`[phat,pci] = gamfit(data)` returns MLEs and 95% percent confidence intervals. The first row of `pci` is the lower bound of the confidence intervals; the last row is the upper bound.

`[phat,pci] = gamfit(data,alpha)` returns `100(1 - alpha)`% confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

`[...] = gamfit(data,alpha,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(data,alpha,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any nonnegative values.

`[...] = gamfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('gamfit')` to see the names and default values of the parameters that `gamfit` accepts in the `options` structure.

Examples

Fit a gamma distribution to random data generated from a specified gamma distribution:

```
a = 2; b = 4;
data = gamrnd(a,b,100,1);

[p,ci] = gamfit(data)
p =
  2.1990  3.7426
ci =
  1.6840  2.8298
  2.7141  4.6554
```

Topics

“Gamma Distribution” on page B-47

Introduced before R2006a

gaminv

Gamma inverse cumulative distribution function

Syntax

```
x = gaminv(p,a)
x = gaminv(p,a,b)

[x,xLo,xUp] = gaminv(p,a,b,pCov)
[x,xLo,xUp] = gaminv(p,a,b,pCov,alpha)
```

Description

`x = gaminv(p,a)` returns the inverse cumulative distribution function (icdf) of the standard gamma distribution with the shape parameter `a`, evaluated at the values in `p`.

`x = gaminv(p,a,b)` returns the icdf of the gamma distribution with shape parameter `a` and the scale parameter `b`, evaluated at the values in `p`.

`[x,xLo,xUp] = gaminv(p,a,b,pCov)` also returns the 95% confidence interval `[xLo,xUp]` of `x` when `a` and `b` are estimates. `pCov` is the covariance matrix of the estimated parameters.

`[x,xLo,xUp] = gaminv(p,a,b,pCov,alpha)` specifies the confidence level for the confidence interval `[xLo,xUp]` to be `100(1–alpha)`%.

Examples

Compute Gamma icdf

Find the median of the gamma distribution with shape parameter `3` and scale parameter `5`.

```
x = gaminv(0.5,3,5)
```

```
x = 13.3703
```

Confidence Interval of Gamma icdf Value

Find a confidence interval estimating the median using gamma distributed data.

Generate a sample of `500` gamma distributed random numbers with shape `2` and scale `5`.

```
x = gamrnd(2,5,500,1);
```

Compute estimates for the parameters.

```
params = gamfit(x)
```

```
params = 1×2
```

```
    1.9820    5.0601
```

Store the estimates for the parameters as `ahat` and `bhat`.

```
ahat = params(1);
bhat = params(2);
```

Compute the covariance of the parameter estimates.

```
[~,nCov] = gamlike(params,x)
```

```
nCov = 2×2

    0.0135   -0.0346
   -0.0346    0.1141
```

Create a confidence interval estimating x.

```
[x,xLo,xUp] = gaminv(0.50,ahat,bhat,nCov)
```

```
x = 8.4021

xLo = 7.8669

xUp = 8.9737
```

Input Arguments

p — Probability values at which to evaluate icdf

scalar value in `[0,1]` | array of scalar values

Probability values at which to evaluate the inverse cdf (icdf), specified as a scalar value or an array of scalar values, where each element is in the range `[0,1]`.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `p` must be a scalar value (not an array).

- To evaluate the icdf at multiple values, specify `p` using an array.
- To evaluate the icdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `p`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gaminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `p`.

Example: `[0.1,0.5,0.9]`

Data Types: `single` | `double`

a — Shape Parameter

positive scalar value | array of positive scalar values

Shape parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the icdf at multiple values, specify `p` using an array.
- To evaluate the icdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `p`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gaminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `p`.

Example: `[1 2 3 5]`

Data Types: `single` | `double`

b — Scale Parameter

1 (default) | positive scalar value | array of positive scalar values

Scale parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the icdf at multiple values, specify `p` using an array.
- To evaluate the icdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `p`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gaminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `p`.

Example: `[1 1 2 2]`

Data Types: `single` | `double`

pCov — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates `a` and `b`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `p`, `a`, and `b` must be scalar values.

You can estimate `a` and `b` by using `gamfit` or `mle`, and estimate the covariance of `a` and `b` by using `gamlike`. For an example, see “Confidence Interval of Gamma icdf Value” on page 33-2555.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is `100(1–alpha)`%, where `alpha` is the probability that the confidence interval does not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

Output Arguments

x — icdf values

scalar value | array of scalar values

icdf values evaluated at the probability values in `p`, returned as a scalar value or an array of scalar values. `x` is the same size as `p`, `a`, and `b`, after any necessary scalar expansion. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `p`.

xLo — Lower confidence bound for x

scalar value | array of scalar values

Lower confidence bound for `x`, returned as a scalar value or an array of scalar values. `xLo` has the same size as `x`.

xUp — Upper confidence bound for x

scalar value | array of scalar values

Upper confidence bound for `x`, returned as a scalar value or an array of scalar values. `xUp` has the same size as `x`.

More About

Gamma icdf

The gamma distribution is a two-parameter family of curves. The parameters *a* and *b* are shape and scale, respectively.

The gamma inverse function in terms of the gamma cdf is

$$x = F^{-1}(p\,|\,a,b) = \left\{x : F(x\,|\,a,b) = p\right\},$$

where

$$p = F(x\,|\,a,b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{\frac{-t}{b}} dt\,.$$

The result *x* is the value such that an observation from the gamma distribution with parameters *a* and *b* falls in [0,*x*] with probability *p*.

For more information, see “Gamma Distribution” on page B-47.

Algorithms

No known analytical solution exists for the integral equation shown in “Gamma icdf” on page 33-2558. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

Alternative Functionality

- `gaminv` is a function specific to the gamma distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use

`icdf`, create a `GammaDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `gaminv` is faster than the generic function `icdf`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Gamma Distribution” on page B-47

Introduced before R2006a

gamlike

Gamma negative log-likelihood

Syntax

```
nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)
```

Description

`nlogL = gamlike(params,data)` returns the negative of the gamma log-likelihood of the parameters, `params`, given `data`. `params(1)=A`, shape parameters, and `params(2)=B`, scale parameters. The parameters in `params` must all be positive

`[nlogL,AVAR] = gamlike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = gamlike(params,data,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any non-negative values.

`gamlike` is a utility function for maximum likelihood estimation of the gamma distribution. Since `gamlike` returns the negative gamma log-likelihood function, minimizing `gamlike` using `fminsearch` is the same as maximizing the likelihood.

Examples

Compute the negative log-likelihood of parameter estimates computed by the `gamfit` function:

```
a = 2; b = 3;
r = gamrnd(a,b,100,1);

[nlogL,AVAR] = gamlike(gamfit(r),r)
nlogL =
  267.5648
AVAR =
  0.0788  -0.1104
 -0.1104  0.1955
```

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Gamma Distribution” on page B-47

Introduced before R2006a

gampdf

Gamma probability density function

Syntax

```
y = gampdf(x,a)
y = gampdf(x,a,b)
```

Description

`y = gampdf(x,a)` returns the probability density function (pdf) of the standard gamma distribution with the shape parameter `a`, evaluated at the values in `x`.

`y = gampdf(x,a,b)` returns the pdf of the gamma distribution with the shape parameter `a` and the scale parameter `b`, evaluated at the values in `x`.

Examples

Compute Gamma pdf

Compute the density of the observed value `5` in the standard gamma distribution with shape parameter `2`.

```
y1 = gampdf(5,2)
```

```
y1 = 0.0337
```

Compute the density of the observed value `5` in the gamma distributions with shape parameter `2` and scale parameters `1` through `5`.

```
y2 = gampdf(5,2,1:5)
```

```
y2 = 1×5

    0.0337    0.1026    0.1049    0.0895    0.0736
```

Input Arguments

x — Values at which to evaluate pdf

nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the pdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gampdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[3 4 7 9]`

Data Types: `single` | `double`

`a` — Shape parameter
positive scalar value | array of positive scalar values

Shape parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gampdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[1 2 3 5]`

Data Types: `single` | `double`

`b` — Scale parameter
1 (default) | positive scalar value | array of positive scalar values

Scale parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gampdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[1 1 2 2]`

Data Types: `single` | `double`

Output Arguments

`y` — pdf values
scalar value | array of scalar values

pdf values evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `y` is the same size as `x`, `a`, and `b` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

More About

Gamma pdf

The gamma distribution is a two-parameter family of curves. The parameters a and b are shape and scale, respectively.

The gamma pdf is

$$y = f(x|a,b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{\frac{-x}{b}},$$

where $\Gamma(\cdot)$ is the Gamma function.

The standard gamma distribution occurs when $b = 1$.

For more information, see “Gamma Distribution” on page B-47.

Alternative Functionality

- `gampdf` is a function specific to the gamma distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create a `GammaDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `gampdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Gamma Distribution” on page B-47

Introduced before R2006a

gamrnd

Gamma random numbers

Syntax

```
r = gamrnd(a,b)
r = gamrnd(a,b,sz1,...,szN)
r = gamrnd(a,b,sz)
```

Description

`r = gamrnd(a,b)` generates a random number from the gamma distribution with the shape parameter `a` and the scale parameter `b`.

`r = gamrnd(a,b,sz1,...,szN)` generates an array of random numbers from the gamma distribution, where `sz1,...,szN` indicates the size of each dimension.

`r = gamrnd(a,b,sz)` generates an array of random numbers from the gamma distribution, where vector `sz` specifies `size(r)`.

Examples

Generate Gamma Random Number

Generate a single random number from the gamma distribution with shape 5 and scale 7.

```
r = gamrnd(5,7)
```

```
r = 68.9857
```

Generate Array of Gamma Random Numbers

Generate five random numbers from the gamma distributions with shape parameter values 1 through 5 and scale parameter 2.

```
a1 = 1:5;
b1 = 2;
r1 = gamrnd(a1,b1)
```

```
r1 = 1×5

    7.1297    6.0918    2.1010    8.7253   29.5447
```

By default, `gamrnd` generates an array that is the same size as `a` and `b` after any necessary scalar expansion so that all scalars are expanded to match the dimensions of the other inputs.

If you specify array dimensions `sz1,...,szN` or `sz`, they must match the dimensions of `a` and `b` after any necessary scalar expansion.

Generate a 2-by-3 array of random numbers from the gamma distribution with shape parameter `3` and scale parameter `7`.

```
sz = [2 3];
r2 = gamrnd(3,7,sz)
```

```
r2 = 2×3

   17.9551   41.3983    7.9865
   16.4204   40.0048   44.1909
```

Generate six random numbers from the gamma distributions with shape parameter values `1` through `6` and scale parameter values `5` through `10` respectively.

```
a3 = 1:6;
b3 = 5:10;
r3 = gamrnd(a3,b3,1,6)
```

```
r3 = 1×6

    9.5930    7.8289   11.0360   15.0367   28.1456   98.2664
```

Input Arguments

a — Shape parameter

positive scalar value | array of positive scalar values

Shape parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

To generate random numbers from multiple distributions, specify `a` and `b` using arrays. If both `a` and `b` are arrays, then the array sizes must be the same. If either `a` or `b` is a scalar, then `gamrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `a` and `b`.

Example: `[3 4 7 9]`

Data Types: `single` | `double`

b — Scale parameter

positive scalar value | array of positive scalar values

Scale parameter of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

To generate random numbers from multiple distributions, specify `a` and `b` using arrays. If both `a` and `b` are arrays, then the array sizes must be the same. If either `a` or `b` is a scalar, then `gamrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `a` and `b`.

Example: `[1 1 2 2]`

Data Types: `single` | `double`

`sz1,...,szN` — Size of each dimension (as separate arguments)
integers

Size of each dimension, specified as separate arguments of integers.

If either `a` or `b` is an array, then the specified dimensions `sz1,...,szN` must match the common dimensions of `a` and `b` after any necessary scalar expansion. The default values of `sz1,...,szN` are the common dimensions.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `gamrnd` ignores trailing dimensions with a size of 1. For example, `gamrnd(2,5,3,1,1,1)` produces a 3-by-1 vector of random numbers from the gamma distribution with shape 2 and scale 5.

Example: `2,4`

Data Types: `single` | `double`

`sz` — Size of each dimension (as a row vector)
row vector of integers

Size of each dimension, specified as a row vector of integers.

If either `a` or `b` is an array, then the specified dimensions `sz` must match the common dimensions of `a` and `b` after any necessary scalar expansion. The default values of `sz` are the common dimensions.

- If you specify a single value [`sz1`], then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `gamrnd` ignores trailing dimensions with a size of 1. For example, `gamrnd(2,5,[3 1 1 1])` produces a 3-by-1 vector of random numbers from the gamma distribution with shape 2 and scale 5.

Example: `[2 4]`

Data Types: `single` | `double`

Output Arguments

`r` — Gamma random numbers
nonnegative scalar value | array of nonnegative scalar values

Gamma random numbers, returned as a nonnegative scalar value or an array of nonnegative scalar values with the dimensions specified by `sz1,...,szN` or `sz`. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `a` and `b`.

Alternative Functionality

- `gamrnd` is a function specific to the gamma distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use

`random`, create a `GammaDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `gamrnd` is faster than the generic function `random`.

- Use `randg` to generate random numbers from the standard gamma distribution (unit scale).
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see "Introduction to Code Generation" on page 32-2 and "General Code Generation Workflow" on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

gamstat

Gamma mean and variance

Syntax

```
[M,V] = gamstat(A,B)
```

Description

`[M,V] = gamstat(A,B)` returns the mean of and variance for the gamma distribution with shape parameters in `A` and scale parameters in `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `M` and `V`. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input. The parameters in `A` and `B` must be positive.

The mean of the gamma distribution with parameters A and B is AB. The variance is AB^2.

Examples

```
[m,v] = gamstat(1:5,1:5)
m =
   1   4   9  16  25
v =
   1   8  27  64  125

[m,v] = gamstat(1:5,1./(1:5))
m =
   1   1   1   1   1
v =
  1.0000  0.5000  0.3333  0.2500  0.2000
```

gather

Gather properties of machine learning model from GPU

Syntax

```
gatheredMdl = gather(mdl)
[gatheredMdl1,gatheredMdl2,...,gatheredMdln] = gather(mdl1,mdl2,...,mdln)
```

Description

`gatheredMdl = gather(mdl)` gathers all properties of the input regression or classification model `mdl` and returns the gathered model `gatheredMdl`. All properties of the output model are stored in the local workspace.

Use `gather` to create a machine learning model with properties stored in the local workspace from a model fitted using data stored as a GPU array. For more details on GPU arrays, see `gpuArray`.

`[gatheredMdl1,gatheredMdl2,...,gatheredMdln] = gather(mdl1,mdl2,...,mdln)` gathers the properties of multiple models `mdl1,mdl2,...,mdln` and returns the corresponding gathered models `gatheredMdl1,gatheredMdl2,...,gatheredMdln`. The number of input arguments and output arguments must match.

Examples

Gather Properties of Linear Regression Model

Gather the properties of a linear regression model fitted with GPU array data.

Load the `carsmall` data set. Create `X` as a numeric matrix that contains three car performance metrics. Create `Y` as a numeric vector that contains the corresponding miles per gallon.

```
load carsmall
X = [Weight,Horsepower,Acceleration];
Y = MPG;
```

Convert the predictor `X` and response `Y` to `gpuArray` (Parallel Computing Toolbox) objects.

```
X = gpuArray(X);
Y = gpuArray(Y);
```

Fit a linear regression model `mdl` by using `fitlm`.

```
mdl = fitlm(X,Y);
```

Display the coefficients of `mdl` and determine whether the estimated coefficient values are GPU arrays.

```
mdl.Coefficients
```

```
ans=4×4 table

Gather Properties of Multiple Models

Gather the properties of a linear regression model and a *k*-nearest neighbor classifier. Both models are fitted using GPU array data.

Load the `carsmall` data set. Create `X` as a numeric matrix that contains three car performance metrics, and convert the predictor `X` to a `gpuArray` object.

```
load carsmall
X = [Weight,Horsepower,Acceleration];
X = gpuArray(X);
```

Fit a linear regression model of `MPG` (miles per gallon) as a function of the predictor `X`.

```
mdlLinear = fitlm(X,MPG);
```

Train a 3-nearest neighbor classifier using the predictor `X` and the classes `Cylinders`. Standardize the noncategorical predictor data.

```
mdlKNN = fitcknn(X,Cylinders,'NumNeighbors',3,'Standardize',1);
```

Gather the properties of the `mdLinear` and `mdlKNN` models.

```
[gMdlLinear,gMdlKNN] = gather(mdlLinear,mdlKNN);
```

Determine whether the *p*-value of the Durbin-Watson test for the regression model `mdlLinear` is a GPU array.

```
isgpuarray(dwtest(mdlLinear))
```

```
ans = logical
   1
```

Determine whether the *p*-value of the Durbin-Watson test for the gathered regression model `gMdlLinear` is a GPU array.

```
isgpuarray(dwtest(gMdlLinear))
```

```
ans = logical
   0
```

Determine whether the resubstitution loss of the classifier `mdlKNN` is a GPU array.

```
isgpuarray(resubLoss(mdlKNN))
```

```
ans = logical
   1
```

Determine whether the resubstitution loss of the gathered classifier `gMdlKNN` is a GPU array.

```
isgpuarray(resubLoss(gMdlKNN))
```

```
ans = logical
   1
```

Input Arguments

`mdl` — Machine learning model fitted with GPU arrays

regression model object | classification model object

Machine learning model fitted with GPU arrays, specified as a regression or classification model object, as given in the following table of supported models.

Model Object Name	Model Description	Model Creation Function
`LinearModel`	Full linear regression model	`fitlm`
`CompactLinearModel`	Compact linear regression model	`LinearModel` object function `compact`
`GeneralizedLinearModel`	Full generalized linear regression model	`fitglm`

Model Object Name	Model Description	Model Creation Function
`CompactGeneralizedLinearModel`	Compact generalized linear regression model	`GeneralizedLinearModel` object function `compact`
`ClassificationKNN`	*k*-nearest neighbor classification model	`fitcknn`

If you want to create a compact model fitted with GPU arrays, the input argument `mdl` of `compact` must be a full model object fitted with GPU array input arguments.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

“Classification Using Nearest Neighbors” on page 18-12

Introduced in R2020b

ge

Class: `qrandstream`

Greater than or equal relation for handles

Syntax

```
h1 >= h2
```

Description

`h1 >= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ge(h1, h2)` stores the result in a logical array of the same dimensions.

`eq` | `gt` | `le` | `lt` | `ne` | `qrandstream`

GeneralizedLinearMixedModel class

Generalized linear mixed-effects model class

Description

A `GeneralizedLinearMixedModel` object represents a regression model of a response variable that contains both fixed and random effects. The object comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a generalized linear mixed-effects (GLME) model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a generalized linear mixed-effects (GLME) model to sample data using `fitglme(tbl, formula)`. For more information, see `fitglme`.

Input Arguments

`tbl` — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-45). You must specify the model for the variables using `formula`.

Data Types: `table`

`formula` — Formula for model specification

character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see Formula on page 33-2587.

Example: `'y ~ treatment +(1|block)'`

Properties

`Coefficients` — Estimates of fixed-effects coefficients

dataset array

Estimates of fixed-effects coefficients and related statistics, stored as a dataset array that has one row for each coefficient and the following columns:

- `Name` — Name of the coefficient
- `Estimate` — Estimated coefficient value

- `SE` — Standard error of the estimate
- `tStat` — *t*-statistic for a test that the coefficient is equal to 0
- `DF` — Degrees of freedom associated with the *t* statistic
- `pValue` — *p*-value for the *t*-statistic
- `Lower` — Lower confidence limit
- `Upper` — Upper confidence limit

To obtain any of these columns as a vector, index into the property using dot notation.

Use the `coefTest` method to perform other tests on the coefficients.

`CoefficientCovariance` — Covariance of estimated fixed-effects vector
matrix

Covariance of estimated fixed-effects vector, stored as a matrix.

Data Types: `single` | `double`

`CoefficientNames` — Names of fixed-effects coefficients
cell array of character vectors

Names of fixed-effects coefficients, stored as a cell array of character vectors. The label for the coefficient of the constant term is `(Intercept)`. The labels for other coefficients indicate the terms that they multiply. When the term includes a categorical predictor, the label also indicates the level of that predictor.

Data Types: `cell`

`DFE` — Degrees of freedom for error
positive integer value

Degrees of freedom for error, stored as a positive integer value. `DFE` is the number of observations minus the number of estimated coefficients.

`DFE` contains the degrees of freedom corresponding to the `'Residual'` method of calculating denominator degrees of freedom for hypothesis tests on fixed-effects coefficients. If n is the number of observations and p is the number of fixed-effects coefficients, then `DFE` is equal to $n - p$.

Data Types: `double`

`Dispersion` — Model dispersion parameter
scalar value

Model dispersion parameter, stored as a scalar value. The dispersion parameter defines the conditional variance of the response.

For observation i, the conditional variance of the response y_i, given the conditional mean μ_i and the dispersion parameter σ^2, in a generalized linear mixed-effects model is

$$\mathrm{var}\left(y_i \middle| \mu_i, \sigma^2\right) = \frac{\sigma^2}{w_i} v(\mu_i),$$

where w_i is the ith observation weight and v is the variance function for the specified conditional distribution of the response. The `Dispersion` property contains an estimate of σ^2 for the specified

GLME model. The value of `Dispersion` depends on the specified conditional distribution of the response. For binomial and Poisson distributions, the theoretical value of `Dispersion` is equal to $\sigma^2 = 1.0$.

- If `FitMethod` is `MPL` or `REMPL` and the `'DispersionFlag'` name-value pair argument in `fitglme` is `true`, then a dispersion parameter is estimated from data for all distributions, including binomial and Poisson distributions.
- If `FitMethod` is `ApproximateLaplace` or `Laplace`, then the `'DispersionFlag'` name-value pair argument in `fitglme` does not apply, and the dispersion parameter is fixed at 1.0 for binomial and Poisson distributions. For all other distributions, `Dispersion` is estimated from data.

Data Types: `double`

`DispersionEstimated` — Flag indicating if dispersion parameter was estimated
`true` | `false`

Flag indicating estimated dispersion parameter, stored as a logical value.

- If `FitMethod` is `ApproximateLaplace` or `Laplace`, then the dispersion parameter is fixed at its theoretical value of 1.0 for binomial and Poisson distributions, and `DispersionEstimated` is `false`. For other distributions, the dispersion parameter is estimated from the data, and `DispersionEstimated` is `true`.
- If `FitMethod` is `MPL` or `REMPL`, and the `'DispersionFlag'` name-value pair argument in `fitglme` is specified as `true`, then the dispersion parameter is estimated for all distributions, including binomial and Poisson distributions, and `DispersionEstimated` is `true`.
- If `FitMethod` is `MPL` or `REMPL`, and the `'DispersionFlag'` name-value pair argument in `fitglme` is specified as `false`, then the dispersion parameter is fixed at its theoretical value for binomial and Poisson distributions, and `DispersionEstimated` is `false`. For distributions other than binomial and Poisson, the dispersion parameter is estimated from the data, and `DispersionEstimated` is `true`.

Data Types: `logical`

`Distribution` — Response distribution name
`'Normal'` | `'Binomial'` | `'Poisson'` | `'Gamma'` | `'InverseGaussian'`

Response distribution name, stored as one of the following:

- `'Normal'` — Normal distribution
- `'Binomial'` — Binomial distribution
- `'Poisson'` — Poisson distribution
- `'Gamma'` — Gamma distribution
- `'InverseGaussian'` — Inverse Gaussian distribution

`FitMethod` — Method used to fit the model
`'MPL'` | `'REMPL'` | `'ApproximateLaplace'` | `'Laplace'`

Method used to fit the model, stored as one of the following.

- `'MPL'` — Maximum pseudo likelihood
- `'REMPL'` — Restricted maximum pseudo likelihood

- `'ApproximateLaplace'` — Maximum likelihood using the approximate Laplace method, with fixed effects profiled out
- `'Laplace'` — Maximum likelihood using the Laplace method

`Formula` — Model specification formula

object

Model specification formula, stored as an object. The model specification formula uses Wilkinson's notation to describe the relationship between the fixed-effects terms, random-effects terms, and grouping variables in the GLME model. For more information see Formula on page 33-2587.

`Link` — Link function characteristics

structure

Link function characteristics, stored as a structure containing the following fields. The link is a function `G` that links the distribution parameter `MU` to the linear predictor `ETA` as follows: `G(MU) = ETA`.

Field	Description
`Name`	Name of the link function
`Link`	Function that defines `G`
`Derivative`	Derivative of `G`
`SecondDerivative`	Second derivative of `G`
`Inverse`	Inverse of `G`

Data Types: `struct`

`LogLikelihood` — Log of likelihood function

scalar value

Log of likelihood function evaluated at the estimated coefficient values, stored as a scalar value. `LogLikelihood` depends on the method used to fit the model.

- If you use `'Laplace'` or `'ApproximateLaplace'`, then `LogLikelihood` is the maximized log likelihood.
- If you use `'MPL'`, then `LogLikelihood` is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use `'REMPL'`, then `LogLikelihood` is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

Data Types: `double`

`ModelCriterion` — Model criterion

table

Model criterion to compare fitted generalized linear mixed-effects models, stored as a table with the following fields.

Field	Description
`AIC`	Akaike information criterion

Field	Description
BIC	Bayesian information criterion
LogLikelihood	• For a model fit using 'Laplace' or 'ApproximateLaplace', LogLikelihood is the maximized log likelihood. • For a model fit using 'MPL', LogLikelihood is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration. • For a model fit using 'REMPL', LogLikelihood is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.
Deviance	–2 times LogLikelihood

NumCoefficients — Number of fixed-effects coefficients
positive integer value

Number of fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumEstimatedCoefficients — Number of estimated fixed-effects coefficients
positive integer value

Number of estimated fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumObservations — Number of observations
positive integer value

Number of observations used in the fit, stored as a positive integer value. NumObservations is the number of rows in the table or dataset array tbl, minus rows excluded using the 'Exclude' name-value pair of fitglme or rows containing NaN values.

Data Types: double

NumPredictors — Number of predictors
positive integer value

Number of variables used as predictors in the generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumVariables — Total number of variables
positive integer value

Total number of variables, including the response and predictors, stored as a positive integer value. If the sample data is in a table or dataset array tbl, then NumVariables is the total number of variables in tbl, including the response variable. NumVariables includes variables, if any, that are not used as predictors or as the response.

Data Types: `double`

`ObservationInfo` — Information about the observations

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following columns.

Name	Description
`Weights`	The weight value for the observation. The default value is 1.
`Excluded`	If the observation was excluded from the fit using the `'Exclude'` name-value pair argument in `fitglme`, then `Excluded` is `true`, or `1`. Otherwise, `Excluded` is `false`, or `0`.
`Missing`	If the observation was excluded from the fit because any response or predictor value is missing, then `Missing` is `true`. Otherwise, `Missing` is `false`. Missing values include `NaN` for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the `<undefined>` value for categorical arrays.
`Subset`	If the observation was used in the fit, then `Subset` is `true`. If the observation was not used in the fit because it is missing or excluded, then `Subset` is `false`.
`BinomSize`	Binomial size for each observation. This column only applies when fitting a binomial distribution.

Data Types: `table`

`ObservationNames` — Names of observations

cell array of character vectors

Names of observations used in the fit, stored as a cell array of character vectors.

- If the data is in a table or dataset array `tbl` that contains observation names, then `ObservationNames` uses those names.
- If the data is provided in matrices, or in a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: `cell`

`PredictorNames` — Names of predictors

cell array of character vectors

Names of the variables used as predictors in the fit, stored as a cell array of character vectors that has the same length as `NumPredictors`.

Data Types: `cell`

ResponseName — Name of response variable
character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

Data Types: `char`

Rsquared — Proportion of variability in the response explained by the fitted model
structure

Proportion of variability in the response explained by the fitted model, stored as a structure. `Rsquared` contains the *R*-squared value of the fitted model, also known as the multiple correlation coefficient. `Rsquared` contains the following fields.

Field	Description
`Ordinary`	R-squared value, stored as a scalar value in a structure. `Rsquared.Ordinary = 1 − SSE./SST`
`Adjusted`	R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure. `Rsquared.Adjusted = 1 − (SSE./SST)*(DFT./DFE)`, where `DFE = n − p`, `DFT = n − 1`, `n` is the total number of observations, and `p` is the number of fixed-effects coefficients.

Data Types: `struct`

SSE — Error sum of squares
positive scalar value

Error sum of squares, stored as a positive scalar value. `SSE` is the weighted sum of the squared conditional residuals, and is calculated as

$$SSE = \sum_{i=1}^{n} w_i^{eff}(y_i - f_i)^2,$$

where n is the number of observations, w_i^{eff} is the ith effective weight, y_i is the ith response, and f_i is the ith fitted value.

The ith effective weight is calculated as

$$w_i^{eff} = \left\{ \frac{w_i}{v_i\left(\mu_i\left(\widehat{\beta}, \widehat{b}\right)\right)} \right\},$$

where v_i is the variance term for the ith observation, $\widehat{\beta}$ and $\widehat{b}$ are estimated values of β and b, respectively.

The ith fitted value is calculated as

$$f_i = g^{-1}\left(x_i^T\widehat{\beta} + z_i^T\widehat{b} + \delta_i\right),$$

where x_i^T is the ith row of the fixed-effects design matrix X, and z_i^T is the ith row of the random-effects design matrix Z. δ_i is the ith offset value.

Data Types: `double`

SSR — Regression sum of squares
positive scalar value

Regression sum of squares, stored as a positive scalar value. SSR is the sum of squares explained by the generalized linear mixed-effects regression, or equivalently the weighted sum of the squared deviations of the conditional fitted values from their weighted mean. SSR is calculated as

$$SSR = \sum_{i=1}^{N} w_i^{eff}\left(f_i - \bar{f}\right)^2,$$

where n is the number of observations, w_i^{eff} is the ith effective weight, f_i is the ith fitted value, and $\bar{f}$ is a weighted average of the fitted values.

The ith effective weight is calculated as

$$w_i^{eff} = \left\{\frac{w_i}{v_i\left(\mu_i\left(\widehat{\beta}, \widehat{b}\right)\right)}\right\},$$

where $\widehat{\beta}$ and $\widehat{b}$ are estimated values of β and b, respectively.

The ith fitted value is calculated as

$$f_i = g^{-1}\left(x_i^T\widehat{\beta} + z_i^T\widehat{b} + \delta_i\right),$$

where x_i^T is the ith row of the fixed-effects design matrix X, and z_i^T is the ith row of the random-effects design matrix Z. δ_i is the ith offset value.

The weighted average of fitted values is calculated as

$$\bar{f} = \frac{\left[\sum_{i=1}^{n} w_i^{eff} f_i\right]}{\sum_{i=1}^{n} w_i^{eff}}.$$

Data Types: `double`

SST — Total sum of squares
positive scalar value

Total sum of squares, stored as a positive scalar value. For a GLME model, SST is defined as SST = SSE + SSR.

Data Types: `double`

`VariableInfo` — Information about the variables
table

Information about the variables used in the fit, stored as a table. `VariableInfo` has one row for each variable and contains the following columns.

Column Name	Description
`Class`	Class of the variable (`'double'`, `'cell'`, `'nominal'`, and so on).
`Range`	Value range of the variable. • For a numerical variable, `Range` is a two-element vector of the form `[min,max]`. • For a cell or categorical variable, `Range` is a cell or categorical array containing all unique values of the variable.
`InModel`	If the variable is a predictor in the fitted model, `InModel` is `true`. If the variable is not in the fitted model, `InModel` is `false`.
`IsCategorical`	If the variable type is treated as a categorical predictor (such as cell, logical, or categorical), then `IsCategorical` is `true`. If the variable is a continuous predictor, then `IsCategorical` is `false`.

Data Types: `table`

`VariableNames` — Names of the variables
cell array of character vectors

Names of all the variables contained in the table or dataset array `tbl`, stored as a cell array of character vectors.

Data Types: `cell`

`Variables` — Variables
table

Variables, stored as a table. If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

Data Types: `table`

Object Functions

anova	Analysis of variance for generalized linear mixed-effects model
coefCI	Confidence intervals for coefficients of generalized linear mixed-effects model
coefTest	Hypothesis test on fixed and random effects of generalized linear mixed-effects model
compare	Compare generalized linear mixed-effects models
covarianceParameters	Extract covariance parameters of generalized linear mixed-effects model
designMatrix	Fixed- and random-effects design matrices

fitted	Fitted responses from generalized linear mixed-effects model
fixedEffects	Estimates of fixed effects and related statistics
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
plotResiduals	Plot residuals of generalized linear mixed-effects model
predict	Predict response of generalized linear mixed-effects model
random	Generate random responses from fitted generalized linear mixed-effects model
randomEffects	Estimates of random effects and related statistics
refit	Refit generalized linear mixed-effects model
residuals	Residuals of fitted generalized linear mixed-effects model
response	Response vector of generalized linear mixed-effects model

Examples

Fit a Generalized Linear Mixed-Effects Model

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ..
    'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Display the model.

