x2*x3`
`x1*(x2 + x3)`	`x1`, `x2`, `x3`, `x1*x2`, `x1*x3`

For more details, see “Wilkinson Notation” on page 11-91.

Algorithms

- `addTerms` treats a categorical predictor as follows:
  - A model with a categorical predictor that has L levels (categories) includes L – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `addTerms` treats the group of L – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the L – 1 indicator variables with the continuous predictor.
  - Interaction terms between two categorical predictors with L and M levels consist of the (L – 1)*(M – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
  - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternative Functionality

- Use `stepwiseglm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `removeTerms` to remove specific terms from a model.
- Use `step` to optimally improve a model by adding or removing terms.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

addTerms

Add terms to linear regression model

Syntax

```
NewMdl = addTerms(mdl,terms)
```

Description

`NewMdl = addTerms(mdl,terms)` returns a linear regression model fitted using the input data and settings in `mdl` with the terms `terms` added.

Examples

Add Terms to Linear Regression Model

Create a linear regression model of the `carsmall` data set without any interactions, and then add an interaction term.

Load the `carsmall` data set and create a model of the MPG as a function of weight and model year.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Weight + Year + Weight^2

Estimated Coefficients:
                    Estimate         SE         tStat       pValue
                   __________    __________    _______    __________

    (Intercept)        54.206        4.7117     11.505    2.6648e-19
    Weight          -0.016404     0.0031249    -5.2493    1.0283e-06
    Year_76            2.0887       0.71491     2.9215     0.0044137
    Year_82            8.1864       0.81531     10.041    2.6364e-16
    Weight^2       1.5573e-06    4.9454e-07      3.149     0.0022303

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885,  Adjusted R-Squared: 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

The model includes five terms, `Intercept`, `Weight`, `Year_76`, `Year_82`, and `Weight^2`, where `Year_76` and `Year_82` are indicator variables for the categorical variable `Year` that has three distinct values.

Add an interaction term between the `Year` and `Weight` variables to `mdl`.

```
terms = 'Year*Weight';
NewMdl = addTerms(mdl,terms)

NewMdl =
Linear regression model:
    MPG ~ 1 + Weight*Year + Weight^2

Estimated Coefficients:
                       Estimate          SE         tStat        pValue
                      ___________    __________    ________    __________

    (Intercept)           48.045         6.779      7.0874    3.3967e-10
    Weight              -0.012624     0.0041455     -3.0454     0.0030751
    Year_76               2.7768        3.0538     0.90931        0.3657
    Year_82               16.416        4.9802      3.2962     0.0014196
    Weight:Year_76    -0.00020693    0.00092403    -0.22394       0.82333
    Weight:Year_82     -0.0032574     0.0018919     -1.7217      0.088673
    Weight^2           1.0121e-06      6.12e-07      1.6538       0.10177

Number of observations: 94, Error degrees of freedom: 87
Root Mean Squared Error: 2.76
R-squared: 0.89,  Adjusted R-Squared: 0.882
F-statistic vs. constant model: 117, p-value = 1.88e-39
```

`NewMdl` includes two additional terms, `Weight*Year_76` and `Weight*Year_82`.

Input Arguments

`mdl` — Linear regression model

`LinearModel` object

Linear regression model, specified as a `LinearModel` object created using `fitlm` or `stepwiselm`.

`terms` — Terms to add to regression model

character vector or string scalar formula in Wilkinson notation | *t*-by-*p* terms matrix

Terms to add to the regression model `mdl`, specified as one of the following:

- Character vector or string scalar formula in “Wilkinson Notation” on page 33-30 representing one or more terms. The variable names in the formula must be valid MATLAB identifiers.
- Terms matrix `T` of size *t*-by-*p*, where *t* is the number of terms and *p* is the number of predictor variables in `mdl`. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

  For example, suppose `mdl` has three variables `A`, `B`, and `C` in that order. Each row of `T` represents one term:

  - `[0 0 0]` — Constant term or intercept
  - `[0 1 0]` — `B`; equivalently, `A^0 * B^1 * C^0`
  - `[1 0 1]` — `A*C`
  - `[2 0 0]` — `A^2`
  - `[0 1 2]` — `B*(C^2)`

`addTerms` treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to add to the model. If you specify a categorical predictor to add to the model, `addTerms` adds a group of indicator variables for the predictor in one step. See “Modify Linear Regression Model Using step” on page 33-5990 for an example that describes how to create indicator variables manually and treat each one as a separate variable.

Output Arguments

`NewMdl` — Linear regression model with additional terms

`LinearModel` object

Linear regression model with additional terms, returned as a `LinearModel` object. `NewMdl` is a newly fitted model that uses the input data and settings in `mdl` with additional terms specified in `terms`.

To overwrite the input argument `mdl`, assign the newly fitted model to `mdl`:

```
mdl = addTerms(mdl,terms);
```

More About

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- − means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
1	Constant (intercept) term
x1^k, where k is a positive integer	x1, $x1^2$, ..., $x1^k$
x1 + x2	x1, x2
x1*x2	x1, x2, x1*x2
x1:x2	x1*x2 only
−x2	Do not include x2
x1*x2 + x3	x1, x2, x3, x1*x2
x1 + x2 + x3 + x1:x2	x1, x2, x3, x1*x2
x1*x2*x3 − x1:x2:x3	x1, x2, x3, x1*x2, x1*x3, x2*x3

Wilkinson Notation	Terms in Standard Notation
`x1*(x2 + x3)`	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Algorithms

- `addTerms` treats a categorical predictor as follows:
  - A model with a categorical predictor that has *L* levels (categories) includes *L* – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `addTerms` treats the group of *L* – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with *L* levels consist of the element-wise product of the *L* – 1 indicator variables with the continuous predictor.
  - Interaction terms between two categorical predictors with *L* and *M* levels consist of the (*L* – 1)*(*M* – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
  - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternative Functionality

- Use `stepwiselm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `removeTerms` to remove specific terms from a model.
- Use `step` to optimally improve a model by adding or removing terms.

adtest

Anderson-Darling test

Syntax

```
h = adtest(x)
h = adtest(x,Name,Value)
[h,p] = adtest( ___ )
[h,p,adstat,cv] = adtest( ___ )
```

Description

`h = adtest(x)` returns a test decision for the null hypothesis that the data in vector `x` is from a population with a normal distribution, using the Anderson-Darling test on page 33-37. The alternative hypothesis is that `x` is not from a population with a normal distribution. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`h = adtest(x,Name,Value)` returns a test decision for the Anderson-Darling test with additional options specified by one or more name-value pair arguments. For example, you can specify a null distribution other than normal, or select an alternative method for calculating the *p*-value.

`[h,p] = adtest( ___ )` also returns the *p*-value, `p`, of the Anderson-Darling test, using any of the input arguments from the previous syntaxes.

`[h,p,adstat,cv] = adtest( ___ )` also returns the test statistic, `adstat`, and the critical value, `cv`, for the Anderson-Darling test.

Examples

Anderson-Darling Test for a Normal Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the exam grades come from a normal distribution. You do not need to specify values for the population parameters.

```
[h,p,adstat,cv] = adtest(x)
```

```
h = logical
   0

p = 0.1854

adstat = 0.5194

cv = 0.7470
```

The returned value of `h = 0` indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Anderson-Darling Test for Extreme Value Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the exam grades come from an extreme value distribution. You do not need to specify values for the population parameters.

```
[h,p] = adtest(x,'Distribution','ev')
```

```
h = logical
   0

p = 0.0714
```

The returned value of `h = 0` indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Anderson-Darling Test Using Specified Probability Distribution

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Create a normal probability distribution object with mean `mu = 75` and standard deviation `sigma = 10`.

```
dist = makedist('normal','mu',75,'sigma',10)
```

```
dist =
  NormalDistribution

  Normal distribution
       mu = 75
    sigma = 10
```

Test the null hypothesis that `x` comes from the hypothesized normal distribution.

```
[h,p] = adtest(x,'Distribution',dist)
```

```
h = logical
   0

p = 0.4687
```

The returned value of `h = 0` indicates that `adtest` fails to reject the null hypothesis at the default 5% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector. Missing observations in `x`, indicated by `NaN`, are ignored.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'MCTol',0.01` conducts the hypothesis test at the 1% significance level, and determines the p-value, `p`, using a Monte Carlo simulation with a maximum Monte Carlo standard error for `p` of 0.01.

Distribution — Hypothesized distribution

`'norm'` (default) | `'exp'` | `'ev'` | `'logn'` | `'weibull'` | probability distribution object

Hypothesized distribution of data vector `x`, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

`'norm'`	Normal distribution
`'exp'`	Exponential distribution
`'ev'`	Extreme value distribution
`'logn'`	Lognormal distribution
`'weibull'`	Weibull distribution

In this case, you do not need to specify population parameters. Instead, `adtest` estimates the distribution parameters from the sample data and tests `x` against a composite hypothesis that it comes from the selected distribution family with parameters unspecified.

Alternatively, you can specify any continuous probability distribution object for the null distribution. In this case, you must specify all the distribution parameters, and `adtest` tests `x` against a simple hypothesis that it comes from the given distribution with its specified parameters.

Example: `'Distribution','exp'`

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`MCTol` — Maximum Monte Carlo standard error
positive scalar value

Maximum Monte Carlo standard error on page 33-38 for the *p*-value, `p`, specified as the comma-separated pair consisting of `'MCTol'` and a positive scalar value. If you use `MCTol`, `adtest` determines `p` using a Monte Carlo simulation, and the name-value pair argument `Asymptotic` must have the value `false`.

Example: `'MCTol',0.01`

Data Types: `single` | `double`

`Asymptotic` — Method for calculating *p*-value
`false` (default) | `true`

Method for calculating the *p*-value of the Anderson-Darling test, specified as the comma-separated pair consisting of `'Asymptotic'` and either `true` or `false`. If you specify `'true'`, `adtest` estimates the *p*-value using the limiting distribution of the Anderson-Darling test statistic. If you specify `false`, `adtest` calculates the *p*-value based on an analytical formula. For sample sizes greater than 120, the limiting distribution estimate is likely to be more accurate than the small sample size approximation method.

- If you specify a distribution family with unknown parameters for the `Distribution` name-value pair, `Asymptotic` must be `false`.
- If you use `MCTol` to calculate the *p*-value using a Monte Carlo simulation, `Asymptotic` must be `false`.

Example: `'Asymptotic',true`

Data Types: `logical`

Output Arguments

`h` — Hypothesis test result
`1` | `0`

Hypothesis test result, returned as a logical value.

- If `h = 1`, this indicates the rejection of the null hypothesis at the `Alpha` significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the `Alpha` significance level.

`p` — *p*-value
scalar value in the range [0,1]

p-value of the Anderson-Darling test, returned as a scalar value in the range [0,1]. `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. `p` is calculated using one of these methods:

- If the hypothesized distribution is a fully specified probability distribution object, `adtest` calculates `p` analytically. If `'Asymptotic'` is `true`, `adtest` uses the asymptotic distribution of the test statistic. If you specify a value for `'MCTol'`, `adtest` uses a Monte Carlo simulation.
- If the hypothesized distribution is specified as a distribution family with unknown parameters, `adtest` retrieves the critical value from a table and uses inverse interpolation to determine the *p*-value. If you specify a value for `'MCTol'`, `adtest` uses a Monte Carlo simulation.

`adstat` — Test statistic

scalar value

Test statistic for the Anderson-Darling test, returned as a scalar value.

- If the hypothesized distribution is a fully specified probability distribution object, `adtest` computes `adstat` using specified parameters.
- If the hypothesized distribution is specified as a distribution family with unknown parameters, `adtest` computes `adstat` using parameters estimated from the sample data.

`cv` — Critical value

scalar value

Critical value for the Anderson-Darling test at the significance level `Alpha`, returned as a scalar value. `adtest` determines `cv` by interpolating into a table based on the specified `Alpha` significance level.

More About

Anderson-Darling Test

The Anderson-Darling test is commonly used to test whether a data sample comes from a normal distribution. However, it can be used to test for another hypothesized distribution, even if you do not fully specify the distribution parameters. Instead, the test estimates any unknown parameters from the data sample.

The test statistic belongs to the family of quadratic empirical distribution function statistics, which measure the distance between the hypothesized distribution, $F(x)$ and the empirical cdf, $F_n(x)$ as

$$n\int_{-\infty}^{\infty}(F_n(x)-F(x))^2w(x)dF(x),$$

over the ordered sample values $x_1 < x_2 < \ldots < x_n$, where $w(x)$ is a weight function and n is the number of data points in the sample.

The weight function for the Anderson-Darling test is

$$w(x) = [F(x)(1-F(x))]^{-1},$$

which places greater weight on the observations in the tails of the distribution, thus making the test more sensitive to outliers and better at detecting departure from normality in the tails of the distribution.

The Anderson-Darling test statistic is

$$A_n^2 = -n - \sum_{i=1}^{n}\frac{2i-1}{n}[\ln(F(X_i)) + \ln(1-F(X_{n+1-i}))],$$

where$\{X_1 < \ldots < X_n\}$ are the ordered sample data points and n is the number of data points in the sample.

In `adtest`, the decision to reject or not reject the null hypothesis is based on comparing the p-value for the hypothesis test with the specified significance level, not on comparing the test statistic with the critical value.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the *p*-value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\widehat{p})(1-\widehat{p})}{\text{mcreps}}},$$

where $\widehat{p}$ is the estimated *p*-value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed.

`adtest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for $\widehat{p}$ less than the value specified for `MCTol`.

Introduced in R2013a

andrewsplot

Andrews plot

Syntax

```
andrewsplot(X)
andrewsplot(X,...,'Standardize',standopt)
andrewsplot(X,...,'Quantile',alpha)
andrewsplot(X,...,'Group',group)
andrewsplot(X,...,'PropName',PropVal,...)
andrewsplot(ax,X,...)
h = andrewsplot(X,...)
```

Description

`andrewsplot(X)` creates an Andrews plot of the multivariate data in the matrix `X`. The rows of `X` correspond to observations, the columns to variables. Andrews plots represent each observation by a function $f(t)$ of a continuous dummy variable t over the interval [0,1]. $f(t)$ is defined for the ith observation in `X` as

$$f(t) = X(i,1)/\sqrt{2} + X(i,2)\sin(2\pi t) + X(i,3)\cos(2\pi t) + \ldots$$

`andrewsplot` treats `NaN` values in `X` as missing values and ignores the corresponding rows.

`andrewsplot(X,...,'Standardize',standopt)` creates an Andrews plot where *`standopt`* is one of the following:

- `'on'` — scales each column of `X` to have mean `0` and standard deviation `1` before making the plot.
- `'PCA'` — creates an Andrews plot from the principal component scores of `X`, in order of decreasing eigenvalue. (See `pca`.)
- `'PCAStd'` — creates an Andrews plot using the standardized principal component scores. (See `pca`.)

`andrewsplot(X,...,'Quantile',alpha)` plots only the median and the `alpha` and (1 – `alpha`) quantiles of $f(t)$ at each value of t. This is useful if `X` contains many observations.

`andrewsplot(X,...,'Group',group)` plots the data in different groups with different colors. Groups are defined by `group`, a numeric array containing a group index for each observation. `group` can also be a categorical array, character matrix, string array, or cell array of character vectors containing a group name for each observation.

`andrewsplot(X,...,'PropName',PropVal,...)` sets optional `Line` object properties to the specified values for all `Line` objects created by `andrewsplot`. (See Line Properties.)

`andrewsplot(ax,X,...)` uses the plot axes specified in `ax`, an `Axes` object. (See `axes`.) Specify `ax` as the first input argument followed by any of the input argument combinations in the previous syntaxes.

`h = andrewsplot(X,...)` returns a column vector of handles to the `Line` objects created by `andrewsplot`, one handle per row of `X`. If you use the `'Quantile'` input parameter, `h` contains one

handle for each of the three `Line` objects created. If you use both the `'Quantile'` and the `'Group'` input parameters, `h` contains three handles for each group.

Examples

Create Andrews Plot to Visualize Grouped Data

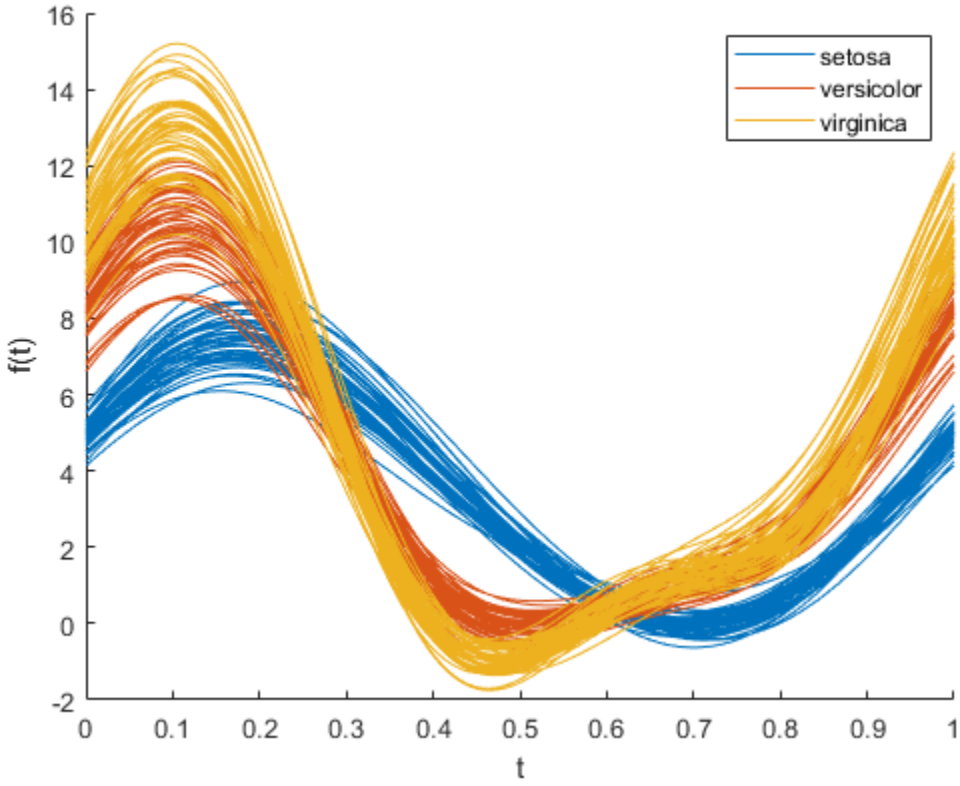
This example shows how to create an Andrews plot to visualize grouped sample data.

Load the sample data.

```
load fisheriris
```

Create an Andrews plot, grouping the sample data by `species`.

```
andrewsplot(meas,'group',species)
```



Create a second, simplified Andrews plot that only displays the median and quartiles of each group.

```
andrewsplot(meas,'group',species,'quantile',.25)
```

anova

Package:

Analysis of variance for linear regression model

Syntax

```
tbl = anova(mdl)
tbl = anova(mdl,anovatype)
tbl = anova(mdl,'component',sstype)
```

Description

`tbl = anova(mdl)` returns a table with component ANOVA statistics.

`tbl = anova(mdl,anovatype)` returns ANOVA statistics of the specified type `anovatype`. For example, specify `anovatype` as `'component'`(default) to return a table with component ANOVA statistics, or specify `anovatype` as `'summary'` to return a table with summary ANOVA statistics.

`tbl = anova(mdl,'component',sstype)` computes component ANOVA statistics using the specified type of sum of squares.

Examples

Component ANOVA Table

Create a component ANOVA table from a linear regression model of the `hospital` data set.

Load the `hospital` data set and create a model of blood pressure as a function of age and gender.

```
load hospital
tbl = table(hospital.Age,hospital.Sex,hospital.BloodPressure(:,2), ...
    'VariableNames',{'Age','Sex','BloodPressure'});
tbl.Sex = categorical(tbl.Sex);
mdl = fitlm(tbl,'BloodPressure ~ Sex + Age^2')
```

```
mdl =
Linear regression model:
    BloodPressure ~ 1 + Age + Sex + Age^2

Estimated Coefficients:
                   Estimate        SE        tStat       pValue
                   _________    ________    ________    _________

    (Intercept)       63.942      19.194      3.3314    0.0012275
    Age              0.90673      1.0442     0.86837      0.38736
    Sex_Male          3.0019      1.3765      2.1808     0.031643
    Age^2          -0.011275    0.013853    -0.81389      0.41772

Number of observations: 100, Error degrees of freedom: 96
```

```
Root Mean Squared Error: 6.83
R-squared: 0.0577,  Adjusted R-Squared: 0.0283
F-statistic vs. constant model: 1.96, p-value = 0.125
```

Create an ANOVA table of the model.

```
tbl = anova(mdl)
```

```
tbl=4×5 table
             SumSq     DF    MeanSq       F        pValue
             ______    __    ______    _______    ________

    Age      18.705     1    18.705    0.40055     0.52831
    Sex      222.09     1    222.09     4.7558    0.031643
    Age^2    30.934     1    30.934    0.66242     0.41772
    Error    4483.1    96    46.699
```

The table displays the following columns for each term except the constant (intercept) term:

- `SumSq` — Sum of squares explained by the term.
- `DF` — Degrees of freedom. In this example, `DF` is 1 for each term in the model and $n - p$ for the error term, where n is the number of observations and p is the number of coefficients (including the intercept) in the model. For example, the `DF` for the error term in this model is 100 – 4 = 96. If any variable in the model is a categorical variable, the `DF` for that variable is the number of indicator variables created for its categories (number of categories – 1).
- `MeanSq` — Mean square, defined by `MeanSq = SumSq/DF`. For example, the mean square of the error term, mean squared error (MSE), is 4.4831e+03/96 = 46.6991.
- `F` — F-statistic value to test the null hypothesis that the corresponding coefficient is zero, computed by `F = MeanSq/MSE`, where `MSE` is the mean squared error. When the null hypothesis is true, the F-statistic follows the F-distribution. The numerator degrees of freedom is the `DF` value for the corresponding term, and the denominator degrees of freedom is $n - p$. In this example, each F-statistic follows an $F_{(1,96)}$-distribution.
- `pValue` — p-value of the F-statistic value. For example, the p-value for `Age` is 0.5283, implying that `Age` is not significant at the 5% significance level given the other terms in the model.

Summary ANOVA Table

Create a summary ANOVA table from a linear regression model of the `hospital` data set.

Load the `hospital` data set and create a model of blood pressure as a function of age and gender.

```
load hospital
tbl = table(hospital.Age,hospital.Sex,hospital.BloodPressure(:,2), ...
    'VariableNames',{'Age','Sex','BloodPressure'});
tbl.Sex = categorical(tbl.Sex);
mdl = fitlm(tbl,'BloodPressure ~ Sex + Age^2')
```

```
mdl =
Linear regression model:
    BloodPressure ~ 1 + Age + Sex + Age^2

Estimated Coefficients:
```

```
                  Estimate        SE        tStat       pValue
                  _________    _________    _________    _________

    (Intercept)       63.942       19.194       3.3314    0.0012275
    Age              0.90673       1.0442      0.86837      0.38736
    Sex_Male          3.0019       1.3765       2.1808     0.031643
    Age^2          -0.011275    0.013853    -0.81389      0.41772

Number of observations: 100, Error degrees of freedom: 96
Root Mean Squared Error: 6.83
R-squared: 0.0577,  Adjusted R-Squared: 0.0283
F-statistic vs. constant model: 1.96, p-value = 0.125
```

Create a summary ANOVA table of the model.

```
tbl = anova(mdl,'summary')
```

```
tbl=7×5 table
                      SumSq     DF    MeanSq       F         pValue
                      ______    __    ______    _______    ________

    Total             4757.8    99    48.059
    Model             274.73     3    91.577      1.961     0.12501
    . Linear           243.8     2     121.9     2.6103    0.078726
    . Nonlinear       30.934     1    30.934    0.66242     0.41772
    Residual          4483.1    96    46.699
    . Lack of fit     1483.1    39    38.028    0.72253     0.85732
    . Pure error        3000    57    52.632
```

The table displays tests for groups of terms: `Total`, `Model`, and `Residual`.

- `Total` — This row shows the total sum of squares (`SumSq`), degrees of freedom (`DF`), and the mean squared error (`MeanSq`). Note that `MeanSq = SumSq/DF`.
- `Model` — This row includes `SumSq`, `DF`, `MeanSq`, *F*-statistic value (`F`), and *p*-value (`pValue`). Because this model includes a nonlinear term (`Age^2`), `anova` partitions the sum of squares (`SumSq`) of `Model` into two parts: `SumSq` explained by the linear terms (`Age` and `Sex`) and `SumSq` explained by the nonlinear term (`Age^2`). The corresponding *F*-statistic values are for testing the significance of the linear terms and the nonlinear term as separate groups. The nonlinear group consists of the `Age^2` term only, so it has the same *p*-value as the `Age^2` term in the “Component ANOVA Table” on page 33-42.
- `Residual` — This row includes `SumSq`, `DF`, `MeanSq`, `F`, and `pValue`. Because the data set includes replications, `anova` partitions the residual `SumSq` into the part for the replications (`Pure error`) and the rest (`Lack of fit`). To test the lack of fit, `anova` computes the *F*-statistic value by comparing the model residuals to the model-free variance estimate computed on the replications. The *F*-statistic value shows no evidence of lack of fit.

Linear Regression with Categorical Predictor

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use `anova` to test the significance of the categorical variable.

Model with Categorical Predictor

Load the `carsmall` data set and create a linear regression model of `MPG` as a function of `Model_Year`. To treat the numeric vector `Model_Year` as a categorical variable, identify the predictor using the `'CategoricalVars'` name-value pair argument.

```
load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Model_Year

Estimated Coefficients:
                    Estimate      SE      tStat       pValue
                    ________    ______    ______    __________

    (Intercept)        17.69     1.0328    17.127    3.2371e-30
    Model_Year_76     3.8839     1.4059    2.7625     0.0069402
    Model_Year_82      14.02     1.4369    9.7571    8.2164e-16

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531,  Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

The model formula in the display, `MPG ~ 1 + Model_Year`, corresponds to

$$\text{MPG} = \beta_0 + \beta_1 I_{\text{Year} = 76} + \beta_2 I_{\text{Year} = 82} + \epsilon,$$

where $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$ are indicator variables whose value is one if the value of `Model_Year` is 76 and 82, respectively. The `Model_Year` variable includes three distinct values, which you can check by using the `unique` function.

```
unique(Model_Year)
```

```
ans = 3×1

    70
    76
    82
```

`fitlm` chooses the smallest value in `Model_Year` as a reference level (`'70'`) and creates two indicator variables $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

Model with Full Indicator Variables

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1 = 70} + (\beta_0 + \beta_1) I_{x_1 = 76} + (\beta_0 + \beta_2) I_{x_2 = 82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

```
mdl =
Linear regression model:
    MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82

Estimated Coefficients:
                     Estimate      SE       tStat       pValue
                     ________    _______    ______    __________

    Model_Year_70      17.69      1.0328    17.127    3.2371e-30
    Model_Year_76     21.574     0.95387    22.617    4.0156e-39
    Model_Year_82      31.71     0.99896    31.743    5.2234e-51

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
```

Choose Reference Level in Model

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```
categories(Year)
```

```
ans = 3x1 cell
    {'70'}
    {'76'}
    {'82'}
```

If you use `Year` as a predictor variable, then `fitlm` chooses the first category `'70'` as a reference level. Reorder `Year` by using the `reordercats` function.

```
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
```

```
ans = 3x1 cell
    {'76'}
    {'70'}
    {'82'}
```

The first category of `Year_reordered` is `'76'`. Create a linear regression model of `MPG` as a function of `Year_reordered`.

```
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

```
mdl2 =
Linear regression model:
    MPG ~ 1 + Model_Year

Estimated Coefficients:
                    Estimate      SE        tStat       pValue
                    ________    _______    _______    __________

    (Intercept)       21.574     0.95387     22.617    4.0156e-39
    Model_Year_70    -3.8839      1.4059    -2.7625     0.0069402
    Model_Year_82     10.136      1.3812     7.3385    8.7634e-11

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531,  Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

`mdl2` uses `'76'` as a reference level and includes two indicator variables $I_{\text{Year = 70}}$ and $I_{\text{Year = 82}}$.

Evaluate Categorical Predictor

The model display of `mdl2` includes a *p*-value of each term to test whether or not the corresponding coefficient is equal to zero. Each *p*-value examines each indicator variable. To examine the categorical variable `Model_Year` as a group of indicator variables, use `anova`. Use the `'components'`(default) option to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```
anova(mdl2,'components')
```

```
ans=2×5 table
                SumSq     DF    MeanSq      F        pValue
                ______    __    ______    _____    __________

    Model_Year    3190.1     2    1595.1    51.56    1.0694e-15
    Error         2815.2    91    30.936
```

The component ANOVA table includes the *p*-value of the `Model_Year` variable, which is smaller than the *p*-values of the indicator variables.

Input Arguments

`mdl` — Linear regression model object

`LinearModel` object | `CompactLinearModel` object

Linear regression model object, specified as a `LinearModel` object created by using `fitlm` or `stepwiselm`, or a `CompactLinearModel` object created by using `compact`.

`anovatype` — ANOVA type

`'component'` (default) | `'summary'`

ANOVA type, specified as one of these values:

- `'component'` — `anova` returns the table `tbl` with ANOVA statistics for each variable in the model except the constant term.

- `'summary'` — `anova` returns the table `tbl` with summary ANOVA statistics for grouped variables and the model as a whole.

For details, see the `tbl` output argument description.

`sstype` — Sum of squares type
`'h'` (default) | 1 | 2 | 3

Sum of squares type for each term, specified as one of the values in this table.

Value	Description
1	Type 1 sum of squares — Reduction in residual sum of squares obtained by adding the term to a fit that already includes the preceding terms
2	Type 2 sum of squares — Reduction in residual sum of squares obtained by adding the term to a model that contains all other terms
3	Type 3 sum of squares — Reduction in residual sum of squares obtained by adding the term to a model that contains all other terms, but with their effects constrained to obey the usual “sigma restrictions” that make models estimable
`'h'`	Hierarchical model — Similar to Type 2, but uses both continuous and categorical factors to determine the hierarchy of terms

The sum of squares for any term is determined by comparing two models. For a model containing main effects but no interactions, the value of `sstype` influences the computations on unbalanced data only.

Suppose you are fitting a model with two factors and their interaction, and the terms appear in the order A, B, AB. Let $R(\cdot)$ represent the residual sum of squares for the model. So, $R(A, B, AB)$ is the residual sum of squares fitting the whole model, $R(A)$ is the residual sum of squares fitting the main effect of A only, and $R(1)$ is the residual sum of squares fitting the mean only. The three sum of squares types are as follows:

Term	Type 1 Sum of Squares	Type 2 Sum of Squares	Type 3 Sum of Squares
A	$R(1) - R(A)$	$R(B) - R(A, B)$	$R(B, AB) - R(A, B, AB)$
B	$R(A) - R(A, B)$	$R(A) - R(A, B)$	$R(A, AB) - R(A, B, AB)$
AB	$R(A, B) - R(A, B, AB)$	$R(A, B) - R(A, B, AB)$	$R(A, B) - R(A, B, AB)$

The models for Type 3 sum of squares have sigma restrictions imposed. This means, for example, that in fitting $R(B, AB)$, the array of AB effects is constrained to sum to 0 over A for each value of B, and over B for each value of A.

For Type 3 sum of squares:

- If `mdl` is a `CompactLinearModel` object and the regression model is nonhierarchical, `anova` returns an error.
- If `mdl` is a `LinearModel` object and the regression model is nonhierarchical, `anova` refits the model using effects coding whenever it needs to compute a Type 3 sum of squares.

- If the regression model in `mdl` is hierarchical, `anova` computes the results without refitting the model.

`sstype` applies only if `anovatype` is `'component'`.

Output Arguments

`tbl` — ANOVA summary statistics table

table

ANOVA summary statistics table, returned as a table.

The contents of `tbl` depend on the ANOVA type specified in `anovatype`.

- If `anovatype` is `'component'`, then `tbl` contains ANOVA statistics for each variable in the model except the constant (intercept) term. The table includes these columns for each variable:

Column	Description
`SumSq`	Sum of squares explained by the term, computed depending on `sstype`
`DF`	Degrees of freedom • `DF` of a numeric variable is 1. • `DF` of a categorical variable is the number of indicator variables created for the category (number of categories – 1). Note that `tbl` contains one row for each categorical variable instead of one row for each indicator variable as in the model display. Use `anova` to test a categorical variable as a group of indicator variables. • `DF` of an error term is $n – p$, where n is the number of observations and p is the number of coefficients in the model.
`MeanSq`	Mean square, defined by `MeanSq = SumSq/DF` `MeanSq` for the error term is the mean squared error (MSE).
`F`	F-statistic value to test the null hypothesis that the corresponding coefficient is zero, computed by `F = MeanSq/MSE` When the null hypothesis is true, the F-statistic follows the F-distribution. The numerator degrees of freedom is the `DF` value for the corresponding term, and the denominator degrees of freedom is $n – p$.
`pValue`	p-value of the F-statistic value

  For an example, see “Component ANOVA Table” on page 33-42.

- If `anovatype` is `'summary'`, then `tbl` contains summary statistics of grouped terms for each row. The table includes the same columns as `'component'` and these rows:

Row	Description
`Total`	Total statistics • `SumSq` — Total sum of squares, which is the sum of the squared deviations of the response around its mean • `DF` — Sum of degrees of freedom of `Model` and `Residual`
`Model`	Statistics for the model as a whole • `SumSq` — Model sum of squares, which is the sum of the squared deviations of the fitted value around the response mean. • `F` and `pValue` — These values provide a test of whether the model as a whole fits significantly better than a degenerate model consisting of only a constant term. If `mdl` includes only linear terms, then `anova` does not decompose `Model` into `Linear` and `NonLinear`.
`Linear`	Statistics for linear terms • `SumSq` — Sum of squares for linear terms, which is the difference between the model sum of squares and the sum of squares for nonlinear terms. • `F` and `pValue` — These values provide a test of whether the model with only linear terms fits better than a degenerate model consisting of only a constant term. `anova` uses the mean squared error that is based on the full model to compute this *F*-value, so the *F*-value obtained by dropping the nonlinear terms and repeating the test is not the same as the value in this row.
`Nonlinear`	Statistics for nonlinear terms • `SumSq` — Sum of squares for nonlinear (higher-order or interaction) terms, which is the increase in the residual sum of squares obtained by keeping only the linear terms and dropping all nonlinear terms. • `F` and `pValue` — These values provide a test of whether the full model fits significantly better than a smaller model consisting of only the linear terms.

Row	Description
`Residual`	Statistics for residuals • `SumSq` — Residual sum of squares, which is the sum of the squared residual values • `MeanSq` — Mean squared error, used to compute the *F*-statistic values for `Model`, `Linear`, and `NonLinear` If `mdl` is a full `LinearModel` object and the sample data contains replications (multiple observations sharing the same predictor values), then `anova` decomposes the residual sum of squares into a sum of squares for the replicated observations (`Lack of fit`) and the remaining sum of squares (`Pure error`).
`Lack of fit`	Lack-of-fit statistics • `SumSq` — Sum of squares due to lack of fit, which is the difference between the residual sum of squares and the replication sum of squares. • `F` and `pValue` — The *F*-statistic value is the ratio of lack-of-fit `MeanSq` to pure error `MeanSq`. The ratio provides a test of bias by measuring whether the variation of the residuals is larger than the variation of the replications. A low *p*-value implies that adding additional terms to the model can improve the fit.
`Pure error`	Statistics for pure error • `SumSq` — Replication sum of squares, obtained by finding the sets of points with identical predictor values, computing the sum of squared deviations around the mean within each set, and pooling the computed values • `MeanSq` — Model-free pure error variance estimate of the response

For an example, see “Summary ANOVA Table” on page 33-43.

Alternative Functionality

More complete ANOVA statistics are available in the `anova1`, `anova2`, and `anovan` functions.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2012a

anova

Class: `LinearMixedModel`

Analysis of variance for linear mixed-effects model

Syntax

```
stats = anova(lme)
stats = anova(lme,Name,Value)
```

Description

`stats = anova(lme)` returns the dataset array `stats` that includes the results of the *F*-tests for each fixed-effects term in the linear mixed-effects model `lme`.

`stats = anova(lme,Name,Value)` also returns the dataset array `stats` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`DFMethod` — Method for computing approximate degrees of freedom

`'residual'` (default) | `'satterthwaite'` | `'none'`

Method for computing approximate degrees of freedom to use in the F-test, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'residual'`	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'satterthwaite'`	Satterthwaite approximation.
`'none'`	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod','satterthwaite'`

Output Arguments

`stats` — Results of *F*-tests for fixed-effects terms

dataset array

Results of *F*-tests for fixed-effects terms, returned as a dataset array with the following columns.

`Term`	Name of the fixed effects term
`Fstat`	*F*-statistic for the term
`DF1`	Numerator degrees of freedom for the *F*-statistic
`DF2`	Denominator degrees of freedom for the *F*-statistic
`pValue`	*p*-value of the test for the term

There is one row for each fixed-effects term. Each term is a continuous variable, a grouping variable, or an interaction between two or more continuous or grouping variables. For each fixed-effects term, `anova` performs an *F*-test (marginal test) to determine if all coefficients representing the fixed-effects term are 0. To perform tests for the type III hypothesis, you must use the `'effects'` contrasts while fitting the linear mixed-effects model.

Examples

F-Tests for Fixed Effects

Load the sample data.

```
load('shift.mat')
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

`Shift` and `Operator` are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and `'effects'` contrasts.

`'effects'` contrasts indicate that the coefficients sum to 0, and `fitlme` creates two contrast-coded variables in the fixed-effects design matrix, X1 and X2, where

$$Shift\_Evening = \begin{cases} 0, & if\ Morning \\ 1, & if\ Evening \\ -1, & if\ Night \end{cases}$$

and

$$Shift\_Morning = \begin{cases} 1, & if\ Morning \\ 0, & if\ Evening \\ -1, & if\ Night \end{cases}.$$

The model corresponds to

$$\text{MorningShift: } QCDev_{im} = \beta_0 + \beta_2 Shift\_Morning_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \ldots, 5,$$
$$\text{EveningShift: } QCDev_{im} = \beta_0 + \beta_1 Shift\_Evening_i + b_{0m} + \varepsilon_{im},$$
$$\text{NightShift: } \quad QCDev_{im} = \beta_0 - \beta_1 Shift\_Evening_i - \beta_2 Shift\_Morning_i + b_{0m} + \varepsilon_{im},$$

where $b \sim N(0, \sigma_b^2)$ and $\epsilon \sim N(0, \sigma^2)$.

```
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)',...
'FitMethod','REML','DummyVarCoding','effects')
```

```
lme =
Linear mixed-effects model fit by REML

Model information:
    Number of observations             15
    Fixed effects coefficients          3
    Random effects coefficients         5
    Covariance parameters               2

Formula:
    QCDev ~ 1 + Shift + (1 | Operator)

Model fit statistics:
    AIC       BIC       LogLikelihood    Deviance
    58.913    61.337    -24.456          48.913

Fixed effects coefficients (95% CIs):
    Name                    Estimate    SE         tStat      DF    pValue
    {'(Intercept)'  }         3.6525    0.94109     3.8812    12    0.0021832
    {'Shift_Evening'}        -0.53293   0.31206    -1.7078    12      0.11339
    {'Shift_Morning'}        -0.91973   0.31206    -2.9473    12     0.012206

    Lower      Upper
     1.6021       5.703
    -1.2129     0.14699
    -1.5997    -0.23981

Random effects covariance parameters (95% CIs):
Group: Operator (5 Levels)
    Name1                 Name2                 Type          Estimate
    {'(Intercept)'}       {'(Intercept)'}       {'std'}       2.0457

    Lower      Upper
    0.98207    4.2612

Group: Error
    Name              Estimate    Lower      Upper
    {'Res Std'}       0.85462     0.52357    1.395
```

Perform an *F*-test to determine if all fixed-effects coefficients are 0.

```
anova(lme)
```

```
ans =
    ANOVA marginal tests: DFMethod = 'Residual'

    Term                   FStat     DF1    DF2    pValue
    {'(Intercept)'}        15.063    1      12     0.0021832
    {'Shift'      }        11.091    2      12     0.0018721
```

The *p*-value for the constant term, 0.0021832, is the same as in the coefficient table in the `lme` display. The *p*-value of 0.0018721 for `Shift` measures the combined significance for both coefficients representing `Shift`.

ANOVA for Fixed-Effects in LME Model

Load the sample data.

```
load('fertilizer.mat')
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently. Use the `'effects'` contrasts when fitting the data for the type III sum of squares.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)',...
'DummyVarCoding','effects')
```

```
lme =
Linear mixed-effects model fit by ML

```

Perform an analysis of variance to test for the fixed-effects.

```
anova(lme)
```

```
ans =
    ANOVA marginal tests: DFMethod = 'Residual'

    Term                         FStat     DF1    DF2    pValue
    {'(Intercept)'      }        1004.2     1     40     5.9086e-30
    {'Tomato'           }        7.1663     4     40     0.00018935
    {'Fertilizer'       }        58.833     3     40     1.0024e-14
    {'Tomato:Fertilizer'}        1.4182    12     40        0.19804
```

The *p*-value for the constant term, 5.9086e-30, is the same as in the coefficient table in the `lme` display. The *p*-values of 0.00018935, 1.0024e-14, and 0.19804 for `Tomato`, `Fertilizer`, and `Tomato:Fertilizer` represent the combined significance for all tomato coefficients, fertilizer coefficients, and coefficients representing the interaction between the tomato and fertilizer, respectively. The *p*-value of 0.19804 indicates that the interaction between tomato and fertilizer is not significant.

Satterthwaite Approximation for Degrees of Freedom

Load the sample data.

```
load('weight.mat')
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit the model using the `'effects'` contrasts.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)',...
        'DummyVarCoding','effects')
```

```
lme =
Linear mixed-effects model fit by ML

Model information:
    Number of observations             120
    Fixed effects coefficients           9
    Random effects coefficients         40
    Covariance parameters                4

Formula:
    y ~ 1 + InitialWeight + Program*Week + (1 + Week | Subject)

Model fit statistics:
    AIC        BIC       LogLikelihood    Deviance
    -22.981    13.257    24.49            -48.981

Fixed effects coefficients (95% CIs):
    Name                       Estimate     SE           tStat       DF
    {'(Intercept)'   }          0.77122      0.24309      3.1725    111
    {'InitialWeight' }        0.0031879    0.0013814      2.3078    111

     0.0023402      0.091195      0.41003
      0.077424       -0.3029     0.016031
    4.1099e-08       0.13198      0.26564
       0.66198      -0.14136     0.090149
       0.82212      -0.10259      0.12892
       0.93282      -0.11082      0.12069

Random effects covariance parameters (95% CIs):
Group: Subject (20 Levels)
    Name1                  Name2                  Type           Estimate
    {'(Intercept)'}        {'(Intercept)'}        {'std' }        0.18407
    {'Week'       }        {'(Intercept)'}        {'corr'}        0.66841
    {'Week'       }        {'Week'       }        {'std' }        0.15033

    Lower      Upper
    0.12281    0.27587
    0.21077    0.88573
    0.11004    0.20537

Group: Error
    Name               Estimate    Lower       Upper
    {'Res Std'}        0.10261     0.087882    0.11981
```

The *p*-values 0.022863 and 4.1099e-08 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they are significant.

Perform an F-test that all fixed-effects coefficients are zero.

```
anova(lme)
```

```
ans =
    ANOVA marginal tests: DFMethod = 'Residual'

    Term                    FStat       DF1    DF2    pValue
    {'(Intercept)'  }         10.065    1      111     0.0019549
    {'InitialWeight'}          5.326    1      111      0.022863
    {'Program'      }          3.6798   3      111      0.014286
    {'Week'         }         34.747    1      111    4.1099e-08
    {'Program:Week' }        0.066648   3      111       0.97748
```

The *p*-values for the constant term, initial weight, and week are the same as in the coefficient table in the previous `lme` output display. The *p*-value of 0.014286 for `Program` represents the combined significance for all program coefficients. Similarly, the *p*-value for the interaction between program and week (`Program:Week`) measures the combined significance for all coefficients representing this interaction.

Now, use the Satterthwaite method to compute the degrees of freedom.

```
anova(lme,'DFMethod','satterthwaite')
```

```
ans =
    ANOVA marginal tests: DFMethod = 'Satterthwaite'

    Term                    FStat       DF1    DF2       pValue
    {'(Intercept)'  }         10.065    1      20.445      0.004695
    {'InitialWeight'}          5.326    1          20      0.031827
    {'Program'      }          3.6798   3       19.14      0.030233
    {'Week'         }         34.747    1          20    9.1346e-06
    {'Program:Week' }        0.066648   3          20       0.97697
```

The Satterthwaite method produces smaller denominator degrees of freedom and slightly larger *p*-values.

Tips

- For each fixed-effects term, `anova` performs an *F*-test (marginal test), that all coefficients representing the fixed-effects term are 0. To perform tests for type III hypotheses, you must set the `'DummyVarCoding'` name-value pair argument to `'effects'` contrasts while fitting your linear mixed-effects model.

anova1

One-way analysis of variance

Syntax

```
p = anova1(y)
p = anova1(y,group)
p = anova1(y,group,displayopt)
[p,tbl] = anova1( ___ )
[p,tbl,stats] = anova1( ___ )
```

Description

`p = anova1(y)` performs one-way ANOVA on page 9-3 for the sample data `y` and returns the *p*-value. `anova1` treats each column of `y` as a separate group. The function tests the hypothesis that the samples in the columns of `y` are drawn from populations with the same mean against the alternative hypothesis that the population means are not all the same. The function also displays the box plot on page 33-71 for each group in `y` and the standard ANOVA table (`tbl`).

`p = anova1(y,group)` performs one-way ANOVA for the sample data `y`, grouped by `group`.

`p = anova1(y,group,displayopt)` enables the ANOVA table and box plot displays when `displayopt` is `'on'` (default) and suppresses the displays when `displayopt` is `'off'`.

`[p,tbl] = anova1( ___ )` returns the ANOVA table (including column and row labels) in the cell array `tbl` using any of the input argument combinations in the previous syntaxes. To copy a text version of the ANOVA table to the clipboard, select **Edit > Copy Text** from the ANOVA table figure.

`[p,tbl,stats] = anova1( ___ )` returns a structure, `stats`, which you can use to perform a multiple comparison test on page 9-18. A multiple comparison test enables you to determine which pairs of group means are significantly different. To perform this test, use `multcompare`, providing the `stats` structure as an input argument.

Examples

One-Way ANOVA

Create sample data matrix `y` with columns that are constants, plus random normal disturbances with mean 0 and standard deviation 1.

```
y = meshgrid(1:5);
rng default; % For reproducibility
y = y + normrnd(0,1,5,5)
```

```
y = 5×5

    1.5377    0.6923    1.6501    3.7950    5.6715
    2.8339    1.5664    6.0349    3.8759    3.7925
   -1.2588    2.3426    3.7254    5.4897    5.7172
```

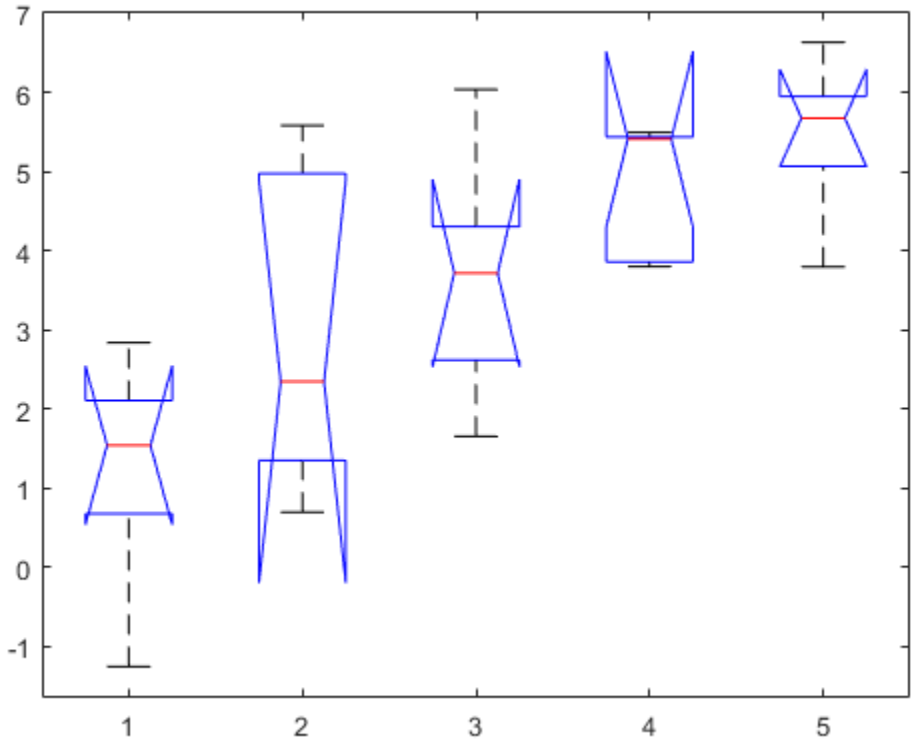
```
    1.8622    5.5784    2.9369    5.4090    6.6302
    1.3188    4.7694    3.7147    5.4172    5.4889
```

Perform one-way ANOVA.

```
p = anova1(y)
```

ANOVA Table

Source	SS	df	MS	F	Prob>F
Columns	53.7238	4	13.4309	6.05	0.0023
Error	44.408	20	2.2204		
Total	98.1318	24			



```
p = 0.0023
```

The ANOVA table shows the between-groups variation (`Columns`) and within-groups variation (`Error`). `SS` is the sum of squares, and `df` is the degrees of freedom. The total degrees of freedom is total number of observations minus one, which is 25 - 1 = 24. The between-groups degrees of freedom is number of groups minus one, which is 5 - 1 = 4. The within-groups degrees of freedom is total degrees of freedom minus the between groups degrees of freedom, which is 24 - 4 = 20.

`MS` is the mean squared error, which is `SS/df` for each source of variation. The *F*-statistic is the ratio of the mean squared errors (13.4309/2.2204). The *p*-value is the probability that the test statistic can

take a value greater than the value of the computed test statistic, i.e., P(F > 6.05). The small *p*-value of 0.0023 indicates that differences between column means are significant.

Compare Beam Strength Using One-Way ANOVA

Input the sample data.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];
alloy = {'st','st','st','st','st','st','st','st',...
         'al1','al1','al1','al1','al1','al1',...
         'al2','al2','al2','al2','al2','al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector strength measures deflections of beams in thousandths of an inch under 3000 pounds of force. The vector alloy identifies each beam as steel (`'st'`), alloy 1 (`'al1'`), or alloy 2 (`'al2'`). Although alloy is sorted in this example, grouping variables do not need to be sorted.

Test the null hypothesis that the steel beams are equal in strength to the beams made of the two more expensive alloys. Turn the figure display off and return the ANOVA results in a cell array.

```
[p,tbl] = anova1(strength,alloy,'off')
```

```
p = 1.5264e-04

tbl=4×6 cell array
  Columns 1 through 5

    {'Source'}    {'SS'      }    {'df'}    {'MS'      }    {'F'       }
    {'Groups'}    {[184.8000]}    {[ 2]}    {[ 92.4000]}    {[ 15.4000]}
    {'Error' }    {[102.0000]}    {[17]}    {[  6.0000]}    {0x0 double}
    {'Total' }    {[286.8000]}    {[19]}    {0x0 double}    {0x0 double}

  Column 6

    {'Prob>F'    }
    {[1.5264e-04]}
    {0x0 double  }
    {0x0 double  }
```

The total degrees of freedom is total number of observations minus one, which is 20 − 1 = 19. The between-groups degrees of freedom is number of groups minus one, which is 3 − 1 = 2. The within-groups degrees of freedom is total degrees of freedom minus the between groups degrees of freedom, which is 19 − 2 = 17.

`MS` is the mean squared error, which is `SS/df` for each source of variation. The *F*-statistic is the ratio of the mean squared errors. The *p*-value is the probability that the test statistic can take a value greater than or equal to the value of the test statistic. The *p*-value of 1.5264e-04 suggests rejection of the null hypothesis.

You can retrieve the values in the ANOVA table by indexing into the cell array. Save the *F*-statistic value and the *p*-value in the new variables `Fstat` and `pvalue`.

```
Fstat = tbl{2,5}
```

```
Fstat = 15.4000

pvalue = tbl{2,6}

pvalue = 1.5264e-04
```

Multiple Comparisons for One-Way ANOVA

Input the sample data.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];
alloy = {'st','st','st','st','st','st','st','st',...
         'al1','al1','al1','al1','al1','al1',...
         'al2','al2','al2','al2','al2','al2'};
```

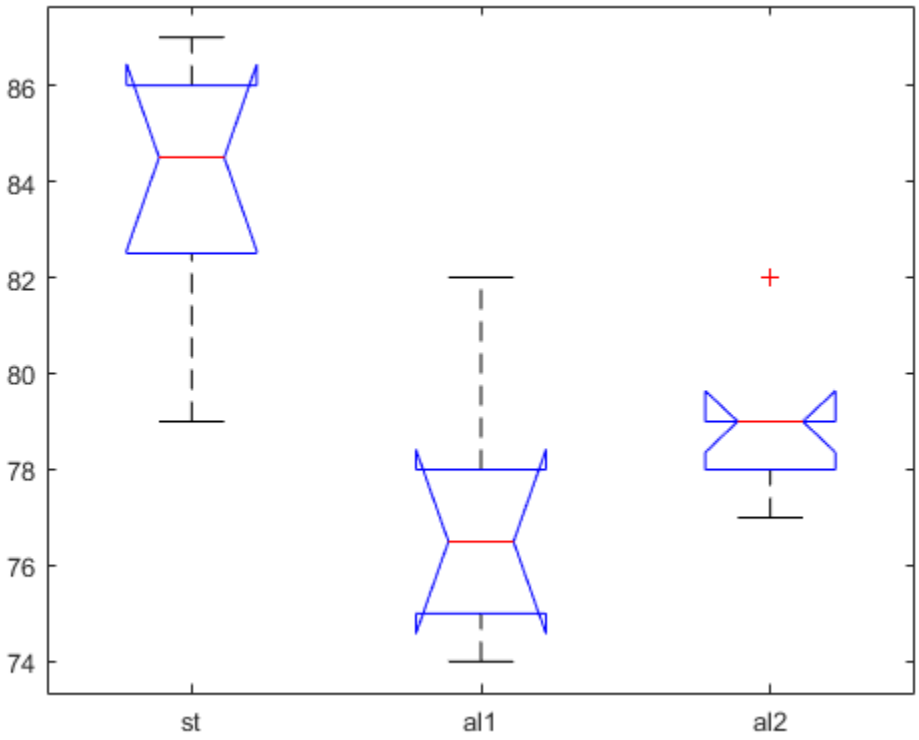
The data are from a study of the strength of structural beams in Hogg (1987). The vector strength measures deflections of beams in thousandths of an inch under 3000 pounds of force. The vector alloy identifies each beam as steel (`st`), alloy 1 (`al1`), or alloy 2 (`al2`). Although alloy is sorted in this example, grouping variables do not need to be sorted.

Perform one-way ANOVA using `anova1`. Return the structure `stats`, which contains the statistics `multcompare` needs for performing “Multiple Comparisons” on page 9-18.

```
[~,~,stats] = anova1(strength,alloy);
```

ANOVA Table

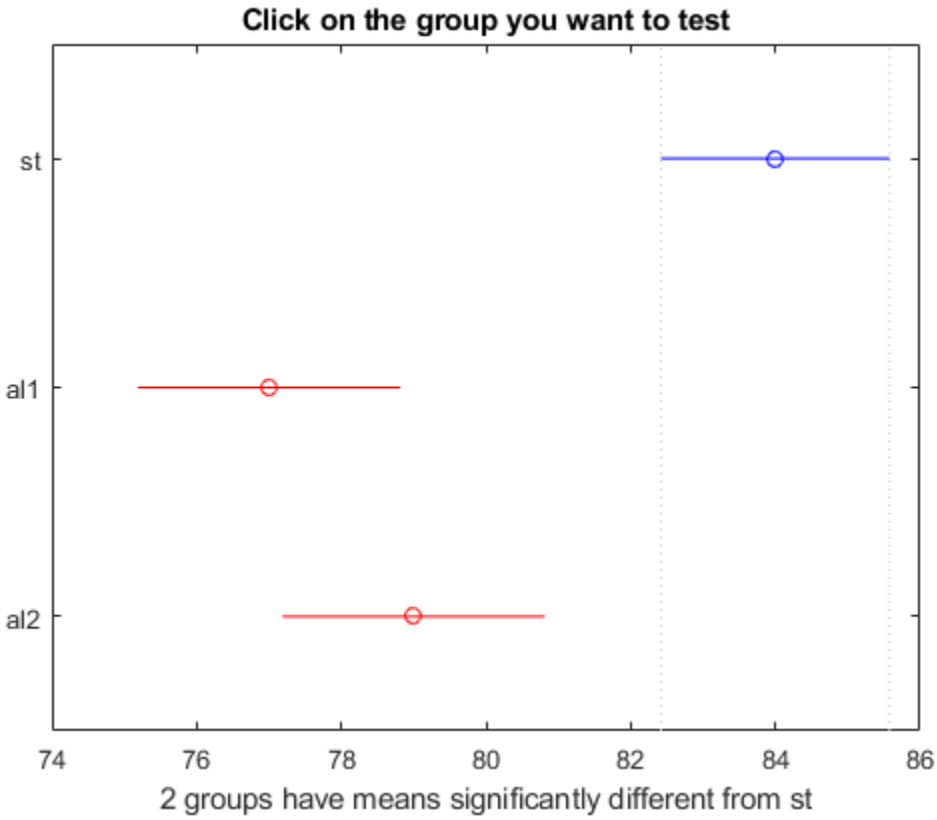
Source	SS	df	MS	F	Prob>F
Groups	184.8	2	92.4	15.4	0.0002
Error	102	17	6		
Total	286.8	19			



The small *p*-value of 0.0002 suggests that the strength of the beams is not the same.

Perform a multiple comparison of the mean strength of the beams.

```
[c,~,~,gnames] = multcompare(stats);
```



Display the comparison results with the corresponding group names.

```
[gnames(c(:,1)), gnames(c(:,2)), num2cell(c(:,3:6))]
```

```
ans=3×6 cell array
  Columns 1 through 5

    {'st' }    {'al1'}    {[ 3.6064]}    {[ 7]}    {[10.3936]}
    {'st' }    {'al2'}    {[ 1.6064]}    {[ 5]}    {[ 8.3936]}
    {'al1'}    {'al2'}    {[-5.6280]}    {[-2]}    {[ 1.6280]}

  Column 6

    {[1.6831e-04]}
    {[    0.0040]}
    {[    0.3560]}
```

The first two columns show the pair of groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for the 95% confidence intervals of the true difference of means. The sixth column shows the *p*-value for a hypothesis that the true difference of means for the corresponding groups is equal to zero.

The first two rows show that both comparisons involving the first group (steel) have confidence intervals that do not include zero. Because the corresponding *p*-values (1.6831e-04 and 0.0040, respectively) are small, those differences are significant.

The third row shows that the differences in strength between the two alloys is not significant. A 95% confidence interval for the difference is [-5.6,1.6], so you cannot reject the hypothesis that the true difference is zero. The corresponding *p*-value of 0.3560 in the sixth column confirms this result.

In the figure, the blue bar represents the comparison interval for mean material strength for steel. The red bars represent the comparison intervals for the mean material strength for alloy 1 and alloy 2. Neither of the red bars overlap with the blue bar, which indicates that the mean material strength for steel is significantly different from that of alloy 1 and alloy 2. To confirm the significant difference by clicking the bars that represent alloy 1 and 2.

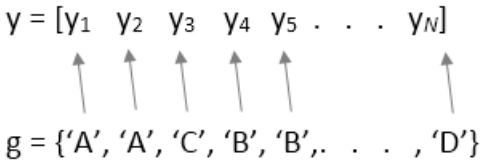
Input Arguments

y — sample data

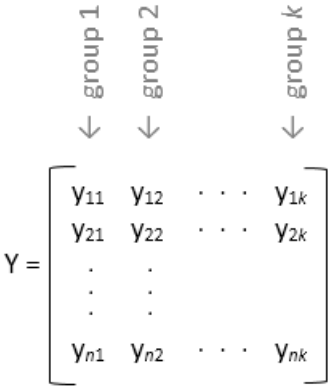
vector | matrix

Sample data, specified as a vector or matrix.

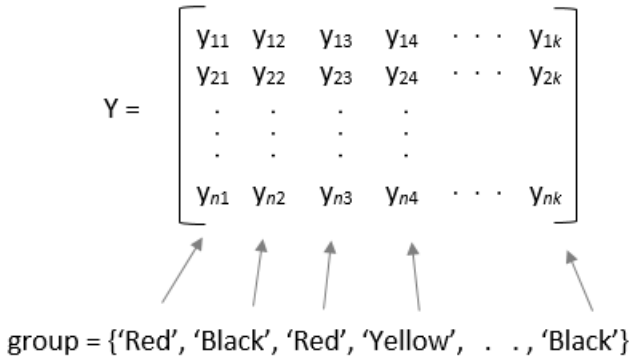
- If `y` is a vector, you must specify the `group` input argument. Each element in `group` represents a group name of the corresponding element in `y`. The `anova1` function treats the `y` values corresponding to the same value of `group` as part of the same group. Use this design when groups have different numbers of elements (unbalanced ANOVA).



- If `y` is a matrix and you do not specify `group`, then `anova1` treats each column of `y` as a separate group. In this design, the function evaluates whether the population means of the columns are equal. Use this design when each group has the same number of elements (balanced ANOVA).



- If `y` is a matrix and you specify `group`, then each element in `group` represents a group name for the corresponding column in `y`. The `anova1` function treats the columns that have the same group name as part of the same group.



Note `anova1` ignores any `NaN` values in `y`. Also, if `group` contains empty or `NaN` values, `anova1` ignores the corresponding observations in `y`. The `anova1` function performs balanced ANOVA if each group has the same number of observations after the function disregards empty or `NaN` values. Otherwise, `anova1` performs unbalanced ANOVA.

Data Types: `single` | `double`

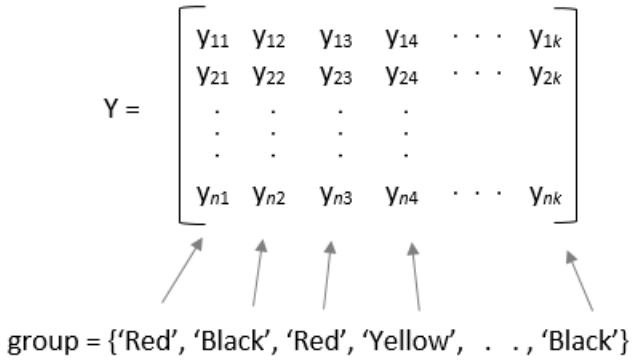
`group` — Grouping variable

numeric vector | logical vector | categorical vector | character array | string array | cell array of character vectors

Grouping variable containing group names, specified as a numeric vector, logical vector, categorical vector, character array, string array, or cell array of character vectors.

- If `y` is a vector, then each element in `group` represents a group name of the corresponding element in `y`. The `anova1` function treats the `y` values corresponding to the same value of `group` as part of the same group.

  
  N is the total number of observations.
- If `y` is a matrix, then each element in `group` represents a group name for the corresponding column in `y`. The `anova1` function treats the columns of `y` that have the same group name as part of the same group.



If you do not want to specify group names for the matrix sample data `y`, enter an empty array (`[]`) or omit this argument. In this case, `anova1` treats each column of `y` as a separate group.

If `group` contains empty or `NaN` values, `anova1` ignores the corresponding observations in `y`.

For more information on grouping variables, see "Grouping Variables" on page 2-45.

Example: `'group',[1,2,1,3,1,...,3,1]` when `y` is a vector with observations categorized into groups 1, 2, and 3

Example: `'group',{'white','red','white','black','red'}` when `y` is a matrix with five columns categorized into groups red, white, and black

Data Types: `single` | `double` | `logical` | `categorical` | `char` | `string` | `cell`

`displayopt` — Indicator to display ANOVA table and box plot
`'on'` (default) | `'off'`

Indicator to display the ANOVA table and box plot, specified as `'on'` or `'off'`. When `displayopt` is `'off'`, `anova1` returns the output arguments, only. It does not display the standard ANOVA table and box plot.

Example: `p = anova(x,group,'off')`

Output Arguments

`p` — *p*-value for the *F*-test
scalar value

p-value for the *F*-test, returned as a scalar value. *p*-value is the probability that the *F*-statistic can take a value larger than the computed test-statistic value. `anova1` tests the null hypothesis that all group means are equal to each other against the alternative hypothesis that at least one group mean is different from the others. The function derives the *p*-value from the cdf of the *F*-distribution.

A *p*-value that is smaller than the significance level indicates that at least one of the sample means is significantly different from the others. Common significance levels are 0.05 or 0.01.

`tbl` — ANOVA table
cell array

ANOVA table, returned as a cell array. `tbl` has six columns.

Column	Definition
`source`	The source of the variability.
`SS`	The sum of squares due to each source.
`df`	The degrees of freedom associated with each source. Suppose N is the total number of observations and k is the number of groups. Then, $N - k$ is the within-groups degrees of freedom (`Error`), $k - 1$ is the between-groups degrees of freedom (`Columns`), and $N - 1$ is the total degrees of freedom. $N - 1 = (N - k) + (k - 1)$
`MS`	The mean squares for each source, which is the ratio `SS/df`.
`F`	F-statistic, which is the ratio of the mean squares.
`Prob>F`	The p-value, which is the probability that the F-statistic can take a value larger than the computed test-statistic value. `anova1` derives this probability from the cdf of F-distribution.

The rows of the ANOVA table show the variability in the data that is divided by the source.

Row	Definition
`Groups`	Variability due to the differences among the group means (variability *between* groups)
`Error`	Variability due to the differences between the data in each group and the group mean (variability *within* groups)
`Total`	Total variability

`stats` — Statistics for multiple comparison tests
structure

Statistics for multiple comparison tests on page 9-18, returned as a structure with the fields described in this table.

Field name	Definition
`gnames`	Names of the groups
`n`	Number of observations in each group
`source`	Source of the `stats` output
`means`	Estimated values of the means
`df`	Error (within-groups) degrees of freedom ($N - k$, where N is the total number of observations and k is the number of groups)
`s`	Square root of the mean squared error

More About

Box Plot

`anova1` returns a box plot of the observations for each group in `y`. Box plots provide a visual comparison of the group location parameters.

On each box, the central mark is the median (2nd quantile, q_2) and the edges of the box are the 25th and 75th percentiles (1st and 3rd quantiles, q_1 and q_3, respectively). The whiskers extend to the most extreme data points that are not considered outliers. The outliers are plotted individually using the `'+'` symbol. The extremes of the whiskers correspond to $q_3 + 1.5 \times (q_3 - q_1)$ and $q_1 - 1.5 \times (q_3 - q_1)$.

Box plots include notches for the comparison of the median values. Two medians are significantly different at the 5% significance level if their intervals, represented by notches, do not overlap. This test is different from the *F*-test that ANOVA performs; however, large differences in the center lines of the boxes correspond to a large *F*-statistic value and correspondingly a small *p*-value. The extremes of the notches correspond to $q_2 - 1.57(q_3 - q_1)/\text{sqrt}(n)$ and $q_2 + 1.57(q_3 - q_1)/\text{sqrt}(n)$, where n is the number of observations without any `NaN` values.

For more information about box plots, see `'Whisker'` and `'Notch'` of `boxplot`.

Introduced before R2006a

anova2

Two-way analysis of variance

Syntax

```
p = anova2(y,reps)
p = anova2(y,reps,displayopt)
[p,tbl] = anova2( ___ )
[p,tbl,stats] = anova2( ___ )
```

Description

`anova2` performs two-way analysis of variance (ANOVA) with balanced designs. To perform two-way ANOVA with unbalanced designs, see `anovan`.

`p = anova2(y,reps)` returns the *p*-values for a balanced two-way ANOVA for comparing the means of two or more columns and two or more rows of the observations in `y`.

`reps` is the number of replicates for each combination of factor groups, which must be constant, indicating a balanced design. For unbalanced designs, use `anovan`. The `anova2` function tests the main effects for column and row factors and their interaction effect. To test the interaction effect, `reps` must be greater than 1.

`anova2` also displays the standard ANOVA table.

`p = anova2(y,reps,displayopt)` enables the ANOVA table display when `displayopt` is `'on'` (default) and suppresses the display when `displayopt` is `'off'`.

`[p,tbl] = anova2( ___ )` returns the ANOVA table (including column and row labels) in cell array `tbl`. To copy a text version of the ANOVA table to the clipboard, select **Edit > Copy Text** menu.

`[p,tbl,stats] = anova2( ___ )` returns a `stats` structure, which you can use to perform a multiple comparison test on page 9-18. A multiple comparison test enables you to determine which pairs of group means are significantly different. To perform this test, use `multcompare`, providing the `stats` structure as input.

Examples

Two-Way ANOVA

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn = 6×3

    5.5000    4.5000    3.5000
    5.5000    4.5000    4.0000
    6.0000    4.0000    3.0000
```

```
    6.5000    5.0000    4.0000
    7.0000    5.5000    5.0000
    7.0000    5.0000    4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands, Gourmet, National, and Generic, respectively. The rows are popper types, oil and air. In the study, researchers popped a batch of each brand three times with each popper, that is, the number of replications is 3. The first three rows correspond to the oil popper, and the last three rows correspond to the air popper. The response values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Save the ANOVA table in the cell array `tbl` for easy access to results.

```
[p,tbl] = anova2(popcorn,3);
```

ANOVA Table

Source	SS	df	MS	F	Prob>F
Columns	15.75	2	7.875	56.7	0
Rows	4.5	1	4.5	32.4	0.0001
Interaction	0.0833	2	0.04167	0.3	0.7462
Error	1.6667	12	0.13889		
Total	22	17			

The column `Prob>F` shows the *p*-values for the three brands of popcorn (0.0000), the two popper types (0.0001), and the interaction between brand and popper type (0.7462). These values indicate that popcorn brand and popper type affect the yield of popcorn, but there is no evidence of an interaction effect of the two.

Display the cell array containing the ANOVA table.

```
tbl
```

```
tbl=6×6 cell array
  Columns 1 through 5

    {'Source'     }    {'SS'     }    {'df'}    {'MS'      }    {'F'       }
    {'Columns'    }    {[15.7500]}    {[ 2]}    {[  7.8750]}    {[ 56.7000]}
    {'Rows'       }    {[ 4.5000]}    {[ 1]}    {[  4.5000]}    {[ 32.4000]}
    {'Interaction'}    {[ 0.0833]}    {[ 2]}    {[  0.0417]}    {[  0.3000]}
    {'Error'      }    {[ 1.6667]}    {[12]}    {[  0.1389]}    {0x0 double}
    {'Total'      }    {[     22]}    {[17]}    {0x0 double}    {0x0 double}

  Column 6

    {'Prob>F'    }
    {[7.6790e-07]}
    {[1.0037e-04]}
    {[    0.7462]}
    {0x0 double  }
    {0x0 double  }
```

Store the *F*-statistic for the factors and factor interaction in separate variables.

```
Fbrands = tbl{2,5}
```

```
Fbrands = 56.7000
```

```
Fpoppertype = tbl{3,5}
```

```
Fpoppertype = 32.4000
```

```
Finteraction = tbl{4,5}
```

```
Finteraction = 0.3000
```

Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn = 6×3

    5.5000    4.5000    3.5000
    5.5000    4.5000    4.0000
    6.0000    4.0000    3.0000
    6.5000    5.0000    4.0000
    7.0000    5.5000    5.0000
    7.0000    5.0000    4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

```
[~,~,stats] = anova2(popcorn,3,'off')
```

```
stats = struct with fields:
      source: 'anova2'
     sigmasq: 0.1389
    colmeans: [6.2500 4.7500 4]
        coln: 6
    rowmeans: [4.5000 5.5000]
        rown: 9
       inter: 1
        pval: 0.7462
          df: 12
```

The `stats` structure includes

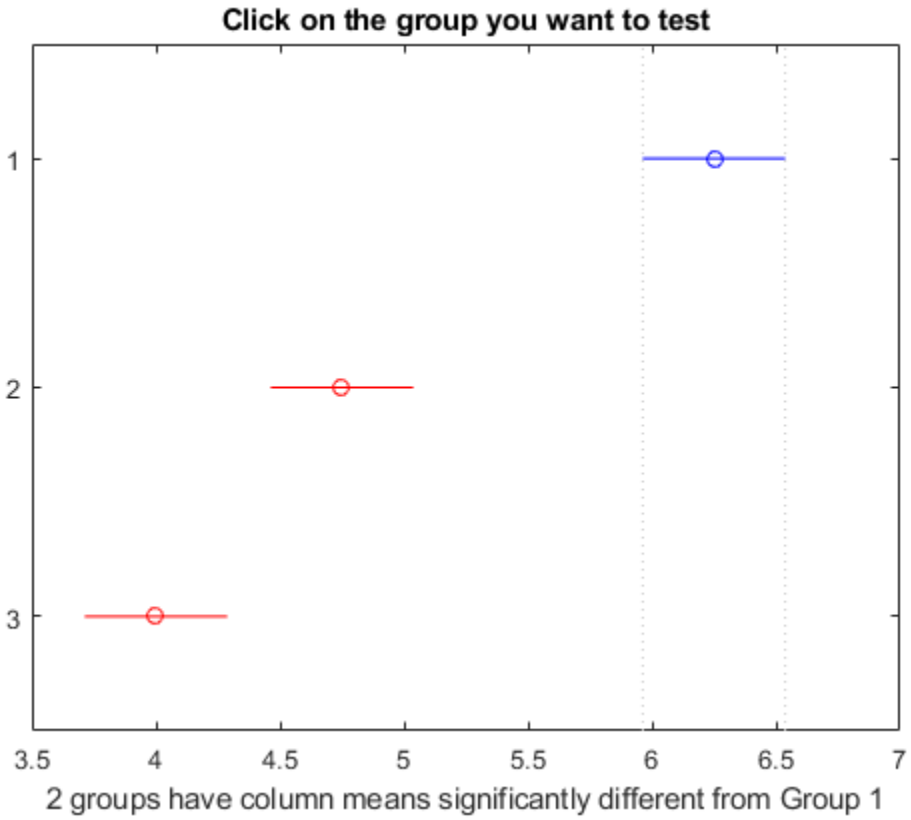
- The mean squared error (`sigmasq`)
- The estimates of the mean yield for each popcorn brand (`colmeans`)

- The number of observations for each popcorn brand (`coln`)
- The estimate of the mean yield for each popper type (`rowmeans`)
- The number of observations for each popper type (`rown`)
- The number of interactions (`inter`)
- The *p*-value that shows the significance level of the interaction term (`pval`)
- The error degrees of freedom (`df`).

Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

```
c = multcompare(stats)
```

```
Note: Your model includes an interaction term.  A test of main effects can be
difficult to interpret when the model includes interactions.
```



```
c = 3×6

    1.0000    2.0000    0.9260    1.5000    2.0740    0.0000
    1.0000    3.0000    1.6760    2.2500    2.8240    0.0000
    2.0000    3.0000    0.1760    0.7500    1.3240    0.0116
```

The first two columns of `c` show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the *p*-

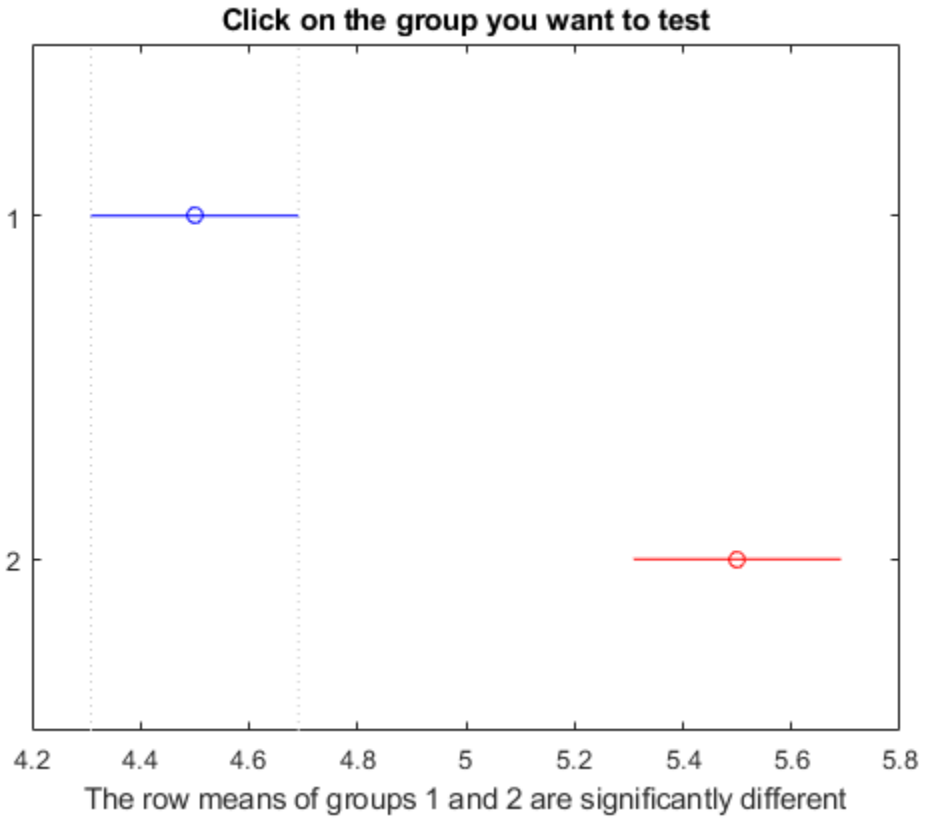
value for a hypothesis test that the corresponding mean difference is equal to zero. All *p*-values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.

The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

```
c = multcompare(stats,'Estimate','row')
```

```
Note: Your model includes an interaction term.  A test of main effects can be
difficult to interpret when the model includes interactions.
```



```
c = 1×6

    1.0000    2.0000   -1.3828   -1.0000   -0.6172    0.0001
```

The small *p*-value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.

Input Arguments

y — Sample data

matrix

Sample data, specified as a matrix. The columns correspond to groups of one factor, and the rows correspond to the groups of the other factor and the replications. Replications are the measurements or observations for each combination of groups (levels) of the row and column factor. For example, in the following data the row factor *A* has three levels, column factor *B* has two levels, and there are two replications (`reps = 2`). The subscripts indicate row, column, and replication, respectively.

$$\begin{matrix} B=1 & B=2 \end{matrix}$$
$$\begin{bmatrix} y_{111} & y_{121} \\ y_{112} & y_{122} \\ y_{211} & y_{221} \\ y_{212} & y_{222} \\ y_{311} & y_{321} \\ y_{312} & y_{322} \end{bmatrix} \begin{matrix} \} A=1 \\ \} A=2 \\ \} A=3 \end{matrix}$$

Data Types: `single` | `double`

reps — Number of replications

1 (default) | an integer number

Number of replications for each combination of groups, specified as an integer number. For example, the following data has two replications (`reps = 2`) for each group combination of row factor *A* and column factor *B*.

$$\begin{matrix} B=1 & B=2 \end{matrix}$$
$$\begin{bmatrix} y_{111} & y_{121} \\ y_{112} & y_{122} \\ y_{211} & y_{221} \\ y_{212} & y_{222} \\ y_{311} & y_{321} \\ y_{312} & y_{322} \end{bmatrix} \begin{matrix} \} A=1 \\ \} A=2 \\ \} A=3 \end{matrix}$$

- When `reps` is `1` (default), `anova2` returns two *p*-values in vector `p`:
  - The *p*-value for the null hypothesis that all samples from factor *B* (i.e., all column samples in `y`) are drawn from the same population.
  - The *p*-value for the null hypothesis, that all samples from factor *A* (i.e., all row samples in `y`) are drawn from the same population.
- When `reps` is greater than `1`, `anova2` also returns the *p*-value for the null hypothesis that factors *A* and *B* have no interaction (i.e., the effects due to factors *A* and *B* are *additive*).

Example: `p = anova(y,3)` specifies that each combination of groups (levels) has three replications.

Data Types: `single` | `double`

`displayopt` — Indicator to display the ANOVA table
`'on'` (default) | `'off'`

Indicator to display the ANOVA table as a figure, specified as `'on'` or `'off'`.

Output Arguments

`p` — *p*-value
scalar value

p-value for the *F*-test, returned as a scalar value. A small *p*-value indicates that the results are statistically significant. Common significance levels are 0.05 or 0.01. For example:

- A sufficiently small *p*-value for the null hypothesis for group means of row factor *A* suggests that at least one row-sample mean is significantly different from the other row-sample means; i.e., there is a main effect due to factor *A*
- A sufficiently small *p*-value for the null hypothesis for group (level) means of column factor *B* suggests that at least one column-sample mean is significantly different from the other column-sample means; i.e., there is a main effect due to factor *B*.
- A sufficiently small *p*-value for combinations of groups (levels) of factors *A* and *B* suggests that there is an interaction between factors *A* and *B*.

`tbl` — ANOVA table
cell array

ANOVA table, returned as a cell array. `tbl` has six columns.

Column name	Definition
`source`	Source of the variability.
`SS`	Sum of squares due to each source.
`df`	Degrees of freedom associated with each source.
`MS`	Mean squares for each source, which is the ratio `SS/df`.
`F`	*F*-statistic, which is the ratio of the mean squares.
`Prob>F`	*p*-value, which is the probability that the *F*-statistic can take a value larger than the computed test-statistic value. `anova2` derives this probability from the cdf of the *F*-distribution.

The rows of the ANOVA table show the variability in the data, divided by the source into three or four parts, depending on the value of `reps`.

Row	Definition
`Columns`	Variability due to the differences among the column means
`Rows`	Variability due to the differences among the row means

Row	Definition
`Interaction`	Variability due to the interaction between rows and columns (if `reps` is greater than its default value of 1)
`Error`	Remaining variability not explained by any systematic source

Data Types: `cell`

`stats` — Statistics for multiple comparison test
structure

Statistics for multiple comparisons tests on page 9-18, returned as a structure. Use `multcompare` to perform multiple comparison tests, supplying `stats` as an input argument. `stats` has nine fields.

Field	Definition
`source`	Source of the `stats` output
`sigmasq`	Mean squared error
`colmeans`	Estimated values of the column means
`coln`	Number of observations for each group in columns
`rowmeans`	Estimated values of the row means
`rown`	Number of observations for each group in rows
`inter`	Number of interactions
`pval`	*p*-value for the interaction term
`df`	Error degrees of freedom (*reps* — 1)*r*c* where *reps* is the number of replications and *c* and *r* are the number of groups in factors, respectively.

Data Types: `struct`

“Two-Way ANOVA” on page 9-11
“Multiple Comparisons” on page 9-18

Introduced before R2006a

anovan

N-way analysis of variance

Syntax

```
p = anovan(y,group)
p = anovan(y,group,Name,Value)
[p,tbl] = anovan( ___ )
[p,tbl,stats] = anovan( ___ )
[p,tbl,stats,terms] = anovan( ___ )
```

Description

`p = anovan(y,group)` returns a vector of *p*-values, one per term, for multiway (*n*-way) analysis of variance (ANOVA) for testing the effects of multiple factors on the mean of the vector `y`.

`anovan` also displays a figure showing the standard ANOVA table.

`p = anovan(y,group,Name,Value)` returns a vector of *p*-values for multiway (*n*-way) ANOVA using additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which predictor variable is continuous, if any, or the type of sum of squares to use.

`[p,tbl] = anovan( ___ )` returns the ANOVA table (including factor labels) in cell array `tbl` for any of the input arguments specified in the previous syntaxes. Copy a text version of the ANOVA table to the clipboard by using the `Copy Text` item on the **Edit** menu.

`[p,tbl,stats] = anovan( ___ )` returns a `stats` structure that you can use to perform a multiple comparison test on page 9-18, which enables you to determine which pairs of group means are significantly different. You can perform such a test using the `multcompare` function by providing the `stats` structure as input.

`[p,tbl,stats,terms] = anovan( ___ )` returns the main and interaction terms used in the ANOVA computations in `terms`.

Examples

Three-Way ANOVA

Load the sample data.

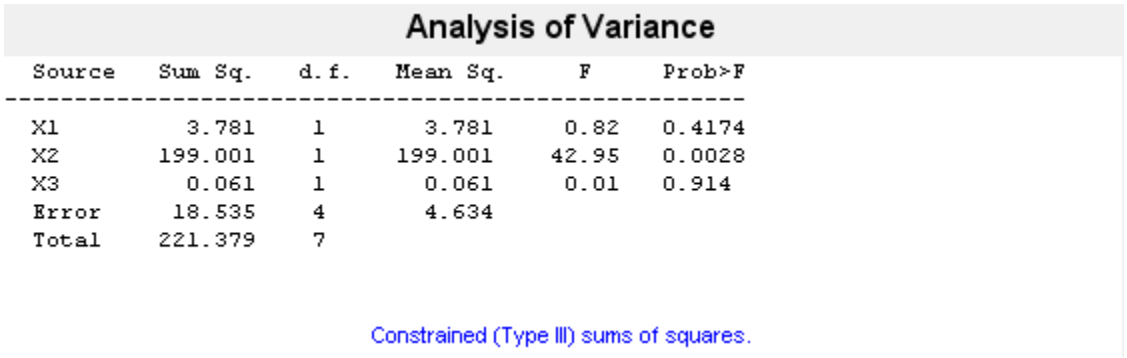
```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi';'hi';'lo';'lo';'hi';'hi';'lo';'lo'};
g3 = {'may';'may';'may';'may';'june';'june';'june';'june'};
```

`y` is the response vector and `g1`, `g2`, and `g3` are the grouping variables (factors). Each factor has two levels ,and every observation in `y` is identified by a combination of factor levels. For example,

observation `y(1)` is associated with level 1 of factor `g1`, level `'hi'` of factor `g2`, and level `'may'` of factor `g3`. Similarly, observation `y(6)` is associated with level 2 of factor `g1`, level `'hi'` of factor `g2`, and level `'june'` of factor `g3`.

Test if the response is the same for all factor levels.

```
p = anovan(y,{g1,g2,g3})
```



Analysis of Variance

Source	Sum Sq.	d.f.	Mean Sq.	F	Prob>F
X1	3.781	1	3.781	0.82	0.4174
X2	199.001	1	199.001	42.95	0.0028
X3	0.061	1	0.061	0.01	0.914
Error	18.535	4	4.634		
Total	221.379	7			

Constrained (Type III) sums of squares.

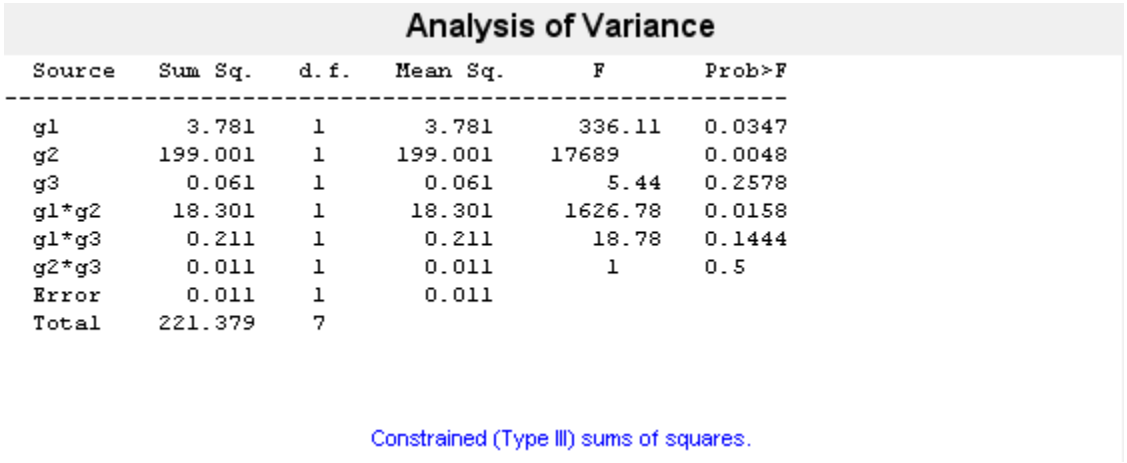
```
p = 3×1

    0.4174
    0.0028
    0.9140
```

In the ANOVA table, `X1`, `X2`, and `X3` correspond to the factors `g1`, `g2`, and `g3`, respectively. The *p*-value 0.4174 indicates that the mean responses for levels 1 and 2 of the factor `g1` are not significantly different. Similarly, the *p*-value 0.914 indicates that the mean responses for levels `'may'` and `'june'`, of the factor `g3` are not significantly different. However, the *p*-value 0.0028 is small enough to conclude that the mean responses are significantly different for the two levels, `'hi'` and `'lo'` of the factor `g2`. By default, `anovan` computes *p*-values just for the three main effects.

Test the two-factor interactions. This time specify the variable names.

```
p = anovan(y,{g1 g2 g3},'model','interaction','varnames',{'g1','g2','g3'})
```



Analysis of Variance

Source	Sum Sq.	d.f.	Mean Sq.	F	Prob>F
g1	3.781	1	3.781	336.11	0.0347
g2	199.001	1	199.001	17689	0.0048
g3	0.061	1	0.061	5.44	0.2578
g1*g2	18.301	1	18.301	1626.78	0.0158
g1*g3	0.211	1	0.211	18.78	0.1444
g2*g3	0.011	1	0.011	1	0.5
Error	0.011	1	0.011		
Total	221.379	7			

Constrained (Type III) sums of squares.

```
p = 6×1
```

```
    0.0347
    0.0048
    0.2578
    0.0158
    0.1444
    0.5000
```

The interaction terms are represented by `g1*g2`, `g1*g3`, and `g2*g3` in the ANOVA table. The first three entries of `p` are the *p*-values for the main effects. The last three entries are the *p*-values for the two-way interactions. The *p*-value of 0.0158 indicates that the interaction between `g1` and `g2` is significant. The *p*-values of 0.1444 and 0.5 indicate that the corresponding interactions are not significant.

Two-Way ANOVA for Unbalanced Design

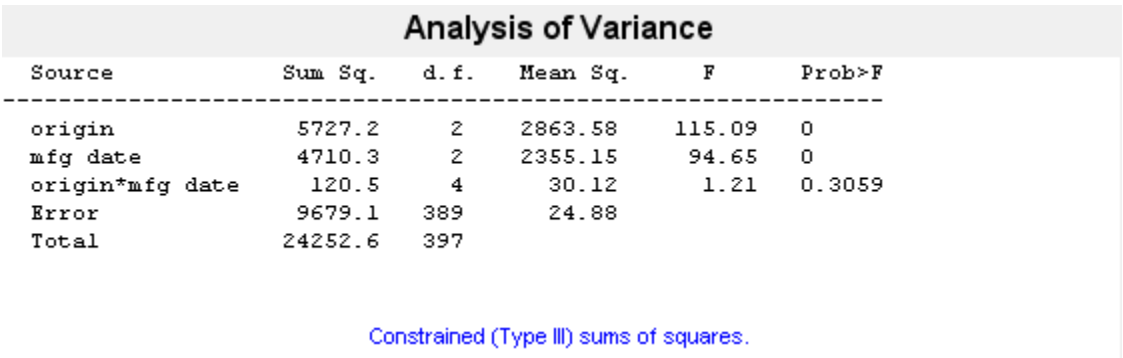
Load the sample data.

```
load carbig
```

The data has measurements on 406 cars. The variable `org` shows where the cars were made and `when` shows when in the year the cars were manufactured.

Study how the mileage depends on when and where the cars were made. Also include the two-way interactions in the model.

```
p = anovan(MPG,{org when},'model',2,'varnames',{'origin','mfg date'})
```



```
p = 3×1

    0.0000
    0.0000
    0.3059
```

The `'model',2` name-value pair argument represents the two-way interactions. The *p*-value for the interaction term, 0.3059, is not small, indicating little evidence that the effect of the time of manufacture (`mfg date`) depends on where the car was made (`origin`). The main effects of origin and manufacturing date, however, are significant, both *p*-values are 0.

Multiple Comparisons for Three-Way ANOVA

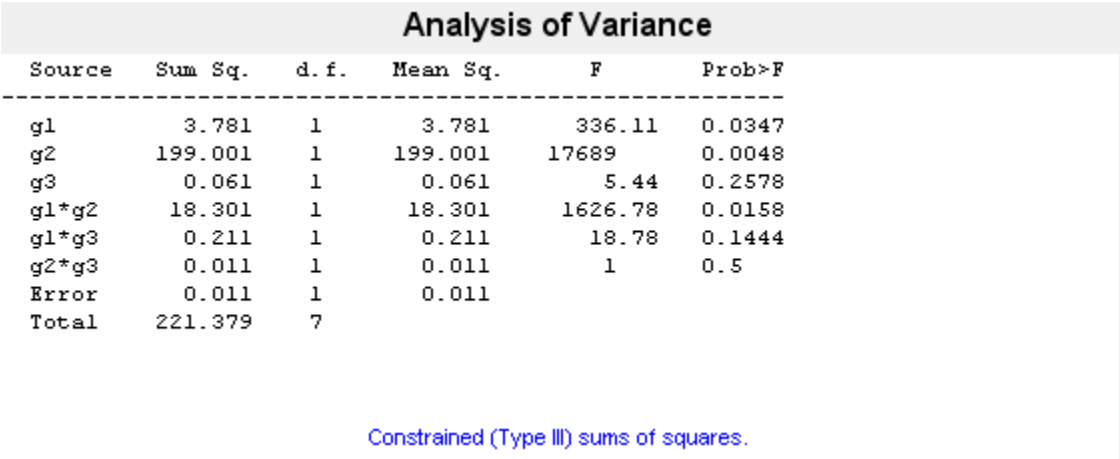
Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi';'hi';'lo';'lo';'hi';'hi';'lo';'lo'};
g3 = {'may';'may';'may';'may';'june';'june';'june';'june'};
```

`y` is the response vector and `g1`, `g2`, and `g3` are the grouping variables (factors). Each factor has two levels, and every observation in `y` is identified by a combination of factor levels. For example, observation `y(1)` is associated with level 1 of factor `g1`, level `'hi'` of factor `g2`, and level `'may'` of factor `g3`. Similarly, observation `y(6)` is associated with level 2 of factor `g1`, level `'hi'` of factor `g2`, and level `'june'` of factor `g3`.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

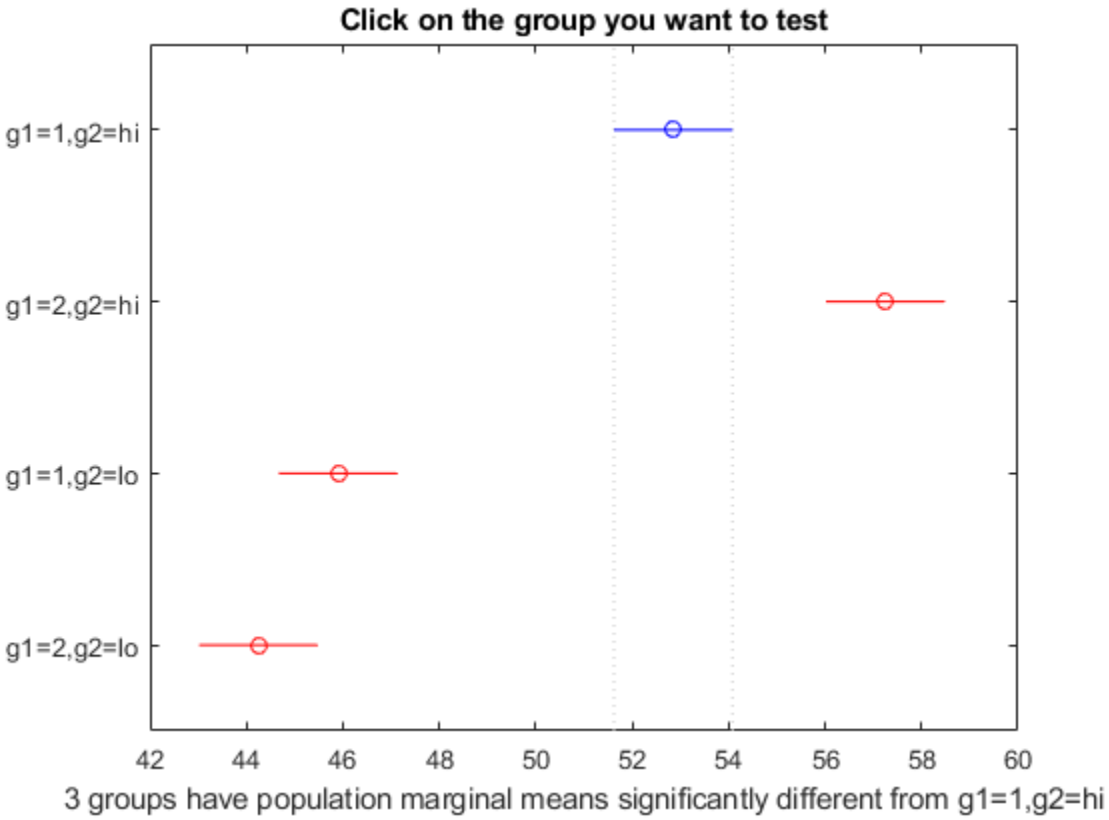
```
[~,~,stats] = anovan(y,{g1 g2 g3},'model','interaction',...
    'varnames',{'g1','g2','g3'});
```



The *p*-value of 0.2578 indicates that the mean responses for levels `'may'` and `'june'` of factor `g3` are not significantly different. The *p*-value of 0.0347 indicates that the mean responses for levels 1 and 2 of factor `g1` are significantly different. Similarly, the *p*-value of 0.0048 indicates that the mean responses for levels `'hi'` and `'lo'` of factor `g2` are significantly different.

Perform multiple comparison tests to find out which groups of the factors `g1` and `g2` are significantly different.

```
results = multcompare(stats,'Dimension',[1 2])
```



```
results = 6×6

    1.0000    2.0000   -6.8604   -4.4000   -1.9396    0.0272
    1.0000    3.0000    4.4896    6.9500    9.4104    0.0170

```

`multcompare` compares the combinations of groups (levels) of the two grouping variables, `g1` and `g2`. In the `results` matrix, the number 1 corresponds to the combination of level `1` of `g1` and level `hi` of `g2`, the number 2 corresponds to the combination of level 2 of `g1` and level `hi` of `g2`. Similarly, the number 3 corresponds to the combination of level `1` of `g1` and level `lo` of `g2`, and the number 4 corresponds to the combination of level 2 of `g1` and level `lo` of `g2`. The last column of the matrix contains the *p*-values.

For example, the first row of the matrix shows that the combination of level `1` of `g1` and level `hi` of `g2` has the same mean response values as the combination of level 2 of `g1` and level `hi` of `g2`. The *p*-value corresponding to this test is 0.0280, which indicates that the mean responses are significantly different. You can also see this result in the figure. The blue bar shows the comparison interval for the mean response for the combination of level `1` of `g1` and level `hi` of `g2`. The red bars are the comparison intervals for the mean response for other group combinations. None of the red bars overlap with the blue bar, which means the mean response for the combination of level `1` of `g1` and level `hi` of `g2` is significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for the group. The bar you click on turns to blue. The bars for the groups that are significantly different are red. The bars for the groups that are not significantly different are gray. For example, if you click on the comparison interval for the combination of level `1` of `g1` and level `lo` of `g2`, the comparison interval for the combination of level `2` of `g1` and level `lo` of `g2` overlaps, and is therefore gray. Conversely, the other comparison intervals are red, indicating significant difference.

Input Arguments

y — Sample data

numeric vector

Sample data, specified as a numeric vector.

Data Types: `single` | `double`

group — Grouping variables

cell array

Grouping variables, i.e. the factors and factor levels of the observations in `y`, specified as a cell array. Each of the cells in `group` contains a list of factor levels identifying the observations in `y` with respect to one of the factors. The list within each cell can be a categorical array, numeric vector, character matrix, string array, or single-column cell array of character vectors, and must have the same number of elements as `y`.

$$
\begin{array}{rcccccccc}
y & = & [& y_1, & y_2, & y_3, & y_4, & y_5, \cdots, & y_N &]' \\
 & & & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \uparrow & \\
g1 & = & \{ & 'A', & 'A', & 'C', & 'B', & 'B', \cdots, & 'D' & \} \\
g2 & = & [& 1 & 2 & 1 & 3 & 1 \cdots, & 2 &] \\
g3 & = & \{ & \text{'hi'}, & \text{'mid'}, & \text{'low'}, & \text{'mid'}, & \text{'hi'}, \cdots, & \text{'low'} & \}
\end{array}
$$

By default, `anovan` treats all grouping variables as fixed effects.

For example, in a study you want to investigate the effects of gender, school, and the education method on the academic success of elementary school students, then you can specify the grouping variables as follows.

Example: `{'Gender','School','Method'}`

Data Types: `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'alpha',0.01,'model','interaction','sstype',2` specifies `anovan` to compute the 99% confidence bounds and p-values for the main effects and two-way interactions using type II sum of squares.

alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level for confidence bounds, specified as the comma-separated pair consisting of`'alpha'` and a scalar value in the range 0 to 1. For a value α, the confidence level is 100*(1–α)%.

Example: `'alpha',0.01` corresponds to 99% confidence intervals

Data Types: `single` | `double`

`continuous` — Indicator for continuous predictors
vector of indices

Indicator for continuous predictors, representing which grouping variables should be treated as continuous predictors rather than as categorical predictors, specified as the comma-separated pair consisting of `'continuous'` and a vector of indices.

For example, if there are three grouping variables and second one is continuous, then you can specify as follows.

Example: `'continuous',[2]`

Data Types: `single` | `double`

`display` — Indicator to display ANOVA table
`'on'` (default) | `'off'`

Indicator to display ANOVA table, specified as the comma-separated pair consisting of `'display'` and `'on'` or `'off'`. When `'display'` is `'off'`, `anovan` only returns the output arguments, and does not display the standard ANOVA table as a figure.

Example: `'display','off'`

`model` — Type of the model
`'linear'` (default) | `'interaction'` | `'full'` | integer value | terms matrix

Type of the model, specified as the comma-separated pair consisting of `'model'` and one of the following:

- `'linear'` — The default `'linear'` model computes only the *p*-values for the null hypotheses on the *N* main effects.
- `'interaction'` — The `'interaction'` model computes the *p*-values for null hypotheses on the *N* main effects and the $\binom{N}{2}$ two-factor interactions.
- `'full'` — The `'full'` model computes the *p*-values for null hypotheses on the *N* main effects and interactions at all levels.
- An integer — For an integer value of *k*, ($k \le N$) for model type, `anovan` computes all interaction levels through the *k*th level. For example, the value 3 means main effects plus two- and three-factor interactions. The values $k = 1$ and $k = 2$ are equivalent to the `'linear'` and `'interaction'` specifications, respectively. The value $k = N$ is equivalent to the `'full'` specification.
- Terms matrix — A matrix of term definitions having the same form as the input to the `x2fx` function. All entries must be `0` or `1` (no higher powers).

  For more precise control over the main and interaction terms that `anovan` computes, you can specify a matrix containing one row for each main or interaction term to include in the ANOVA model. Each row defines one term using a vector of *N* zeros and ones. The table below illustrates the coding for a 3-factor ANOVA for factors *A*, *B*, and *C*.

Matrix Row	ANOVA Term
`[1 0 0]`	Main term *A*
`[0 1 0]`	Main term *B*
`[0 0 1]`	Main term *C*
`[1 1 0]`	Interaction term *AB*
`[1 0 1]`	Interaction term *AC*
`[0 1 1]`	Interaction term *BC*
`[1 1 1]`	Interaction term *ABC*

For example, if there are three factors *A*, *B*, and *C*, and `'model',[0 1 0;0 0 1;0 1 1]`, then `anovan` tests for the main effects *B* and *C*, and the interaction effect *BC*, respectively.

A simple way to generate the terms matrix is to modify the `terms` output, which codes the terms in the current model using the format described above. If `anovan` returns `[0 1 0;0 0 1;0 1 1]` for `terms`, for example, and there is no significant interaction *BC*, then you can recompute ANOVA on just the main effects *B* and *C* by specifying `[0 1 0;0 0 1]` for `model`.

Example: `'model',[0 1 0;0 0 1;0 1 1]`

Example: `'model','interaction'`

Data Types: `char` | `string` | `single` | `double`

`nested` — Nesting relationships
matrix of 0’s and 1’s

Nesting relationships among the grouping variables, specified as the comma-separated pair consisting of `'nested'` and a matrix *M* of 0’s and 1’s, i.e.*M*(*i*,*j*) = 1 if variable *i* is nested in variable *j*.

You cannot specify nesting in a continuous variable.

For example, if there are two grouping variables District and School, where School is nested in District, then you can express this relationship as follows.

Example: `'nested',[0 0;1 0]`

Data Types: `single` | `double`

`random` — Indicator for random variables
vector of indices

Indicator for random variables, representing which grouping variables are random, specified as the comma-separated pair consisting of `'random'` and a vector of indices. By default, `anovan` treats all grouping variables as fixed.

`anovan` treats an interaction term as random if any of the variables in the interaction term is random.

Example: `'random',[3]`

Data Types: `single` | `double`

`sstype` — Type of sum of squares
3 (default) | 1 | 2 | `'h'`

Type of sum squares, specified as the comma-separated pair consisting of `'sstype'` and the following:

- 1 — Type I sum of squares. The reduction in residual sum of squares obtained by adding that term to a fit that already includes the terms listed before it.
- 2 — Type II sum of squares. The reduction in residual sum of squares obtained by adding that term to a model consisting of all other terms that do not contain the term in question.
- 3 — Type III sum of squares. The reduction in residual sum of squares obtained by adding that term to a model containing all other terms, but with their effects constrained to obey the usual "sigma restrictions" that make models estimable.
- `'h'` — Hierarchical model. Similar to type 2, but with continuous as well as categorical factors used to determine the hierarchy of terms.

The sum of squares for any term is determined by comparing two models. For a model containing main effects but no interactions, the value of `sstype` influences the computations on unbalanced data only.

Suppose you are fitting a model with two factors and their interaction, and the terms appear in the order *A*, *B*, *AB*. Let $R(\cdot)$ represent the residual sum of squares for the model. So, $R(A, B, AB)$ is the residual sum of squares fitting the whole model, $R(A)$ is the residual sum of squares fitting the main effect of *A* only, and $R(1)$ is the residual sum of squares fitting the mean only. The three sum of squares types are as follows:

Term	Type 1 Sum of Squares	Type 2 Sum of Squares	Type 3 Sum of Squares
A	$R(1) - R(A)$	$R(B) - R(A, B)$	$R(B, AB) - R(A, B, AB)$
B	$R(A) - R(A, B)$	$R(A) - R(A, B)$	$R(A, AB) - R(A, B, AB)$
AB	$R(A, B) - R(A, B, AB)$	$R(A, B) - R(A, B, AB)$	$R(A, B) - R(A, B, AB)$

The models for Type 3 sum of squares have sigma restrictions imposed. This means, for example, that in fitting $R(B, AB)$, the array of *AB* effects is constrained to sum to 0 over *A* for each value of *B*, and over *B* for each value of *A*.

Example: `'sstype','h'`

Data Types: `single` | `double` | `char` | `string`

`varnames` — Names of grouping variables
`X1,X2,...,XN` (default) | character matrix | string array | cell array of character vectors

Names of grouping variables, specified as the comma-separating pair consisting of `'varnames'` and a character matrix, a string array, or a cell array of character vectors.

Example: `'varnames',{'Gender','City'}`

Data Types: `char` | `string` | `cell`

Output Arguments

p — *p*-values
vector

p-values, returned as a vector.

Output vector `p` contains *p*-values for the null hypotheses on the *N* main effects and any interaction terms specified. Element `p(1)` contains the *p*-value for the null hypotheses that samples at all levels of factor *A* are drawn from the same population; element `p(2)` contains the *p*-value for the null hypotheses that samples at all levels of factor *B* are drawn from the same population; and so on.

For example, if there are three factors *A*, *B*, and *C*, and `'model',[0 1 0;0 0 1;0 1 1]`, then the output vector `p` contains the *p*-values for the null hypotheses on the main effects *B* and *C* and the interaction effect *BC*, respectively.

A sufficiently small *p*-value corresponding to a factor suggests that at least one group mean is significantly different from the other group means; that is, there is a main effect due to that factor. It is common to declare a result significant if the *p*-value is less than 0.05 or 0.01.

`tbl` — ANOVA table

cell array

ANOVA table, returned as a cell array. The ANOVA table has seven columns:

Column name	Definition
`source`	Source of the variability.
`SS`	Sum of squares due to each source.
`df`	Degrees of freedom associated with each source.
`MS`	Mean squares for each source, which is the ratio `SS/df`.
`Singular?`	Indication of whether the term is singular.
`F`	*F*-statistic, which is the ratio of the mean squares.
`Prob>F`	The *p*-values, which is the probability that the *F*-statistic can take a value larger than a computed test-statistic value. `anovan` derives these probabilities from the cdf of *F*-distribution.

The ANOVA table also contains the following columns if at least one of the grouping variables is specified as random using the name-value pair argument `random`:

Column name	Definition
`Type`	Type of each source; `'fixed'` for a fixed effect or `'random'` for a random effect.
`Expected MS`	Text representation of the expected value for the mean square. `Q(source)` represents a quadratic function of `source` and `V(source)` represents the variance of `source`.
`MS denom`	Denominator of the *F*-statistic.
`d.f. denom`	Degrees of freedom for the denominator of the *F*-statistic.
`Denom. defn.`	Text representation of the denominator of the *F*-statistic. `MS(source)` represents the mean square of `source`.

Column name	Definition
`Var. est.`	Variance component estimate.
`Var. lower bnd`	Lower bound of the 95% confidence interval for the variance component estimate.
`Var. upper bnd`	Upper bound of the 95% confidence interval for the variance component estimate.

`stats` — Statistics
structure

Statistics to use in a multiple comparison test on page 9-18 using the `multcompare` function, returned as a structure.

`anovan` evaluates the hypothesis that the different groups (levels) of a factor (or more generally, a term) have the same effect, against the alternative that they do not all have the same effect. Sometimes it is preferable to perform a test to determine which pairs of levels are significantly different, and which are not. Use the `multcompare` function to perform such tests by supplying the `stats` structure as input.

The `stats` structure contains the fields listed below, in addition to a number of other fields required for doing multiple comparisons using the `multcompare` function:

Field	Description
`coeffs`	Estimated coefficients
`coeffnames`	Name of term for each coefficient
`vars`	Matrix of grouping variable values for each term
`resid`	Residuals from the fitted model

The `stats` structure also contains the following fields if at least one of the grouping variables is specified as random using the name-value pair argument `random`:

Field	Description
`ems`	Expected mean squares
`denom`	Denominator definition
`rtnames`	Names of random terms
`varest`	Variance component estimates (one per random term)
`varci`	Confidence intervals for variance components

`terms` — Main and interaction terms
matrix

Main and interaction terms, returned as a matrix. The terms are encoded in the output matrix `terms` using the same format described above for input `model`. When you specify `model` itself in this format, the matrix returned in `terms` is identical.

Introduced before R2006a

anova

Class: RepeatedMeasuresModel

Analysis of variance for between-subject effects

Syntax

```
anovatbl = anova(rm)
anovatbl = anova(rm,'WithinModel',WM)
```

Description

`anovatbl = anova(rm)` returns the analysis of variance results for the repeated measures model `rm`.

`anovatbl = anova(rm,'WithinModel',WM)` returns the analysis of variance results it performs using the response or responses specified by the within-subject model `WM`.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`WM` — Within-subject model

`'separatemeans'` (default) | `'orthogonalcontrasts'` | character vector or string scalar defining a model specification | *r*-by-*nc* matrix specifying *nc* contrasts

Within-subject model, specified as one of the following:

- `'separatemeans'` — The response is the average of the repeated measures (average across the within-subject model).
- `'orthogonalcontrasts'` — This is valid when the within-subject model has a single numeric factor *T*. Responses are the average, the slope of centered *T*, and, in general, all orthogonal contrasts for a polynomial up to *T*^(*p* – 1), where *p* is the number of rows in the within-subject model. `anova` multiplies `Y`, the response you use in the repeated measures model `rm` by the orthogonal contrasts, and uses the columns of the resulting product matrix as the responses.

  `anova` computes the orthogonal contrasts for *T* using the *Q* factor of a QR factorization on page 33-96 of the Vandermonde matrix on page 33-96.
- A character vector or string scalar that defines a model specification in the within-subject factors. Responses are defined by the terms in that model. `anova` multiplies *Y*, the response matrix you use in the repeated measures model `rm` by the terms of the model, and uses the columns of the result as the responses.

For example, if there is a Time factor and `'Time'` is the model specification, then `anova` uses two terms, the constant and the uncentered Time term. The default is `'1'` to perform on the average response.

- An *r*-by-*nc* matrix, *C*, specifying *nc* contrasts among the *r* repeated measures. If *Y* represents the matrix of repeated measures you use in the repeated measures model `rm`, then the output `tbl` contains a separate analysis of variance for each column of *Y***C*.

The `anova` table contains a separate univariate analysis of variance results for each response.

Example: `'WithinModel','Time'`

Example: `'WithinModel','orthogonalcontrasts'`

Output Arguments

`anovatbl` — Results of analysis of variance

table

Results of analysis of variance for between-subject effects, returned as a table. This includes all terms on the between-subjects model and the following columns.

Column Name	Definition
`Within`	Within-subject factors
`Between`	Between-subject factors
`SumSq`	Sum of squares
`DF`	Degrees of freedom
`MeanSq`	Mean squared error
`F`	*F*-statistic
`pValue`	*p*-value corresponding to the *F*-statistic

Examples

Analysis of Variance for Average Response

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform analysis of variance.

```
anova(rm)
```

```
ans=3×7 table
     Within     Between     SumSq     DF     MeanSq       F          pValue
    ________    ________    ______    ___    _______    ______    ___________

    Constant    constant    7201.7      1     7201.7     19650    2.0735e-158
    Constant    species     309.61      2      154.8    422.39     1.1517e-61
    Constant    Error       53.875    147    0.36649
```

There are 150 observations and 3 species. The degrees of freedom for species is 3 - 1 = 2, and for error it is 150 - 3 = 147. The small *p*-value of 1.1517e-61 indicates that the measurements differ significantly according to species.

Panel Data

Load the sample panel data.

```
load('panelData.mat');
```

The dataset array, `panelData`, contains yearly observations on eight cities for 6 years. The first variable, `Growth`, measures economic growth (the response variable). The second and third variables are city and year indicators, respectively. The last variable, `Employ`, measures employment (the predictor variable). This is simulated data.

Store the data in a table array and define city as a nominal variable.

```
t = table(panelData.Growth,panelData.City,panelData.Year,...
    'VariableNames',{'Growth','City','Year'});
```

Convert the data in a proper format to do repeated measures analysis.

```
t = unstack(t,'Growth','Year','NewDataVariableNames',...
    {'year1','year2','year3','year4','year5','year6'});
```

Add the mean employment level over the years as a predictor variable to the table `t`.

```
t(:,8) = table(grpstats(panelData.Employ,panelData.City));
t.Properties.VariableNames{'Var8'} = 'meanEmploy';
```

Define the within-subjects variable.

```
Year = [1 2 3 4 5 6]';
```

Fit a repeated measures model, where the growth figures over the 6 years are the responses and the mean employment is the predictor variable.

```
rm = fitrm(t,'year1-year6 ~ meanEmploy','WithinDesign',Year);
```

Perform analysis of variance.

```
anovatbl = anova(rm,'WithinModel',Year)
```

```
anovatbl=3×7 table
     Within       Between        SumSq       DF      MeanSq         F         pValue
    _________    __________    __________    __    __________    ________    _________

    Contrast1    constant          588.17    1         588.17    0.038495      0.85093
    Contrast1    meanEmploy    3.7064e+05    1     3.7064e+05      24.258    0.0026428
    Contrast1    Error              91675    6          15279
```

Longitudinal Data

Load the sample data.

```
load('longitudinalData.mat');
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M']';
```

Store the data in a proper table array format to do repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Perform analysis of variance.

```
anovatbl = anova(rm)
```

```
anovatbl=3×7 table
     Within     Between     SumSq     DF    MeanSq      F         pValue
    ________    ________    ______    __    ______    ______    __________

    Constant    constant     54702     1     54702    1079.2    1.1897e-14
    Constant    Gender      2251.7     1    2251.7    44.425    1.0693e-05
    Constant    Error        709.6    14    50.685
```

There are 2 genders and 16 observations, so the degrees of freedom for gender is (2 - 1) = 1 and for error it is (16 - 2)*(2 - 1) = 14. The small *p*-value of 1.0693e-05 indicates that there is a significant effect of gender on blood pressure.

Repeat analysis of variance using orthogonal contrasts.

```
anovatbl = anova(rm,'WithinModel','orthogonalcontrasts')
```

```
anovatbl=15×7 table

```

More About

Vandermonde Matrix

Vandermonde matrix is the matrix where columns are the powers of the vector a, that is, $V(i,j) = a(i)^{(n-j)}$, where n is the length of a.

QR Factorization

QR factorization of an m-by-n matrix A is the factorization that matrix into the product $A = Q*R$, where R is an m-by-n upper triangular matrix and Q is an m-by-m unitary matrix.

“Model Specification for Repeated Measures Models” on page 9-54

ansaribradley

Ansari-Bradley test

Syntax

```
h = ansaribradley(x,y)
h = ansaribradley(x,y,Name,Value)
[h,p] = ansaribradley( ___ )
[h,p,stats] = ansaribradley( ___ )
```

Description

`h = ansaribradley(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from the same distribution, using the Ansari-Bradley test on page 33-100. The alternative hypothesis is that the data in `x` and `y` comes from distributions with the same median and shape but different dispersions (e.g., variances). The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`h = ansaribradley(x,y,Name,Value)` returns a test decision for the Ansari-Bradley test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level, conduct a one-sided test, or use a normal approximation to calculate the value of the test statistic.

`[h,p] = ansaribradley( ___ )` also returns the *p*-value, `p`, of the test, using any of the input arguments in the previous syntaxes.

`[h,p,stats] = ansaribradley( ___ )` also returns the structure `stats` containing information about the test statistic.

Examples

Ansari-Bradley Test for Equal Variances

Load the sample data. Create data vectors of miles per gallon (`MPG`) measurements for the model years 1982 and 1976.

```
load carsmall
x = MPG(Model_Year==82);
y = MPG(Model_Year==76);
```

Test the null hypothesis that the miles per gallon measured in cars from 1982 and 1976 have equal variances.

```
[h,p,stats] = ansaribradley(x,y)
```

```
h = 0
```

```
p = 0.8426
```

```
stats = struct with fields:
        W: 526.9000
```

```
    Wstar: 0.1986
```

The returned value of `h = 0` indicates that `ansaribradley` does not reject the null hypothesis at the default 5% significance level.

Ansari-Bradley One-Sided Hypothesis Test

Load the sample data. Create data vectors of miles per gallon (`MPG`) measurements for the model years 1982 and 1976.

```
load carsmall
x = MPG(Model_Year==82);
y = MPG(Model_Year==76);
```

Test the null hypothesis that the miles per gallon measured in cars from 1982 and 1976 have equal variances, against the alternative hypothesis that the variance of cars from 1982 is greater than that of cars from 1976.

```
[h,p,stats] = ansaribradley(x,y,'Tail','right')
```

```
h = 0

p = 0.5787

stats = struct with fields:
        W: 526.9000
    Wstar: 0.1986
```

The returned value of `h = 0` indicates that `ansaribradley` does not reject the null hypothesis that the variance in miles per gallon is the same for the two model years, when the alternative is that the variance of cars from 1982 is greater than that of cars from 1976.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ansaribradley` performs separate tests along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays on page 33-101, `ansaribradley` works along the first nonsingleton dimension on page 33-101. `x` and `y` must have the same size along all remaining dimensions.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ansaribradley` performs separate tests along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays on page 33-101, `ansaribradley` works along the first nonsingleton dimension on page 33-101. `x` and `y` must have the same size along all remaining dimensions.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','right','Alpha',0.01` specifies a right-tailed hypothesis test at the 1% significance level.

`Alpha` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`Dim` — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim',1` tests the column means, while `'Dim',2` tests the row means.

Example: `'Dim',2`

Data Types: `single` | `double`

`Tail` — Type of alternative hypothesis

`'both'` (default) | `'left'` | `'right'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'both'`	Test the alternative hypothesis that the dispersion parameters of `x` and `y` are not equal.
`'right'`	Test the alternative hypothesis that the dispersion parameter of `x` is greater than that of `y`.
`'left'`	Test the alternative hypothesis that the dispersion parameter of `x` is less than that of `y`.

Example: `'Tail','right'`

Method — Computation method
'exact' | 'approximate'

Computation method for the test statistic, specified as the comma-separated pair consisting of 'Method' and one of the following.

'exact'	Compute p using an exact calculation of the distribution of the test statistic W. This is the default if *n*, the total number of rows in x and y, is 25 or less. Note that *n* is computed before any NaN values (representing missing data) are removed.
'approximate'	Compute p using a normal approximation for the statistic W*. This is the default if *n*, the total number of rows in x and y, is greater than 25.

Example: 'Method','exact'

Output Arguments

h — Hypothesis test result
1 | 0

Hypothesis test result, returned as 1 or 0.

- If h = 1, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If h = 0, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

stats — Test statistics
structure

Test statistics for the Ansari-Bradley test, returned as a structure containing:

- W — Value of the test statistic, which is the sum of the Ansari-Bradley ranks for the x sample.
- Wstar — Approximate normal statistic W*.

More About

Ansari-Bradley Test

The Ansari-Bradley test is a nonparametric alternative to the two-sample *F*-test of equal variances. It does not require the assumption that x and y come from normal distributions. The dispersion of a distribution is generally measured by its variance or standard deviation, but the Ansari-Bradley test can be used with samples from distributions that do not have finite variances.

This test requires that the samples have equal medians. Under that assumption, and if the distributions of the samples are continuous and identical, the test is independent of the distributions. If the samples do not have the same medians, the results can be misleading. In that case, Ansari and

Bradley recommend subtracting the median, but then the distribution of the resulting test under the null hypothesis is no longer independent of the common distribution of `x` and `y`. If you want to perform the tests with medians subtracted, you should subtract the medians from `x` and `y` before calling `ansaribradley`.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if `x` is a 1-by-3-by-4 array, then `x` is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if `x` is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of `x`.

Introduced before R2006a

aoctool

Interactive analysis of covariance

Syntax

```
aoctool(x,y,group)
aoctool(x,y,group,alpha)
aoctool(x,y,group,alpha,xname,yname,gname)
aoctool(x,y,group,alpha,xname,yname,gname,displayopt)
aoctool(x,y,group,alpha,xname,yname,gname,displayopt,model)
h = aoctool(...)
[h,atab,ctab] = aoctool(...)
[h,atab,ctab,stats] = aoctool(...)
```

Description

`aoctool(x,y,group)` fits a separate line to the column vectors, `x` and `y`, for each group defined by the values in the array `group`. `group` may be a categorical variable, numeric vector, character array, string array, or cell array of character vectors. These types of models are known as one-way analysis of covariance (ANOCOVA) models. The output consists of three figures:

- An interactive graph of the data and prediction curves
- An ANOVA table
- A table of parameter estimates

You can use the figures to change models and to test different parts of the model. More information about interactive use of the `aoctool` function appears in “Analysis of Covariance Tool” on page 9-39.

`aoctool(x,y,group,alpha)` determines the confidence levels of the prediction intervals. The confidence level is `100(1-alpha)`%. The default value of `alpha` is 0.05.

`aoctool(x,y,group,alpha,xname,yname,gname)` specifies the name to use for the `x`, `y`, and `g` variables in the graph and tables. If you enter simple variable names for the `x`, `y`, and `g` arguments, the `aoctool` function uses those names. If you enter an expression for one of these arguments, you can specify a name to use in place of that expression by supplying these arguments. For example, if you enter `m(:,2)` as the `x` argument, you might choose to enter `'Col 2'` as the `xname` argument.

`aoctool(x,y,group,alpha,xname,yname,gname,displayopt)` enables the graph and table displays when *`displayopt`* is `'on'` (default) and suppresses those displays when *`displayopt`* is `'off'`.

`aoctool(x,y,group,alpha,xname,yname,gname,displayopt,model)` specifies the initial model to fit. The value of *`model`* can be any of the following:

- `'same mean'` — Fit a single mean, ignoring grouping
- `'separate means'` — Fit a separate mean to each group
- `'same line'` — Fit a single line, ignoring grouping
- `'parallel lines'` — Fit a separate line to each group, but constrain the lines to be parallel

- `'separate lines'` — Fit a separate line to each group, with no constraints

`h = aoctool(...)` returns a vector of handles to the line objects in the plot.

`[h,atab,ctab] = aoctool(...)` returns cell arrays containing the entries in ANOVA table (`atab`) and the table of coefficient estimates (`ctab`). (You can copy a text version of either table to the clipboard by using the `Copy Text` item on the **Edit** menu.)

`[h,atab,ctab,stats] = aoctool(...)` returns a `stats` structure that you can use to perform a follow-up multiple comparison test. The ANOVA table output includes tests of the hypotheses that the slopes or intercepts are all the same, against a general alternative that they are not all the same. Sometimes it is preferable to perform a test to determine which pairs of values are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying the `stats` structure as input. You can test either the slopes, the intercepts, or population marginal means (the heights of the curves at the mean `x` value).

Examples

This example illustrates how to fit different models non-interactively. After loading the smaller car data set and fitting a separate-slopes model, you can examine the coefficient estimates.

```
load carsmall
[h,a,c,s] = aoctool(Weight,MPG,Model_Year,0.05,...
                    '','','','off','separate lines');
c(:,1:2)
ans =
  'Term'       'Estimate'
  'Intercept'  [45.97983716833132]
  ' 70'        [-8.58050531454973]
  ' 76'        [-3.89017396094922]
  ' 82'        [12.47067927549897]
  'Slope'      [-0.00780212907455]
  ' 70'        [ 0.00195840368824]
  ' 76'        [ 0.00113831038418]
  ' 82'        [-0.00309671407243]
```

Roughly speaking, the lines relating `MPG` to `Weight` have an intercept close to 45.98 and a slope close to -0.0078. Each group's coefficients are offset from these values somewhat. For instance, the intercept for the cars made in 1970 is 45.98-8.58 = 37.40.

Next, try a fit using parallel lines. (The ANOVA table shows that the parallel-lines fit is significantly worse than the separate-lines fit.)

```
[h,a,c,s] = aoctool(Weight,MPG,Model_Year,0.05,...
                    '','','','off','parallel lines');

c(:,1:2)

ans =

  'Term'       'Estimate'
  'Intercept'  [43.38984085130596]
  ' 70'        [-3.27948192983761]
  ' 76'        [-1.35036234809006]
  ' 82'        [ 4.62984427792768]
  'Slope'      [-0.00664751826198]
```

Again, there are different intercepts for each group, but this time the slopes are constrained to be the same.