```
disp(glme)
```

Random effects covariance parameters:
Group: factory (20 Levels)
    Name1                Name2                Type           Estimate
    {'(Intercept)'}      {'(Intercept)'}      {'std'}        0.31381

Group: Error
    Name                       Estimate
    {'sqrt(Dispersion)'}       1
```

The `Model information` table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a `Poisson` distribution, the link function is `Log`, and the fit method is `Laplace`.

`Formula` indicates the model specification using Wilkinson's notation.

The `Model fit statistics` table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (`AIC`), Bayesian information criterion (`BIC`) values, log likelihood (`LogLikelihood`), and deviance (`Deviance`) values.

The `Fixed effects coefficients` table indicates that `fitglme` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (`Name`) contains the name of each fixed-effects coefficient, column 2 (`Estimate`) contains its estimated value, and column 3 (`SE`) contains the standard error of the coefficient. Column 4 (`tStat`) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (`DF`) and column 6 (`pValue`) contain the degrees of freedom and *p*-value that correspond to the *t*-statistic, respectively. The last two columns (`Lower` and `Upper`) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

`Random effects covariance parameters` displays a table for each grouping variable (here, only `factory`), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, `std` indicates that `fitglme` returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglme` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

More About

Formula

In general, a formula for model specification is a character vector or string scalar of the form `'y ~ terms'`. For generalized linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms, respectively, and *R* is the number of grouping variables in the model.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, X_j, which can be continuous or grouping variables
- Grouping variables, g_1, g_2, ..., g_R,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random`$_1$`|g`$_1$`) + ... + (random`$_R$`|g`$_R$`)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random`$_1$ is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1, and similarly `random`$_R$ is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
`1`	Constant (intercept) term
`X^k`, where `k` is a positive integer	`X`, X^2, ..., X^k
`X1 + X2`	`X1`, `X2`
`X1*X2`	`X1`, `X2`, `X1.*X2 (elementwise multiplication of X1 and X2)`
`X1:X2`	`X1.*X2` only
`- X2`	Do not include `X2`
`X1*X2 + X3`	`X1`, `X2`, `X3`, `X1*X2`
`X1 + X2 + X3 + X1:X2`	`X1`, `X2`, `X3`, `X1*X2`
`X1*X2*X3 - X1:X2:X3`	`X1`, `X2`, `X3`, `X1*X2`, `X1*X3`, `X2*X3`
`X1*(X2 + X3)`	`X1`, `X2`, `X3`, `X1*X2`, `X1*X3`

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
`'y ~ X1 + X2'`	Fixed effects for the intercept, `X1` and `X2`. This is equivalent to `'y ~ 1 + X1 + X2'`.
`'y ~ -1 + X1 + X2'`	No intercept and fixed effects for `X1` and `X2`. The implicit intercept term is suppressed by including `-1`.
`'y ~ 1 + (1 | g1)'`	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable `g1`.
`'y ~ X1 + (1 | g1)'`	Random intercept model with a fixed slope.

Formula	Description
`'y ~ X1 + (X1 | g1)'`	Random intercept and slope, with possible correlation between them. This is equivalent to `'y ~ 1 + X1 + (1 + X1|g1)'`.
`'y ~ X1 + (1 | g1) + (-1 + X1 | g1)'`	Independent random effects terms for intercept and slope.
`'y ~ 1 + (1 | g1) + (1 | g2) + (1 | g1:g2)'`	Random intercept model with independent main effects for `g1` and `g2`, plus an independent interaction effect.

GeneralizedLinearModel

Generalized linear regression model class

Description

`GeneralizedLinearModel` is a fitted generalized linear regression model. A generalized linear regression model is a special class of nonlinear models that describe a nonlinear relationship between a response and predictors. A generalized linear regression model has generalized characteristics of a linear regression model. The response variable follows a normal, binomial, Poisson, gamma, or inverse Gaussian distribution with parameters including the mean response μ. A link function f defines the relationship between μ and the linear combination of predictors.

Use the properties of a `GeneralizedLinearModel` object to investigate a fitted generalized linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data. Use the object functions to predict responses and to modify, evaluate, and visualize the model.

Creation

Create a `GeneralizedLinearModel` object by using `fitglm` or `stepwiseglm`.

`fitglm` fits a generalized linear regression model to data using a fixed model specification. Use `addTerms`, `removeTerms`, or `step` to add or remove terms from the model. Alternatively, use `stepwiseglm` to fit a model using stepwise generalized linear regression.

Properties

Coefficient Estimates

`CoefficientCovariance` — Covariance matrix of coefficient estimates
numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a p-by-p matrix of numeric values. p is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-58.

Data Types: `single` | `double`

`CoefficientNames` — Coefficient names
cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: `cell`

`Coefficients` — Coefficient values

table

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — *t*-statistic for a test that the coefficient is zero
- `pValue` — *p*-value for the *t*-statistic

Use `coefTest` to perform linear hypothesis tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```
beta = mdl.Coefficients.Estimate
```

Data Types: `table`

`NumCoefficients` — Number of model coefficients

positive integer

This property is read-only.

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

Data Types: `double`

`NumEstimatedCoefficients` — Number of estimated coefficients

positive integer

This property is read-only.

Number of estimated coefficients in the model, specified as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

Data Types: `double`

Summary Statistics

`Deviance` — Deviance of fit

numeric value

This property is read-only.

Deviance of the fit, specified as a numeric value. The deviance is useful for comparing two models when one model is a special case of the other model. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of

estimated parameters between the two models. For more information, see “Deviance” on page 33-2606.

Data Types: `single` | `double`

`DFE` — Degrees of freedom for error
positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: `double`

`Diagnostics` — Observation diagnostics
table

This property is read-only.

Observation diagnostics, specified as a table that contains one row for each observation and the columns described in this table.

Column	Meaning	Description
`Leverage`	Diagonal elements of `HatMatrix`	`Leverage` for each observation indicates to what extent the fit is determined by the observed predictor values. A value close to `1` indicates that the fit is largely determined by that observation, with little contribution from the other observations. A value close to `0` indicates that the fit is largely determined by the other observations. For a model with `P` coefficients and `N` observations, the average value of `Leverage` is `P/N`. A `Leverage` value greater than `2*P/N` indicates high leverage.
`CooksDistance`	Cook's distance of scaled change in fitted values	`CooksDistance` is a measure of scaled change in fitted values. An observation with `CooksDistance` greater than three times the mean Cook's distance can be an outlier.
`HatMatrix`	Projection matrix to compute fitted from observed responses	`HatMatrix` is an `N`-by-`N` matrix such that `Fitted = HatMatrix*Y`, where `Y` is the response vector and `Fitted` is the vector of fitted response values.

The software computes these values on the scale of the linear combination of the predictors, stored in the `LinearPredictor` field of the `Fitted` and `Residuals` properties. For example, the software computes the diagnostic values by using the fitted response and adjusted response values from the model `mdl`.

```
Yfit = mdl.Fitted.LinearPredictor
Yadjusted = mdl.Fitted.LinearPredictor + mdl.Residuals.LinearPredictor
```

`Diagnostics` contains information that is helpful in finding outliers and influential observations. For more details, see “Leverage” on page 33-2605, “Cook’s Distance” on page 33-2604, and “Hat Matrix” on page 33-2605.

Use `plotDiagnostics` to plot observation diagnostics.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain `NaN` values in the `CooksDistance` column and zeros in the `Leverage` and `HatMatrix` columns.

To obtain any of these columns as an array, index into the property using dot notation. For example, obtain the hat matrix in the model `mdl`:

```
HatMatrix = mdl.Diagnostics.HatMatrix;
```

Data Types: `table`

`Dispersion` — Scale factor of variance of response
numeric scalar

This property is read-only.

Scale factor of the variance of the response, specified as a numeric scalar.

If the `'DispersionFlag'` name-value pair argument of `fitglm` or `stepwiseglm` is `true`, then the function estimates the `Dispersion` scale factor in computing the variance of the response. The variance of the response equals the theoretical variance multiplied by the scale factor.

For example, the variance function for the binomial distribution is $p(1–p)/n$, where p is the probability parameter and n is the sample size parameter. If `Dispersion` is near `1`, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If `Dispersion` is larger than `1`, the data set is “overdispersed” relative to the binomial distribution.

Data Types: `double`

`DispersionEstimated` — Flag to indicate use of dispersion scale factor
logical value

This property is read-only.

Flag to indicate whether `fitglm` used the `Dispersion` scale factor to compute standard errors for the coefficients in `Coefficients.SE`, specified as a logical value. If `DispersionEstimated` is `false`, `fitglm` used the theoretical value of the variance.

- `DispersionEstimated` can be `false` only for the binomial and Poisson distributions.
- Set `DispersionEstimated` by setting the `'DispersionFlag'` name-value pair argument of `fitglm` or `stepwiseglm`.

Data Types: `logical`

`Fitted` — Fitted response values based on input data
table

This property is read-only.

Fitted (predicted) values based on the input data, specified as a table that contains one row for each observation and the columns described in this table.

Column	Description
`Response`	Predicted values on the scale of the response

Column	Description
`LinearPredictor`	Predicted values on the scale of the linear combination of the predictors (same as the link function applied to the `Response` fitted values)
`Probability`	Fitted probabilities (included only with the binomial distribution)

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the vector `f` of fitted values on the response scale in the model `mdl`:

```
f = mdl.Fitted.Response
```

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Data Types: `table`

`LogLikelihood` — Loglikelihood
numeric value

This property is read-only.

Loglikelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

Data Types: `single` | `double`

`ModelCriterion` — Criterion for model comparison
structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- `AIC` — Akaike information criterion. `AIC = –2*logL + 2*m`, where `logL` is the loglikelihood and `m` is the number of estimated parameters.
- `AICc` — Akaike information criterion corrected for the sample size. `AICc = AIC + (2*m*(m + 1))/(n – m – 1)`, where `n` is the number of observations.
- `BIC` — Bayesian information criterion. `BIC = –2*logL + m*log(n)`.
- `CAIC` — Consistent Akaike information criterion. `CAIC = –2*logL + m*(log(n) + 1)`.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

`Residuals` — Residuals for fitted model

table

This property is read-only.

Residuals for the fitted model, specified as a table that contains one row for each observation and the columns described in this table.

Column	Description
`Raw`	Observed minus fitted values
`LinearPredictor`	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors
`Pearson`	Raw residuals divided by the estimated standard deviation of the response
`Anscombe`	Residuals defined on transformed data with the transformation selected to remove skewness
`Deviance`	Residuals based on the contribution of each observation to the deviance

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain `NaN` values.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the ordinary raw residual vector `r` in the model `mdl`:

```
r = mdl.Residuals.Raw
```

Data Types: `table`

`Rsquared` — R-squared value for model

structure

This property is read-only.

R-squared value for the model, specified as a structure with five fields.

Field	Description	Equation
`Ordinary`	Ordinary (unadjusted) R-squared	$R^2_{\text{Ordinary}} = 1 - \frac{\text{SSE}}{\text{SST}}$ `SSE` is the sum of squared errors, and `SST` is the total sum of squared deviations of the response vector from the mean of the response vector.
`Adjusted`	R-squared adjusted for the number of coefficients	$R^2_{\text{Adjusted}} = 1 - \frac{\text{SSE}}{\text{SST}} \cdot \frac{N-1}{\text{DFE}}$ N is the number of observations (`NumObservations`), and `DFE` is the degrees of freedom for the error (residuals).

Field	Description	Equation
`LLR`	Loglikelihood ratio	$R^2_{\text{LLR}} = 1 - \frac{L}{L_0}$ L is the loglikelihood of the fitted model (`LogLikelihood`), and L_0 is the loglikelihood of a model that includes only a constant term. R^2_{LLR} is the McFadden pseudo R-squared value [1] for logistic regression models.
`Deviance`	Deviance R-squared	$R^2_{\text{Deviance}} = 1 - \frac{D}{D_0}$ D is the deviance of the fitted model (`Deviance`), and D_0 is the deviance of a model that includes only a constant term.
`AdjGeneralized`	Adjusted generalized R-squared	$R^2_{\text{AdjGeneralized}} = \frac{1 - \exp\left(\frac{2(L_0 - L)}{N}\right)}{1 - \exp\left(\frac{2L_0}{N}\right)}$ $R^2_{\text{AdjGeneralized}}$ is the Nagelkerke adjustment [2] to a formula proposed by Maddala [3], Cox and Snell [4], and Magee [5] for logistic regression models.

To obtain any of these values as a scalar, index into the property using dot notation. For example, to obtain the adjusted R-squared value in the model `mdl`, enter:

```
r2 = mdl.Rsquared.Adjusted
```

Data Types: `struct`

SSE — Sum of squared errors
numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

Data Types: `single` | `double`

SSR — Regression sum of squares
numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

Data Types: `single` | `double`

SST — Total sum of squares
numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector `y` from the `mean(y)`.

Data Types: `single` | `double`

Fitting Information

`Steps` — Stepwise fitting information

structure

This property is read-only.

Stepwise fitting information, specified as a structure with the fields described in this table.

Field	Description
`Start`	Formula representing the starting model
`Lower`	Formula representing the lower bound model. The terms in `Lower` must remain in the model.
`Upper`	Formula representing the upper bound model. The model cannot contain more terms than `Upper`.
`Criterion`	Criterion used for the stepwise algorithm, such as `'sse'`
`PEnter`	Threshold for `Criterion` to add a term
`PRemove`	Threshold for `Criterion` to remove a term
`History`	Table representing the steps taken in the fit

The `History` table contains one row for each step, including the initial fit, and the columns described in this table.

Column	Description
`Action`	Action taken during the step: • `'Start'` — First step • `'Add'` — A term is added • `'Remove'` — A term is removed
`TermName`	• If `Action` is `'Start'`, `TermName` specifies the starting model specification. • If `Action` is `'Add'` or `'Remove'`, `TermName` specifies the term added or removed in the step.
`Terms`	Model specification in a “Terms Matrix” on page 33-2606
`DF`	Regression degrees of freedom after the step
`delDF`	Change in regression degrees of freedom from the previous step (negative for steps that remove a term)
`Deviance`	Deviance (residual sum of squares) at the step (only for a generalized linear regression model)
`FStat`	*F*-statistic that leads to the step
`PValue`	*p*-value of the *F*-statistic

The structure is empty unless you fit the model using stepwise regression.

Data Types: `struct`

Input Data

`Distribution` — Generalized distribution information

structure

This property is read-only.

Generalized distribution information, specified as a structure with the fields described in this table.

Field	Description
`Name`	Name of the distribution: `'normal'`, `'binomial'`, `'poisson'`, `'gamma'`, or `'inverse gaussian'`
`DevianceFunction`	Function that computes the components of the deviance as a function of the fitted parameter values and the response values
`VarianceFunction`	Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When `DispersionEstimated` is `true`, the software multiplies the variance function by `Dispersion` in the computation of the coefficient standard errors.

Data Types: `struct`

`Formula` — Model information

`LinearFormula` object

This property is read-only.

Model information, specified as a `LinearFormula` object.

Display the formula of the fitted model `mdl` using dot notation:

```
mdl.Formula
```

`Link` — Link function

structure

This property is read-only.

Link function, specified as a structure with the fields described in this table.

Field	Description
`Name`	Name of the link function, specified as a character vector. If you specify the link function using a function handle, then `Name` is `''`.
`Link`	Function f that defines the link function, specified as a function handle
`Derivative`	Derivative of f, specified as a function handle
`Inverse`	Inverse of f, specified as a function handle

The link function is a function f that links the distribution parameter μ to the fitted linear combination Xb of the predictors:

$$f(\mu) = Xb.$$

Data Types: `struct`

`NumObservations` — Number of observations

positive integer

This property is read-only.

Number of observations the fitting function used in fitting, specified as a positive integer. `NumObservations` is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `'Exclude'` name-value pair argument) or rows with missing values.

Data Types: `double`

`NumPredictors` — Number of predictor variables

positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: `double`

`NumVariables` — Number of variables

positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

`NumVariables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `double`

`ObservationInfo` — Observation information

table

This property is read-only.

Observation information, specified as an *n*-by-4 table, where *n* is equal to the number of rows of input data. `ObservationInfo` contains the columns described in this table.

Column	Description
`Weights`	Observation weights, specified as a numeric value. The default value is `1`.
`Excluded`	Indicator of excluded observations, specified as a logical value. The value is `true` if you exclude the observation from the fit by using the `'Exclude'` name-value pair argument.
`Missing`	Indicator of missing observations, specified as a logical value. The value is `true` if the observation is missing.
`Subset`	Indicator of whether or not the fitting function uses the observation, specified as a logical value. The value is `true` if the observation is not excluded or missing, meaning the fitting function uses the observation.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the weight vector `w` of the model `mdl`:

```
w = mdl.ObservationInfo.Weights
```

Data Types: `table`

`ObservationNames` — Observation names
cell array of character vectors

This property is read-only.

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array.

Data Types: `cell`

`Offset` — Offset variable
numeric vector

This property is read-only.

Offset variable, specified as a numeric vector with the same length as the number of rows in the data. `Offset` is passed from `fitglm` or `stepwiseglm` in the `'Offset'` name-value pair argument. The fitting functions use `Offset` as an additional predictor variable with a coefficient value fixed at `1`. In other words, the formula for fitting is

$f(\mu)$ ~ `Offset + (terms involving real predictors)`

where f is the link function. The `Offset` predictor has coefficient `1`.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `double`

`PredictorNames` — Names of predictors used to fit model
cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: `cell`

`ResponseName` — Response variable name
character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

`VariableInfo` — Information about variables

table

This property is read-only.

Information about variables contained in `Variables`, specified as a table with one row for each variable and the columns described in this table.

Column	Description
`Class`	Variable class, specified as a cell array of character vectors, such as `'double'` and `'categorical'`
`Range`	Variable range, specified as a cell array of vectors • Continuous variable — Two-element vector `[min,max]`, the minimum and maximum values • Categorical variable — Vector of distinct variable values
`InModel`	Indicator of which variables are in the fitted model, specified as a logical vector. The value is `true` if the model includes the variable.
`IsCategorical`	Indicator of categorical variables, specified as a logical vector. The value is `true` if the variable is categorical.

`VariableInfo` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

`VariableNames` — Names of variables

cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` contains the values specified by the `'VarNames'` name-value pair argument of the fitting method. The default value of `'VarNames'` is `{'x1','x2',...,'xn','y'}`.

`VariableNames` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `cell`

`Variables` — Input data

table

This property is read-only.

Input data, specified as a table. `Variables` contains both predictor and response values. If the fit is based on a table or dataset array, `Variables` contains all the data from the table or dataset array. Otherwise, `Variables` is a table created from the input data matrix `X` and the response vector `y`.

`Variables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

Object Functions

Create `CompactGeneralizedLinearModel`

compact	Compact generalized linear regression model

Add or Remove Terms from Generalized Linear Model

addTerms	Add terms to generalized linear regression model
removeTerms	Remove terms from generalized linear regression model
step	Improve generalized linear regression model by adding or removing terms

Predict Responses

feval	Predict responses of generalized linear regression model using one input for each predictor
predict	Predict responses of generalized linear regression model
random	Simulate responses with random noise for generalized linear regression model

Evaluate Generalized Linear Model

coefCI	Confidence intervals of coefficient estimates of generalized linear regression model
coefTest	Linear hypothesis test on generalized linear regression model coefficients
devianceTest	Analysis of deviance for generalized linear regression model
partialDependence	Compute partial dependence

Visualize Generalized Linear Model and Summary Statistics

plotDiagnostics	Plot observation diagnostics of generalized linear regression model
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
plotResiduals	Plot residuals of generalized linear regression model
plotSlice	Plot of slices through fitted generalized linear regression surface

Gather Properties of Generalized Linear Model

gather	Gather properties of machine learning model from GPU

Examples

Create Generalized Linear Regression Model

Fit a logistic regression model of the probability of smoking as a function of age, weight, and sex, using a two-way interaction model.

Load the `hospital` data set.

```
load hospital
```

Convert the dataset array to a table.

```
tbl = dataset2table(hospital);
```

Specify the model using a formula that includes two-way interactions and lower-order terms.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(tbl,modelspec,'Distribution','binomial')
```

```
mdl =
Generalized linear regression model:
    logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
    Distribution = Binomial

Estimated Coefficients:
                        Estimate         SE         tStat      pValue
                       ___________    _________    ________    _______

    (Intercept)            -6.0492       19.749     -0.3063    0.75938
    Sex_Male               -2.2859       12.424    -0.18399    0.85402
    Age                    0.11691      0.50977     0.22934    0.81861
    Weight                0.031109      0.15208     0.20455    0.83792
    Sex_Male:Age          0.020734      0.20681     0.10025    0.92014
    Sex_Male:Weight        0.01216     0.053168     0.22871     0.8191
    Age:Weight         -0.00071959    0.0038964    -0.18468    0.85348

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535
```

The large *p*-value indicates that the model might not differ statistically from a constant.

Create Generalized Linear Regression Model Using Stepwise Regression

Create response data using three of 20 predictor variables, and create a generalized linear model using stepwise regression from a constant model to see if `stepwiseglm` finds the correct predictors.

Generate sample data that has 20 predictor variables. Use three of the predictors to generate the Poisson response variable.

```
rng default % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear regression model using the Poisson distribution. Specify the starting model as a model that contains only a constant (intercept) term. Also, specify a model with an intercept and linear term for each predictor as the largest model to consider as the fit by using the `'Upper'` name-value pair argument.

```
mdl =  stepwiseglm(X,y,'constant','Upper','linear','Distribution','poisson')
```

```
1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

mdl =
Generalized linear regression model:
    log(y) ~ 1 + x5 + x10 + x15
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE       tStat       pValue
                   ________    ________    ______    __________

    (Intercept)     1.0115     0.064275    15.737    8.4217e-56
    x5             0.39508     0.066665    5.9263    3.0977e-09
    x10            0.18863      0.05534    3.4085     0.0006532
    x15            0.29295     0.053269    5.4995    3.8089e-08

100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

`stepwiseglm` finds the three correct predictors: `x5`, `x10`, and `x15`.

More About

Canonical Link Function

The default link function for a generalized linear model is the canonical link function. You can specify a link function when you fit a model with `fitglm` or `stepwiseglm` by using the `'Link'` name-value pair argument.

Distribution	Canonical Link Function Name	Link Function	Mean (Inverse) Function
`'normal'`	`'identity'`	$f(\mu) = \mu$	$\mu = Xb$
`'binomial'`	`'logit'`	$f(\mu) = \log(\mu/(1 - \mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
`'poisson'`	`'log'`	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
`'gamma'`	`-1`	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
`'inverse gaussian'`	`-2`	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Cook's Distance

Cook's distance is the scaled change in fitted values, which is useful for identifying outliers in the observations for predictor variables. Cook's distance shows the influence of each observation on the fitted response values. An observation with Cook's distance larger than three times the mean Cook's distance might be an outlier.

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p\widehat{\varphi}} \frac{h_{ii}}{(1 - h_{ii})^2},$$

where

- $\widehat{\varphi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i\widehat{\beta}$, where
  - g is the link function.
  - y_i is the observed response.
  - x_i is the observation.
  - $\widehat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the ith diagonal element of the Hat Matrix on page 33-2605 H.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the ith diagonal term h_{ii} of the hat matrix H. Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n, where n is the number of observations.

Hat Matrix

The hat matrix is a projection matrix that projects the vector of response observations onto the vector of predictions.

The hat matrix H is defined in terms of the data matrix X and a diagonal weight matrix W:

$H = X(X^TWX)^{-1}X^TW^T$.

W has diagonal elements w_i:

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to x_ib.
- g' is the derivative of the link function g.
- V is the variance function.
- μ_i is the ith mean.

The diagonal elements H_{ii} satisfy

$$0 \le h_{ii} \le 1$$

$$\sum_{i=1}^{n} h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Deviance

Deviance is a generalization of the residual sum of squares. It measures the goodness of fit compared to a saturated model.

Deviance of a model M_1 is twice the difference between the loglikelihood of the model M_1 and the saturated model M_s. A saturated model is a model with the maximum number of parameters that you can estimate.

For example, if you have n observations (y_i, $i = 1, 2, ..., n$) with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model with the parameters b. Then the deviance of the model M_1 is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where b_1 and b_s contain the estimated parameters for the model M_1 and the saturated model, respectively. The deviance has a chi-square distribution with n – p degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in the model M_1.

Assume you have two different generalized linear regression models M_1 and M_2, and M_1 has a subset of the terms in M_2. You can assess the fit of the models by comparing the deviances D_1 and D_2 of the two models. The difference of the deviances is

$$\begin{aligned} D = D_2 - D_1 &= -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, the difference D has a chi-square distribution with degrees of freedom v equal to the difference in the number of parameters estimated in M_1 and M_2. You can obtain the p-value for this test by using `1 - chi2cdf(D,v)`.

Typically, you examine D using a model M_2 with a constant term and no predictors. Therefore, D has a chi-square distribution with p – 1 degrees of freedom. If the dispersion is estimated, the difference divided by the estimated dispersion has an F distribution with p – 1 numerator degrees of freedom and n – p denominator degrees of freedom.

Terms Matrix

A terms matrix `T` is a t-by-(p + 1) matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `x1`, `x2`, and `x3` and the response variable `y` in the order `x1`, `x2`, `x3`, and `y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `x2`; equivalently, `x1^0 * x2^1 * x3^0`
- `[1 0 1 0]` — `x1*x3`
- `[2 0 0 0]` — `x1^2`
- `[0 1 2 0]` — `x2*(x3^2)`

The `0` at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and

response variables in a matrix and column vector, then you must include `0` for the response variable in the last column of each row.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `random` functions support code generation.
- When you fit a model by using `fitglm` or `stepwiseglm`, you cannot specify `Link`, `Derivative`, and `Inverse` fields of the `'Link'` name-value pair argument as anonymous functions. That is, you cannot generate code using a generalized linear model that was created using anonymous functions for links. Instead, define functions for link components.

For more information, see “Introduction to Code Generation” on page 32-2.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The following object functions fully support GPU arrays:
  - `feval`
  - `predict`
  - `random`
  - `partialDependence`
  - `plotPartialDependence`
- The following object functions support model objects fitted with GPU array input arguments:
  - `compact`
  - `addTerms`

- `removeTerms`
- `step`
- `coefCI`
- `coefTest`
- `devianceTest`
- `plotDiagnostics`
- `plotResiduals`
- `plotSlice`
- `gather`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Generalized Linear Model Workflow” on page 12-28
“Generalized Linear Models” on page 12-9

Introduced in R2012a

generateCode

Package: `classreg.learning.coder.config.svm`

Generate C/C++ code using coder configurer

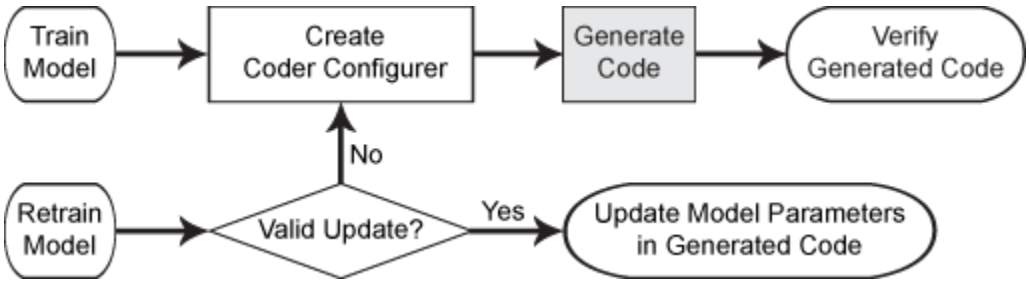
Syntax

```
generateCode(configurer)
generateCode(configurer,cfg)
generateCode( ___ ,'OutputPath',outputPath)
```

Description

After training a machine learning model, create a coder configurer for the model by using `learnerCoderConfigurer`. Modify the properties of the configurer to specify code generation options. Then use `generateCode` to generate C/C++ code for the `predict` and `update` functions of the machine learning model. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow using a coder configurer. Use `generateCode` for the highlighted step.



`generateCode(configurer)` generates a MEX (MATLAB Executable) function for the `predict` and `update` functions of a machine learning model by using `configurer`. The generated MEX function is named *`outputFileName`*, which is the file name stored in the `OutputFileName` property of `configurer`.

To generate a MEX function, `generateCode` first generates the following MATLAB files required to generate code and stores them in the current folder:

- `predict.m`, `update.m`, and `initialize.m` — `predict.m` and `update.m` are the entry-point functions for the `predict` and `update` functions of the machine learning model, respectively, and these two functions call `initialize.m`.
- A MAT-file that includes machine learning model information — `generateCode` uses the `saveLearnerForCoder` function to save machine learning model information in a MAT-file whose file name is stored in the `OutputFileName` property of a coder configurer. `initialize.m` loads the saved MAT-file by using the `loadLearnerForCoder` function.

After generating the necessary MATLAB files, `generateCode` creates the MEX function and the code for the MEX function in the `codegen\mex\`*`outputFileName`* folder and copies the MEX function to the current folder.

`generateCode(configurer,cfg)` generates C/C++ code using the build type specified by `cfg`.

`generateCode( ___ ,'OutputPath',outputPath)` specifies the folder path for the output files in addition to any of the input arguments in previous syntaxes. `generateCode` generates the MATLAB files in the folder specified by `outputPath` and generates C/C++ code in the folder `outputPath \codegen\`*`type`*`\`*`outputFileName`* where *`type`* is the build type specified by `cfg`.

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carsmall` data set and train a support vector machine (SVM) regression model.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

`Mdl` is a `RegressionSVM` object.

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)
```

```
configurer =
  RegressionSVMCoderConfigurer with properties:

   Update Inputs:
             Alpha: [1x1 LearnerCoderInput]
    SupportVectors: [1x1 LearnerCoderInput]
             Scale: [1x1 LearnerCoderInput]
              Bias: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]

   Code Generation Parameters:
        NumOutputs: 1
    OutputFileName: 'RegressionSVMModel'

  Properties, Methods
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
initialize('update',varargin{:});
end
```

```
type initialize.m
```

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                       SupportVectors
        %                       Scale
        %                       Bias
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
```

```
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end
```

Specify Build Type

Train a machine learning model and generate code by using the coder configurer of the trained model. When generating code, specify the build type and other configuration options using a code generation configuration object.