Introduced before R2006a

append

Class: `TreeBagger`

Append new trees to ensemble

Syntax

```
B = append(B,other)
```

Description

`B = append(B,other)` appends the trees from the `other` ensemble to those in `B`. This method checks for consistency of the `X` and `Y` properties of the two ensembles, as well as consistency of their compact objects and out-of-bag indices, before appending the trees. The output ensemble `B` takes training parameters such as `FBoot`, `Prior`, `Cost`, and `other` from the `B` input. There is no attempt to check if these training parameters are consistent between the two objects.

See Also

`combine`

barttest

Bartlett's test

Syntax

```
ndim = barttest(x,alpha)
[ndim,prob,chisquare] = barttest(x,alpha)
```

Description

`ndim = barttest(x,alpha)` returns the number of dimensions necessary to explain the nonrandom variation in the data matrix `x` at the `alpha` significance level.

`[ndim,prob,chisquare] = barttest(x,alpha)` also returns the significance values for the hypothesis tests `prob`, and the χ^2 values associated with the tests `chisquare`.

Examples

Determine Dimensions Needed to Explain Nonrandom Data Variation

Generate a 20-by-6 matrix of random numbers from a multivariate normal distribution with mean `mu = [0 0]` and covariance `sigma = [1 0.99; 0.99 1]`.

```
rng default  % for reproducibility
mu = [0 0];
sigma = [1 0.99; 0.99 1];
X = mvnrnd(mu,sigma,20);  % columns 1 and 2
X(:,3:4) = mvnrnd(mu,sigma,20);  % columns 3 and 4
X(:,5:6) = mvnrnd(mu,sigma,20);  % columns 5 and 6
```

Determine the number of dimensions necessary to explain the nonrandom variation in data matrix X. Report the significance values for the hypothesis tests.

```
[ndim, prob] = barttest(X,0.05)
```

```
ndim = 3

prob = 5×1

    0.0000
    0.0000
    0.0000
    0.5148
    0.3370
```

The returned value of `ndim` indicates that three dimensions are necessary to explain the nonrandom variation in X.

Input Arguments

`x` — Input data

matrix of scalar values

Input data, specified as a matrix of scalar values.

Data Types: `single` | `double`

`alpha` — Significance level

`0.05` (default) | scalar value in the range `(0,1)`

Significance level of the hypothesis test, specified as a scalar value in the range `(0,1)`.

Example: `0.1`

Data Types: `single` | `double`

Output Arguments

`ndim` — Number of dimensions

positive integer value

Number of dimensions, returned as a positive integer value. The dimension is determined by a series of hypothesis tests. The test for `ndim = 1` tests the hypothesis that the variances of the data values along each principal component are equal, the test for `ndim = 2` tests the hypothesis that the variances along the second through last components are equal, and so on. The null hypothesis is that the number of dimensions is equal to the number of the largest unequal eigenvalues of the covariance matrix of `x`.

`prob` — Significance value

vector of scalar values in the range `(0,1)`

Significance value for the hypothesis tests, returned as a vector of scalar values in the range `(0,1)`. Each element in `prob` corresponds to an element of `chisquare`.

`chisquare` — Test statistics

vector of scalar values

Test statistics for each dimension's hypothesis test, returned as a vector of scalar values.

Introduced before R2006a

BayesianOptimization

Bayesian optimization results

Description

A `BayesianOptimization` object contains the results of a Bayesian optimization. It is the output of `bayesopt` or a fit function that accepts the `OptimizeHyperparameters` name-value pair such as `fitcdiscr`. In addition, a `BayesianOptimization` object contains data for each iteration of `bayesopt` that can be accessed by a plot function or an output function.

Creation

Create a `BayesianOptimization` object using the `bayesopt` function or a fit function with the `OptimizeHyperparameters` name-value pair.

Properties

Problem Definition Properties

`ObjectiveFcn` — `ObjectiveFcn` argument used by `bayesopt`
function handle

This property is read-only.

`ObjectiveFcn` argument used by `bayesopt`, returned as a function handle.

- If you call `bayesopt` directly, `ObjectiveFcn` is the `bayesopt` objective function argument.
- If you call a fit function containing the `'OptimizeHyperparameters'` name-value pair argument, `ObjectiveFcn` is a function handle that returns the misclassification rate for classification or returns the logarithm of one plus the cross-validation loss for regression, measured by five-fold cross-validation.

Data Types: `function_handle`

`VariableDescriptions` — `VariableDescriptions` argument that `bayesopt` used
vector of `optimizableVariable` objects

This property is read-only.

`VariableDescriptions` argument that `bayesopt` used, returned as a vector of `optimizableVariable` objects.

- If you called `bayesopt` directly, `VariableDescriptions` is the `bayesopt` variable description argument.
- If you called a fit function with the `OptimizeHyperparameters` name-value pair, `VariableDescriptions` is the vector of hyperparameters.

`Options` — Options that `bayesopt` used

structure

This property is read-only.

Options that `bayesopt` used, returned as a structure.

- If you called `bayesopt` directly, `Options` is the options used in `bayesopt`, which are the name-value pairs See `bayesopt` “Input Arguments” on page 33-132.
- If you called a fit function with the `OptimizeHyperparameters` name-value pair, `Options` are the default `bayesopt` options, modified by the `HyperparameterOptimizationOptions` name-value pair.

`Options` is a read-only structure containing the following fields.

Option Name	Meaning
`AcquisitionFunctionName`	Acquisition function name. See “Acquisition Function Types” on page 10-3.
`IsObjectiveDeterministic`	`true` means the objective function is deterministic, `false` otherwise.
`ExplorationRatio`	Used only when `AcquisitionFunctionName` is `'expected-improvement-plus'` or `'expected-improvement-per-second-plus'`. See “Plus” on page 10-5.
`MaxObjectiveEvaluations`	Objective function evaluation limit.
`MaxTime`	Time limit.
`XConstraintFcn`	Deterministic constraints on variables. See “Deterministic Constraints — XConstraintFcn” on page 10-38.
`ConditionalVariableFcn`	Conditional variable constraints. See “Conditional Constraints — ConditionalVariableFcn” on page 10-39.
`NumCoupledConstraints`	Number of coupled constraints. See “Coupled Constraints” on page 10-40.
`CoupledConstraintTolerances`	Coupled constraint tolerances. See “Coupled Constraints” on page 10-40.
`AreCoupledConstraintsDeterministic`	Logical vector specifying whether each coupled constraint is deterministic.
`Verbose`	Command-line display level.
`OutputFcn`	Function called after each iteration. See “Bayesian Optimization Output Functions” on page 10-19.
`SaveVariableName`	Variable name for the `@assignInBase` output function.
`SaveFileName`	File name for the `@saveToFile` output function.

Option Name	Meaning
`PlotFcn`	Plot function called after each iteration. See “Bayesian Optimization Plot Functions” on page 10-11
`InitialX`	Points where `bayesopt` evaluated the objective function.
`InitialObjective`	Objective function values at `InitialX`.
`InitialConstraintViolations`	Coupled constraint function values at `InitialX`.
`InitialErrorValues`	Error values at `InitialX`.
`InitialObjectiveEvaluationTimes`	Objective function evaluation times at `InitialX`.
`InitialIterationTimes`	Time for each iteration, including objective function evaluation and other computations.

Data Types: `struct`

Solution Properties

`MinObjective` — Minimum observed value of objective function
real scalar

This property is read-only.

Minimum observed value of objective function, returned as a real scalar. When there are coupled constraints or evaluation errors, this value is the minimum over all observed points that are feasible according to the final constraint and Error models.

Data Types: `double`

`XAtMinObjective` — Observed point with minimum objective function value
1-by-`D` table

This property is read-only.

Observed point with minimum objective function value, returned as a `1`-by-`D` table, where `D` is the number of variables.

Data Types: `table`

`MinEstimatedObjective` — Minimum estimated value of objective function
real scalar

This property is read-only.

Minimum estimated value of objective function, returned as a real scalar. `MinEstimatedObjective` uses the final objective model.

`MinEstimatedObjective` is the same as the `CriterionValue` result of `bestPoint` with default criterion.

Data Types: `double`

`XAtMinEstimatedObjective` — Point with minimum estimated objective function value
1-by-`D` table

This property is read-only.

Point with minimum estimated objective function value, returned as a 1-by-D table, where D is the number of variables. `XAtMinEstimatedObjective` uses the final objective model.

Data Types: `table`

`NumObjectiveEvaluations` — Number of objective function evaluations
positive integer

This property is read-only.

Number of objective function evaluations, returned as a positive integer. This includes the initial evaluations to form a posterior model as well as evaluation during the optimization iterations.

Data Types: `double`

`TotalElapsedTime` — Total elapsed time of optimization in seconds
positive scalar

This property is read-only.

Total elapsed time of optimization in seconds, returned as a positive scalar.

Data Types: `double`

`NextPoint` — Next point to evaluate if optimization continues
1-by-D table

This property is read-only.

Next point to evaluate if optimization continues, returned as a 1-by-D table, where D is the number of variables.

Data Types: `table`

Trace Properties

`XTrace` — Points where the objective function was evaluated
T-by-D table

This property is read-only.

Points where the objective function was evaluated, returned as a T-by-D table, where T is the number of evaluation points and D is the number of variables.

Data Types: `table`

`ObjectiveTrace` — Objective function values
column vector of length T

This property is read-only.

Objective function values, returned as a column vector of length T, where T is the number of evaluation points. `ObjectiveTrace` contains the history of objective function evaluations.

Data Types: `double`

`ObjectiveEvaluationTimeTrace` — Objective function evaluation times
column vector of length `T`

This property is read-only.

Objective function evaluation times, returned as a column vector of length `T`, where `T` is the number of evaluation points. `ObjectiveEvaluationTimeTrace` includes the time in evaluating coupled constraints, because the objective function computes these constraints.

Data Types: `double`

`IterationTimeTrace` — Iteration times
column vector of length `T`

This property is read-only.

Iteration times, returned as a column vector of length `T`, where `T` is the number of evaluation points. `IterationTimeTrace` includes both objective function evaluation time and other overhead.

Data Types: `double`

`ConstraintsTrace` — Coupled constraint values
T-by-K array

This property is read-only.

Coupled constraint values, returned as a `T`-by-`K` array, where `T` is the number of evaluation points and `K` is the number of coupled constraints.

Data Types: `double`

`ErrorTrace` — Error indications
column vector of length `T` of `-1` or `1` entries

This property is read-only.

Error indications, returned as a column vector of length `T` of `-1` or `1` entries, where `T` is the number of evaluation points. Each `1` entry indicates that the objective function errored or returned `NaN` on the corresponding point in `XTrace`. Each `-1` entry indicates that the objective function value was computed.

Data Types: `double`

`FeasibilityTrace` — Feasibility indications
logical column vector of length `T`

This property is read-only.

Feasibility indications, returned as a logical column vector of length `T`, where `T` is the number of evaluation points. Each `1` entry indicates that the final constraint model predicts feasibility at the corresponding point in `XTrace`.

Data Types: `logical`

`FeasibilityProbabilityTrace` — Probability that evaluation point is feasible
column vector of length `T`

This property is read-only.

Probability that evaluation point is feasible, returned as a column vector of length `T`, where `T` is the number of evaluation points. The probabilities come from the final constraint model, including the error constraint model, on the corresponding points in `XTrace`.

Data Types: `double`

`IndexOfMinimumTrace` — Which evaluation gave minimum feasible objective
column vector of integer indices of length `T`

This property is read-only.

Which evaluation gave minimum feasible objective, returned as a column vector of integer indices of length `T`, where `T` is the number of evaluation points. Feasibility is determined with respect to the constraint models that existed at each iteration, including the error constraint model.

Data Types: `double`

`ObjectiveMinimumTrace` — Minimum observed objective
column vector of length `T`

This property is read-only.

Minimum observed objective, returned as a column vector of integer indices of length `T`, where `T` is the number of evaluation points.

Data Types: `double`

`EstimatedObjectiveMinimumTrace` — Minimum estimated objective
column vector of length `T`

This property is read-only.

Minimum estimated objective, returned as a column vector of integer indices of length `T`, where `T` is the number of evaluation points. The estimated objective at each iteration is determined with respect to the objective model that existed at that iteration.

Data Types: `double`

`UserDataTrace` — Auxiliary data from the objective function
cell array of length `T`

This property is read-only.

Auxiliary data from the objective function, returned as a cell array of length `T`, where `T` is the number of evaluation points. Each entry in the cell array is the `UserData` returned in the third output of the objective function.

Data Types: `cell`

Object Functions

bestPoint	Best point in a Bayesian optimization according to a criterion
plot	Plot Bayesian optimization results
predictConstraints	Predict coupled constraint violations at a set of points
predictError	Predict error value at a set of points
predictObjective	Predict objective function at a set of points
predictObjectiveEvaluationTime	Predict objective function run times at a set of points

resume	Resume a Bayesian optimization

Examples

Create a BayesianOptimization Object Using bayesopt

This example shows how to create a `BayesianOptimization` object by using `bayesopt` to minimize cross-validation loss.

Optimize hyperparameters of a KNN classifier for the `ionosphere` data, that is, find KNN hyperparameters that minimize the cross-validation loss. Have `bayesopt` minimize over the following hyperparameters:

- Nearest-neighborhood sizes from 1 to 30
- Distance functions `'chebychev'`, `'euclidean'`, and `'minkowski'`.

For reproducibility, set the random seed, set the partition, and set the `AcquisitionFunctionName` option to `'expected-improvement-plus'`. To suppress iterative display, set `'Verbose'` to `0`. Pass the partition `c` and fitting data `X` and `Y` to the objective function `fun` by creating `fun` as an anonymous function that incorporates this data. See “Parameterizing Functions”.

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus')
```

Create a BayesianOptimization Object Using a Fit Function

This example shows how to minimize the cross-validation loss in the `ionosphere` data using Bayesian optimization of an SVM classifier.

Load the data.

```
load ionosphere
```

Optimize the classification using the `'auto'` parameters.

```
rng default % For reproducibility
Mdl = fitcsvm(X,Y,'OptimizeHyperparameters','auto')
```

```

Topics

“Bayesian Optimization Workflow” on page 10-25

Introduced in R2016b

bayesopt

Select optimal machine learning hyperparameters using Bayesian optimization

Syntax

```
results = bayesopt(fun,vars)
results = bayesopt(fun,vars,Name,Value)
```

Description

`results = bayesopt(fun,vars)` attempts to find values of `vars` that minimize `fun(vars)`.

Note To include extra parameters in an objective function, see “Parameterizing Functions”.

`results = bayesopt(fun,vars,Name,Value)` modifies the optimization process according to the `Name,Value` arguments.

Examples

Create a BayesianOptimization Object Using bayesopt

This example shows how to create a `BayesianOptimization` object by using `bayesopt` to minimize cross-validation loss.

Optimize hyperparameters of a KNN classifier for the `ionosphere` data, that is, find KNN hyperparameters that minimize the cross-validation loss. Have `bayesopt` minimize over the following hyperparameters:

- Nearest-neighborhood sizes from 1 to 30
- Distance functions `'chebychev'`, `'euclidean'`, and `'minkowski'`.

For reproducibility, set the random seed, set the partition, and set the `AcquisitionFunctionName` option to `'expected-improvement-plus'`. To suppress iterative display, set `'Verbose'` to `0`. Pass the partition `c` and fitting data `X` and `Y` to the objective function `fun` by creating `fun` as an anonymous function that incorporates this data. See “Parameterizing Functions”.

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus')
```

Bayesian Optimization with Coupled Constraints

A coupled constraint is one that can be evaluated only by evaluating the objective function. In this case, the objective function is the cross-validated loss of an SVM model. The coupled constraint is that the number of support vectors is no more than 100. The model details are in “Optimize a Cross-Validated SVM Classifier Using bayesopt” on page 10-45.

Create the data for classification.

```
rng default
grnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
redpts = zeros(100,2);
grnpts = redpts;
for i = 1:100
    grnpts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);
end
cdata = [grnpts;redpts];
grp = ones(200,1);
grp(101:200) = -1;
c = cvpartition(200,'KFold',10);
sigma = optimizableVariable('sigma',[1e-5,1e5],'Transform','log');
box = optimizableVariable('box',[1e-5,1e5],'Transform','log');
```

The objective function is the cross-validation loss of the SVM model for partition `c`. The coupled constraint is the number of support vectors minus 100.5. This ensures that 100 support vectors give a negative constraint value, but 101 support vectors give a positive value. The model has 200 data points, so the coupled constraint values range from -99.5 (there is always at least one support vector) to 99.5. Positive values mean the constraint is not satisfied.

```
function [objective,constraint] = mysvmfun(x,cdata,grp,c)
SVMModel = fitcsvm(cdata,grp,'KernelFunction','rbf',...
    'BoxConstraint',x.box,...
    'KernelScale',x.sigma);
cvModel = crossval(SVMModel,'CVPartition',c);
objective = kfoldLoss(cvModel);
constraint = sum(SVMModel.IsSupportVector)-100.5;
```

Pass the partition `c` and fitting data `cdata` and `grp` to the objective function `fun` by creating `fun` as an anonymous function that incorporates this data. See “Parameterizing Functions”.

```
fun = @(x)mysvmfun(x,cdata,grp,c);
```

Set the `NumCoupledConstraints` to `1` so the optimizer knows that there is a coupled constraint. Set options to plot the constraint model.

```
results = bayesopt(fun,[sigma,box],'IsObjectiveDeterministic',true,...
    'NumCoupledConstraints',1,'PlotFcn',...
    {@plotMinObjective,@plotConstraintModels},...
    'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);
```

Parallel Bayesian Optimization

Improve the speed of a Bayesian optimization by using parallel objective function evaluation.

Prepare variables and the objective function for Bayesian optimization.

The objective function is the cross-validation error rate for the ionosphere data, a binary classification problem. Use `fitcsvm` as the classifier, with `BoxConstraint` and `KernelScale` as the parameters to optimize.

```
load ionosphere
box = optimizableVariable('box',[1e-4,1e3],'Transform','log');
kern = optimizableVariable('kern',[1e-4,1e3],'Transform','log');
vars = [box,kern];
fun = @(vars)kfoldLoss(fitcsvm(X,Y,'BoxConstraint',vars.box,'KernelScale',vars.kern,...
    'Kfold',5));
```

Search for the parameters that give the lowest cross-validation error by using parallel Bayesian optimization.

```
results = bayesopt(fun,vars,'UseParallel',true);
```

```
Copying objective function to workers...
Done copying objective function to workers.
```

```
_____________________________________________________________
Optimization completed.
MaxObjectiveEvaluations of 30 reached.
Total function evaluations: 30
Total elapsed time: 48.2085 seconds.
Total objective function evaluation time: 128.3472

Best observed feasible point:
       box         kern
    _________    _________

    0.0015925    0.0050225

Observed objective function value = 0.10826
Estimated objective function value = 0.10846
Function evaluation time = 4.0711

Best estimated feasible point (according to models):
       box         kern
    _________    _________

    0.0015925    0.0050225

Estimated objective function value = 0.10846
Estimated function evaluation time = 2.8307
```

Return the best feasible point in the Bayesian model `results` by using the `bestPoint` function. Use the default criterion `min-visited-upper-confidence-interval`, which determines the best feasible point as the visited point that minimizes an upper confidence interval on the objective function value.

```
zbest = bestPoint(results)
```

```
zbest=1×2 table
       box          kern
    _________    _________

    0.0015925    0.0050225
```

The table `zbest` contains the optimal estimated values for the `'BoxConstraint'` and `'KernelScale'` name-value pair arguments. Use these values to train a new optimized classifier.

```
Mdl = fitcsvm(X,Y,'BoxConstraint',zbest.box,'KernelScale',zbest.kern);
```

Observe that the optimal parameters are in `Mdl`.

```
Mdl.BoxConstraints(1)
```

```
ans = 0.0016
```

```
Mdl.KernelParameters.Scale
```

```
ans = 0.0050
```

Input Arguments

`fun` — Objective function

function handle | `parallel.pool.Constant` whose `Value` is a function handle

Objective function, specified as a function handle or, when the `UseParallel` name-value pair is `true`, a `parallel.pool.Constant` whose `Value` is a function handle. Typically, `fun` returns a measure of loss (such as a misclassification error) for a machine learning model that has tunable hyperparameters to control its training. `fun` has these signatures:

```
objective = fun(x)
% or
[objective,constraints] = fun(x)
% or
[objective,constraints,UserData] = fun(x)
```

`fun` accepts `x`, a 1-by-`D` table of variable values, and returns `objective`, a real scalar representing the objective function value `fun(x)`.

Optionally, `fun` also returns:

- `constraints`, a real vector of coupled constraint violations. For a definition, see “Coupled Constraints” on page 33-140. `constraint(j) > 0` means constraint `j` is violated. `constraint(j) < 0` means constraint `j` is satisfied.
- `UserData`, an entity of any type (such as a scalar, matrix, structure, or object). For an example of a custom plot function that uses `UserData`, see “Create a Custom Plot Function” on page 10-12.

For details about using `parallel.pool.Constant` with `bayesopt`, see “Placing the Objective Function on Workers” on page 10-8.

Example: `@objfun`

Data Types: `function_handle`

`vars` — Variable descriptions

vector of `optimizableVariable` objects defining the hyperparameters to be tuned

Variable descriptions, specified as a vector of `optimizableVariable` objects defining the hyperparameters to be tuned.

Example: `[X1,X2]`, where `X1` and `X2` are `optimizableVariable` objects

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `results = bayesopt(fun,vars,'AcquisitionFunctionName','expected-improvement-plus')`

Algorithm Control

`AcquisitionFunctionName` — Function to choose next evaluation point

`'expected-improvement-per-second-plus'` (default) | `'expected-improvement'` | `'expected-improvement-plus'` | `'expected-improvement-per-second'` | `'lower-confidence-bound'` | `'probability-of-improvement'`

Function to choose next evaluation point, specified as one of the listed choices.

Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.

Example: `'AcquisitionFunctionName','expected-improvement-per-second'`

`IsObjectiveDeterministic` — Specify deterministic objective function

`false` (default) | `true`

Specify deterministic objective function, specified as `false` or `true`. If `fun` is stochastic (that is, `fun(x)` can return different values for the same `x`), then set `IsObjectiveDeterministic` to `false`. In this case, `bayesopt` estimates a noise level during optimization.

Example: `'IsObjectiveDeterministic',true`

Data Types: `logical`

`ExplorationRatio` — Propensity to explore

`0.5` (default) | positive real

Propensity to explore, specified as a positive real. Applies to the `'expected-improvement-plus'` and `'expected-improvement-per-second-plus'` acquisition functions. See “Plus” on page 10-5.

Example: `'ExplorationRatio',0.2`

Data Types: `double`

`GPActiveSetSize` — Fit Gaussian Process model to `GPActiveSetSize` or fewer points
`300` (default) | positive integer

Fit Gaussian Process model to `GPActiveSetSize` or fewer points, specified as a positive integer. When `bayesopt` has visited more than `GPActiveSetSize` points, subsequent iterations that use a GP model fit the model to `GPActiveSetSize` points. `bayesopt` chooses points uniformly at random without replacement among visited points. Using fewer points leads to faster GP model fitting, at the expense of possibly less accurate fitting.

Example: `'GPActiveSetSize',80`

Data Types: `double`

`UseParallel` — Compute in parallel
`false` (default) | `true`

Compute in parallel, specified as `false` (do not compute in parallel) or `true` (compute in parallel). Computing in parallel requires Parallel Computing Toolbox.

`bayesopt` performs parallel objective function evaluations concurrently on parallel workers. For algorithmic details, see “Parallel Bayesian Optimization” on page 10-7.

Example: `'UseParallel',true`

Data Types: `logical`

`ParallelMethod` — Imputation method for parallel worker objective function values
`'clipped-model-prediction'` (default) | `'model-prediction'` | `'max-observed'` | `'min-observed'`

Imputation method for parallel worker objective function values, specified as `'clipped-model-prediction'`, `'model-prediction'`, `'max-observed'`, or `'min-observed'`. To generate a new point to evaluate, `bayesopt` fits a Gaussian process to all points, including the points being evaluated on workers. To fit the process, `bayesopt` imputes objective function values for the points that are currently on workers. `ParallelMethod` specifies the method used for imputation.

- `'clipped-model-prediction'` — Impute the maximum of these quantities:
  - Mean Gaussian process prediction at the point `x`
  - Minimum observed objective function among feasible points visited
  - Minimum model prediction among all feasible points
- `'model-prediction'` — Impute the mean Gaussian process prediction at the point `x`.
- `'max-observed'` — Impute the maximum observed objective function value among feasible points.
- `'min-observed'` — Impute the minimum observed objective function value among feasible points.

Example: `'ParallelMethod','max-observed'`

`MinWorkerUtilization` — Tolerance on number of active parallel workers
`floor(0.8*Nworkers)` (default) | positive integer

Tolerance on the number of active parallel workers, specified as a positive integer. After `bayesopt` assigns a point to evaluate, and before it computes a new point to assign, it checks whether fewer

than `MinWorkerUtilization` workers are active. If so, `bayesopt` assigns random points within bounds to all available workers. Otherwise, `bayesopt` calculates the best point for one worker. `bayesopt` creates random points much faster than fitted points, so this behavior leads to higher utilization of workers, at the cost of possibly poorer points. For details, see “Parallel Bayesian Optimization” on page 10-7.

Example: `'MinWorkerUtilization',3`

Data Types: `double`

Starting and Stopping

`MaxObjectiveEvaluations` — Objective function evaluation limit

`30` (default) | positive integer

Objective function evaluation limit, specified as a positive integer.

Example: `'MaxObjectiveEvaluations',60`

Data Types: `double`

`MaxTime` — Time limit

`Inf` (default) | positive real

Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`.

Run time can exceed `MaxTime` because `bayesopt` does not interrupt function evaluations.

Example: `'MaxTime',3600`

Data Types: `double`

`NumSeedPoints` — Number of initial evaluation points

`4` (default) | positive integer

Number of initial evaluation points, specified as a positive integer. `bayesopt` chooses these points randomly within the variable bounds, according to the setting of the `Transform` setting for each variable (uniform for `'none'`, logarithmically spaced for `'log'`).

Example: `'NumSeedPoints',10`

Data Types: `double`

Constraints

`XConstraintFcn` — Deterministic constraints on variables

`[]` (default) | function handle

Deterministic constraints on variables, specified as a function handle.

For details, see “Deterministic Constraints — XConstraintFcn” on page 10-38.

Example: `'XConstraintFcn',@xconstraint`

Data Types: `function_handle`

`ConditionalVariableFcn` — Conditional variable constraints

`[]` (default) | function handle

Conditional variable constraints, specified as a function handle.

For details, see “Conditional Constraints — ConditionalVariableFcn” on page 10-39.

Example: `'ConditionalVariableFcn',@condfun`

Data Types: `function_handle`

`NumCoupledConstraints` — Number of coupled constraints
`0` (default) | positive integer

Number of coupled constraints, specified as a positive integer. For details, see “Coupled Constraints” on page 10-40.

Note `NumCoupledConstraints` is required when you have coupled constraints.

Example: `'NumCoupledConstraints',3`

Data Types: `double`

`AreCoupledConstraintsDeterministic` — Indication of whether coupled constraints are deterministic
`true` for all coupled constraints (default) | logical vector

Indication of whether coupled constraints are deterministic, specified as a logical vector of length `NumCoupledConstraints`. For details, see “Coupled Constraints” on page 10-40.

Example: `'AreCoupledConstraintsDeterministic',[true,false,true]`

Data Types: `logical`

Reports, Plots, and Halting

`Verbose` — Command-line display level
`1` (default) | `0` | `2`

Command-line display level, specified as `0`, `1`, or `2`.

- `0` — No command-line display.
- `1` — At each iteration, display the iteration number, result report (see the next paragraph), objective function model, objective function evaluation time, best (lowest) observed objective function value, best (lowest) estimated objective function value, and the observed constraint values (if any). When optimizing in parallel, the display also includes a column showing the number of active workers, counted after assigning a job to the next worker.

  The result report for each iteration is one of the following:

  - `Accept` — The objective function returns a finite value, and all constraints are satisfied.
  - `Best` — Constraints are satisfied, and the objective function returns the lowest value among feasible points.
  - `Error` — The objective function returns a value that is not a finite real scalar.
  - `Infeas` — At least one constraint is violated.
- `2` — Same as `1`, adding diagnostic information such as time to select the next point, model fitting time, indication that "plus" acquisition functions declare overexploiting, and parallel workers are being assigned to random points due to low parallel utilization.

Example: `'Verbose',2`

Data Types: `double`

`OutputFcn` — Function called after each iteration
`{}` (default) | function handle | cell array of function handles

Function called after each iteration, specified as a function handle or cell array of function handles. An output function can halt the solver, and can perform arbitrary calculations, including creating variables or plotting. Specify several output functions using a cell array of function handles.

There are two built-in output functions:

- `@assignInBase` — Constructs a `BayesianOptimization` instance at each iteration and assigns it to a variable in the base workspace. Choose a variable name using the `SaveVariableName` name-value pair.
- `@saveToFile` — Constructs a `BayesianOptimization` instance at each iteration and saves it to a file in the current folder. Choose a file name using the `SaveFileName` name-value pair.

You can write your own output functions. For details, see “Bayesian Optimization Output Functions” on page 10-19.

Example: `'OutputFcn',{@saveToFile @myOutputFunction}`

Data Types: `cell` | `function_handle`

`SaveFileName` — File name for the `@saveToFile` output function
`'BayesoptResults.mat'` (default) | character vector | string scalar

File name for the `@saveToFile` output function, specified as a character vector or string scalar. The file name can include a path, such as `'../optimizations/September2.mat'`.

Example: `'SaveFileName','September2.mat'`

Data Types: `char` | `string`

`SaveVariableName` — Variable name for the `@assignInBase` output function
`'BayesoptResults'` (default) | character vector | string scalar

Variable name for the `@assignInBase` output function, specified as a character vector or string scalar.

Example: `'SaveVariableName','September2Results'`

Data Types: `char` | `string`

`PlotFcn` — Plot function called after each iteration
`{@plotObjectiveModel,@plotMinObjective}` (default) | `'all'` | function handle | cell array of function handles

Plot function called after each iteration, specified as `'all'`, a function handle, or a cell array of function handles. A plot function can halt the solver, and can perform arbitrary calculations, including creating variables, in addition to plotting.

Specify no plot function as `[]`.

`'all'` calls all built-in plot functions. Specify several plot functions using a cell array of function handles.

The built-in plot functions appear in the following tables.

Model Plots — Apply When D ≤ 2	Description
`@plotAcquisitionFunction`	Plot the acquisition function surface.
`@plotConstraintModels`	Plot each constraint model surface. Negative values indicate feasible points. Also plot a *P*(feasible) surface. Also plot the error model, if it exists, which ranges from −1 to 1. Negative values mean that the model probably does not error, positive values mean that it probably does error. The model is: Plotted error = 2*Probability(error) – 1.
`@plotObjectiveEvaluationTimeModel`	Plot the objective function evaluation time model surface.
`@plotObjectiveModel`	Plot the `fun` model surface, the estimated location of the minimum, and the location of the next proposed point to evaluate. For one-dimensional problems, plot envelopes one credible interval above and below the mean function, and envelopes one noise standard deviation above and below the mean.

Trace Plots — Apply to All D	Description
`@plotObjective`	Plot each observed function value versus the number of function evaluations.
`@plotObjectiveEvaluationTime`	Plot each observed function evaluation run time versus the number of function evaluations.
`@plotMinObjective`	Plot the minimum observed and estimated function values versus the number of function evaluations.
`@plotElapsedTime`	Plot three curves: the total elapsed time of the optimization, the total function evaluation time, and the total modeling and point selection time, all versus the number of function evaluations.

You can write your own plot functions. For details, see “Bayesian Optimization Plot Functions” on page 10-11.

Note When there are coupled constraints, iterative display and plot functions can give counterintuitive results such as:

- A *minimum objective* plot can increase.
- The optimization can declare a problem infeasible even when it showed an earlier feasible point.

The reason for this behavior is that the decision about whether a point is feasible can change as the optimization progresses. `bayesopt` determines feasibility with respect to its constraint model, and this model changes as `bayesopt` evaluates points. So a “minimum objective” plot can increase when the minimal point is later deemed infeasible, and the iterative display can show a feasible point that is later deemed infeasible.

Example: `'PlotFcn','all'`

Data Types: `char` | `string` | `cell` | `function_handle`

Initialization

`InitialX` — Initial evaluation points

`NumSeedPoints`-by-`D` random initial points within bounds (default) | `N`-by-`D` table

Initial evaluation points, specified as an `N`-by-`D` table, where `N` is the number of evaluation points, and `D` is the number of variables.

Note If only `InitialX` is provided, it is interpreted as initial points to evaluate. The objective function is evaluated at `InitialX`.

If any other initialization parameters are also provided, `InitialX` is interpreted as prior function evaluation data. The objective function is not evaluated. Any missing values are set to `NaN`.

Data Types: `table`

`InitialObjective` — Objective values corresponding to `InitialX`

`[]` (default) | length-`N` vector

Objective values corresponding to `InitialX`, specified as a length-`N` vector, where `N` is the number of evaluation points.

Example: `'InitialObjective',[17;-3;-12.5]`

Data Types: `double`

`InitialConstraintViolations` — Constraint violations of coupled constraints

`[]` (default) | `N`-by-`K` matrix

Constraint violations of coupled constraints, specified as an `N`-by-`K` matrix, where `N` is the number of evaluation points and `K` is the number of coupled constraints. For details, see “Coupled Constraints” on page 10-40.

Data Types: `double`

`InitialErrorValues` — Errors for `InitialX`

`[]` (default) | length-`N` vector with entries `-1` or `1`

Errors for `InitialX`, specified as a length-`N` vector with entries `-1` or `1`, where `N` is the number of evaluation points. Specify `-1` for no error, and `1` for an error.

Example: `'InitialErrorValues',[-1,-1,-1,-1,1]`

Data Types: `double`

`InitialUserData` — Initial data corresponding to `InitialX`

`[]` (default) | length-`N` cell vector

Initial data corresponding to `InitialX`, specified as a length-`N` cell vector, where `N` is the number of evaluation points.

Example: `'InitialUserData',{2,3,-1}`

Data Types: `cell`

`InitialObjectiveEvaluationTimes` — Evaluation times of objective function at `InitialX`
`[]` (default) | length-`N` vector

Evaluation times of objective function at `InitialX`, specified as a length-`N` vector, where `N` is the number of evaluation points. Time is measured in seconds.

Data Types: `double`

`InitialIterationTimes` — Times for the first `N` iterations
`{}` (default) | length-`N` vector

Times for the first `N` iterations, specified as a length-`N` vector, where `N` is the number of evaluation points. Time is measured in seconds.

Data Types: `double`

Output Arguments

`results` — Bayesian optimization results
`BayesianOptimization` object

Bayesian optimization results, returned as a `BayesianOptimization` object.

More About

Coupled Constraints

Coupled constraints are those constraints whose value comes from the objective function calculation. See “Coupled Constraints” on page 10-40.

Tips

- Bayesian optimization is not reproducible if one of these conditions exists:
  - You specify an acquisition function whose name includes `per-second`, such as `'expected-improvement-per-second'`. The `per-second` modifier indicates that optimization depends on the run time of the objective function. For more details, see “Acquisition Function Types” on page 10-3.
  - You specify to run Bayesian optimization in parallel. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For more details, see “Parallel Bayesian Optimization” on page 10-7.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` name-value argument to `true` in the call to this function.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016b

bbdesign

Box-Behnken design

Syntax

```
dBB = bbdesign(n)
[dBB,blocks] = bbdesign(n)
[...] = bbdesign(n,param,val)
```

Description

`dBB = bbdesign(n)` generates a Box-Behnken design for `n` factors. `n` must be an integer `3` or larger. The output matrix `dBB` is *m*-by-`n`, where *m* is the number of runs in the design. Each row represents one run, with settings for all factors represented in the columns. Factor values are normalized so that the cube points take values between `-1` and `1`.

`[dBB,blocks] = bbdesign(n)` requests a blocked design. The output `blocks` is an *m*-by-1 vector of block numbers for each run. Blocks indicate runs that are to be measured under similar conditions to minimize the effect of inter-block differences on the parameter estimates.

`[...] = bbdesign(n,param,val)` specifies one or more optional parameter/value pairs for the design. The following table lists valid parameter/value pairs.

Parameter	Description	Values
`'center'`	Number of center points.	Integer. The default depends on `n`.
`'blocksize'`	Maximum number of points per block.	Integer. The default is `Inf`.

Examples

The following creates a 3-factor Box-Behnken design:

```
dBB = bbdesign(3)
dBB =
    -1    -1     0
    -1     1     0
     1    -1     0
     1     1     0
    -1     0    -1
    -1     0     1
     1     0    -1
     1     0     1
     0    -1    -1
     0    -1     1
     0     1    -1
     0     1     1
     0     0     0
     0     0     0
     0     0     0
```

The center point is run 3 times to allow for a more uniform estimate of the prediction variance over the entire design space.

Visualize the design as follows:

```
plot3(dBB(:,1),dBB(:,2),dBB(:,3),'ro',...
         'MarkerFaceColor','b')
X = [1 -1 -1 -1 1 -1 -1 -1 1 1 -1 -1; ...
     1 1 1 -1 1 1 1 -1 1 1 -1 -1];
Y = [-1 -1 1 -1 -1 -1 1 -1 1 -1 1 -1; ...
     1 -1 1 1 1 -1 1 1 1 -1 1 -1];
Z = [1 1 1 1 -1 -1 -1 -1 -1 -1 -1 -1; ...
     1 1 1 1 -1 -1 -1 -1 1 1 1 1];
line(X,Y,Z,'Color','b')
axis square equal
```

bestPoint

Best point in a Bayesian optimization according to a criterion

Syntax

```
x = bestPoint(results)
x = bestPoint(results,Name,Value)
[x,CriterionValue] = bestPoint( ___ )
[x,CriterionValue,iteration] = bestPoint( ___ )
```

Description

`x = bestPoint(results)` returns the best feasible point in the Bayesian model `results` according to the default criterion `'min-visited-upper-confidence-interval'`.

`x = bestPoint(results,Name,Value)` modifies the best point using name-value pairs.

`[x,CriterionValue] = bestPoint( ___ )`, for any previous syntax, also returns the value of the criterion at `x`.

`[x,CriterionValue,iteration] = bestPoint( ___ )` also returns the iteration number at which the best point was returned. Applies when the `Criterion` name-value pair is `'min-observed'`, `'min-visited-mean'`, or the default `'min-visited-upper-confidence-interval'`.

Examples

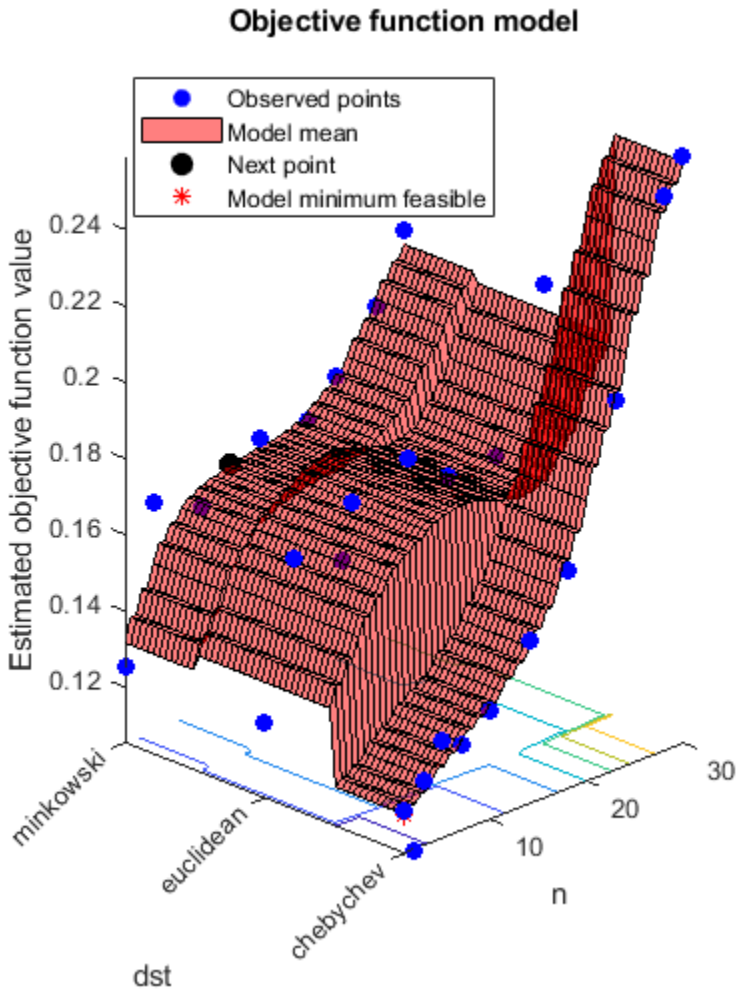
Best Point of an Optimized KNN Classifier

This example shows how to obtain the best point of an optimized classifier.

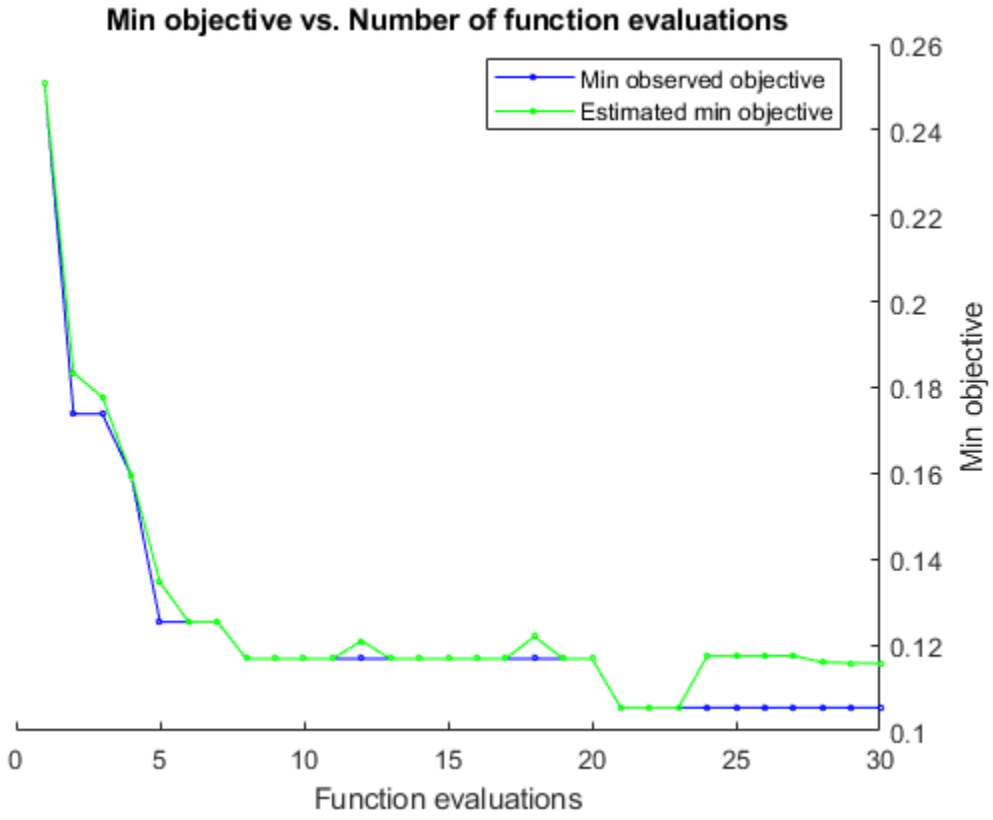
Optimize a KNN classifier for the `ionosphere` data, meaning find parameters that minimize the cross-validation loss. Minimize over nearest-neighborhood sizes from 1 to 30, and over the distance functions `'chebychev'`, `'euclidean'`, and `'minkowski'`.

For reproducibility, set the random seed, and set the `AcquisitionFunctionName` option to `'expected-improvement-plus'`.

```
load ionosphere
rng(11)
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...
    'Distance',char(x.dst),'NSMethod','exhaustive'));
results = bayesopt(fun,[num,dst],'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus');
```



Objective function model
Observed points
Model mean
Next point
Model minimum feasible
Estimated objective function value
0.24
0.22
0.2
0.18
0.16
0.14
0.12
minkowski
euclidean
chebychev
dst
10
20
30
n



Obtain the best point according to the default `'min-visited-upper-confidence-interval'` criterion.

```
x = bestPoint(results)
```

```
x=1×2 table
    n       dst
    _    _________

    1    chebychev
```

The lowest estimated cross-validation loss occurs for one nearest neighbor and `'chebychev'` distance.

Careful examination of the objective function model plot shows a point with two nearest neighbors and `'chebychev'` distance that has a lower objective function value. Find this point using a different criterion.

```
x = bestPoint(results,'Criterion','min-observed')
```

```
x=1×2 table
    n       dst
    _    _________

    2    chebychev
```

Also find the minimum observed objective function value, and the iteration number at which it was observed.

```
[x,CriterionValue,iteration] = bestPoint(results,'Criterion','min-observed')
```

```
x=1×2 table
    n       dst
    _    _________

    2    chebychev

CriterionValue = 0.1054

iteration = 21
```

Input Arguments

`results` — Bayesian optimization results

`BayesianOptimization` object

Bayesian optimization results, specified as a `BayesianOptimization` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `x = bestPoint(results,'Criterion','min-observed')`

`Criterion` — Best point criterion

`'min-visited-upper-confidence-interval'` (default) | `'min-observed'` | `'min-mean'` | `'min-upper-confidence-interval'` | `'min-visited-mean'`

Best point criterion, specified as the comma-separated pair consisting of `'Criterion'` and a criterion name. The names are case-insensitive, do not require `-` characters, and require only enough characters to make the name uniquely distinguishable.

Criterion Name	Meaning
`'min-observed'`	`x` is the feasible point with minimum observed objective.
`'min-mean'`	`x` is the feasible point where the objective model mean is minimized.
`'min-upper-confidence-interval'`	`x` is the feasible point minimizing an upper confidence interval of the objective model. See `alpha`.
`'min-visited-mean'`	`x` is the feasible point where the objective model mean is minimized among the visited points.
`'min-visited-upper-confidence-interval'`	`x` is the feasible point minimizing an upper confidence interval of the objective model among the visited points. See `alpha`.

Example: `'Criterion','min-visited-mean'`

alpha — Probability that modeled objective mean exceeds CriterionValue
0.01 (default) | scalar between 0 and 1

Probability that the modeled objective mean exceeds CriterionValue, specified as the comma-separated pair consisting of 'alpha' and a scalar between 0 and 1. alpha relates to the 'min-upper-confidence-interval' and 'min-visited-upper-confidence-interval' Criterion values. The definition for the upper confidence interval is the value Y where

$P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha}$,

where fun is the objective function, and the mean is calculated with respect to the posterior distribution Q.

Example: 'alpha',0.05

Data Types: double

Output Arguments

x — Best point
1-by-D table

Best point, returned as a 1-by-D table, where D is the number of variables. The meaning of "best" is with respect to Criterion.

CriterionValue — Value of criterion
real scalar

Value of criterion, returned as a real scalar. The value depends on the setting of the Criterion name-value pair, which has a default value of 'min-visited-upper-confidence-interval'.

Criterion Name	Meaning
'min-observed'	Minimum observed objective.
'min-mean'	Minimum of model mean.
'min-upper-confidence-interval'	Value Y satisfying the equation $P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha}$.
'min-visited-mean'	Minimum of observed model mean.
'min-visited-upper-confidence-interval'	Value Y satisfying the equation $P(\text{mean}_Q(\text{fun}(x)) > Y) = \text{alpha}$ among observed points.

iteration — Iteration number at which best point was observed
positive integer

Iteration number at which best point was observed, returned as a positive integer. The best point is defined by CriterionValue.

Introduced in R2016b

betacdf

Beta cumulative distribution function

Syntax

```
p = betacdf(x,a,b)
p = betacdf(x,a,b,'upper')
```

Description

`p = betacdf(x,a,b)` returns the beta cdf at each of the values in `x` using the corresponding parameters in `a` and `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must all be positive, and the values in `x` must lie on the interval [0,1].

`p = betacdf(x,a,b,'upper')` returns the complement of the beta cdf at each of the values in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The beta cdf for a given value `x` and given pair of parameters `a` and `b` is

$$p = F(x|a,b) = \frac{1}{B(a,b)}\int_0^x t^{a-1}(1-t)^{b-1}dt$$

where $B(\cdot)$ is the Beta function.

Examples

Compute Beta Distribution CDF

Compute the cdf for a beta distribution with parameters `a = 2` and `b = 2`.

```
x = 0.1:0.2:0.9;
a = 2;
b = 2;
p = betacdf(x,a,b)
```

```
p = 1×5

    0.0280    0.2160    0.5000    0.7840    0.9720
```

```
a = [1 2 3];
p = betacdf(0.5,a,a)
```

```
p = 1×3

    0.5000    0.5000    0.5000
```

betafit

Beta parameter estimates

Syntax

```
phat = betafit(data)
[phat,pci] = betafit(data,alpha)
```

Description

`phat = betafit(data)` computes the maximum likelihood estimates of the beta distribution parameters *a* and *b* from the data in the vector `data` and returns a column vector containing the *a* and *b* estimates, where the beta cdf is given by

$$F(x \mid a,b) = \frac{1}{B(a,b)} \int_0^x t^{a-1}(1-t)^{b-1} dt$$

and $B(\cdot)$ is the Beta function. The elements of `data` must lie in the open interval (0, 1), where the beta distribution is defined. However, it is sometimes also necessary to fit a beta distribution to data that include exact zeros or ones. For such data, the beta likelihood function is unbounded, and standard maximum likelihood estimation is not possible. In that case, `betafit` maximizes a modified likelihood that incorporates the zeros or ones by treating them as if they were values that have been left-censored at `sqrt(realmin)` or right-censored at 1-`eps`/2, respectively.

`[phat,pci] = betafit(data,alpha)` returns confidence intervals on the *a* and *b* parameters in the 2-by-2 matrix `pci`. The first column of the matrix contains the lower and upper confidence bounds for parameter *a*, and the second column contains the confidence bounds for parameter *b*. The optional input argument `alpha` is a value in the range [0, 1] specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals. The confidence intervals are based on a normal approximation for the distribution of the logs of the parameter estimates.

Examples

This example generates 100 beta distributed observations. The true *a* and *b* parameters are 4 and 3, respectively. Compare these to the values returned in `p` by the beta fit. Note that the columns of `ci` both bracket the true parameters.

```
data = betarnd(4,3,100,1);
[p,ci] = betafit(data,0.01)
p =
    5.5328    3.8097
ci =
    3.6538    2.6197
    8.3781    5.5402
```

Topics

“Beta Distribution” on page B-6

Introduced before R2006a

betainv

Beta inverse cumulative distribution function

Syntax

```
X = betainv(P,A,B)
```

Description

`X = betainv(P,A,B)` computes the inverse of the beta cdf with parameters specified by `A` and `B` for the corresponding probabilities in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `P` must lie on the interval [0, 1].

The inverse beta cdf for a given probability p and a given pair of parameters a and b is

$$x = F^{-1}(p \mid a, b) = \left\{x : F(x \mid a, b) = p\right\}$$

where

$$p = F(x \mid a, b) = \frac{1}{B(a, b)} \int_0^x t^{a-1}(1-t)^{b-1} dt$$

and $B(\cdot)$ is the Beta function. Each element of output `X` is the value whose cumulative probability under the beta cdf defined by the corresponding parameters in `A` and `B` is specified by the corresponding value in `P`.

Examples

```
p = [0.01 0.5 0.99];
x = betainv(p,10,5)
x =
  0.3726  0.6742  0.8981
```

According to this result, for a beta cdf with $a = 10$ and $b = 5$, a value less than or equal to 0.3726 occurs with probability 0.01. Similarly, values less than or equal to 0.6742 and 0.8981 occur with respective probabilities 0.5 and 0.99.

Algorithms

The `betainv` function uses Newton's method with modifications to constrain steps to the allowable range for x, i.e., [0 1].

Introduced before R2006a

betalike

Beta negative log-likelihood

Syntax

```
nlogL = betalike(params,data)
[nlogL,AVAR] = betalike(params,data)
```

Description

`nlogL = betalike(params,data)` returns the negative of the beta log-likelihood function for the beta parameters *a* and *b* specified in vector `params` and the observations specified in the column vector `data`.

The elements of `data` must lie in the open interval (0, 1), where the beta distribution is defined. However, it is sometimes also necessary to fit a beta distribution to data that include exact zeros or ones. For such data, the beta likelihood function is unbounded, and standard maximum likelihood estimation is not possible. In that case, `betalike` computes a modified likelihood that incorporates the zeros or ones by treating them as if they were values that have been left-censored at `sqrt(realmin)` or right-censored at 1-`eps`/2, respectively.

`[nlogL,AVAR] = betalike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates if the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`betalike` is a utility function for maximum likelihood estimation of the beta distribution. The likelihood assumes that all the elements in the data sample are mutually independent. Since `betalike` returns the negative beta log-likelihood function, minimizing `betalike` using `fminsearch` is the same as maximizing the likelihood.

Examples

This example continues the `betafit` example, which calculates estimates of the beta parameters for some randomly generated beta distributed data.

```
r = betarnd(4,3,100,1);
[nlogl,AVAR] = betalike(betafit(r),r)
nlogl =

  -27.5996

AVAR =

    0.2783    0.1316
    0.1316    0.0867
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Beta Distribution” on page B-6

Introduced before R2006a

betapdf

Beta probability density function

Syntax

```
Y = betapdf(X,A,B)
```

Description

`Y = betapdf(X,A,B)` computes the beta pdf at each of the values in `X` using the corresponding parameters in `A` and `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions of the other inputs. The parameters in `A` and `B` must all be positive, and the values in `X` must lie on the interval `[0, 1]`.

The beta probability density function for a given value x and given pair of parameters a and b is

$$y = f(x \mid a, b) = \frac{1}{B(a, b)} x^{a-1}(1-x)^{b-1} I_{[0,1]}(x)$$

where $B(\cdot)$ is the Beta function. The uniform distribution on (0 1) is a degenerate case of the beta pdf where $a = 1$ and $b = 1$.

A *likelihood function* is the pdf viewed as a function of the parameters. Maximum likelihood estimators (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of x.

Examples

```
a = [0.5 1; 2 4]
a =
  0.5000  1.0000
  2.0000  4.0000
y = betapdf(0.5,a,a)
y =
  0.6366  1.0000
  1.5000  2.1875
```

Extended Capabilities

betarnd

Beta random numbers

Syntax

```
R = betarnd(A,B)
R = betarnd(A,B,m,n,...)
R = betarnd(A,B,[m,n,...])
```

Description

`R = betarnd(A,B)` generates random numbers from the beta distribution with parameters specified by `A` and `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input.

`R = betarnd(A,B,m,n,...)` or `R = betarnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the beta distribution with parameters `A` and `B`. `A` and `B` can each be scalars or arrays of the same size as `R`.

Examples

```
a = [1 1;2 2];
b = [1 2;1 2];

r = betarnd(a,b)
r =
  0.6987  0.6139
  0.9102  0.8067

r = betarnd(10,10,[1 5])
r =
  0.5974  0.4777  0.5538  0.5465  0.6327

r = betarnd(4,2,2,3)
r =
  0.3943  0.6101  0.5768
  0.5990  0.2760  0.5474
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.

- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

betastat

Beta mean and variance

Syntax

```
[M,V] = betastat(A,B)
```

Description

`[M,V] = betastat(A,B)`, with `A>0` and `B>0`, returns the mean of and variance for the beta distribution with parameters specified by `A` and `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `M` and `V`. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input.

The mean of the beta distribution with parameters a and b is $a/(a + b)$ and the variance is

$$\frac{ab}{(a+b+1)(a+b)^2}$$

Examples

If parameters a and b are equal, the mean is 1/2.

```
a = 1:6;
[m,v] = betastat(a,a)
m =
  0.5000  0.5000  0.5000  0.5000  0.5000  0.5000
v =
  0.0833  0.0500  0.0357  0.0278  0.0227  0.0192
```

Extended Capabilities

Introduced before R2006a

binocdf

Binomial cumulative distribution function

Syntax

```
y = binocdf(x,n,p)
y = binocdf(x,n,p,'upper')
```

Description

`y = binocdf(x,n,p)` computes a binomial cumulative distribution function at each of the values in `x` using the corresponding number of trials in `n` and the probability of success for each trial in `p`.

`x`, `n`, and `p` can be vectors, matrices, or multidimensional arrays of the same size. Alternatively, one or more arguments can be scalars. The `binocdf` function expands scalar inputs to constant arrays with the same dimensions as the other inputs.

`y = binocdf(x,n,p,'upper')` returns the complement of the binomial cumulative distribution function at each value in `x`, using an algorithm that computes the extreme upper tail probabilities more accurately than the default algorithm.

Examples

Compute and Plot Binomial Cumulative Distribution Function

Compute and plot the binomial cumulative distribution function for the specified range of integer values, number of trials, and probability of success for each trial.

A baseball team plays 100 games in a season and has a 50-50 chance of winning each game. Find the probability of the team winning more than 55 games in a season.

```
format long
1 - binocdf(55,100,0.5)
```

```
ans =
   0.135626512036917
```

Find the probability of the team winning between 50 and 55 games in a season.

```
binocdf(55,100,0.5) - binocdf(49,100,0.5)
```

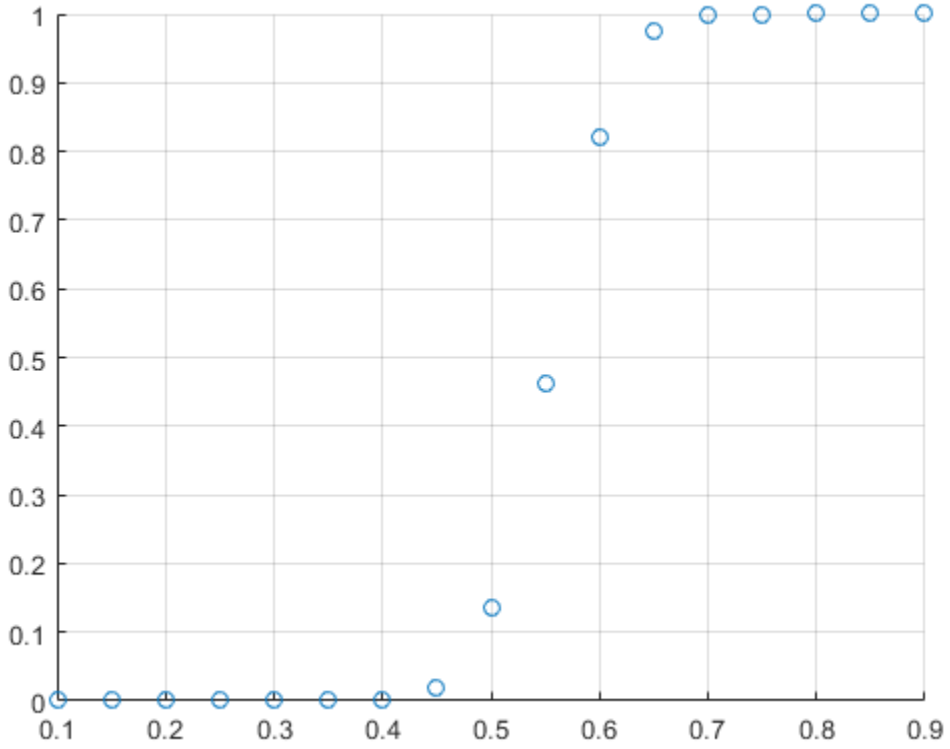
```
ans =
   0.404168106656672
```

Compute the probabilities of the team winning more than 55 games in a season if the chance of winning each game ranges from 10% to 90%.

```
chance = 0.1:0.05:0.9;
y = 1 - binocdf(55,100,chance);
```

Plot the results.

```
scatter(chance,y)
grid on
```



Compute Extreme Upper Tail Probabilities

Compute the complement of the binomial cumulative distribution function with more accurate upper tail probabilities.

A baseball team plays 100 games in a season and has a 50-50 chance of winning each game. Find the probability of the team winning more than 95 games in a season.

```
format long
1 - binocdf(95,100,0.5)
```

```
ans =
     0
```

This result shows that the probability is so close to 1 (within `eps`) that subtracting it from 1 gives 0. To approximate the extreme upper tail probabilities better, compute the complement of the binomial cumulative distribution function directly instead of computing the difference.

```
binocdf(95,100,0.5,'upper')
```

```
ans =
     3.224844447881779e-24
```

Alternatively, use the `binopdf` function to find the probabilities of the team winning 96, 97, 98, 99, and 100 games in a season. Find the sum of these probabilities by using the `sum` function.

```
sum(binopdf(96:100,100,0.5),'all')
```

```
ans =
     3.224844447881779e-24
```

Input Arguments

x — Values at which to evaluate binomial cdf

integer from interval `[0 n]` | array of integers from interval `[0 n]`

Values at which to evaluate the binomial cdf, specified as an integer or an array of integers. All values of `x` must belong to the interval `[0 n]`, where `n` is the number of trials.

Example: `[0 1 3 4]`

Data Types: `single` | `double`

n — Number of trials

positive integer | array of positive integers

Number of trials, specified as a positive integer or an array of positive integers.

Example: `[10 20 50 100]`

Data Types: `single` | `double`

p — Probability of success for each trial

scalar value from interval `[0 1]` | array of scalar values from interval `[0 1]`

Probability of success for each trial, specified as a scalar value or an array of scalar values. All values of `p` must belong to the interval `[0 1]`.

Example: `[0.01 0.1 0.5 0.7]`

Data Types: `single` | `double`

Output Arguments

y — Binomial cdf values

scalar value | array of scalar values

Binomial cdf values, returned as a scalar value or an array of scalar values. Each element in `y` is the binomial cdf value of the distribution evaluated at the corresponding element in `x`.

Data Types: `single` | `double`

More About

Binomial Cumulative Distribution Function

The binomial cumulative distribution function lets you obtain the probability of observing less than or equal to x successes in n trials, with the probability p of success on a single trial.

The binomial cumulative distribution function for a given value x and a given pair of parameters n and p is

$$y = F(x \mid n, p) = \sum_{i=0}^{x} \binom{n}{i} p^i (1-p)^{(n-i)} I_{(0,1,\ldots,n)}(i).$$

The resulting value y is the probability of observing up to x successes in n independent trials, where the probability of success in any given trial is p. The indicator function $I_{(0,1,\ldots,n)}(i)$ ensures that x only adopts values of $0,1,\ldots,n$.

Alternative Functionality

- `binocdf` is a function specific to binomial distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, specify the probability distribution name and its parameters. Alternatively, create a `BinomialDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `binocdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

binofit

Binomial parameter estimates

Syntax

```
phat = binofit(x,n)
[phat,pci] = binofit(x,n)
[phat,pci] = binofit(x,n,alpha)
```

Description

`phat = binofit(x,n)` returns a maximum likelihood estimate of the probability of success in a given binomial trial based on the number of successes, `x`, observed in `n` independent trials. If `x = (x(1), x(2), ... x(k))` is a vector, `binofit` returns a vector of the same size as `x` whose ith entry is the parameter estimate for `x(i)`. All `k` estimates are independent of each other. If `n = (n(1), n(2), ..., n(k))` is a vector of the same size as `x`, the binomial fit, `binofit`, returns a vector whose ith entry is the parameter estimate based on the number of successes `x(i)` in `n(i)` independent trials. A scalar value for `x` or `n` is expanded to the same size as the other input.

`[phat,pci] = binofit(x,n)` returns the probability estimate, `phat`, and the 95% confidence intervals, `pci`. `binofit` uses the Clopper-Pearson method to calculate confidence intervals.

`[phat,pci] = binofit(x,n,alpha)` returns the `100(1 - alpha)`% confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

Note `binofit` behaves differently than other Statistics and Machine Learning Toolbox functions that compute parameter estimates, in that it returns independent estimates for each entry of `x`. By comparison, `expfit` returns a single parameter estimate based on all the entries of `x`.

Unlike most other distribution fitting functions, the `binofit` function treats its input `x` vector as a collection of measurements from separate samples. If you want to treat `x` as a single sample and compute a single parameter estimate for it, you can use `binofit(sum(x),sum(n))` when `n` is a vector, and `binofit(sum(X),N*length(X))` when `n` is a scalar.

Examples

This example generates a binomial sample of 100 elements, where the probability of success in a given trial is 0.6, and then estimates this probability from the outcomes in the sample.

```
r = binornd(100,0.6);
[phat,pci] = binofit(r,100)
phat =
  0.5800
pci =
  0.4771  0.6780
```

The 95% confidence interval, `pci`, contains the true value, 0.6.

`binocdf` | `binoinv` | `binopdf` | `binornd` | `binostat` | `mle`

Topics

“Binomial Distribution” on page B-10

Introduced before R2006a

binoinv

Binomial inverse cumulative distribution function

Syntax

```
X = binoinv(Y,N,P)
```

Description

`X = binoinv(Y,N,P)` returns the smallest integer `X` such that the binomial cdf evaluated at `X` is equal to or exceeds `Y`. You can think of `Y` as the probability of observing `X` successes in `N` independent trials where `P` is the probability of success in each trial. Each `X` is a positive integer less than or equal to `N`.

`Y`, `N`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `N` must be positive integers, and the values in both `P` and `Y` must lie on the interval [0 1].

Examples

If a baseball team has a 50-50 chance of winning any game, what is a reasonable range of games this team might win over a season of 162 games?

```
binoinv([0.05 0.95],162,0.5)
ans =
    71    91
```

This result means that in 90% of baseball seasons, a .500 team should win between 71 and 91 games.

Introduced before R2006a

binopdf

Binomial probability density function

Syntax

```
y = binopdf(x,n,p)
```

Description

`y = binopdf(x,n,p)` computes the binomial probability density function at each of the values in `x` using the corresponding number of trials in `n` and probability of success for each trial in `p`.

`x`, `n`, and `p` can be vectors, matrices, or multidimensional arrays of the same size. Alternatively, one or more arguments can be scalars. The `binopdf` function expands scalar inputs to constant arrays with the same dimensions as the other inputs.

Examples

Compute and Plot Binomial Probability Density Function

Compute and plot the binomial probability density function for the specified range of integer values, number of trials, and probability of success for each trial.

In one day, a quality assurance inspector tests 200 circuit boards. 2% of the boards have defects. Compute the probability that the inspector will find no defective boards on any given day.

```
binopdf(0,200,0.02)
```

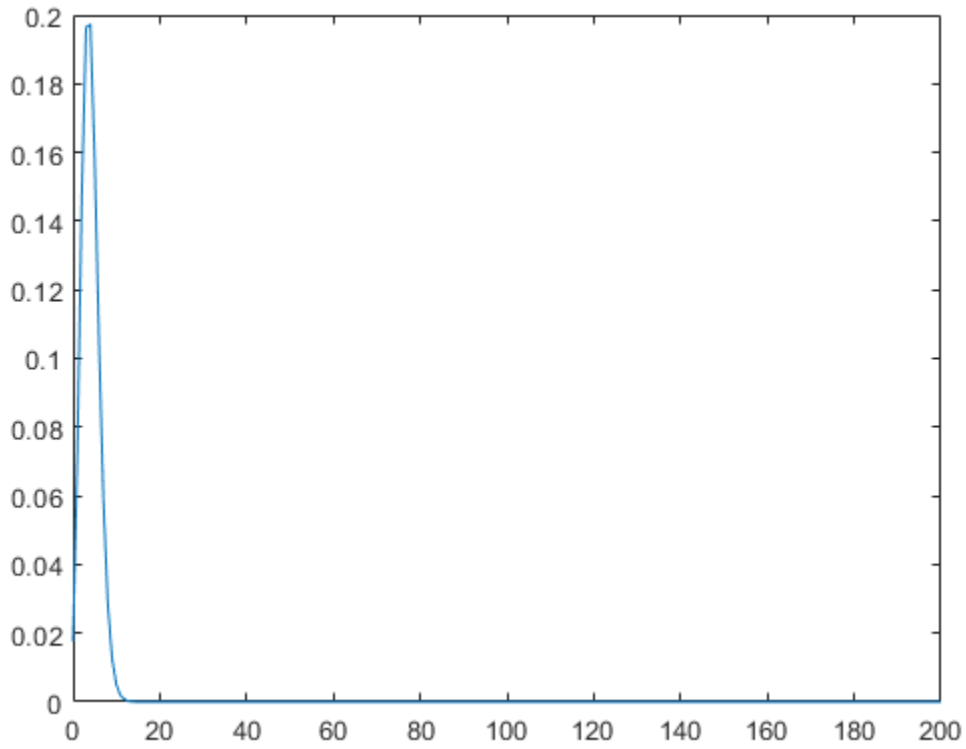
```
ans = 0.0176
```

Compute the binomial probability density function values at each value from 0 to 200. These values correspond to the probabilities that the inspector will find 0, 1, 2, ..., 200 defective boards on any given day.

```
defects = 0:200;
y = binopdf(defects,200,.02);
```

Plot the resulting binomial probability values.

```
plot(defects,y)
```



Compute the most likely number of defective boards that the inspector finds in a day.

```
[x,i] = max(y);
defects(i)
```

```
ans = 4
```

Input Arguments

x — Values at which to evaluate binomial pdf

integer from interval `[0 n]` | array of integers from interval `[0 n]`

Values at which to evaluate the binomial pdf, specified as an integer or an array of integers. All values of `x` must belong to the interval `[0 n]`, where `n` is the number of trials.

Example: `[0,1,3,4]`

Data Types: `single` | `double`

n — Number of trials

positive integer | array of positive integers

Number of trials, specified as a positive integer or an array of positive integers.

Example: `[10,20,50,100]`

Data Types: `single` | `double`

p — Probability of success for each trial
scalar value from interval `[0 1]` | array of scalar values from interval `[0 1]`

Probability of success for each trial, specified as a scalar value or an array of scalar values. All values of `p` must belong to the interval `[0 1]`.

Example: `[0.01,0.1,0.5,0.7]`

Data Types: `single` | `double`

Output Arguments

y — Binomial pdf values
scalar value | array of scalar values

Binomial pdf values, returned as a scalar value or array of scalar values. Each element in `y` is the binomial pdf value of the distribution evaluated at the corresponding element in `x`.

Data Types: `single` | `double`

More About

Binomial Probability Density Function

The binomial probability density function lets you obtain the probability of observing exactly x successes in n trials, with the probability p of success on a single trial.

The binomial probability density function for a given value x and given pair of parameters n and p is

$$y = f(x \mid n, p) = \binom{n}{x} p^x q^{(n-x)} I_{(0,1,\ldots,n)}(x)$$

where $q = 1 - p$. The resulting value y is the probability of observing exactly x successes in n independent trials, where the probability of success in any given trial is p. The indicator function $I_{(0,1,\ldots,n)}(x)$ ensures that x only adopts values of 0, 1, ..., n.

Alternative Functionality

- `binopdf` is a function specific to binomial distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, specify the probability distribution name and its parameters. Alternatively, create a `BinomialDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `binopdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

binornd

Random numbers from binomial distribution

Syntax

```
r = binornd(n,p)
r = binornd(n,p,sz1,...,szN)
r = binornd(n,p,sz)
```

Description

`r = binornd(n,p)` generates random numbers from the binomial distribution specified by the number of trials `n` and the probability of success for each trial `p`.

`n` and `p` can be vectors, matrices, or multidimensional arrays of the same size. Alternatively, one or more arguments can be scalars. The `binornd` function expands scalar inputs to constant arrays with the same dimensions as the other inputs. The function returns a vector, matrix, or multidimensional array `r` of the same size as `n` and `p`.

`r = binornd(n,p,sz1,...,szN)` generates an array of random numbers from the binomial distribution with the scalar parameters `n` and `p`, where `sz1,...,szN` indicates the size of each dimension.

`r = binornd(n,p,sz)` generates an array of random numbers from the binomial distribution with the scalar parameters `n` and `p`, where vector `sz` specifies `size(r)`.

Examples

Array of Random Numbers from Several Binomial Distributions

Generate an array of random numbers from the binomial distributions. For each distribution, you specify the number of trials and the probability of success for each trial.

Specify the numbers of trials.

```
n = 10:10:60
```

```
n = 1×6

    10    20    30    40    50    60
```

Specify the probabilities of success for each trial.

```
p = 1./n
```

```
p = 1×6

    0.1000    0.0500    0.0333    0.0250    0.0200    0.0167
```

Generate random numbers from the binomial distributions.

```
r = binornd(n,p)
```

```
r = 1×6

     0     1     1     0     1     1
```

Array of Random Numbers from One Binomial Distribution

Generate an array of random numbers from one binomial distribution. Here, the distribution parameters `n` and `p` are scalars.

Use the `binornd` function to generate random numbers from the binomial distribution with 100 trials, where the probability of success in each trial is 0.2. The function returns one number.

```
r_scalar = binornd(100,0.2)
```

```
r_scalar = 20
```

Generate a 2-by-3 array of random numbers from the same distribution by specifying the required array dimensions.

```
r_array = binornd(100,0.2,2,3)
```

```
r_array = 2×3

    18    23    20
    18    24    23
```

Alternatively, specify the required array dimensions as a vector.

```
r_array = binornd(100,0.2,[2 3])
```

```
r_array = 2×3

    21    21    20
    26    18    23
```

Input Arguments

n — Number of trials

positive integer | array of positive integers

Number of trials, specified as a positive integer or an array of positive integers.

Example: `[10 20 50 100]`

Data Types: `single` | `double`

p — Probability of success for each trial

scalar value | array of scalar values

Probability of success for each trial, specified as a scalar value or an array of scalar values. All values of `p` must belong to the interval `[0 1]`.

Example: `[0.01 0.1 0.5 0.7]`

Data Types: `single` | `double`

`sz1,...,szN` — Size of each dimension (as separate arguments)
integers

Size of each dimension, specified as separate arguments of integers. For example, specifying `5,3,2` generates a 5-by-3-by-2 array of random numbers from the binomial probability distribution.

If either `n` or `p` is an array, then the specified dimensions `sz1,...,szN` must match the common dimensions of `n` and `p` after any necessary scalar expansion. The default values of `sz1,...,szN` are the common dimensions.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `binornd` ignores trailing dimensions with a size of 1. For example, `binornd(n,p,3,1,1,1)` produces a 3-by-1 vector of random numbers.

Example: `5,3,2`

Data Types: `single` | `double`

`sz` — Size of each dimension (as a row vector)
row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying `[5 3 2]` generates a 5-by-3-by-2 array of random numbers from the binomial probability distribution.

If either `n` or `p` is an array, then the specified dimensions `sz` must match the common dimensions of `n` and `p` after any necessary scalar expansion. The default values of `sz` are the common dimensions.

- If you specify a single value `[sz1]`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `binornd` ignores trailing dimensions with a size of 1. For example, `binornd(n,p,[3 1 1 1])` produces a 3-by-1 vector of random numbers.

Example: `[5 3 2]`

Data Types: `single` | `double`

Output Arguments

`r` — Random numbers from binomial distribution
scalar value | array of scalar values

Random numbers from the binomial distribution, returned as a scalar value or an array of scalar values.

Data Types: `single` | `double`

Alternative Functionality

- `binornd` is a function specific to binomial distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Alternatively, create a `BinomialDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `binornd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB in these two cases:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Distributed Arrays

Partition large arrays across the combined memory of your cluster using Parallel Computing Toolbox™.

This function fully supports distributed arrays. For more information, see “Run MATLAB Functions with Distributed Arrays” (Parallel Computing Toolbox).

binostat

Binomial mean and variance

Syntax

```
[M,V] = binostat(N,P)
```

Description

`[M,V] = binostat(N,P)` returns the mean of and variance for the binomial distribution with parameters specified by the number of trials, `N`, and probability of success for each trial, `P`. `N` and `P` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `M` and `V`. A scalar input for `N` or `P` is expanded to a constant array with the same dimensions as the other input.

The mean of the binomial distribution with parameters n and p is np. The variance is npq, where $q = 1 – p$.

Examples

```
n = logspace(1,5,5)
n =
     10     100    1000    10000   100000

[m,v] = binostat(n,1./n)
m =
   1   1   1   1   1
v =
  0.9000  0.9900  0.9990  0.9999  1.0000

[m,v] = binostat(n,1/2)
m =
      5     50     500    5000    50000
v =
  1.0e+04 *
  0.0003  0.0025  0.0250  0.2500  2.5000
```

binScatterPlot

Scatter plot of bins for tall arrays

Syntax

```
binScatterPlot(X,Y)
binScatterPlot(X,Y,nbins)
binScatterPlot(X,Y,Xedges,Yedges)
binScatterPlot(X,Y,Name,Value)
h = binScatterPlot( ___ )
```

Description

`binScatterPlot(X,Y)` creates a binned scatter plot of the data in `X` and `Y`. The `binScatterPlot` function uses an automatic binning algorithm that returns bins with a uniform area, chosen to cover the range of elements in `X` and `Y` and reveal the underlying shape of the distribution.

`binScatterPlot(X,Y,nbins)` specifies the number of bins to use in each dimension.

`binScatterPlot(X,Y,Xedges,Yedges)` specifies the edges of the bins in each dimension using the vectors `Xedges` and `Yedges`.

`binScatterPlot(X,Y,Name,Value)` specifies additional options with one or more name-value pair arguments using any of the previous syntaxes. For example, you can specify `'Color'` and a valid color option to change the color theme of the plot, or `'Gamma'` with a positive scalar to adjust the level of detail.

`h = binScatterPlot( ___ )` returns a `Histogram2` object. Use this object to inspect properties of the plot.

Examples

Binned Scatter Plot of Normally Distributed Random Data

Create two tall vectors of random data. Create a binned scatter plot for the data.

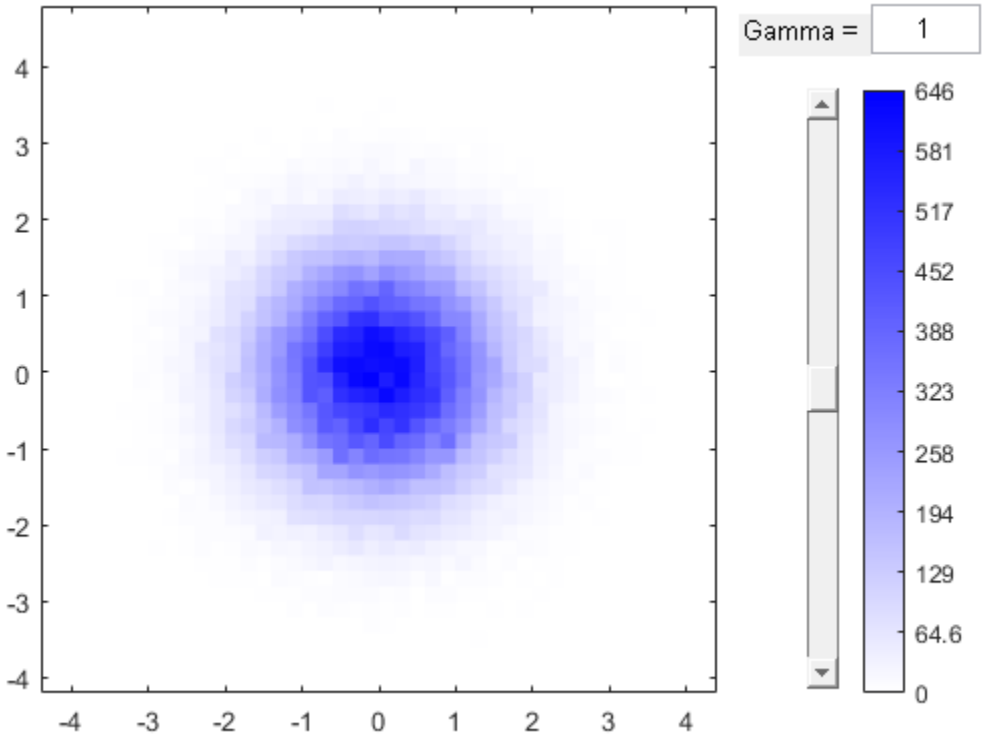
When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)

X = tall(randn(1e5,1));
Y = tall(randn(1e5,1));
binScatterPlot(X,Y)
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.53 sec
Evaluation completed in 1 sec
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.18 sec
Evaluation completed in 0.24 sec
```



The resulting figure contains a slider to adjust the level of detail in the image.

Specify Number of Scatter Plot Bins

Specify a scalar value as the third input argument to use the same number of bins in each dimension, or a two-element vector to use a different number of bins in each dimension.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

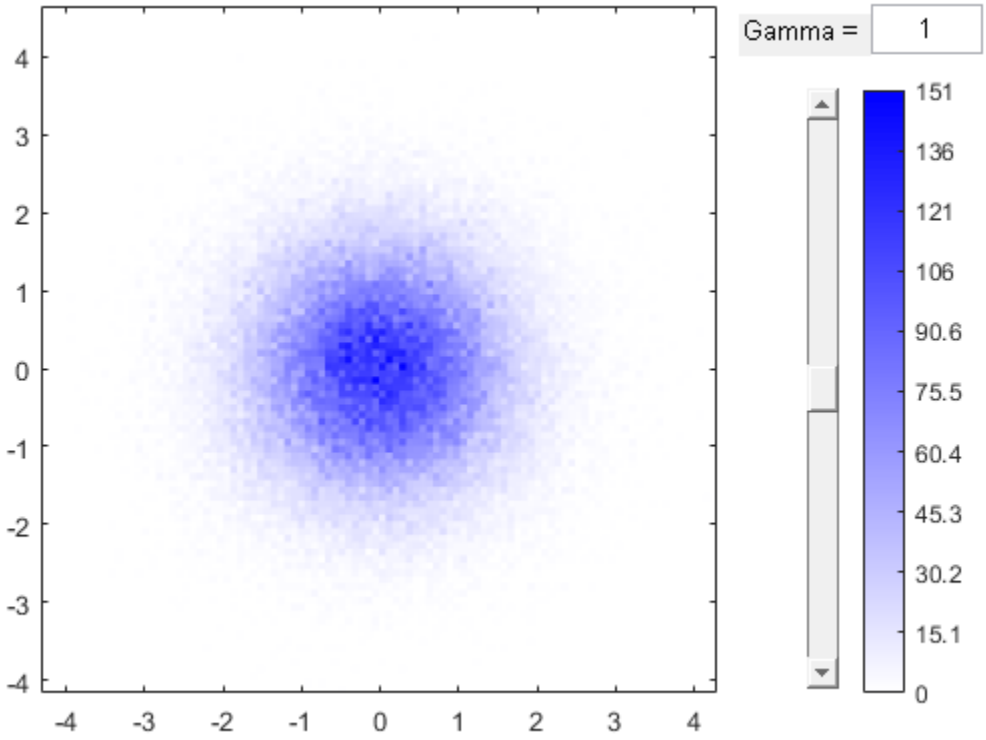
```
mapreducer(0)
```

Plot a binned scatter plot of random data sorted into 100 bins in each dimension.

```
X = tall(randn(1e5,1));
Y = tall(randn(1e5,1));
binScatterPlot(X,Y,100)
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.35 sec
```

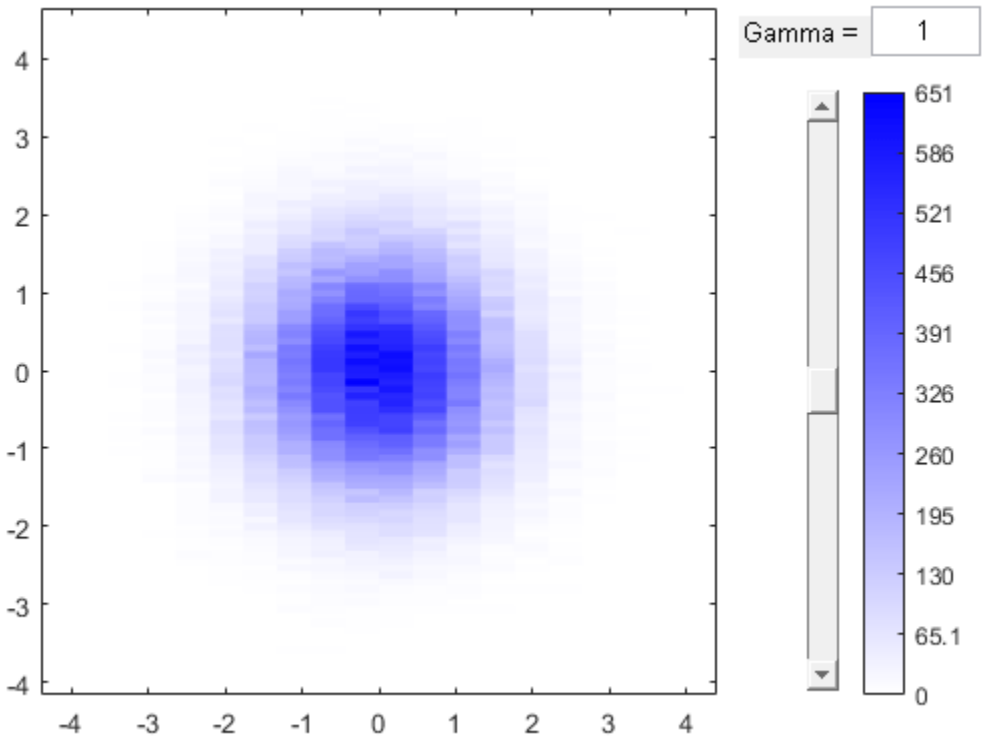
```
Evaluation completed in 0.55 sec
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.17 sec
Evaluation completed in 0.26 sec
```



Use 20 bins in the *x*-dimension and continue to use 100 bins in the *y*-dimension.

```
binScatterPlot(X,Y,[20 100])
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.18 sec
Evaluation completed in 0.27 sec
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.17 sec
Evaluation completed in 0.24 sec
```



Specify Bin Edges for Scatter Plot

Plot a binned scatter plot of random data with specific bin edges. Use bin edges of `Inf` and `-Inf` to capture outliers.

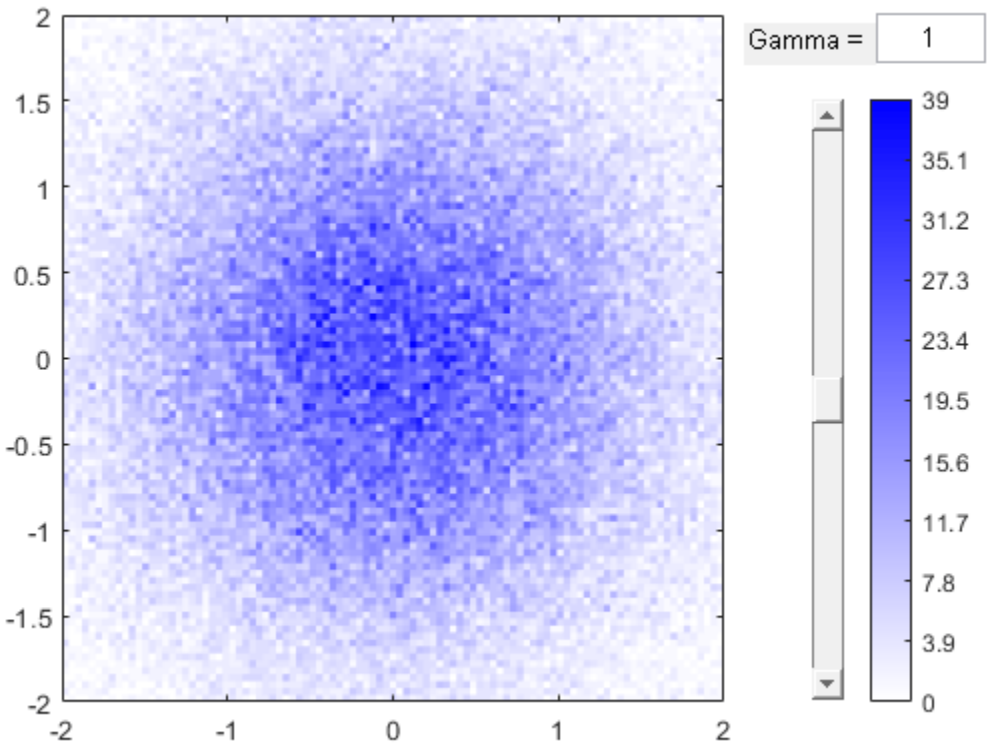
When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)
```

Create a binned scatter plot with 100 bin edges between `[-2 2]` in each dimension. The data outside the specified bin edges is not included in the plot.

```
X = tall(randn(1e5,1));
Y = tall(randn(1e5,1));
Xedges = linspace(-2,2);
Yedges = linspace(-2,2);
binScatterPlot(X,Y,Xedges,Yedges)
```

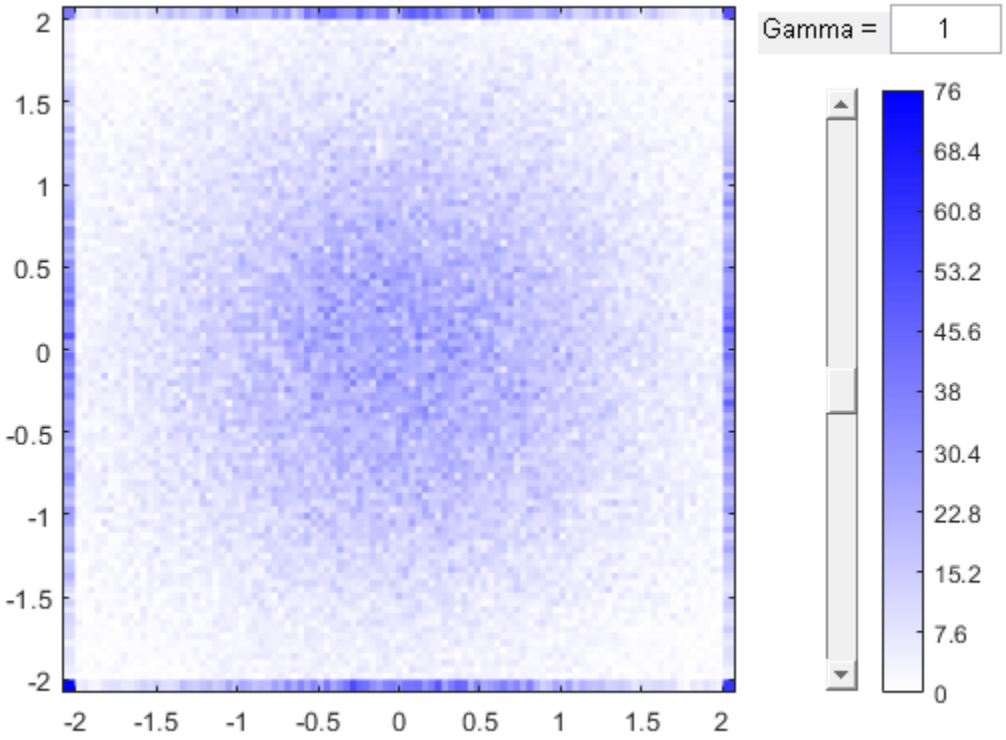
```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 1.2 sec
Evaluation completed in 1.6 sec
```



Use coarse bins extending to infinity on the edges of the plot to capture outliers.

```
Xedges = [-Inf linspace(-2,2) Inf];
Yedges = [-Inf linspace(-2,2) Inf];
binScatterPlot(X,Y,Xedges,Yedges)
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.34 sec
Evaluation completed in 0.51 sec
```



Adjust Plot Color Theme

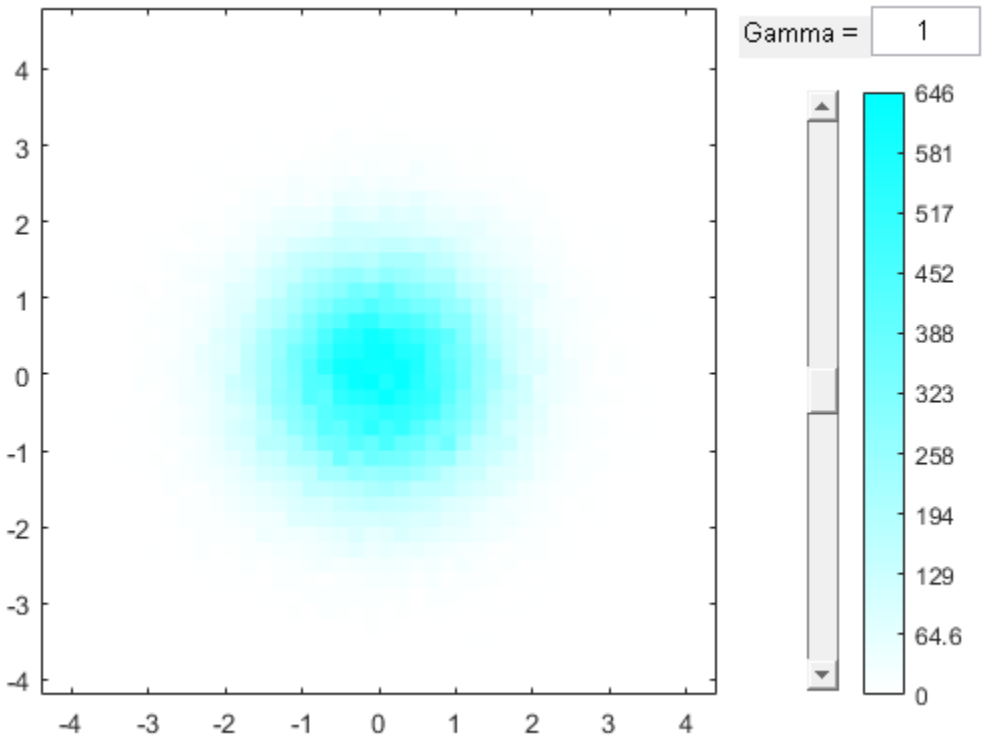
Plot a binned scatter plot of random data, specifying `'Color'` as `'c'`.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)

X = tall(randn(1e5,1));
Y = tall(randn(1e5,1));
binScatterPlot(X,Y,'Color','c')
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 1.6 sec
Evaluation completed in 3.4 sec
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 0.34 sec
Evaluation completed in 0.46 sec
```



Input Arguments

`X,Y` — Data to distribute among bins (as separate arguments)

tall vectors | tall matrices | tall multidimensional arrays

Data to distribute among bins, specified as separate arguments of tall vectors, matrices, or multidimensional arrays. `X` and `Y` must be the same size. If `X` and `Y` are not vectors, then `binScatterPlot` treats them as single column vectors, `X(:)` and `Y(:)`.

Corresponding elements in `X` and `Y` specify the *x* and *y* coordinates of 2-D data points, `[X(k),Y(k)]`. The underlying data types of `X` and `Y` can be different, but `binScatterPlot` concatenates these inputs into a single `N`-by-2 tall matrix of the dominant underlying data type.

`binScatterPlot` ignores all `NaN` values. Similarly, `binScatterPlot` ignores `Inf` and `-Inf` values, unless the bin edges explicitly specify `Inf` or `-Inf` as a bin edge.

Note If `X` or `Y` contain integers of type `int64` or `uint64` that are larger than `flintmax`, then it is recommended that you explicitly specify the bin edges.`binScatterPlot` automatically bins the input data using double precision, which lacks integer precision for numbers greater than `flintmax`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

nbins — Number of bins in each dimension
scalar | vector

Number of bins in each dimension, specified as a positive scalar integer or two-element vector of positive integers. If you do not specify `nbins`, then `binScatterPlot` automatically calculates how many bins to use based on the values in `X` and `Y`.

- If `nbins` is a scalar, then `binScatterPlot` uses that many bins in each dimension.
- If `nbins` is a vector, then `nbins(1)` specifies the number of bins in the *x*-dimension and `nbins(2)` specifies the number of bins in the *y*-dimension.

Example: `binScatterPlot(X,Y,20)` uses 20 bins in each dimension.

Example: `binScatterPlot(X,Y,[10 20])` uses 10 bins in the x-dimension and 20 bins in the y-dimension.

Xedges — Bin edges in *x*-dimension
vector

Bin edges in *x*-dimension, specified as a vector. `Xedges(1)` is the first edge of the first bin in the *x*-dimension, and `Xedges(end)` is the outer edge of the last bin.

The value `[X(k),Y(k)]` is in the `(i,j)`th bin if `Xedges(i)` ≤ `X(k)` < `Xedges(i+1)` **and** `Yedges(j)` ≤ `Y(k)` < `Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `[X(k),Y(k)]` falls into the `i`th bin in the last row if `Xedges(end-1)` ≤ `X(k)` ≤ `Xedges(end)` **and** `Yedges(i)` ≤ `Y(k)` < `Yedges(i+1)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Yedges — Bin edges in *y*-dimension
vector

Bin edges in *y*-dimension, specified as a vector. `Yedges(1)` is the first edge of the first bin in the *y*-dimension, and `Yedges(end)` is the outer edge of the last bin.

The value `[X(k),Y(k)]` is in the `(i,j)`th bin if `Xedges(i)` ≤ `X(k)` < `Xedges(i+1)` **and** `Yedges(j)` ≤ `Y(k)` < `Yedges(j+1)`. The last bins in each dimension also include the last (outer) edge. For example, `[X(k),Y(k)]` falls into the `i`th bin in the last row if `Xedges(end-1)` ≤ `X(k)` ≤ `Xedges(end)` **and** `Yedges(i)` ≤ `Y(k)` < `Yedges(i+1)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `binScatterPlot(X,Y,'BinWidth',[5 10])`

BinMethod — Binning algorithm
`'auto'` (default) | `'scott'` | `'integers'`

Binning algorithm, specified as the comma-separated pair consisting of `'BinMethod'` and one of these values.

Value	Description
`'auto'`	The default `'auto'` algorithm uses a maximum of 100 bins and chooses a bin width to cover the data range and reveal the shape of the underlying distribution.
`'scott'`	Scott's rule is optimal if the data is close to being jointly normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin size of `[3.5*std(X)*numel(X)^(-1/4), 3.5*std(Y)*numel(Y)^(-1/4)]`.
`'integers'`	The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 65536 bins (2^{16}). If the data range is greater than 65536, then the integer rule uses wider bins instead.

Note The `BinMethod` property of the resulting `Histogram2` object always has a value of `'manual'`.

`BinWidth` — Width of bins in each dimension

scalar | vector

Width of bins in each dimension, specified as the comma-separated pair consisting of `'BinWidth'` and a scalar or two-element vector of positive integers, `[xWidth yWidth]`. A scalar value indicates the same bin width for each dimension.

If you specify `BinWidth`, then `binScatterPlot` can use a maximum of 1024 bins (2^{10}) along each dimension. If instead the specified bin width requires more bins, then `binScatterPlot` uses a larger bin width corresponding to the maximum number of bins.

Example: `binScatterPlot(X,Y,'BinWidth',[5 10])` uses bins with size `5` in the `x`-dimension and size `10` in the `y`-dimension.

`Color` — Plot color theme

`'b'` (default) | `'y'` | `'m'` | `'c'` | `'r'` | `'g'` | `'k'`

Plot color theme, specified as the comma-separated pair consisting of `'Color'` and one of these options.

Option	Description
`'b'`	Blue
`'m'`	Magenta
`'c'`	Cyan
`'r'`	Red
`'g'`	Green

Option	Description
`'y'`	Yellow
`'k'`	Black

`Gamma` — Gamma correction
1 (default) | positive scalar

Gamma correction, specified as the comma-separated pair consisting of `'Gamma'` and a positive scalar. Use this option to adjust the brightness and color intensity to affect the amount of detail in the image.

- `gamma < 1` — As gamma decreases, the shading of bins with smaller bin counts becomes progressively darker, including more detail in the image.
- `gamma > 1` — As gamma increases, the shading of bins with smaller bin counts becomes progressively lighter, removing detail from the image.
- The default value of 1 does not apply any correction to the display.

`XBinLimits` — Bin limits in *x*-dimension
vector

Bin limits in *x*-dimension, specified as the comma-separated pair consisting of `'XBinLimits'` and a two-element vector, `[xbmin,xbmax]`. The vector indicates the first and last bin edges in the *x*-dimension.

`binScatterPlot` only plots data that falls within the bin limits inclusively, `Data(Data(:,1)>=xbmin & Data(:,1)<=xbmax)`.

`YBinLimits` — Bin limits in *y*-dimension
vector

Bin limits in *y*-dimension, specified as the comma-separated pair consisting of `'YBinLimits'` and a two-element vector, `[ybmin,ybmax]`. The vector indicates the first and last bin edges in the *y*-dimension.

`binScatterPlot` only plots data that falls within the bin limits inclusively, `Data(Data(:,2)>=ybmin & Data(:,2)<=ybmax)`.

Output Arguments

`h` — Binned scatter plot
`Histogram2` object

Binned scatter plot, returned as a `Histogram2` object. For more information, see Histogram2 Properties.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

biplot

Biplot

Syntax

```
biplot(coefs)
biplot(coefs,Name,Value)

biplot(ax, ___ )

h = biplot( ___ )
```

Description

`biplot(coefs)` creates a biplot of the coefficients in the matrix `coefs`. The biplot is 2-D if `coefs` has two columns or 3-D if it has three columns. The axes in the biplot represent the columns of `coefs`, and the vectors in the biplot represent the rows of `coefs` (the observed variables).

`biplot(coefs,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify `'Positive','true'` to restrict the biplot to the positive quadrant (in 2-D) or octant (in 3-D).

`biplot(ax, ___ )` uses the plot axes specified by the `Axes` object `ax`. Specify `ax` as the first input argument followed by any of the input argument combinations in the previous syntaxes.

`h = biplot( ___ )` returns a column vector of handles to the graphics objects created by `biplot`. Use `h` to query and modify properties of specific graphics objects. For more information, see Graphics Object Properties.

Examples

Biplot of Coefficients and Scores

Create a biplot of the first three principal component coefficients, the observations, and the observed variables for the `carsmall` data set.

Load the sample data.

```
load carsmall
```

Create a matrix consisting of the variables `Acceleration`, `Displacement`, `Horsepower`, `MPG`, and `Weight`. Delete rows in the matrix that have missing values.

```
X = [Acceleration Displacement Horsepower MPG Weight];
X = rmmissing(X);
```

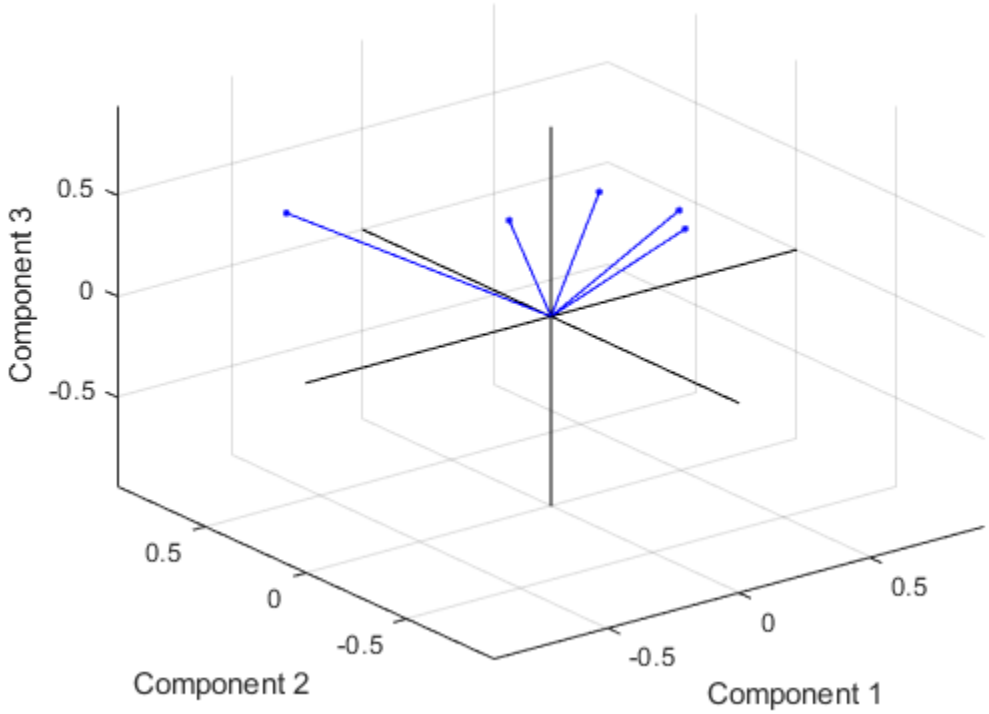
Standardize `X` and perform a principal component analysis.

```
Z = zscore(X); % Standardized data
[coefs,score] = pca(Z);
```

The 5-by-5 matrix `coefs` contains the principal component coefficients (one column for each principal component). The matrix `score` contains the principal component scores (the observations).

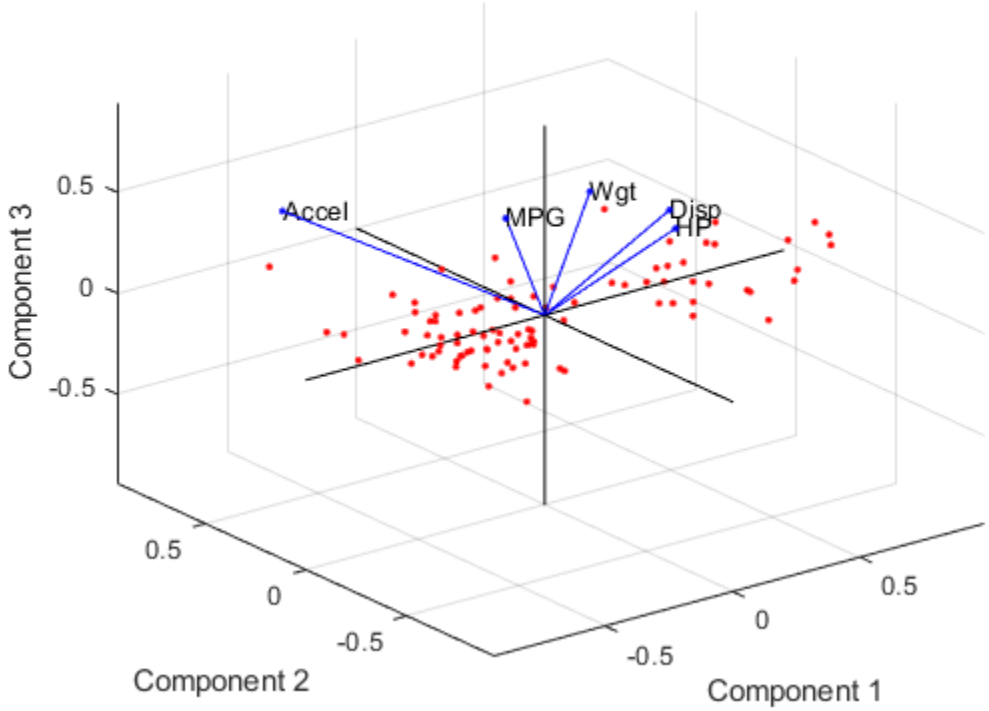
Create a biplot of the first three principal component coefficients. The axes of the biplot represent the columns of `coefs`, and the vectors in the biplot represent the rows of `coefs`.

```
biplot(coefs(:,1:3))
```



Create a more detailed biplot by labeling each variable and plotting the observations in the space of the first three principal components.

```
vbls = {'Accel','Disp','HP','MPG','Wgt'}; % Labels for the variables
biplot(coefs(:,1:3),'Scores',score(:,1:3),'VarLabels',vbls);
```



Specify Axes for Biplot

Load the `fisheriris` data set, standardize the flower measurements in `meas`, and perform a principal component analysis.

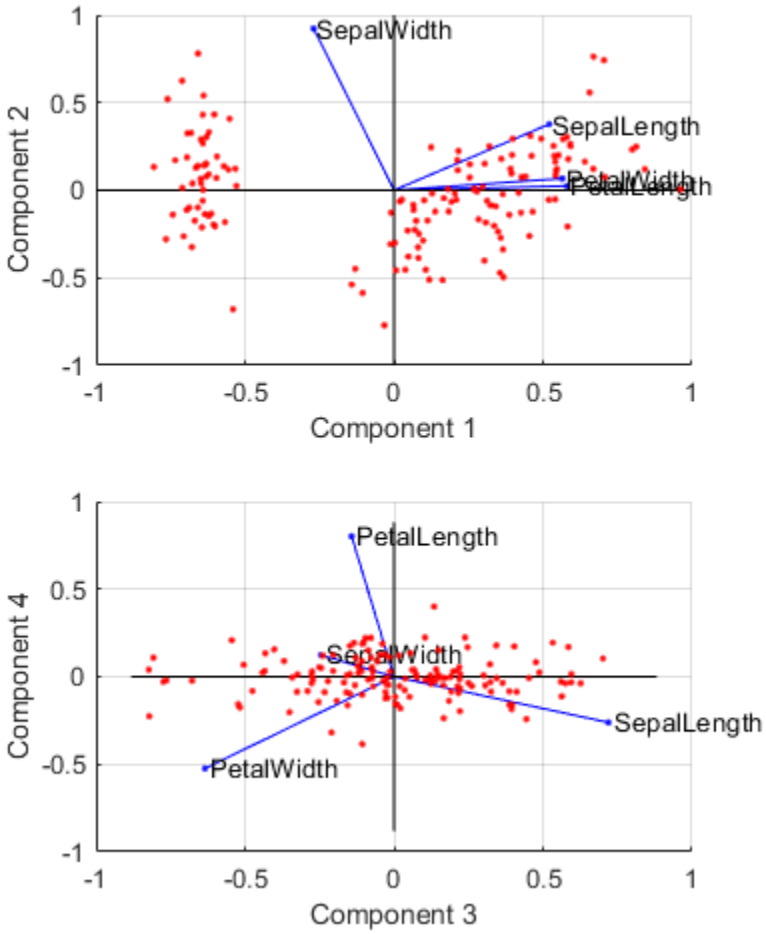
```
load fisheriris
Z = zscore(meas);
[coefs,scores] = pca(Z);
```

Create a figure with two subplots and return the `Axes` objects as `ax1` and `ax2`. Create a biplot in each set of axes by referring to the corresponding `Axes` object. In the top subplot, display a biplot using the first two principal components. In the bottom subplot, display a biplot using the third and fourth principal components. Specify the x-axis and y-axis limits by passing the corresponding `Axes` objects to the `xlim` and `ylim` functions. Change the x-axis and y-axis labels in the bottom plot by passing `ax2` to `xlabel` and `ylabel`.

```
figure('Units','normalized','Position',[0.3 0.3 0.3 0.5])
variables = {'SepalLength','SepalWidth','PetalLength','PetalWidth'};
ax1 = subplot(2,1,1); % Top subplot
biplot(ax1,coefs(:,1:2),'Scores',scores(:,1:2),'VarLabels',variables);
xlim(ax1,[-1 1])
ylim(ax1,[-1 1])

ax2 = subplot(2,1,2); % Bottom subplot
```

```
biplot(ax2,coefs(:,3:4),'Scores',scores(:,3:4),'VarLabels',variables);
xlim(ax2,[-1 1])
ylim(ax2,[-1 1])
xlabel(ax2,'Component 3')
ylabel(ax2,'Component 4')
```



Modify Biplot Properties

Control the appearance of a biplot by specifying supported line property names and values, and by using handles to the graphics objects created by `biplot`.

Load the sample data.

```
load carsmall
```

Create a matrix consisting of the variables `Acceleration`, `Displacement`, and `MPG`. Delete rows in the matrix that have missing values.

```
X = [Acceleration Displacement MPG];
X = rmmissing(X);
```

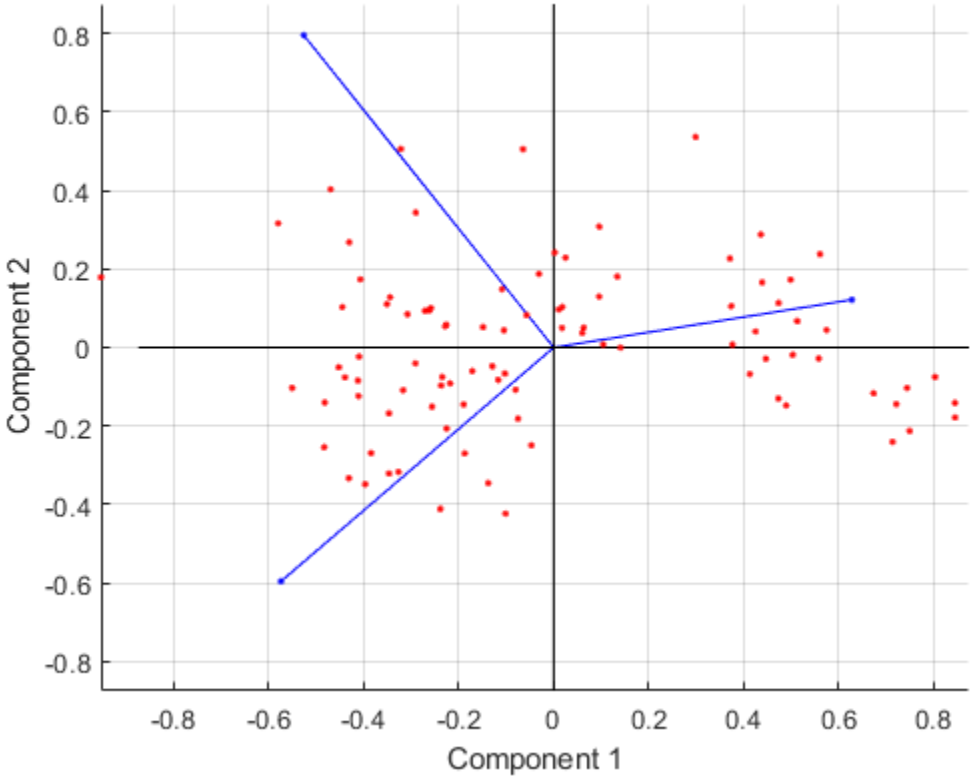
Standardize X and perform a principal component analysis.

```
Z = zscore(X); % Standardized data
[coefs,score] = pca(Z);
```

The 3-by-3 matrix `coefs` contains the principal component coefficients (one column for each principal component). The matrix `score` contains the principal component scores (the observations).

Create a biplot of the observations in the space of the first two principal components. Use the default properties for the biplot.

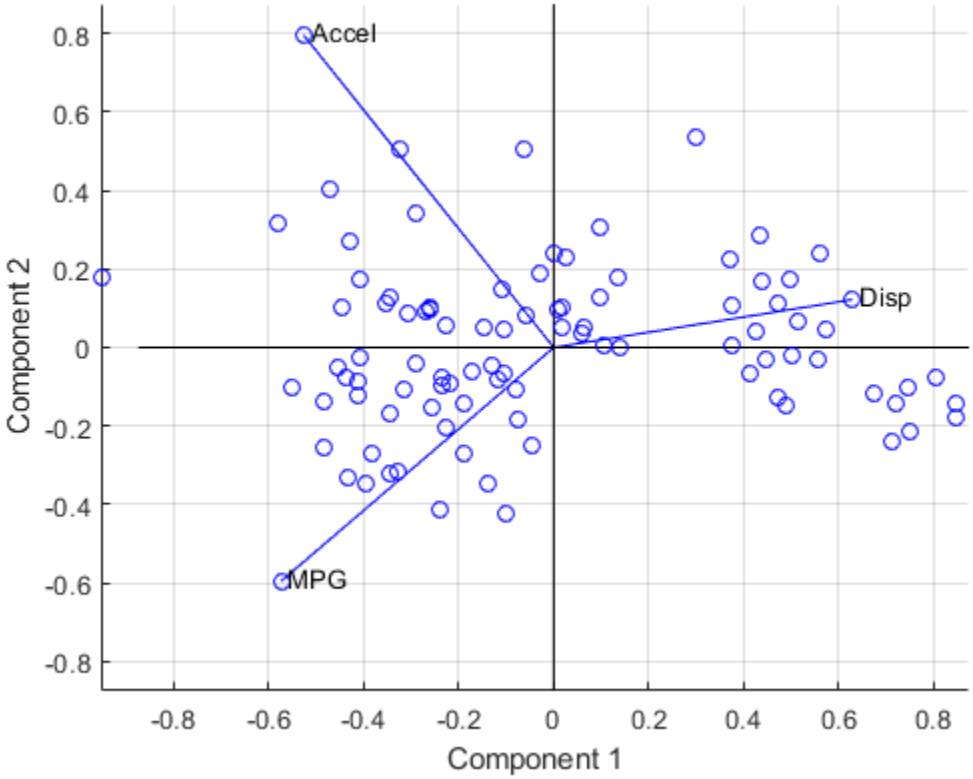
```
h = biplot(coefs(:,1:2),'Scores',score(:,1:2));
```



h is a vector of handles to graphics objects. You can modify the properties of the line objects returned by `biplot`.

Label the three variables for easy identification. Specify circles as the marker symbol and blue as the line color for all line objects.

```
vbls = {'Accel','Disp','MPG'}; % Array of variable labels
h1 = biplot(coefs(:,1:2),'Scores',score(:,1:2),...
    'Color','b','Marker','o','VarLabels',vbls);
```



`h1` is a vector of handles to graphics objects. View the first few elements of `h1`.

```
h1(1:10) % First ten object handles
```

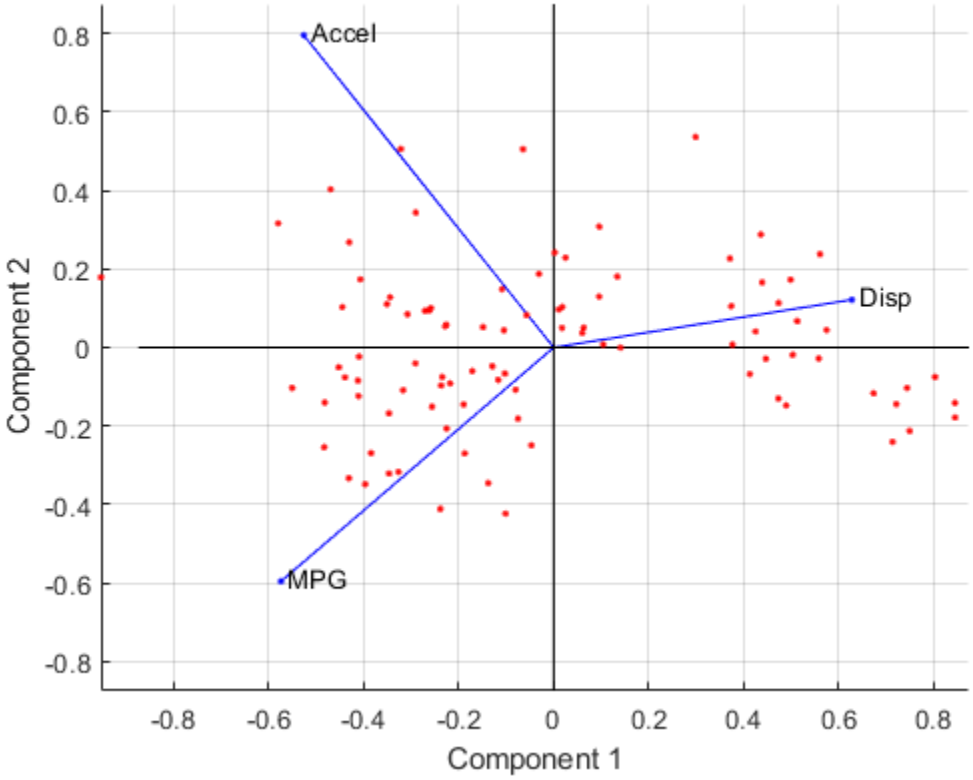
```
ans =
  10x1 graphics array:

  Line    (varline)
  Line    (varline)
  Line    (varline)
  Line    (varmarker)
  Line    (varmarker)
  Line    (varmarker)
  Text    (varlabel)
  Text    (varlabel)
  Text    (varlabel)
  Line    (obsmarker)
```

The handles for the variable labels (`h1(7:9)`) are text. Therefore, the settings specified for the line properties do not affect these labels.

Create another biplot of the observations in the space of the first two principal components, and label the three variables for easy identification.

```
h2 = biplot(coefs(:,1:2),'Scores',score(:,1:2),'VarLabels',vbls);
```



`h2` is a vector of handles to graphics objects. View the first few elements of `h2`.

```
h2(1:10) % First ten object handles
```

```
ans =
  10x1 graphics array:

  Line    (varline)
  Line    (varline)
  Line    (varline)
  Line    (varmarker)
  Line    (varmarker)
  Line    (varmarker)
  Text    (varlabel)
  Text    (varlabel)
  Text    (varlabel)
  Line    (obsmarker)
```

`h2` contains 104 object handles.

- The first three handles (`h(1:3)`) correspond to line handles for the three variables.
- Handles `h(4:6)` correspond to marker handles for the three variables.
- Handles `h(7:9)` correspond to text handles for the three variables.
- The next 94 handles correspond to line handles for the observations.

- The last handle corresponds to a line handle for the axis lines.

Modify specific properties of the biplot by using handles to the graphics objects.

Change the line color of the variables (vectors).

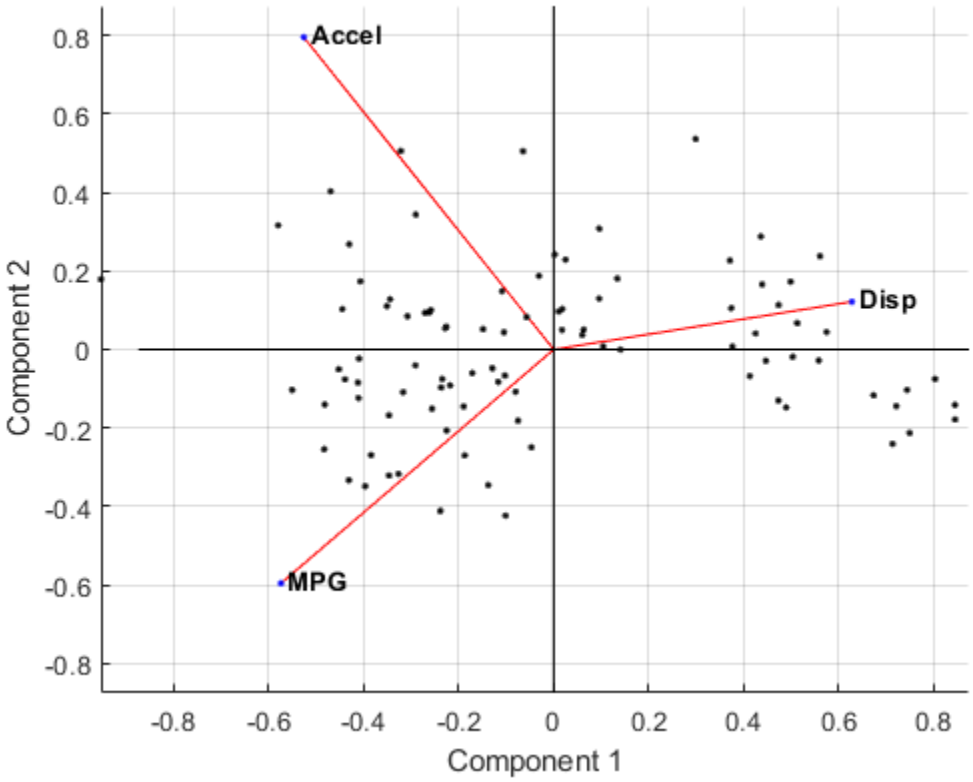
```
for k = 1:3
    h2(k).Color = 'r'; % Specify red as the line color
end
```

Modify the font of the variable labels.

```
for k = 7:9
    h2(k).FontWeight = 'bold';  % Specify bold font
end
```

Change the color of the observation markers.

```
for k = 10:103
    h2(k).MarkerEdgeColor = 'k';  % Specify black color for the observations
end
```



Input Arguments

`coefs` — Coefficients

matrix

Coefficients, specified as a matrix that has two or three columns. If `coefs` has two columns, then the biplot is 2-D; if `coefs` has three columns, then the biplot is 3-D. The columns of `coefs` usually contain principal component coefficients created with `pca` or `pcacov`, or factor loadings estimated with `factoran`. The axes in the biplot represent columns of `coefs`, and the vectors in the biplot represent rows of `coefs` (the observed variables).

Data Types: `single` | `double`

ax — Axes for plot
`Axes` object

Axes for the plot, specified as an `Axes` object. If you do not specify `ax`, then `biplot` creates the plot using the current axes. For more information on creating an `Axes` object, see `axes`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `biplot(coefs,'VarLabels',varlabels)` labels each vector (variable) with the text in the array `varlabels`.

`Scores` — Scores
matrix

Scores, specified as the comma-separated pair consisting of `'Scores'` and a matrix with the same number of columns as `coefs`. `Scores` usually contains principal component scores created with `pca` or factor scores estimated with `factoran`. The `biplot` function represents each row of `Scores` (the observations) as points and each row of `coefs` (the observed variables) as vectors.

Example: `'Scores',score(:,1:3)`

Data Types: `single` | `double`

`VarLabels` — Variable labels
character array | string array | cell array

Variable labels, specified as the comma-separated pair consisting of `'VarLabels'` and a character array, string array, or cell array. `biplot` labels each vector (observed variable) with the text in the array.

Example: `'VarLabels',varlabels`

Data Types: `char` | `string` | `cell`

`ObsLabels` — Observation labels
character array | string array | cell array

Observation labels, specified as the comma-separated pair consisting of `'ObsLabels'` and a character array, string array, or cell array. `biplot` uses the text in the array as observation names when displaying data cursors.

Example: `'ObsLabels',obslabels`

Data Types: `char` | `string` | `cell`

`Positive` — Indicator for plotting in positive coordinates
`false` (default) | `true`

Indicator for plotting in the positive coordinates, specified as the comma-separated pair consisting of `'Positive'` and one of these logical values.

Value	Description
`false`	Creates the biplot over the range `+/– max(coefs(:))` for all coordinates (default)
`true`	Restricts the biplot to the positive quadrant (in 2-D) or octant (in 3-D)

Example: `'Positive',true`

Data Types: `logical`

`PropertyName` — Property name
supported line property value

Property name, specified as the comma-separated pair consisting of a property name and its associated value for one or more supported Line Properties. These properties are the names and values for all primitive line graphics objects created by `biplot`. The specified property names control the appearance and behavior of the graphics objects.

Example: `'Marker','square','MarkerSize',10`

Output Arguments

`h` — Handles to graphics objects
column vector

Handles to the graphics objects created by `biplot`, returned as a column vector. The vector contains handles in this order:

1. Handles corresponding to variables (line handles first, followed by marker handles then text handles)
2. Handles corresponding to observations (marker handles first, followed by text handles)
3. Handles corresponding to the axis lines

You can use the handles to query and modify properties of specific graphics objects. See Graphics Object Handles and Graphics Arrays for more details.

Algorithms

A biplot allows you to visualize the magnitude and sign of each variable's contribution to the first two or three principal components, and to represent each observation in terms of those components. The `biplot` function:

- Imposes a sign convention, forcing the element with the largest magnitude in each column of `coefs` to be positive. This action flips some of the vectors in `coefs` to the opposite direction, but often makes the plot easier to read. Interpretation of the plot is unaffected, because changing the sign of a coefficient vector does not change its meaning.
- Scales the scores so that they fit on the plot. That is, the function divides each score by the maximum absolute value of all scores, and multiplies by the maximum coefficient length of `coefs`. Then `biplot` changes the sign of the score coordinates according to the sign convention for the coefficients.

bootci

Bootstrap confidence interval

Syntax

```
ci = bootci(nboot,bootfun,d)
ci = bootci(nboot,bootfun,d1,...,dN)
ci = bootci(nboot,{bootfun,d},Name,Value)
ci = bootci(nboot,{bootfun,d1,...,dN},Name,Value)
[ci,bootstat] = bootci( ___ )
```

Description

`ci = bootci(nboot,bootfun,d)` computes a 95% bootstrap confidence interval for each statistic computed by the function `bootfun`. The `bootci` function uses `nboot` bootstrap samples in its computation, and creates each bootstrap sample by sampling with replacement from the rows of `d`.