Load the `ionosphere` data set and train a binary support vector machine (SVM) classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` object.

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Create a code generation configuration object by using `coder.config` (MATLAB Coder). Specify `'dll'` to generate a dynamic library and specify the `GenerateReport` property as `true` to enable the code generation report.

```
cfg = coder.config('dll');
cfg.GenerateReport = true;
```

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Use `generateCode` and the configuration object `cfg` to generate code. Also, specify the output folder path.

```
generateCode(configurer,cfg,'OutputPath','testPath')
```

```
Specified folder does not exist. Folder has been created.
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'
Code generation successful: To view the report, open('codegen\dll\ClassificationSVMModel\html\rep
```

`generateCode` creates the specified folder. The function also generates the MATLAB files required to generate code and stores them in the folder. Then `generateCode` generates C code in the `testPath\codegen\dll\ClassificationSVMModel` folder.

Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

```
t = templateSVM('KernelFunction','gaussian','Standardize',true);
```

Train a multiclass ECOC model using the template `t`.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

`Mdl` is a `ClassificationECOC` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the `predict` function, which are the predicted labels and negated average binary losses.

```
configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)
```

```
configurer =
  ClassificationECOCCoderConfigurer with properties:

   Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
             Prior: [1x1 LearnerCoderInput]
              Cost: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]

   Code Generation Parameters:
        NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'

  Properties, Methods
```

`configurer` is a `ClassificationECOCCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object. The display shows the tunable input arguments of `predict` and `update`: `X`, `BinaryLearners`, `Prior`, and `Cost`.

Specify Coder Attributes of Parameters

Specify the coder attributes of `predict` arguments (predictor data and the name-value pair arguments `'Decoding'` and `'BinaryLoss'`) and `update` arguments (support vectors of the SVM learners) so that you can use these arguments as the input arguments of `predict` and `update` in the generated code.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 4 predictors, so the second value of the `SizeVector` attribute must be 4 and the second value of the `VariableDimensions` attribute must be `false`.

Next, modify the coder attributes of `BinaryLoss` and `Decoding` to use the `'BinaryLoss'` and `'Decoding'` name-value pair arguments in the generated code. Display the coder attributes of `BinaryLoss`.

```
configurer.BinaryLoss
```

```
ans =
  EnumeratedInput with properties:

            Value: 'hinge'
    SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
        Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the `Value` attribute of `BinaryLoss` as `'exponential'`.

```
configurer.BinaryLoss.Value = 'exponential';
configurer.BinaryLoss
```

```
ans =
  EnumeratedInput with properties:

            Value: 'exponential'
    SelectedOption: 'Built-in'
    BuiltInOptions: {1x7 cell}
        IsConstant: 1
```

```
        Tunability: 1
```

If you modify attribute values when `Tunability` is `false` (logical 0), the software sets the `Tunability` to `true` (logical 1).

Display the coder attributes of `Decoding`.

```
configurer.Decoding
```

```
ans =
  EnumeratedInput with properties:

             Value: 'lossweighted'
    SelectedOption: 'Built-in'
    BuiltInOptions: {'lossweighted'  'lossbased'}
        IsConstant: 1
        Tunability: 0
```

Specify the `IsConstant` attribute of `Decoding` as `false` so that you can use all available values in `BuiltInOptions` in the generated code.

```
configurer.Decoding.IsConstant = false;
configurer.Decoding
```

```
ans =
  EnumeratedInput with properties:

             Value: [1x1 LearnerCoderInput]
    SelectedOption: 'NonConstant'
    BuiltInOptions: {'lossweighted'  'lossbased'}
        IsConstant: 0
        Tunability: 1
```

The software changes the `Value` attribute of `Decoding` to a `LearnerCoderInput` object so that you can use both `'lossweighted'` and `'lossbased'` as the value of `'Decoding'`. Also, the software sets the `SelectedOption` to `'NonConstant'` and the `Tunability` to `true`.

Finally, modify the coder attributes of `SupportVectors` in `BinaryLearners`. Display the coder attributes of `SupportVectors`.

```
configurer.BinaryLearners.SupportVectors
```

```
ans =
  LearnerCoderInput with properties:

            SizeVector: [54 4]
    VariableDimensions: [1 0]
              DataType: 'double'
            Tunability: 1
```

The default value of `VariableDimensions` is `[true false]` because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.

```
configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constrai
```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

```
configurer
```

```
configurer =
  ClassificationECOCCoderConfigurer with properties:

   Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
             Prior: [1x1 LearnerCoderInput]
              Cost: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]
        BinaryLoss: [1x1 EnumeratedInput]
          Decoding: [1x1 EnumeratedInput]

   Code Generation Parameters:
        NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'

  Properties, Methods
```

The display now includes `BinaryLoss` and `Decoding` as well.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the ECOC classification model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.

- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified `'Decoding'` as a tunable input argument by changing the `IsConstant` attribute before generating the code, you also need to specify it in the call to the MEX function, even though `'lossweighted'` is the default value of `'Decoding'`.

```
[label,NegLoss] = predict(Mdl,X,'BinaryLoss','exponential');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decodi
```

Compare `label` to `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
   1
```

`isequal` returns logical 1 (`true`) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`NegLoss_mex` might include round-off differences compared to `NegLoss`. In this case, compare `NegLoss_mex` to `NegLoss`, allowing a small tolerance.

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =

  0x1 empty double column vector
```

The comparison confirms that `NegLoss` and `NegLoss_mex` are equal within the tolerance `1e–8`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify `'KernelScale'` as `'auto'` so that the software selects an appropriate scale factor using a heuristic procedure.

```
t_new = templateSVM('KernelFunction','gaussian','Standardize',true,'KernelScale','auto');
retrainedMdl = fitcecoc(X,Y,'Learners',t_new);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationECOCModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```
[label,NegLoss] = predict(retrainedMdl,X,'BinaryLoss','exponential','Decoding','lossbased');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential','Decodi
isequal(label,label_mex)

ans = logical
   1

find(abs(NegLoss-NegLoss_mex) > 1e-8)

ans =

  0x1 empty double column vector
```

The comparison confirms that `label` and `label_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

Input Arguments

`configurer` — Coder configurer

coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	`ClassificationTreeCoderConfigurer`
SVM for one-class and binary classification	`ClassificationSVMCoderConfigurer`
Linear model for binary classification	`ClassificationLinearCoderConfigurer`
Multiclass model for SVMs and linear models	`ClassificationECOCCoderConfigurer`
Binary decision tree for regression	`RegressionTreeCoderConfigurer`
Support vector machine (SVM) regression	`RegressionSVMCoderConfigurer`
Linear regression	`RegressionLinearCoderConfigurer`

`cfg` — Build type

`'mex'` (default) | `'dll'` | `'lib'` | code generation configuration object

Build type, specified as `'mex'`, `'dll'`, `'lib'`, or a code generation configuration object created by `coder.config`.

`generateCode` generates C/C++ code using one of the following build types.

- `'mex'` — Generates a MEX function that has a platform-dependent extension. A MEX function is a C/C++ program that is executable from the Command Window. Before generating a C/C++ library for deployment, generate a MEX function to verify that the generated code provides the correct functionality.

- `'dll'` — Generate a dynamic C/C++ library.
- `'lib'` — Generate a static C/C++ library.
- Code generation configuration object created by `coder.config` — Generate C/C++ code using the code generation configuration object to customize code generation options. You can specify the build type and other configuration options using the object. For example, modify the `GenerateReport` parameter to enable the code generation report, and modify the `TargetLang` parameter to generate C++ code. The default value of the `TargetLang` parameter is `'C'`, generating C code.

  ```
  cfg = coder.config('mex');
  cfg.GenerateReport = true;
  cfg.TargetLang = 'C++';
  ```

  For details, see the `-config` option of `codegen`, `coder.config`, and “Configure Build Settings” (MATLAB Coder).

`generateCode` generates C/C++ code in the folder `outputPath\codegen\`*`type`*`\`*`outputFileName`*, where *`type`* is the build type specified by the `cfg` argument and *`outputFileName`* is the file name stored in the `OutputFileName` property of `configurer`.

`outputPath` — Folder path for output files
current folder (default) | character vector | string scalar

Folder path for the output files of `generateCode`, specified as a character vector or string array.

The specified folder path can be an absolute path or a relative path to the current folder path.

- The path must not contain spaces because they can lead to code generation failures in certain operating system configurations.
- The path also cannot contain non-7-bit ASCII characters, such as Japanese characters.

If the specified folder does not exist, then `generateCode` creates the folder.

`generateCode` searches the specified folder for the four MATLAB files: `predict.m`, `update.m`, `initialize.m`, and a MAT-file that includes machine learning model information. If the four files do not exist in the folder, then `generateCode` generates the files. Otherwise, `generateCode` does not generate any MATLAB files.

`generateCode` generates C/C++ code in the folder `outputPath\codegen\`*`type`*`\`*`outputFileName`*, where *`type`* is the build type specified by the `cfg` argument and *`outputFileName`* is the file name stored in the `OutputFileName` property of `configurer`.

Example: `'C:\myfiles'`

Data Types: `char` | `string`

Limitations

- The `generateCode` function uses the `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` functions, so the code generation limitations of these functions also apply to the `generateCode` function. For details, see the function reference pages `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.
- For the code generation usage notes and limitations of a machine learning model and its object functions, see the Code Generation sections of the corresponding reference pages.

Model	Model Object	predict Function
Binary decision tree for multiclass classification	`CompactClassificationTree`	`predict`
SVM for one-class and binary classification	`CompactClassificationSVM`	`predict`
Linear model for binary classification	`ClassificationLinear`	`predict`
Multiclass model for SVMs and linear models	`CompactClassificationECOC`	`predict`
Binary decision tree for regression	`CompactRegressionTree`	`predict`
SVM regression	`CompactRegressionSVM`	`predict`
Linear regression	`RegressionLinear`	`predict`

Alternative Functionality

- If you want to modify the MATLAB files (`predict.m`, `update.m`, and `initialize.m`) according to your code generation workflow, then use `generateFiles` to generate these files and use `codegen` to generate code.

Introduced in R2018b

generateFiles

Package: `classreg.learning.coder.config.svm`

Generate MATLAB files for code generation using coder configurer

Syntax

```
generateFiles(configurer)
generateFiles(configurer,'OutputPath',outputPath)
```

Description

`generateFiles(configurer)` generates the MATLAB files required to generate C/C++ code by using the coder configurer `configurer`, and saves the generated files in the current folder.

To customize the code generation workflow, use `generateFiles` and `codegen`. If you do not need to customize your workflow, use `generateCode`.

`generateFiles` generates the following MATLAB files:

- `predict.m`, `update.m`, and `initialize.m` — `predict.m` and `update.m` are the entry-point functions for the `predict` and `update` functions of the machine learning model, respectively, and these two functions call `initialize.m`. You can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project.
- A MAT-file that includes machine learning model information — `generateFiles` uses the `saveLearnerForCoder` function to save machine learning model information in a MAT-file whose file name is stored in the `OutputFileName` property of a coder configurer. `initialize.m` loads the saved MAT-file by using the `loadLearnerForCoder` function.

After you generate these files, generate C/C++ code by using `codegen` and the prepared `codegen` argument stored in the `CodeGenerationArguments` property of a coder configurer.

If the folder already includes all four MATLAB files, then `generateFiles` does not generate any files.

`generateFiles(configurer,'OutputPath',outputPath)` generates the MATLAB files in the folder specified by `outputPath`.

Examples

Generate MATLAB® Files for Code Generation

Train a machine learning model and then generate the MATLAB files required to generate C/C++ code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `ionosphere` data set and train a binary support vector machine (SVM) classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` object.

Create a coder configurer for the `ClassificationSVM` object.

```
configurer = learnerCoderConfigurer(Mdl,X);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Use `generateFiles` to generate the MATLAB files required to generate C/C++ code for the `predict` and `update` functions of the model.

```
generateFiles(configurer)
```

`generateFiles` generates `predict.m`, `update.m`, `initialize.m`, and `ClassificationSVMModel.mat` (a MAT-file that includes machine learning model information).

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files.

```
type predict.m % Display contents of predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:03:16
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m % Display contents of update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:03:16
initialize('update',varargin{:});
end
```

```
type initialize.m % Display contents of initialize.m
```

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:03:16
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('ClassificationSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                       SupportVectors
        %                       SupportVectorLabels
        %                       Scale
        %                       Bias
        %                       Prior
        %                       Cost
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
```

```
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end
```

Generate C/C++ code by using `codegen` (MATLAB Coder) and the prepared `codegen` argument stored in the `CodeGenerationArguments` property of `configurer`.

```
cfArgs = configurer.CodeGenerationArguments;
codegen(cfArgs{:})
```

```
Code generation successful.
```

Input Arguments

`configurer` — Coder configurer

coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	`ClassificationTreeCoderConfigurer`
SVM for one-class and binary classification	`ClassificationSVMCoderConfigurer`
Linear model for binary classification	`ClassificationLinearCoderConfigurer`
Multiclass model for SVMs and linear models	`ClassificationECOCCoderConfigurer`
Binary decision tree for regression	`RegressionTreeCoderConfigurer`
Support vector machine (SVM) regression	`RegressionSVMCoderConfigurer`
Linear regression	`RegressionLinearCoderConfigurer`

`outputPath` — Folder path for output files

current folder (default) | character vector | string scalar

Folder path for the output files of `generateFiles`, specified as a character vector or string array.

The specified folder path can be an absolute path or a relative path to the current folder path.

- The path must not contain spaces because they can lead to code generation failures in certain operating system configurations.
- The path also cannot contain non-7-bit ASCII characters, such as Japanese characters.

If the specified folder does not exist, then `generateFiles` creates the folder.

`generateFiles` searches the specified folder for the four MATLAB files: `predict.m`, `update.m`, `initialize.m`, and a MAT-file that includes machine learning model information. If the four files do

not exist in the folder, then `generateFiles` generates the files. Otherwise, `generateFiles` does not generate any MATLAB files.

Example: `'C:\myfiles'`

Data Types: `char` | `string`

Alternative Functionality

- To customize the code generation workflow, use `generateFiles` and `codegen`. If you do not need to customize your workflow, use `generateCode`. In addition to generating the four MATLAB files generated by `generateFiles`, the `generateCode` function also generates the C/C++ code.

generateLearnerDataTypeFcn

Generate function that defines data types for fixed-point code generation

Syntax

```
generateLearnerDataTypeFcn(filename,X)
generateLearnerDataTypeFcn(filename,X,Name,Value)
```

Description

To generate fixed-point C/C++ code for the `predict` function of a machine learning model, use `generateLearnerDataTypeFcn`, `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`.

- After training a machine learning model, save the model using `saveLearnerForCoder`.
- Create a structure that defines fixed-point data types by using the function generated from `generateLearnerDataTypeFcn`.
- Define an entry-point function that loads the model by using both `loadLearnerForCoder` and the structure, and then calls the `predict` function.
- Generate code using `codegen`, and then verify the generated code.

The `generateLearnerDataTypeFcn` function requires Fixed-Point Designer, and generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

This flow chart shows the fixed-point code generation workflow for the `predict` function of a machine learning model. Use `generateLearnerDataTypeFcn` for the highlighted step.

`generateLearnerDataTypeFcn(filename,X)` generates a data type function on page 33-2631 that defines fixed-point data types for the variables required to generate fixed-point C/C++ code for prediction of a machine learning model. `filename` stores the machine learning model, and `X` contains the predictor data for the `predict` function of the model.

Use the generated function to create a structure that defines fixed-point data types. Then, use the structure as the input argument `T` of `loadLearnerForCoder`.

`generateLearnerDataTypeFcn(filename,X,Name,Value)` specifies additional options by using one or more name-value pair arguments. For example, you can specify `'WordLength',32` to use 32-bit word length for the fixed-point data types.

Examples

Generate Fixed-Point C/C++ Code for Prediction

After training a machine learning model, save the model using `saveLearnerForCoder`. For fixed-point code generation, specify the fixed-point data types of the variables required for prediction by

using the data type function generated by `generateLearnerDataTypeFcn`. Then, define an entry-point function that loads the model by using both `loadLearnerForCoder` and the specified fixed-point data types, and calls the `predict` function of the model. Use `codegen` (MATLAB Coder) to generate fixed-point C/C++ code for the entry-point function, and then verify the generated code.

Before generating code using `codegen`, you can use `buildInstrumentedMex` (Fixed-Point Designer) and `showInstrumentationResults` (Fixed-Point Designer) to optimize the fixed-point data types to improve the performance of the fixed-point code. Record minimum and maximum values of named and internal variables for prediction by using `buildInstrumentedMex`. View the instrumentation results using `showInstrumentationResults`; then, based on the results, tune the fixed-point data type properties of the variables. For details regarding this optional step, see “Fixed-Point Code Generation for Prediction of SVM” on page 32-87.

Train Model

Load the `ionosphere` data set and train a binary SVM classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y,'KernelFunction','gaussian');
```

`Mdl` is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'myMdl');
```

Define Fixed-Point Data Types

Use `generateLearnerDataTypeFcn` to generate a function that defines the fixed-point data types of the variables required for prediction of the SVM model.

```
generateLearnerDataTypeFcn('myMdl',X)
```

`generateLearnerDataTypeFcn` generates the `myMdl_datatype` function.

Create a structure `T` that defines the fixed-point data types by using `myMdl_datatype`.

```
T = myMdl_datatype('Fixed')
```

```
T = struct with fields:
               XDataType: [0x0 embedded.fi]
           ScoreDataType: [0x0 embedded.fi]
    InnerProductDataType: [0x0 embedded.fi]
```

The structure `T` includes the fields for the named and internal variables required to run the `predict` function. Each field contains a fixed-point object, returned by `fi` (Fixed-Point Designer). The fixed-point object specifies fixed-point data type properties, such as word length and fraction length. For example, display the fixed-point data type properties of the predictor data.

```
T.XDataType
```

```
ans =

[]
```

```
          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 14

        RoundingMethod: Floor
        OverflowAction: Wrap
           ProductMode: FullPrecision
  MaxProductWordLength: 128
               SumMode: FullPrecision
      MaxSumWordLength: 128
```

Define Entry-Point Function

Define an entry-point function named `myFixedPointPredict` that does the following:

- Accept the predictor data `X` and the fixed-point data type structure `T`.
- Load a fixed-point version of a trained SVM classification model by using both `loadLearnerForCoder` and the structure `T`.
- Predict labels and scores using the loaded model.

```
type myFixedPointPredict.m % Display contents of myFixedPointPredict.m file
```

```
function [label,score] = myFixedPointPredict(X,T) %#codegen
Mdl = loadLearnerForCoder('myMdl','DataType',T);
[label,score] = predict(Mdl,X);
end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

Generate Code

The `XDataType` field of the structure `T` specifies the fixed-point data type of the predictor data. Convert `X` to the type specified in `T.XDataType` by using the `cast` (Fixed-Point Designer) function.

```
X_fx = cast(X,'like',T.XDataType);
```

Generate code for the entry-point function using `codegen`. Specify `X_fx` and constant folded `T` as input arguments of the entry-point function.

```
codegen myFixedPointPredict -args {X_fx,coder.Constant(T)}
```

```
Code generation successful.
```

`codegen` generates the MEX function `myFixedPointPredict_mex` with a platform-dependent extension.

Verify Generated Code

Pass predictor data to `predict` and `myFixedPointPredict_mex` to compare the outputs.

```
[labels,scores] = predict(Mdl,X);
[labels_fx,scores_fx] = myFixedPointPredict_mex(X_fx,T);
```

Compare the outputs from `predict` and `myFixedPointPredict_mex`.

```
verify_labels = isequal(labels,labels_fx)
```

```
verify_labels = logical
   1
```

`isequal` returns logical 1 (true), which means `labels` and `labels_fx` are equal. If the labels are not equal, you can compute the percentage of incorrectly classified labels as follows.

```
sum(strcmp(labels_fx,labels)==0)/numel(labels_fx)*100
```

```
ans = 0
```

Find the maximum of the relative differences between the score outputs.

```
relDiff_scores = max(abs((scores_fx.double(:,1)-scores(:,1))./scores(:,1)))
```

```
relDiff_scores = 0.0055
```

If you are not satisfied with the comparison results and want to improve the precision of the generated code, you can tune the fixed-point data types and regenerate the code. For details, see "Tips" on page 33-2632 in `generateLearnerDataTypeFcn`, "Data Type Function" on page 33-2631, and "Fixed-Point Code Generation for Prediction of SVM" on page 32-87.

Input Arguments

`filename` — Name of MAT-file that contains structure array representing model object

character vector | string scalar

Name of the MATLAB formatted binary file (MAT-file) that contains the structure array representing a model object, specified as a character vector or string scalar.

You must create the `filename` file using `saveLearnerForCoder`, and the model in `filename` can be one of the following:

- Classification model
  - Decision tree (`CompactClassificationTree`)
  - Ensemble of decision trees (`CompactClassificationEnsemble`, `ClassificationBaggedEnsemble`)
  - SVM (support vector machine) (`CompactClassificationSVM`)
- Regression model
  - Decision tree (`CompactRegressionTree`)
  - Ensemble of decision trees (`CompactRegressionEnsemble`, `RegressionBaggedEnsemble`)
  - SVM (`CompactRegressionSVM`)

The extension of the `filename` file must be `.mat`. If `filename` has no extension, then `generateLearnerDataTypeFcn` appends `.mat`.

If `filename` does not include a full path, then `generateLearnerDataTypeFcn` loads the file from the current folder.

Example: `'myMdl'`

Data Types: `char` | `string`

`X` — Predictor data
numeric matrix

Predictor data for the `predict` function of the model stored in `filename`, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `generateLearnerDataTypeFcn(filename,X,'OutputFunctionName','myDataTypeFcn','WordLength',32)` generates a data type function named `myDataTypeFcn` that uses 32 bits for the word length when defining the fixed-point data type for each variable.

`OutputFunctionName` — Name of generated function
`filename` plus `_datatype` (default) | character vector | string scalar

Name of the generated function, specified as the comma-separated pair consisting of `'OutputFunctionName'` and a character vector or string scalar. The `'OutputFunctionName'` value must be a valid MATLAB function name.

The default function name is the file name in `filename` followed by `_datatype`. For example, if `filename` is `myMdl`, then the default function name is `myMdl_datatype`.

Example: `'OutputFunctionName','myDataTypeFcn'`

Data Types: `char` | `string`

`WordLength` — Word length in bits
16 (default) | numeric scalar

Word length in bits, specified as the comma-separated pair consisting of `'WordLength'` and a numeric scalar.

The generated data type function on page 33-2631 defines a fixed-point object for each variable using the specified `'WordLength'` value. If a variable requires a longer word length than the specified value, the software doubles the word length for the variable.

The optimal word length depends on your target hardware properties. When the specified word length is longer than the longest word size of your target hardware, the generated code contains multiword operations.

For details, see “Fixed-Point Data Types” (Fixed-Point Designer).

Example: `'WordLength',32`

Data Types: `single` | `double`

`OutputRange` — Range of `predict` output
range simulated using `X` (default) | numeric vector of two elements

Range of the output argument of the `predict` function, specified as the comma-separated pair consisting of `'OutputRange'` and a numeric vector of two elements (minimum and maximum values of the output).

The `'OutputRange'` value specifies the range of predicted class scores for a classification model and the range of predicted responses for a regression model. The following tables list the output arguments for which you can specify the range by using the `'OutputRange'` name-value pair argument.

Classification Model

Model	`predict` Function of Model	Output Argument
Decision tree	`predict`	`score`
Ensemble of decision trees	`predict`	`score`
SVM	`predict`	`score`

Regression Model

Model	`predict` Function of Model	Output Argument
Decision tree	`predict`	`Yfit`
Ensemble of decision trees	`predict`	`Yfit`
SVM	`predict`	`yfit`

When `X` contains a large number of observations and the range for the output argument is known, specify the `'OutputRange'` value to reduce the amount of computation.

If you do not specify the `'OutputRange'` value, then the software simulates the output range using the predictor data `X` and the `predict` function.

The software determines the span of numbers that the fixed-point data can represent by using the `'OutputRange'` value and the `'PercentSafetyMargin'` value.

Example: `'OutputRange',[0,1]`

Data Types: `single` | `double`

`PercentSafetyMargin` — Safety margin percentage
10 (default) | numeric scalar

Safety margin percentage, specified as the comma-separated pair consisting of `'PercentSafetyMargin'` and a numeric scalar.

For each variable, the software simulates the range of the variable and adds the specified safety margin to determine the span of numbers that the fixed-point data can represent. Then, the software proposes the maximum fraction length that does not cause overflows.

Use caution when you specify the `'PercentSafetyMargin'` value. If a variable range is large, then increasing the safety margin can cause underflow, because the software decreases fraction length to represent a larger range using a given word length.

Example: `'PercentSafetyMargin',15`

Data Types: `single` | `double`

More About

Data Type Function

Use the data type function generated by `generateLearnerDataTypeFcn` to create a structure that defines fixed-point data types for the variables required to generate fixed-point C/C++ code for prediction of a machine learning model. Use the output structure of the data type function as the input argument `T` of `loadLearnerForCoder`.

If `filename` is `'myMdl'`, then `generateLearnerDataTypeFcn` generates a data type function named `myMdl_datatype`. The `myMdl_datatype` function supports this syntax:

```
T = myMdl_datatype(dt)
```

`T = myMdl_datatype(dt)` returns a data type structure that defines data types for the variables required to generate fixed-point C/C++ code for prediction of a machine learning model.

Each field of `T` contains a fixed-point object returned by `fi`. The input argument `dt` specifies the `DataType` property of the fixed-point object.

- Specify `dt` as `'Fixed'`(default) for fixed-point code generation.
- Specify `dt` as `'Double'` to simulate floating-point behavior of the fixed-point code.

Use the output structure `T` as the second input argument of `loadLearnerForCoder`.

The structure `T` contains the fields in the following table. These fields define the data types for the variables that directly influence the precision of the model. These variables, along with other named and internal variables, are required to run the `predict` function of the model.

Description	Fields

Common fields for classification	• `XDataType` (input)
	• `ScoreDataType` (output or internal variable) and `TransformedScoreDataType` (output)
	  • If you train a model using the default `'ScoreTransform'` value of `'none'` or `'identity'` (that is, you do not transform predicted scores), then the `ScoreDataType` field influences the precision of the output scores.
	  • If you train a model using a value of `'ScoreTransform'` other than `'none'` or `'identity'` (that is, you do transform predicted scores), then the `ScoreDataType` field influences the precision of the internal untransformed scores. The `TransformedScoreDataType` field influences the precision of the transformed output scores.

Common fields for regression	• `XDataType` (input) • `YFitDataType` (output)

Description	Fields
Additional fields for an ensemble of decision trees	• `WeakLearnerOutputDataType` (internal variable) — Data type for outputs from weak learners. • `AggregatedLearnerWeightsDataType` (internal variable) — Data type for a weighted aggregate of the outputs from weak learners, applicable only if you train a model using bagging (`'Method','bag'`). The software computes predicted scores (`ScoreDataType`) by dividing the aggregate by the sum of learner weights.
Additional fields for SVM	• `XnormDataType` (internal variable), applicable only if you train a model using `'Standardize'` or `'KernelScale'` • `InnerProductDataType` (internal variable)

The software proposes the maximum fraction length that does not cause overflows, based on the default word length (16) and safety margin (10%) for each variable.

The following code shows the data type function `myMdl_datatype`, generated by `generateLearnerDataTypeFcn` when `filename` is `'myMdl'` and the model in the `filename` file is an SVM classifier.

```
function T = myMdl_datatype(dt)

if nargin < 1
    dt = 'Fixed';
end

% Set fixed-point math settings
fm = fimath('RoundingMethod','Floor', ...
    'OverflowAction','Wrap', ...
    'ProductMode','FullPrecision', ...
    'MaxProductWordLength',128, ...
    'SumMode','FullPrecision', ...
    'MaxSumWordLength',128);

% Data type for predictor data
T.XDataType = fi([],true,16,14,fm,'DataType',dt);

% Data type for output score
T.ScoreDataType = fi([],true,16,14,fm,'DataType',dt);

% Internal variables
% Data type of the squared distance dist = (x-sv)^2 for the Gaussian kernel G(x,sv) = exp(-dist)
% where x is the predictor data for an observation and sv is a support vector
T.InnerProductDataType = fi([],true,16,6,fm,'DataType',dt);

end
```

Tips

- To improve the precision of the generated fixed-point code, you can tune the fixed-point data types. Modify the fixed-point data types by updating the data type function on page 33-2631 (`myMdl_datatype`) and creating a new structure, and then regenerate the code using the new structure. You can update the `myMdl_datatype` function in one of two ways:

- Regenerate the `myMdl_datatype` function by using `generateLearnerDataTypeFcn` and its name-value pair arguments.
  - Increase the word length by using the `'WordLength'` name-value pair argument.
  - Decrease the safety margin by using the `'PercentSafetyMargin'` name-value pair argument.

  If you increase the word length or decrease the safety margin, the software can propose a longer fraction length, and therefore, improve the precision of the generated code based on the given data set.
- Manually modify the fixed-point data types in the function file (`myMdl_datatype.m`). For each variable, you can tune the word length and fraction length and specify fixed-point math settings using a `fimath` object.

- In the generated fixed-point code, a large number of operations or a large variable range can result in loss of precision, compared to the precision of the corresponding floating-point code. When training an SVM model, keep the following tips in mind to avoid loss of precision in the generated fixed-point code:
  - Data standardization (`'Standardize'`) — To avoid overflows in the model property values of support vectors in an SVM model, you can standardize the predictor data. Instead of using the `'Standardize'` name-value pair argument when training the model, standardize the predictor data before passing the data to the fitting function and the `predict` function so that the fixed-point code does not include the operations for the standardization.
  - Kernel function (`'KernelFunction'`) — Using the Gaussian kernel or linear kernel is preferable to using a polynomial kernel. A polynomial kernel requires higher computational complexity than the other kernels, and the output of a polynomial kernel function is unbounded.
  - Kernel scale (`'KernelScale'`) — Using a kernel scale requires additional operations if the value of `'KernelScale'` is not 1.
  - The prediction of a one-class classification problem might have loss of precision if the predicted class score values have a large range.

Compatibility Considerations

Specify precision of transformed scores before and after their transformation
Behavior changed in R2020a

In R2019b, you could train an SVM classifier for fixed-point code generation with some nondefault score transforms (`'ismax'`, `'sign'`, `'symmetric'`, or `'symmetricismax'`). The `generateLearnerDataTypeFcn` function generated a data type function whose output structure contained only one field related to the scores, `ScoreDataType`. This field influenced the precision of the output scores both before and after their transformation.

Starting in R2020a, when you train an SVM classifier with a score transform other than `'none'` or `'identity'`, the `generateLearnerDataTypeFcn` function generates a data type function whose output structure `T` contains two fields related to the scores: `ScoreDataType` and `TransformedScoreDataType`. Use these fields to influence the precision of the output scores before and after their transformation, respectively. For more details, see “Data Type Function” on page 33-2631.

To update your code, rerun the `generateLearnerDataTypeFcn` function and then regenerate the output structure `T`.

Topics

“Fixed-Point Code Generation for Prediction of SVM” on page 32-87

Introduced in R2019b

gencfeatures

Perform automated feature engineering for classification

Syntax

```
[Transformer,NewTbl] = gencfeatures(Tbl,ResponseVarName,q)
[Transformer,NewTbl] = gencfeatures(Tbl,Y,q)
[Transformer,NewTbl] = gencfeatures(Tbl,formula,q)
[Transformer,NewTbl] = gencfeatures(___,Name,Value)
```

Description

The `gencfeatures` function enables you to automate the feature engineering process in the context of a machine learning workflow. Before passing tabular training data to a classifier, you can create new features from the predictors in the data by using `gencfeatures`. Use the returned data to train the classifier.

To better understand the generated features, use the `describe` function of the returned `FeatureTransformer` object. To apply the same training set feature transformations to a test set, use the `transform` function of the `FeatureTransformer` object.

`[Transformer,NewTbl] = gencfeatures(Tbl,ResponseVarName,q)` uses automated feature engineering to create `q` features from the predictors in `Tbl`. The software assumes that the `ResponseVarName` variable in `Tbl` is the response and does not create new features from this variable. `gencfeatures` returns a `FeatureTransformer` object (`Transformer`) and a new table (`NewTbl`) that contains the transformed features.

By default, `gencfeatures` assumes that generated features are used to train an interpretable linear model with a binary response variable. If you have a multiclass response variable and you want to generate features to improve the accuracy of a bagged ensemble, specify `'TargetLearner','bag'`.

`[Transformer,NewTbl] = gencfeatures(Tbl,Y,q)` assumes that the vector `Y` is the response variable and creates new features from the variables in `Tbl`.

`[Transformer,NewTbl] = gencfeatures(Tbl,formula,q)` uses the explanatory model `formula` to determine the response variable in `Tbl` and the subset of `Tbl` predictors from which to create new features.

`[Transformer,NewTbl] = gencfeatures(___,Name,Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can change the expected learner type, the method for selecting new features, and the standardization method for transformed data.

Examples

Interpret Linear Model with Generated Features

Use automated feature engineering to generate new features. Train a linear classifier using the generated features. Interpret the relationship between the generated features and the trained model.

Load the `patients` data set. Create a table from a subset of the variables.

```
load patients
Tbl = table(Age,Diastolic,Gender,Height,SelfAssessedHealthStatus, ...
    Systolic,Weight,Smoker);
```

Generate 10 new features from the variables in `Tbl`. Specify the `Smoker` variable as the response. By default, `gencfeatures` assumes that the new features will be used to train a binary linear classifier.

```
rng("default") % For reproducibility
[T,NewTbl] = gencfeatures(Tbl,"Smoker",10)
```

```
T =

        -0.71693              5                3               3               6           0.3
         -1.2734              2                1               1               2           1.2
         -1.1361              1                2               2               1             1
         0.60534              1                6               5               1          -0.9
          1.0677              8                8               6               8          -0.2
         -1.2734              3                1               1               4           0.9
          1.0677              7                8               6               8          -0.9
      ⋮
```

`T` is a `FeatureTransformer` object that can be used to transform new data, and `newTbl` contains the new features generated from the `Tbl` data.

To better understand the generated features, use the `describe` object function of the `FeatureTransformer` object. For example, inspect the first two generated features.

```
describe(T,1:2)
```

```
                          Type        IsOriginal    InputVariables                          Tr
                      ____________    __________    ______________    ____________________________

    zsc(Systolic.^2)  Numeric           false         Systolic        power(  ,2)
                                                                      Standardization with z-sc
    eb8(Diastolic)    Categorical       false         Diastolic       Equal-width binning (numbe
```

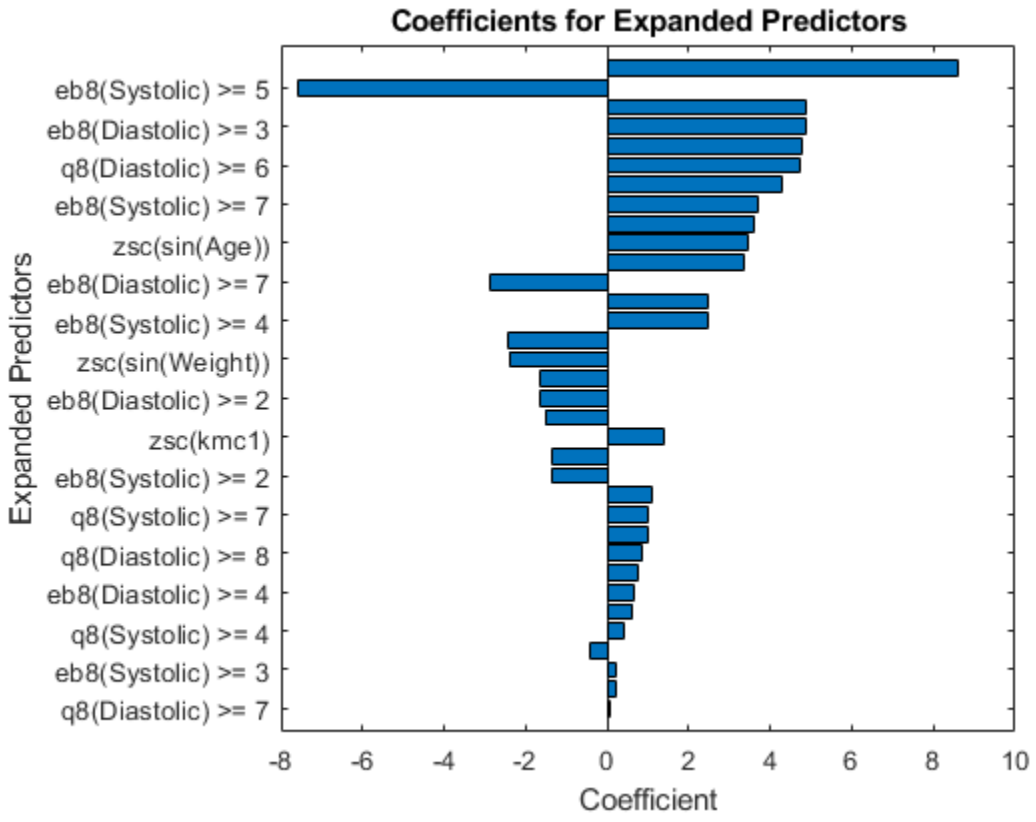
The first feature in `newTbl` is a numeric variable, created by first squaring the values of the `Systolic` variable and then converting the results to z-scores. The second feature in `newTbl` is a categorical variable, created by binning the values of the `Systolic` variable into 50 equiprobable bins.

Use the generated features to fit a linear classifier without any regularization.

```
Mdl = fitclinear(NewTbl,"Smoker","Lambda",0);
```

Plot the coefficients of the predictors used to train `Mdl`. Note that `fitclinear` expands categorical predictors before fitting a model.

```
p = length(Mdl.Beta);
[sortedCoefs,expandedIndex] = sort(Mdl.Beta,"ComparisonMethod","abs");
sortedExpandedPreds = Mdl.ExpandedPredictorNames(expandedIndex);
bar(sortedCoefs,"Horizontal","on")
yticks(1:2:p)
yticklabels(sortedExpandedPreds(1:2:end))
xlabel("Coefficient")
ylabel("Expanded Predictors")
title("Coefficients for Expanded Predictors")
```



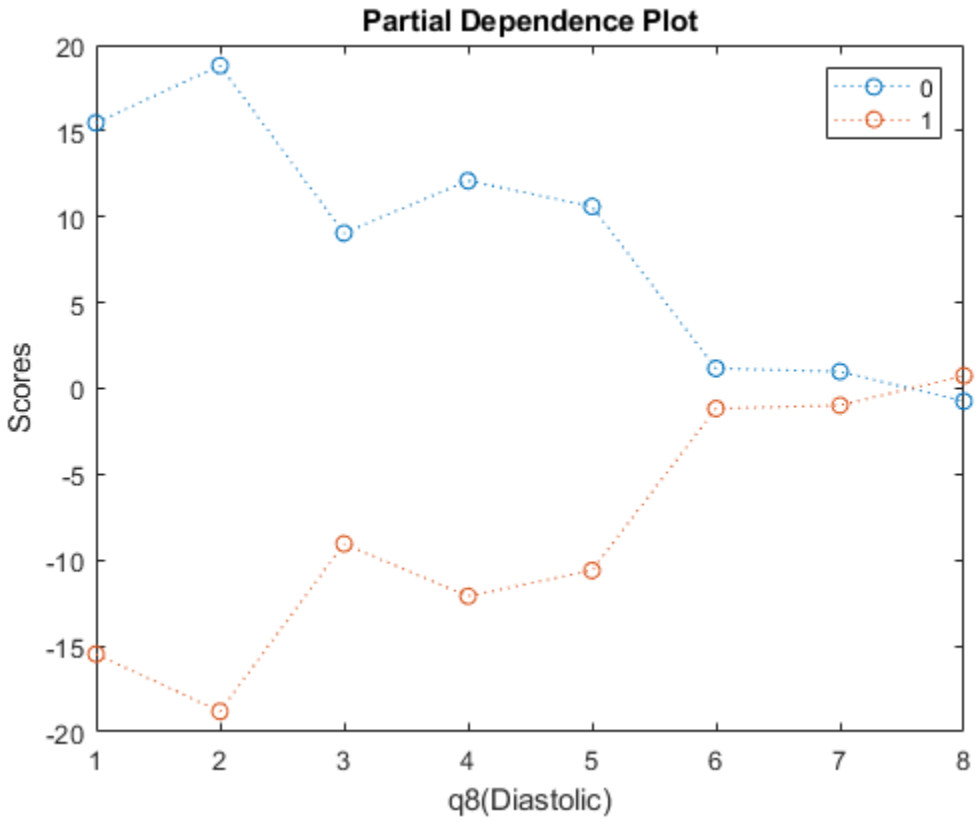
Identify the predictors whose coefficients have larger absolute values.

```
bigCoefs = abs(sortedCoefs) >= 4;
flip(sortedExpandedPreds(bigCoefs))
```

```
ans = 1×7 cell
    {'zsc(Systolic.^2)'}    {'eb8(Systolic) >= 5'}    {'q8(Diastolic) >= 3'}    {'eb8(Diastolic)
```

You can use partial dependence plots to analyze the categorical features whose levels have large coefficients in terms of absolute value. For example, inspect the partial dependence plot for the `q8(Diastolic)` variable, whose levels `q8(Diastolic) >= 3` and `q8(Diastolic) >= 6` have coefficients with large absolute values. These two levels correspond to noticeable changes in the predicted scores.

```
plotPartialDependence(Mdl,"q8(Diastolic)",Mdl.ClassNames,NewTbl);
```



Improve Accuracy for Interpretable Linear Model

Generate new features to improve the model accuracy for an interpretable linear model. Compare the test set accuracy of a linear model trained on the original data to the test set accuracy of a linear model trained on the transformed features.

Load the `ionosphere` data set. Convert the matrix of predictors `X` to a table.

```
load ionosphere
tbl = array2table(X);
```

Partition the data into training and test sets. Use approximately 70% of the observations as training data, and 30% of the observations as test data. Partition the data using `cvpartition`.

```
rng("default") % For reproducibility of the partition
cvp = cvpartition(Y,"Holdout",0.3);

trainIdx = training(cvp);
trainTbl = tbl(training(cvp),:);
trainY = Y(trainIdx);

testIdx = test(cvp);
testTbl = tbl(testIdx,:);
testY = Y(testIdx);
```

Use the training data to generate 45 new features. Inspect the returned `FeatureTransformer` object.

```
[T,newTrainTbl] = gencfeatures(trainTbl,trainY,45);
T
```

```
T =
  FeatureTransformer with properties:

                    Type: 'classification'
           TargetLearner: 'linear'
    NumEngineeredFeatures: 45
      NumOriginalFeatures: 0
         TotalNumFeatures: 45
```

All the generated features are engineered features rather than original features in `trainTbl`.

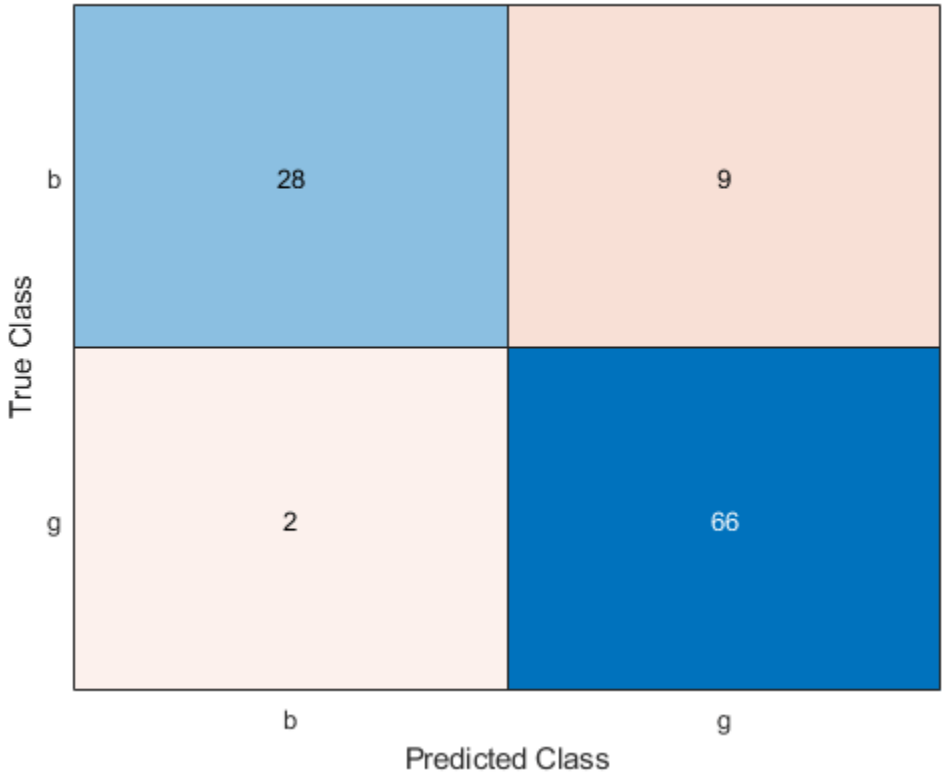
Apply the transformations stored in the object `T` to the test data.

```
newTestTbl = transform(T,testTbl);
```

Compare the test set performances of a linear classifier trained on the original features and a linear classifier trained on the new features.

Fit a linear model without transforming the data. Check the test set performance of the model using a confusion matrix.

```
originalMdl = fitclinear(trainTbl,trainY);
originalPredictedLabels = predict(originalMdl,testTbl);
cm = confusionchart(testY,originalPredictedLabels);
```

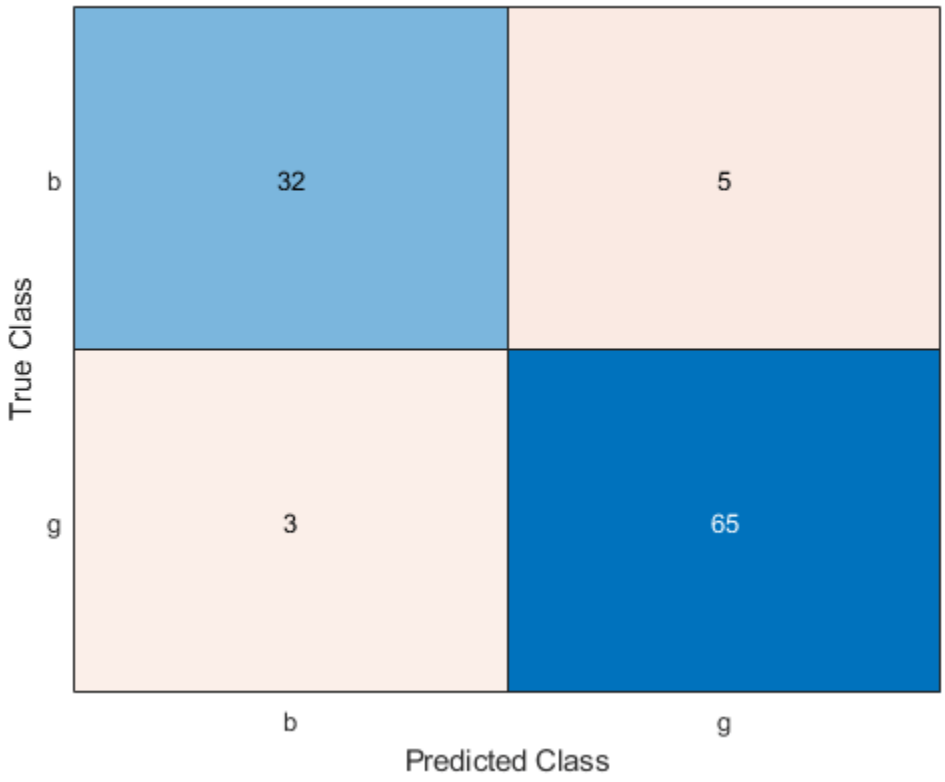


```
confusionMatrix = cm.NormalizedValues;
originalTestAccuracy = sum(diag(confusionMatrix))/sum(confusionMatrix,"all")
```

```
originalTestAccuracy = 0.8952
```

Fit a linear model with the transformed data. Check the test set performance of the model using a confusion matrix.

```
newMdl = fitclinear(newTrainTbl,trainY);
newPredictedLabels = predict(newMdl,newTestTbl);
newcm = confusionchart(testY,newPredictedLabels);
```



```
newConfusionMatrix = newcm.NormalizedValues;
newTestAccuracy = sum(diag(newConfusionMatrix))/sum(newConfusionMatrix,"all")
```

```
newTestAccuracy = 0.9238
```

The linear classifier trained on the transformed data seems to outperform the linear classifier trained on the original data.

Generate New Features to Improve Bagged Ensemble Accuracy

Use `gencfeatures` to engineer new features before training a bagged ensemble classifier. Before making predictions on new data, apply the same feature transformations to the new data set. Compare the test set performance of the ensemble that uses the engineered features to the test set performance of the ensemble that uses the original features.

Read the sample file `CreditRating_Historical.dat` into a table. The predictor data consists of financial ratios and industry sector information for a list of corporate customers. The response variable consists of credit ratings assigned by a rating agency. Preview the first few rows of the data set.

```
creditrating = readtable("CreditRating_Historical.dat");
head(creditrating)
```

```
ans=8×8 table
     ID      WC_TA     RE_TA     EBIT_TA    MVE_BVTD    S_TA     Industry    Rating
```

```
    _____    ______    ______    _______    ________    _____    ________    _______

    62394     0.013     0.104     0.036      0.447      0.142        3       {'BB' }
    48608     0.232     0.335     0.062      1.969      0.281        8       {'A'  }
    42444     0.311     0.367     0.074      1.935      0.366        1       {'A'  }
    48631     0.194     0.263     0.062      1.017      0.228        4       {'BBB'}
    43768     0.121     0.413     0.057      3.647      0.466       12       {'AAA'}
    39255    -0.117    -0.799      0.01      0.179      0.082        4       {'CCC'}
    62236     0.087     0.158     0.049      0.816      0.324        2       {'BBB'}
    39354     0.005     0.181     0.034      2.597      0.388        7       {'AA' }
```

Because each value in the `ID` variable is a unique customer ID, that is, `length(unique(creditrating.ID))` is equal to the number of observations in `creditrating`, the `ID` variable is a poor predictor. Remove the `ID` variable from the table, and convert the `Industry` variable to a `categorical` variable.

```
creditrating = removevars(creditrating,"ID");
creditrating.Industry = categorical(creditrating.Industry);
```

Convert the `Rating` response variable to an ordinal `categorical` variable.

```
creditrating.Rating = categorical(creditrating.Rating, ...
    ["AAA","AA","A","BBB","BB","B","CCC"],"Ordinal",true);
```

Partition the data into training and test sets. Use approximately 75% of the observations as training data, and 25% of the observations as test data. Partition the data using `cvpartition`.

```
rng("default") % For reproducibility of the partition
c = cvpartition(creditrating.Rating,"Holdout",0.25);
trainingIndices = training(c); % Indices for the training set
testIndices = test(c); % Indices for the test set
creditTrain = creditrating(trainingIndices,:);
creditTest = creditrating(testIndices,:);
```

Use the training data to generate 40 new features to fit a bagged ensemble. By default, the 40 features can include original features if the software considers them to be important variables.

```
[T,newCreditTrain] = gencfeatures(creditTrain,"Rating",40, ...
    "TargetLearner","bag");
T
```

```
T =
  FeatureTransformer with properties:

                    Type: 'classification'
           TargetLearner: 'bag'
    NumEngineeredFeatures: 34
      NumOriginalFeatures: 6
         TotalNumFeatures: 40
```

Because `T.NumOriginalFeatures` is `6`, the function keeps all the original predictors.

Create `newCreditTest` by applying the transformations stored in the object `T` to the test data.

```
newCreditTest = transform(T,creditTest);
```

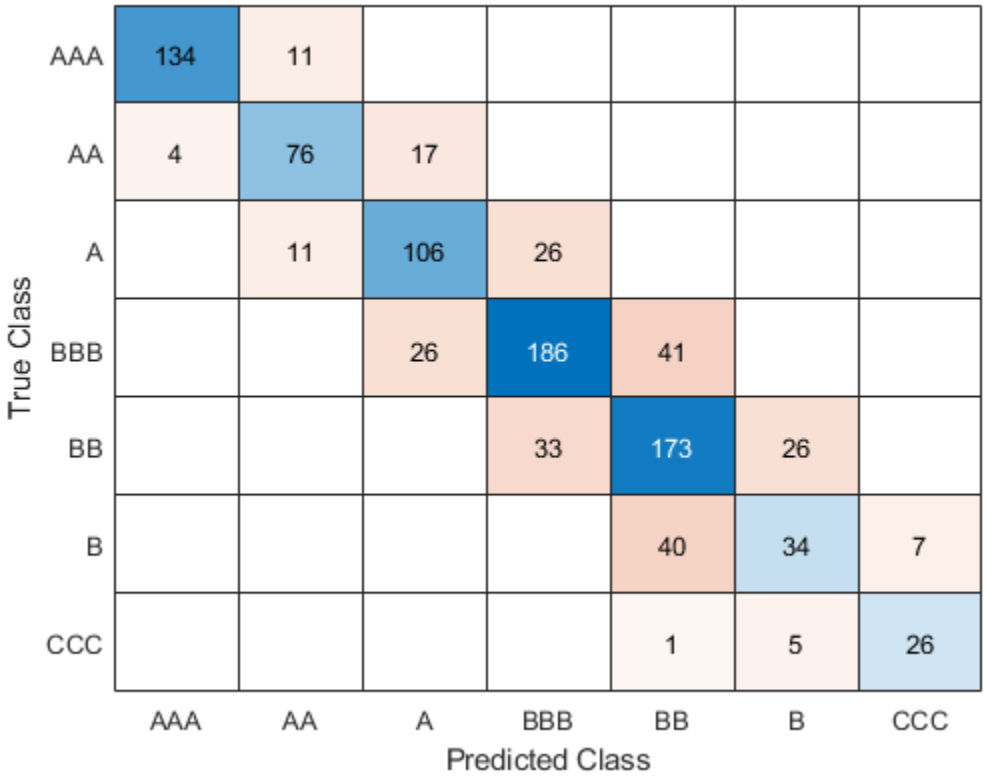
Compare the test set performances of a bagged ensemble trained on the original features and a bagged ensemble trained on the new features.

Train a bagged ensemble using the original training set `creditTrain`. Compute the accuracy of the model on the original test set `creditTest`. Visualize the results using a confusion matrix.

```
originalMdl = fitcensemble(creditTrain,"Rating","Method","Bag");
originalTestAccuracy = 1 - loss(originalMdl,creditTest, ...
    "Rating","LossFun","classiferror")
```

```
originalTestAccuracy = 0.7481
```

```
predictedTestLabels = predict(originalMdl,creditTest);
confusionchart(creditTest.Rating,predictedTestLabels);
```

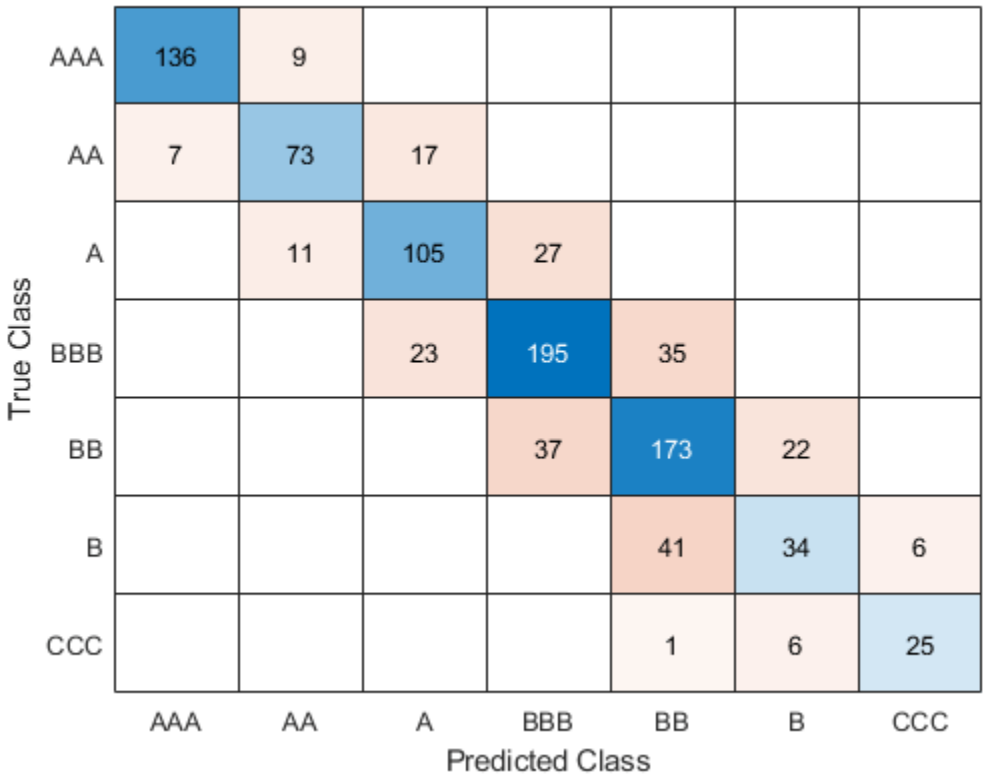


Train a bagged ensemble using the transformed training set `newCreditTrain`. Compute the accuracy of the model on the transformed test set `newCreditTest`. Visualize the results using a confusion matrix.

```
newMdl = fitcensemble(newCreditTrain,"Rating","Method","Bag");
newTestAccuracy = 1 - loss(newMdl,newCreditTest, ...
    "Rating","LossFun","classiferror")
```

```
newTestAccuracy = 0.7543
```

```
newPredictedTestLabels = predict(newMdl,newCreditTest);
confusionchart(newCreditTest.Rating,newPredictedTestLabels)
```



The bagged ensemble trained on the transformed data seems to outperform the bagged ensemble trained on the original data.

Compute Cross-Validation Loss Using Generated Features

Generate features to train a linear classifier. Compute the cross-validation classification error of the model by using the `crossval` function.

Load the `ionosphere` data set, and create a table containing the predictor data.

```
load ionosphere
Tbl = array2table(X);
```

Create a random partition for stratified 5-fold cross-validation.

```
rng("default") % For reproducibility of the partition
cvp = cvpartition(Y,"KFold",5);
```

Compute the cross-validation classification loss for a linear model trained on the original features in `Tbl`.

```
CVMdl = fitclinear(Tbl,Y,"CVPartition",cvp);
cvloss = kfoldLoss(CVMdl)
```

```
cvloss = 0.1339
```

Create the custom function `myloss` (shown at the end of this example). This function generates 20 features from the training data, and then applies the same training set transformations to the test data. The function then fits a linear classifier to the training data and computes the test set loss.

Note: If you use the live script file for this example, the `myloss` function is already included at the end of the file. Otherwise, you need to create this function at the end of your .m file or add it as a file on the MATLAB® path.

Compute the cross-validation classification loss for a linear model trained on features generated from the predictors in `Tbl`.

```
newcvloss = mean(crossval(@myloss,Tbl,Y,"Partition",cvp))
```

```
newcvloss = 0.0770
```

```
function testloss = myloss(TrainTbl,trainY,TestTbl,testY)
[Transformer,NewTrainTbl] = gencfeatures(TrainTbl,trainY,20);
NewTestTbl = transform(Transformer,TestTbl);
Mdl = fitclinear(NewTrainTbl,trainY);
testloss = loss(Mdl,NewTestTbl,testY, ...
    "LossFun","classiferror");
end
```

Input Arguments

`Tbl` — Original features

table

Original features, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to create new features from any of the remaining variables in `Tbl`, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to create new features from only a subset of the remaining variables in `Tbl`, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl` as predictors, and might create new features from `Y`.

Data Types: `char` | `string`

q — Number of features

positive integer scalar

Number of features, specified as a positive integer scalar. For example, you can set `q` to approximately `1.5*size(Tbl,2)`, which is about 1.5 times the number of original features.

Data Types: `single` | `double`

Y — Response variable

numeric vector | categorical vector

Response variable, specified as a numeric or categorical vector. The length of `Y` must be equal to the number of rows in `Tbl`.

formula — Explanatory model of response variable and subset of predictor variables

character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables.

To create new features from only a subset of the predictor variables in `Tbl`, use a formula. If you specify a formula, then the software does not create new features from any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `gencfeatures(Tbl,'Y',10,'TargetLearner','bag','FeatureSelection','oob')` specifies that the expected learner type is a bagged ensemble classifier and the method for selecting features is an out-of-bag, predictor importance technique.

TargetLearner — Expected learner type

`'linear'` (default) | `'bag'`

Expected learner type, specified as `'linear'` or `'bag'`. The software creates and selects new features assuming that they will be used to train this type of model.

Value	Expected Model
`'linear'`	`ClassificationLinear` — Appropriate for binary classification only

Value	Expected Model
`'bag'`	`ClassificationBaggedEnsemble` — Appropriate for binary and multiclass classification

By default, `TargetLearner` is `'linear'`, which supports binary response variables only. If you have a multiclass response variable and you want to generate new features, you must set `TargetLearner` to `'bag'`.

Example: `'TargetLearner','bag'`

`IncludeInputVariables` — Method for including original features in `Tbl`
`'auto'` (default) | `'include'` | `'select'` | `'omit'`

Method for including the original features in `Tbl` in the new table `NewTbl`, specified as one of the values in this table.

Value	Description
`'auto'`	This value is equivalent to: • `'select'` when `TargetLearner` is `'linear'` • `'include'` when `TargetLearner` is `'bag'`
`'include'`	The software includes all original features that can be used as predictors by the target learner, and excludes unsupported features, such as `datetime` and `duration` variables.
`'select'`	The software includes original features that are supported by the target learner and considered to be important by the specified feature selection method (`FeatureSelectionMethod`).
`'omit'`	The software omits the original features.

Example: `'IncludeInputVariables','include'`

Data Types: `logical`

`FeatureSelectionMethod` — Method for selecting new features
`'auto'` (default) | `'oob'` | `'mrmr'` | `'lasso'`

Method for selecting new features, specified as one of the values in this table. The software generates many features and uses this method to select the important features to include in `NewTbl`.

Value	Description
`'auto'`	This value is equivalent to: • `'lasso'` when `TargetLearner` is `'linear'` • `'oob'` when `TargetLearner` is `'bag'`

Value	Description
`'oob'`	Out-of-bag, predictor importance estimates by permutation — Available when `TargetLearner` is `'bag'`
`'mrmr'`	Minimum redundancy maximum relevance (MRMR) — Available when `TargetLearner` is `'linear'` or `'bag'`
`'lasso'`	Lasso regularization — Available when `TargetLearner` is `'linear'`

Example: `'FeatureSelection','mrmr'`

`TransformedDataStandardization` — Standardization method for transformed data
`'auto'` (default) | `'none'` | `'zscore'` | `'mad'` | `'range'`

Standardization method for the transformed data, specified as one of the values in this table.