`ci = bootci(nboot,bootfun,d1,...,dN)` creates each bootstrap sample by sampling with replacement from the rows of the nonscalar data arguments in `d1,...,dN`. These nonscalar arguments must have the same number of rows. The `bootci` function passes the samples of nonscalar data and the unchanged scalar data arguments in `d1,...,dN` to `bootfun`.

`ci = bootci(nboot,{bootfun,d},Name,Value)` specifies options using one or more name-value arguments. For example, you can change the type of confidence interval by specifying the `'Type'` name-value argument.

Note that you must pass the `bootfun` and `d` arguments to `bootci` as a single cell array.

`ci = bootci(nboot,{bootfun,d1,...,dN},Name,Value)` specifies options using one or more name-value arguments. For example, you can change the significance level of the confidence interval by specifying the `'Alpha'` name-value argument.

Note that you must pass the `bootfun` and `d1,...,dN` arguments to `bootci` as a single cell array.

`[ci,bootstat] = bootci( ___ )` also returns the bootstrapped statistic computed for each of the `nboot` bootstrap replicate samples, using any of the input argument combinations in the previous syntaxes. Each row of `bootstat` contains the results of applying `bootfun` to one bootstrap sample.

Examples

Bootstrap Confidence Interval

Compute the confidence interval for the capability index in statistical process control.

Generate 30 random numbers from the normal distribution with mean 1 and standard deviation 1.

```
rng('default') % For reproducibility
y = normrnd(1,1,30,1);
```

Specify the lower and upper specification limits of the process. Define the capability index.

```
LSL = -3;
USL = 3;
capable = @(x)(USL-LSL)./(6*std(x));
```

Compute the 95% confidence interval for the capability index by using 2000 bootstrap samples. By default, `bootci` uses the bias corrected and accelerated percentile method to construct the confidence interval.

```
ci = bootci(2000,capable,y)
```

```
ci = 2×1

    0.5937
    0.9900
```

Compute the studentized confidence interval for the capability index.

```
sci = bootci(2000,{capable,y},'Type','student')
```

```
sci = 2×1

    0.5193
    0.9930
```

Bootstrap Confidence Intervals for Nonlinear Regression Model Coefficients

Compute bootstrap confidence intervals for the coefficients of a nonlinear regression model. The technique used in this example involves bootstrapping the predictor and response values, and assumes that the predictor variable is random. For a technique that assumes the predictor variable is fixed and bootstraps the residuals, see “Bootstrap Confidence Intervals for Linear Regression Model Coefficients” on page 33-203.

Note: This example uses `nlinfit`, which is useful when you only need the coefficient estimates or residuals of a nonlinear regression model and you need to repeat fitting a model multiple times, as in the case of bootstrapping. If you need to investigate a fitted regression model further, create a nonlinear regression model object by using `fitnlm`. You can create confidence intervals for the coefficients of the resulting model by using the `coefCI` object function, although this function does not use bootstrapping.

Generate data from the nonlinear regression model $y = b_1 + b_2 \cdot exp(-b_3 x) + \epsilon$, where $b_1 = 1$, $b_2 = 3$, and $b_3 = 2$ are coefficients; the predictor variable x is exponentially distributed with mean 2; and the error term ϵ is normally distributed with mean 0 and standard deviation 0.1.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));

rng('default') % For reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Create a function handle for the nonlinear regression model that uses the initial values in `beta0`.

```
beta0 = [2;2;2];
beta = @(predictor,response)nlinfit(predictor,response,modelfun,beta0)
```

```
beta = function_handle with value:
    @(predictor,response)nlinfit(predictor,response,modelfun,beta0)
```

Compute the 95% bootstrap confidence intervals for the coefficients of the nonlinear regression model. Create the bootstrap samples from the generated data `x` and `y`.

```
ci = bootci(1000,beta,x,y)
```

```
ci = 2×3

    0.9821    2.9552    2.0180
    1.0410    3.1623    2.2695
```

The first two confidence intervals include the true coefficient values $b_1 = 1$ and $b_2 = 3$, respectively. However, the third confidence interval does not include the true coefficient value $b_3 = 2$.

Now compute the 99% bootstrap confidence intervals for the model coefficients.

```
newci = bootci(1000,{beta,x,y},'Alpha',0.01)
```

```
newci = 2×3

    0.9730    2.9112    1.9562
    1.0469    3.1876    2.3133
```

All three confidence intervals include the true coefficient values.

Bootstrap Confidence Intervals for Linear Regression Model Coefficients

Compute bootstrap confidence intervals for the coefficients of a linear regression model. The technique used in this example involves bootstrapping the residuals and assumes that the predictor variable is fixed. For a technique that assumes the predictor variable is random and bootstraps the predictor and response values, see “Bootstrap Confidence Intervals for Nonlinear Regression Model Coefficients” on page 33-202.

Note: This example uses `regress`, which is useful when you only need the coefficient estimates or residuals of a regression model and you need to repeat fitting a model multiple times, as in the case of bootstrapping. If you need to investigate a fitted regression model further, create a linear regression model object by using `fitlm`. You can create confidence intervals for the coefficients of the resulting model by using the `coefCI` object function, although this function does not use bootstrapping.

Load the sample data.

```
load hald
```

Perform a linear regression and compute the residuals.

```
x = [ones(size(heat)),ingredients];
y = heat;
b = regress(y,x);
yfit = x*b;
resid = y - yfit;
```

Compute the 95% bootstrap confidence intervals for the coefficients of the linear regression model. Create the bootstrap samples from the residuals. Use normal approximated intervals with bootstrapped bias and standard error by specifying `'Type','normal'`. You cannot use the default confidence interval type in this case.

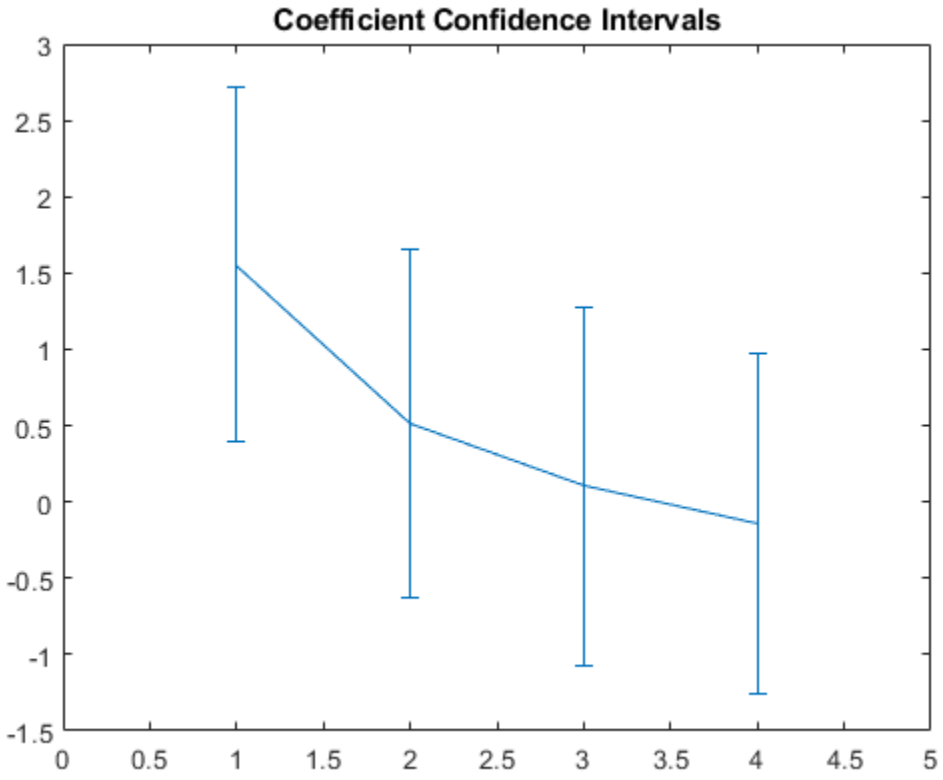
```
ci = bootci(1000,{@(bootr)regress(yfit+bootr,x),resid}, ...
    'Type','normal')
```

```
ci = 2×5

  -47.7130    0.3916   -0.6298   -1.0697   -1.2604
  172.4899    2.7202    1.6495    1.2778    0.9704
```

Plot the estimated coefficients `b`, omitting the intercept term, and display error bars showing the coefficient confidence intervals.

```
slopes = b(2:end)';
lowerBarLengths = slopes-ci(1,2:end);
upperBarLengths = ci(2,2:end)-slopes;
errorbar(1:4,slopes,lowerBarLengths,upperBarLengths)
xlim([0 5])
title('Coefficient Confidence Intervals')
```



Only the first nonintercept coefficient is significantly different from 0.

Confidence Intervals for Multiple Statistics

Compute the mean and standard deviation of 100 bootstrap samples. Find the 95% confidence interval for each statistic.

Generate 100 random numbers from the exponential distribution with mean 5.

```
rng('default') % For reproducibility
y = exprnd(5,100,1);
```

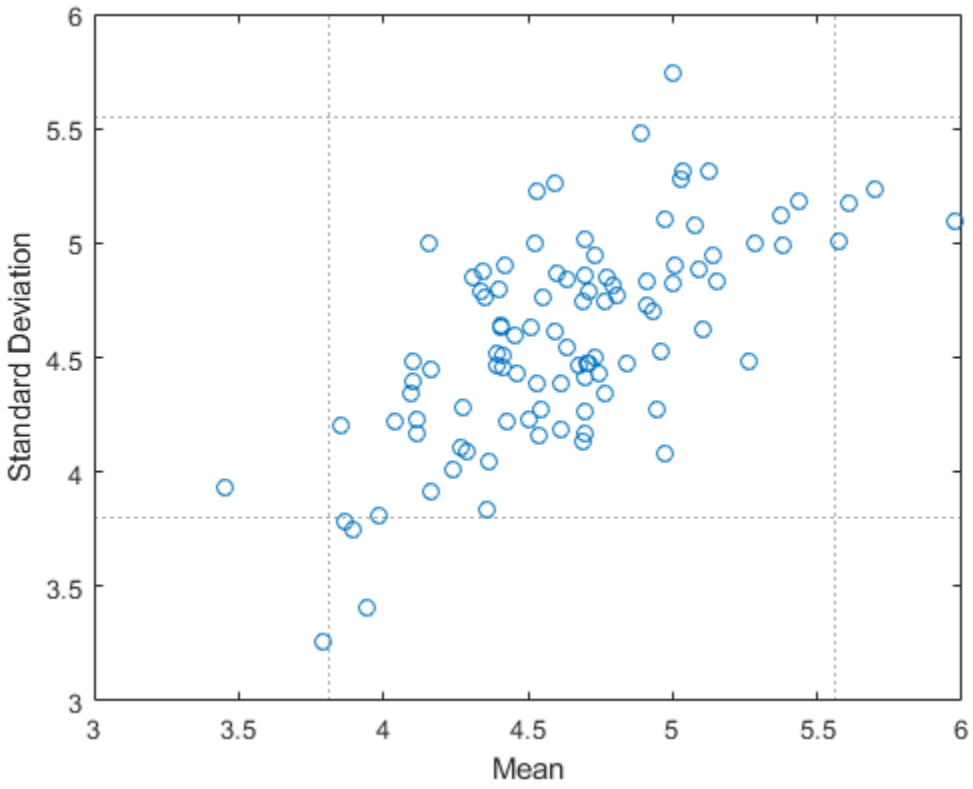
Draw 100 bootstrap samples from the vector `y`. For each bootstrap sample, compute the mean and standard deviation. Find the 95% bootstrap confidence interval for the mean and standard deviation.

```
[ci,bootstat] = bootci(100,@(x)[mean(x) std(x)],y);
```

`ci(:,1)` contains the lower and upper bounds of the mean confidence interval, and `c(:,2)` contains the lower and upper bounds of the standard deviation confidence interval. Each row of `bootstat` contains the mean and standard deviation of a bootstrap sample.

Plot the mean and standard deviation of each bootstrap sample as a point. Plot the lower and upper bounds of the mean confidence interval as dotted vertical lines, and plot the lower and upper bounds of the standard deviation confidence interval as dotted horizontal lines.

```
plot(bootstat(:,1),bootstat(:,2),'o')
xline(ci(1,1),':')
xline(ci(2,1),':')
yline(ci(1,2),':')
yline(ci(2,2),':')
xlabel('Mean')
ylabel('Standard Deviation')
```



Input Arguments

nboot — Number of bootstrap samples

positive integer scalar

Number of bootstrap samples to draw, specified as a positive integer scalar. To create each bootstrap sample, `bootci` randomly selects with replacement `n` out of the `n` rows of nonscalar data in `d` or `d1,...,dN`.

Example: `100`

Data Types: `single` | `double`

bootfun — Function to apply to each sample

function handle

Function to apply to each sample, specified as a function handle. The function can be a custom or built-in function. You must specify `bootfun` with the `@` symbol.

Example: `@mean`

Data Types: `function_handle`

d — Data to sample from

column vector | matrix

Data to sample from, specified as a column vector or matrix. The `n` rows of `d` correspond to observations. When you use multiple data input arguments `d1,...,dN`, you can specify some arguments as scalar values, but all nonscalar arguments must have the same number of rows.

If you use a single vector argument `d`, you can specify it as a row vector. `bootci` then samples from the elements of the vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `bootci(100,{@mean,1:6'},'Alpha',0.1)` specifies to draw 100 bootstrap samples from the values 1 through 6, take the mean of each sample, and then compute the 90% confidence interval for the sample mean.

Alpha — Significance level

`0.05` (default) | positive scalar in (0,1)

Significance level, specified as a positive scalar between 0 and 1. `bootci` computes the `100*(1-Alpha)` bootstrap confidence interval of each statistic defined by the function `bootfun`.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

Type — Confidence interval type

`'bca'` (default) | `'norm'` | `'per'` | `'cper'` | `'stud'` | ...

Confidence interval type, specified as one of the values in this table.

Value	Description
`'norm'` or `'normal'`	Normal approximated interval with bootstrapped bias and standard error [1]
`'per'` or `'percentile'`	Basic percentile method
`'cper'` or `'corrected percentile'`	Bias corrected percentile method [2]
`'bca'`	Bias corrected and accelerated percentile method [3], [4] — Involves a z_0 factor that is computed using the proportion of bootstrap values that are less than the original sample value. To produce reasonable results when the sample is lumpy, the software computes z_0 by including half of the bootstrap values that are the same as the original sample value.

Value	Description
`'stud'` or `'student'`	Studentized confidence interval [3]

Example: `'Type','student'`

`NBootStd` — Number of bootstrap samples for studentized standard error estimate
`100` (default) | positive integer scalar

Number of bootstrap samples for the studentized standard error estimate, specified as a positive integer scalar.

`bootci` computes the studentized bootstrap confidence interval of the statistic defined by the function `bootfun`, and estimates the standard error of the bootstrap statistics by using `NBootStd` bootstrap data samples.

Note To use this name-value argument, the `Type` value must be `'stud'` or `'student'`. Specify either `NBootStd` or `StdErr`, but not both.

Example: `'NBootStd',50`

Data Types: `single` | `double`

`StdErr` — Function used to compute studentized standard error estimate
function handle

Function used to compute the studentized standard error estimate, specified as a function handle.

`bootci` computes the studentized bootstrap confidence interval of the statistic defined by the function `bootfun`, and estimates the standard error of the bootstrap statistics by using the function `StdErr`. The `StdErr` function must take the same arguments as `bootfun` and return the standard error of the statistic computed by `bootfun`.

Note To use this name-value argument, the `Type` value must be `'stud'` or `'student'`. Specify either `NBootStd` or `StdErr`, but not both.

Example: `'StdErr',@std`

Data Types: `function_handle`

`Weights` — Observation weights
`ones(n,1)/n` (default) | nonnegative vector

Observation weights, specified as a nonnegative vector with at least one positive element. The number of elements in `Weights` must be equal to the number of rows `n` in the data `d` or `d1,...,dN`. To obtain one bootstrap sample, `bootci` randomly selects with replacement `n` out of `n` rows of data using these weights as multinomial sampling probabilities.

Data Types: `single` | `double`

`Options` — Options for computing iterations in parallel and setting random numbers
structure

Options for computing bootstrap iterations in parallel and setting random numbers during the bootstrap sampling, specified as a structure. Create the `Options` structure with `statset`. This table lists the option fields and their values.

Field Name	Value	Default
`UseParallel`	Set this value to `true` to compute bootstrap iterations in parallel.	`false`
`UseSubstreams`	Set this value to `true` to run computations in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type that allows substreams: `'mlfg6331_64'` or `'mrg32k3a'`.	`false`
`Streams`	Specify this value as a `RandStream` object or cell array of such objects. Use a single object except when the `UseParallel` value is `true` and the `UseSubstreams` value is `false`. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify `Streams`, then `bootci` uses the default stream or streams.

Note You need Parallel Computing Toolbox to run computations in parallel.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Output Arguments

`ci` — Confidence interval bounds

vector with two rows | matrix with two rows | multidimensional array with two rows

Confidence interval bounds, returned as a vector, matrix, or multidimensional array with two rows.

- If `bootfun` returns a scalar, then `ci` is a vector containing the lower and upper bounds of the confidence interval.
- If `bootfun` returns a vector of length *m*, then `ci` is a matrix of size 2-by-*m*, where `ci(1,:)` are lower bounds and `ci(2,:)` are upper bounds.
- If `bootfun` returns a multidimensional array, then `ci` is an array, where `ci(1,:,...)` is an array of lower bounds and `ci(2,:,...)` is an array of upper bounds.

`bootstat` — Bootstrap statistics

column vector | matrix

Bootstrap statistics, returned as a column vector or matrix with `nboot` rows. The `i`th row of `bootstat` corresponds to the results of applying `bootfun` to the `i`th bootstrap sample. If `bootfun`

returns a matrix or array, then the `bootci` function first converts this output to a row vector before storing it in `bootstat`.

Introduced in R2006a

bootstrp

Bootstrap sampling

Syntax

```
bootstat = bootstrp(nboot,bootfun,d)
bootstat = bootstrp(nboot,bootfun,d1,...,dN)
bootstat = bootstrp(___,Name,Value)
[bootstat,bootsam] = bootstrp(___)
```

Description

`bootstat = bootstrp(nboot,bootfun,d)` draws `nboot` bootstrap data samples from `d`, computes statistics on each sample using the function `bootfun`, and returns the results in `bootstat`. The `bootstrp` function creates each bootstrap sample by sampling with replacement from the rows of `d`. Each row of the output argument `bootstat` contains the results of applying `bootfun` to one bootstrap sample.

`bootstat = bootstrp(nboot,bootfun,d1,...,dN)` draws `nboot` bootstrap samples from the data in `d1,...,dN`. The nonscalar data arguments in `d1,...,dN` must have the same number of rows, `n`. The `bootstrp` function creates each bootstrap sample by sampling with replacement from the indices `1:n` and selecting the corresponding rows of the nonscalar `d1,...,dN`. The function passes the sample of nonscalar data and the unchanged scalar data arguments in `d1,...,dN` to `bootfun`.

`bootstat = bootstrp(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can add observation weights to your data or compute bootstrap iterations in parallel.

`[bootstat,bootsam] = bootstrp(___)` also returns `bootsam`, an `n`-by-`nboot` matrix of bootstrap sample indices, where `n` is the number of rows in the original, nonscalar data. Each column in `bootsam` corresponds to one bootstrap sample and contains the row indices of the values drawn from the nonscalar data to create that sample.

To get the bootstrap sample indices without applying a function to the samples, set `bootfun` to empty (`[]`).

Examples

Estimate Density of Bootstrapped Statistic

Estimate the kernel density of bootstrapped means.

Generate 100 random numbers from the exponential distribution with mean 5.

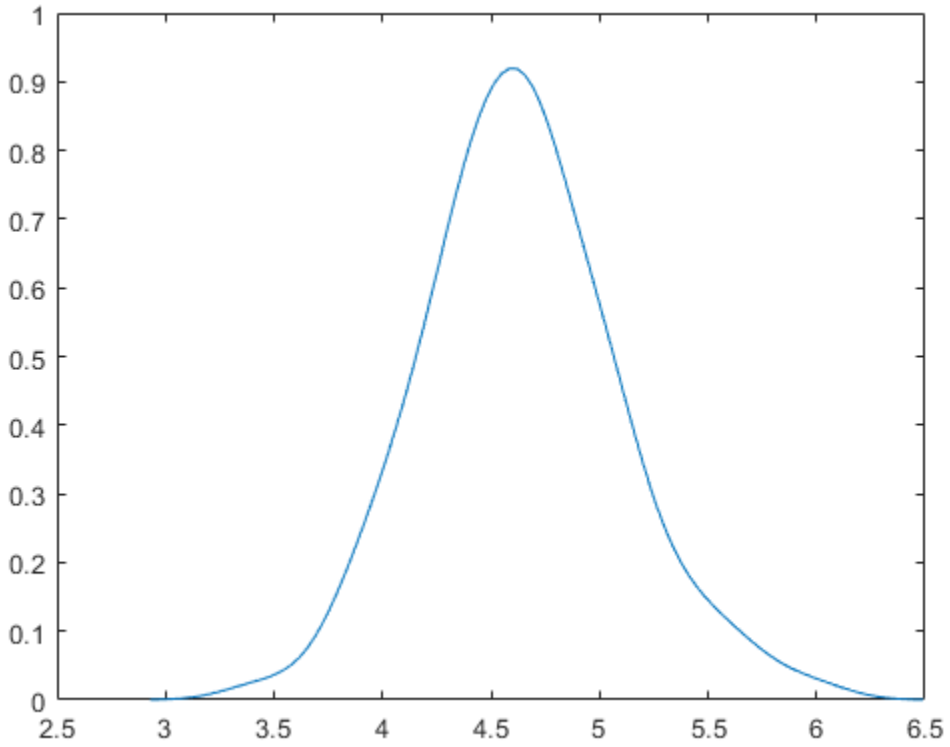
```
rng('default')  % For reproducibility
y = exprnd(5,100,1);
```

Compute a sample of 100 bootstrapped means of random samples taken from the vector `y`.

```
m = bootstrp(100,@mean,y);
```

Plot an estimate of the density of the bootstrapped means.

```
[fi,xi] = ksdensity(m);
plot(xi,fi)
```



Bootstrapping Multiple Statistics

Compute and plot the means and standard deviations of 100 bootstrap samples.

Generate 100 random numbers from the exponential distribution with mean 5.

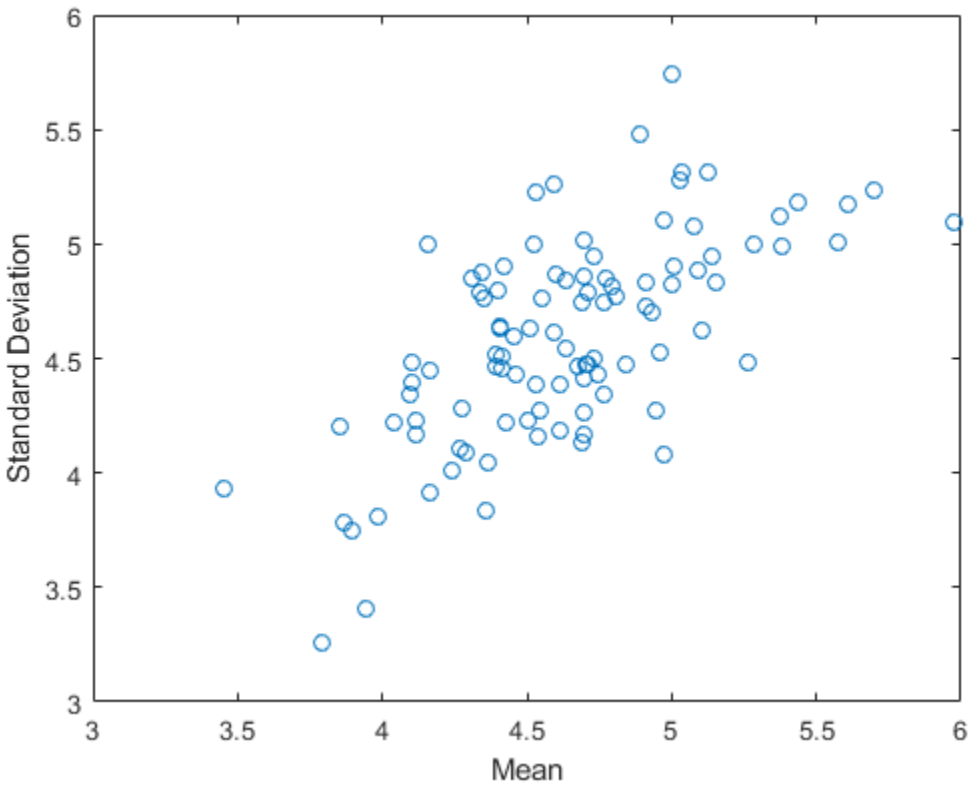
```
rng('default')  % For reproducibility
y = exprnd(5,100,1);
```

Compute a sample of 100 bootstrapped means and standard deviations of random samples taken from the vector `y`.

```
stats = bootstrp(100,@(x)[mean(x) std(x)],y);
```

Plot the bootstrap estimate pairs.

```
plot(stats(:,1),stats(:,2),'o')
xlabel('Mean')
ylabel('Standard Deviation')
```



Bootstrap Samples of Observations

Take bootstrap samples of patient data, compute the mean measurements for each data sample, and visualize the results.

Load the `patients` data set. Create the matrix `patientData` containing age, weight, and height measurements. Each row of `patientData` corresponds to one patient.

```
load patients
patientData = [Age Weight Height];
```

Create 200 bootstrap data samples from the data in `patientData`. To create each sample, randomly select with replacement 100 rows (that is, `size(patientData,1)`) from the rows in `patientData`. For each sample, calculate the mean age, weight, and height measurements. Each row of `bootstat` contains the three mean measurements for one bootstrap sample.

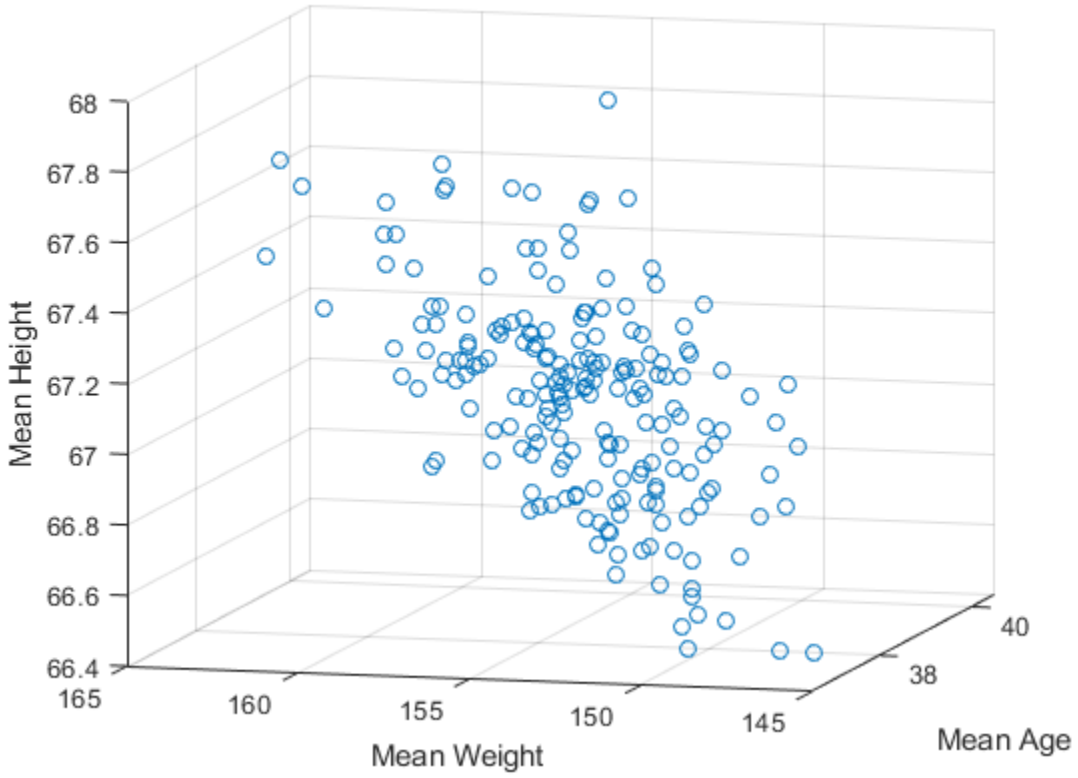
```
rng('default') % For reproducibility
bootstat = bootstrp(200,@mean,patientData);
```

Visualize the mean measurements for all 200 bootstrap data samples. Note that bootstrap samples with greater mean weights tend to have greater mean heights.

```
scatter3(bootstat(:,1),bootstat(:,2),bootstat(:,3))
xlabel('Mean Age')
```

```
ylabel('Mean Weight')
zlabel('Mean Height')

view([-75 10])
```



Bootstrapping Correlation Coefficient Standard Error

Compute a correlation coefficient standard error using bootstrap resampling of the sample data.

Load the `lawdata` data set, which contains the LSAT score and law school GPA for 15 students.

```
load lawdata
rng('default')  % For reproducibility
size(lsat)
```

```
ans = 1×2

    15     1
```

```
size(gpa)
```

```
ans = 1×2

    15     1
```

Create 1000 data samples by resampling the 15 data points, and compute the correlation between the two variables for each data sample.

```
[bootstat,bootsam] = bootstrp(1000,@corr,lsat,gpa);
```

Display the first 5 bootstrapped correlation coefficients.

```
bootstat(1:5,:)
```

```
ans = 5×1

    0.9874
    0.4918
    0.5459
    0.8458
    0.8959
```

Display the indices of the data selected for the first 5 bootstrap samples.

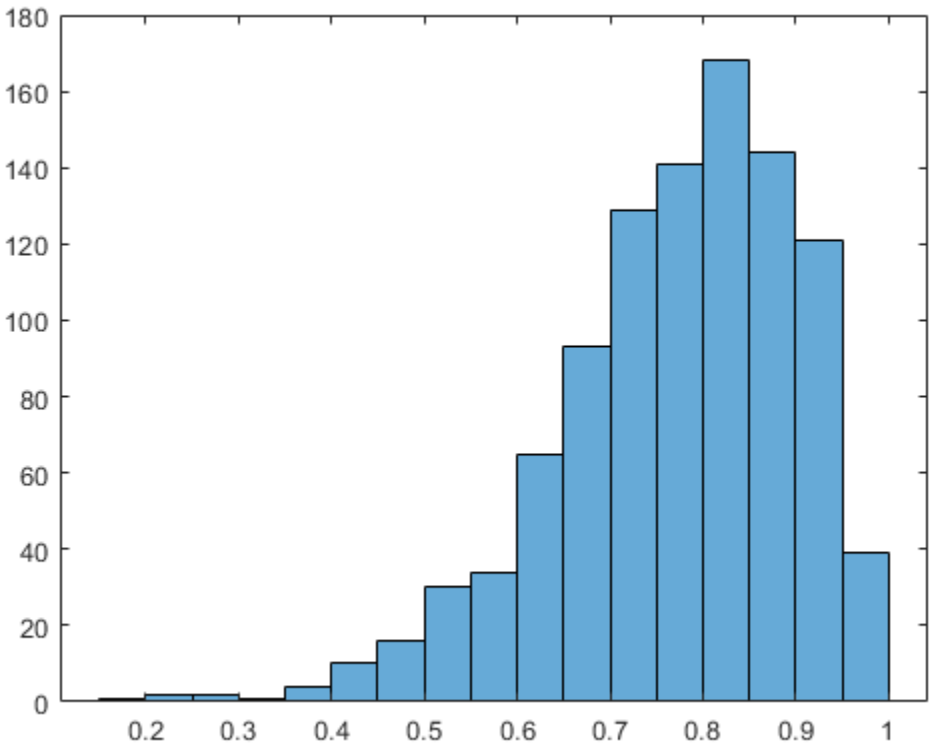
```
bootsam(:,1:5)
```

```
ans = 15×5

    13     3    11     8    12
    14     7     1     7     4
     2    14     5    10     8
    14    12     1    11    11
    10    15     2    12    14
     2    10    13     5    15
     5     1    11    11     9
     9    13     5    10     3
    15    15    15     3     3
    15    11     1     2     4
     ⋮
```

Create a histogram that shows the variation of the correlation coefficient across all the bootstrap samples.

```
histogram(bootstat)
```



The sample minimum is positive, indicating that the relationship between LSAT score and GPA is not accidental.

Finally, compute a bootstrap standard of error for the estimated correlation coefficient.

```
se = std(bootstat)
```

```
se = 0.1285
```

Compare Bootstrap Samples with Different Observation Weights

Compare bootstrap samples with different observation weights. Create a custom function that computes statistics for each sample.

Create 50 bootstrap samples from the numbers 1 through 6. To create each sample, `bootstrp` randomly chooses with replacement from the numbers 1 through 6, six times. This process is similar to rolling a die six times. For each sample, the custom function `countfun` (shown at the end of this example) counts the number of 1s in the sample.

```
rng('default') %For reproducibility
counts = bootstrp(50,@countfun,(1:6)');
```

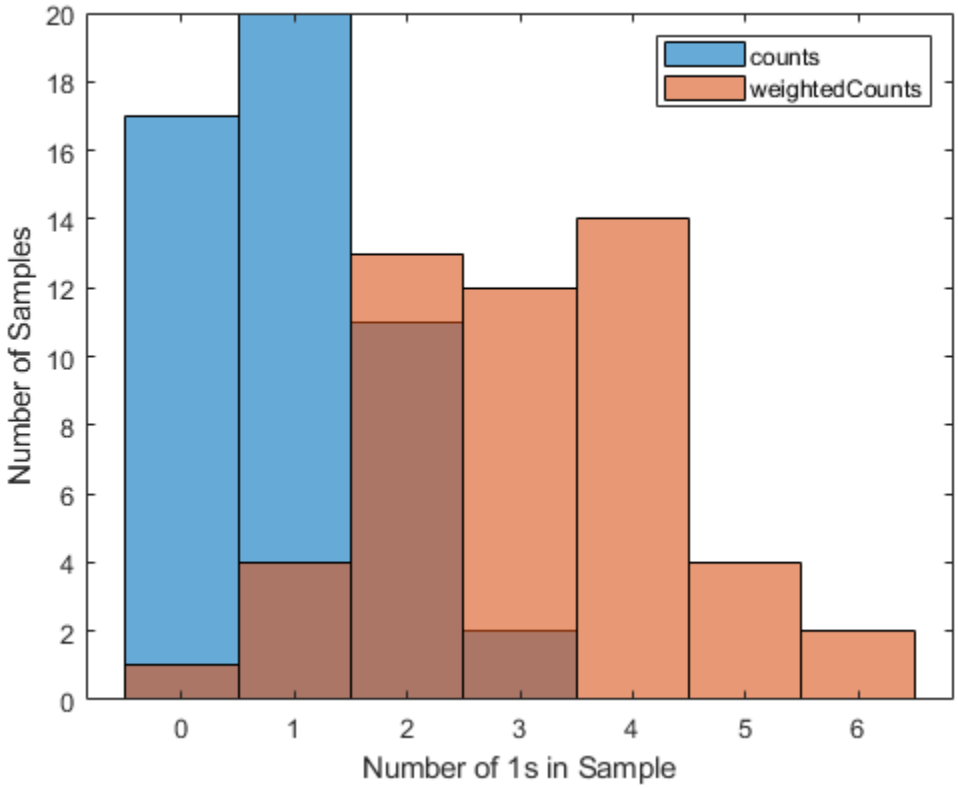
Note: If you use the live script file for this example, the `countfun` function is already included at the end of the file. Otherwise, you need to create this function at the end of your .m file or add it as a file on the MATLAB® path.

Create 50 bootstrap samples from the numbers 1 through 6, but assign different weights to the numbers. Each time `bootstrp` randomly chooses from the numbers 1 through 6, the probability of choosing a 1 is `0.5`, the probability of choosing a 2 is `0.1`, and so on. Again, `countfun` counts the number of 1s in each sample.

```
weights = [0.5 0.1 0.1 0.1 0.1 0.1]';
weightedCounts = bootstrp(50,@countfun,(1:6)','Weights',weights);
```

Compare the two sets of bootstrap samples by using histograms.

```
histogram(counts)
hold on
histogram(weightedCounts)
legend
xlabel('Number of 1s in Sample')
ylabel('Number of Samples')
hold off
```



The two sets of bootstrap samples have different distributions; in particular, the samples in the second set tend to contain more 1s. For example, of the 50 samples in the first set, only two samples contain more than two 1s. By contrast, of the 50 samples in the second set (with observation weights), 12 + 14 + 4 + 2 = 32 samples contain more than two 1s.

This code creates the function `countfun`.

```
function numberofones = countfun(sample)
numberofones = sum(sample == 1);
end
```

Bootstrapping Regression Model

Estimate the standard errors for a coefficient vector in a linear regression by bootstrapping the residuals.

Note: This example uses `regress`, which is useful when you simply need the coefficient estimates or residuals of a regression model and you need to repeat fitting a model multiple times, as in the case of bootstrapping. If you need to investigate a fitted regression model further, create a linear regression model object by using `fitlm`.

Load the sample data.

```
load hald
```

Perform a linear regression, and compute the residuals.

```
x = [ones(size(heat)),ingredients];
y = heat;
b = regress(y,x);
yfit = x*b;
resid = y - yfit;
```

Estimate the standard errors by bootstrapping the residuals.

```
se = std(bootstrp(1000,@(bootr)regress(yfit+bootr,x),resid))
```

```
se = 1×5

   56.1752    0.5940    0.5815    0.5989    0.5691
```

Input Arguments

`nboot` — Number of bootstrap samples

positive integer scalar

Number of bootstrap samples to draw, specified as a positive integer scalar. To create each bootstrap sample, `bootstrp` randomly selects with replacement `n` out of the `n` rows of (nonscalar) data in `d` or `d1,...,dN`.

Example: `100`

Data Types: `single` | `double`

`bootfun` — Function to apply to each sample

function handle

Function to apply to each sample, specified as a function handle. The function can be a custom or built-in function. You must specify `bootfun` with the `@` symbol.

For an example that uses a custom function, see “Compare Bootstrap Samples with Different Observation Weights” on page 33-216.

Example: `@mean`

Data Types: `function_handle`

`d` — Data to sample from

column vector | matrix

Data to sample from, specified as a column vector or matrix. The `n` rows of `d` correspond to observations. When you use multiple data input arguments `d1,...,dN`, you can specify some arguments as scalar values, but all nonscalar arguments must have the same number of rows.

If you use a single vector argument `d`, you can specify it as a row vector. `bootstrp` then samples from the elements of the vector.

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `bootstrp(4,@mean,(1:2)','Weights',[0.4 0.6]')` specifies to draw four bootstrap samples from the values `1` and `2` and take the mean of each sample. For each draw, the probability of getting a `1` is `0.4`, and the probability of getting a `2` is `0.6`.

`Weights` — Observation weights

`ones(n,1)/n` (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a nonnegative vector with at least one positive element. The number of elements in `Weights` must be equal to the number of rows `n` in the data `d` or `d1,...,dN`. To obtain one bootstrap sample, `bootstrp` randomly selects with replacement `n` out of `n` rows of data using the weights as multinomial sampling probabilities.

Data Types: `single` | `double`

`Options` — Options for computing in parallel and setting random numbers

structure

Options for computing bootstrap iterations in parallel and setting random numbers during the bootstrap sampling, specified as the comma-separated pair consisting of `'Options'` and a structure. Create the `Options` structure with `statset`. This table lists the option fields and their values.

Field Name	Value	Default
`UseParallel`	Set this value to `true` to compute bootstrap iterations in parallel.	`false`
`UseSubstreams`	Set this value to `true` to run computations in parallel in a reproducible manner. To compute reproducibly, set `Streams` to a type that allows substreams: `'mlfg6331_64'` or `'mrg32k3a'`.	`false`

Field Name	Value	Default
`Streams`	Specify this value as a `RandStream` object or cell array of such objects. Use a single object except when the `UseParallel` value is `true` and the `UseSubstreams` value is `false`. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify `Streams`, then `bootstrp` uses the default stream or streams.

Note You need Parallel Computing Toolbox to run computations in parallel.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Output Arguments

`bootstat` — Bootstrap sample statistics

column vector | matrix

Bootstrap sample statistics, returned as a column vector or matrix with `nboot` rows. The `i`th row of `bootstat` corresponds to the results of applying `bootfun` to the `i`th bootstrap sample. If `bootfun` returns a matrix or array, then the `bootstrp` function first converts this output to a row vector before storing it in `bootstat`.

`bootsam` — Bootstrap sample indices

numeric matrix

Bootstrap sample indices, returned as an `n`-by-`nboot` numeric matrix, where `n` is the number of rows in the original, nonscalar data. Each column in `bootsam` corresponds to one bootstrap sample and contains the row indices of the values drawn from the nonscalar data to create that sample.

For example, if each data input argument in `d1,...,dN` contains 16 values, and `nboot = 4`, then `bootsam` is a 16-by-4 matrix. The first column contains the indices of the 16 values drawn from `d1,...,dN` for the first bootstrap sample, the second column contains the indices for the second bootstrap sample, and so on. The bootstrap indices are the same for all input data sets `d1,...,dN`.

Tips

- To get the bootstrap sample indices `bootsam` without applying a function to the samples, set `bootfun` to empty (`[]`).

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Resampling Statistics” on page 3-14

Introduced before R2006a

boxplot

Visualize summary statistics with box plot

Syntax

```
boxplot(x)
boxplot(x,g)

boxplot(ax, ___ )

boxplot( ___ ,Name,Value)
```

Description

`boxplot(x)` creates a box plot of the data in `x`. If `x` is a vector, `boxplot` plots one box. If `x` is a matrix, `boxplot` plots one box for each column of `x`.

On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively. The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the `'+'` symbol.

`boxplot(x,g)` creates a box plot using one or more grouping variables contained in `g`. `boxplot` produces a separate box for each set of `x` values that share the same `g` value or values.

`boxplot(ax, ___ )` creates a box plot using the axes specified by the axes graphic object `ax`, using any of the previous syntaxes.

`boxplot( ___ ,Name,Value)` creates a box plot with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the box style or order.

Examples

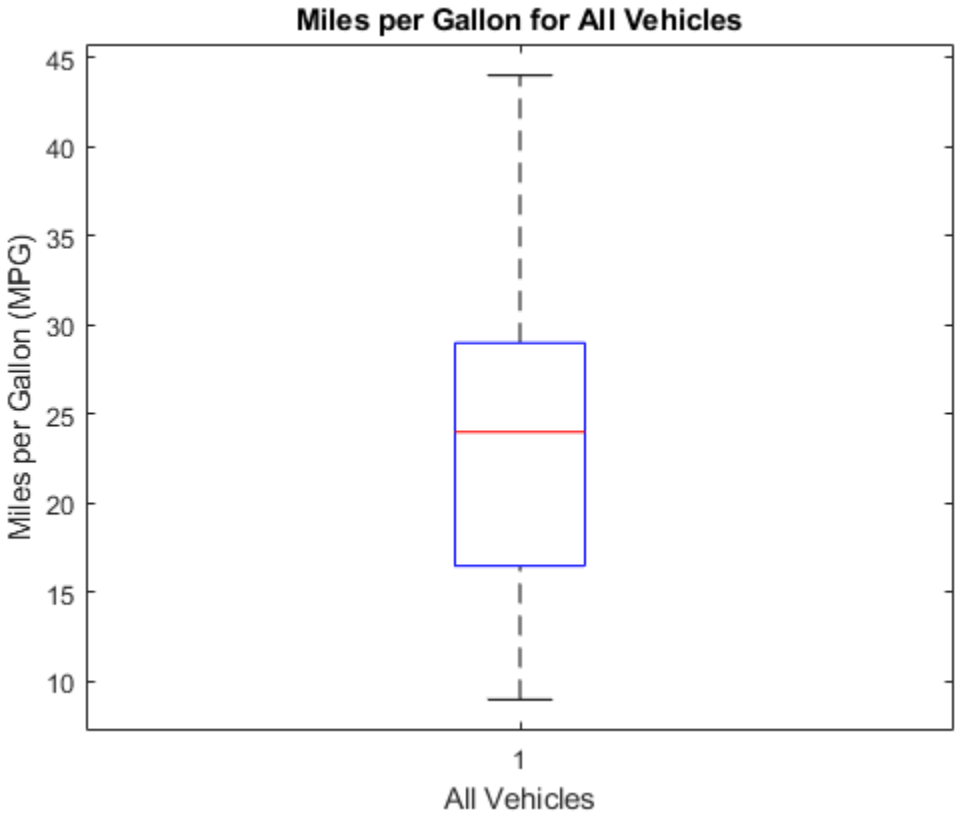
Create a Box Plot

Load the sample data.

```
load carsmall
```

Create a box plot of the miles per gallon (`MPG`) measurements. Add a title and label the axes.

```
boxplot(MPG)
xlabel('All Vehicles')
ylabel('Miles per Gallon (MPG)')
title('Miles per Gallon for All Vehicles')
```



The boxplot shows that the median miles per gallon for all vehicles in the sample data is approximately 24. The minimum value is about 9, and the maximum value is about 44.

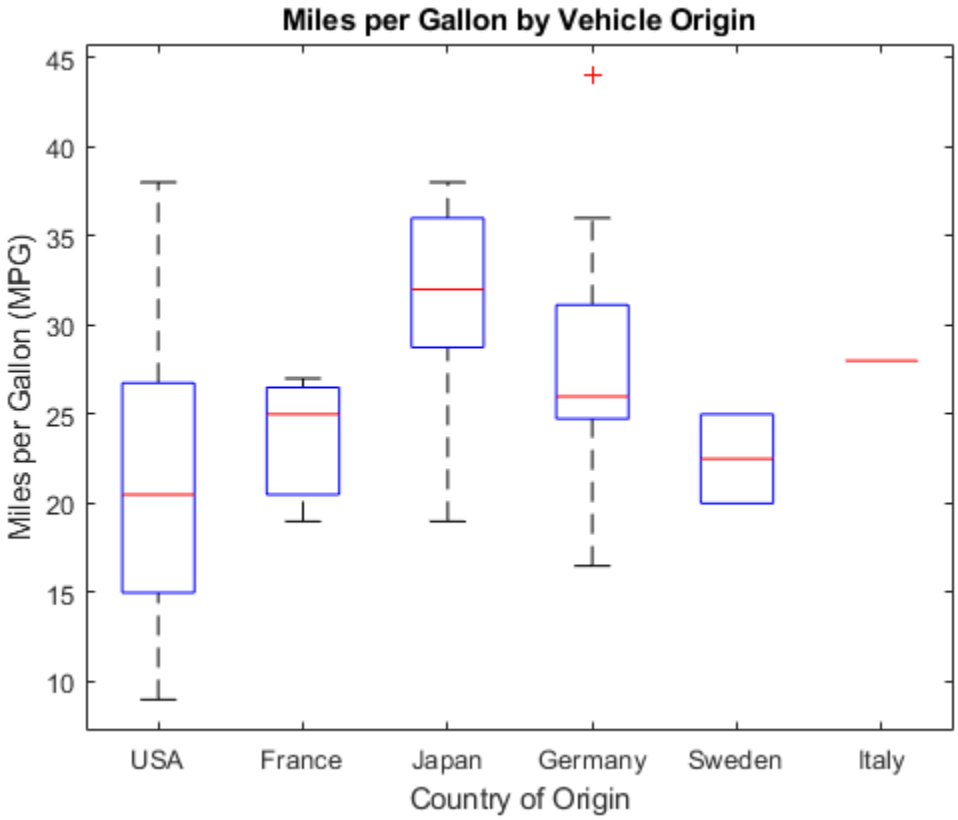
Create Box Plots for Grouped Data

Load the sample data.

```
load carsmall
```

Create a box plot of the miles per gallon (`MPG`) measurements from the sample data, grouped by the vehicles' country of origin (`Origin`). Add a title and label the axes.

```
boxplot(MPG,Origin)
title('Miles per Gallon by Vehicle Origin')
xlabel('Country of Origin')
ylabel('Miles per Gallon (MPG)')
```



Each box visually represents the MPG data for cars from the specified country. Italy's "box" appears as a single line because the sample data contains only one observation for this group.

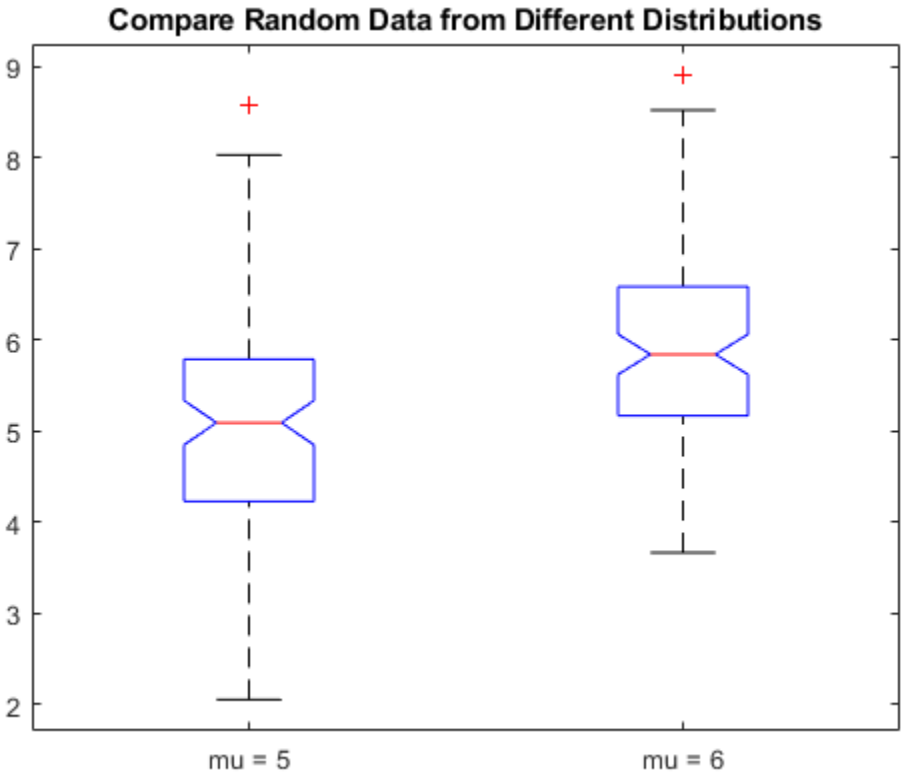
Create Notched Box Plots

Generate two sets of sample data. The first sample, `x1`, contains random numbers generated from a normal distribution with `mu = 5` and `sigma = 1`. The second sample, `x2`, contains random numbers generated from a normal distribution with `mu = 6` and `sigma = 1`.

```
rng default  % For reproducibility
x1 = normrnd(5,1,100,1);
x2 = normrnd(6,1,100,1);
```

Create notched box plots of `x1` and `x2`. Label each box with its corresponding `mu` value.

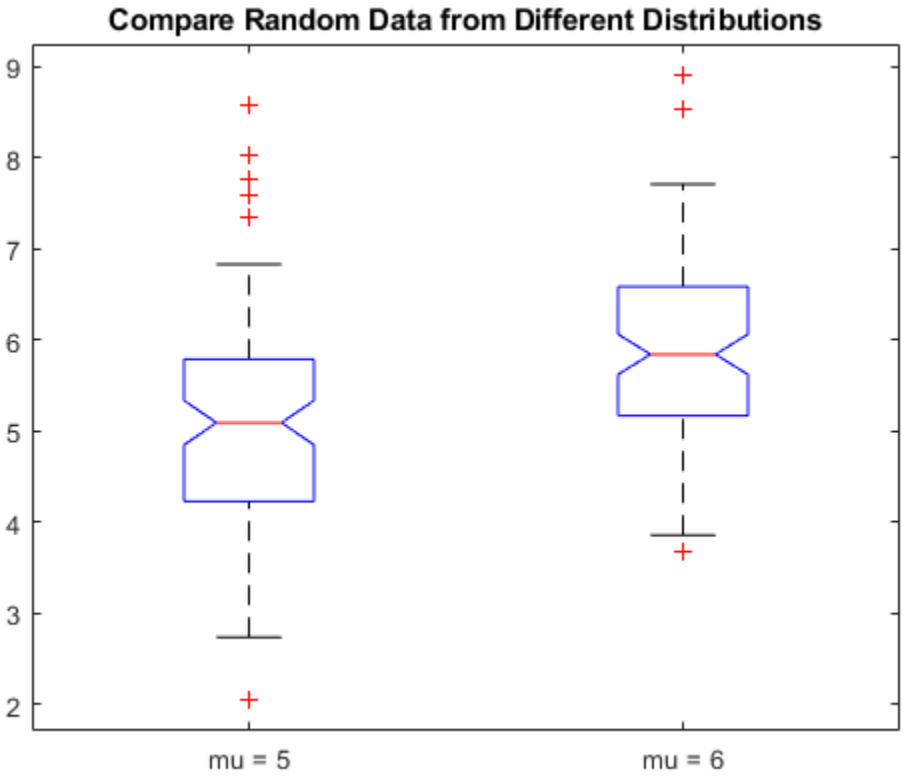
```
figure
boxplot([x1,x2],'Notch','on','Labels',{'mu = 5','mu = 6'})
title('Compare Random Data from Different Distributions')
```



The boxplot shows that the difference between the medians of the two groups is approximately 1. Since the notches in the box plot do not overlap, you can conclude, with 95% confidence, that the true medians do differ.

The following figure shows the box plot for the same data with the maximum whisker length specified as 1.0 times the interquartile range. Data points beyond the whiskers are displayed using +.

```
figure
boxplot([x1,x2],'Notch','on','Labels',{'mu = 5','mu = 6'},'Whisker',1)
title('Compare Random Data from Different Distributions')
```



With the smaller whiskers, `boxplot` displays more data points as outliers.

Create Compact Box Plots

Create a 100-by-25 matrix of random numbers generated from a standard normal distribution to use as sample data.

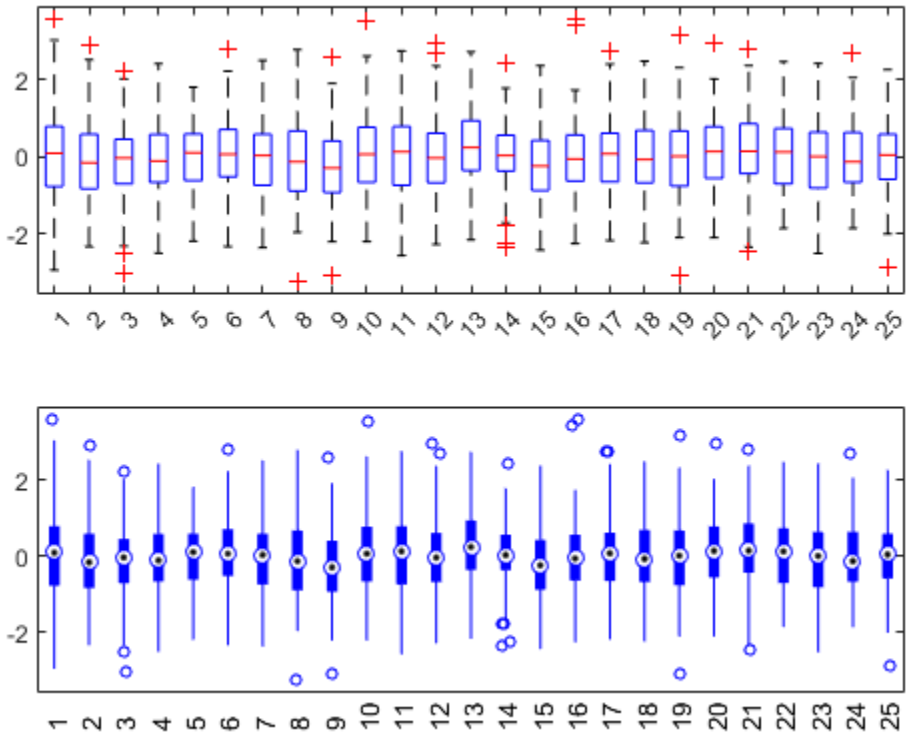
```
rng default  % For reproducibility
x = randn(100,25);
```

Create two box plots for the data in `x` on the same figure. Use the default formatting for the top plot, and compact formatting for the bottom plot.

```
figure

subplot(2,1,1)
boxplot(x)

subplot(2,1,2)
boxplot(x,'PlotStyle','compact')
```



Each plot presents the same data, but the compact formatting may improve readability for plots with many boxes.

Box Plots for Vectors of Varying Length

Create box plots for data vectors of varying length by using a grouping variable.

Randomly generate three column vectors of varying length: one of length `5`, one of length `10`, and one of length `15`. Combine the data into a single column vector of length `30`.

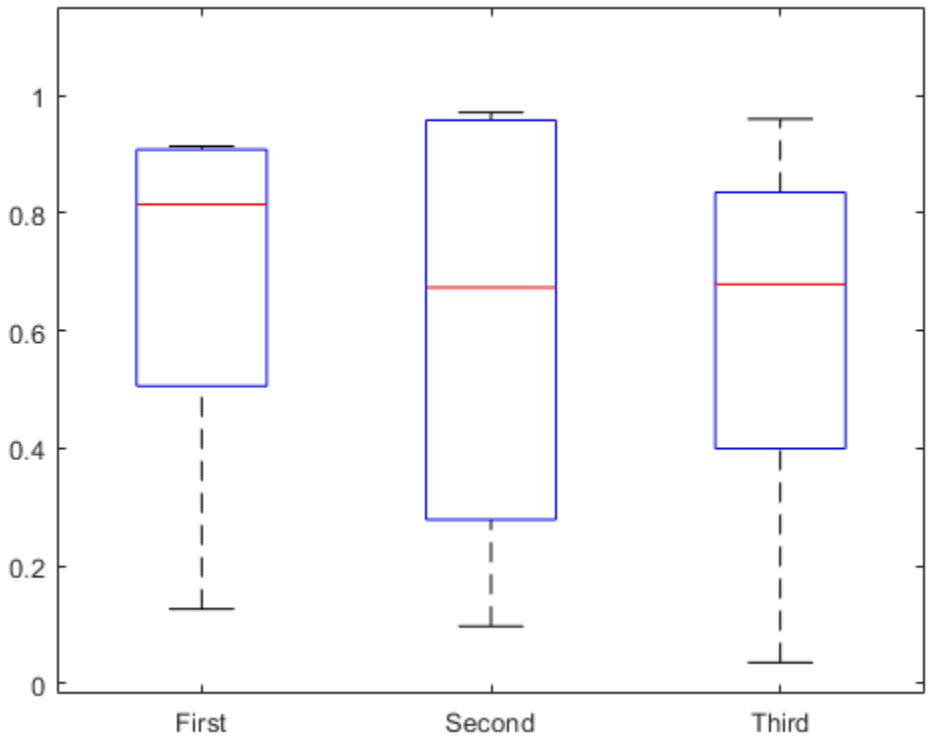
```
rng('default')  % For reproducibility
x1 = rand(5,1);
x2 = rand(10,1);
x3 = rand(15,1);
x = [x1; x2; x3];
```

Create a grouping variable that assigns the same value to rows that correspond to the same vector in `x`. For example, the first five rows of `g` have the same value, `First`, because the first five rows of `x` all come from the same vector, `x1`.

```
g1 = repmat({'First'},5,1);
g2 = repmat({'Second'},10,1);
g3 = repmat({'Third'},15,1);
g = [g1; g2; g3];
```

Create the box plots.

```
boxplot(x,g)
```



Input Arguments

x — Input data

numeric vector | numeric matrix

Input data, specified as a numeric vector or numeric matrix. If `x` is a vector, `boxplot` plots one box. If `x` is a matrix, `boxplot` plots one box for each column of `x`.

On each box, the central mark indicates the median, and the bottom and top edges of the box indicate the 25th and 75th percentiles, respectively. The whiskers extend to the most extreme data points not considered outliers, and the outliers are plotted individually using the `'+'` symbol.

Data Types: `single` | `double`

g — Grouping variables

numeric vector | character array | string array | cell array | categorical array

Grouping variables, specified as a numeric vector, character array, string array, cell array, or categorical array. You can specify multiple grouping variables in `g` by using a cell array of these variable types or a matrix. If you specify multiple grouping variables, they must all be the same length.

If `x` is a vector, then the grouping variables must contain one row for each element of `x`. If `x` is a matrix, then the grouping variables must contain one row for each column of `x`. Groups that contain a missing value (`NaN`), an empty character vector, an empty or `<missing>` string, or an `<undefined>` value in a grouping variable are omitted, and are not counted in the number of groups considered by other parameters.

By default, `boxplot` sorts character and string grouping variables in the order they initially appear in the data, categorical grouping variables by the order of their levels, and numeric grouping variables in numeric order. To control the order of groups, do one of the following:

- Use categorical variables in `g` and specify the order of their levels.
- Use the `'GroupOrder'` name-value pair argument.
- Pre-sort your data.

Data Types: `single` | `double` | `char` | `string` | `cell` | `categorical`

ax — Axes on which to plot
axes graphic object

Axes on which to plot, specified as an axes graphic object. If you do not specify `ax`, then `boxplot` creates the plot using the current axis. For more information on creating an axes graphic object, see `axes` and Axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Notch','on','Labels',{'mu = 5','mu = 6'}` creates a notched box plot and labels the two boxes `mu = 5` and `mu = 6`, from left to right

Box Appearance

BoxStyle — Box style
`'outline'` | `'filled'`

Box style, specified as the comma-separated pair consisting of `'BoxStyle'` and one of the following.

Name	Value
`'outline'`	Plot boxes using an unfilled box with dashed whiskers. This is the default if `'PlotStyle'` is `'traditional'`.
`'filled'`	Plot boxes using a narrow filled box with lines for whiskers. This is the default if `'PlotStyle'` is `'compact'`.

Example: `'BoxStyle','filled'`

Colors — Box colors
RGB triplet | character vector or string scalar of color names

Box colors, specified as the comma-separated pair consisting of `'Colors'` and an RGB triplet, character vector, or string scalar. An RGB triplet is a three-element row vector whose elements

specify the intensities of the red, green, and blue components of the color, respectively. Each intensity must be in the range [0,1].

The following table lists the available color characters and their equivalent RGB triplet values.

Long Name	Short Name	RGB Triplet
Yellow	`'y'`	`[1 1 0]`
Magenta	`'m'`	`[1 0 1]`
Cyan	`'c'`	`[0 1 1]`
Red	`'r'`	`[1 0 0]`
Green	`'g'`	`[0 1 0]`
Blue	`'b'`	`[0 0 1]`
White	`'w'`	`[1 1 1]`
Black	`'k'`	`[0 0 0]`

You can specify multiple colors either as a character vector or string scalar of color names (for example, `'rgbm'`) or a three-column matrix of RGB values. The sequence is replicated or truncated as required, so for example, `'rb'` gives boxes that alternate red and blue.

If you do not specify the name-value pair `'ColorGroup'`, then `boxplot` uses the same color scheme for all boxes. If you do specify `'ColorGroup'`, then the default is a modified `hsv` `colormap`.