Value	Description
`'auto'`	This value is equivalent to: • `'zscore'` when `TargetLearner` is `'linear'` • `'none'` when `TargetLearner` is `'bag'`
`'none'`	Use raw data
`'zscore'`	Center and scale to have mean 0 and standard deviation 1
`'mad'`	Center and scale to have median 0 and median absolute deviation 1
`'range'`	Scale range of data to [0,1]

Example: `'TransformedDataStandardization','range'`

`CategoricalEncodingLimit` — Maximum number of categories allowed in categorical predictor
nonnegative integer scalar | `Inf`

Maximum number of categories allowed in a categorical predictor, specified as a nonnegative integer scalar. If a categorical predictor has more than the specified number of categories, than `gencfeatures` does not create new features from the predictor. The default value is `50` when `TargetLearner` is `'linear'` and `Inf` when `TargetLearner` is `'ensemble'`.

Example: `'CategoricalEncodingLimit',20`

Data Types: `single` | `double`

Output Arguments

`Transformer` — Engineered feature transformer
`FeatureTransformer` object

Engineered feature transformer, returned as a `FeatureTransformer` object. To better understand the engineered features, use the `describe` object function of `Transformer`. To apply the same feature transformations on a new data set, use the `transform` object function of `Transformer`.

`NewTbl` — Generated features
table

Generated features, returned as a table. Each row corresponds to an observation, and each column corresponds to a generated feature. If the response variable is included in `Tbl`, then `NewTbl` also includes the response variable. Use this table to train a classification model of type `TargetLearner`.

`NewTbl` contains generated features in the following order: original features, engineered features as ranked by the feature selection method, and the response variable.

Tips

- By default, when `TargetLearner` is `'linear'`, the software generates new features from numeric predictors by using z-scores (see `TransformedDataStandardization`). You can change the type of standardization for the transformed features; however, using some method of standardization, thereby avoiding the `'none'` specification, is strongly recommended. Linear model fitting works best with standardized data.

Introduced in R2021a

geocdf

Geometric cumulative distribution function

Syntax

```
y = geocdf(x,p)
y = geocdf(x,p,'upper')
```

Description

`y = geocdf(x,p)` returns the cumulative distribution function (cdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval `[0,1]`.

`y = geocdf(x,p,'upper')` returns the complement of the geometric distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Geometric Distribution cdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing three or fewer tails ("failures") before tossing a heads?

To solve, determine the value of the cumulative distribution function (cdf) for the geometric distribution at x equal to 3. The probability of success (tossing a heads) p in any given trial is 0.5.

```
x = 3;
p = 0.5;
y = geocdf(x,p)
```

```
y = 0.9375
```

The returned value of y indicates that the probability of observing three or fewer tails before tossing a heads is 0.9375.

More About

Geometric Distribution cdf

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x \mid p) = 1 - (1 - p)^{x + 1};\ x = 0, 1, 2, \ldots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing up to x trials before a success, when the probability of success in any given trial is p.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Geometric Distribution” on page B-63

Introduced before R2006a

geoinv

Geometric inverse cumulative distribution function

Syntax

```
x = geoinv(y,p)
```

Description

`x = geoinv(y,p)` returns the inverse cumulative distribution function (icdf) of the geometric distribution at each value in `y` using the corresponding probabilities in `p`.

`geoinv` returns the smallest positive integer `x` such that the geometric cdf evaluated at `x` is equal to or exceeds `y`. You can think of `y` as the probability of observing `x` successes in a row in independent trials, where `p` is the probability of success in each trial.

`y` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `p` or `y` is expanded to a constant array with the same dimensions as the other input. The values in `p` and `y` must lie on the interval `[0,1]`.

Examples

Compute Geometric Distribution icdf

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. If we want no more than a ten percent chance that the car does not start, what is the maximum number of days in a row that we should try to start the car?

To solve, compute the inverse cdf of the geometric distribution. In this example, a "success" means the car does not start, while a "failure" means the car does start. The probability of success for each trial *p* equals 0.03, while the probability of observing *x* failures in a row before observing a success *y* equals 0.1.

```
y = 0.1;
p = 0.03;
x = geoinv(y,p)
```

```
x = 3
```

The returned result indicates that if we start the car three times, there is at least a ten percent chance that it will not start on one of those tries. Therefore, if we want no greater than a ten percent chance that the car will not start, we should only attempt to start it for a maximum of two days in a row.

We can confirm this result by evaluating the cdf at values of *x* equal to 2 and 3, given the probability of success for each trial *p* equal to 0.03.

```
y2 = geocdf(2,p)  % cdf for x = 2
```

```
y2 = 0.0873
```

```
y3 = geocdf(3,p)  % cdf for x = 3
```

```
y3 = 0.1147
```

The returned results indicate an 8.7% chance of the car not starting if we try two days in a row, and an 11.5% chance of not starting if we try three days in a row.

Introduced before R2006a

geomean

Geometric mean

Syntax

```
m = geomean(X)
m = geomean(X,'all')
m = geomean(X,dim)
m = geomean(X,vecdim)
m = geomean( ___ ,nanflag)
```

Description

`m = geomean(X)` returns the geometric mean on page 33-2659 of `X`.

- If `X` is a vector, then `geomean(X)` is the geometric mean of the elements in `X`.
- If `X` is a matrix, then `geomean(X)` is a row vector containing the geometric mean of each column of `X`.
- If `X` is a multidimensional array, then `geomean` operates along the first nonsingleton dimension of `X`.

`m = geomean(X,'all')` returns the geometric mean of all the elements in `X`.

`m = geomean(X,dim)` returns the geometric mean along the operating dimension `dim` of `X`.

`m = geomean(X,vecdim)` returns the geometric mean over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `geomean(X,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the geometric mean of the elements on the corresponding page of `X`.

`m = geomean( ___ ,nanflag)` specifies whether to exclude `NaN` values from the calculation, using any of the input argument combinations in previous syntaxes. By default, `geomean` includes `NaN` values in the calculation (`nanflag` has the value `'includenan'`). To exclude `NaN` values, set the value of `nanflag` to `'omitnan'`.

Examples

Compare Geometric and Arithmetic Mean

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a matrix of exponential random numbers with 5 rows and 4 columns.

```
X = exprnd(1,5,4)
```

```
X = 5×4
```

```
    0.2049    2.3275    1.8476    1.9527
    0.0989    1.2783    0.0298    0.8633
    2.0637    0.6035    0.0438    0.0880
    0.0906    0.0434    0.7228    0.2329
    0.4583    0.0357    0.2228    0.0414
```

Compute the geometric and arithmetic means of the columns of X.

```
geometric = geomean(X)
```

```
geometric = 1×4

    0.2805    0.3083    0.2079    0.2698
```

```
arithmetic = mean(X)
```

```
arithmetic = 1×4

    0.5833    0.8577    0.5734    0.6357
```

The arithmetic mean is greater than the geometric mean for all the columns of X.

Geometric Mean of All Elements

Find the geometric mean over multiple dimensions by using the `'all'` input argument.

Create a 2-by-5-by-4 array X.

```
X = reshape(1:40,[2 5 4])
```

```
X =
X(:,:,1) =

     1     3     5     7     9
     2     4     6     8    10

X(:,:,2) =

    11    13    15    17    19
    12    14    16    18    20

X(:,:,3) =

    21    23    25    27    29
    22    24    26    28    30

X(:,:,4) =

    31    33    35    37    39
    32    34    36    38    40
```

Find the geometric mean of all the elements of X.

```
m = geomean(X,'all')
```

```
m = 15.7685
```

m is the geometric mean of the entire array X.

Geometric Mean Along Specified Dimensions

Find the geometric mean along different operating dimensions and vectors of dimensions for a multidimensional array.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =
X(:,:,1) =

     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15

X(:,:,2) =

    16    19    22    25    28
    17    20    23    26    29
    18    21    24    27    30
```

Find the geometric mean of X along the default dimension.

```
gmean1 = geomean(X)
```

```
gmean1 =
gmean1(:,:,1) =

    1.8171    4.9324    7.9581   10.9696   13.9761

gmean1(:,:,2) =

   16.9804   19.9833   22.9855   25.9872   28.9885
```

By default, geomean operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the first dimension of X. Therefore, gmean1 is a 1-by-5-by-2 array.

Find the geometric mean of X along the second dimension.

```
gmean2 = geomean(X,2)
```

```
gmean2 =
gmean2(:,:,1) =
```

```
    5.1549
    6.5784
    7.8155

gmean2(:,:,2) =

   21.5814
   22.6004
   23.6177
```

`gmean2` is a 3-by-1-by-2 array.

Find the geometric mean of `X` along the third dimension.

```
gmean3 = geomean(X,3)

gmean3 = 3×5

    4.0000    8.7178   12.4097   15.8114   19.0788
    5.8310   10.0000   13.5647   16.9115   20.1494
    7.3485   11.2250   14.6969   18.0000   21.2132
```

`gmean3` is a 3-by-5 array.

Find the geometric mean of each page of `X` by specifying the first and second dimensions using the `vecdim` input argument.

```
mpage = geomean(X,[1 2])

mpage =
mpage(:,:,1) =

    6.4234

mpage(:,:,2) =

   22.5845
```

For example, `mpage(1,1,2)` is the geometric mean of the elements in `X(:,:,2)`.

Find the geometric mean of the elements in each `X(i,:,:)` slice by specifying the second and third dimensions.

```
mrow = geomean(X,[2 3])

mrow = 3×1

   10.5475
   12.1932
   13.5862
```

For example, `mrow(3)` is the geometric mean of the elements in `X(3,:,:)`, and is equivalent to specifying `geomean(X(3,:,:),'all')`.

Geometric Mean Excluding NaN

Create a vector and compute its `geomean`, excluding `NaN` values.

```
x = 1:10;
x(3) = nan; % Replace the third element of x with a NaN value
n = geomean(x,'omitnan')
```

```
n = 4.7408
```

If you do not specify `'omitnan'`, then `geomean(x)` returns `NaN`.

Input Arguments

X — Input data

nonnegative vector | nonnegative matrix | nonnegative multidimensional array

Input data that represents a sample from a population, specified as a nonnegative vector, matrix, or multidimensional array.

- If `X` is a vector, then `geomean(X)` is the geometric mean of the elements in `X`.
- If `X` is a matrix, then `geomean(X)` is a row vector containing the geometric mean of each column of `X`.
- If `X` is a multidimensional array, then `geomean` operates along the first nonsingleton dimension of `X`.

To specify the operating dimension when `X` is a matrix or an array, use the `dim` input argument.

Data Types: `single` | `double`

dim — Dimension

positive integer scalar

Dimension along which to operate, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension of `X` whose size does not equal 1.

Consider a two-dimensional array `X`:

- If `dim` is equal to 1, then `geomean(X,1)` returns a row vector containing the geometric mean for each column in `X`.
- If `dim` is equal to 2, then `geomean(X,2)` returns a column vector containing the geometric mean for each row in `X`.

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `geomean` returns `X`.

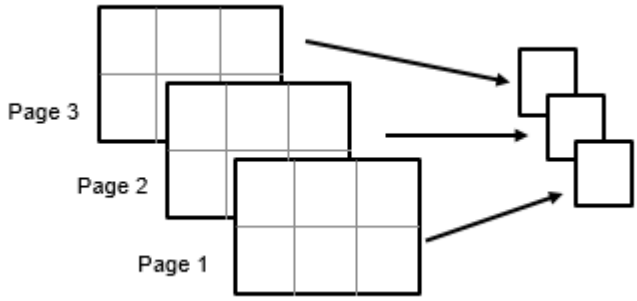
Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `m` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `m`.

For example, if `X` is a 2-by-3-by-3 array, then `geomean(X,[1 2])` returns a 1-by-1-by-3 array. Each element of the output is the geometric mean of the elements on the corresponding page of `X`.



Data Types: `single` | `double`

`nanflag` — `NaN` condition
`'includenan'` (default) | `'omitnan'`

`NaN` condition, specified as one of these values:

- `'includenan'` — Include `NaN` values when computing the `geomean`. This returns `NaN`.
- `'omitnan'` — Ignore `NaN` values in the input.

Data Types: `char` | `string`

Output Arguments

`m` — Geometric mean
scalar | vector | matrix | multidimensional array

Geometric mean, returned as a scalar, vector, matrix, or multidimensional array.

More About

Geometric Mean

The geometric mean of a sample `X` is

$$m = \left[\prod_{i=1}^{n} x_i \right]^{\frac{1}{n}}$$

where n is the number of values in `X`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- These input arguments are not supported: `'all'`, `vecdim`, and `nanflag`.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

geopdf

Geometric probability density function

Syntax

```
y = geopdf(x,p)
```

Description

`y = geopdf(x,p)` returns the probability density function (pdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval `[0,1]`.

Examples

Compute Geometric Distribution pdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing exactly three tails ("failures") before tossing a heads?

To solve, determine the value of the probability density function (pdf) for the geometric distribution at `x` equal to `3`. The probability of success (tossing a heads) `p` in any given trial is `0.5`.

```
x = 3;
p = 0.5;
y = geopdf(x,p)
```

```
y = 0.0625
```

The returned value of `y` indicates that the probability of observing exactly three tails before tossing a heads is `0.0625`.

More About

Geometric Distribution pdf

The probability density function (pdf) of the geometric distribution is

$$y = f(x \mid p) = p(1-p)^x \quad ; \quad x = 0, 1, 2, \ldots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing exactly x trials before a success, when the probability of success in any given trial is p. For discrete distributions, the pdf is also known as the probability mass function (pmf).

Extended Capabilities

geornd

Geometric random numbers

Syntax

```
r = geornd(p)
r = geornd(p,m,n,...)
r = geornd(p,[m,n,...])
```

Description

`r = geornd(p)` generates random numbers from a geometric distribution with probability parameter `p`. `p` can be a vector, a matrix, or a multidimensional array. The size of `r` is equal to the size of `p`. The parameters in `p` must lie in the interval `[0,1]`.

`r = geornd(p,m,n,...)` or `r = geornd(p,[m,n,...])` generates a multidimensional `m`-by-`n`-by-`...` array containing random numbers from the geometric distribution with probability parameter `p`. `p` can be a scalar or an array of the same size as `r`.

The geometric distribution is useful to model the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is the constant `p`.

Examples

Generate Random Numbers from Geometric Distribution

Generate a single random number from a geometric distribution with probability parameter *p* equal to 0.01.

```
rng default  % For reproducibility
p = 0.01;
r1 = geornd(0.01)
```

```
r1 = 20
```

The returned random number represents a single experiment in which 20 failures were observed before a success, where each independent trial has a probability of success *p* equal to 0.01.

Generate a 1-by-5 array of random numbers from a geometric distribution with probability parameter *p* equal to 0.01.

```
r2 = geornd(p,1,5)
```

```
r2 = 1×5

     9   205     9    45   231
```

Each random number in the returned array represents the result of an experiment to determine the number of failures observed before a success, where each independent trial has a probability of success *p* equal to 0.01.

Generate a 1-by-3 array containing one random number from each of the three geometric distributions corresponding to the parameters in the 1-by-3 array of probabilities *p*.

```
p = [0.01 0.1 0.5];
r3 = geornd(p,[1 3])
```

```
r3 = 1×3

   127     5     0
```

Each element of the returned 1-by-3 array `r3` contains one random number generated from the geometric distribution described by the corresponding parameter in `P`. For example, the first element in `r3` represents an experiment in which 127 failures were observed before a success, where each independent trial has a probability of success *p* equal to 0.01. The second element in `r3` represents an experiment in which 5 failures were observed before a success, where each independent trial has a probability of success *p* equal to 0.1. The third element in `r3` represents an experiment in which zero failures were observed before a success - in other words, the first attempt was a success - where each independent trial has a probability of success *p* equal to 0.5.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

geostat

Geometric mean and variance

Syntax

```
[m,v] = geostat(p)
```

Description

`[m,v] = geostat(p)` returns the mean `m` and variance `v` of a geometric distribution with corresponding probability parameters in `p`. `p` can be a vector, a matrix, or a multidimensional array. The parameters in `p` must lie in the interval `[0,1]`.

Examples

Compute Mean and Variance of Geometric Distribution

Define a probability vector that contains six different parameter values.

```
p = 1./(1:6)
```

```
p = 1×6

    1.0000    0.5000    0.3333    0.2500    0.2000    0.1667
```

Compute the mean and variance of the geometric distribution that corresponds to each value contained in probability vector.

```
[m,v] = geostat(1./(1:6))
```

```
m = 1×6

         0    1.0000    2.0000    3.0000    4.0000    5.0000

v = 1×6

         0    2.0000    6.0000   12.0000   20.0000   30.0000
```

The returned values indicate that, for example, the mean of a geometric distribution with probability parameter *p* equal to 1/3 is 2, and its variance is 6.

More About

Geometric Distribution Mean and Variance

The mean of the geometric distribution is mean = $\frac{1-p}{p}$, and the variance of the geometric distribution is var = $\frac{1-p}{p^2}$, where p is the probability of success.

Extended Capabilities

GapEvaluation

Package: `clustering.evaluation`
Superclasses: `ClusterCriterion`

Gap criterion clustering evaluation object

Description

`GapEvaluation` is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x,clust,'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x,clust,'Gap',Name,Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an *N*-by-*P* matrix. *N* is the number of observations, and *P* is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

`'kmeans'` | `'linkage'` | `'gmdistribution'` | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

`'kmeans'`	Cluster the data in `x` using the `kmeans` clustering algorithm, with `'EmptyAction'` set to `'singleton'` and `'Replicates'` set to `5`.
`'linkage'`	Cluster the data in `x` using the `clusterdata` agglomerative clustering algorithm, with `'Linkage'` set to `'ward'`.
`'gmdistribution'`	Cluster the data in `x` using the `gmdistribution` Gaussian mixture distribution algorithm, with `'SharedCov'` set to `true` and `'Replicates'` set to `5`.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can specify a clustering algorithm using a function handle. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.

- A numeric *n*-by-*K* matrix of score for *n* observations and *K* classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a *n*-by-*K* matrix containing the proposed clustering solutions. *n* is the number of observations in the sample data, and *K* is the number of proposed clustering solutions. Column *j* contains the cluster indices for each of the *N* points in the *j*th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

B — Number of reference data sets

`100` (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of `'B'` and a positive integer value.

Example: `'B',150`

Data Types: `single` | `double`

Distance — Distance metric

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

`'sqEuclidean'`	Squared Euclidean distance
`'Euclidean'`	Euclidean distance
`'cityblock'`	Sum of absolute differences
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors)
`'correlation'`	One minus the sample correlation between points (treated as sequences of values)

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using a function handle. The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by-*n* vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2-by-*n* matrix corresponding to multiple rows of `X`. `distfun` must return an m_2-by-1 vector of distances `d2`, whose *k*th element is the distance between `XI` and `XJ(k,:)`.

`Distance` only accepts a function handle if the clustering algorithm `clust` accepts a function handle as the distance metric. For example, the `kmeans` clustering algorithm does not accept a function

handle as the distance metric. Therefore, if you use the `kmeans` algorithm and then specify a function handle for `Distance`, the software errors.

- When `clust` is `'kmeans'` or `'gmdistribution'`, `evalclusters` uses the distance metric specified for `Distance` to cluster the data.
- If `clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.
- If `clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: `'Distance','Euclidean'`

Data Types: `single` | `double` | `char` | `string` | `function_handle`

`KList` — List of number of clusters to evaluate
vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is `'gap'`, `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: `'KList',[1:6]`

Data Types: `single` | `double`

`ReferenceDistribution` — Reference data generation method
`'PCA'` (default) | `'uniform'`

Reference data generation method, specified as the comma-separated pair consisting of `'ReferenceDistributions'` and one of the following.

`'PCA'`	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix `x`.
`'uniform'`	Generate reference data uniformly over the range of each feature in the data matrix `x`.

Example: `'ReferenceDistribution','uniform'`

`SearchMethod` — Method for selecting optimal number of clusters
`'globalMaxSE'` (default) | `'firstMaxSE'`

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of `'SearchMethod'` and one of the following.

`'globalMaxSE'`	Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying $$\text{Gap}(K) \geq GAPMAX - \text{SE}(GAPMAX),$$ where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, $GAPMAX$ is the largest gap value, and $\text{SE}(GAPMAX)$ is the standard error corresponding to the largest gap value.
`'firstMaxSE'`	Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying $$\text{Gap}(K) \geq \text{Gap}(K+1) - \text{SE}(K+1),$$ where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, and $\text{SE}(K+1)$ is the standard error of the clustering solution with $K+1$ clusters.

Example: `'SearchMethod','globalMaxSE'`

Properties

`B`

Number of data sets generated from the reference distribution, stored as a positive integer value.

`ClusteringFunction`

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

`CriterionName`

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

`CriterionValues`

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

`Distance`

Distance metric used for clustering data, stored as a valid distance metric name.

`ExpectedLogW`

Expectation of the natural logarithm of W based on the generated reference data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance metric `Distance`.

`InspectedK`

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

LogW

Natural logarithm of *W* based on the input data, stored as a vector of scalar values. *W* is the within-cluster dispersion computed using the distance metric `Distance`.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix `X`, minus the number of missing (`NaN`) values in `X`, stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

ReferenceDistribution

Reference data generation method, stored as a valid reference distribution name.

SE

Standard error of the natural logarithm of *W* with respect to the reference data for each number of clusters in `InspectedK`, stored as a vector of scalar values. *W* is the within-cluster dispersion computed using the distance metric `Distance`.

SearchMethod

Method for determining the optimal number of clusters, stored as a valid search method name.

StdLogW

Standard deviation of the natural logarithm of *W* with respect to the reference data for each number of clusters in `InspectedK`. *W* is the within-cluster dispersion computed using the distance metric `Distance`.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

increaseB	Increase reference data sets

Inherited Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values
compact	Compact clustering evaluation object

Examples

Evaluate Clustering Solution Using Gap Criterion

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```
load fisheriris
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using `kmeans`.

```
rng('default');  % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
```

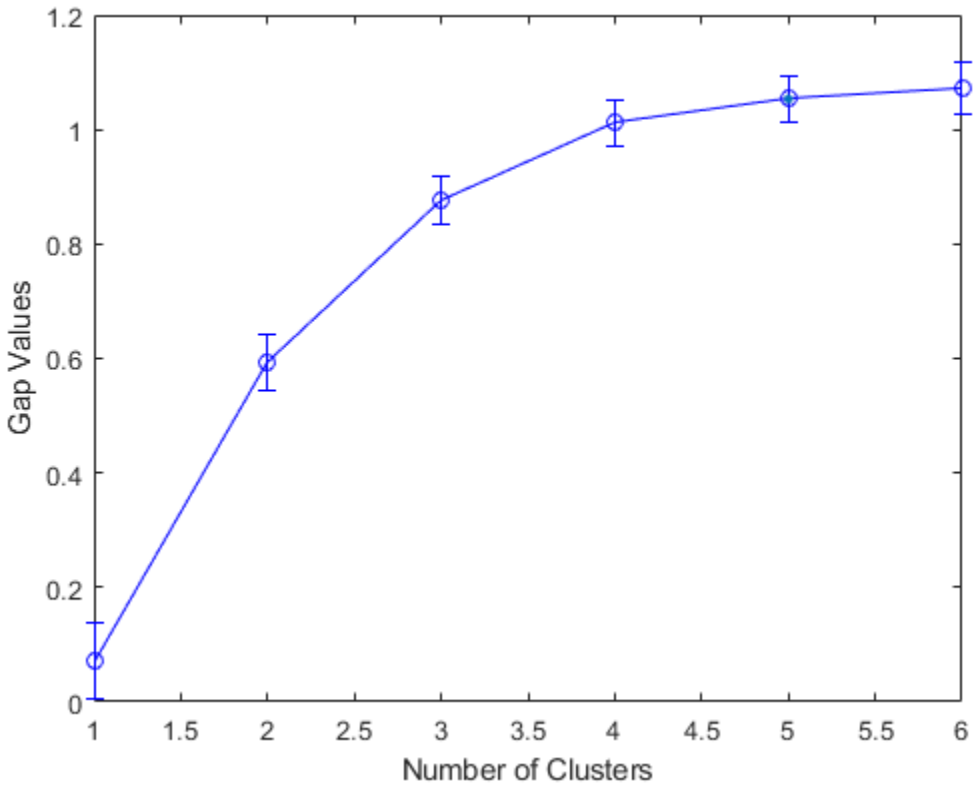
```
eva =
  GapEvaluation with properties:

    NumObservations: 150
         InspectedK: [1 2 3 4 5 6]
    CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
           OptimalK: 5
```

The `OptimalK` value indicates that, based on the gap criterion, the optimal number of clusters is five.

Plot the gap criterion values for each number of clusters tested.

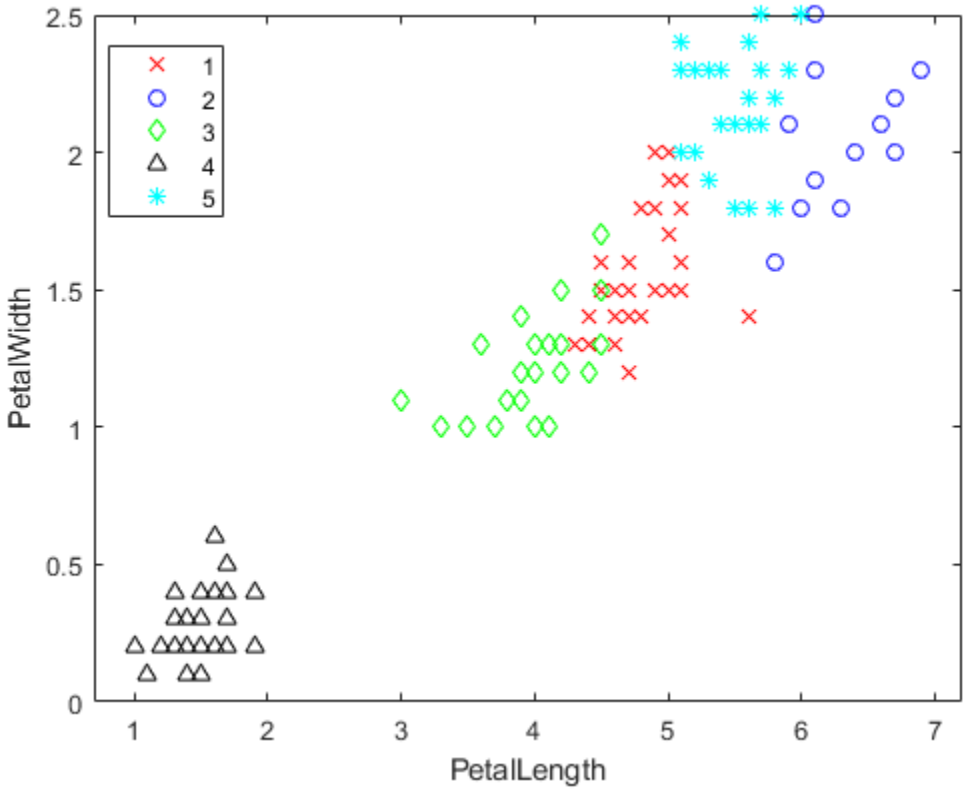
```
plot(eva)
```



Based on the plot, the maximum value of the gap criterion occurs at six clusters. However, the value at five clusters is within one standard error of the maximum, so the suggested optimal number of clusters is five.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
figure
PetalLength = meas(:,3);
PetalWidth = meas(:,4);
ClusterGroup = eva.OptimalY;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgkc','xod^*');
```



The plot shows cluster 4 in the lower-left corner, completely separated from the other four clusters. Cluster 4 contains flowers with the smallest petal widths and lengths. Cluster 2 is in the upper-right corner and contains flowers with the largest petal widths and lengths. Cluster 5 is next to cluster 2 and contains flowers with similar petal widths as the flowers in cluster 2, but smaller petal lengths than the flowers in cluster 2. Clusters 1 and 3 are near the center of the plot and contain flowers with measurements between the extremes.

More About

Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

$$Gap_n(k) = E_n^*\{\log(W_k)\} - \log(W_k),$$

where n is the sample size, k is the number of clusters being evaluated, and W_k is the pooled within-cluster dispersion measurement

$$W_k = \sum_{r=1}^{k} \frac{1}{2n_r} D_r,$$

where n_r is the number of data points in cluster r, and D_r is the sum of the pairwise distances for all points in cluster r.

The expected value $E_n^*\{\log(W_k)\}$ is determined by Monte Carlo sampling from a reference distribution, and `log(`W_k`)` is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

Topics
Class Attributes
Property Attributes

get

Class: `dataset`

(Not Recommended) Access dataset array properties

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

Description

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by *`PropertyName`*.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

Examples

Create a dataset array from Fisher's iris data and access the information.

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
               {meas,'SL','SW','PL','PW'},...
               'ObsNames',NameObs);

get(iris)
   Description: ''
   Units: {}
   DimNames: {'Observations' 'Variables'}
   UserData: []
   ObsNames: {150x1 cell}
   VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}

ON = get(iris,'ObsNames');
ON(1:3)
ans =
    'Obs1'
    'Obs2'
    'Obs3'
```

getlabels

(Not Recommended) Access nominal or ordinal array labels

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” data type instead.

Syntax

```
labels = getlabels(A)
```

Description

`labels = getlabels(A)` returns the labels of the levels in the nominal or ordinal array `A` as a cell array of character vectors, `labels`. If `A` is an ordinal array, `getlabels` returns the labels in the order of the levels.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

See Also

`getlevels` | `nominal` | `ordinal`

Topics

gevcdf

Generalized extreme value cumulative distribution function

Syntax

```
p = gevcdf(x,k,sigma,mu)
p = gevcdf(x,k,sigma,mu,'upper')
```

Description

`p = gevcdf(x,k,sigma,mu)` returns the cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gevcdf(x,k,sigma,mu,'upper')` returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblcdf` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

Topics

“Generalized Extreme Value Distribution” on page B-55

Introduced before R2006a

gevfit

Generalized extreme value parameter estimates

Syntax

```
parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)
```

Description

`parmhat = gevfit(X)` returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in X. `parmhat(1)` is the shape parameter, `k`, `parmhat(2)` is the scale parameter, `sigma`, and `parmhat(3)` is the location parameter, `mu`.

`[parmhat,parmci] = gevfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gevfit(X,alpha)` returns `100(1-alpha)`% confidence intervals for the parameter estimates.

`[...] = gevfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gevfit')` for parameter names and default values. Pass in `[]` for `alpha` to use the default values.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblfit` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evfit` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution is defined for `k*(X-mu)/sigma > -1`.

gevinv

Generalized extreme value inverse cumulative distribution function

Syntax

```
X = gevinv(P,k,sigma,mu)
```

Description

`X = gevinv(P,k,sigma,mu)` returns the inverse cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter `mu`, evaluated at the values in `P`. The size of `X` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblinv` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evinv` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that $k*(X-mu)/sigma > -1$.

Introduced before R2006a

gevlike

Generalized extreme value negative log-likelihood

Syntax

```
nlogL = gevlike(params,data)
[nlogL,ACOV] = gevlike(params,data)
```

Description

`nlogL = gevlike(params,data)` returns the negative of the log-likelihood `nlogL` for the generalized extreme value (GEV) distribution, evaluated at parameters `params`. `params(1)` is the shape parameter, `k`, `params(2)` is the scale parameter, `sigma`, and `params(3)` is the location parameter, `mu`.

`[nlogL,ACOV] = gevlike(params,data)` returns the inverse of Fisher's information matrix, `ACOV`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `ACOV` are their asymptotic variances. `ACOV` is based on the observed Fisher's information, not the expected information.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wbllike` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evlike` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

gevpdf

Generalized extreme value probability density function

Syntax

```
Y = gevpdf(X,k,sigma,mu)
```

Description

`Y = gevpdf(X,k,sigma,mu)` returns the pdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`, evaluated at the values in `X`. The size of `Y` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblpdf` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

gevrnd

Generalized extreme value random numbers

Syntax

```
R = gevrnd(k,sigma,mu)
R = gevrnd(k,sigma,mu,m,n,...)
R = gevrnd(k,sigma,mu,[m,n,...])
```

Description

`R = gevrnd(k,sigma,mu)` returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gevrnd(k,sigma,mu,m,n,...)` or `R = gevrnd(k,sigma,mu,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the GEV distribution with parameters `k`, `sigma`, and `mu`. The `k`, `sigma`, `mu` parameters can each be scalars or arrays of the same size as `R`.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblrnd` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evrnd` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

gevstat

Generalized extreme value mean and variance

Syntax

```
[M,V] = gevstat(k,sigma,mu)
```

Description

`[M,V] = gevstat(k,sigma,mu)` returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The sizes of `M` and `V` are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

When `k < 0`, the GEV is the type III extreme value distribution. When `k > 0`, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblstat` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evstat` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of `X` such that `k*(X-mu)/sigma > -1`.

“Generalized Extreme Value Distribution” on page B-55

Introduced before R2006a

gline

Interactively add line to plot

Syntax

```
gline(h)
gline
hline = gline(...)
```

Description

`gline(h)` allows you to draw a line segment in the figure with handle `h` by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

`gline` with no input arguments defaults to `h = gcf` and draws in the current figure.

`hline = gline(...)` returns the handle `hline` to the line.

Examples

Use `gline` to connect two points in a plot:

```
x = 1:10;

y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```

`lsline` | `refcurve` | `refline`

Introduced before R2006a

glmfit

Fit generalized linear regression model

Syntax

```
b = glmfit(X,y,distr)
b = glmfit(X,y,distr,Name,Value)
[b,dev] = glmfit(___)
[b,dev,stats] = glmfit(___)
```

Description

`b = glmfit(X,y,distr)` returns a vector `b` of coefficient estimates for a generalized linear regression model of the responses in `y` on the predictors in `X`, using the distribution `distr`.

`b = glmfit(X,y,distr,Name,Value)` specifies additional options using one or more name-value arguments. For example, you can specify `'Constant','off'` to omit the constant term from the model.

`[b,dev] = glmfit(___)` also returns the value `dev`, the deviance on page 33-2701 of the fit.

`[b,dev,stats] = glmfit(___)` also returns the model statistics `stats`.

Examples

Fit Generalized Linear Model with Probit Link

Fit a generalized linear regression model, and compute predicted (estimated) values for the predictor data using the fitted model.

Create a sample data set.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

`x` contains the predictor variable values. Each `y` value is the number of successes in the corresponding number of trials in `n`.

Fit a probit regression model for `y` on `x`.

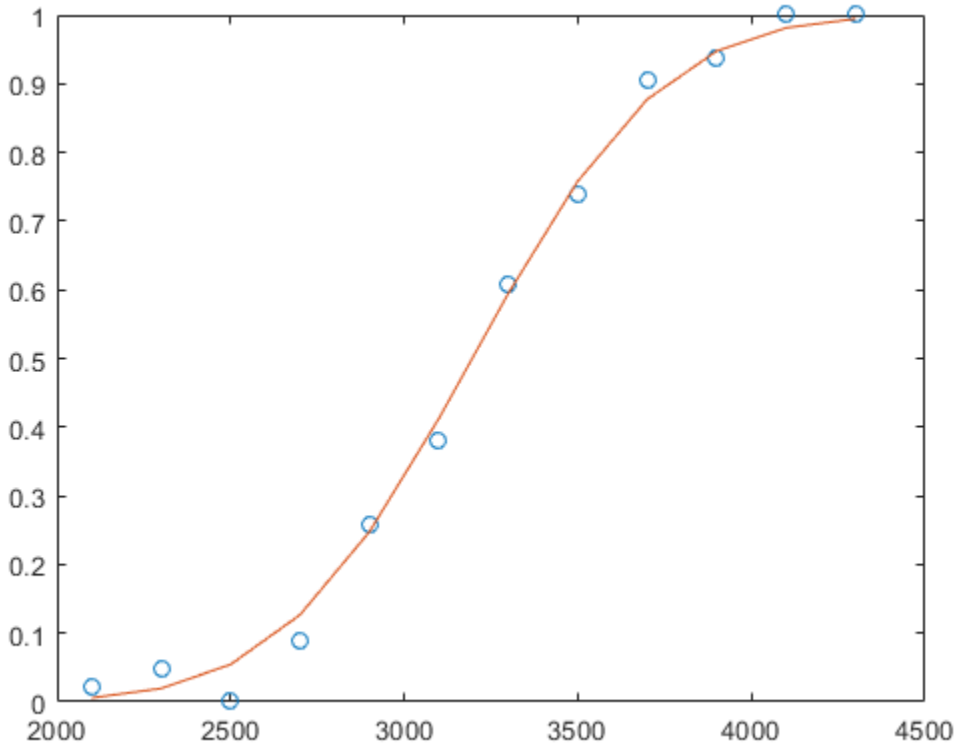
```
b = glmfit(x,[y n],'binomial','Link','probit');
```

Compute the estimated number of successes.

```
yfit = glmval(b,x,'probit','Size',n);
```

Plot the observed success percent and estimated success percent versus the `x` values.

```
plot(x,y./n,'o',x,yfit./n,'-')
```



Fit Generalized Linear Model Using Custom Link Function

Define a custom link function and use it to fit a generalized linear regression model.

Load the sample data.

```
load fisheriris
```

The column vector `species` contains iris flowers of three different species: setosa, versicolor, and virginica. The matrix `meas` contains four types of measurements for the flowers, the length and width of sepals and petals in centimeters.

Define the predictor variables and response variable.

```
X = meas(51:end,:);
y = strcmp('versicolor',species(51:end));
```

Define a custom link function for a logit link function. Create three function handles that define the link function, the derivative of the link function, and the inverse link function. Store them in a cell array.

```
link = @(mu) log(mu./(1-mu));
derlink = @(mu) 1./(mu.*(1-mu));
invlink = @(resp) 1./(1+exp(-resp));
F = {link,derlink,invlink};
```

Fit a logistic regression model using `glmfit` with the custom link function.

```
b = glmfit(X,y,'binomial','link',F)
```

```
b = 5×1

   42.6378
    2.4652
    6.6809
   -9.4294
  -18.2861
```

Fit a generalized linear model by using the built-in `logit` link function, and compare the results.

```
b = glmfit(X,y,'binomial','link','logit')
```

```
b = 5×1

   42.6378
    2.4652
    6.6809
   -9.4294
  -18.2861
```

Perform Deviance Test

Fit a generalized linear regression model that contains an intercept and linear term for each predictor. Perform a deviance test that determines whether the model fits significantly better than a constant model.

Generate sample data using Poisson random numbers with two underlying predictors `X(:,1)` and `X(:,2)`.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Fit a generalized linear regression model that contains an intercept and linear term for each predictor.

```
[b,dev] = glmfit(X,y,'poisson');
```

The second output argument `dev` is a “Deviance” on page 33-2701 of the fit.

Fit a generalized linear regression model that contains only an intercept. Specify the predictor variable as a column of 1s, and specify `'Constant'` as `'off'` so that `glmfit` does not include a constant term in the model.

```
[~,dev_noconstant] = glmfit(ones(100,1),y,'poisson','Constant','off');
```

Compute the difference between `dev_constant` and `dev`.

```
D = dev_noconstant - dev

D = 2.9533e+05
```

`D` has a chi-square distribution with 2 degrees of freedom. The degrees of freedom equal the difference in the number of estimated parameters in the model corresponding to `dev` and the number of estimated parameters in the constant model. Find the *p*-value for a deviance test.

```
p = 1 - chi2cdf(D,2)

p = 0
```

The small *p*-value indicates that the model differs significantly from a constant.

Alternatively, you can create a generalized linear regression model of Poisson data by using the `fitglm` function. The model display includes the statistic (`Chi^2-statistic vs. constant model`) and *p*-value.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson')

mdl =
Generalized linear regression model:
    log(y) ~ 1 + x1 + x2
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE        tStat     pValue
                   ________    _________    ______    ______

    (Intercept)     1.0405      0.022122    47.034      0
    x1              0.9968      0.003362    296.49      0
    x2               1.987     0.0063433    313.24      0

100 observations, 97 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

You can also use the `devianceTest` function with the fitted model object.

```
devianceTest(mdl)

ans=2×4 table
                            Deviance     DFE     chi2Stat     pValue
                           __________    ___    __________    ______

    log(y) ~ 1             2.9544e+05    99
    log(y) ~ 1 + x1 + x2         107.4    97     2.9533e+05       0
```

Input Arguments

X — Predictor variables

numeric matrix

Predictor variables, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, `glmfit` includes a constant term in the model. Do not add a column of 1s directly to `X`. You can change the default behavior of `glmfit` by specifying the `'Constant'` name-value argument.

Data Types: `single` | `double`

`y` — Response variable
vector | matrix

Response variable, specified as a vector or matrix.

- If `distr` is not `'binomial'`, then `y` must be an *n*-by-1 vector, where *n* is the number of observations. Each entry in `y` is the response for the corresponding row of `X`. The data type must be single or double.
- If `distr` is `'binomial'`, then `y` is an *n*-by-1 vector indicating success or failure at each observation, or an *n*-by-2 matrix whose first column indicates the number of successes for each observation and second column indicates the number of trials for each observation.

Data Types: `single` | `double` | `logical` | `categorical`

`distr` — Distribution of response variable
`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as one of the values in this table.

Value	Description
`'normal'`	Normal distribution (default)
`'binomial'`	Binomial distribution
`'poisson'`	Poisson distribution
`'gamma'`	Gamma distribution
`'inverse gaussian'`	Inverse Gaussian distribution

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `b = glmfit(X,y,'normal','link','probit')` specifies that the distribution of the response is normal and instructs `glmfit` to use the probit link function.

`B0` — Initial values for coefficient estimates
numeric vector

Initial values for the coefficient estimates, specified as a numeric vector. The default values are initial fitted values derived from the input data.

Data Types: `single` | `double`

`Constant` — Indicator for constant term
`'on'` (default) | `'off'`

Indicator for the constant term (intercept) in the fit, specified as either `'on'` to include the constant term or `'off'` to remove it from the model.

- `'on'` (default) — `glmfit` includes a constant term in the model and returns a (p + 1)-by-1 vector of coefficient estimates `b`, where p is the number of predictors in `X`. The coefficient of the constant term is the first element of `b`.
- `'off'` — `glmfit` omits the constant term and returns a p-by-1 vector of coefficient estimates `b`.

Example: `'Constant','off'`

`EstDisp` — Indicator to compute dispersion parameter
`'off'` for `'binomial'` and `'poisson'` distributions (default) | `'on'`

Indicator to compute a dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as `'on'` or `'off'`.

Value	Description
`'on'`	Estimate a dispersion parameter when computing standard errors. The estimated dispersion parameter value is the sum of squared Pearson residuals divided by the degrees of freedom for error (DFE).
`'off'`	Use the theoretical value of 1 when computing standard errors (default).

The fitting function always estimates the dispersion for other distributions.

Example: `'EstDisp','on'`

`Link` — Link function
canonical link function (default) | scalar value | structure or cell array of custom link function

Link function to use in place of the canonical link function, specified as one of the built-in link functions in the following table or a custom link function.

Link Function Name	Link Function	Mean (Inverse) Function
`'identity'` (default for `'normal'` distribution)	$f(\mu) = \mu$	$\mu = Xb$
`'log'` (default for `'poisson'` distribution)	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
`'logit'` (default for `'binomial'` distribution)	$f(\mu) = \log(\mu/(1 - \mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
`'probit'`	$f(\mu) = \Phi^{-1}(\mu)$, where Φ is the cumulative distribution function of the standard normal distribution	$\mu = \Phi(Xb)$
`'loglog'`	$f(\mu) = \log(-\log(\mu))$	$\mu = \exp(-\exp(Xb))$
`'comploglog'`	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
`'reciprocal'` (default for `'gamma'` distribution)	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$

Link Function Name	Link Function	Mean (Inverse) Function
p (a number, default for the 'inverse gaussian' distribution with $p = -2$)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$

The default `'Link'` value is the canonical link function, which depends on the distribution of the response variable specified by the `distr` argument.

You can specify a custom link function using a structure or cell array.

- Structure with three fields. Each field of the structure (for example, `S`) holds a function handle that accepts a vector of inputs and returns a vector of the same size:
  - `S.Link` — Link function, $f(\mu)$ = `S.Link`(μ)
  - `S.Derivative` — Derivative of the link function
  - `S.Inverse` — Inverse link function, μ = `S.Inverse`(Xb)
- Cell array of the form `{FL FD FI}` that defines the link function (`FL(mu)`), the derivative of the link function (`FD = dFL(mu)/dmu`), and the inverse link function (`FI = FL^(−1)`). Each entry holds a function handle that accepts a vector of inputs and returns a vector of the same size.

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

Example: `'Link','probit'`

Data Types: `single` | `double` | `char` | `string` | `struct` | `cell`

`Offset` — Offset variable

[ ] (default) | numeric vector

Offset variable in the fit, specified as a numeric vector with the same length as the response `y`.

`glmfit` uses `Offset` as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

$f(\mu)$ = `Offset` + $X*b$,

where f is the link function, μ is the mean response, and $X*b$ is the linear combination of predictors X. The `Offset` predictor has coefficient `1`.

For example, consider a Poisson regression model. Suppose, for theoretical reasons, the number of counts is to be proportional to a predictor `A`. By using the log link function and specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double`

`Options` — Optimization options

`statset('glmfit')` (default) | structure

Optimization options, specified as a structure. This argument determines the control parameters for the iterative algorithm that `glmfit` uses.

Create the `'Options'` value by using the function `statset` or by creating a structure array containing the fields and values described in this table.

Field Name	Value	Default Value
`Display`	Amount of information displayed by the algorithm • `'off'` — Displays no information • `'final'` — Displays the final output	`'off'`
`MaxIter`	Maximum number of iterations allowed, specified as a positive integer	`100`
`TolX`	Termination tolerance for the parameters, specified as a positive scalar	`1e-6`

You can also enter `statset('glmfit')` in the Command Window to see the names and default values of the fields that `glmfit` accepts in the `'Options'` name-value argument.

Example: `'Options',statset('Display','final','MaxIter',1000)` specifies to display the final information of the iterative algorithm results, and change the maximum number of iterations allowed to 1000.

Data Types: `struct`

`Weights` — Observation weights
`ones(n,1)` (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: `single` | `double`

Output Arguments

`b` — Coefficient estimates
numeric vector

Coefficient estimates, returned as a numeric vector.

- If `'Constant'` is `'on'` (default), then `glmfit` includes a constant term in the model and returns a (p + 1)-by-1 vector of coefficient estimates `b`, where p is the number of predictors in `X`. The coefficient of the constant term is the first element of `b`.
- If `'Constant'` is `'off'`, then `glmfit` omits the constant term and returns a p-by-1 vector of coefficient estimates `b`.

`dev` — Deviance of fit
numeric value

Deviance of the fit, returned as a numeric value. The deviance is useful for comparing two models when one model is a special case of the other model. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models.

For more information, see “Deviance” on page 33-2701.

`stats` — Model statistics
structure

Model statistics, returned as a structure with the following fields:

- `beta` — Coefficient estimates `b`
- `dfe` — Degrees of freedom for error
- `sfit` — Estimated dispersion parameter
- `s` — Theoretical or estimated dispersion parameter
- `estdisp` — 0 when `'EstDisp'` is `'off'` and 1 when `'EstDisp'` is `'on'`
- `covb` — Estimated covariance matrix for `b`
- `se` — Vector of standard errors of the coefficient estimates `b`
- `coeffcorr` — Correlation matrix for `b`
- `t` — *t* statistics for `b`
- `p` — *p*-values for `b`
- `resid` — Vector of residuals
- `residp` — Vector of Pearson residuals
- `residd` — Vector of deviance residuals
- `resida` — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then `stats.s` is equal to `stats.sfit`. Also, the elements of `stats.se` differ by the factor `stats.s` from their theoretical values.

More About

Deviance

Deviance is a generalization of the residual sum of squares. It measures the goodness of fit compared to a saturated model.

Deviance of a model M_1 is twice the difference between the loglikelihood of the model M_1 and the saturated model M_s. A saturated model is a model with the maximum number of parameters that you can estimate.

For example, if you have n observations (y_i, $i = 1, 2, \ldots, n$) with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b,y)$ denote the maximum value of the likelihood function for a model with the parameters b. Then the deviance of the model M_1 is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where b_1 and b_s contain the estimated parameters for the model M_1 and the saturated model, respectively. The deviance has a chi-square distribution with n – p degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in the model M_1.

Assume you have two different generalized linear regression models M_1 and M_2, and M_1 has a subset of the terms in M_2. You can assess the fit of the models by comparing the deviances D_1 and D_2 of the two models. The difference of the deviances is

$$\begin{aligned} D = D_2 - D_1 &= -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, the difference D has a chi-square distribution with degrees of freedom v equal to the difference in the number of parameters estimated in M_1 and M_2. You can obtain the p-value for this test by using `1 - chi2cdf(D,v)`.

Typically, you examine D using a model M_2 with a constant term and no predictors. Therefore, D has a chi-square distribution with p – 1 degrees of freedom. If the dispersion is estimated, the difference divided by the estimated dispersion has an F distribution with p – 1 numerator degrees of freedom and n – p denominator degrees of freedom.

Tips

- `glmfit` treats `NaN`s in `X` or `y` as missing values and ignores them.

Alternative Functionality

`glmfit` is useful when you simply need the output arguments of the function or when you want to repeat fitting a model multiple times in a loop. If you need to investigate a fitted model further, create a generalized linear regression model object `GeneralizedLinearModel` by using `fitglm` or `stepwiseglm`. A `GeneralizedLinearModel` object provides more features than `glmfit`.

- Use the properties of `GeneralizedLinearModel` to investigate a fitted model. The object properties include information about the coefficient estimates, summary statistics, fitting method, and input data.
- Use the object functions of `GeneralizedLinearModel` to predict responses and to modify, evaluate, and visualize the generalized linear regression model.
- You can find the information in the output of `glmfit` using the properties and object functions of `GeneralizedLinearModel`.

Output of `glmfit`	**Equivalent Values in `GeneralizedLinearModel`**
`b`	See the `Estimate` column of the `Coefficients` property.
`dev`	See the `Deviance` property.
`stats`	See the model display in the Command Window. You can find the statistics in the model properties (`CoefficientCovariance`, `Coefficients`, `Dispersion`, `DispersionEstimated`, and `Residuals`). The dispersion parameter in `stats.s` of `glmfit` is the scale factor for the standard errors of coefficients, whereas the dispersion parameter in the `Dispersion` property of a generalized linear model is the scale factor for the variance of the response. Therefore, `stats.s` is the square root of the `Dispersion` value.

Introduced before R2006a

glmval

Generalized linear model values

Syntax

```
yhat = glmval(b,X,link)
[yhat,dylo,dyhi] = glmval(b,X,link,stats)
[...] = glmval(...,param1,val1,param2,val2,...)
```

Description

`yhat = glmval(b,X,link)` computes predicted values for the generalized linear model with link function `link` and predictors `X`. Distinct predictor variables should appear in different columns of `X`. `b` is a vector of coefficient estimates as returned by the `glmfit` function. `link` can be any of the character vectors, string scalars, or custom-defined link functions used as values for the `'link'` name-value pair argument in the `glmfit` function.

Note By default, `glmval` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmval` using the `'constant'` parameter.

`[yhat,dylo,dyhi] = glmval(b,X,link,stats)` also computes 95% confidence bounds for the predicted values. When the `stats` structure output of the `glmfit` function is specified, `dylo` and `dyhi` are also returned. `dylo` and `dyhi` define a lower confidence bound of `yhat-dylo`, and an upper confidence bound of `yhat+dyhi`. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

`[...] = glmval(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are listed in this table:

Parameter	Value
`'confidence'` — the confidence level for the confidence bounds	A scalar between 0 and 1
`'size'` — the size parameter (N) for a binomial model	A scalar, or a vector with one value for each row of X
`'offset'` — used as an additional predictor variable, but with a coefficient value fixed at 1.0	A vector
`'constant'`	• `'on'` — Includes a constant term in the model. The coefficient of the constant term is the first element of `b`. • `'off'` — Omit the constant term
`'simultaneous'` — Compute simultaneous confidence intervals (`true`), or compute non-simultaneous confidence intervals (default `false`)	`true` or `false`

Examples

Fit Generalized Linear Model with Probit Link

Fit a generalized linear regression model, and compute predicted (estimated) values for the predictor data using the fitted model.

Create a sample data set.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

`x` contains the predictor variable values. Each `y` value is the number of successes in the corresponding number of trials in `n`.

Fit a probit regression model for `y` on `x`.

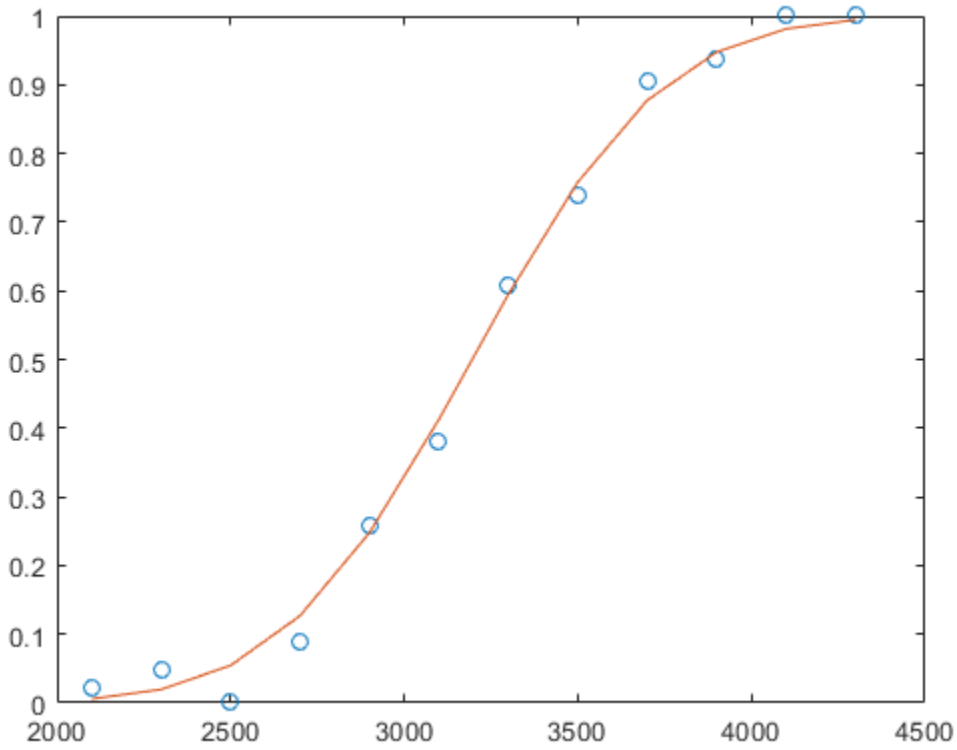
```
b = glmfit(x,[y n],'binomial','Link','probit');
```

Compute the estimated number of successes.

```
yfit = glmval(b,x,'probit','Size',n);
```

Plot the observed success percent and estimated success percent versus the `x` values.

```
plot(x,y./n,'o',x,yfit./n,'-')
```



Use Custom-Defined Link Function

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each `y` value is the number of successes in corresponding number of trials in `n`, and `x` contains the predictor variable values.

Define three function handles, created by using `@`, that define the link, the derivative of the link, and the inverse link for a probit link function,. Store the handles in a cell array.

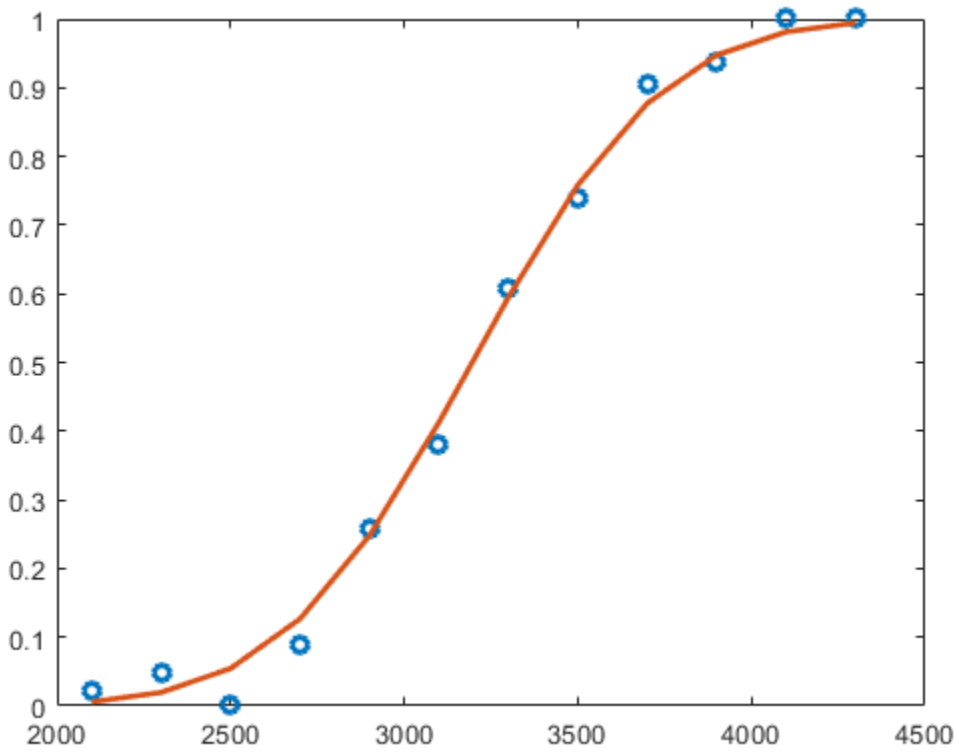
```
link = @(mu) norminv(mu);
derlink = @(mu) 1 ./ normpdf(norminv(mu));
invlink = @(resp) normcdf(resp);
F = {link, derlink, invlink};
```

Fit a generalized linear model for `y` on `x` by using the link function that you defined.

```
b = glmfit(x,[y n],'binomial','link',F);
```

Compute the estimated number of successes. Plot the observed and estimated percent success versus the `x` values.

```
yfit = glmval(b,x,F,'size',n);
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)
```



Generate Code from Function That Predicts Responses Given New Data

Train a generalized linear model, and then generate code from a function that classifies new observations based on the model. This example is based on the “Use Custom-Defined Link Function” on page 33-2706 example.

Enter the sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Suppose that the inverse normal pdf is an appropriate link function for the problem.

Define a function named `myInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the inverse of the standard normal cdf.

```
function in = myInvNorm(mu) %#codegen
%myInvNorm Inverse of standard normal cdf for code generation
%   myInvNorm is a GLM link function that accepts a numeric vector mu, and
%   returns in, which is a numeric vector of corresponding values of the
%   inverse of the standard normal cdf.
```

```
%
in = norminv(mu);
end
```

Define another function named `myDInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the derivative of the link function.

```
function din = myDInvNorm(mu) %#codegen
%myDInvNorm Derivative of inverse of standard normal cdf for code
%generation
%   myDInvNorm corresponds to the derivative of the GLM link function
%   myInvNorm. myDInvNorm accepts a numeric vector mu, and returns din,
%   which is a numeric vector of corresponding derivatives of the inverse
%   of the standard normal cdf.
%
din = 1./normpdf(norminv(mu));
end
```

Define another function named `myInvInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the inverse of the link function.

```
function iin = myInvInvNorm(mu) %#codegen
%myInvInvNorm Standard normal cdf for code generation
%   myInvInvNorm is the inverse of the GLM link function myInvNorm.
%   myInvInvNorm accepts a numeric vector mu, and returns iin, which is a
%   numeric vector of corresponding values of the standard normal cdf.
%
iin = normcdf(mu);
end
```

Create a structure array that specifies each of the link functions. Specifically, the structure array contains fields named `'Link'`, `'Derivative'`, and `'Inverse'`. The corresponding values are the names of the functions.

```
link = struct('Link','myInvNorm','Derivative','myDInvNorm',...
    'Inverse','myInvInvNorm')
```

```
link =

  struct with fields:

         Link: 'myInvNorm'
   Derivative: 'myDInvNorm'
      Inverse: 'myInvInvNorm'
```

Fit a GLM for `y` on `x` using the link function `link`. Return the structure array of statistics.

```
[b,~,stats] = glmfit(x,[y n],'binomial','link',link);
```

`b` is a 2-by-1 vector of regression coefficients.

In your current working folder, define a function called `classifyGLM.m` that:

- Accepts measurements with columns corresponding to those in `x`, regression coefficients whose dimensions correspond to `b`, a link function, the structure of GLM statistics, and any valid `glmval` name-value pair argument
- Returns predictions and confidence interval margins of error

```
function [yhat,lo,hi] = classifyGLM(b,x,link,varargin) %#codegen
%CLASSIFYGLM Classify measurements using GLM model
%   CLASSIFYGLM classifies the n observations in the n-by-1 vector x using
%   the GLM model with regression coefficients b and link function link,
%   and then returns the n-by-1 vector of predicted values in yhat.
%   CLASSIFYGLM also returns margins of error for the predictions using
%   additional information in the GLM statistics structure stats.
narginchk(3,Inf);
if(isstruct(varargin{1}))
    stats = varargin{1};
    [yhat,lo,hi] = glmval(b,x,link,stats,varargin{2:end});
else
    yhat = glmval(b,x,link,varargin{:});
end
end
```

Generate a MEX function from `classifyGLM.m`. Because C uses static typing, `codegen` must determine the properties of all variables in MATLAB® files at compile time. To ensure that the MEX function can use the same inputs, use the `-args` argument to specify the following in the order given:

- Regression coefficients `b` as a compile-time constant
- In-sample observations `x`
- Link function as a compile-time constant
- Resulting GLM statistics as a compile-time constant
- Name `'Confidence'` as a compile-time constant
- Confidence level 0.9

To designate arguments as compile-time constants, use `coder.Constant`.

```
codegen -config:mex classifyGLM -args {coder.Constant(b),x,coder.Constant(link),coder.Constant(s
```

```
Code generation successful.
```

`codegen` generates the MEX file `classifyGLM_mex.mexw64` in your current folder. The file extension depends on your system platform.

Compare predictions by using `glmval` and `classifyGLM_mex`. Specify name-value pair arguments in the same order as in the `-args` argument in the call to `codegen`.

```
[yhat1,melo1,mehi1] = glmval(b,x,link,stats,'Confidence',0.9);
[yhat2,melo2,mehi2] = classifyGLM_mex(b,x,link,stats,'Confidence',0.9);

comp1 = (yhat1 - yhat2)'*(yhat1 - yhat2);
```

```
agree1 = comp1 < eps
comp2 = (melo1 - melo2)'*(melo1 - melo2);
agree2 = comp2 < eps
comp3 = (mehi1 - mehi2)'*(mehi1 - mehi2);
agree3 = comp3 < eps
```

```
agree1 =

  logical

   1

agree2 =

  logical

   1

agree3 =

  logical

   1
```

The generated MEX function produces the same predictions as `predict`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Argument	Notes and Limitations
`b`	`b` must be a compile-time constant (the value of `b` cannot change while `codegen` generates the C/C++ code). You can designate variables as compile-time constants using `coder.Constant`.
`X`	Must be a double- or single-precision numeric matrix
`link`	• Does not support function handles, that is, functions created using `@`. • Must be a compile-time constant.