Example: `'Colors','rgbm'`

`MedianStyle` — Median style
`'line'` | `'target'`

Median style, specified as the comma-separated pair consisting of `'MedianStyle'` and one of the following.

Name	Value
`'line'`	Draw a line to represent the median in each box. This is the default when `'PlotStyle'` is `'traditional'`.
`'target'`	Draw a black dot inside a white circle to represent the median in each box. This is the default when `'PlotStyle'` is `'compact'`.

Example: `'MedianStyle','target'`

`Notch` — Marker for comparison intervals
`'off'` (default) | `'on'` | `'marker'`

Marker for comparison intervals, specified as the comma-separated pair consisting of `'Notch'` and one of the following.

Name	Value
`'off'`	Omit comparison intervals from box display.

Name	Value
`'on'`	If `'PlotStyle'` is `'traditional'`, draw comparison intervals using notches. If `'PlotStyle'` is `'compact'`, draw comparison intervals using triangular markers.
`'marker'`	Draw comparison intervals using triangular markers.

Two medians are significantly different at the 5% significance level if their intervals do not overlap. `boxplot` represents interval endpoints using the extremes of the notches or the centers of the triangular markers. The notch extremes correspond to $q_2 - 1.57(q_3 - q_1)/\text{sqrt}(n)$ and $q_2 + 1.57(q_3 - q_1)/\text{sqrt}(n)$, where q_2 is the median (50th percentile), q_1 and q_3 are the 25th and 75th percentiles, respectively, and n is the number of observations without any `NaN` values. If the sample size is small, the notches might extend beyond the end of the box.

Example: `'Notch','on'`

`OutlierSize` — Marker size for outliers
positive numeric value

Marker size for outliers, specified as the comma-separated pair consisting of `'OutlierSize'` and a positive numeric value. The specified value represents the marker size in points.

If `'PlotStyle'` is `'traditional'`, then the default value for `OutlierSize` is 6. If `'PlotStyle'` is `'compact'`, then the default value for `OutlierSize` is 4.

Example: `'OutlierSize',8`

Data Types: `single` | `double`

`PlotStyle` — Plot style
`'traditional'` (default) | `'compact'`

Plot style, specified as the comma-separated pair consisting of `'PlotStyle'` and one of the following.

Name	Value
`'traditional'`	Plot boxes using a traditional box style.
`'compact'`	Plot boxes using a smaller box style designed for plots with many groups. This style changes the defaults for some other parameters.

Example: `'PlotStyle','compact'`

`Symbol` — Symbol and color for outliers
line specification

Symbol and color for outliers, specified as the comma-separated pair consisting of `'Symbol'` and a line specification. See the `LineSpec` parameter in `plot` for available line specifications.

If `'PlotStyle'` is `'traditional'`, then the default value is `'r+'`, which plots each outlier using a red `'+'` symbol.

If 'PlotStyle' is 'compact', then the default value is 'o', which plots each outlier using an 'o' symbol in the same color as the corresponding box.

If you omit the symbol, then the outliers appear invisible. If you omit the color, then the outliers appear in the same color as the box.

Example: 'kx'

Widths — Box width

numeric scalar | numeric vector

Box width, specified as the comma-separated pair consisting of 'Widths' and a numeric scalar or numeric vector. If the number of boxes is not equal to the number of width values specified, then the list of values is replicated or truncated as necessary.

This name-value pair argument does not alter the spacing between boxes. Therefore, if you specify a large value for 'Widths', the boxes might overlap.

The default box width is equal to half of the minimum separation between boxes, which is 0.5 when the 'Positions' name-value pair argument takes its default value.

Example: 'Widths',0.3

Data Types: single | double

Group Appearance

ColorGroup — Grouping variable for box color change

[] (default) | numeric vector | character array | string array | cell array | categorical array

Grouping variable for box color change, specified as the comma-separated pair consisting of 'ColorGroup' and a grouping variable. The grouping variable is a numeric vector, character array, string array, cell array, or categorical array. The box color changes when the specified grouping variable changes. The default value [] indicates that the box color does not change based on the group.

Data Types: single | double | char | string | cell | categorical

FactorDirection — Order of factors on plot

'data' (default) | 'list' | 'auto'

Order of factors on plot, specified as the comma-separated pair consisting of 'FactorDirection' and one of the following.

Name	Value
'data'	Factors appear with the first value next to the plot origin.
'list'	Factors appear left-to-right if on the x-axis, or top-to-bottom if on the y-axis.
'auto'	If the grouping variables are numeric, then boxplot uses 'data'. If the grouping variables are character arrays, string arrays, cell arrays, or categorical arrays, then boxplot uses 'list'.

`FullFactors` — Plot all group factors
`'off'` (default) | `'on'`

Plot all group factors, specified as the comma-separated pair consisting of `'FullFactors'` and either `'off'` or `'on'`. If `'off'`, then `boxplot` plots one box for each unique row of grouping variables. If `'on'`, then `boxplot` plots one box for each possible combination of grouping variable values, including combinations that do not appear in the data.

Example: `'FullFactors','on'`

`FactorGap` — Distance between different grouping factors
`[]` | positive numeric value | vector of positive numeric values | `'auto'`

Distance between different grouping factors, specified as the comma-separated pair consisting of `'FactorGap'` and a positive numeric value, a vector of positive numeric values, or `'auto'`. If you specify a vector, then the vector length must be less than or equal to the number of grouping variables.

`'FactorGap'` represents the distance of the gap between different factors of a grouping variable, expressed as a percentage of the width of the plot. For example, if you specify `[3,1]`, then the gap is three percent of the width of the plot between groups with different values of the first grouping variable, and one percent between groups with the same value of the first grouping variable but different values for the second.

If you specify `'auto'`, then `boxplot` selects a gap distance automatically. The value `[]` indicates no change in gap size between different factors.

If `'PlotStyle'` is `'traditional'`, then the default value for `FactorGap` is `[]`. If `'PlotStyle'` is `'compact'`, then the default value is `'auto'`.

Example: `'FactorGap',[3,1]`

Data Types: `single` | `double` | `char` | `string`

`FactorSeparator` — Separation between grouping factors
`[]` | positive integer | vector of positive integers | `'auto'`

Separation between grouping factors, specified as the comma-separated pair consisting of `'FactorSeparator'` and a positive integer or a vector of positive integers, or `'auto'`. If you specify a vector, then the length of the vector should be less than or equal to the number of grouping variables. The integer values must be in the range [1,*G*], where *G* is the number of grouping variables.

`'FactorSeparator'` specifies which factors should have their values separated by a grid line. For example, `[1,2]` adds a separator line when the first or second grouping variable changes value.

If `'PlotStyle'` is `'traditional'`, then the default value for `FactorSeparator` is `[]`. If `'PlotStyle'` is `'compact'`, then the default value is `'auto'`.

Example: `'FactorSeparator',[1,2]`

Data Types: `single` | `double` | `char` | `string`

`GroupOrder` — Plotting order of groups
`[]` (default) | string array | cell array

Plotting order of groups, specified as the comma-separated pair consisting of `'GroupOrder'` and a string array or cell array containing the names of the grouping variables. If you have multiple

grouping variables, separate values with a comma. You can also use categorical arrays as grouping variables to control the order of the boxes. The default value `[]` does not reorder the boxes.

Data Types: `string` | `cell`

Data Limits and Maximum Distances

`DataLim` — Extreme data limits

`[-Inf,Inf]` (default) | two-element numeric vector

Extreme data limits, specified as the comma-separated pair consisting of `'DataLim'` and a two-element numeric vector containing the lower and upper limits, respectively. The values specified for `'DataLim'` are used by `'ExtremeMode'` to determine which data points are extreme.

Data Types: `single` | `double`

`ExtremeMode` — Handling method for extreme data

`'clip'` (default) | `'compress'`

Handling method for extreme data, specified as the comma-separated pair consisting of `'ExtremeMode'` and one of the following.

Name	Value
`'clip'`	If any data values fall outside the limits specified by `'DataLim'`, then `boxplot` displays these values at `DataLim` on the plot.
`'compress'`	If any data values fall outside the limits specified by `'DataLim'` , then `boxplot` displays these values evenly distributed in a region just outside `DataLim`, retaining the relative order of the points.

If any data points lie outside the limit specified by `'DataLim'`, then the limit is marked with a dotted line. If any data points are compressed, then two gray lines mark the compression region. Values at `–Inf` or `Inf` can be clipped or compressed, but `NaN` values do not appear on the plot. Box notches are drawn to scale and may extend beyond the bounds if the median is inside the limit. Box notches are not drawn if the median is outside the limits.

Example: `'ExtremeMode','compress'`

`Jitter` — Maximum outlier displacement distance

numeric value

Maximum outlier displacement distance, specified as the comma-separated pair consisting of `'Jitter'` and a numeric value. `Jitter` is the maximum distance to displace outliers along the factor axis by a uniform random amount, in order to make duplicate points visible. If you specify `'Jitter'` equal to 1, then the jitter regions just touch between the closest adjacent groups.

If `'PlotStyle'` is `'traditional'`, then the default value for `Jitter` is 0. If `'PlotStyle'` is `'compact'`, then the default value is 0.5.

Example: `'Jitter',1`

Data Types: `single` | `double`

`Whisker` — Multiplier for maximum whisker length

1.5 (default) | positive numeric value

Multiplier for the maximum whisker length, specified as the comma-separated pair consisting of `'Whisker'` and a positive numeric value. The maximum whisker length is the product of `Whisker` and the interquartile range.

`boxplot` draws points as outliers if they are greater than $q_3 + w \times (q_3 - q_1)$ or less than $q_1 - w \times (q_3 - q_1)$, where w is the multiplier `Whisker`, and q_1 and q_3 are the 25th and 75th percentiles of the sample data, respectively.

The default value for `'Whisker'` corresponds to approximately +/–2.7σ and 99.3 percent coverage if the data are normally distributed. The plotted whisker extends to the *adjacent value*, which is the most extreme data value that is not an outlier.

Specify `'Whisker'` as 0 to give no whiskers and to make every point outside of q_1 and q_3 an outlier.

Example: `'Whisker',0`

Data Types: `single` | `double`

Plot Appearance

`Labels` — Box labels

character array | string array | cell array | numeric vector | numeric matrix

Box labels, specified as the comma-separated pair consisting of `'Labels'` and a character array, string array, cell array, or numeric vector containing the box label names. Specify one label per `x` value or one label per group. To specify multiple label variables, use a numeric matrix or a cell array containing any of the accepted data types.

To remove labels from a plot , use the following command: `set(gca,'XTickLabel',{' '})`.

Data Types: `char` | `string` | `cell` | `single` | `double`

`LabelOrientation` — Label orientation

`'inline'` | `'horizontal'`

Label orientation, specified as the comma-separated pair consisting of `'LabelOrientation'` and one of the following.

Name	Value
`'inline'`	Rotate box labels to be vertical. This is the default when `'PlotStyle'` is `'compact'`.
`'horizontal'`	Leave box labels horizontal. This is the default when `'PlotStyle'` is `'traditional'`.

If the labels are on the *y* axis, then both settings leave the labels horizontal.

Example: `'LabelOrientation','inline'`

`LabelVerbosity` — Labels to display on plot

`'all'` | `'minor'` | `'majorminor'`

Labels to display on plot, specified as the comma-separated pair consisting of `'LabelVerbosity'` and one of the following.

Name	Value
`'all'`	Display a label for every value of a grouping variable. This is the default when `'PlotStyle'` is `'traditional'`.
`'minor'`	For any grouping variable, display the value corresponding to box `j` only if that value differs from the value corresponding to box `(j − 1)`.
`'majorminor'`	For any grouping variable `g(:,i)`, display the value corresponding to box `j`, only if that value differs from the value of `g(:,i)` corresponding to box `(j − 1)`, or if the condition above holds for at least one of the grouping variables `g(:,1),…,g(:,i-1)`. This is the default when `'PlotStyle'` is `'compact'`.

Example: `'LabelVerbosity','minor'`

`Orientation` — Plot orientation
`'vertical'` (default) | `'horizontal'`

Plot orientation, specified as the comma-separated pair consisting of `'Orientation'` and one of the following.

Name	Value
`'vertical'`	Plot `x` on the *y*-axis.
`'horizontal'`	Plot `x` on the *x*-axis.

Example: `'horizontal'`

`Positions` — Box positions
numeric vector

Box positions, specified as the comma-separated pair consisting of `'Positions'` and a numeric vector containing one entry for each group or `x` value. The default is 1:*NumGroups*, where *NumGroups* is the number of groups.

Data Types: `single` | `double`

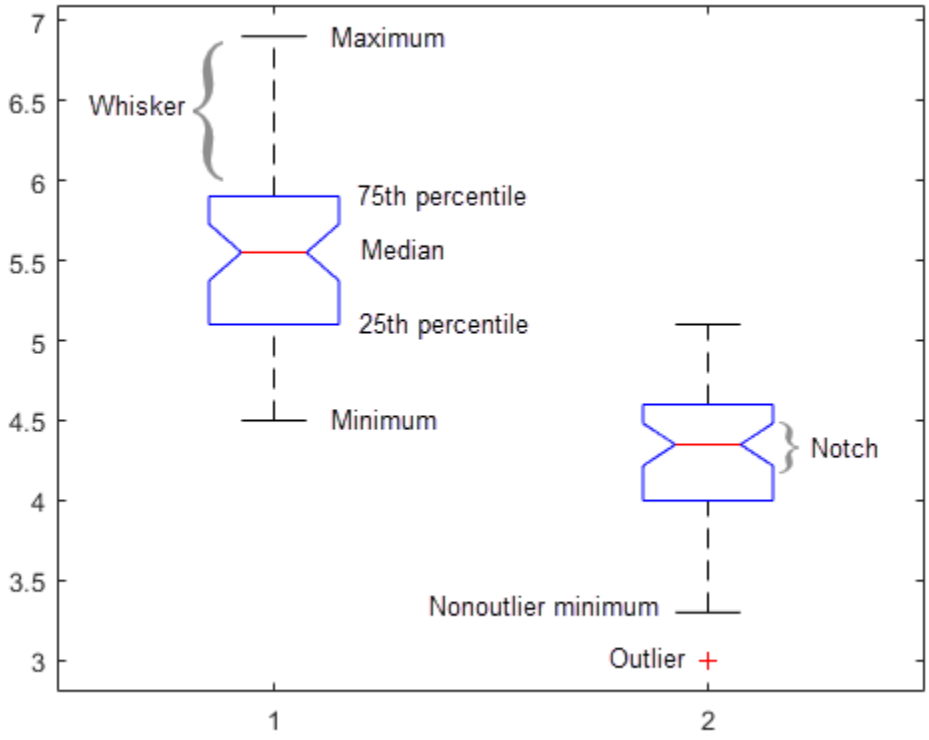
More About

Box Plot

A box plot provides a visualization of summary statistics for sample data and contains the following features:

- The bottom and top of each box are the 25th and 75th percentiles of the sample, respectively. The distance between the bottom and top of each box is the interquartile range.
- The red line in the middle of each box is the sample median. If the median is not centered in the box, the plot shows sample skewness.
- The whiskers are lines extending above and below each box. Whiskers go from the end of the interquartile range to the furthest observation within the whisker length (the *adjacent value*).

- Observations beyond the whisker length are marked as outliers. By default, an outlier is a value that is more than 1.5 times the interquartile range away from the bottom or top of the box. However, you can adjust this value by using additional input arguments. An outlier appears as a red + sign.
- Notches display the variability of the median between samples. The width of a notch is computed so that boxes whose notches do not overlap have different medians at the 5% significance level. The significance level is based on a normal distribution assumption, but comparisons of medians are reasonably robust for other distributions. Comparing box plot medians is like a visual hypothesis test, analogous to the *t* test used for means.



Tips

- `boxplot` creates a visual representation of the data, but does not return numeric values. To calculate the relevant summary statistics for the sample data, use the following functions:
  - `min` — Find the minimum value in the sample data.
  - `max` — Find the maximum value in the sample data.
  - `median` — Find the median value in the sample data.
  - `quantile` — Find the quantile values in the sample data. For example, to compute the 25th and 75th percentiles of `x`, specify `quantile(x,[0.25 0.75])`. For more information on how the percentiles are computed, see “Algorithms” on page 33-5103.
  - `iqr` — Find the interquartile range in the sample data.

  - `grpstats` — Calculate summary statistics for the sample data, organized by group.
- You can see data values and group names using the data cursor in the figure window. The cursor shows the original values of any points affected by the `datalim` parameter. You can label the group to which an outlier belongs using the `gname` function.
- To modify graphics properties of a box plot component, use `findobj` with the `Tag` property to find the component's handle. `Tag` values for box plot components depend on parameter settings, and are listed in the following table.

Parameter Settings	Tag Values
All settings	• `'Box'` • `'Outliers'`
When `'PlotStyle'` is `'traditional'`	• `'Median'` • `'Upper Whisker'` • `'Lower Whisker'` • `'Upper Adjacent Value'` • `'Lower Adjacent Value'`
When `'PlotStyle'` is `'compact'`	• `'Whisker'` • `'MedianOuter'` • `'MedianInner'`
When `'Notch'` is `'marker'`	• `'NotchLo'` • `'NotchHi'`

Alternative Functionality

You can also create a `BoxChart` object by using the `boxchart` function. Although `boxchart` does not include all the functionality of `boxplot`, it has some advantages. Unlike `boxplot`, the `boxchart` function:

- Allows for categorical rulers along the group axis
- Provides the option of a legend
- Works well with the `hold on` command
- Has an improved visual design that helps you see notches more easily

To control the appearance and behavior of the object, change the BoxChart Properties.

Introduced before R2006a

boundary

Piecewise distribution boundaries

Syntax

```
[p,q] = boundary(pd)
[p,q] = boundary(pd,j)
```

Description

`[p,q] = boundary(pd)` returns the boundary points between segments in `pd`, the piecewise distribution. `p` is a vector of the cumulative probabilities at the boundaries, and `q` is a vector of the corresponding quantiles.

`[p,q] = boundary(pd,j)` returns boundary values of the `j`th boundary.

Examples

Boundaries in `paretotails` Object

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the boundary points between segments in a `paretotails` object by using the object function `boundary`.

Generate a sample data set containing 20% outliers.

```
rng('default');  % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)
```

```
pd =
Piecewise distribution with 3 segments
      -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
   -1.33251 < x < 1.80149  (0.1 < p < 0.9): interpolated empirical cdf
        1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the boundary values between the piecewise segments by using the `boundary` function.

```
[p,q] = boundary(pd)
```

```
p = 2×1
```

```
    0.1000
    0.9000

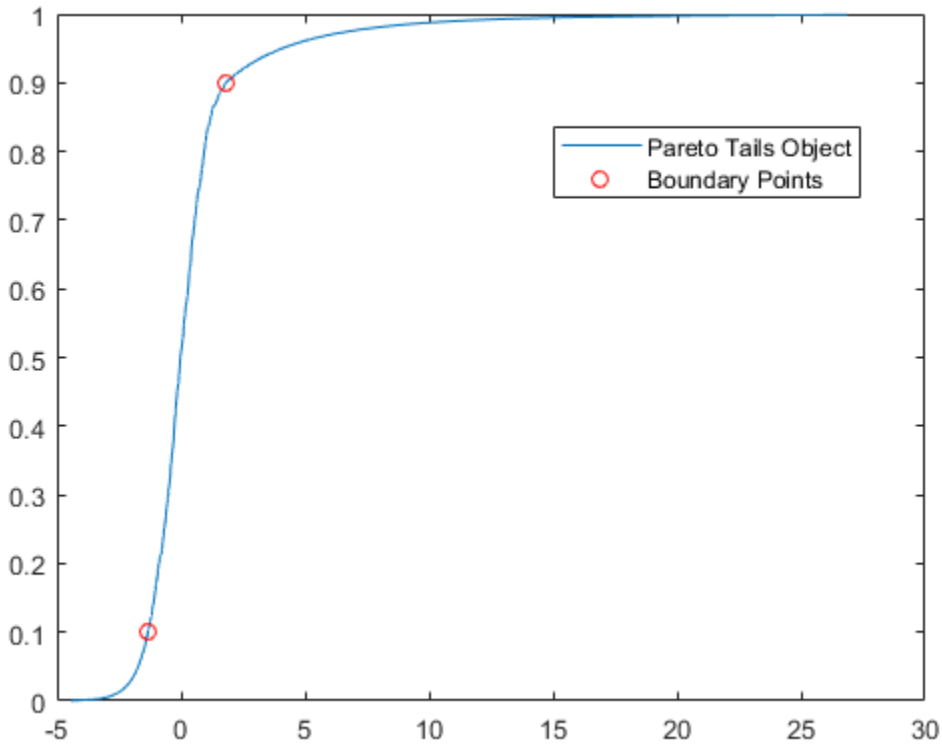
q = 2×1

   -1.3325
    1.8015
```

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles.

Plot the cdf of the `paretotails` object and mark the boundary points on the figure.

```
xi = sort(x);
plot(xi,cdf(pd,xi))
hold on
plot(q,p,'ro')
legend('Pareto Tails Object','Boundary Points','Location','best')
hold off
```



Input Arguments

pd — Piecewise distribution with Pareto tails

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

`j` — Boundary index
positive integer

Boundary index indicating which boundary to return, specified as a positive integer.

Data Types: `single` | `double`

Output Arguments

`p` — Cumulative probability at boundary
numeric vector of range `(0,1)` values

Cumulative probability at each boundary, returned as a numeric vector of range `(0,1)` values.

`q` — Quantile at boundary
numeric vector

Quantile at each boundary, returned as a numeric vector.

CalinskiHarabaszEvaluation

Package: `clustering.evaluation`
Superclasses: `ClusterCriterion`

Calinski-Harabasz criterion clustering evaluation object

Description

`CalinskiHarabaszEvaluation` is an object consisting of sample data, clustering data, and Calinski-Harabasz criterion values used to evaluate the optimal number of clusters. Create a Calinski-Harabasz criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x,clust,'CalinskiHarabasz')` creates a Calinski-Harabasz criterion clustering evaluation object.

`eva = evalclusters(x,clust,'CalinskiHarabasz',Name,Value)` creates a Calinski-Harabasz criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an *N*-by-*P* matrix. *N* is the number of observations, and *P* is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

`'kmeans'` | `'linkage'` | `'gmdistribution'` | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

`'kmeans'`	Cluster the data in `x` using the `kmeans` clustering algorithm, with `'EmptyAction'` set to `'singleton'` and `'Replicates'` set to `5`.
`'linkage'`	Cluster the data in `x` using the `clusterdata` agglomerative clustering algorithm, with `'Linkage'` set to `'ward'`.
`'gmdistribution'`	Cluster the data in `x` using the `gmdistribution` Gaussian mixture distribution algorithm, with `'SharedCov'` set to `true` and `'Replicates'` set to `5`.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can specify a clustering algorithm using a function handle. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric *n*-by-*K* matrix of score for *n* observations and *K* classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a *n*-by-*K* matrix containing the proposed clustering solutions. *n* is the number of observations in the sample data, and *K* is the number of proposed clustering solutions. Column *j* contains the cluster indices for each of the *N* points in the *j*th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:6]` specifies to test 1, 2, 3, 4, 5, and 6 clusters to find the optimal number.

`KList` — List of number of clusters to evaluate
vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is `'gap'`, `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: `'KList',[1:6]`

Data Types: `single` | `double`

Properties

`ClusteringFunction`

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

`CriterionName`

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

`CriterionValues`

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

`InspectedK`

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

`Missing`

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `X` is not used in the clustering solution.

`NumObservations`

Number of observations in the data matrix `X`, minus the number of missing (`NaN`) values in `X`, stored as a positive integer value.

`OptimalK`

Optimal number of clusters, stored as a positive integer value.

`OptimalY`

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

`X`

Data used for clustering, stored as a matrix of numerical values.

Methods

Inherited Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values
compact	Compact clustering evaluation object

Examples

Evaluate the Clustering Solution Using Calinski-Harabasz Criterion

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using `kmeans`.

```
rng('default');  % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])
```

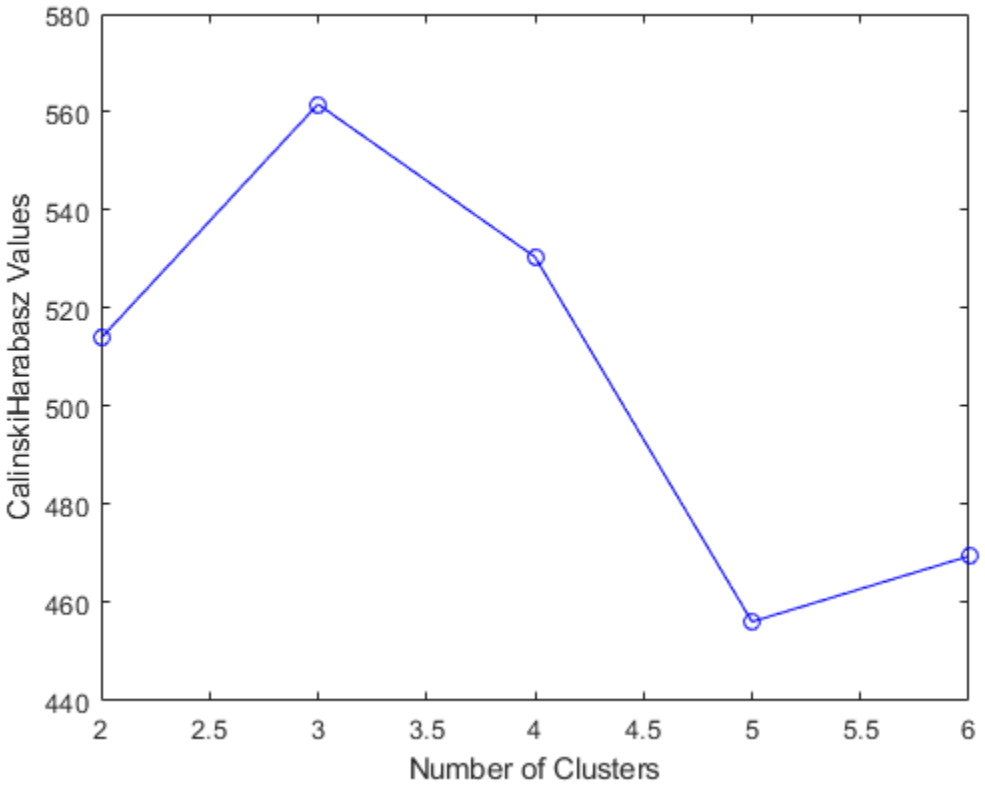
```
eva =
  CalinskiHarabaszEvaluation with properties:
```

```
    NumObservations: 150
         InspectedK: [1 2 3 4 5 6]
    CriterionValues: [Inf 513.9245 561.6278 530.4871 456.1279 469.5068]
           OptimalK: 1
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

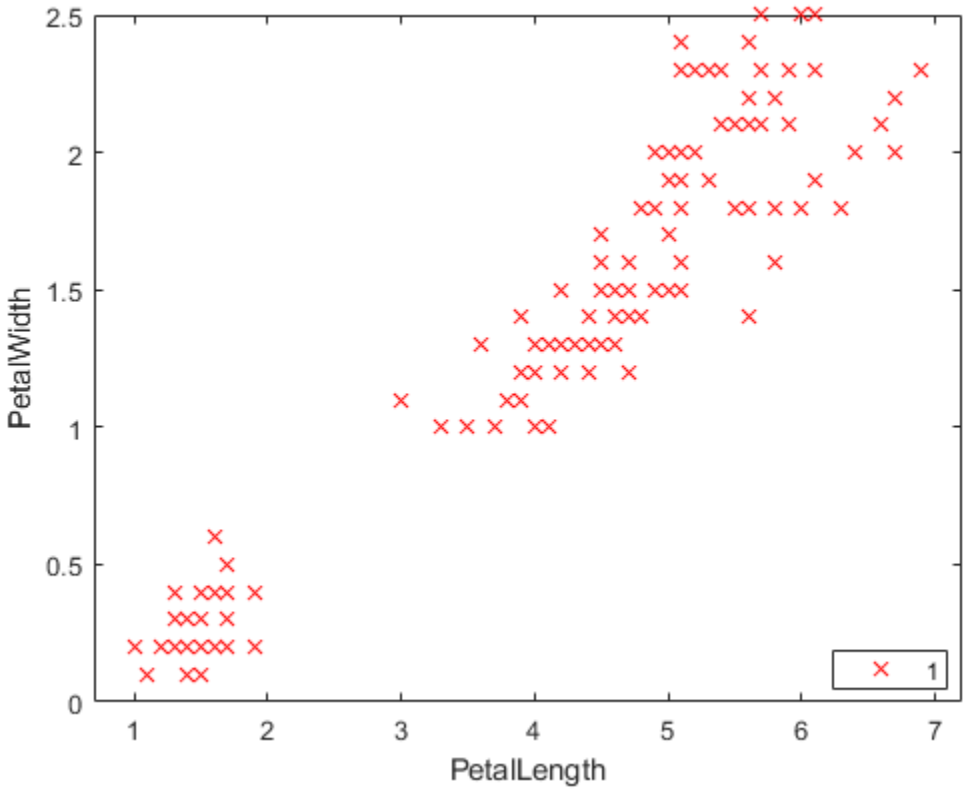
```
figure;
plot(eva);
```



The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
PetalLength = meas(:,3);
PetalWidth = meas(:,4);
ClusterGroup = eva.OptimalY;
figure;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbg','xod');
```



The plot shows cluster 3 in the lower-left corner, completely separated from the other two clusters. Cluster 3 contains flowers with the smallest petal widths and lengths. Cluster 1 is in the upper-right corner, and contains flowers with the largest petal widths and lengths. Cluster 2 is near the center of the plot, and contains flowers with measurements between these two extremes.

More About

Calinski-Harabasz Criterion

The Calinski-Harabasz criterion is sometimes called the variance ratio criterion (VRC). The Calinski-Harabasz index is defined as

$$VRC_k = \frac{SS_B}{SS_W} \times \frac{(N-k)}{(k-1)},$$

where SS_B is the overall between-cluster variance, SS_W is the overall within-cluster variance, k is the number of clusters, and N is the number of observations.

The overall between-cluster variance SS_B is defined as

$$SS_B = \sum_{i=1}^{k} n_i \|m_i - m\|^2,$$

where k is the number of clusters, n_i is the number of observations in cluster i, m_i is the centroid of cluster i, m is the overall mean of the sample data, and $\|m_i - m\|$ is the L^2 norm (Euclidean distance) between the two vectors.

The overall within-cluster variance SS_W is defined as

$$SS_W = \sum_{i=1}^{k} \sum_{x \in c_i} \|x - m_i\|^2,$$

where k is the number of clusters, x is a data point, c_i is the ith cluster, m_i is the centroid of cluster i, and $\|x - m_i\|$ is the L^2 norm (Euclidean distance) between the two vectors.

Well-defined clusters have a large between-cluster variance (SS_B) and a small within-cluster variance (SS_W). The larger the VRC_k ratio, the better the data partition. To determine the optimal number of clusters, maximize VRC_k with respect to k. The optimal number of clusters is the solution with the highest Calinski-Harabasz index value.

The Calinski-Harabasz criterion is best suited for k-means clustering solutions with squared Euclidean distances.

Class Attributes
Property Attributes

candexch

D-optimal design from candidate set using row exchanges

Syntax

```
rlist = candexch(C,nrows)
rlist = candexch(C,nrows,Name,Value)
```

Description

`rlist = candexch(C,nrows)` uses a row-exchange algorithm to select a *D*-optimal design from the candidate set `C`.

`rlist = candexch(C,nrows,Name,Value)` generates a *D*-optimal design with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`C`

`N`-by-`P` matrix containing the values of `P` model terms at each of `N` points.

Default:

`nrows`

The desired number of rows in the design.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`display`

When `'on'`, displays iteration number. Disable the display by setting to `'off'`.

Default: `'on'`, except when the `UseParallel` option is `true`

`init`

`nrows`-by-`P` matrix giving an initial design.

Default: A random subset of the rows of `C`

`maxiter`

Maximum number of iterations, a positive integer.

Default: `10`

`options`

A structure that specifies whether to run in parallel, and specifies the random stream or streams. This option requires Parallel Computing Toolbox.

Create the `options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `candexch` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case

  - `UseParallel` is `true`
  - `UseSubstreams` is `false`

  In that case, use a cell array the same size as the Parallel pool.

Default: `[]`

`start`

An `nobs`-by-*p* matrix of factor settings, specifying a set of `nobs` fixed design points to include in the design. `candexch` finds `nrows` additional rows to add to the `start` design. The parameter provides the same functionality as the `daugment` function, using a row-exchange algorithm rather than a coordinate-exchange algorithm.

Default: `[]`

`tries`

Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first.

Default: 1

Output Arguments

`rlist`

Vector of length `nrows` listing the selected rows.

Examples

This example shows how to generate a *D*-optimal design when there is a restriction on the candidate set, so the `rowexch` function isn't appropriate.

```
F = (fullfact([5 5 5])-1)/4; % factor settings in unit cube
T = sum(F,2)<=1.51;         % find rows matching a restriction
F = F(T,:);                 % take only those rows
C = [ones(size(F,1),1) F F.^2];
```

```
                            % compute model terms including
                            % a constant and all squared terms
R = candexch(C,12);         % find a D-optimal 12-point subset
X = F(R,:);                 % get factor settings
```

Algorithms

`candexch` selects a starting design `X` at random, and uses a row-exchange algorithm to iteratively replace rows of `X` by rows of `C` in an attempt to improve the determinant of `X'*X`.

Alternatives

The `rowexch` function also generates *D*-optimal designs using a row-exchange algorithm, but it automatically generates a candidate set that is appropriate for a specified model. The `daugment` function augments a set of fixed design points using a coordinate-exchange algorithm; the `'start'` parameter provides the same functionality using the row exchange algorithm.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

candgen

Candidate set generation

Syntax

```
dC = candgen(nfactors,'model')
[dC,C] = candgen(nfactors,'model')
[...] = candgen(nfactors,'model','Name',value)
```

Description

`dC = candgen(nfactors,'model')` generates a candidate set `dC` of treatments appropriate for estimating the parameters in the *`model`* with `nfactors` factors. `dC` has `nfactors` columns and one row for each candidate treatment. *`model`* is one of the following:

- `'linear'` — Constant and linear terms. This is the default.
- `'interaction'` — Constant, linear, and interaction terms
- `'quadratic'` — Constant, linear, interaction, and squared terms
- `'purequadratic'` — Constant, linear, and squared terms

Alternatively, *`model`* can be a matrix specifying polynomial terms of arbitrary order. In this case, *`model`* should have one column for each factor and one row for each term in the model. The entries in any row of *`model`* are powers for the factors in the columns. For example, if a model has factors `X1`, `X2`, and `X3`, then a row `[0 1 2]` in *`model`* specifies the term `(X1.^0).*(X2.^1).*(X3.^2)`. A row of all zeros in *`model`* specifies a constant term, which can be omitted.

`[dC,C] = candgen(nfactors,'model')` also returns the design matrix `C` evaluated at the treatments in `dC`. The order of the columns of `C` for a full quadratic model with *n* terms is:

1. The constant term
2. The linear terms in order 1, 2, ..., *n*
3. The interaction terms in order (1, 2), (1, 3), ..., (1, *n*), (2, 3), ..., (*n* – 1, *n*)
4. The squared terms in order 1, 2, ..., *n*

Other models use a subset of these terms, in the same order.

Pass `C` to `candexch` to generate a *D*-optimal design using a coordinate-exchange algorithm.

`[...] = candgen(nfactors,'model','Name',value)` specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify *`Name`* inside single quotes.

Name	Value
`bounds`	Lower and upper bounds for each factor, specified as a 2-by-`nfactors` matrix. Alternatively, this value can be a cell array containing `nfactors` elements, each element specifying the vector of allowable values for the corresponding factor.

Name	Value
`categorical`	Indices of categorical predictors.
`levels`	Vector of number of levels for each factor.

Note The `rowexch` function automatically generates a candidate set using `candgen`, and then creates a *D*-optimal design from that candidate set using `candexch`. Call `candexch` separately to specify your own candidate set to the row-exchange algorithm.

Examples

The following example uses `rowexch` to generate a five-run design for a two-factor pure quadratic model using a candidate set that is produced internally:

```
dRE1 = rowexch(2,5,'purequadratic','tries',10)
dRE1 =
    -1     1
     0     0
     1    -1
     1     0
     1     1
```

The same thing can be done using `candgen` and `candexch` in sequence:

```
[dC,C] = candgen(2,'purequadratic') % Candidate set, C
dC =
    -1    -1
     0    -1
     1    -1
    -1     0
     0     0
     1     0
    -1     1
     0     1
     1     1
C =
     1    -1    -1     1     1
     1     0    -1     0     1
     1     1    -1     1     1
     1    -1     0     1     0
     1     0     0     0     0
     1     1     0     1     0
     1    -1     1     1     1
     1     0     1     0     1
     1     1     1     1     1
treatments = candexch(C,5,'tries',10) % Find D-opt subset
treatments =
     2
     1
     7
     3
     4
dRE2 = dC(treatments,:) % Display design
dRE2 =
     0    -1
```

```
    -1    -1
    -1     1
     1    -1
    -1     0
```

candexch | rowexch

Introduced before R2006a

canoncorr

Canonical correlation

Syntax

```
[A,B] = canoncorr(X,Y)
[A,B,r] = canoncorr(X,Y)
[A,B,r,U,V] = canoncorr(X,Y)
[A,B,r,U,V,stats] = canoncorr(X,Y)
```

Description

`[A,B] = canoncorr(X,Y)` computes the sample canonical coefficients for the data matrices `X` and `Y`.

`[A,B,r] = canoncorr(X,Y)` also returns `r`, a vector of the sample canonical correlations.

`[A,B,r,U,V] = canoncorr(X,Y)` also returns `U` and `V`, matrices of the canonical scores for `X` and `Y`, respectively.

`[A,B,r,U,V,stats] = canoncorr(X,Y)` also returns `stats`, a structure containing information related to testing the sequence of hypotheses that the remaining correlations are all zero.

Examples

Compute Sample Canonical Correlation

Perform canonical correlation analysis for a sample data set.

The data set `carbig` contains measurements for 406 cars from the years 1970 to 1982.

Load the sample data.

```
load carbig;
data = [Displacement Horsepower Weight Acceleration MPG];
```

Define X as the matrix of displacement, horsepower, and weight observations, and `Y` as the matrix of acceleration and MPG observations. Omit rows with insufficient data.

```
nans = sum(isnan(data),2) > 0;
X = data(~nans,1:3);
Y = data(~nans,4:5);
```

Compute the sample canonical correlation.

```
[A,B,r,U,V] = canoncorr(X,Y);
```

View the output of `A` to determine the linear combinations of displacement, horsepower, and weight that make up the canonical variables of `X`.

```
A
```

```
A = 3×2

    0.0025    0.0048
    0.0202    0.0409
   -0.0000   -0.0027
```

`A(3,1)` is displayed as `-0.000` because it is very small. Display `A(3,1)` separately.

```
A(3,1)
```

```
ans = -2.4737e-05
```

The first canonical variable of `X` is `u1 = 0.0025*Disp + 0.0202*HP - 0.000025*Wgt`.

The second canonical variable of `X` is `u2 = 0.0048*Disp + 0.0409*HP - 0.0027*Wgt`.

View the output of `B` to determine the linear combinations of acceleration and MPG that make up the canonical variables of `Y`.

```
B
```

```
B = 2×2

   -0.1666   -0.3637
   -0.0916    0.1078
```

The first canonical variable of `Y` is `v1 = -0.1666*Accel - 0.0916*MPG`.

The second canonical variable of `Y` is `v2 = -0.3637*Accel + 0.1078*MPG`.

Plot the scores of the canonical variables of `X` and `Y` against each other.

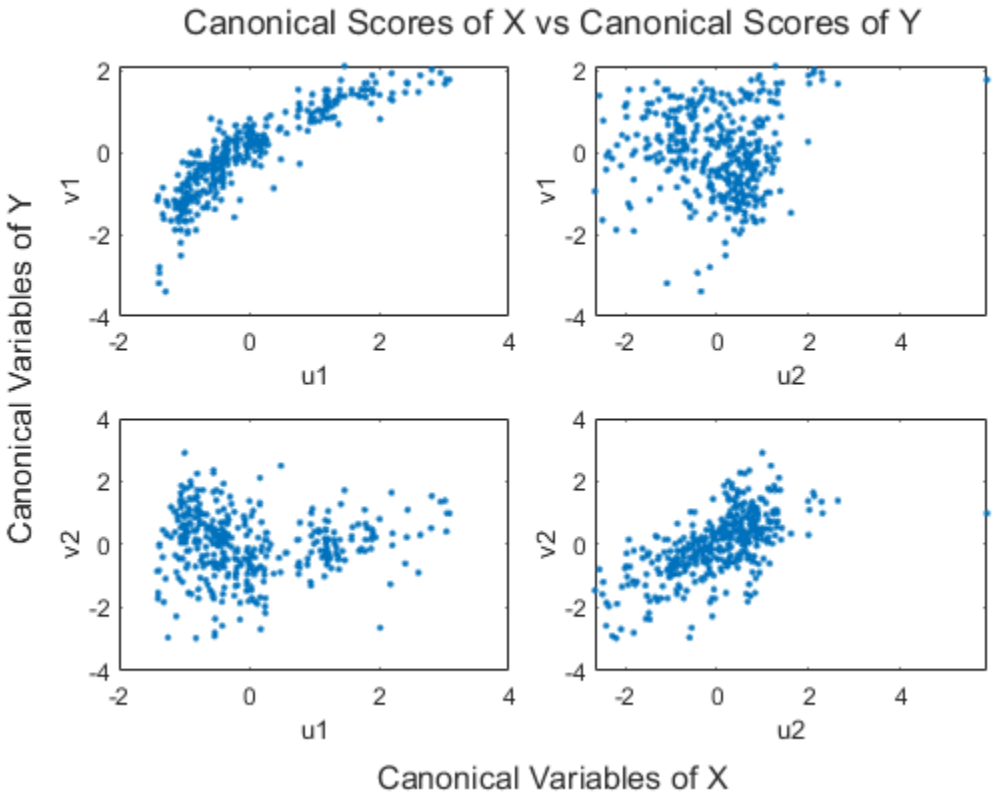
```
t = tiledlayout(2,2);
title(t,'Canonical Scores of X vs Canonical Scores of Y')
xlabel(t,'Canonical Variables of X')
ylabel(t,'Canonical Variables of Y')
t.TileSpacing = 'compact';

nexttile
plot(U(:,1),V(:,1),'.')
xlabel('u1')
ylabel('v1')

nexttile
plot(U(:,2),V(:,1),'.')
xlabel('u2')
ylabel('v1')

nexttile
plot(U(:,1),V(:,2),'.')
xlabel('u1')
ylabel('v2')

nexttile
plot(U(:,2),V(:,2),'.')
xlabel('u2')
ylabel('v2')
```



The pairs of canonical variables $\{u_i, v_i\}$ are ordered from the strongest to weakest correlation, with all other pairs independent.

Return the correlation coefficient of the variables `u1` and `v1`.

```
r(1)
```

```
ans = 0.8782
```

Input Arguments

X — Input matrix

matrix

Input matrix, specified as an n-by-d_1 matrix. The rows of `X` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

Y — Input matrix

matrix

Input matrix, specified as an n-by-d_2 matrix where `X` is an n-by-d_1 matrix. The rows of `Y` correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

Output Arguments

A — Sample canonical coefficients for X variables

matrix

Sample canonical coefficients for the variables in X, returned as a d_1-by-d matrix, where d = min(rank(X),rank(Y)).

The jth column of A contains the linear combination of variables that makes up the jth canonical variable for X.

If X is less than full rank, `canoncorr` gives a warning and returns zeros in the rows of A corresponding to dependent columns of X.

B — Sample canonical coefficients for Y variables

matrix

Sample canonical coefficients for the variables in Y, returned as a d_2-by-d matrix, where d = min(rank(X),rank(Y)).

The jth column of B contains the linear combination of variables that makes up the jth canonical variable for Y.

If Y is less than full rank, `canoncorr` gives a warning and returns zeros in the rows of B corresponding to dependent columns of Y.

r — Sample canonical correlations

vector

Sample canonical correlations, returned as a 1-by-d vector, where d = min(rank(X),rank(Y)).

The jth element of `r` is the correlation between the jth columns of U and V.

U — Canonical scores for the X variables

matrix

Canonical scores for the variables in X, returned as an n-by-d matrix, where X is an n-by-d_1 matrix and d = min(rank(X),rank(Y)).

V — Canonical scores for the Y variables

matrix

Canonical scores for the variables in Y, returned as an n-by-d matrix, where Y is an n-by-d_2 matrix and d = min(rank(X),rank(Y)).

stats — Hypothesis test information

structure

Hypothesis test information, returned as a structure. This information relates to the sequence of d null hypotheses $H_0^{(k)}$ that the (k+1)st through dth correlations are all zero for k=1,...,d-1, and d = min(rank(X),rank(Y)).

The fields of `stats` are 1-by-d vectors with elements corresponding to the values of k.

Field	Description
`Wilks`	Wilks' lambda (likelihood ratio) statistic
`df1`	Degrees of freedom for the chi-squared statistic, and the numerator degrees of freedom for the F statistic
`df2`	Denominator degrees of freedom for the F statistic
`F`	Rao's approximate F statistic for $H_0^{(k)}$
`pF`	Right-tail significance level for `F`
`chisq`	Bartlett's approximate chi-squared statistic for $H_0^{(k)}$ with Lawley's modification
`pChisq`	Right-tail significance level for `chisq`

`stats` has two other fields (`dfe` and `p`), which are equal to `df1` and `pChisq`, respectively, and exist for historical reasons.

Data Types: `struct`

More About

Canonical Correlation Analysis

The canonical scores of the data matrices X and Y are defined as

$$U_i = Xa_i$$
$$V_i = Yb_i$$

where a_i and b_i maximize the Pearson correlation coefficient $\rho(U_i,V_i)$ subject to being uncorrelated to all previous canonical scores and scaled so that U_i and V_i have zero mean and unit variance.

The canonical coefficients of X and Y are the matrices A and B with columns a_i and b_i, respectively.

The canonical variables of X and Y are the linear combinations of the columns of X and Y given by the canonical coefficients in A and B respectively.

The canonical correlations are the values $\rho(U_i,V_i)$ measuring the correlation of each pair of canonical variables of X and Y.

Algorithms

`canoncorr` computes `A`, `B`, and `r` using `qr` and `svd`. `canoncorr` computes `U` and `V` as `U = (X–mean(X))*A` and `V = (Y–mean(Y))*B`.

`manova1` | `pca`

Introduced before R2006a

capability

Process capability indices

Syntax

```
S = capability(data,specs)
```

Description

`S = capability(data,specs)` estimates capability indices for measurements in `data` given the specifications in `specs`. `data` can be either a vector or a matrix of measurements. If `data` is a matrix, indices are computed for the columns. `specs` can be either a two-element vector of the form `[L,U]` containing lower and upper specification limits, or (if `data` is a matrix) a two-row matrix with the same number of columns as `data`. If there is no lower bound, use `-Inf` as the first element of `specs`. If there is no upper bound, use `Inf` as the second element of `specs`.

The output `S` is a structure with the following fields:

- `mu` — Sample mean
- `sigma` — Sample standard deviation
- `P` — Estimated probability of being within limits
- `Pl` — Estimated probability of being below `L`
- `Pu` — Estimated probability of being above `U`
- `Cp` — `(U-L)/(6*sigma)`
- `Cpl` — `(mu-L)./(3.*sigma)`
- `Cpu` — `(U-mu)./(3.*sigma)`
- `Cpk` — `min(Cpl,Cpu)`

Indices are computed under the assumption that data values are independent samples from a normal population with constant mean and variance.

Indices divide a “specification width” (between specification limits) by a “process width” (between control limits). Higher ratios indicate a process with fewer measurements outside of specification.

Examples

Compute Capability Indices

Simulate a sample from a process with a mean of 3 and a standard deviation of 0.005.

```
rng default; % for reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99.

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
       mu: 3.0006
    sigma: 0.0058
        P: 0.9129
       Pl: 0.0339
       Pu: 0.0532
       Cp: 0.5735
      Cpl: 0.6088
      Cpu: 0.5382
      Cpk: 0.5382
```

Visualize the specification and process widths.

```
capaplot(data,[2.99 3.01]);
grid on
```

`capaplot` | `histfit`

Introduced in R2006b

capaplot

Process capability plot

Syntax

```
p = capaplot(data,specs)
[p,h] = capaplot(data,specs)
```

Description

`p = capaplot(data,specs)` estimates the mean of and variance for the observations in input vector `data`, and plots the pdf of the resulting T distribution. The observations in `data` are assumed to be normally distributed. The output, `p`, is the probability that a new observation from the estimated distribution will fall within the range specified by the two-element vector `specs`. The portion of the distribution between the lower and upper bounds specified in `specs` is shaded in the plot.

`[p,h] = capaplot(data,specs)` additionally returns handles to the plot elements in `h`.

`capaplot` treats `NaN` values in `data` as missing, and ignores them.

Examples

Create a Process Capability Plot

Randomly generate sample data from a normal process with a mean of 3 and a standard deviation of 0.005.

```
rng default; % For reproducibility
data = normrnd(3,0.005,100,1);
```

Compute capability indices if the process has an upper specification limit of 3.01 and a lower specification limit of 2.99.

```
S = capability(data,[2.99 3.01])
```

```
S = struct with fields:
       mu: 3.0006
    sigma: 0.0058
        P: 0.9129
       Pl: 0.0339
       Pu: 0.0532
       Cp: 0.5735
      Cpl: 0.6088
      Cpu: 0.5382
      Cpk: 0.5382
```

Visualize the specification and process widths.

```
capaplot(data,[2.99 3.01]);
grid on
```

`capability` | `histfit`

Introduced before R2006a

caseread

Read case names from file

Syntax

```
names = caseread(filename)
names = caseread
```

Description

`names = caseread(filename)` reads the contents of `filename` and returns a character array `names`. The `caseread` function treats each line of the file as a separate case name. Specify `filename` as either the name of a file in the current folder or the complete path name of a file.

`filename` can have one of the following file extensions:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

`names = caseread` opens the Select File to Open dialog box so that you can interactively select the file to read.

Examples

Write and Read Case Names

Create a character array of case names representing months.

```
months = char('January','February', ...
    'March','April','May');
```

Write the names to a file named `months.dat`. View the contents of the file by using the `type` function.

```
casewrite(months,'months.dat')
type months.dat
```

```
January
February
March
April
May
```

Read the names in the `months.dat` file.

```
names = caseread('months.dat')
```

```
names = 5x8 char array
    'January '
    'February'
    'March   '
```

```
    'April   '
    'May     '
```

Input Arguments

`filename` — Name of file to read

character vector | string scalar

Name of the file to read, specified as a character vector or string scalar.

Depending on the location of the file, `filename` has one of these forms.

Location of File	Form
Current folder or folder on the MATLAB path	Specify the name of the file in `filename`. **Example:** `'myTextFile.csv'`
Folder that is not the current folder or a folder on the MATLAB path	Specify the full or relative path name in `filename`. **Example:** `'C:\myFolder\myTextFile.csv'`

Example: `'months.dat'`

Data Types: `char` | `string`

Alternative Functionality

Instead of using `casewrite` and `caseread` with character arrays, consider using `writecell` and `readcell` with cell arrays. For example:

```
months = {'January';'February';'March';'April';'May'};
writecell(months,'months.dat')
names = readcell('months.dat')
```

```
names =

  5×1 cell array

    {'January' }
    {'February'}
    {'March'   }
    {'April'   }
    {'May'     }
```

See Also

`casewrite` | `gname` | `readcell` | `readtable` | `writecell` | `writetable`

Introduced before R2006a

casewrite

Write case names to file

Syntax

```
casewrite(strmat,filename)
casewrite(strmat)
```

Description

`casewrite(strmat,filename)` writes the contents of the character array or string column vector `strmat` to a file `filename`. Each row of `strmat` represents one case name, and `casewrite` writes each name to a separate line in `filename`. Specify `filename` as either a file name (to write the file to the current folder) or a complete path name (to write the file to a different folder).

`filename` can have one of the following file extensions:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

`casewrite(strmat)` opens the Select File to Write dialog box so that you can interactively specify the file to write.

Examples

Write and Read Case Names

Create a character array of case names representing months.

```
months = char('January','February', ...
    'March','April','May');
```

Write the names to a file named `months.dat`. View the contents of the file by using the `type` function.

```
casewrite(months,'months.dat')
type months.dat
```

```
January
February
March
April
May
```

Read the names in the `months.dat` file.

```
names = caseread('months.dat')
```

```
names = 5x8 char array
    'January '
    'February'
```

```
    'March   '
    'April   '
    'May     '
```

Input Arguments

`strmat` — Case names

character array | string column vector

Case names, specified as a character array or string column vector. Each row of `strmat` corresponds to a case name and becomes a line in `filename`.

Data Types: `char` | `string`

`filename` — Name of file to write

character vector | string scalar

Name of the file to write, specified as a character vector or string scalar.

Depending on the location you are writing to, `filename` has one of these forms.

Location of File	Form
Current folder	Specify the name of the file in `filename`. **Example:** `'myTextFile.csv'`
Folder that is different from the current folder	Specify the full or relative path name in `filename`. **Example:** `'C:\myFolder\myTextFile.csv'`

Example: `'months.dat'`

Data Types: `char` | `string`

Alternative Functionality

Instead of using `casewrite` and `caseread` with character arrays, consider using `writecell` and `readcell` with cell arrays. For example:

```
months = {'January';'February';'March';'April';'May'};
writecell(months,'months.dat')
names = readcell('months.dat')
```

```
names =

  5×1 cell array

    {'January' }
    {'February'}
    {'March'   }
    {'April'   }
    {'May'     }
```

DaviesBouldinEvaluation

Package: `clustering.evaluation`
Superclasses: `ClusterCriterion`

Davies-Bouldin criterion clustering evaluation object

Description

`DaviesBouldinEvaluation` is an object consisting of sample data, clustering data, and Davies-Bouldin criterion values used to evaluate the optimal number of clusters. Create a Davies-Bouldin criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x,clust,'DaviesBouldin')` creates a Davies-Bouldin criterion clustering evaluation object.

`eva = evalclusters(x,clust,'DaviesBouldin',Name,Value)` creates a Davies-Bouldin criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an *N*-by-*P* matrix. *N* is the number of observations, and *P* is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

`'kmeans'` | `'linkage'` | `'gmdistribution'` | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

`'kmeans'`	Cluster the data in `x` using the `kmeans` clustering algorithm, with `'EmptyAction'` set to `'singleton'` and `'Replicates'` set to `5`.
`'linkage'`	Cluster the data in `x` using the `clusterdata` agglomerative clustering algorithm, with `'Linkage'` set to `'ward'`.
`'gmdistribution'`	Cluster the data in `x` using the `gmdistribution` Gaussian mixture distribution algorithm, with `'SharedCov'` set to `true` and `'Replicates'` set to `5`.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can specify a clustering algorithm using a function handle. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric *n*-by-*K* matrix of score for *n* observations and *K* classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a *n*-by-*K* matrix containing the proposed clustering solutions. *n* is the number of observations in the sample data, and *K* is the number of proposed clustering solutions. Column *j* contains the cluster indices for each of the *N* points in the *j*th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5]` specifies to test 1, 2, 3, 4, and 5 clusters to find the optimal number.

`KList` — List of number of clusters to evaluate
vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is `'gap'`, `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: `'KList',[1:6]`

Data Types: `single` | `double`

Properties

`ClusteringFunction`

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

`CriterionName`

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

`CriterionValues`

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

`InspectedK`

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

`Missing`

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `X` is not used in the clustering solution.

`NumObservations`

Number of observations in the data matrix `X`, minus the number of missing (`NaN`) values in `X`, stored as a positive integer value.

`OptimalK`

Optimal number of clusters, stored as a positive integer value.

`OptimalY`

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

`X`

Data used for clustering, stored as a matrix of numerical values.

Methods

Inherited Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values
compact	Compact clustering evaluation object

Examples

Evaluate the Clustering Solution Using Davies-Bouldin Criterion

Evaluate the optimal number of clusters using the Davies-Bouldin clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

```
rng('default');  % For reproducibility
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];

mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];

mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];

N = 200;

X = [mvnrnd(mu1,sigma1,N);...
```

```
    mvnrnd(mu2,sigma2,N);...
    mvnrnd(mu3,sigma3,N)];
```

Evaluate the optimal number of clusters using the Davies-Bouldin criterion. Cluster the data using `kmeans`.

```
E = evalclusters(X,'kmeans','DaviesBouldin','klist',[1:6])
```

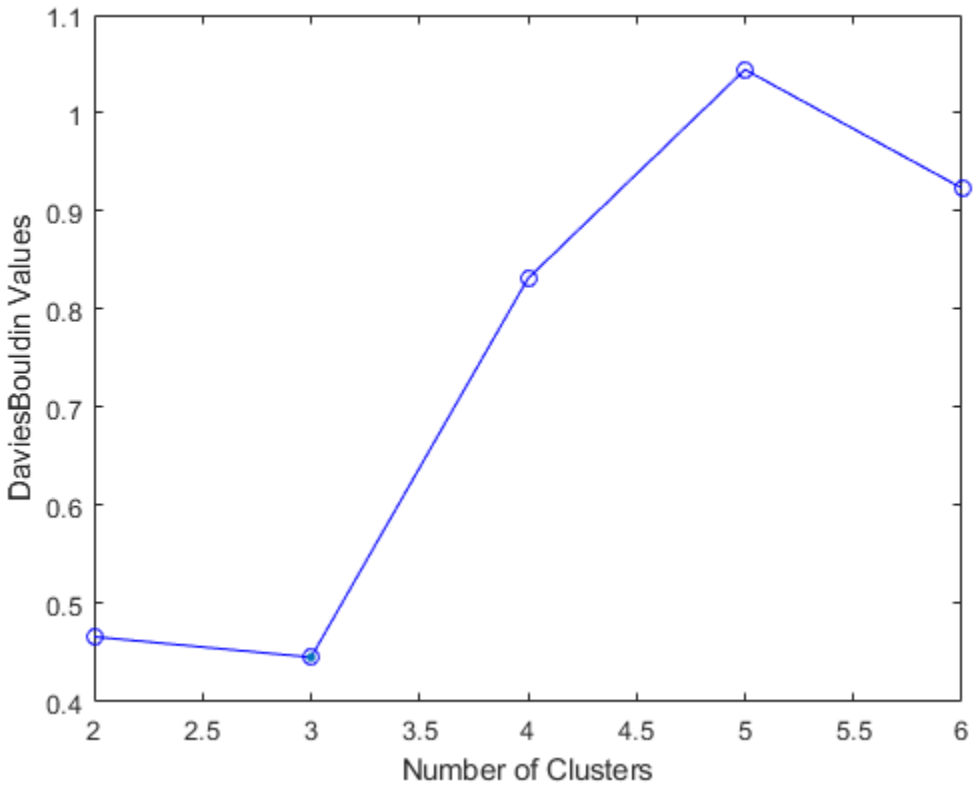
```
E =
  DaviesBouldinEvaluation with properties:

    NumObservations: 600
        InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 0.4663 0.4454 0.8316 1.0444 0.9236]
           OptimalK: 3
```

The `OptimalK` value indicates that, based on the Davies-Bouldin criterion, the optimal number of clusters is three.

Plot the Davies-Bouldin criterion values for each number of clusters tested.

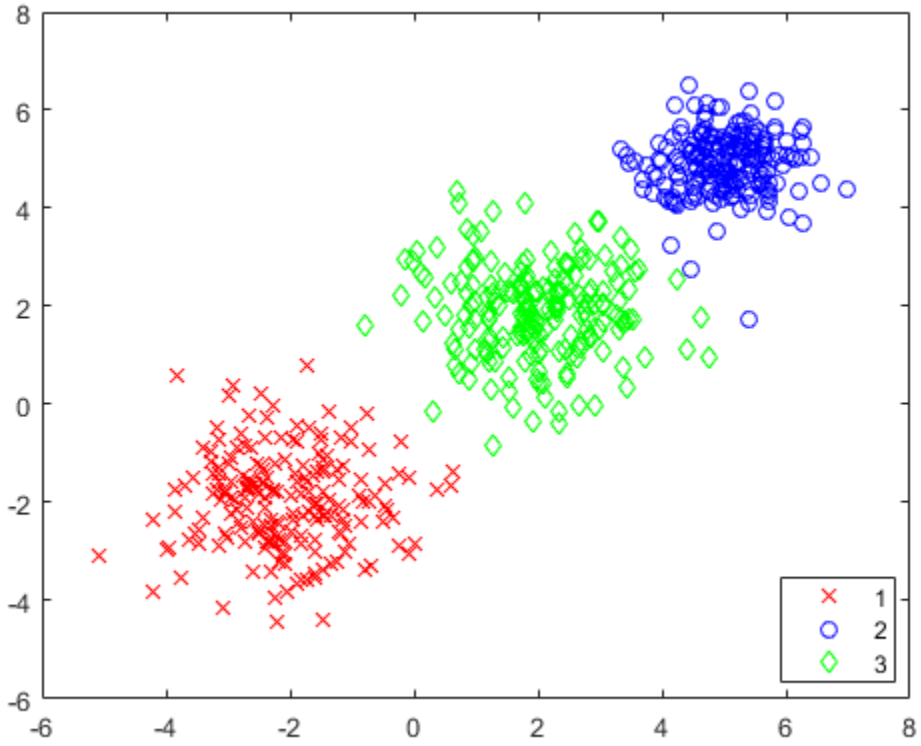
```
figure;
plot(E)
```



The plot shows that the lowest Davies-Bouldin value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```
figure;
gscatter(X(:,1),X(:,2),E.OptimalY,'rbg','xod')
```



The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is in the upper-right corner, and cluster 3 is near the center of the plot.

More About

Davies-Bouldin Criterion

The Davies-Bouldin criterion is based on a ratio of within-cluster and between-cluster distances. The Davies-Bouldin index is defined as

$$DB = \frac{1}{k}\sum_{i=1}^{k} \max_{j \neq i}\{D_{i,j}\},$$

where $D_{i,j}$ is the within-to-between cluster distance ratio for the ith and jth clusters. In mathematical terms,

$$D_{i,j} = \frac{\left(\bar{d}_i + \bar{d}_j\right)}{d_{i,j}}.$$

$\bar{d}_i$ is the average distance between each point in the ith cluster and the centroid of the ith cluster. $\bar{d}_j$ is the average distance between each point in the jth cluster and the centroid of the jth cluster. $d_{i,j}$ is the Euclidean distance between the centroids of the ith and jth clusters.

The maximum value of $D_{i,j}$ represents the worst-case within-to-between cluster ratio for cluster i. The optimal clustering solution has the smallest Davies-Bouldin index value.

Topics
Class Attributes
Property Attributes

cat

Class: `dataset`

(Not Recommended) Concatenate dataset arrays

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = cat(dim, ds1, ds2, ...)
```

Description

`ds = cat(dim, ds1, ds2, ...)` concatenates the dataset arrays `ds1, ds2, ...` along dimension `dim` by calling the `dataset/horzcat` or `dataset/vertcat` method. `dim` must be 1 or 2.

See Also

`horzcat` | `vertcat`

cdf

Cumulative distribution function for Gaussian mixture distribution

Syntax

```
y = cdf(gm,X)
```

Description

`y = cdf(gm,X)` returns the cumulative distribution function (cdf) of the Gaussian mixture distribution `gm`, evaluated at the values in `X`.

Examples

Compute cdf Values

Create a `gmdistribution` object and compute its cdf values.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```
mu = [1 2;-3 -5];
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:     1     2

Component 2:
Mixing proportion: 0.500000
Mean:    -3    -5
```

Compute the cdf values of `gm`.

```
X = [0 0;1 2;3 3;5 3];
cdf(gm,X)
```

```
ans = 4×1

    0.5011
    0.6250
    0.9111
    0.9207
```

Plot cdf

Create a `gmdistribution` object and plot its cdf.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

```
p = [0.4 0.6];               % Mixing proportions
mu = [1 2;-3 -5];            % Means
sigma = cat(3,[2 .5],[1 1])  % Covariances 1-by-2-by-2 array
```

```
sigma =
sigma(:,:,1) =

    2.0000    0.5000

sigma(:,:,2) =

     1     1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object by using the `gmdistribution` function.