Argument	Notes and Limitations
`stats`	Must be a compile-time constant
`'Constant'` name-value pair argument	Must be a compile-time constant
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to specify a confidence level of 0.9, include `{coder.Constant('Confidence'),coder.Constant(0.9)}` in the `-args` value of `codegen`.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

glyphplot

Glyph plot

Syntax

```
glyphplot(X)
glyphplot(X,'glyph','face')
glyphplot(X,'glyph','face','features',f)
glyphplot(X,...,'grid',[rows,cols])
glyphplot(X,...,'grid',[rows,cols],'page',p)
glyphplot(X,...,'centers',C)
glyphplot(X,...,'centers',C,'radius',r)
glyphplot(X,...,'obslabels',labels)
glyphplot(X,...,'standardize',method)
glyphplot(X,...,prop1,val1,...)
h = glyphplot(X,...)
```

Description

`glyphplot(X)` creates a star plot from the multivariate data in the *n*-by-*p* matrix `X`. Rows of `X` correspond to observations, columns to variables. A star plot represents each observation as a "star" whose *i*th spoke is proportional in length to the *i*th coordinate of that observation. `glyphplot` standardizes `X` by shifting and scaling each column separately onto the interval `[0,1]` before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats `NaN`s in `X` as missing values, and does not plot the corresponding rows of `X`. `glyphplot(X,'glyph','star')` is a synonym for `glyphplot(X)`.

`glyphplot(X,'glyph','face')` creates a face plot from `X`. A face plot represents each observation as a "face," whose *i*th facial feature is drawn with a characteristic proportional to the *i*th coordinate of that observation. The features are described in "Face Features" on page 33-2713.

`glyphplot(X,'glyph','face','features',f)` creates a face plot where the *i*th element of the index vector `f` defines which facial feature will represent the *i*th column of `X`. `f` must contain integers from `0` to `17`, where `0` indicate that the corresponding column of `X` should not be plotted. See "Face Features" on page 33-2713 for more information.

`glyphplot(X,...,'grid',[rows,cols])` organizes the glyphs into a `rows`-by-`cols` grid.

`glyphplot(X,...,'grid',[rows,cols],'page',p)` organizes the glyph into one or more pages of a `rows`-by-`cols` grid, and displays the page `p`. If `p` is a vector, `glyphplot` displays multiple pages in succession. If `p` is `'all'`, `glyphplot` displays all pages. If `p` is `'scroll'`, `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X,...,'centers',C)` creates a plot with each glyph centered at the locations in the *n*-by-2 matrix `C`.

`glyphplot(X,...,'centers',C,'radius',r)` creates a plot with glyphs positioned using `C`, and scale the glyphs so the largest has radius `r`.

`glyphplot(X,...,'obslabels',labels)` labels each glyph with the text in `labels`. By default, the glyphs are labelled `1:N`. Use `''` for blank labels.

`glyphplot(X,...,'standardize',method)` standardizes `X` before making the plot. Choices for *`method`* are

- `'column'` — Maps each column of `X` separately onto the interval [0,1]. This is the default.
- `'matrix'` — Maps the entire matrix `X` onto the interval `[0,1]`.
- `'PCA'` — Transforms `X` to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval `[0,1]`.
- `'off'` — No standardization. Negative values in `X` may make a star plot uninterpretable.

`glyphplot(X,...,prop1,val1,...)` sets properties to the specified property values for all line graphics objects created by `glyphplot`.

`h = glyphplot(X,...)` returns a matrix of handles to the graphics objects created by `glyphplot`. For a star plot, `h(:,1)` and `h(:,2)` contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, `h(:,1)` and `h(:,2)` contain object handles to the lines making up each face and to the pupils, respectively. `h(:,3)` contains handles to the text objects for the labels, if present.

Face Features

The following table describes the correspondence between the columns of the vector `f`, the value of the `'Features'` input parameter, and the facial features of the glyph plot. If `X` has fewer than 17 columns, unused features are displayed at their default value.

Column	Facial Feature
1	Size of face
2	Forehead/jaw relative arc length
3	Shape of forehead
4	Shape of jaw
5	Width between eyes
6	Vertical position of eyes
7	Height of eyes
8	Width of eyes (this also affects eyebrow width)
9	Angle of eyes (this also affects eyebrow angle)
10	Vertical position of eyebrows
11	Width of eyebrows (relative to eyes)
12	Angle of eyebrows (relative to eyes)
13	Direction of pupils
14	Length of nose
15	Vertical position of mouth
16	Shape of mouth
17	Mouth arc length

Examples

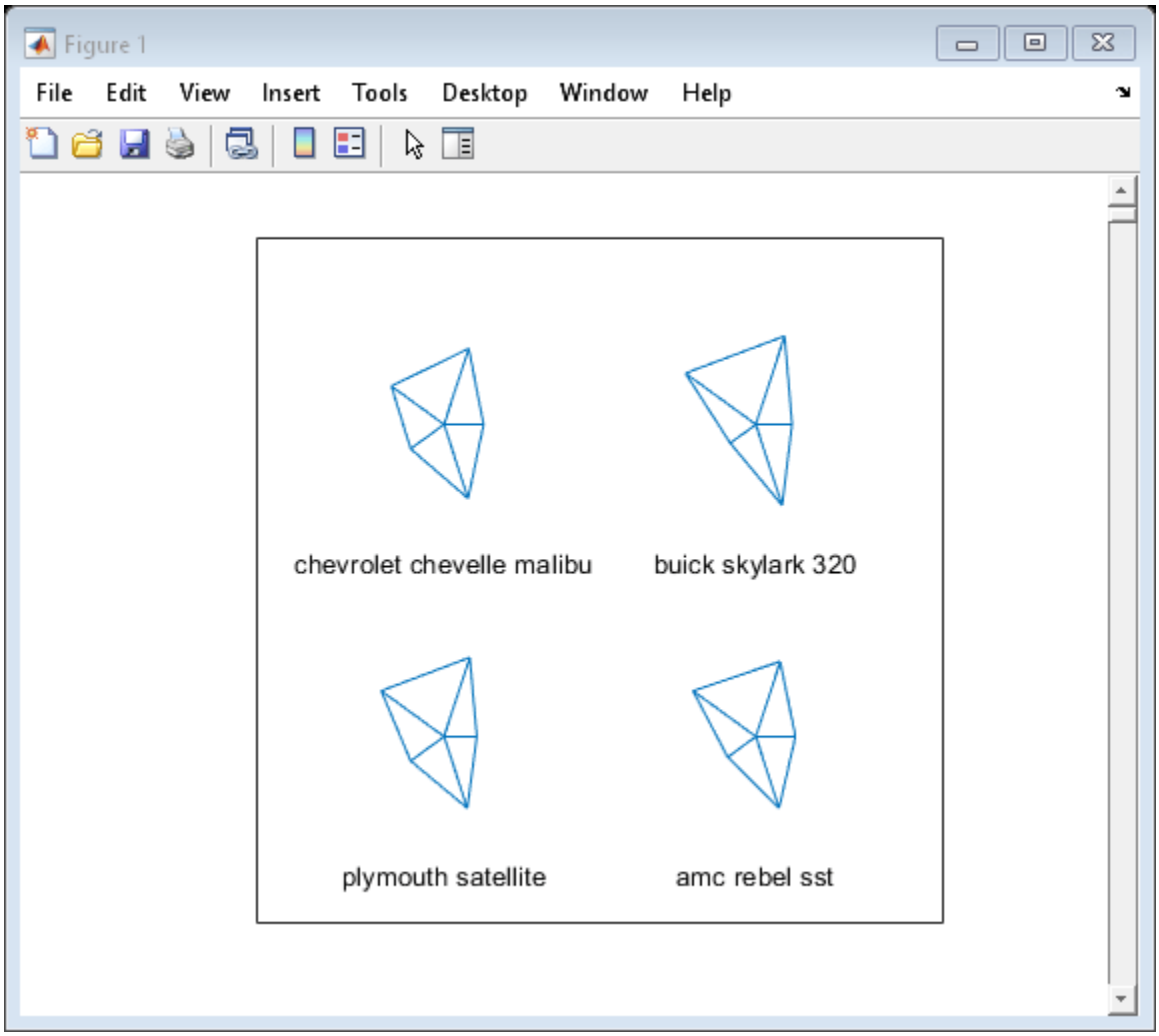
Star and Face Plots of Multivariate Data

Load the sample data.

```
load carsmall
X = [Acceleration Displacement Horsepower MPG Weight];
```

Create a star plot of the data in X . Standardize the data before plotting.

```
glyphplot(X,'standardize','column','obslabels',Model,'grid',[2 2],...
            'page','scroll');
```



Create a face plot of the data in X .

```
glyphplot(X,'glyph','face','obslabels',Model,'grid',[2 3],'page',9);
```

Introduced before R2006a

gmdistribution

Create Gaussian mixture model

Description

A `gmdistribution` object stores a Gaussian mixture distribution, also called a Gaussian mixture model (GMM), which is a multivariate distribution that consists of multivariate Gaussian distribution components. Each component is defined by its mean and covariance. The mixture is defined by a vector of mixing proportions, where each mixing proportion represents the fraction of the population described by a corresponding component.

Creation

You can create a `gmdistribution` model object in two ways.

- Use the `gmdistribution` function (described here) to create a `gmdistribution` model object by specifying the distribution parameters.
- Use the `fitgmdist` function to fit a `gmdistribution` model object to data given a fixed number of components.

Syntax

```
gm = gmdistribution(mu,sigma)
gm = gmdistribution(mu,sigma,p)
```

Description

`gm = gmdistribution(mu,sigma)` creates a `gmdistribution` model object using the specified means `mu` and covariances `sigma` with equal mixing proportions.

`gm = gmdistribution(mu,sigma,p)` specifies the mixing proportions of multivariate Gaussian distribution components.

Input Arguments

`mu` — Means
k-by-*m* numeric matrix

Means of multivariate Gaussian distribution components, specified as a *k*-by-*m* numeric matrix, where *k* is the number of components and *m* is the number of variables in each component. `mu(i,:)` is the mean of component `i`.

Data Types: `single` | `double`

`sigma` — Covariances
numeric vector | numeric matrix | numeric array

Covariances of multivariate Gaussian distribution components, specified as a numeric vector, matrix, or array.

Given that *k* is the number of components and *m* is the number of variables in each component, `sigma` is one of the values in this table.

Value	Description
m-by-*m*-by-*k* array	`sigma(:,:,i)` is the covariance matrix of component `i`.
1-by-*m*-by-*k* array	Covariance matrices are diagonal. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.
m-by-*m* matrix	Covariance matrices are the same across components.
1-by-*m* vector	Covariance matrices are diagonal and the same across components.

Data Types: `single` | `double`

`p` — Mixing proportions of mixture components
numeric vector of length *k*

Mixing proportions of mixture components, specified as a numeric vector of length *k*, where *k* is the number of components. The default is a row vector of (1/*k*)s, which sets equal proportions. If `p` does not sum to `1`, `gmdistribution` normalizes it.

Data Types: `single` | `double`

Properties

Distribution Parameters

`mu` — Means
k-by-*m* numeric matrix

This property is read-only.

Means of multivariate Gaussian distribution components, specified as a *k*-by-*m* numeric matrix, where *k* is the number of components and *m* is the number of variables in each component. `mu(i,:)` is the mean of component `i`.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `mu` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

`Sigma` — Covariances
numeric vector | numeric matrix | numeric array

This property is read-only.

Covariances of multivariate Gaussian distribution components, specified as a numeric vector, matrix, or array.

Given that *k* is the number of components and *m* is the number of variables in each component, `Sigma` is one of the values in this table.

Value	Description
m-by-*m*-by-*k* array	`Sigma(:,:,i)` is the covariance matrix of component `i`.
1-by-*m*-by-*k* array	Covariance matrices are diagonal. `Sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.
m-by-*m* matrix	Covariance matrices are the same across components.
1-by-*m* vector	Covariance matrices are diagonal and the same across components.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `sigma` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

`ComponentProportion` — Mixing proportions of mixture components
1-by-*k* numeric vector

This property is read-only.

Mixing proportions of mixture components, specified as a 1-by-*k* numeric vector.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `p` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

Distribution Characteristics

`CovarianceType` — Type of covariance matrices
`'diagonal'` | `'full'`

This property is read-only.

Type of covariance matrices, specified as either `'diagonal'` or `'full'`.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the type of covariance matrices in the `sigma` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the `'CovarianceType'` name-value pair argument of `fitgmdist` sets this property.

`DistributionName` — Distribution name
`'gaussian mixture distribution'` (default)

This property is read-only.

Distribution name, specified as `'gaussian mixture distribution'`.

`NumComponents` — Number of mixture components
positive integer

This property is read-only.

Number of mixture components, k, specified as a positive integer.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the input arguments `mu`, `sigma`, and `p` of `gmdistribution` set this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the `k` input argument of `fitgmdist` sets this property.

Data Types: `single` | `double`

`NumVariables` — Number of variables
positive integer

This property is read-only.

Number of variables in the multivariate Gaussian distribution components, m, specified as a positive integer.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the input arguments `mu`, `sigma`, and `p` of `gmdistribution` set this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the input data `X` of `fitgmdist` sets this property.

Data Types: `double`

`SharedCovariance` — Flag indicating shared covariance
`true` | `false`

This property is read-only.

Flag indicating whether a covariance matrix is shared across mixture components, specified as `true` or `false`.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the type of covariance matrices in the `sigma` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the `'SharedCovariance'` name-value pair argument of `fitgmdist` sets this property.

Data Types: `logical`

Properties for Fitted Object

The following properties apply only to a fitted object you create by using `fitgmdist`. The values of these properties are empty if you create a `gmdistribution` object by using the `gmdistribution` function.

`AIC` — Akaike Information Criterion
scalar

This property is read-only.

Akaike information criterion (AIC), specified as a scalar. `AIC = 2*NlogL + 2*p`, where `NlogL` is the negative loglikelihood (the `NegativeLogLikelihood` property) and `p` is the number of estimated parameters.

AIC is a model selection tool you can use to compare multiple models fit to the same data. AIC is a likelihood-based measure of model fit that includes a penalty for complexity, specifically, the number of parameters. When you compare multiple models, a model with a smaller value of AIC is better.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

`BIC` — Bayes Information Criterion
scalar

This property is read-only.

Bayes information criterion (BIC), specified as a scalar. `BIC = 2*NlogL + p*log(n)`, where `NlogL` is the negative loglikelihood (the `NegativeLogLikelihood` property), `n` is the number of observations, and `p` is the number of estimated parameters.

BIC is a model selection tool you can use to compare multiple models fit to the same data. BIC is a likelihood-based measure of model fit that includes a penalty for complexity, specifically, the number of parameters. When you compare multiple models, a model with the lowest BIC value is the best fitting model.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

`Converged` — Flag indicating convergence
`true` | `false`

This property is read-only.

Flag indicating whether the Expectation-Maximization (EM) algorithm is converged when fitting a Gaussian mixture model, specified as `true` or `false`.

You can change the optimization options by using the `'Options'` name-value pair argument of `fitgmdist`.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `logical`

`NegativeLogLikelihood` — Negative loglikelihood
scalar

This property is read-only.

Negative loglikelihood of the fitted Gaussian mixture model given the input data `X` of `fitgmdist`, specified as a scalar.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

`NumIterations` — Number of iterations
positive integer

This property is read-only.

Number of iterations in the Expectation-Maximization (EM) algorithm, specified as a positive integer.

You can change the optimization options, including the maximum number of iterations allowed, by using the `'Options'` name-value pair argument of `fitgmdist`.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `double`

`ProbabilityTolerance` — Tolerance for posterior probabilities
nonnegative scalar value in range `[0,1e-6]`

This property is read-only.

Tolerance for posterior probabilities, specified as a nonnegative scalar value in the range `[0,1e-6]`.

The `'ProbabilityTolerance'` name-value pair argument of `fitgmdist` sets this property.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

`RegularizationValue` — Regularization parameter value
nonnegative scalar

This property is read-only.

Regularization parameter value, specified as a nonnegative scalar.

The `'RegularizationValue'` name-value pair argument of `fitgmdist` sets this property.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

Object Functions

cdf	Cumulative distribution function for Gaussian mixture distribution
cluster	Construct clusters from Gaussian mixture distribution
mahal	Mahalanobis distance to Gaussian mixture component
pdf	Probability density function for Gaussian mixture distribution
posterior	Posterior probability of Gaussian mixture component
random	Random variate from Gaussian mixture distribution

Examples

Create Gaussian Mixture Distribution Using gmdistribution

Create a two-component bivariate Gaussian mixture distribution by using the `gmdistribution` function.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
mu = [1 2;-3 -5];
sigma = cat(3,[2 .5],[1 1]) % 1-by-2-by-2 array
```

```
sigma =
sigma(:,:,1) =

    2.0000    0.5000

sigma(:,:,2) =

     1     1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object. By default, the `gmdistribution` function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:     1     2

Component 2:
Mixing proportion: 0.500000
Mean:    -3    -5
```

List the properties of the `gm` object.

```
properties(gm)
```

```
Properties for class gmdistribution:

    NumVariables
    DistributionName
    NumComponents
    ComponentProportion
    SharedCovariance
    NumIterations
    RegularizationValue
    NegativeLogLikelihood
    CovarianceType
    mu
```

```
    Sigma
    AIC
    BIC
    Converged
    ProbabilityTolerance
```

You can access these properties by using dot notation. For example, access the `ComponentProportion` property, which represents the mixing proportions of mixture components.

```
gm.ComponentProportion
```

```
ans = 1×2

    0.5000    0.5000
```

A `gmdistribution` object has properties that apply only to a fitted object. The fitted object properties are `AIC`, `BIC`, `Converged`, `NegativeLogLikelihood`, `NumIterations`, `ProbabilityTolerance`, and `RegularizationValue`. The values of the fitted object properties are empty if you create an object by using the `gmdistribution` function and specifying distribution parameters. For example, access the `NegativeLogLikelihood` property by using dot notation.

```
gm.NegativeLogLikelihood
```

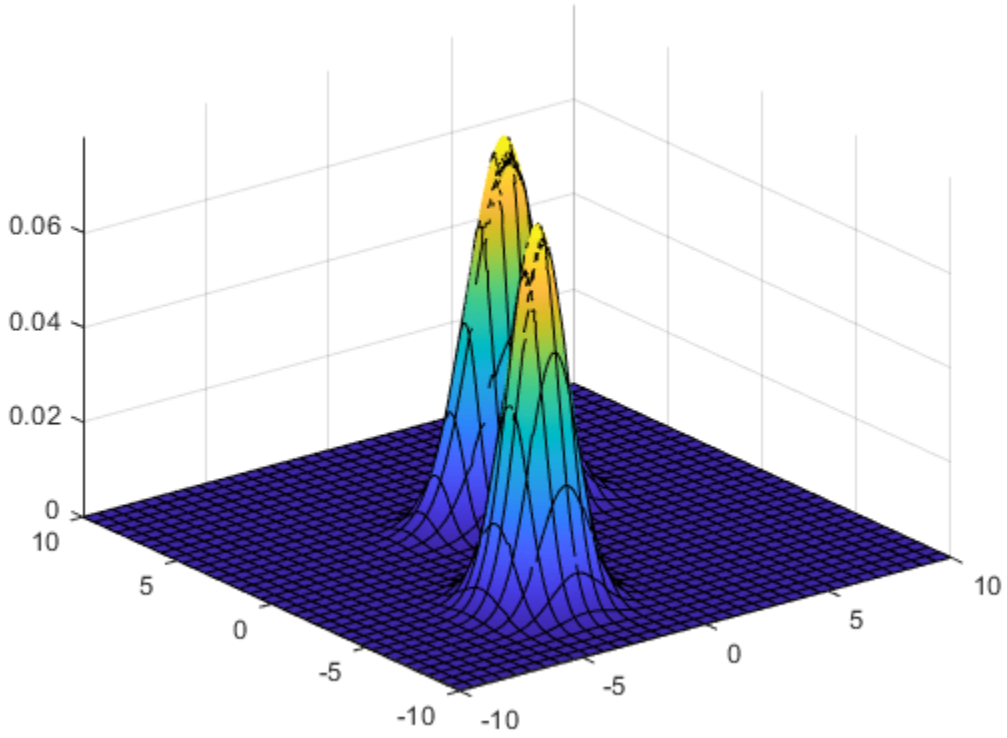
```
ans =

     []
```

After you create a `gmdistribution` object, you can use the object functions. Use `cdf` and `pdf` to compute the values of the cumulative distribution function (cdf) and the probability density function (pdf). Use `random` to generate random vectors. Use `cluster`, `mahal`, and `posterior` for cluster analysis.

Visualize the object by using `pdf` and `fsurf`.

```
gmPDF = @(x,y) arrayfun(@(x0,y0) pdf(gm,[x0 y0]),x,y);
fsurf(gmPDF,[-10 10])
```



Fit Gaussian Mixture Model to Data Using `fitgmdist`

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
mu1 = [1 2];           % Mean of the 1st component
sigma1 = [2 0; 0 .5]; % Covariance of the 1st component
mu2 = [-3 -5];         % Mean of the 2nd component
sigma2 = [1 0; 0 1];  % Covariance of the 2nd component
```

Generate an equal number of random variates from each component, and combine the two sets of random variates.

```
rng('default') % For reproducibility
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];
```

The combined data set X contains random variates following a mixture of two bivariate Gaussian distributions.

Fit a two-component GMM to X.

```
gm = fitgmdist(X,2)
```

```
gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:   -2.9617   -4.9727

Component 2:
Mixing proportion: 0.500000
Mean:    0.9539    2.0261
```

List the properties of the gm object.

```
properties(gm)
```

```
Properties for class gmdistribution:

    NumVariables
    DistributionName
    NumComponents
    ComponentProportion
    SharedCovariance
    NumIterations
    RegularizationValue
    NegativeLogLikelihood
    CovarianceType
    mu
    Sigma
    AIC
    BIC
    Converged
    ProbabilityTolerance
```

You can access these properties by using dot notation. For example, access the NegativeLogLikelihood property, which represents the negative loglikelihood of the data X given the fitted model.

```
gm.NegativeLogLikelihood
```

```
ans = 7.0584e+03
```

After you create a gmdistribution object, you can use the object functions. Use cdf and pdf to compute the values of the cumulative distribution function (cdf) and the probability density function (pdf). Use random to generate random variates. Use cluster, mahal, and posterior for cluster analysis.

Plot X by using scatter. Visualize the fitted model gm by using pdf and fcontour.

```
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
gmPDF = @(x,y) arrayfun(@(x0,y0) pdf(gm,[x0 y0]),x,y);
fcontour(gmPDF,[-8 6])
```

Introduced in R2007b

gname

Add case names to plot

Syntax

```
gname(cases)
gname
h = gname(cases,line_handle)
```

Description

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array, string array, or cell array of character vectors, in which each row of the character array or each element of the string array or cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a string array, cell array of character vectors, or character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

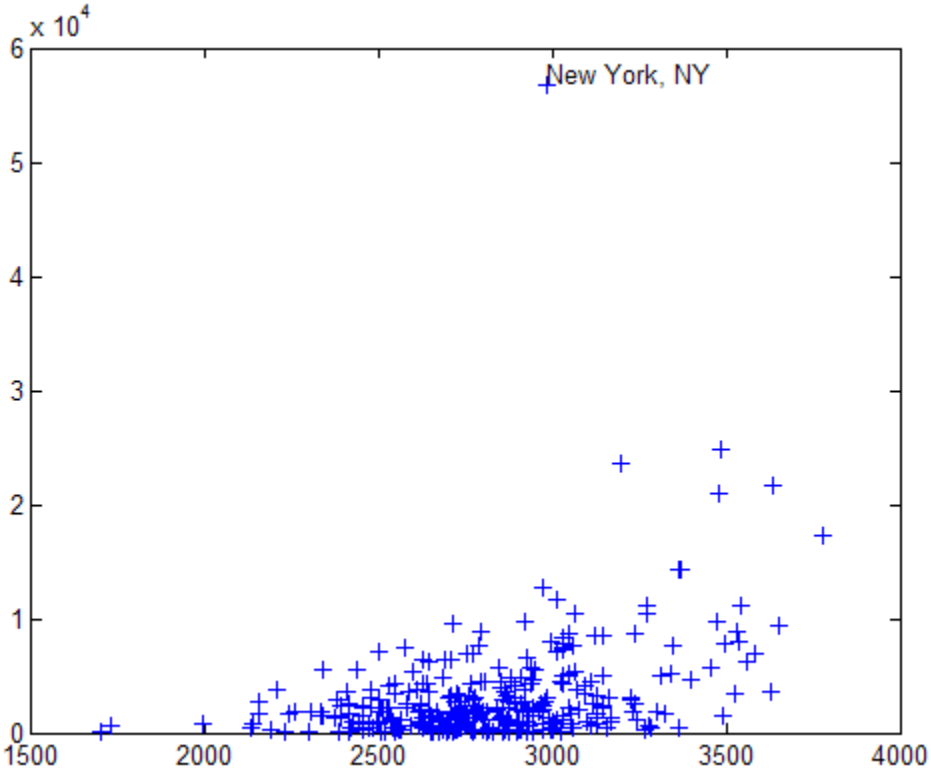
`h = gname(cases,line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

Examples

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```
load cities
education = ratings(:,6);
arts = ratings(:,7);
plot(education,arts,'+')
gname(names)
```



Click the point at the top of the graph to display its label, “New York.”

gpcdf

Generalized Pareto cumulative distribution function

Syntax

```
p = gpcdf(x,k,sigma,theta)
p = gpcdf(x,k,sigma,theta,'upper')
```

Description

`p = gpcdf(x,k,sigma,theta)` returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gpcdf(x,k,sigma,theta,'upper')` returns the complement of the cdf of the generalized Pareto (GP) distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`x > theta`, or, when

$k < 0$, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

gpfit

Generalized Pareto parameter estimates

Syntax

```
parmhat = gpfit(x)
[parmhat,parmci] = gpfit(x)
[parmhat,parmci] = gpfit(x,alpha)
[...] = gpfit(x,alpha,options)
```

Description

`parmhat = gpfit(x)` returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in `x`. `parmhat(1)` is the tail index (shape) parameter, `k` and `parmhat(2)` is the scale parameter, `sigma`. `gpfit` does not fit a threshold (location) parameter.

`[parmhat,parmci] = gpfit(x)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gpfit(x,alpha)` returns `100(1-alpha)`% confidence intervals for the parameter estimates.

`[...] = gpfit(x,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gpfit')` for parameter names and default values.

Other functions for the generalized Pareto, such as `gpcdf` allow a threshold parameter, `theta`. However, `gpfit` does not estimate theta. It is assumed to be known, and subtracted from `x` before calling `gpfit`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`k > theta`, or, when $k < 0$, for

$$0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$$

gpinv

Generalized Pareto inverse cumulative distribution function

Syntax

```
x = gpinv(p,k,sigma,theta)
```

Description

`x = gpinv(p,k,sigma,theta)` returns the inverse cdf for a generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter `theta`, evaluated at the values in `p`. The size of `x` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`x > theta`, or, when

$k < 0$, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

gplike

Generalized Pareto negative loglikelihood

Syntax

```
nlogL = gplike(params,data)
[nlogL,acov] = gplike(params,data)
```

Description

`nlogL = gplike(params,data)` returns the negative of the loglikelihood `nlogL` for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters `params`. `params(1)` is the tail index (shape) parameter, `k`, and `params(2)` is the scale parameter. `gplike` does not allow a threshold (location) parameter.

`[nlogL,acov] = gplike(params,data)` returns the inverse of Fisher's information matrix, `acov`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `acov` are their asymptotic variances. `acov` is based on the observed Fisher's information, not the expected information.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for

`x > theta`, or, when

$k < 0$, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

gppdf

Generalized Pareto probability density function

Syntax

```
p = gppdf(x,k,sigma,theta)
```

Description

`p = gppdf(x,k,sigma,theta)` returns the pdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

`k < 0`, $0 \le \frac{x-\theta}{\sigma} \le -\frac{1}{k}$.

gplotmatrix

Matrix of scatter plots by group

Syntax

```
gplotmatrix(X,[],group)
gplotmatrix(X,Y,group)
gplotmatrix(X,Y,group,clr,sym,siz)
gplotmatrix(X,Y,group,clr,sym,siz,doleg)
gplotmatrix(X,[],group,clr,sym,siz,doleg,dispopt)
gplotmatrix(X,[],group,clr,sym,siz,doleg,dispopt,xnam)
gplotmatrix(X,Y,group,clr,sym,siz,doleg,[],xnam,ynam)

gplotmatrix(parent,___)

[h,ax,bigax] = gplotmatrix(___)
```

Description

`gplotmatrix(X,[],group)` creates a matrix of scatter plots and histograms of the data in `X`, grouped by the grouping variable in `group`. Each off-diagonal plot in the resulting figure is a scatter plot of a column of `X` against another column of `X`. The software also plots the outlines of the grouped histograms in the diagonal plots of the plot matrix. `X` and `group` must have the same number of rows.

`gplotmatrix(X,Y,group)` creates a matrix of scatter plots. Each plot in the resulting figure is a scatter plot of a column of `X` against a column of `Y`. For example, if `X` has p columns and `Y` has q columns, then the figure contains a q-by-p matrix of scatter plots. All plots are grouped by the grouping variable `group`. The input arguments `X`, `Y`, and `group` must all have the same number of rows.

`gplotmatrix(X,Y,group,clr,sym,siz)` specifies the marker color `clr`, symbol `sym`, and size `siz` for each group.

`gplotmatrix(X,Y,group,clr,sym,siz,doleg)` controls whether a legend is displayed in the figure. `gplotmatrix` creates a legend by default.

`gplotmatrix(X,[],group,clr,sym,siz,doleg,dispopt)` controls the display options for the diagonal plots in the plot matrix of `X`.

`gplotmatrix(X,[],group,clr,sym,siz,doleg,dispopt,xnam)` labels the x-axes and y-axes of the scatter plots using the column names specified in `xnam`. The input argument `xnam` must contain one name for each column of `X`. Set `dispopt` to `'variable'` to display the variable names along the diagonal of the scatter plot matrix.

`gplotmatrix(X,Y,group,clr,sym,siz,doleg,[],xnam,ynam)` labels the x-axes and y-axes of the scatter plots using the column names specified in `xnam` and `ynam`. The input arguments `xnam` and `ynam` must contain one name for each column of `X` and `Y`, respectively.

`gplotmatrix(parent,___)` creates the scatter plot matrix in the figure or panel specified by `parent`. Specify `parent` as the first input argument followed by any of the input argument combinations in the previous syntaxes.

`[h,ax,bigax] = gplotmatrix( ___ )` returns graphics handles to the individual plots and the entire scatter plot matrix.

You can pass in `[]` for `clr`, `sym`, `siz`, `doleg`, and `dispopt` to use their default values.

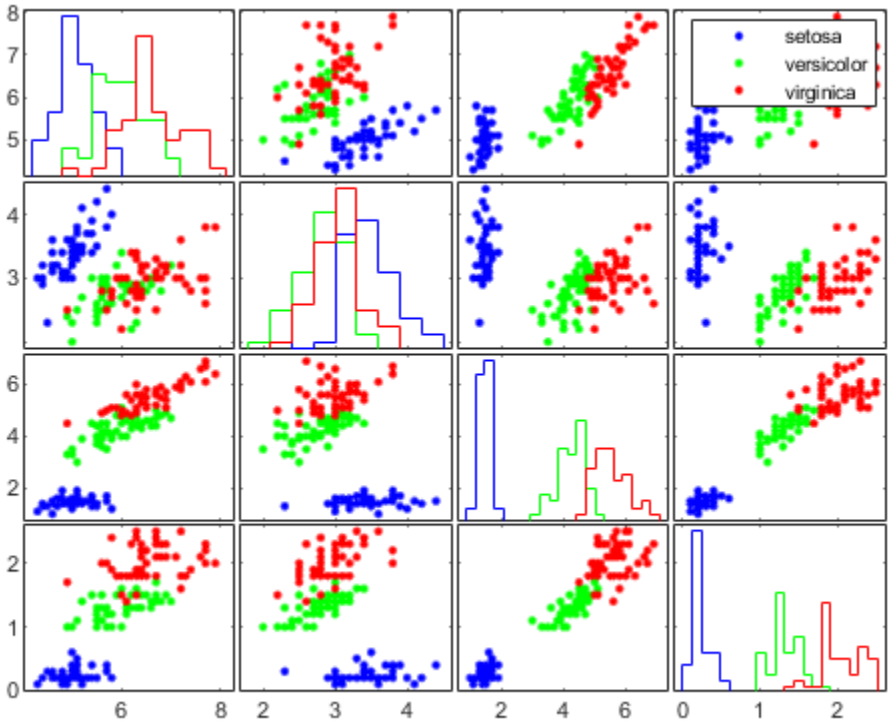
Examples

Scatter Plots with Grouped Data

Create a matrix of scatter plots for each combination of variables in a data set. Group the data according to a separate variable.

Load the `fisheriris` data set, which contains flower data. The four columns of `meas` are the sepal length, sepal width, petal length, and petal width of the flowers. `species` contains the flower species names: setosa, versicolor, and virginica. Visually compare the flower measurements across flower species.