```
gm = gmdistribution(mu,sigma,p)
```

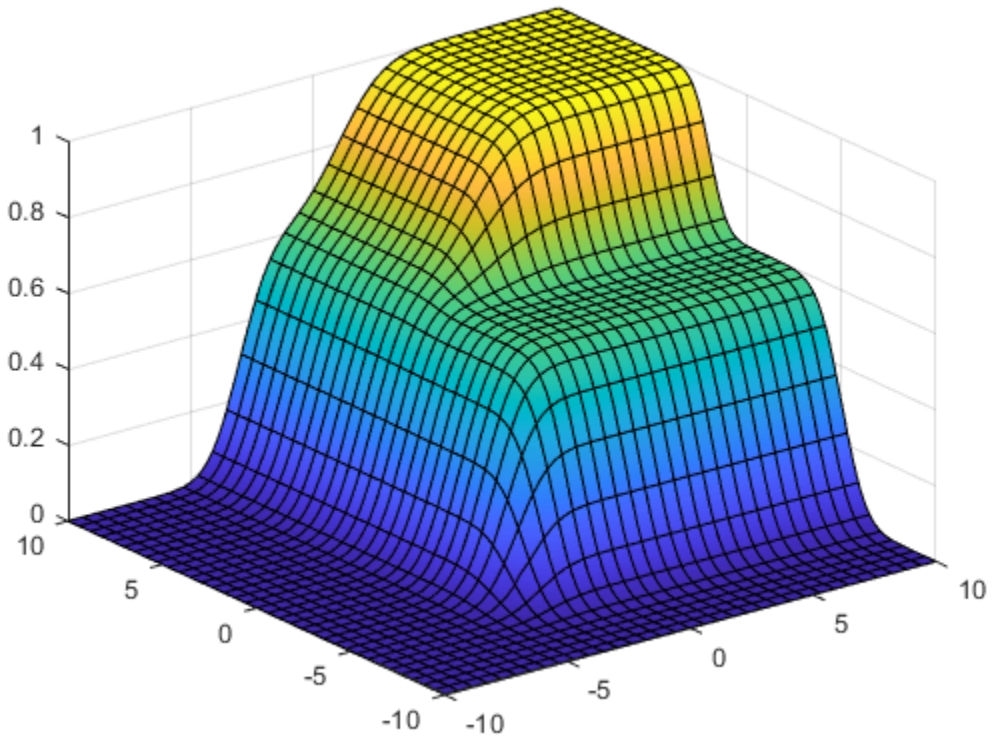
```
gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.400000
Mean:     1     2

Component 2:
Mixing proportion: 0.600000
Mean:    -3    -5
```

Plot the cdf of the Gaussian mixture distribution by using `fsurf`.

```
gmCDF = @(x,y) arrayfun(@(x0,y0) cdf(gm,[x0 y0]),x,y);
fsurf(gmCDF,[-10 10])
```



Input Arguments

gm — Gaussian mixture distribution
`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Values at which to evaluate cdf
n-by-*m* numeric matrix

Values at which to evaluate the cdf, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

Data Types: `single` | `double`

Output Arguments

y — cdf values
n-by-1 numeric vector

cdf values of the Gaussian mixture distribution `gm`, evaluated at `X`, returned as an *n*-by-1 numeric vector, where *n* is the number of observations in `X`.

ccdesign

Central composite design

Syntax

```
dCC = ccdesign(n)
[dCC,blocks] = ccdesign(n)
[...] = ccdesign(n,'Name',value)
```

Description

`dCC = ccdesign(n)` generates a central composite design for `n` factors. `n` must be an integer `2` or larger. The output matrix `dCC` is *m*-by-`n`, where *m* is the number of runs in the design. Each row represents one run, with settings for all factors represented in the columns. Factor values are normalized so that the cube points take values between `-1` and `1`.

`[dCC,blocks] = ccdesign(n)` requests a blocked design. The output `blocks` is an *m*-by-1 vector of block numbers for each run. Blocks indicate runs that are to be measured under similar conditions to minimize the effect of inter-block differences on the parameter estimates.

`[...] = ccdesign(n,'Name',value)` specifies one or more optional name/value pairs for the design. Valid parameters and their values are listed in the following table. Specify *`Name`* in single quotes.

Parameter	Description	Values	Value Description
`center`	Number of center points.	Integer	Number of center points to include.
		`'uniform'`	Select number of center points to give uniform precision.
		`'orthogonal'`	Select number of center points to give an orthogonal design. This is the default.
`fraction`	Fraction of full-factorial cube, expressed as an exponent of 1/2.	`0`	Whole design. Default when $n \le 4$.
		`1`	1/2 fraction. Default when $4 < n \le 7$ or $n > 11$.
		`2`	1/4 fraction. Default when $7 < n \le 9$
		`3`	1/8 fraction. Default when $n = 10$.
		`4`	1/16 fraction. Default when $n = 11$.
`type`	Type of CCD.	`'circumscribed'`	Circumscribed (CCC). This is the default.

Parameter	Description	Values	Value Description
		`'inscribed'`	Inscribed (CCI).
		`'faced'`	Faced (CCF).
`blocksize`	Maximum number of points per block.	Integer	The default is `Inf`.

Examples

Two-Factor Central Composite Design

Create a 2-factor central composite design.

```
dCC = ccdesign(2,'type','circumscribed')
```

```
dCC = 16×2

   -1.0000   -1.0000
   -1.0000    1.0000
    1.0000   -1.0000
    1.0000    1.0000
   -1.4142         0
    1.4142         0
         0   -1.4142
         0    1.4142
         0         0
         0         0
    ⋮
```

The center point is run 8 times to reduce the correlations among the coefficient estimates.

Visualize the design.

```
plot(dCC(:,1),dCC(:,2),'ro','MarkerFaceColor','b')
X = [1 -1 -1 -1; 1 1 1 -1];
Y = [-1 -1 1 -1; 1 -1 1 1];
line(X,Y,'Color','b')
axis square equal
```

`bbdesign`

Introduced before R2006a

cdf

Package: `prob`

Cumulative distribution function

Syntax

```
y = cdf('name',x,A)
y = cdf('name',x,A,B)
y = cdf('name',x,A,B,C)
y = cdf('name',x,A,B,C,D)

y = cdf(pd,x)

y = cdf(___,'upper')
```

Description

`y = cdf('name',x,A)` returns the cumulative distribution function (cdf) for the one-parameter distribution family specified by `'name'` and the distribution parameter `A`, evaluated at the values in `x`.

`y = cdf('name',x,A,B)` returns the cdf for the two-parameter distribution family specified by `'name'` and the distribution parameters `A` and `B`, evaluated at the values in `x`.

`y = cdf('name',x,A,B,C)` returns the cdf for the three-parameter distribution family specified by `'name'` and the distribution parameters `A`, `B`, and `C`, evaluated at the values in `x`.

`y = cdf('name',x,A,B,C,D)` returns the cdf for the four-parameter distribution family specified by `'name'` and the distribution parameters `A`, `B`, `C`, and `D`, evaluated at the values in `x`.

`y = cdf(pd,x)` returns the cdf of the probability distribution object `pd`, evaluated at the values in `x`.

`y = cdf(___,'upper')` returns the complement of the cdf using an algorithm that more accurately computes the extreme upper-tail probabilities. `'upper'` can follow any of the input arguments in the previous syntaxes.

Examples

Compute Normal Distribution cdf

Create a standard normal distribution object with the mean, μ, equal to 0 and the standard deviation, σ, equal to 1.

```
mu = 0;
sigma = 1;
pd = makedist('Normal','mu',mu,'sigma',sigma);
```

Define the input vector x to contain the values at which to calculate the cdf.

```
x = [-2,-1,0,1,2];
```

Compute the cdf values for the standard normal distribution at the values in x.

```
y = cdf(pd,x)
```

```
y = 1×5

    0.0228    0.1587    0.5000    0.8413    0.9772
```

Each value in y corresponds to a value in the input vector x. For example, at the value x equal to 1, the corresponding cdf value y is equal to 0.8413.

Alternatively, you can compute the same cdf values without creating a probability distribution object. Use the `cdf` function, and specify a standard normal distribution using the same parameter values for μ and σ.

```
y2 = cdf('Normal',x,mu,sigma)
```

```
y2 = 1×5

    0.0228    0.1587    0.5000    0.8413    0.9772
```

The cdf values are the same as those computed using the probability distribution object.

Compute Poisson Distribution cdf

Create a Poisson distribution object with the rate parameter, λ, equal to 2.

```
lambda = 2;
pd = makedist('Poisson','lambda',lambda);
```

Define the input vector x to contain the values at which to calculate the cdf.

```
x = [0,1,2,3,4];
```

Compute the cdf values for the Poisson distribution at the values in x.

```
y = cdf(pd,x)
```

```
y = 1×5

    0.1353    0.4060    0.6767    0.8571    0.9473
```

Each value in y corresponds to a value in the input vector x. For example, at the value x equal to 3, the corresponding cdf value y is equal to 0.8571.

Alternatively, you can compute the same cdf values without creating a probability distribution object. Use the `cdf` function, and specify a Poisson distribution using the same value for the rate parameter, λ.

```
y2 = cdf('Poisson',x,lambda)
```

```
y2 = 1×5

    0.1353    0.4060    0.6767    0.8571    0.9473
```

The cdf values are the same as those computed using the probability distribution object.

Plot Standard Normal Distribution cdf

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =
  NormalDistribution

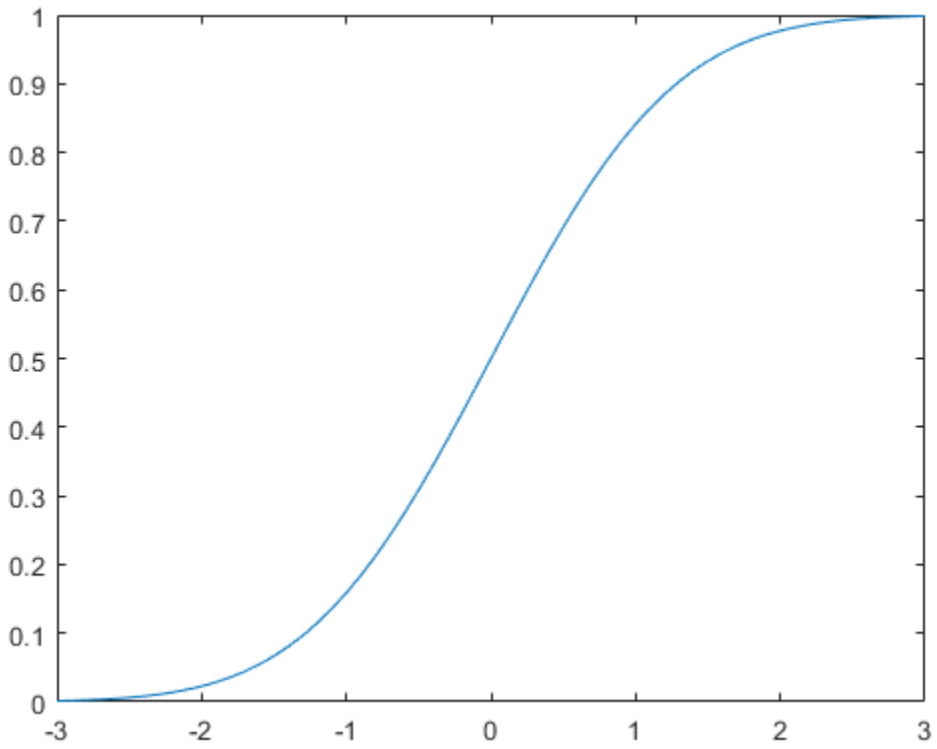
  Normal distribution
       mu = 0
    sigma = 1
```

Specify the x values and compute the cdf.

```
x = -3:.1:3;
p = cdf(pd,x);
```

Plot the cdf of the standard normal distribution.

```
plot(x,p)
```



Plot Gamma Distribution cdf

Create three gamma distribution objects. The first uses the default parameter values. The second specifies `a = 1` and `b = 2`. The third specifies `a = 2` and `b = 1`.

```
pd_gamma = makedist('Gamma')

pd_gamma =
  GammaDistribution

  Gamma distribution
    a = 1
    b = 1

pd_12 = makedist('Gamma','a',1,'b',2)

pd_12 =
  GammaDistribution

  Gamma distribution
    a = 1
    b = 2

pd_21 = makedist('Gamma','a',2,'b',1)
```

```
pd_21 =
  GammaDistribution

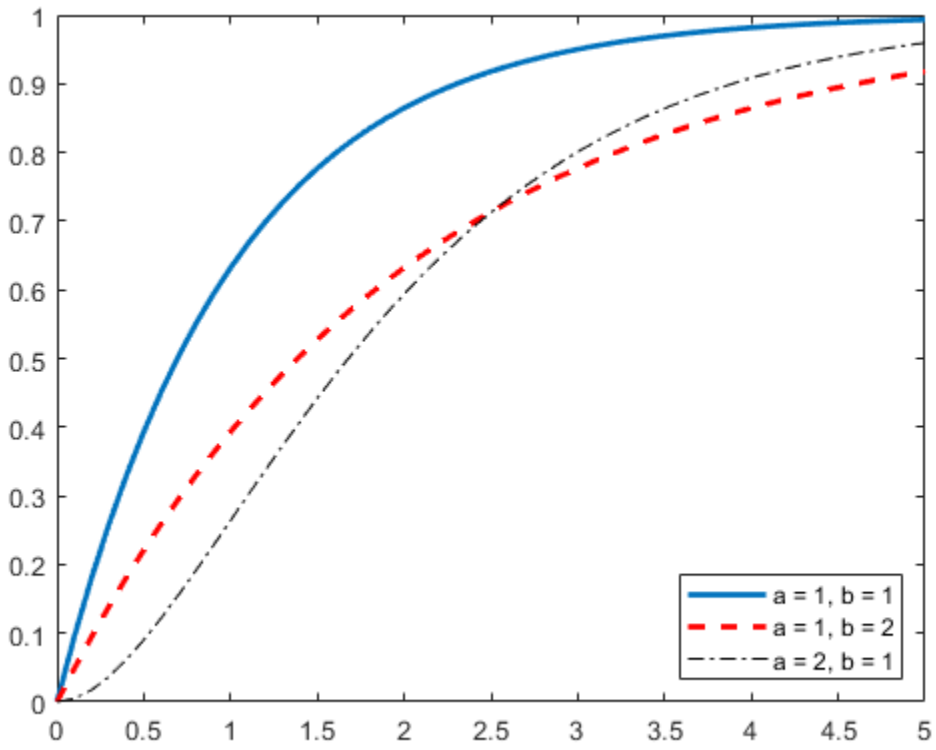
  Gamma distribution
    a = 2
    b = 1
```

Specify the x values and compute the cdf for each distribution.

```
x = 0:.1:5;
cdf_gamma = cdf(pd_gamma,x);
cdf_12 = cdf(pd_12,x);
cdf_21 = cdf(pd_21,x);
```

Create a plot to visualize how the cdf of the gamma distribution changes when you specify different values for the shape parameters a and b.

```
figure;
J = plot(x,cdf_gamma);
hold on;
K = plot(x,cdf_12,'r--');
L = plot(x,cdf_21,'k-.');
set(J,'LineWidth',2);
set(K,'LineWidth',2);
legend([J K L],'a = 1, b = 1','a = 1, b = 2','a = 2, b = 1','Location','southeast');
hold off;
```



Fit Pareto Tails to t Distribution and Compute the cdf

Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9.

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
```

```
p = 2×1

    0.1000
    0.9000

q = 2×1

   -1.8487
    2.0766
```

Compute the cdf at the values in `q`.

```
cdf(obj,q)
```

```
ans = 2×1

    0.1000
    0.9000
```

Input Arguments

`'name'` — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

`'name'`	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
`'Beta'`	“Beta Distribution” on page B-6	a first shape parameter	b second shape parameter	—	—
`'Binomial'`	“Binomial Distribution” on page B-10	n number of trials	p probability of success for each trial	—	—
`'BirnbaumSaunders'`	“Birnbaum-Saunders Distribution” on page B-18	β scale parameter	γ shape parameter	—	—
`'Burr'`	“Burr Type XII Distribution” on page B-19	α scale parameter	c first shape parameter	k second shape parameter	—
`'Chisquare'`	“Chi-Square Distribution” on page B-28	ν degrees of freedom	—	—	—

'name'	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Exponential'	"Exponential Distribution" on page B-33	μ mean	—	—	—

Example: 'Normal'

x — Values at which to evaluate cdf
scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x, A, B, C, and D are arrays, then the array sizes must be the same. In this case, cdf expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Example: `[0.1,0.25,0.5,0.75,0.9]`

Data Types: `single` | `double`

`A` — First probability distribution parameter
scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `x`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`B` — Second probability distribution parameter
scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `x`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`C` — Third probability distribution parameter
scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `x`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`D` — Fourth probability distribution parameter
scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `x`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `cdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`pd` — Probability distribution
probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
`makedist`	Create a probability distribution object using specified parameter values.

Function or App	Description
`fitdist`	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
`paretotails`	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

Output Arguments

y — cdf values

scalar value | array of scalar values

cdf values, returned as a scalar value or an array of scalar values. `y` is the same size as `x` after any necessary scalar expansion. Each element in `y` is the cdf value of the distribution, specified by the corresponding elements in the distribution parameters (`A`, `B`, `C`, and `D`) or the probability distribution object (`pd`), evaluated at the corresponding element in `x`.

Alternative Functionality

- `cdf` is a generic function that accepts either a distribution by its name `'name'` or a probability distribution object `pd`. It is faster to use a distribution-specific function, such as `normcdf` for the normal distribution and `binocdf` for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-14.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `'name'` must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 32-82.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

cdfplot

Empirical cumulative distribution function (cdf) plot

Syntax

```
cdfplot(x)
h = cdfplot(x)
[h,stats] = cdfplot(x)
```

Description

`cdfplot(x)` creates an empirical cumulative distribution function (cdf) plot for the data in `x`. For a value t in `x`, the empirical cdf $F(t)$ is the proportion of the values in `x` less than or equal to t.

`h = cdfplot(x)` returns a handle of the empirical cdf plot line object. Use `h` to query or modify properties of the object after you create it. For a list of properties, see Line Properties.

`[h,stats] = cdfplot(x)` also returns a structure including summary statistics for the data in `x`.

Examples

Compare Empirical cdf to Theoretical cdf

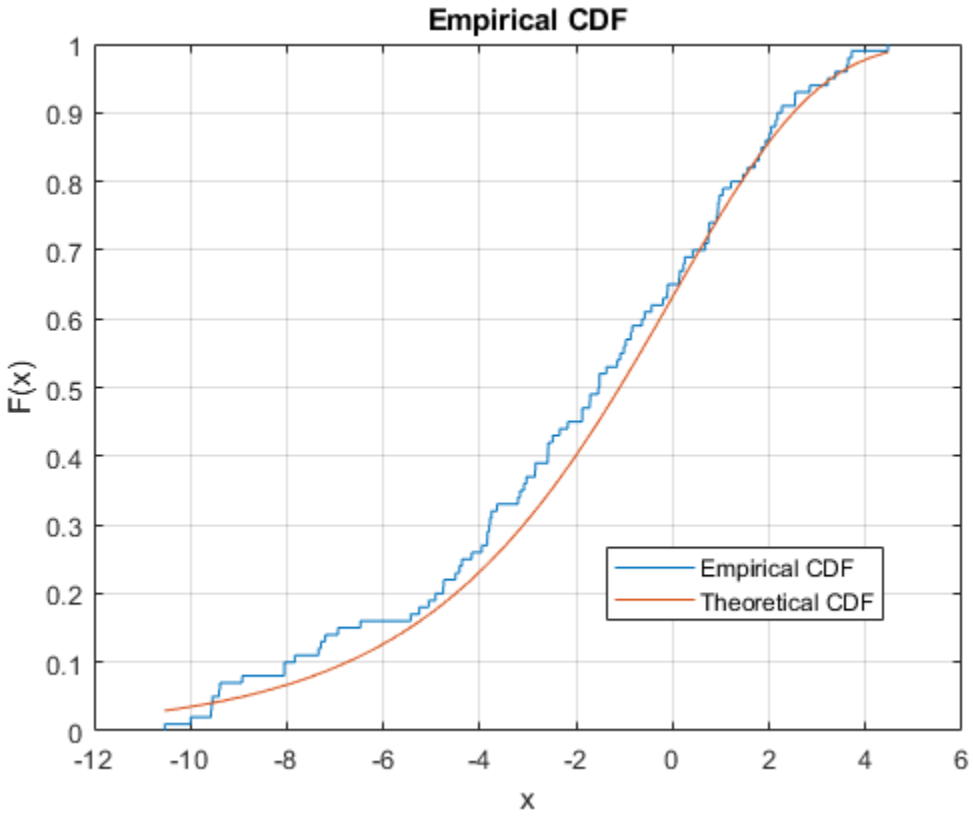
Plot the empirical cdf of a sample data set and compare it to the theoretical cdf of the underlying distribution of the sample data set. In practice, a theoretical cdf can be unknown.

Generate a random sample data set from the extreme value distribution with a location parameter of 0 and a scale parameter of 3.

```
rng('default')  % For reproducibility
y = evrnd(0,3,100,1);
```

Plot the empirical cdf of the sample data set and the theoretical cdf on the same figure.

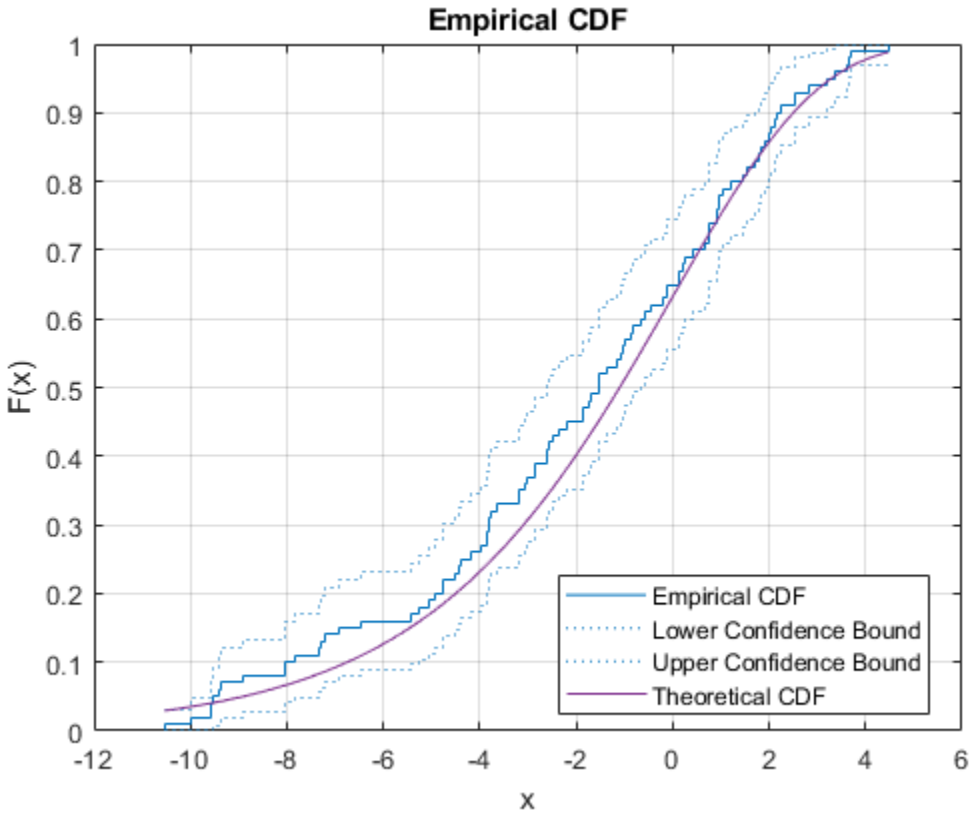
```
cdfplot(y)
hold on
x = linspace(min(y),max(y));
plot(x,evcdf(x,0,3))
legend('Empirical CDF','Theoretical CDF','Location','best')
hold off
```



The plot shows the similarity between the empirical cdf and the theoretical cdf.

Alternatively, you can use the `ecdf` function. The `ecdf` function also plots the 95% confidence intervals estimated by using Greenwood's Formula. For details, see “Greenwood’s Formula” on page 33-1279.

```
ecdf(y,'Bounds','on')
hold on
plot(x,evcdf(x,0,3))
grid on
title('Empirical CDF')
legend('Empirical CDF','Lower Confidence Bound','Upper Confidence Bound','Theoretical CDF','Loca
hold off
```



Test for Standard Normal Distribution

Perform the one-sample Kolmogorov-Smirnov test by using `kstest`. Confirm the test decision by visually comparing the empirical cumulative distribution function (cdf) to the standard normal cdf.

Load the `examgrades` data set. Create a vector containing the first column of the exam grade data.

```
load examgrades
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector, because `kstest` tests for a standard normal distribution by default.

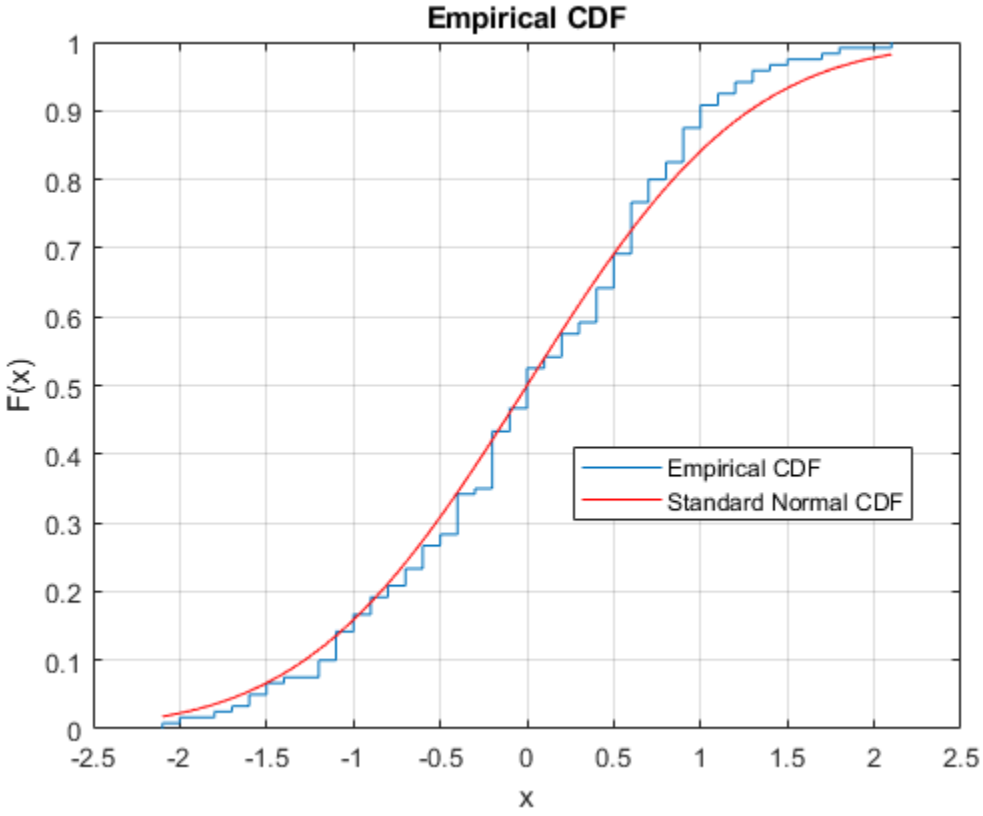
```
x = (test1-75)/10;
h = kstest(x)
```

```
h = logical
   0
```

The returned value of `h = 0` indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
cdfplot(x)
hold on
x_values = linspace(min(x),max(x));
plot(x_values,normcdf(x_values,0,1),'r-')
legend('Empirical CDF','Standard Normal CDF','Location','best')
```



The figure shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

Input Arguments

x — Input data

numeric vector

Input data, specified as a numeric vector.

Data Types: `single` | `double`

Output Arguments

h — Handle of plot line object

chart line object

Handle of the empirical cdf plot line object, returned as a chart line object. Use `h` to query or modify properties of the object after you create it. For a list of properties, see Line Properties.

`stats` — Summary statistics
structure

Summary statistics for the data in `x`, returned as a structure with the following fields:

Field	Description
`min`	Minimum value
`max`	Maximum value
`mean`	Sample mean
`median`	Sample median (50th percentile)
`std`	Sample standard deviation

Tips

- `cdfplot` is useful for examining the distribution of a sample data set. You can overlay a theoretical cdf on the same plot of `cdfplot` to compare the empirical distribution of the sample to the theoretical distribution. For an example, see “Compare Empirical cdf to Theoretical cdf” on page 33-296.
- The `kstest`, `kstest2`, and `lillietest` functions compute test statistics derived from an empirical cdf. `cdfplot` is useful in helping you to understand the output from these functions. For an example, see “Test for Standard Normal Distribution” on page 33-298.

Alternative Functionality

You can use the `ecdf` function to find the empirical cdf values and create an empirical cdf plot. The `ecdf` function enables you to indicate censored data and compute the confidence bounds for the estimated cdf values.

cell2dataset

(Not Recommended) Convert cell array to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = cell2dataset(C)
ds = cell2dataset(C,Name,Value)
```

Description

`ds = cell2dataset(C)` converts a cell array to a `dataset` array.

`ds = cell2dataset(C,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Cell Array to Dataset Array

Convert a cell array to a dataset array using the default options.

Create a cell array to convert.

```
C = {'Name','Gender','SystolicBP','DiastolicBP';
     'CLARK','M',124,93;
     'BROWN','F',122,80;
     'MARTIN','M',130,92}
```

```
C=4×4 cell array
    {'Name'  }    {'Gender'}    {'SystolicBP'}    {'DiastolicBP'}
    {'CLARK' }    {'M'     }    {[       124]}    {[         93]}
    {'BROWN' }    {'F'     }    {[       122]}    {[         80]}
    {'MARTIN'}    {'M'     }    {[       130]}    {[         92]}
```

Convert the cell array to a dataset array.

```
ds = cell2dataset(C)
```

```
ds =
    Name              Gender       SystolicBP    DiastolicBP
    {'CLARK' }        {'M'}        124           93
    {'BROWN' }        {'F'}        122           80
    {'MARTIN'}        {'M'}        130           92
```

The first row of `C` become the variable names in the output dataset array, `ds`.

Create a Dataset Array with Multicolumn Variables

Convert a cell array to a dataset array containing multicolumn variables.

Create a cell array to convert.

```
C = {'Name','Gender','SystolicBP','DiastolicBP';
     'CLARK','M',124,93;
     'BROWN','F',122,80;
     'MARTIN','M',130,92}
```

```
C=4×4 cell array
    {'Name'  }    {'Gender'}    {'SystolicBP'}    {'DiastolicBP'}
    {'CLARK' }    {'M'     }    {[       124]}    {[         93]}
    {'BROWN' }    {'F'     }    {[       122]}    {[         80]}
    {'MARTIN'}    {'M'     }    {[       130]}    {[         92]}
```

Convert the cell array to a dataset array, combining the systolic and diastolic blood pressure measurements into one variable named `BloodPressure`.

```
ds = cell2dataset(C,'NumCols',[1,1,2]);
ds.Properties.VarNames{3} = 'BloodPressure';
ds
```

```
ds =
    Name              Gender       BloodPressure
    {'CLARK' }        {'M'}        124          93
    {'BROWN' }        {'F'}        122          80
    {'MARTIN'}        {'M'}        130          92
```

The output dataset array has three observations and three variables.

Input Arguments

`C` — Input cell array

cell array

Input cell array to convert to a dataset array, specified as an *M*-by-*N* cell array. Each column of `C` becomes a variable in the output dataset array, `ds`. By default, `cell2dataset` assumes that the first row of `C` contains variable names.

Data Types: `cell` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ReadVarNames',false,'ReadObsNames',true` specifies that the first row of the cell array does not contain variable names, but the first column contains observation names.

ReadVarNames — Indicator for whether or not to read variable names
`true` (default) | `false`

Indicator for whether or not to read variable names from the first row of the input cell array, specified as the comma-separated pair consisting of `'ReadVarNames'` and either `true` or `false`. The default value is `true`, unless variable names are specified using the name-value pair argument `VarNames`. When `ReadVarNames` is `false`, `cell2dataset` creates default variable names if you do not provide any.

Example: `'ReadVarNames',false`

VarNames — Variable names for output dataset array
string array | cell array of character vectors

Variable names for the output dataset array, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors. You must provide a variable name for each variable in `ds`. The names must be valid MATLAB identifiers, and must be unique.

Example: `'VarNames',{'myVar1','myVar2','myVar3'}`

ReadObsNames — Indicator for whether or not to read observation names
`false` (default) | `true`

Indicator for whether or not to read observation names from the input cell array, specified as the comma-separated pair consisting of `'ReadObsNames'` and either `true` or `false`. When `ReadObsNames` has the value `true`, `cell2dataset` creates observation names in `ds` using the first column of `C`, and sets `ds.Properties.DimNames` equal to `{C{1,1},'Variables'}`.

Example: `'ReadObsNames',true`

ObsNames — Observation names for output dataset array
string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of `'ObsNames'` and a string array or cell array of character vectors. The names do not need to be valid MATLAB identifiers, but they must be unique.

NumCols — Number of columns for each variable
vector of nonnegative integers

Number of columns for each variable in `ds`, specified as the comma-separated pair consisting of `'NumCols'` and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `cell2dataset` combines multiple columns in `C` into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(C,2)`, or `size(C,1)` of `ReadObsNames` is equal to `true`.

For example, to convert a cell array with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as `'NumCols',[1,1,3,1,2]`.

Output Arguments

ds — Output dataset array
dataset array

Output dataset array, returned by default with a variable for each column of `C`, an observation for each row of `C` (except for the first row), and variable names corresponding to the first row of `C`.

- If you set `ReadVarNames` equal to `false` (or specify `VarNames`), then there is an observation in `ds` for each row of `C`, and `cell2dataset` creates default variable names (or uses the names in `VarNames`).
- If you set `ReadObsNames` equal to `true`, then `cell2dataset` uses the first column of `C` as observation names.
- If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

“Dataset Arrays” on page 2-112

Introduced in R2012b

cellstr

Class: `dataset`

(Not Recommended) Create cell array of character vectors from dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = cellstr(A)
B = cellstr(A,VARS)
```

Description

`B = cellstr(A)` returns the contents of the dataset `A`, converted to a cell array of character vectors. The variables in the dataset must support the conversion and must have compatible sizes.

`B = cellstr(A,VARS)` returns the contents of the dataset variables specified by `VARS`. `VARS` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

See Also

`double` | `replacedata`

chi2cdf

Chi-square cumulative distribution function

Syntax

```
p = chi2cdf(x,nu)
p = chi2cdf(x,nu,'upper')
```

Description

`p = chi2cdf(x,nu)` returns the cumulative distribution function (cdf) of the chi-square distribution with degrees of freedom `nu`, evaluated at the values in `x`.

`p = chi2cdf(x,nu,'upper')` returns the complement of the cdf, evaluated at the values in `x` with degrees of freedom `nu`, using an algorithm that more accurately computes the extreme upper-tail probabilities than subtracting the lower tail value from 1.

Examples

Compute Chi-Square cdf

Compute the probability that an observation from the chi-square distribution with `5` degrees of freedom is in the interval `[0 3]`.

```
p1 = chi2cdf(3,5)
```

```
p1 = 0.3000
```

Compute the probability that an observation from the chi-square distributions with degrees of freedom `1` through `5` is in the interval `[0 3]`.

```
p2 = chi2cdf(3,1:5)
```

```
p2 = 1×5

    0.9167    0.7769    0.6084    0.4422    0.3000
```

The mean of the chi-square distribution is equal to the degrees of freedom. Compute the probability that an observation is in the interval `[0 nu]` for degrees of freedom `1` through `6`.

```
nu = 1:6;
x = nu;
p3 = chi2cdf(x,nu)
```

```
p3 = 1×6

    0.6827    0.6321    0.6084    0.5940    0.5841    0.5768
```

As the degrees of freedom increase, the probability that an observation from a chi-square distribution with degrees of freedom `nu` is less than the mean value approaches `0.5`.

Complementary cdf (Tail Distribution)

Determine the probability that an observation from the chi-square distribution with 3 degrees of freedom is in on the interval `[100 Inf]`.

```
p1 = 1 - chi2cdf(100,3)
```

```
p1 = 0
```

`chi2cdf(100,3)` is nearly `1`, so `p1` becomes `0`. Specify `'upper'` so that `chi2cdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = chi2cdf(100,3,'upper')
```

```
p2 = 1.5542e-21
```

Input Arguments

x — Values at which to evaluate cdf

nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the cdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2cdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[3 4 7 9]`

Data Types: `single` | `double`

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the chi-square distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2cdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

Output Arguments

p — cdf values

scalar value | array of scalar values

cdf values evaluated at the values in x, returned as a scalar value or an array of scalar values. p is the same size as x and nu after any necessary scalar expansion. Each element in p is the cdf value of the distribution specified by the corresponding element in nu, evaluated at the corresponding element in x.

More About

Chi-Square cdf

The chi-square distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom.

The cdf of the chi-square distribution is

$$p = F(x|\nu) = \int_0^x \frac{t^{(\nu-2)/2}e^{-t/2}}{2^{\nu/2}\Gamma(\nu/2)}dt,$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the chi-square distribution with ν degrees of freedom falls in the interval $[0, x]$.

For more information, see “Chi-Square Distribution” on page B-28.

Alternative Functionality

- `chi2cdf` is a function specific to the chi-square distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `chi2cdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also

Topics
“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2gof

Chi-square goodness-of-fit test

Syntax

```
h = chi2gof(x)
h = chi2gof(x,Name,Value)
[h,p] = chi2gof(___)
[h,p,stats] = chi2gof(___)
```

Description

`h = chi2gof(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with a mean and variance estimated from `x`, using the chi-square goodness-of-fit test on page 33-315. The alternative hypothesis is that the data does not come from such a distribution. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, and `0` otherwise.

`h = chi2gof(x,Name,Value)` returns a test decision for the chi-square goodness-of-fit test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than normal, or change the significance level of the test.

`[h,p] = chi2gof(___)` also returns the *p*-value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,stats] = chi2gof(___)` also returns the structure `stats`, containing information about the test statistic.

Examples

Test for Normal Distribution

Create a standard normal probability distribution object. Generate a data vector `x` using random numbers from the distribution.

```
pd = makedist('Normal');
rng default;  % for reproducibility
x = random(pd,100,1);
```

Test the null hypothesis that the data in `x` comes from a population with a normal distribution.

```
h = chi2gof(x)
```

```
h = 0
```

The returned value `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level.

Test Hypothesis at Different Significance Level

Create a standard normal probability distribution object. Generate a data vector `x` using random numbers from the distribution.

```
pd = makedist('Normal');
rng default;  % for reproducibility
x = random(pd,100,1);
```

Test the null hypothesis that the data in `x` comes from a population with a normal distribution at the 1% significance level.

```
[h,p] = chi2gof(x,'Alpha',0.01)
```

```
h = 0
```

```
p = 0.3775
```

The returned value `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the 1% significance level.

Test for Weibull Distribution Using Probability Distribution Object

Load the light bulb lifetime sample data.

```
load lightbulb
```

Create a vector from the first column of the data matrix, which contains the lifetime in hours of the light bulbs.

```
x = lightbulb(:,1);
```

Test the null hypothesis that the data in `x` comes from a population with a Weibull distribution. Use `fitdist` to create a probability distribution object with `A` and `B` parameters estimated from the data.

```
pd = fitdist(x,'Weibull');
h = chi2gof(x,'CDF',pd)
```

```
h = 1
```

The returned value `h = 1` indicates that `chi2gof` rejects the null hypothesis at the default 5% significance level.

Test for Poisson Distribution

Create six bins, numbered 0 through 5, to use for data pooling.

```
bins = 0:5;
```

Create a vector containing the observed counts for each bin and compute the total number of observations.

```
obsCounts = [6 16 10 12 4 2];
n = sum(obsCounts);
```

Fit a Poisson probability distribution object to the data and compute the expected count for each bin. Use the transpose operator `.'` to transform `bins` and `obsCounts` from row vectors to column vectors.

```
pd = fitdist(bins','Poisson','Frequency',obsCounts');
expCounts = n * pdf(pd,bins);
```

Test the null hypothesis that the data in `obsCounts` comes from a Poisson distribution with a lambda parameter equal to `lambdaHat`.

```
[h,p,st] = chi2gof(bins,'Ctrs',bins,...
                        'Frequency',obsCounts, ...
                        'Expected',expCounts,...
                        'NParams',1)
```

```
h = 0

p = 0.4654

st = struct with fields:
    chi2stat: 2.5550
          df: 3
       edges: [-0.5000 0.5000 1.5000 2.5000 3.5000 5.5000]
           O: [6 16 10 12 6]
           E: [7.0429 13.8041 13.5280 8.8383 6.0284]
```

The returned value `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level. The vector `E` contains the expected counts for each bin under the null hypothesis, and `O` contains the observed counts for each bin.

Test for Normal Distribution Using Function Handle

Use the probability distribution function `normcdf` as a function handle in the chi-square goodness-of-fit test (`chi2gof`).

Test the null hypothesis that the sample data in the input vector `x` comes from a normal distribution with parameters μ and σ equal to the mean (`mean`) and standard deviation (`std`) of the sample data, respectively.

```
rng('default') % For reproducibility
x = normrnd(50,5,100,1);
h = chi2gof(x,'cdf',{@normcdf,mean(x),std(x)})
```

```
h = 0
```

The returned result `h = 0` indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NBins',8,'Alpha',0.01` pools the data into eight bins and conducts the hypothesis test at the 1% significance level.

`NBins` — Number of bins

`10` (default) | positive integer value

Number of bins to use for the data pooling, specified as the comma-separated pair consisting of `'NBins'` and a positive integer value. If you specify a value for `NBins`, do not specify a value for `Ctrs` or `Edges`.

Example: `'NBins',8`

Data Types: `single` | `double`

`Ctrs` — Bin centers

vector

Bin centers, specified as the comma-separated pair consisting of `'Ctrs'` and a vector of center values for each bin. If you specify a value for `Ctrs`, do not specify a value for `NBins` or `Edges`.

Example: `'Ctrs',[1 2 3 4 5]`

Data Types: `single` | `double`

`Edges` — Bin edges

vector

Bin edges, specified as the comma-separated pair consisting of `'Edges'` and a vector of edge values for each bin. If you specify a value for `Edges`, do not specify a value for `NBins` or `Ctrs`.

Example: `'Edges',[-2.5 -1.5 -0.5 0.5 1.5 2.5]`

Data Types: `single` | `double`

`CDF` — cdf of hypothesized distribution

probability distribution object | function handle | cell array

The cdf of the hypothesized distribution, specified as the comma-separated pair consisting of `'CDF'` and a probability distribution object, function handle, or cell array.

- If `CDF` is a probability distribution object, the degrees of freedom account for whether you estimate the parameters using `fitdist` or specify them using `makedist`.
- If `CDF` is a function handle, the distribution function must take `x` as its only argument.
- If `CDF` is a cell array, the first element must be a function handle, and the remaining elements must be parameter values, one per cell. The function must take `x` as its first argument, and the other parameters in the array as later arguments.

If you specify a value for `CDF`, do not specify a value for `Expected`.

Example: `'CDF',pd_object`

Data Types: `single` | `double`

`Expected` — Expected counts
vector of nonnegative values

Expected counts for each bin, specified as the comma-separated pair of `'Expected'` and a vector of nonnegative values. If `Expected` depends on estimated parameters, use `NParams` to ensure that `chi2gof` correctly calculates the degrees of freedom. If you specify a value for `Expected`, do not specify a value for `CDF`.

Example: `'Expected',[19.1446 18.3789 12.3224 8.2432 4.1378]`

Data Types: `single` | `double`

`NParams` — Number of estimated parameters
positive integer value

Number of estimated parameters used to describe the null distribution, specified as the comma-separated pair consisting of `'NParams'` and a positive integer value. This value adjusts the degrees of freedom of the test based on the number of estimated parameters used to compute the cdf or expected counts.

The default value for `NParams` depends on how you specify the null distribution:

- If you specify `CDF` as a probability distribution object, `NParams` is equal to the number of estimated parameters used to create the object.
- If you specify `CDF` as a function name or handle, the default value of `NParams` is `0`.
- If you specify `CDF` as a cell array, the default value of `NParams` is the number of parameters in the array.
- If you specify `Expected`, the default value of `NParams` is `0`.

Example: `'NParams',1`

Data Types: `single` | `double`

`EMin` — Minimum expected count per bin
`5` (default) | nonnegative integer value

Minimum expected count per bin, specified as the comma-separated pair consisting of `'EMin'` and a nonnegative integer value. If the bin at the extreme end of either tail has an expected value less than `EMin`, it is combined with a neighboring bin until the count in each extreme bin is at least `5`. If any interior bins have a count less than `5`, `chi2gof` displays a warning, but does not combine the interior bins. In that case, you should use fewer bins, or provide bin centers or edges, to increase the expected counts in all bins. Specify `EMin` as `0` to prevent the combining of bins.

Example: `'EMin',0`

Data Types: `single` | `double`

`Frequency` — Frequency
vector of nonnegative integer values

Frequency of data values, specified as the comma-separated pair consisting of `'Frequency'` and a vector of nonnegative integer values that is the same length as the vector `x`.

Example: `'Frequency',[20 16 13 10 8]`

Data Types: `single` | `double`

`Alpha` — Significance level
`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

Output Arguments

`h` — Hypothesis test result
`1` | `0`

Hypothesis test result, returned as `1` or `0`.

- If `h = 1`, this indicates the rejection of the null hypothesis at the `Alpha` significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the `Alpha` significance level.

`p` — *p*-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

`stats` — Test statistics
structure

Test statistics, returned as a structure containing the following:

- `chi2stat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.
- `edges` — Vector of bin edges after pooling.
- `O` — Vector of observed counts for each bin.
- `E` — Vector of expected counts for each bin.

More About

Chi-Square Goodness-of-Fit Test

The chi-square goodness-of-fit test determines if a data sample comes from a specified probability distribution, with parameters estimated from the data.

The test groups the data into bins, calculating the observed and expected counts for those bins, and computing the chi-square test statistic

$$\chi^2 = \sum_{i=1}^{N} (O_i - E_i)^2 / E_i \,,$$

where O_i are the observed counts and E_i are the expected counts based on the hypothesized distribution. The test statistic has an approximate chi-square distribution when the counts are sufficiently large.

Algorithms

`chi2gof` compares the value of the test statistic to a chi-square distribution with degrees of freedom equal to *nbins* - 1 - *nparams*, where *nbins* is the number of bins used for the data pooling and *nparams* is the number of estimated parameters used to determine the expected counts. If there are not enough degrees of freedom to conduct the test, `chi2gof` returns the *p*-value as `NaN`.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2inv

Chi-square inverse cumulative distribution function

Syntax

```
x = chi2inv(p,nu)
```

Description

`x = chi2inv(p,nu)` returns the inverse cumulative distribution function (icdf) of the chi-square distribution with degrees of freedom `nu`, evaluated at the probability values in `p`.

Examples

Compute Chi-Square icdf

Find the 95th percentile for the chi-square distribution with `10` degrees of freedom.

```
x = chi2inv(0.95,10)
```

```
x = 18.3070
```

If you generate random numbers from this chi-square distribution, you would observe numbers greater than `18.3` only `5%` of the time.

Median of Chi-Square Distributions

Compute the medians of the chi-square distributions with degrees of freedom one through six.

```
x = chi2inv(0.50,1:6)
```

```
x = 1×6

    0.4549    1.3863    2.3660    3.3567    4.3515    5.3481
```

Input Arguments

p — Probability values at which to evaluate icdf

scalar value in `[0,1]` | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value or an array of scalar values, where each element is in the range `[0,1]`.

- To evaluate the icdf at multiple values, specify `p` using an array.

- To evaluate the icdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `p` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2inv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding probabilities in `p`.

Example: `[0.1,0.5,0.9]`

Data Types: `single` | `double`

`nu` — Degrees of freedom
positive scalar value | array of positive scalar values

Degrees of freedom for the chi-square distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the icdf at multiple values, specify `p` using an array.
- To evaluate the icdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `p` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2inv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding probabilities in `p`.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

Output Arguments

`x` — icdf values
scalar value | array of scalar values

icdf values evaluated at the probabilities in `p`, returned as a scalar value or an array of scalar values. `x` is the same size as `p` and `nu` after any necessary scalar expansion. Each element in `x` is the icdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding probabilities in `p`.

More About

Chi-Square icdf

The chi-square distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom.

The icdf of the chi-square distribution is

$$x = F^{-1}(p|\nu) = \left\{x: F(x|\nu) = p\right\},$$

where

$$p = F(x|\nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2}\Gamma(\nu/2)} dt,$$

ν is the degrees of freedom, and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the chi-square distribution with ν degrees of freedom falls in the interval [0, x].

For more information, see “Chi-Square Distribution” on page B-28.

Alternative Functionality

- `chi2inv` is a function specific to the chi-square distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `chi2inv` is faster than the generic function `icdf`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2pdf

Chi-square probability density function

Syntax

```
y = chi2pdf(x,nu)
```

Description

`y = chi2pdf(x,nu)` returns the probability density function (pdf) of the chi-square distribution with `nu` degrees of freedom, evaluated at the values in `x`.

Examples

Compute Chi-Square pdf

Compute the density of the observed value 2 in the chi-square distribution with 3 degrees of freedom.

```
y1 = chi2pdf(2,3)
```

```
y1 = 0.2076
```

Compute the density of the observed value 4 in the chi-square distributions with degrees of freedom 1 through 6.

```
y2 = chi2pdf(4,1:6)
```

```
y2 = 1×6

    0.0270    0.0677    0.1080    0.1353    0.1440    0.1353
```

The mean of the chi-square distribution is equal to the degrees of freedom. Compute the density of the mean for the chi-square distributions with degrees of freedom 1 through 6.

```
nu = 1:6;
x = nu;
y3 = chi2pdf(x,nu)
```

```
y3 = 1×6

    0.2420    0.1839    0.1542    0.1353    0.1220    0.1120
```

As the degrees of freedom increase, the density of the mean decreases.

Input Arguments

x — Values at which to evaluate pdf

nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the pdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2pdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[3 4 7 9]`

Data Types: `single` | `double`

`nu` — Degrees of freedom
positive scalar value | array of positive scalar values

Degrees of freedom for the chi-square distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `chi2pdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

Output Arguments

`y` — pdf values
scalar value | array of scalar values

pdf values evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x` and `nu` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

More About

Chi-Square pdf

The chi-square distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom.

The pdf of the chi-square distribution is

$$y = f(x|\nu) = \frac{x^{(\nu-2)/2}e^{-x/2}}{2^{\frac{\nu}{2}}\Gamma(\nu/2)},$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function.

For more information, see “Chi-Square Distribution” on page B-28.

Alternative Functionality

- `chi2pdf` is a function specific to the chi-square distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `chi2pdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2rnd

Chi-square random numbers

Syntax

```
r = chi2rnd(nu)
r = chi2rnd(nu,sz1,...,szN)
r = chi2rnd(nu,sz)
```

Description

`r = chi2rnd(nu)` generates a random number from the chi-square distribution with `nu` degrees of freedom.

`r = chi2rnd(nu,sz1,...,szN)` generates an array of random numbers from the chi-square distribution, where `sz1,...,szN` indicates the size of each dimension.

`r = chi2rnd(nu,sz)` generates an array of random numbers from the chi-square distribution, where vector `sz` specifies `size(r)`.

Examples

Generate Chi-Square Random Number

Generate a single random number from the chi-square distribution with `10` degrees of freedom.

```
nu = 10;
r = chi2rnd(nu)
```

```
r = 19.7102
```

Generate Chi-Square Random Numbers

Generate a 1-by-6 array of chi-square random numbers with `1` degree of freedom.

```
nu1 = ones(1,6);  % 1-by-6 array of ones
r1 = chi2rnd(nu1)
```

```
r1 = 1×6

    2.5368    0.2447    0.4314    2.0153    0.0418    4.3486
```

By default, `chi2rnd` generates an array that is the same size as `nu`.

If you specify `nu` as a scalar, `chi2rnd` expands `nu` into a constant array with dimensions specified by `sz1,...,szN`.

Generate a 2-by-6 array of chi-square random numbers, all with 3 degrees of freedom.

```
nu2 = 3;
sz1 = 2;
sz2 = 6;
r2 = chi2rnd(nu2,sz1,sz2)
```

```
r2 = 2×6

    0.5761    5.3582    1.0124    0.9851    1.0529    3.0765
    7.9240    1.7373    0.6291    7.0240    1.8496    2.2690
```

If you specify both `nu` and `sz` as arrays, then the dimensions specified by `sz` must match the dimension of `nu`.

Generate a 1-by-6 array of chi-square random numbers with 3 to 8 degrees of freedom.

```
nu3 = 3:8;
sz = [1 6];
r3 = chi2rnd(nu3,sz)
```

```
r3 = 1×6

    3.9690    7.0961    4.5651    2.4606   13.5038    8.8495
```

Input Arguments

`nu` — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the chi-square distribution, specified as a positive scalar value or an array of positive scalar values.

To generate random numbers from multiple distributions, specify `nu` using an array. Each element in `r` is the random number generated from the distribution specified by the corresponding element in `nu`.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

`sz1,...,szN` — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers.

If `nu` is an array, then the specified dimensions `sz1,...,szN` must match the dimensions of `nu`. The default values of `sz1,...,szN` are the dimensions of `nu`.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `chi2rnd` ignores trailing dimensions with a size of 1. For example, `chi2rnd(5,3,1,1,1)` produces a 3-by-1 vector of random numbers from the distribution with five degrees of freedom.

Example: `2,3`

Data Types: `single` | `double`

`sz` — Size of each dimension (as a row vector)
row vector of integers

Size of each dimension, specified as a row vector of integers.

If `nu` is an array, then the specified dimensions `sz` must match the dimensions of `nu`. The default values of `sz` are the dimensions of `nu`.

- If you specify a single value [`sz1`], then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `chi2rnd` ignores trailing dimensions with a size of 1. For example, `chi2rnd(5,[3 1 1 1])` produces a 3-by-1 vector of random numbers from the distribution with five degrees of freedom.

Example: `[2 3]`

Data Types: `single` | `double`

Output Arguments

`r` — Chi-square random numbers
scalar value | array of scalar values

Chi-square random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1,...,szN` or `sz`. Each element in `r` is the random number generated from the distribution specified by the corresponding element in `nu`.

Alternative Functionality

- `chi2rnd` is a function specific to the chi-square distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Note that the distribution-specific function `chi2rnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

chi2stat

Chi-square mean and variance

Syntax

```
[M,V] = chi2stat(NU)
```

Description

`[M,V] = chi2stat(NU)` returns the mean of and variance for the chi-square distribution with degrees of freedom parameters specified by `NU`. `NU` can be a vector, a matrix, or a multidimensional array. The degrees of freedom parameters in `NU` must be positive.

The mean of the chi-square distribution is ν, the degrees of freedom parameter, and the variance is 2ν.

Examples

```
nu = 1:10;
nu = nu'*nu;
[m,v] = chi2stat(nu)
m =
 1   2   3   4   5   6   7   8   9  10

Topics

“Chi-Square Distribution” on page B-28

Introduced before R2006a

cholcov

Cholesky-like covariance decomposition

Syntax

```
T = cholcov(SIGMA)
[T,num] = cholcov(SIGMA)
[T,num] = cholcov(SIGMA,0)
```

Description

`T = cholcov(SIGMA)` computes `T` such that `SIGMA = T'*T`. `SIGMA` must be square, symmetric, and positive semi-definite. If `SIGMA` is positive definite, then `T` is the square, upper triangular Cholesky factor. If `SIGMA` is not positive definite, `T` is computed from an eigenvalue decomposition of `SIGMA`. `T` is not necessarily triangular or square in this case. Any eigenvectors whose corresponding eigenvalue is close to zero (within a small tolerance) are omitted. If any remaining eigenvalues are negative, `T` is empty.

`[T,num] = cholcov(SIGMA)` returns the number `num` of negative eigenvalues of `SIGMA`, and `T` is empty if `num` is positive. If `num` is zero, `SIGMA` is positive semi-definite. If `SIGMA` is not square and symmetric, `num` is `NaN` and `T` is empty.

`[T,num] = cholcov(SIGMA,0)` returns `num` equal to zero if `SIGMA` is positive definite, and `T` is the Cholesky factor. If `SIGMA` is not positive definite, `num` is a positive integer and `T` is empty. `[...] = cholcov(SIGMA,1)` is equivalent to `[...] = cholcov(SIGMA)`.

Examples

The following 4-by-4 covariance matrix is rank-deficient:

```
C1 = [2 1 1 2;1 2 1 2;1 1 2 2;2 2 2 3]
C1 =
     2     1     1     2
     1     2     1     2
     1     1     2     2
     2     2     2     3
rank(C1)
ans =
     3
```

Use `cholcov` to factor `C1`:

```
T = cholcov(C1)
T =
   -0.2113    0.7887   -0.5774         0
    0.7887   -0.2113   -0.5774         0
    1.1547    1.1547    1.1547    1.7321

C2 = T'*T
C2 =
    2.0000   1.0000   1.0000   2.0000
```

```
    1.0000   2.0000   1.0000   2.0000
    1.0000   1.0000   2.0000   2.0000
    2.0000   2.0000   2.0000   3.0000
```

Use `T` to generate random data with the specified covariance:

```
C3 = cov(randn(1e6,3)*T)
C3 =
    1.9973    0.9982    0.9995    1.9975
    0.9982    1.9962    0.9969    1.9956
    0.9995    0.9969    1.9980    1.9972
    1.9975    1.9956    1.9972    2.9951
```

Introduced in R2007a

ClassificationBaggedEnsemble

Package: `classreg.learning.classif`
Superclasses: `ClassificationEnsemble`

Classification ensemble grown by resampling

Description

`ClassificationBaggedEnsemble` combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a bagged classification ensemble object using `fitcensemble`. Set the name-value pair argument `'Method'` of `fitcensemble` to `'Bag'` to use bootstrap aggregation (bagging, for example, random forest).

Properties

`BinEdges`

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
```

```
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`ClassNames`

List of the elements in `Y` with duplicates removed. `ClassNames` can be a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument `Y`. (The software treats string arrays as cell arrays of character vectors.)

`CombineWeights`

Character vector describing how `ens` combines weak learner weights, either `'WeightedSum'` or `'WeightedAverage'`.

`ExpandedPredictorNames`

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

`FitInfo`

Numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

`FitInfoDescription`

Character vector describing the meaning of the `FitInfo` array.

`FResample`

Numeric scalar between `0` and `1`. `FResample` is the fraction of training data `fitcensemble` resampled at random for every weak learner when constructing the ensemble.

`HyperparameterOptimizationResults`

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`

- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

`Method`

Character vector describing the method that creates `ens`.

`ModelParameters`

Parameters used in training `ens`.

`NumTrained`

Number of trained weak learners in `ens`, a scalar.

`PredictorNames`

Cell array of names for the predictor variables, in the order in which they appear in `X`.

`ReasonForTermination`

Character vector describing the reason `fitcensemble` stopped adding weak learners to the ensemble.

`Replace`

Logical value indicating if the ensemble was trained with replacement (`true`) or without replacement (`false`).

`ResponseName`

Character vector with the name of the response variable `Y`.

`ScoreTransform`

Function handle for transforming scores, or character vector representing a built-in transformation function. `'none'` means no transformation; equivalently, `'none'` means `@(x)x`. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

```
ens.ScoreTransform = @function
```

`Trained`

Trained learners, a cell array of compact classification models.

`TrainedWeights`

Numeric vector of trained weights for the weak learners in `ens`. `TrainedWeights` has `T` elements, where `T` is the number of weak learners in `learners`.

`UseObsForLearner`

Logical matrix of size `N`-by-`NumTrained`, where `N` is the number of observations in the training data and `NumTrained` is the number of trained weak learners. `UseObsForLearner(I,J)` is `true` if observation `I` was used for training learner `J`, and is `false` otherwise.

`W`

Scaled `weights`, a vector with length `n`, the number of rows in `X`. The sum of the elements of `W` is `1`.

`X`

Matrix or table of predictor values that trained the ensemble. Each column of `X` represents one variable, and each row represents one observation.

`Y`

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as `X`. Each row of `Y` represents the classification of the corresponding row of `X`.

Object Functions

compact	Compact classification ensemble
compareHoldout	Compare accuracies of two classification models using new data
crossval	Cross validate ensemble
edge	Classification edge
lime	Local interpretable model-agnostic explanations (LIME)
loss	Classification error
margin	Classification margins
oobEdge	Out-of-bag classification edge
oobLoss	Out-of-bag classification error
oobMargin	Out-of-bag classification margins
oobPermutedPredictorImportance	Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of classification trees
oobPredict	Predict out-of-bag response of ensemble
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Classify observations using ensemble of classification models
predictorImportance	Estimates of predictor importance for classification ensemble of decision trees
removeLearners	Remove members of compact classification ensemble
resubEdge	Classification edge by resubstitution
resubLoss	Classification error by resubstitution
resubMargin	Classification margins by resubstitution
resubPredict	Classify observations in ensemble of classification models
resume	Resume training ensemble
shapley	Shapley values
testckfold	Compare accuracies of two classification models by repeated cross-validation

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Train Bagged Ensemble of Classification Trees

Load the `ionosphere` data set.

```
load ionosphere
```

You can train a bagged ensemble of 100 classification trees using all measurements.

```
Mdl = fitcensemble(X,Y,'Method','Bag')
```

`fitcensemble` uses a default template tree object `templateTree()` as a weak learner when `'Method'` is `'Bag'`. In this example, for reproducibility, specify `'Reproducible',true` when you create a tree template object, and then use the object as a weak learner.

```
rng('default') % For reproducibility
t = templateTree('Reproducible',true); % For reproducibiliy of random predictor selections
Mdl = fitcensemble(X,Y,'Method','Bag','Learners',t)
```

```
Mdl =
  ClassificationBaggedEnsemble
             ResponseName: 'Y'
    CategoricalPredictors: []
                ClassNames: {'b'  'g'}
           ScoreTransform: 'none'
          NumObservations: 351
                NumTrained: 100
                    Method: 'Bag'
              LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: []
       FitInfoDescription: 'None'
                 FResample: 1
                   Replace: 1
          UseObsForLearner: [351x100 logical]

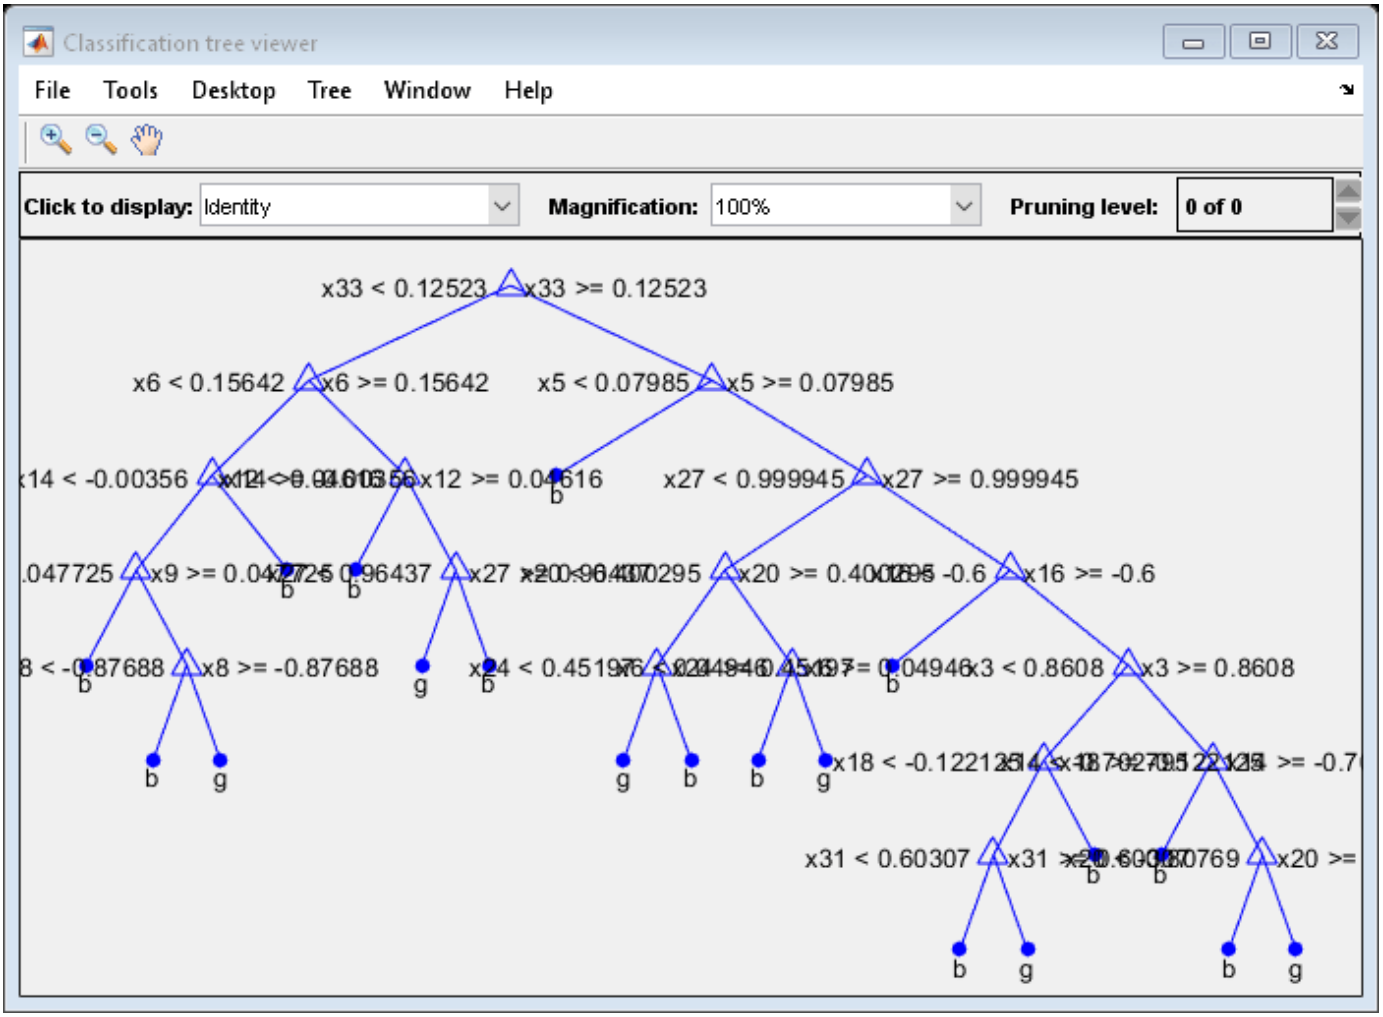
  Properties, Methods
```

`Mdl` is a `ClassificationBaggedEnsemble` model object.

`Mdl.Trained` is the property that stores a 100-by-1 cell vector of the trained classification trees (`CompactClassificationTree` model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trained{1},'Mode','graph')
```



By default, `fitcensemble` grows deep decision trees for bagged ensembles.

Estimate the in-sample misclassification rate.

```
L = resubLoss(Mdl)
```

```
L = 0
```

`L` is 0, which indicates that `Mdl` is perfect at classifying the training data.

Tip

For a bagged ensemble of classification trees, the `Trained` property of `ens` stores a cell vector of `ens.NumTrained` `CompactClassificationTree` model objects. For a textual or graphical display of tree *`t`* in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- To integrate the prediction of an ensemble into Simulink, you can use the ClassificationEnsemble Predict block in the Statistics and Machine Learning Toolbox library or a MATLAB Function block with the `predict` function.
- When you train an ensemble by using `fitcensemble`, code generation limitations for the weak learners used in the ensemble also apply to the ensemble. For more details, see the Code Generation sections of `CompactClassificationDiscriminant` and `CompactClassificationTree`.
- For fixed-point code generation, you must train an ensemble using tree learners.

For more information, see “Introduction to Code Generation” on page 32-2.

ClassificationECOC

Multiclass model for support vector machines (SVMs) and other classifiers

Description

`ClassificationECOC` is an error-correcting output codes (ECOC) classifier on page 33-350 for multiclass learning, where the classifier consists of multiple binary learners such as support vector machines (SVMs). Trained `ClassificationECOC` classifiers store training data, parameter values, prior probabilities, and coding matrices. Use these classifiers to perform tasks such as predicting labels or posterior probabilities for new data (see `predict`).

Creation

Create a `ClassificationECOC` object by using `fitcecoc`.

If you specify linear or kernel binary learners without specifying cross-validation options, then `fitcecoc` returns a `CompactClassificationECOC` object instead.

Properties

After you create a `ClassificationECOC` model object, you can use dot notation to access its properties. For an example, see “Train Multiclass Model Using SVM Learners” on page 33-344.

ECOC Properties

`BinaryLearners` — Trained binary learners
cell vector of model objects

Trained binary learners, specified as a cell vector of model objects. The number of binary learners depends on the number of classes in `Y` and the coding design.

The software trains `BinaryLearner{j}` according to the binary problem specified by `CodingMatrix(:,j)`. For example, for multiclass learning using SVM learners, each element of `BinaryLearners` is a `CompactClassificationSVM` classifier.

Data Types: `cell`

`BinaryLoss` — Binary learner loss function
`'binodeviance'` | `'exponential'` | `'hamming'` | `'hinge'` | `'linear'` | `'logit'` | `'quadratic'`

Binary learner loss function, specified as a character vector representing the loss function name.

If you train using binary learners that use different loss functions, then the software sets `BinaryLoss` to `'hamming'`. To potentially increase accuracy, specify a binary loss function other than the default during a prediction or loss computation by using the `'BinaryLoss'` name-value pair argument of `predict` or `loss`.

Data Types: `char`

`BinaryY` — Binary learner class labels

numeric matrix

Binary learner class labels, specified as a numeric matrix. `BinaryY` is a `NumObservations`-by-*L* matrix, where *L* is the number of binary learners (`length(Mdl.BinaryLearners)`).

Elements of `BinaryY` are `-1`, `0`, or `1`, and the value corresponds to a dichotomous class assignment. This table describes how learner `j` assigns observation `k` to a dichotomous class corresponding to the value of `BinaryY(k,j)`.

Value	Dichotomous Class Assignment
`-1`	Learner `j` assigns observation `k` to a negative class.
`0`	Before training, learner `j` removes observation `k` from the data set.
`1`	Learner `j` assigns observation `k` to a positive class.

Data Types: `double`

`BinEdges` — Bin edges for numeric predictors

cell array of numeric vectors | [ ]

This property is read-only.

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

Data Types: `cell`

`CodingMatrix` — Class assignment codes
numeric matrix

Class assignment codes for the binary learners, specified as a numeric matrix. `CodingMatrix` is a *K*-by-*L* matrix, where *K* is the number of classes and *L* is the number of binary learners.

The elements of `CodingMatrix` are `–1`, `0`, or `1`, and the values correspond to dichotomous class assignments. This table describes how learner `j` assigns observations in class `i` to a dichotomous class corresponding to the value of `CodingMatrix(i,j)`.

Value	Dichotomous Class Assignment
`–1`	Learner `j` assigns observations in class `i` to a negative class.
`0`	Before training, learner `j` removes observations in class `i` from the data set.
`1`	Learner `j` assigns observations in class `i` to a positive class.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64`

`CodingName` — Coding design name
character vector

Coding design name, specified as a character vector. For more details, see “Coding Design” on page 33-351.

Data Types: `char`

`LearnerWeights` — Binary learner weights
numeric row vector

Binary learner weights, specified as a numeric row vector. The length of `LearnerWeights` is equal to the number of binary learners (`length(Mdl.BinaryLearners)`).

`LearnerWeights(j)` is the sum of the observation weights that binary learner `j` uses to train its classifier.

The software uses `LearnerWeights` to fit posterior probabilities by minimizing the Kullback-Leibler divergence. The software ignores `LearnerWeights` when it uses the quadratic programming method of estimating posterior probabilities.

Data Types: `double` | `single`

Other Classification Properties

`CategoricalPredictors` — Categorical predictor indices
vector of positive integers | `[ ]`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

`ClassNames` — Unique class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels `Y`. (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

`Cost` — Misclassification costs
square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

`Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

`ExpandedPredictorNames` — Expanded predictor names
cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

`ModelParameters` — Parameter values
object

Parameter values, such as the name-value pair argument values, used to train the ECOC classifier, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation. For example, list the templates containing parameters of the binary learners by using `Mdl.ModelParameters.BinaryLearner`.

`NumObservations` — Number of observations
positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: `double`

`PredictorNames` — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data `X`, specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in `X`.

Data Types: `cell`

`Prior` — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as the number of classes in `ClassNames`, and the order of the elements corresponds to the order of the classes in `ClassNames`.

`fitcecoc` incorporates misclassification costs differently among different types of binary learners.

Data Types: `double`

`ResponseName` — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

`RowsUsed` — Rows used in fitting

`[]` (default) | logical vector

Rows of the original training data used in fitting the `ClassificationECOC` model, specified as a logical vector. This property is empty if all rows are used.

Data Types: `logical`

`ScoreTransform` — Score transformation function to apply to predicted scores

`'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | `'none'` | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

To change the score transformation function to *`function`*, for example, use dot notation.

- For a built-in function, enter this code and replace *`function`* with a value in the table.

  ```
  Mdl.ScoreTransform = 'function';
  ```

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$

Value	Description
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

- For a MATLAB function or a function that you define, enter its function handle.

  ```
  Mdl.ScoreTransform = @function;
  ```

  `function` must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Data Types: `char` | `function_handle`

`W` — Observation weights
numeric vector

Observation weights used to train the ECOC classifier, specified as a numeric vector. `W` has `NumObservations` elements.

The software normalizes the weights used for training so that `sum(W,'omitnan')` is `1`.

Data Types: `single` | `double`

`X` — Unstandardized predictor data
numeric matrix | table

Unstandardized predictor data used to train the ECOC classifier, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

Data Types: `single` | `double` | `table`

`Y` — Observed class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Observed class labels used to train the ECOC classifier, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `Y` has `NumObservations` elements and has the same data type as the input argument `Y` of `fitcecoc`. (The software treats string arrays as cell arrays of character vectors.)

Each row of `Y` represents the observed classification of the corresponding row of `X`.

Data Types: `categorical` | `char` | `logical` | `single` | `double` | `cell`

Hyperparameter Optimization Properties

`HyperparameterOptimizationResults` — Cross-validation optimization of hyperparameters
`BayesianOptimization` object | table

This property is read-only.

Cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property is nonempty if the `'OptimizeHyperparameters'` name-value pair argument is nonempty when you create the model. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure when you create the model.

Value of `Optimizer` Field	**Value of `HyperparameterOptimizationResults`**
`'bayesopt'` (default)	Object of class `BayesianOptimization`
`'gridsearch'` or `'randomsearch'`	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Object Functions

compact	Reduce size of multiclass error-correcting output codes (ECOC) model
compareHoldout	Compare accuracies of two classification models using new data
crossval	Cross-validate multiclass error-correcting output codes (ECOC) model
discardSupportVectors	Discard support vectors of linear SVM binary learners in ECOC model
edge	Classification edge for multiclass error-correcting output codes (ECOC) model
loss	Classification loss for multiclass error-correcting output codes (ECOC) model
margin	Classification margins for multiclass error-correcting output codes (ECOC) model
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Classify observations using multiclass error-correcting output codes (ECOC) model
resubEdge	Resubstitution classification edge for multiclass error-correcting output codes (ECOC) model
lime	Local interpretable model-agnostic explanations (LIME)
resubLoss	Resubstitution classification loss for multiclass error-correcting output codes (ECOC) model
resubMargin	Resubstitution classification margins for multiclass error-correcting output codes (ECOC) model
resubPredict	Classify observations in multiclass error-correcting output codes (ECOC) model
shapley	Shapley values
testckfold	Compare accuracies of two classification models by repeated cross-validation

Examples

Train Multiclass Model Using SVM Learners

Train a multiclass error-correcting output codes (ECOC) model using support vector machine (SVM) binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train a multiclass ECOC model using the default options.

```
Mdl = fitcecoc(X,Y)
```

```
Mdl =
  ClassificationECOC
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
           BinaryLearners: {3x1 cell}
               CodingName: 'onevsone'

  Properties, Methods
```

`Mdl` is a `ClassificationECOC` model. By default, `fitcecoc` uses SVM binary learners and a one-versus-one coding design. You can access `Mdl` properties using dot notation.

Display the class names and the coding design matrix.

```
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
CodingMat = Mdl.CodingMatrix
```

```
CodingMat = 3×3

     1     1     0
    -1     0     1
     0    -1    -1
```

A one-versus-one coding design for three classes yields three binary learners. The columns of `CodingMat` correspond to the learners, and the rows correspond to the classes. The class order is the same as the order in `Mdl.ClassNames`. For example, `CodingMat(:,1)` is `[1; –1; 0]` and indicates that the software trains the first SVM binary learner using all observations classified as `'setosa'` and `'versicolor'`. Because `'setosa'` corresponds to `1`, it is the positive class; `'versicolor'` corresponds to `–1`, so it is the negative class.

You can access each binary learner using cell indexing and dot notation.

```
Mdl.BinaryLearners{1}   % The first binary learner

ans =
  CompactClassificationSVM
            ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: [-1 1]
           ScoreTransform: 'none'
                     Beta: [4x1 double]
                     Bias: 1.4505
         KernelParameters: [1x1 struct]

  Properties, Methods
```

Compute the resubstitution classification error.

```
error = resubLoss(Mdl)

error = 0.0067
```

The classification error on the training data is small, but the classifier might be an overfitted model. You can cross-validate the classifier using `crossval` and compute the cross-validation classification error instead.

Inspect Binary Learner Properties of ECOC Classifier

Train an ECOC classifier using SVM binary learners. Then, access properties of the binary learners, such as estimated parameters, by using dot notation.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Train an ECOC classifier using SVM binary learners and the default coding design (one-versus-one). Standardize the predictors and save the support vectors.

```
t = templateSVM('Standardize',true,'SaveSupportVectors',true);
predictorNames = {'petalLength','petalWidth'};
responseName = 'irisSpecies';
classNames = {'setosa','versicolor','virginica'}; % Specify class order
Mdl = fitcecoc(X,Y,'Learners',t,'ResponseName',responseName,...
    'PredictorNames',predictorNames,'ClassNames',classNames)

Mdl =
  ClassificationECOC
           PredictorNames: {'petalLength'  'petalWidth'}
             ResponseName: 'irisSpecies'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
```

```
           BinaryLearners: {3x1 cell}
               CodingName: 'onevsone'

  Properties, Methods
```

`t` is a template object that contains options for SVM classification. The function `fitcecoc` uses default values for the empty (`[]`) properties. `Mdl` is a `ClassificationECOC` classifier. You can access properties of `Mdl` using dot notation.

Display the class names and the coding design matrix.

```
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
Mdl.CodingMatrix
```

```
ans = 3×3

     1     1     0
    -1     0     1
     0    -1    -1
```

The columns correspond to SVM binary learners, and the rows correspond to the distinct classes. The row order is the same as the order in the `ClassNames` property of `Mdl`. For each column:

- `1` indicates that `fitcecoc` trains the SVM using observations in the corresponding class as members of the positive group.
- `-1` indicates that `fitcecoc` trains the SVM using observations in the corresponding class as members of the negative group.
- `0` indicates that the SVM does not use observations in the corresponding class.

In the first SVM, for example, `fitcecoc` assigns all observations to `'setosa'` or `'versicolor'`, but not `'virginica'`.

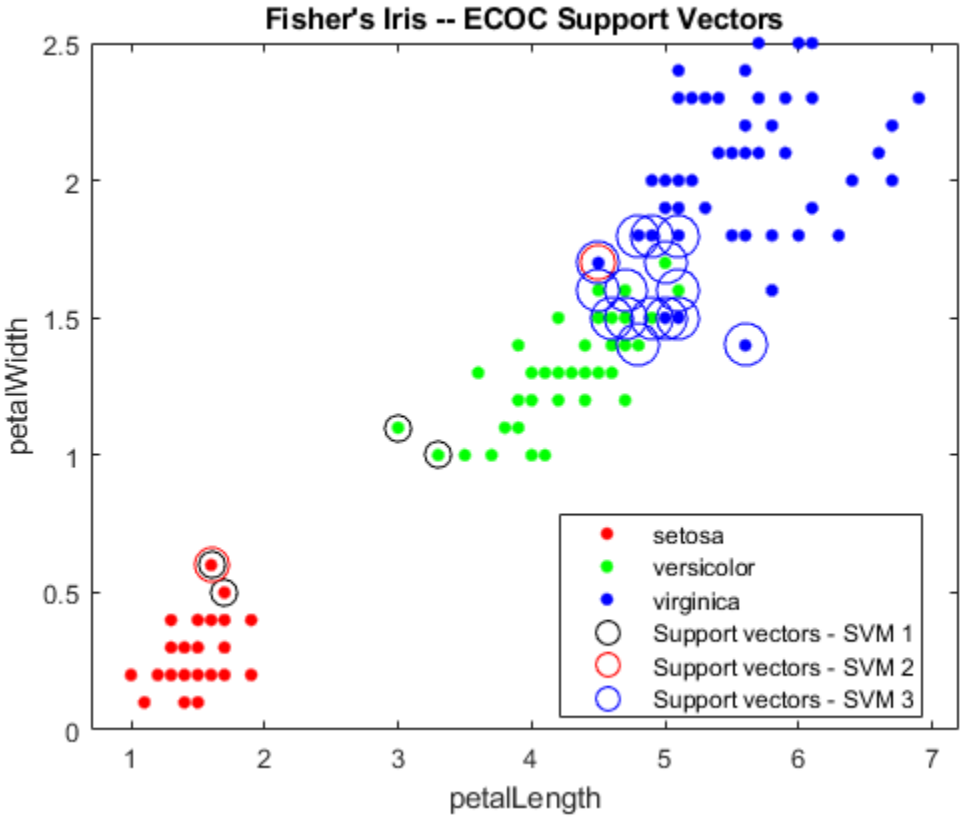
Access properties of the SVMs using cell subscripting and dot notation. Store the standardized support vectors of each SVM. Unstandardize the support vectors.

```
L = size(Mdl.CodingMatrix,2); % Number of SVMs
sv = cell(L,1); % Preallocate for support vector indices
for j = 1:L
    SVM = Mdl.BinaryLearners{j};
    sv{j} = SVM.SupportVectors;
    sv{j} = sv{j}.*SVM.Sigma + SVM.Mu;
end
```

`sv` is a cell array of matrices containing the unstandardized support vectors for the SVMs.

Plot the data, and identify the support vectors.

```
figure
gscatter(X(:,1),X(:,2),Y);
hold on
markers = {'ko','ro','bo'}; % Should be of length L
for j = 1:L
    svs = sv{j};
    plot(svs(:,1),svs(:,2),markers{j},...
        'MarkerSize',10 + (j - 1)*3);
end
title('Fisher''s Iris -- ECOC Support Vectors')
xlabel(predictorNames{1})
ylabel(predictorNames{2})
legend([classNames,{'Support vectors - SVM 1',...
    'Support vectors - SVM 2','Support vectors - SVM 3'}],...
    'Location','Best')
hold off
```



You can pass `Mdl` to these functions:

- `predict`, to classify new observations
- `resubLoss`, to estimate the classification error on the training data
- `crossval`, to perform 10-fold cross-validation

Cross-Validate ECOC Classifier

Cross-validate an ECOC classifier with SVM binary learners, and estimate the generalized classification error.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```
t = templateSVM('Standardize',true)
```

```
t =
Fit template for classification SVM.

                     Alpha: [0x1 double]
           BoxConstraint: []
               CacheSize: []
           CachingMethod: ''
              ClipAlphas: []
  DeltaGradientTolerance: []
                 Epsilon: []
           GapTolerance: []
           KKTTolerance: []
          IterationLimit: []
          KernelFunction: ''
             KernelScale: []
           KernelOffset: []
   KernelPolynomialOrder: []
                 NumPrint: []
                       Nu: []
         OutlierFraction: []
       RemoveDuplicates: []
        ShrinkagePeriod: []
                  Solver: ''
        StandardizeData: 1
     SaveSupportVectors: []
         VerbosityLevel: []
                Version: 2
                 Method: 'SVM'
                   Type: 'classification'
```

`t` is an SVM template. Most of the template object properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```
CVMdl = crossval(Mdl);
```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalized classification error.

```
genError = kfoldLoss(CVMdl)
```

```
genError = 0.0400
```

The generalized classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

More About

Error-Correcting Output Codes Model

An error-correcting output codes (ECOC) model reduces the problem of classification with three or more classes to a set of binary classification problems.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.

Assume the following:

- The classification problem has three classes.
- The coding design is one-versus-one. For three classes, this coding design is

	Learner 1	Learner 2	Learner 3
Class 1	1	1	0
Class 2	−1	0	1
Class 3	0	−1	−1

- The decoding scheme uses loss g.
- The learners are SVMs.

To build this classification model, the ECOC algorithm follows these steps.

1. Learner 1 trains on observations in Class 1 or Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly.
2. Let M be the coding design matrix with elements m_{kl}, and s_l be the predicted classification score for the positive class of learner l. The algorithm assigns a new observation to the class ($\widehat{k}$) that minimizes the aggregation of the losses for the L binary learners.

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{l=1}^{L} |m_{kl}| g(m_{kl}, s_l)}{\sum_{l=1}^{L} |m_{kl}|}.$$

ECOC models can improve classification accuracy, compared to other multiclass models [2].

Coding Design

A coding design is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design, for a particular column (or binary learner):

- A row containing 1 directs the binary learner to group all observations in the corresponding class into a positive class.
- A row containing –1 directs the binary learner to group all observations in the corresponding class into a negative class.
- A row containing 0 directs the binary learner to ignore all observations in the corresponding class.

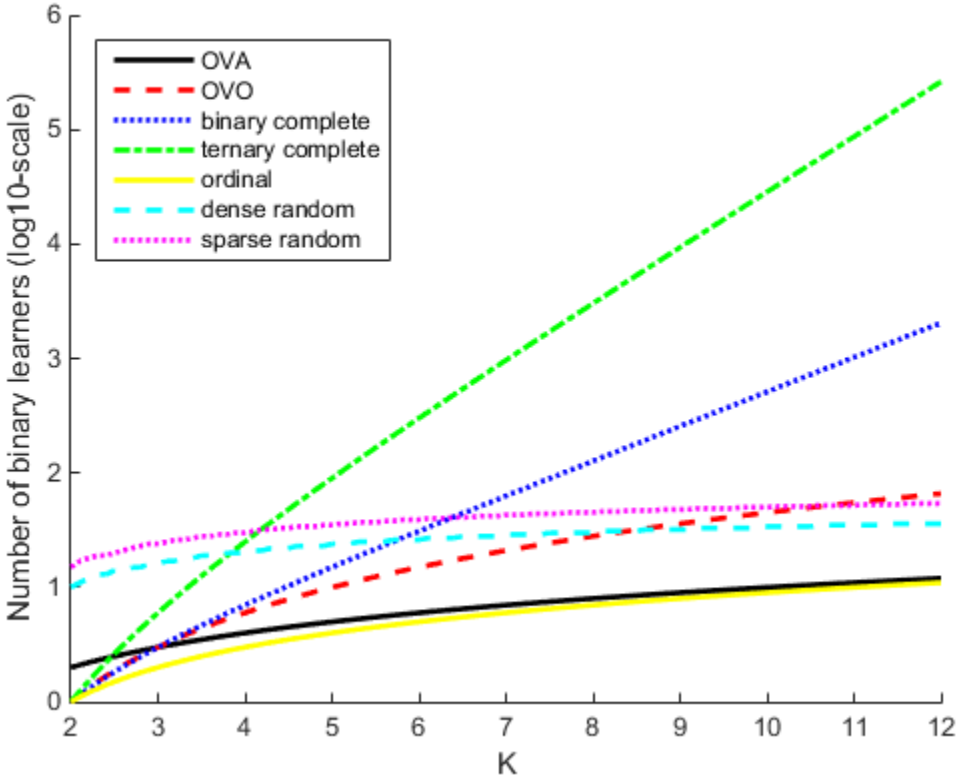
Coding design matrices with large, minimal, pairwise row distances based on the Hamming measure are optimal. For details on the pairwise row distance, see “Random Coding Design Matrices” on page 33-1646 and [4].

This table describes popular coding designs.

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
one-versus-all (OVA)	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.	K	2
one-versus-one (OVO)	For each binary learner, one class is positive, another is negative, and the rest are ignored. This design exhausts all combinations of class pair assignments.	$K(K – 1)/2$	1
binary complete	This design partitions the classes into all binary combinations, and does not ignore any classes. That is, all class assignments are −1 and 1 with at least one positive class and one negative class in the assignment for each binary learner.	$2^{K-1} – 1$	2^{K-2}

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
ternary complete	This design partitions the classes into all ternary combinations. That is, all class assignments are `0`, `−1`, and `1` with at least one positive class and one negative class in the assignment for each binary learner.	$(3^K - 2^{K+1} + 1)/2$	3^{K-2}
ordinal	For the first binary learner, the first class is negative and the rest are positive. For the second binary learner, the first two classes are negative and the rest are positive, and so on.	$K - 1$	1
dense random	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 33-1646.	Random, but approximately $10 \log_2 K$	Variable
sparse random	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 33-1646.	Random, but approximately $15 \log_2 K$	Variable

This plot compares the number of binary learners for the coding designs with increasing K.



Algorithms

Random Coding Design Matrices

For a given number of classes K, the software generates random coding design matrices as follows.

1. The software generates one of these matrices:
   a. Dense random — The software assigns 1 or –1 with equal probability to each element of the K-by-L_d coding design matrix, where $L_d \approx \lceil 10\log_2 K \rceil$.
   b. Sparse random — The software assigns 1 to each element of the K-by-L_s coding design matrix with probability 0.25, –1 with probability 0.25, and 0 with probability 0.5, where $L_s \approx \lceil 15\log_2 K \rceil$.
2. If a column does not contain at least one 1 and at least one –1, then the software removes that column.
3. For distinct columns u and v, if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal, pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^{L} \left|m_{k_1 l}\right| \left|m_{k_2 l}\right| \left|m_{k_1 l} - m_{k_2 l}\right|,$$

where $m_{k,l}$ is an element of coding design matrix j.

Support Vector Storage

By default and for efficiency, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties for all linear SVM binary learners. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors',true)
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Alternative Functionality

You can use these alternative algorithms to train a multiclass model:

- Classification ensembles—see `fitcensemble` and `ClassificationEnsemble`
- Classification trees—see `fitctree` and `ClassificationTree`
- Discriminant analysis classifiers—see `fitcdiscr` and `ClassificationDiscriminant`
- *k*-nearest neighbor classifiers—see `fitcknn` and `ClassificationKNN`
- Naive Bayes classifiers—see `fitcnb` and `ClassificationNaiveBayes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train an ECOC model by using `fitcecoc`, the following restrictions apply.
  - You cannot fit posterior probabilities by using the `'FitPosterior'` name-value pair argument.
  - All binary learners must be either SVM classifiers or linear classification models. For the `'Learners'` name-value pair argument, you can specify:
    - `'svm'` or `'linear'`

- An SVM template object or a cell array of such objects (see `templateSVM`)
- A linear classification model template object or a cell array of such objects (see `templateLinear`)

- When you generate code using a coder configurer for `predict` and `update`, the following additional restrictions apply for binary learners.

  - If you use a cell array of SVM template objects, the value of `'Standardize'` for SVM learners must be consistent. For example, if you specify `'Standardize',true` for one SVM learner, you must specify the same value for all SVM learners.
  - If you use a cell array of SVM template objects, and you use one SVM learner with a linear kernel (`'KernelFunction','linear'`) and another with a different type of kernel function, then you must specify `'SaveSupportVectors',true` for the learner with a linear kernel.

  For details, see `ClassificationECOCCoderConfigurer`. For information on name-value pair arguments that you cannot modify when you retrain a model, see “Tips” on page 33-6501.
- Code generation limitations for SVM classifiers and linear classification models also apply to ECOC classifiers, depending on the choice of binary learners. For more details, see “Code Generation” on page 33-807 of the `CompactClassificationSVM` class and “Code Generation” on page 33-419 of the `ClassificationLinear` class.

For more information, see “Introduction to Code Generation” on page 32-2.

ClassificationECOCCoderConfigurer

Coder configurer for multiclass model using binary learners

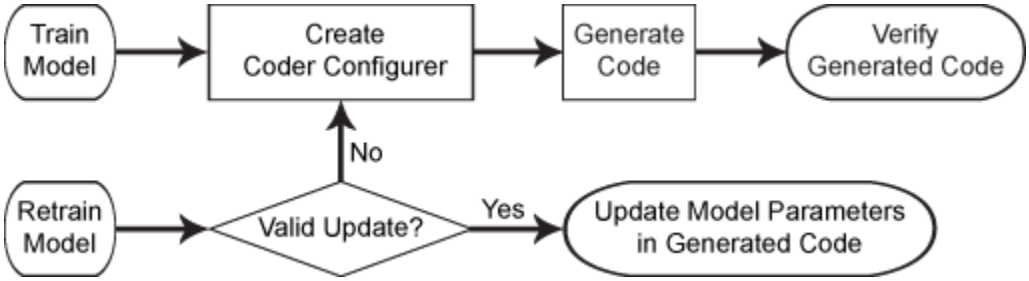
Description

A `ClassificationECOCCoderConfigurer` object is a coder configurer of a multiclass error-correcting output codes (ECOC) classification model (`ClassificationECOC` or `CompactClassificationECOC`) that uses support vector machine (SVM) or linear binary learners.

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes of model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the ECOC model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.



For the code generation usage notes and limitations of a multiclass ECOC classification model, see the Code Generation sections of `CompactClassificationECOC`, `predict`, and `update`.

Creation

After training a multiclass ECOC classification model with SVM or linear binary learners by using `fitcecoc`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

`X` — Coder attributes of predictor data

`LearnerCoderInput` object

Coder attributes of predictor data to pass to the generated C/C++ code for the `predict` function of the ECOC classification model, specified as a `LearnerCoderInput` on page 33-371 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.

  - If the `Value` attribute of the `ObservationsIn` property for the `ClassificationECOCCoderConfigurer` is `'rows'`, then this `SizeVector` value is `[n p]`, where `n` corresponds to the number of observations and `p` corresponds to the number of predictors.
  - If the `Value` attribute of the `ObservationsIn` property for the `ClassificationECOCCoderConfigurer` is `'columns'`, then this `SizeVector` value is `[p n]`.

  To switch the elements of `SizeVector` (for example, to change `[n p]` to `[p n]`), modify the `Value` attribute of the `ObservationsIn` property for the `ClassificationECOCCoderConfigurer` accordingly. You cannot modify the `SizeVector` value directly.
- `VariableDimensions` — The default value is `[0 0]`, which indicates that the array size is fixed as specified in `SizeVector`.

  You can set this value to `[1 0]` if the `SizeVector` value is `[n p]` or to `[0 1]` if it is `[p n]`, which indicates that the array has variable-size rows and fixed-size columns. For example, `[1 0]` specifies that the first value of `SizeVector` (`n`) is the upper bound for the number of rows, and the second value of `SizeVector` (`p`) is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations (in rows) of three predictor variables (in columns), specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of X:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of X (number of observations) has a variable size and the second dimension of X (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

`BinaryLoss` — Coder attributes of binary learner loss function
`EnumeratedInput` object

Coder attributes of the binary learner loss function (`'BinaryLoss'` name-value pair argument of `predict`), specified as an `EnumeratedInput` on page 33-372 object.

The default attribute values of the `EnumeratedInput` object are based on the default values of the `predict` function:

- `Value` — Binary learner loss function, specified as one of the character vectors in `BuiltInOptions` or a character vector designating a custom function name. If the binary learners are SVMs or linear classification models of SVM learners, the default value is `'hinge'`. If the binary learners are linear classification models of logistic regression learners, the default value is `'quadratic'`.

  To use a custom option, define a custom function on the MATLAB search path, and specify `Value` as the name of the custom function.
- `SelectedOption` — This value is `'Built-in'`(default) or `'Custom'`. The software sets `SelectedOption` according to `Value`. This attribute is read-only.
- `BuiltInOptions` — Cell array of `'hamming'`, `'linear'`, `'quadratic'`, `'exponential'`, `'binodeviance'`, `'hinge'`, and `'logit'`. This attribute is read-only.
- `IsConstant` — This value must be `true`.
- `Tunability` — The default value is `false`. If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

`Decoding` — Coder attributes of decoding scheme
`EnumeratedInput` object

Coder attributes of the decoding scheme (`'Decoding'` name-value pair argument of `predict`), specified as an `EnumeratedInput` on page 33-372 object.

The default attribute values of the `EnumeratedInput` object are based on the default values of the `predict` function:

- `Value` — Decoding scheme value, specified as `'lossweighted'`(default), `'lossbased'`, or a `LearnerCoderInput` on page 33-371 object.

  If you set `IsConstant` to `false`, then the software changes `Value` to a `LearnerCoderInput` on page 33-371 object with these read-only coder attribute values:

  - `SizeVector` — `[1 12]`

- `VariableDimensions` — `[0 1]`
- `DataType` — `'char'`
- `Tunability` — 1

The input in the generated code is a variable-size, tunable character vector that is either `'lossweighted'` or `'lossbased'`.

- `SelectedOption` — This value is `'Built-in'`(default) or `'NonConstant'`. The software sets `SelectedOption` according to `Value`. This attribute is read-only.
- `BuiltInOptions` — Cell array of `'lossweighted'` and `'lossbased'`. This attribute is read-only.
- `IsConstant` — The default value is `true`. If you set this value to `false`, the software changes `Value` to a `LearnerCoderInput` object.
- `Tunability` — The default value is `false`. If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

`ObservationsIn` — Coder attributes of predictor data observation dimension
`EnumeratedInput` object

Coder attributes of the predictor data observation dimension (`'ObservationsIn'` name-value pair argument of `predict`), specified as an `EnumeratedInput` on page 33-372 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the `'ObservationsIn'` name-value pair argument determines the default values of the `EnumeratedInput` coder attributes:

- `Value` — The default value is the predictor data observation dimension you use when creating the coder configurer, specified as `'rows'` or `'columns'`. If you do not specify `'ObservationsIn'` when creating the coder configurer, the default value is `'rows'`.

  This value must be `'rows'` for a model that uses SVM binary learners.
- `SelectedOption` — This value is always `'Built-in'`. This attribute is read-only.
- `BuiltInOptions` — Cell array of `'rows'` and `'columns'`. This attribute is read-only.
- `IsConstant` — This value must be `true`.
- `Tunability` — The default value is `false` if you specify `'ObservationsIn','rows'` when creating the coder configurer, and `true` if you specify `'ObservationsIn','columns'`. If you set `Tunability` to `false`, the software sets `Value` to `'rows'`. If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

`NumOutputs` — Number of outputs in `predict`
1 (default) | 2 | 3

Number of output arguments to return from the generated C/C++ code for the `predict` function of the ECOC classification model, specified as 1, 2, or 3.

The output arguments of `predict` are, in order: `label` (predicted class labels), `NegLoss` (negated average binary losses), and `PBScore` (positive-class scores). `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function, where `n` is the `NumOutputs` value.

After creating the coder configurer `configurer`, you can specify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of an ECOC classification model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

`update` Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 33-371 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

`BinaryLearners` — Coder attributes of trained binary learners
`ClassificationSVMCoderConfigurer` object | `ClassificationLinearCoderConfigurer` object

Coder attributes of the trained binary learners (`BinaryLearners` of an ECOC classification model), specified as a `ClassificationSVMCoderConfigurer` object (for SVM binary learners) or a `ClassificationLinearCoderConfigurer` object (for linear binary learners).

Use the `update` arguments of the SVM or linear coder configurer object to specify the coder attributes of all binary learners.

- For `ClassificationSVMCoderConfigurer`, the `update` arguments are `Alpha`, `Beta`, `Bias`, `Cost`, `Mu`, `Prior`, `Scale`, `Sigma`, `SupportVectorLabels`, and `SupportVectors`.
- For `ClassificationLinearCoderConfigurer`, the `update` arguments are `Beta`, `Bias`, `Cost`, and `Prior`.

For the configuration of `BinaryLearners`, the software uses only the `update` argument properties and ignores the other properties of the object.

When you train an ECOC model with SVM binary learners, each learner can have a different number of support vectors. Therefore, the software configures the default attribute values of the `LearnerCoderInput` on page 33-371 objects for `Alpha`, `SupportVectorLabels`, and `SupportVectors` to accommodate all binary learners, based on the input argument `Mdl` of `learnerCoderConfigurer`.

- `SizeVector`
  - This value is `[s 1]` for `Alpha` and `SupportVectorLabels`, where `s` is the largest number of support vectors in the binary learners.
  - This value is `[s p]` for `SupportVectors`, where `p` is the number of predictors.
- `VariableDimensions` — This value is `[0 0]` or `[1 0]`. If each learner has the same number of support vectors, the default value is `[0 0]`. Otherwise, this value must be `[1 0]`.

  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function, and the model stores the linear predictor coefficients (`Beta`) without the support vectors and related values, then this value must be `false`. Otherwise, this value must be `true`.

For details about the other `update` arguments, see `update` arguments on page 33-548 of `ClassificationSVMCoderConfigurer` and `update` arguments on page 33-423 of `ClassificationLinearCoderConfigurer`.

`Cost` — Coder attributes of misclassification cost
`LearnerCoderInput` object

Coder attributes of the misclassification cost (`Cost` of an ECOC classification model), specified as a `LearnerCoderInput` on page 33-371 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[c c]`, where `c` is the number of classes.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — The default value is `true`.

`Prior` — Coder attributes of prior probabilities
`LearnerCoderInput` object

Coder attributes of the prior probabilities (`Prior` of an ECOC classification model), specified as a `LearnerCoderInput` on page 33-371 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[1 c]`, where `c` is the number of classes.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — The default value is `true`.

Other Configurer Options

`OutputFileName` — File name of generated C/C++ code
`'ClassificationECOCModel'` (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `ClassificationECOCCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

`Verbose` — Verbosity level
`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
`true` (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
`false` (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

`CodeGenerationArguments` — `codegen` arguments
cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

`PredictInputs` — List of tunable input arguments of `predict`
cell array

This property is read-only.

List of tunable input arguments of the entry-point function `predict.m` for code generation, specified as a cell array. The cell array contains another cell array that includes `coder.PrimitiveType` objects and `coder.Constant` objects.

If you modify the coder attributes of `predict` arguments on page 33-357, then the software updates the corresponding objects accordingly. If you specify the `Tunability` attribute as `false`, then the software removes the corresponding objects from the `PredictInputs` list.

The cell array in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

`UpdateInputs` — List of tunable input arguments of `update`
cell array

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure. The structure includes a `coder.CellType` object for `BinaryLearners` and `coder.PrimitiveType` objects for `Cost` and `Prior`.

If you modify the coder attributes of `update` arguments on page 33-360, then the software updates the corresponding objects accordingly. If you specify the `Tunability` attribute as `false`, then the software removes the corresponding object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

generateCode	Generate C/C++ code using coder configurer
generateFiles	Generate MATLAB files for code generation using coder configurer
validatedUpdateInputs	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load Fisher's iris data set and train a multiclass ECOC model using SVM binary learners.

```
load fisheriris
X = meas;
Y = species;
Mdl = fitcecoc(X,Y);
```

`Mdl` is a `ClassificationECOC` object.

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)
```

```
configurer =
  ClassificationECOCCoderConfigurer with properties:

   Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
             Prior: [1x1 LearnerCoderInput]
              Cost: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]

   Code Generation Parameters:
        NumOutputs: 1
    OutputFileName: 'ClassificationECOCModel'

  Properties, Methods
```

`configurer` is a `ClassificationECOCCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the ECOC classification model (`Mdl`) with default settings.

```
generateCode(configurer)

generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m

function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:00:25
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end

type update.m

function update(varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:00:25
initialize('update',varargin{:});
end

type initialize.m

function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:00:25
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('ClassificationECOCModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: BinaryLearners
        %                       Prior
        %                       Cost
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
```

```
        end
end
end
```

Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

```
t = templateSVM('KernelFunction','gaussian','Standardize',true);
```

Train a multiclass ECOC model using the template `t`.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

`Mdl` is a `ClassificationECOC` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the `predict` function, which are the predicted labels and negated average binary losses.

```
configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)
```

```
configurer =
  ClassificationECOCCoderConfigurer with properties:

   Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
             Prior: [1x1 LearnerCoderInput]
              Cost: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]

   Code Generation Parameters:
        NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'
```

```
  Properties, Methods
```

`configurer` is a `ClassificationECOCCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object. The display shows the tunable input arguments of `predict` and `update`: `X`, `BinaryLearners`, `Prior`, and `Cost`.

Specify Coder Attributes of Parameters

Specify the coder attributes of `predict` arguments (predictor data and the name-value pair arguments `'Decoding'` and `'BinaryLoss'`) and `update` arguments (support vectors of the SVM learners) so that you can use these arguments as the input arguments of `predict` and `update` in the generated code.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 4 predictors, so the second value of the `SizeVector` attribute must be 4 and the second value of the `VariableDimensions` attribute must be `false`.

Next, modify the coder attributes of `BinaryLoss` and `Decoding` to use the `'BinaryLoss'` and `'Decoding'` name-value pair arguments in the generated code. Display the coder attributes of `BinaryLoss`.

```
configurer.BinaryLoss
```

```
ans =
  EnumeratedInput with properties:

            Value: 'hinge'
    SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
        Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the `Value` attribute of `BinaryLoss` as `'exponential'`.

```
configurer.BinaryLoss.Value = 'exponential';
configurer.BinaryLoss
```

```
ans =
  EnumeratedInput with properties:
```

```
             Value: 'exponential'
    SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
        Tunability: 1
```

If you modify attribute values when `Tunability` is `false` (logical 0), the software sets the `Tunability` to `true` (logical 1).

Display the coder attributes of `Decoding`.

```
configurer.Decoding
```

```
ans =
  EnumeratedInput with properties:

             Value: 'lossweighted'
    SelectedOption: 'Built-in'
    BuiltInOptions: {'lossweighted'  'lossbased'}
        IsConstant: 1
        Tunability: 0
```

Specify the `IsConstant` attribute of `Decoding` as `false` so that you can use all available values in `BuiltInOptions` in the generated code.

```
configurer.Decoding.IsConstant = false;
configurer.Decoding
```

```
ans =
  EnumeratedInput with properties:

             Value: [1x1 LearnerCoderInput]
    SelectedOption: 'NonConstant'
    BuiltInOptions: {'lossweighted'  'lossbased'}
        IsConstant: 0
        Tunability: 1
```

The software changes the `Value` attribute of `Decoding` to a `LearnerCoderInput` object so that you can use both `'lossweighted'` and `'lossbased'` as the value of `'Decoding'`. Also, the software sets the `SelectedOption` to `'NonConstant'` and the `Tunability` to `true`.

Finally, modify the coder attributes of `SupportVectors` in `BinaryLearners`. Display the coder attributes of `SupportVectors`.

```
configurer.BinaryLearners.SupportVectors
```

```
ans =
  LearnerCoderInput with properties:

            SizeVector: [54 4]
    VariableDimensions: [1 0]
              DataType: 'double'
            Tunability: 1
```

The default value of `VariableDimensions` is `[true false]` because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.

```
configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constrain
```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

```
configurer
```

```
configurer =
  ClassificationECOCCoderConfigurer with properties:

   Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
             Prior: [1x1 LearnerCoderInput]
              Cost: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]
        BinaryLoss: [1x1 EnumeratedInput]
          Decoding: [1x1 EnumeratedInput]

   Code Generation Parameters:
        NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'

  Properties, Methods
```

The display now includes `BinaryLoss` and `Decoding` as well.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the ECOC classification model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified `'Decoding'` as a tunable input argument by changing the `IsConstant` attribute before generating the code, you also need to specify it in the call to the MEX function, even though `'lossweighted'` is the default value of `'Decoding'`.

```
[label,NegLoss] = predict(Mdl,X,'BinaryLoss','exponential');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decodi
```

Compare `label` to `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
   1
```

`isequal` returns logical 1 (`true`) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`NegLoss_mex` might include round-off differences compared to `NegLoss`. In this case, compare `NegLoss_mex` to `NegLoss`, allowing a small tolerance.

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =

  0x1 empty double column vector
```

The comparison confirms that `NegLoss` and `NegLoss_mex` are equal within the tolerance `1e–8`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify `'KernelScale'` as `'auto'` so that the software selects an appropriate scale factor using a heuristic procedure.

```
t_new = templateSVM('KernelFunction','gaussian','Standardize',true,'KernelScale','auto');
retrainedMdl = fitcecoc(X,Y,'Learners',t_new);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationECOCModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```
[label,NegLoss] = predict(retrainedMdl,X,'BinaryLoss','exponential','Decoding','lossbased');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decodi
isequal(label,label_mex)
```

```
ans = logical
   1
```

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =

  0x1 empty double column vector
```

The comparison confirms that `label` and `label_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

More About

`LearnerCoderInput` Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
`SizeVector`	Array size if the corresponding `VariableDimensions` value is `false`. Upper bound of the array size if the corresponding `VariableDimensions` value is `true`. To allow an unbounded array, specify the bound as `Inf`.
`VariableDimensions`	Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as `true` (logical 1) or `false` (logical 0): • A value of `true` (logical 1) means that the corresponding dimension has a variable size. • A value of `false` (logical 0) means that the corresponding dimension has a fixed size.
`DataType`	Data type of the array

Attribute Name	Description
`Tunability`	Indicator specifying whether or not `predict` or `update` includes the argument as an input in the generated code, specified as `true` (logical 1) or `false` (logical 0). If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the coefficients `Alpha` in `BinaryLearners` of the coder configurer `configurer`:

```
configurer.BinaryLearners.Alpha.SizeVector = [100 1];
configurer.BinaryLearners.Alpha.VariableDimensions = [1 0];
configurer.BinaryLearners.Alpha.DataType = 'double';
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

`EnumeratedInput` Object

A coder configurer uses an `EnumeratedInput` object to specify the coder attributes of `predict` input arguments that have a finite set of available values.

An `EnumeratedInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description

`Value`	Value of the `predict` argument in the generated code, specified as a character vector or a `LearnerCoderInput` on page 33-371 object.
	• Character vector in `BuiltInOptions` — You can specify one of the `BuiltInOptions` using either the option name or its index value. For example, to choose the first option, specify `Value` as either the first character vector in `BuiltInOptions` or `1`.
	• Character vector designating a custom function name — To use a custom option, define a custom function on the MATLAB search path, and specify `Value` as the name of the custom function.
	• `LearnerCoderInput` on page 33-371 object — If you set `IsConstant` to `false` (logical 0), then the software changes `Value` to a `LearnerCoderInput` on page 33-371 object with the following read-only coder attribute values. These values indicate that the input in the generated code is a variable-size, tunable character vector that is one of the available values in `BuiltInOptions`.
	  • `SizeVector` — `[1 c]`, indicating the upper bound of the array size, where `c` is the length of the longest available character vector in `Option`
	  • `VariableDimensions` — `[0 1]`, indicating that the array is a variable-size vector
	  • `DataType` — `'char'`
	  • `Tunability` — 1
	The default value of `Value` is consistent with the default value of the corresponding `predict` argument, which is one of the character vectors in `BuiltInOptions`.

`SelectedOption`	Status of the selected option, specified as `'Built-in'`, `'Custom'`, or `'NonConstant'`. The software sets `SelectedOption` according to `Value`: • `'Built-in'`(default) — When `Value` is one of the character vectors in `BuiltInOptions` • `'Custom'` — When `Value` is a character vector that is not in `BuiltInOptions` • `'NonConstant'` — When `Value` is a `LearnerCoderInput` on page 33-371 object This attribute is read-only.
`BuiltInOptions`	List of available character vectors for the corresponding `predict` argument, specified as a cell array. This attribute is read-only.

Attribute Name	Description
`IsConstant`	Indicator specifying whether or not the array value is a compile-time constant (`coder.Constant`) in the generated code, specified as `true` (logical 1, default) or `false` (logical 0). If you set this value to `false`, then the software changes `Value` to a `LearnerCoderInput` on page 33-371 object.
`Tunability`	Indicator specifying whether or not `predict` includes the argument as an input in the generated code, specified as `true` (logical 1) or `false` (logical 0, default). If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of `BinaryLoss` of the coder configurer `configurer`:

```
configurer.BinaryLoss.Value = 'linear';
```

Introduced in R2019a

ClassificationDiscriminant class

Superclasses: `CompactClassificationDiscriminant`

Discriminant analysis classification

Description

A `ClassificationDiscriminant` object encapsulates a discriminant analysis classifier, which is a Gaussian mixture model for data generation. A `ClassificationDiscriminant` object can predict responses for new data using the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

Construction

Create a `ClassificationDiscriminant` object by using `fitcdiscr`.

Properties

`BetweenSigma`

`p`-by-`p` matrix, the between-class covariance, where `p` is the number of predictors.

`CategoricalPredictors`

Categorical predictor indices, which is always empty (`[]`) .

`ClassNames`

List of the elements in the training data `Y` with duplicates removed. `ClassNames` can be a categorical array, cell array of character vectors, character array, logical vector, or a numeric vector. `ClassNames` has the same data type as the data in the argument `Y`. (The software treats string arrays as cell arrays of character vectors.)

`Coeffs`

`k`-by-`k` structure of coefficient matrices, where `k` is the number of classes. `Coeffs(i,j)` contains coefficients of the linear or quadratic boundaries between classes `i` and `j`. Fields in `Coeffs(i,j)`:

- `DiscrimType`
- `Class1` — `ClassNames(i)`
- `Class2` — `ClassNames(j)`
- `Const` — A scalar
- `Linear` — A vector with `p` components, where `p` is the number of columns in `X`
- `Quadratic` — `p`-by-`p` matrix, exists for quadratic `DiscrimType`

The equation of the boundary between class `i` and class `j` is

`Const + Linear * x + x' * Quadratic * x = 0`,

where x is a column vector of length p.

If fitcdiscr had the FillCoeffs name-value pair set to 'off' when constructing the classifier, Coeffs is empty ([]).

Cost

Square matrix, where Cost(i,j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of Cost corresponds to the order of the classes in ClassNames. The number of rows and columns in Cost is the number of unique classes in the response.

Change a Cost matrix using dot notation: obj.Cost = costMatrix.

Delta

Value of the Delta threshold for a linear discriminant model, a nonnegative scalar. If a coefficient of obj has magnitude smaller than Delta, obj sets this coefficient to 0, and so you can eliminate the corresponding predictor from the model. Set Delta to a higher value to eliminate more predictors.

Delta must be 0 for quadratic discriminant models.

Change Delta using dot notation: obj.Delta = newDelta.

DeltaPredictor

Row vector of length equal to the number of predictors in obj. If DeltaPredictor(i) < Delta then coefficient i of the model is 0.

If obj is a quadratic discriminant model, all elements of DeltaPredictor are 0.

DiscrimType

Character vector specifying the discriminant type. One of:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

Change DiscrimType using dot notation: obj.DiscrimType = newDiscrimType.

You can change between linear types, or between quadratic types, but cannot change between linear and quadratic types.

Gamma

Value of the Gamma regularization parameter, a scalar from 0 to 1. Change Gamma using dot notation: obj.Gamma = newGamma.

- If you set 1 for linear discriminant, the discriminant sets its type to 'diagLinear'.

- If you set a value between `MinGamma` and `1` for linear discriminant, the discriminant sets its type to `'linear'`.
- You cannot set values below the value of the `MinGamma` property.
- For quadratic discriminant, you can set either `0` (for `DiscrimType 'quadratic'`) or `1` (for `DiscrimType 'diagQuadratic'`).

`HyperparameterOptimizationResults`

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

`LogDetSigma`

Logarithm of the determinant of the within-class covariance matrix. The type of `LogDetSigma` depends on the discriminant type:

- Scalar for linear discriminant analysis
- Vector of length `K` for quadratic discriminant analysis, where `K` is the number of classes

`MinGamma`

Nonnegative scalar, the minimal value of the Gamma parameter so that the correlation matrix is invertible. If the correlation matrix is not singular, `MinGamma` is `0`.

`ModelParameters`

Parameters used in training `obj`.

`Mu`

Class means, specified as a `K`-by-`p` matrix of scalar values class means of size. `K` is the number of classes, and `p` is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

`NumObservations`

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data `X` when there are missing values in `X` or response `Y`.

`PredictorNames`

Cell array of names for the predictor variables, in the order in which they appear in the training data `X`.

`Prior`

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

Add or change a `Prior` vector using dot notation: `obj.Prior = priorVector`.

`ResponseName`

Character vector describing the response variable `Y`.

`ScoreTransform`

Character vector representing a built-in transformation function, or a function handle for transforming scores. `'none'` means no transformation; equivalently, `'none'` means `@(x)x`. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitcdiscr`.

Implement dot notation to add or change a `ScoreTransform` function using one of the following:

- `cobj.ScoreTransform = '`*`function`*`'`
- `cobj.ScoreTransform = @`*`function`*

`Sigma`

Within-class covariance matrix or matrices. The dimensions depend on `DiscrimType`:

- `'linear'` (default) — Matrix of size `p`-by-`p`, where `p` is the number of predictors
- `'quadratic'` — Array of size `p`-by-`p`-by-`K`, where `K` is the number of classes
- `'diagLinear'` — Row vector of length `p`
- `'diagQuadratic'` — Array of size `1`-by-`p`-by-`K`
- `'pseudoLinear'` — Matrix of size `p`-by-`p`
- `'pseudoQuadratic'` — Array of size `p`-by-`p`-by-`K`

`W`

Scaled `weights`, a vector with length `n`, the number of rows in `X`.

`X`

Matrix of predictor values. Each column of `X` represents one predictor (variable), and each row represents one observation.

`Xcentered`

`X` data with class means subtracted. If `Y(i)` is of class `j`,

`Xcentered(i,:) = X(i,:) - Mu(j,:)`,

where `Mu` is the class mean property.

`Y`

A categorical array, cell array of character vectors, character array, logical vector, or a numeric vector with the same number of rows as `X`. Each row of `Y` represents the classification of the corresponding row of `X`.

Object Functions

compact	Compact discriminant analysis classifier
compareHoldout	Compare accuracies of two classification models using new data
crossval	Cross-validated discriminant analysis classifier
cvshrink	Cross-validate regularization of linear discriminant
edge	Classification edge
lime	Local interpretable model-agnostic explanations (LIME)
logp	Log unconditional probability density for discriminant analysis classifier
loss	Classification error
mahal	Mahalanobis distance to class means
margin	Classification margins
nLinearCoeffs	Number of nonzero linear coefficients
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Predict labels using discriminant analysis classification model
resubEdge	Classification edge by resubstitution
resubLoss	Classification error by resubstitution
resubMargin	Classification margins by resubstitution
resubPredict	Predict resubstitution labels of discriminant analysis classification model
shapley	Shapley values
testckfold	Compare accuracies of two classification models by repeated cross-validation

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Train Discriminant Analysis Model

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using the entire data set.

```
Mdl = fitcdiscr(meas,species)
```

```
Mdl =
  ClassificationDiscriminant
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
          ScoreTransform: 'none'
         NumObservations: 150
             DiscrimType: 'linear'
                      Mu: [3x4 double]
                  Coeffs: [3x3 struct]
```

```
  Properties, Methods
```

`Mdl` is a `ClassificationDiscriminant` model. To access its properties, use dot notation. For example, display the group means for each predictor.

```
Mdl.Mu
```

```
ans = 3×4

    5.0060    3.4280    1.4620    0.2460
    5.9360    2.7700    4.2600    1.3260
    6.5880    2.9740    5.5520    2.0260
```

To predict labels for new observations, pass `Mdl` and predictor data to `predict`.

More About

Discriminant Classification

The model for discriminant analysis is:

- Each class (`Y`) generates data (`X`) using a multivariate normal distribution. That is, the model assumes `X` has a Gaussian mixture distribution (`gmdistribution`).
  - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
  - For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\widehat{y} = \underset{y = 1, \ldots, K}{\operatorname{argmin}} \sum_{k = 1}^{K} \widehat{P}(k|x) C(y|k),$$

where

- $\widehat{y}$ is the predicted classification.
- K is the number of classes.
- $\widehat{P}(k|x)$ is the posterior probability on page 20-6 of class k for observation x.
- $C(y|k)$ is the cost on page 20-7 of classifying an observation as y when its true class is k.

For details, see “Prediction Using Discriminant Analysis Models” on page 20-6.

Regularization

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ, that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X, and let $\widehat{X}$ be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}\left(\widehat{X}^T * \widehat{X}\right).$$

The regularized covariance matrix $\tilde{\Sigma}$ is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq$ `MinGamma`, $\tilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k, and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X, and let $\tilde{C}$ be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1}(\mu_k - \mu_0) = \left[(x - \mu_0)^T D^{-1/2}\right]\left[\tilde{C}^{-1} D^{-1/2}(\mu_k - \mu_0)\right].$$

The parameter δ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $\left[\tilde{C}^{-1} D^{-1/2}(\mu_k - \mu_0)\right]$ is set to zero if it is smaller in magnitude than the threshold δ. Therefore, for class k, if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq$ `DeltaPredictor(i)`, all classes k have

$$\left|\tilde{C}^{-1} D^{-1/2}(\mu_k - \mu_0)\right| \leq \delta.$$

Therefore, when $\delta \geq$ `DeltaPredictor(i)`, the regularized classifier does not use predictor `i`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a discriminant analysis model by using `fitcdiscr` or create a compact discriminant analysis model by using `makecdiscr`, the value of the `'ScoreTransform'` name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 32-2.

Topics

“Discriminant Analysis Classification” on page 20-2

Introduced in R2011b

ClassificationEnsemble

Package: `classreg.learning.classif`
Superclasses: `CompactClassificationEnsemble`

Ensemble classifier

Description

`ClassificationEnsemble` combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners. It stores data used for training, can compute resubstitution predictions, and can resume training if desired.

Construction

Create a classification ensemble object using `fitcensemble`.

Properties

`BinEdges`

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`ClassNames`

List of the elements in `Y` with duplicates removed. `ClassNames` can be a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. `ClassNames` has the same data type as the data in the argument `Y`. (The software treats string arrays as cell arrays of character vectors.)

`CombineWeights`

Character vector describing how `ens` combines weak learner weights, either `'WeightedSum'` or `'WeightedAverage'`.

`Cost`

Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response. This property is read-only.

`ExpandedPredictorNames`

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

`FitInfo`

Numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

`FitInfoDescription`

Character vector describing the meaning of the `FitInfo` array.

`HyperparameterOptimizationResults`

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`

- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

`LearnerNames`

Cell array of character vectors with names of weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{'Tree'}`.

`Method`

Character vector describing the method that creates `ens`.

`ModelParameters`

Parameters used in training `ens`.

`NumObservations`

Numeric scalar containing the number of observations in the training data.

`NumTrained`

Number of trained weak learners in `ens`, a scalar.

`PredictorNames`

Cell array of names for the predictor variables, in the order in which they appear in `X`.

`Prior`

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`. The number of elements of `Prior` is the number of unique classes in the response. This property is read-only.

`ReasonForTermination`

Character vector describing the reason `fitcensemble` stopped adding weak learners to the ensemble.

`ResponseName`

Character vector with the name of the response variable `Y`.

`ScoreTransform`

Function handle for transforming scores, or character vector representing a built-in transformation function. `'none'` means no transformation; equivalently, `'none'` means `@(x)x`. For a list of built-in transformation functions and the syntax of custom transformation functions, see `fitctree`.

Add or change a `ScoreTransform` function using dot notation:

```
ens.ScoreTransform = 'function'
```

or

`ens.ScoreTransform = @function`

`Trained`

A cell vector of trained classification models.

- If `Method` is `'LogitBoost'` or `'GentleBoost'`, then `ClassificationEnsemble` stores trained learner `j` in the `CompactRegressionLearner` property of the object stored in `Trained{j}`. That is, to access trained learner `j`, use `ens.Trained{j}.CompactRegressionLearner`.
- Otherwise, cells of the cell vector contain the corresponding, compact classification models.

`TrainedWeights`

Numeric vector of trained weights for the weak learners in `ens`. `TrainedWeights` has `T` elements, where `T` is the number of weak learners in `learners`.

`UsePredForLearner`

Logical matrix of size `P`-by-`NumTrained`, where `P` is the number of predictors (columns) in the training data `X`. `UsePredForLearner(i,j)` is `true` when learner `j` uses predictor `i`, and is `false` otherwise. For each learner, the predictors have the same order as the columns in the training data `X`.

If the ensemble is not of type `Subspace`, all entries in `UsePredForLearner` are `true`.

`W`

Scaled `weights`, a vector with length `n`, the number of rows in `X`. The sum of the elements of `W` is `1`.

`X`

Matrix or table of predictor values that trained the ensemble. Each column of `X` represents one variable, and each row represents one observation.

`Y`

Numeric vector, categorical vector, logical vector, character array, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

Object Functions

compact	Compact classification ensemble
compareHoldout	Compare accuracies of two classification models using new data
crossval	Cross validate ensemble
edge	Classification edge
lime	Local interpretable model-agnostic explanations (LIME)
loss	Classification error
margin	Classification margins
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Classify observations using ensemble of classification models
predictorImportance	Estimates of predictor importance for classification ensemble of decision trees

removeLearners	Remove members of compact classification ensemble
resubEdge	Classification edge by resubstitution
resubLoss	Classification error by resubstitution
resubMargin	Classification margins by resubstitution
resubPredict	Classify observations in ensemble of classification models
resume	Resume training ensemble
shapley	Shapley values
testckfold	Compare accuracies of two classification models by repeated cross-validation

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Train Boosted Classification Ensemble

Load the `ionosphere` data set.

```
load ionosphere
```

Train a boosted ensemble of 100 classification trees using all measurements and the `AdaBoostM1` method.

```
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1')
```

```
Mdl =
  ClassificationEnsemble
             ResponseName: 'Y'
    CategoricalPredictors: []
              ClassNames: {'b'  'g'}
          ScoreTransform: 'none'
         NumObservations: 351
              NumTrained: 100
                  Method: 'AdaBoostM1'
            LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                 FitInfo: [100x1 double]
      FitInfoDescription: {2x1 cell}

  Properties, Methods
```

`Mdl` is a `ClassificationEnsemble` model object.

`Mdl.Trained` is the property that stores a 100-by-1 cell vector of the trained classification trees (`CompactClassificationTree` model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trained{1},'Mode','graph')
```