```
load fisheriris
gplotmatrix(meas,[],species)
```



In the matrix of scatter plots, the x-axis of the leftmost column of scatter plots corresponds to sepal length, the first column in `meas`. Similarly, the y-axis of the bottom row of scatter plots corresponds to petal width, the last column in `meas`. Therefore, the scatter plot in the bottom left of the matrix compares sepal length values (along the x-axis) to petal width values (along the y-axis). The color of each point depends on the species of the flower.

The diagonal plots are histograms rather than scatter plots. For example, the plot in the top left of the matrix shows the distribution of sepal length values for each species of flower.

Create Scatter Plot Matrix with Subset of Variables

Create scatter plots comparing a subset of the variables in a data set to another subset of variables. Group the data according to a separate variable.

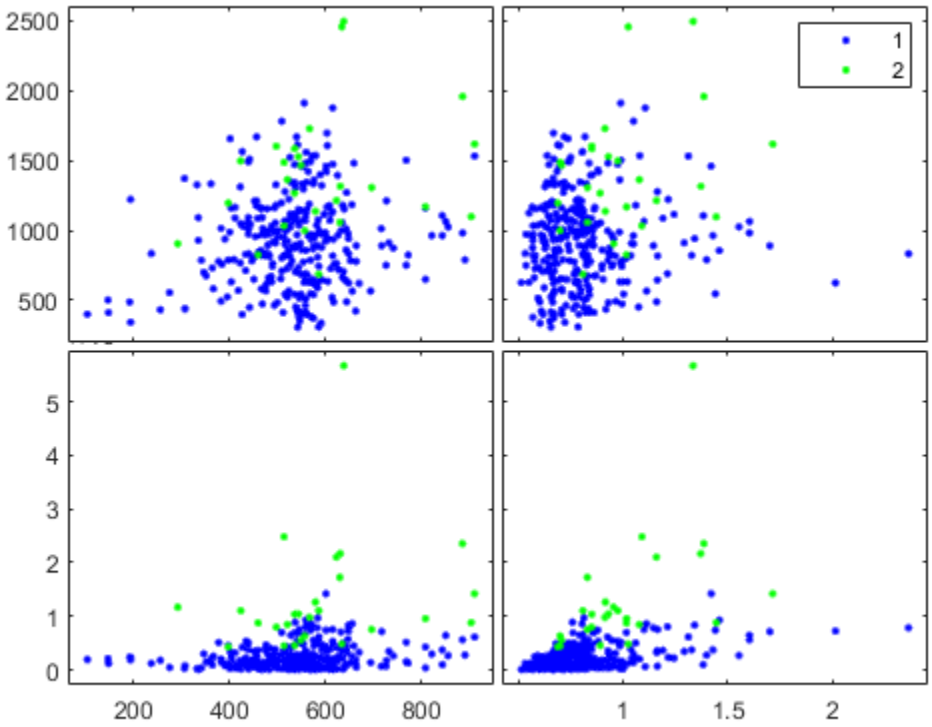
Load the `discrim` data set.

```
load discrim
```

The `ratings` array contains rating values of 329 US cities for the nine categories listed in the `categories` array. The `group` array contains a city size code that is equal to `2` for the 26 largest cities, and `1` otherwise.

Create a matrix of scatter plots to compare the first two categories, `climate` and `housing`, with the fourth and seventh categories, `crime` and `arts`. Specify `group` as the grouping variable to visually distinguish the data for large and small cities.

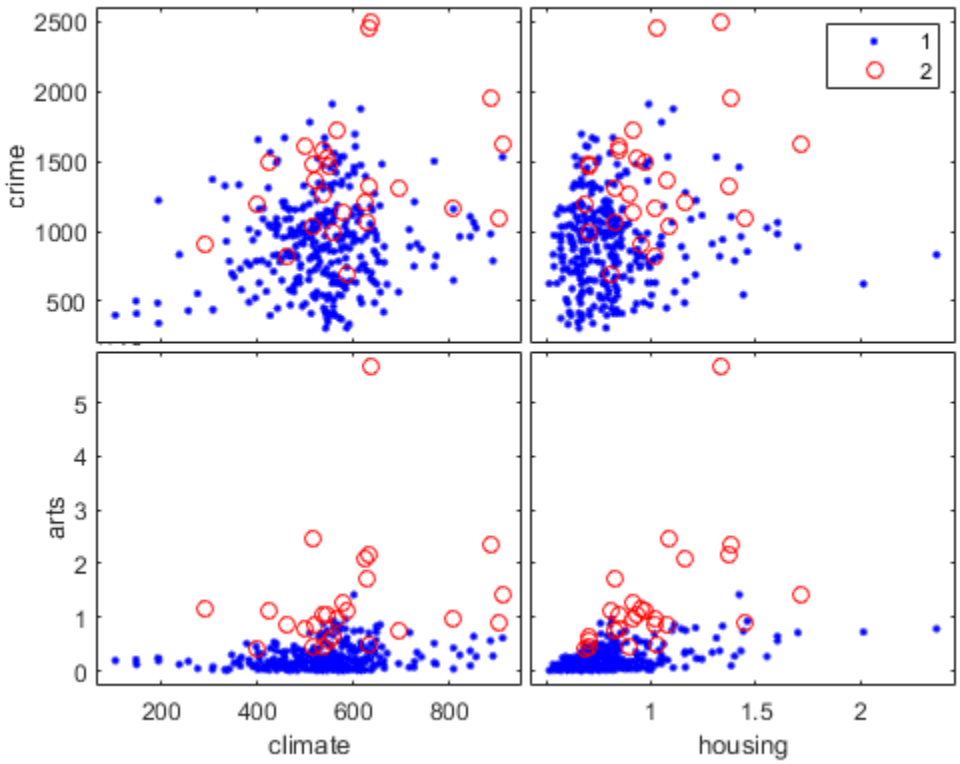
```
X = ratings(:,1:2);
Y = ratings(:,[4 7]);
gplotmatrix(X,Y,group)
```



The matrix of scatter plots shows the specified comparisons, with each city size group represented by a different color.

Adjust the appearance of the plots by specifying marker colors and symbols, and labeling the axes with the rating categories.

```
xnames = categories(1:2,:);
ynames = categories([4 7],:);
gplotmatrix(X,Y,group,'br','.o',[],'on',[],xnames,ynames)
```



Scatter Plot Matrix with Multiple Grouping Variables

Create a matrix of scatter plots comparing data variables by using two grouping variables.

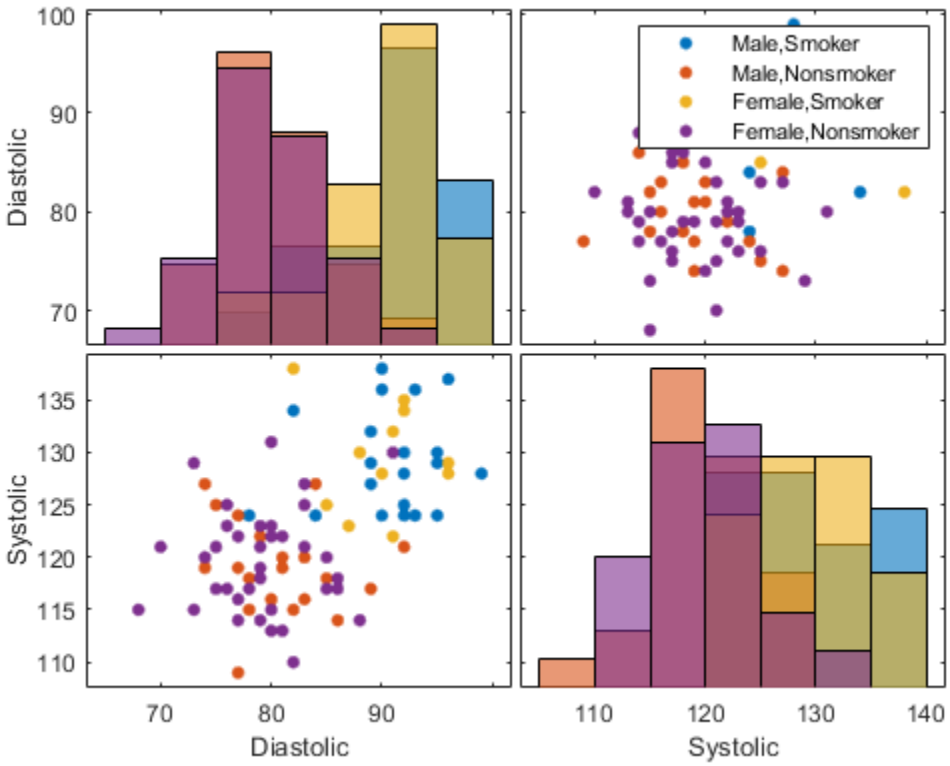
Load the `patients` data set. Compare patient diastolic and systolic blood pressure values. Group the patients according to their gender and smoker status. Convert `Smoker` to a categorical variable to have more descriptive labels in the legend. Display grouped histograms along the diagonal of the plot matrix by using the `'grpbars'` display option, and label the axes.

```
load patients
X = [Diastolic Systolic];
labeledSmoker = categorical(Smoker,[true false],{'Smoker','Nonsmoker'});
group = {Gender,labeledSmoker};
color = lines(4)
```

```
color = 4×3

         0    0.4470    0.7410
    0.8500    0.3250    0.0980
    0.9290    0.6940    0.1250
    0.4940    0.1840    0.5560
```

```
xnames = {'Diastolic','Systolic'};
gplotmatrix(X,[],group,color,[],[],[],'grpbars',xnames)
```



For example, the scatter plot in the bottom left of the matrix shows that smokers (blue and yellow markers) tend to have higher diastolic and systolic blood pressure values, regardless of gender.

Modify Scatter Plot Matrix Appearance

Create a matrix of scatter plots that display grouped data. Modify the appearance of one of the scatter plots.

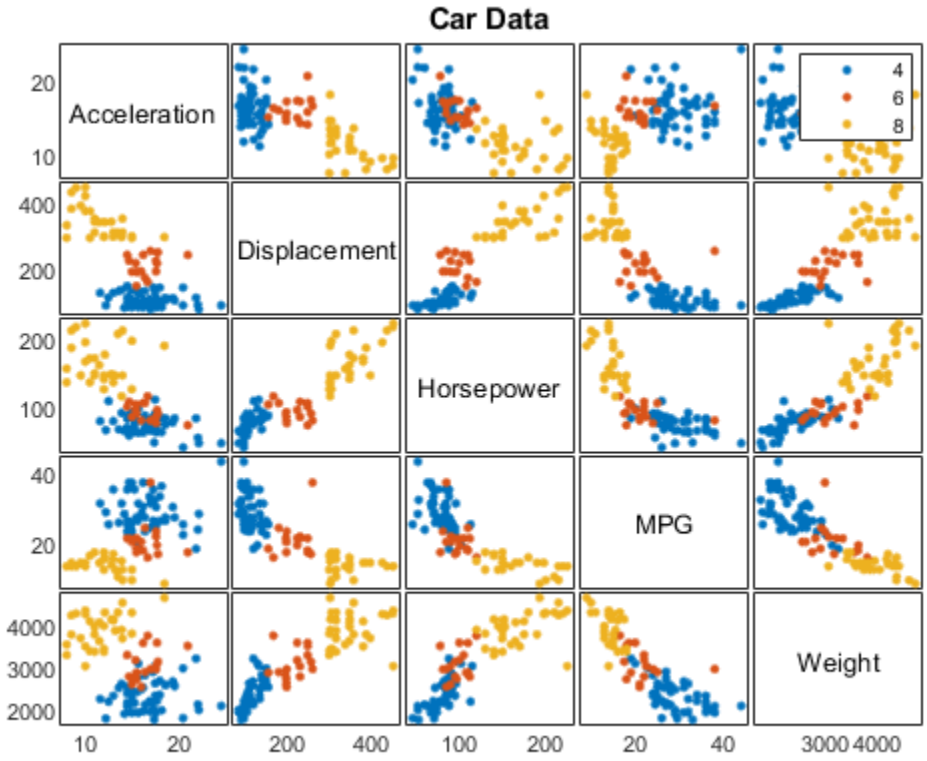
Load the `carsmall` data set. Create a scatter plot matrix using different car measurements. Group the cars by the number of cylinders. Specify the group colors, and display the car variable names along the diagonal of the plot matrix. Add a title to the plot matrix.

```
load carsmall
X = [Acceleration Displacement Horsepower MPG Weight];
color = lines(3)
```

```
color = 3×3

         0    0.4470    0.7410
    0.8500    0.3250    0.0980
    0.9290    0.6940    0.1250
```

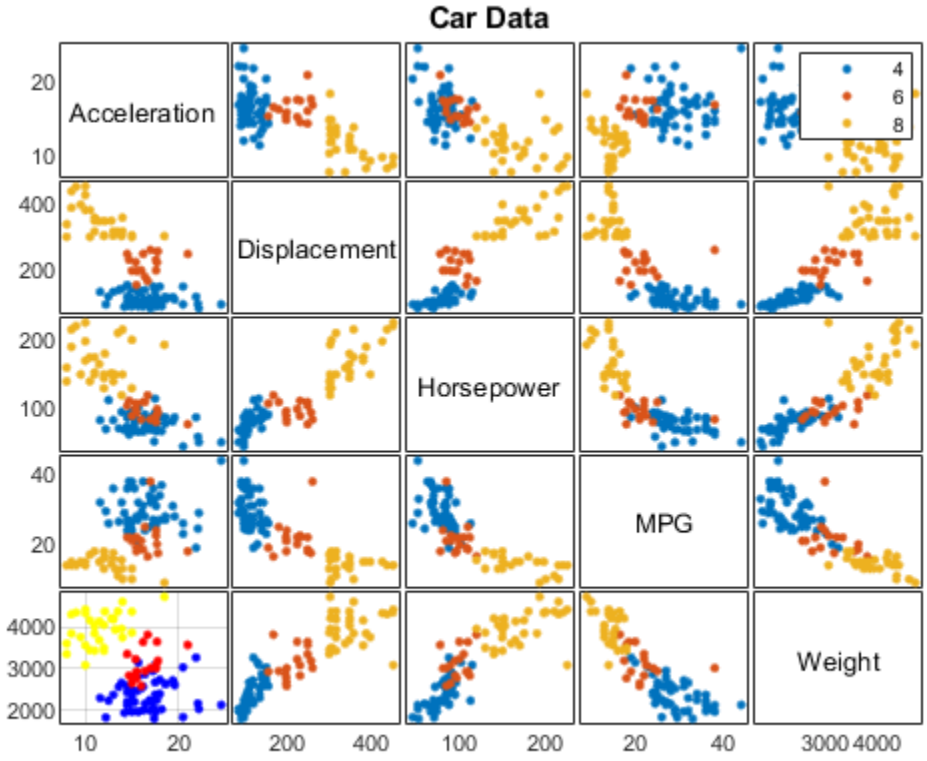
```
xnames = {'Acceleration','Displacement','Horsepower','MPG','Weight'};
[h,ax] = gplotmatrix(X,[],Cylinders,color,[],[],[],'variable',xnames);
title('Car Data')
```



Change the appearance of the scatter plot in the bottom left of the matrix by using `h` and `ax`. First, change the colors of the data points in the scatter plot. Then, add grid lines to the scatter plot.

```
bottomleftPlot = h(5,1,:);
bottomleftPlot(1).Color = 'blue';
bottomleftPlot(2).Color = 'red';
bottomleftPlot(3).Color = 'yellow';

bottomleftAxes = ax(5,1);
bottomleftAxes.XGrid = 'on';
bottomleftAxes.YGrid = 'on';
```



Input Arguments

X — Input data

numeric matrix | datetime array | duration array

Input data, specified as an *n*-by-*p* numeric matrix, datetime array, or duration array. `gplotmatrix` creates a matrix of plots using the columns of `X`. If you do not specify an additional input matrix `Y`, then `gplotmatrix` creates a *p*-by-*p* matrix of plots. The off-diagonal plots are scatter plots, and the diagonal plots depend on the value of `dispopt`. In each scatter plot, `gplotmatrix` plots one column of `X` against another column of `X`. The points in the scatter plots are grouped according to `group`.

If you specify `Y`, then `gplotmatrix` creates a *q*-by-*p* matrix of scatter plots using the *p* columns of `X` and the *q* columns of `Y`.

Data Types: `single` | `double` | `datetime` | `duration`

Y — Input data

numeric matrix | datetime array | duration array

Input data, specified as an *n*-by-*q* numeric matrix, datetime array, or duration array. `gplotmatrix` creates a *q*-by-*p* matrix of scatter plots using the *p* columns of `X` and the *q* columns of `Y`. For each column of the plot matrix, the *x*-axis values of the scatter plots are the same as the values in the corresponding column of `X`. Similarly, for each row of the plot matrix, the *y*-axis values of the scatter plots are the same as the values in the corresponding column of `Y`. The points in the scatter plots are grouped according to `group`.

X and Y must have the same number of rows.

Data Types: `single` | `double` | `datetime` | `duration`

`group` — Grouping variable

categorical vector | numeric vector | logical vector | character array | string array | cell array

Grouping variable, specified as a categorical vector, numeric vector, logical vector, character array, string array, or cell array of character vectors. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. In any case, `group` must have the same number of rows as X. Points in the same group appear on the graph with the same marker color, symbol, and size.

Example:
```
categorical({'blue','red','yellow','blue','yellow','red','red','yellow','blue
','red'})
```

Example: `{Smoker,Gender}` where `Smoker` and `Gender` are grouping variables

Data Types: `categorical` | `single` | `double` | `logical` | `char` | `string` | `cell`

`clr` — Marker colors

character vector | string scalar | string array | cell array of character vectors | matrix of RGB values

Marker colors, specified as one of the following:

- Character vector or string scalar of color short names.
- String array or cell array of character vectors designating color names or short names.
- Three-column matrix of RGB values in the range [0,1]. The three columns represent the R (red) value, G (green) value, and B (blue) value.

You can choose among these predefined colors and their equivalent RGB triplets.

Color Name	Short Name	RGB Triplet	Appearance
`'red'`	`'r'`	`[1 0 0]`	
`'green'`	`'g'`	`[0 1 0]`	
`'blue'`	`'b'`	`[0 0 1]`	
`'cyan'`	`'c'`	`[0 1 1]`	
`'magenta'`	`'m'`	`[1 0 1]`	
`'yellow'`	`'y'`	`[1 1 0]`	
`'black'`	`'k'`	`[0 0 0]`	
`'white'`	`'w'`	`[1 1 1]`	

When the total number of groups exceeds the number of specified colors, `gplotmatrix` cycles through the specified colors.

Example: `{'blue','black','green'}`

Example: `[0 0 1; 0 0.5 0.5; 0.5 0.5 0.5]`

Data Types: `char` | `string` | `cell` | `single` | `double`

`sym` — Marker symbols

`'.'` (default) | character vector | string scalar

Marker symbols, specified as a character vector or string scalar.

You can choose among these marker options.

Value	Description
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'s'`	Square
`'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'p'`	Five-pointed star (pentagram)
`'h'`	Six-pointed star (hexagram)
`'none'`	No markers

By default, `gplotmatrix` assigns `'.'` as the marker symbol for each group. When the total number of groups exceeds the number of specified symbols, `gplotmatrix` cycles through the specified symbols.

Example: `'x'`

Example: `'xo+'`

Data Types: `char` | `string`

`siz` — Marker sizes

positive numeric vector

Marker sizes, specified as a positive numeric vector. The default value is determined by the number of observations. When the total number of groups exceeds the number of specified sizes, `gplotmatrix` cycles through the specified sizes.

Example: `[6 12]`

Data Types: `single` | `double`

`doleg` — Option to include legend

`'on'` (default) | `'off'`

Option to include a legend, specified as either `'on'` or `'off'`. By default, the legend is displayed in the figure.

dispopt — Display options for diagonal plots
'stairs' (default) | 'hist' | 'grpbars' | 'none' | 'variable'

Display options for the diagonal plots in the plot matrix, specified as 'stairs', 'hist','grpbars', 'none', or 'variable'. This table describes the different display options.

Value	Description
'stairs'	Plot the outlines of grouped histograms.
'hist'	Plot histograms.
'grpbars'	Plot grouped histograms.
'none'	Display blank plots.
'variable'	Display variable names. To use this display option, you must specify xnam.

The default is 'stairs' when group contains more than one group. Otherwise, gplotmatrix displays a single histogram in each diagonal plot.

To generate the histograms, gplotmatrix uses the 'pdf' type of normalization for numeric data and the 'count' type of normalization for datetime and duration data. (See the 'Normalization' name-value pair argument of histogram.) Note that the y-axis tick mark labels do not apply to the histograms. Use data tips to see the correct histogram values.

xnam — X column names
character array | string array | cell array of character vectors

X column names, specified as a character array, string array, or cell array of character vectors. xnam must contain one name for each column of X.

Example: {'Sepal Length','Sepal Width','Petal Length','Petal Width'}

Data Types: char | string | cell

ynam — Y column names
character array | string array | cell array of character vectors

Y column names, specified as a character array, string array, or cell array of character vectors. ynam must contain one name for each column of Y.

Example: {'Diastolic','Systolic'}

Data Types: char | string | cell

parent — Parent container
Figure object | Panel object

Parent container, specified as a Figure or Panel object.

Output Arguments

h — Line handles to individual plots
array of Line and Histogram objects

Line handles to individual plots, returned as a one of these arrays:

- *p*-by-*p*-by-*k* array of `Line` and `Histogram` objects if you do not specify `Y`
- *q*-by-*p*-by-*k* array of `Line` objects if you specify both `X` and `Y`

p is the number of columns in `X`, *q* is the number of columns in `Y`, and *k* is the number of unique groups in `group`.

Each scatter plot has *k* corresponding `Line` objects in `h`, and each histogram has *k* corresponding `Histogram` objects in `h`.

ax — Axes handles to individual plots
matrix of `Axes` objects

Axes handles to individual plots, returned as a matrix of `Axes` objects. If `dispopt` is `'hist'`, `'stairs'`, or `'grpbars'`, then `ax` contains one extra row of handles to invisible axes where the histograms are plotted.

bigax — Axes handle to entire plot matrix
`Axes` object

Axes handle to the entire plot matrix, returned as an `Axes` object. `bigax` points to the current axes, so a subsequent `title`, `xlabel`, or `ylabel` command produces labels that are centered with respect to the entire plot matrix.

gprnd

Generalized Pareto random numbers

Syntax

```
r = gprnd(k,sigma,theta)
r = gprnd(k,sigma,theta,m,n,...)
R = gprnd(K,sigma,theta,[m,n,...])
```

Description

`r = gprnd(k,sigma,theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`. The size of `r` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `r` is the size of the other parameters.

`r = gprnd(k,sigma,theta,m,n,...)` or `R = gprnd(K,sigma,theta,[m,n,...])` generates an `m`-by-`n`-by-... array. The `k`, `sigma`, `theta` parameters can each be scalars or arrays of the same size as `r`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$0 \le \frac{x-\theta}{\sigma} \le -\frac{1}{k}$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

gpstat

Generalized Pareto mean and variance

Syntax

```
[m,v] = gpstat(k,sigma,theta)
```

Description

`[m,v] = gpstat(k,sigma,theta)` returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`.

The default value for `theta` is 0.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. When $k \geq 0$, the GP has positive density for `x > theta`, or when

$k < 0$, $0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$.

growTrees

Class: `TreeBagger`

Train additional trees and add to ensemble

Syntax

```
B = growTrees(B,ntrees)
B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)
```

Description

`B = growTrees(B,ntrees)` grows `ntrees` new trees and appends them to those trees already stored in the ensemble `B`.

`B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

`'NumPrint'`	Specifies that a diagnostic message showing training progress should display after every `value` training cycles (grown trees). Default is no diagnostic messages.

`'Options'`	A `struct` that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:
	• `'UseParallel'` — If `true` and Parallel Computing Toolbox is installed, then the software uses an existing parallel pool for parallel trees, or, depending on parallel preferences, the software opens and uses a new pool if none is currently open. Otherwise, the software computes in serial. Default is `false`, meaning serial computation.
	For dual-core systems and above, `TreeBagger` parallelizes training using Intel Threading Building Blocks (TBB). Therefore, using the `'UseParallel'` option on a single computer may not speed up computation much and may consume more memory than in serial. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.
	• `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
	• `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `growTrees` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
	  • `UseParallel` is `true`
	  • `UseSubstreams` is `false`
	In that case, use a cell array the same size as the Parallel pool.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

grp2idx

Create index vector from grouping variable

Syntax

```
[g,gN] = grp2idx(s)
[g,gN,gL] = grp2idx(s)
```

Description

`[g,gN] = grp2idx(s)` creates an index vector `g` from the grouping variable `s`. The output `g` is a vector of integer values from 1 up to the number *K* of distinct groups. `gN` is a cell array of character vectors representing the list of group names.

`[g,gN,gL] = grp2idx(s)` also returns a column vector `gL` representing the list of the group levels with the same data type as `s`.

Examples

Create Index Vector from Categorical Vector

Create a categorical vector by using `discretize` and convert it to an index vector by using `grp2idx`.

Load the `hospital` data set and convert the ages in `hospital.Ages` to categorical values representing the ages by decade.

```
load hospital
edges = 0:10:100; % Bin edges
labels = strcat(num2str((0:10:90)','%d'),{'s'}); % Labels for the bins
s = discretize(hospital.Age,edges,'Categorical',labels);
```

Display the ages and the groups of ages for the first five samples.

```
ages = hospital.Age(1:5)
```

```
ages = 5×1

    38
    43
    38
    40
    49
```

```
groups = s(1:5)
```

```
groups = 5x1 categorical
     30s
     40s
     30s
```

```
     40s
     40s
```

Create an index vector from the categorical vector `s`.

```
[g,gN,gL] = grp2idx(s);
```

Display the index values corresponding to the first five samples.

```
g(1:5)
```

```
ans = 5×1

     4
     5
     4
     5
     5
```

Reproduce the input argument `s` using the output `gL`.

```
gL(g(1:5))
```

```
ans = 5x1 categorical
     30s
     40s
     30s
     40s
     40s
```

Use `gN(g)` to reproduce the input argument `s` as a cell array of character vectors.

```
gN(g(1:5))
```

```
ans = 5x1 cell
    {'30s'}
    {'40s'}
    {'30s'}
    {'40s'}
    {'40s'}
```

Input Arguments

`s` — Grouping variable

categorical vector | numeric vector | logical vector | `datetime` vector | duration vector | string array | cell array of character vectors | character array

Grouping variable, specified as a categorical, numeric, logical, `datetime`, or duration vector, a string array, a cell array of character vectors, or a character array with each row representing a group label.

`grp2idx` treats `NaN`s (numeric, duration, or logical), `''` (empty character arrays or cell arrays of character vectors), `""` (empty strings), `<missing>` values (string), `<undefined>` values

(categorical), and NaTs (`datetime`) in `s` as missing values and returns `NaN`s in the corresponding rows of `g`. The outputs `gN` and `gL` do not include entries for missing values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `cell` | `categorical` | `datetime` | `duration`

Output Arguments

`g` — Group index

positive integer vector

Group index, returned as a positive integer vector with values from 1 up to the number K of distinct groups in `s`.

`gN` — List of group names

cell array of character vectors

List of group names, returned as a cell array of character vectors.

The order of `gN` depends on the data type of the grouping variable `s`.

- For numeric and logical vectors, the order is the sorted order of `s`.
- For categorical vectors, the order is the order of `categories(s)`.
- For other data types, the order is the order of first appearance in `s`.

`gN(g)` reproduces the contents of `s` in a cell array.

`gL` — List of group levels

categorical vector | numeric vector | logical vector | `datetime` vector | duration vector | cell array of character vectors | character array

List of group levels, returned as the same data type as `s`: a categorical, numeric, logical, `datetime`, or duration vector, a cell array of character vectors, or a character array with each row representing a group label. (The software treats string arrays as cell arrays of character vectors.)

The set of groups and their order in `gL` are the same as those in `gN`, but `gL` has the same data type as `s`.

If `s` is a character matrix, then `gL(g,:)` reproduces `s`; otherwise, `gL(g)` reproduces `s`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `s` can be a numeric, logical, or character vector or a cell array of character vectors. Code generation does not support a categorical, `datetime`, or duration vector or a string array for the input argument.
- In the generated code, the second and third outputs, `gN` and `gL`, are identical. `gN` and `gL` have the same data type as the input argument `s`.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Grouping Variables” on page 2-45

Introduced before R2006a

grpstats

Summary statistics organized by group

Syntax

```
statarray = grpstats(tbl,groupvar)
statarray = grpstats(tbl,groupvar,whichstats)
statarray = grpstats(tbl,groupvar,whichstats,Name,Value)

means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)

grpstats(X,group,alpha)
```

Description

`statarray = grpstats(tbl,groupvar)` returns a table or dataset array with the means for the data groups specified in `tbl` determined by the values of the grouping variable or variables specified in `groupvar`.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character vector or string scalar), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a string array or cell array of character vectors containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in `tbl` (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`.

`statarray = grpstats(tbl,groupvar,whichstats)` returns the group values for the summary statistics types specified in `whichstats`.

`statarray = grpstats(tbl,groupvar,whichstats,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`means = grpstats(X,group)` returns a column vector or matrix with the means of the groups of the data in the matrix or vector `X` determined by the values of the grouping variable or variables, `group`. The rows of `means` correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in `means` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character vector or string scalar), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `group` is a string array or cell array of grouping variables, then there is a row in `means` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.

- If X is a matrix, then means is a matrix with the same number of columns as X. Each column of means has the group means for the corresponding column of X.

[stats1,...,statsN] = grpstats(X,group,whichstats) returns column vectors or arrays with group values for the summary statistic types specified in whichstats.

[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha) specifies the significance level for confidence and prediction intervals.

grpstats(X,group,alpha) plots the means of the groups of data in the vector or matrix X determined by the values of the grouping variable, group. The grouping variable values are on the horizontal plot axis. Each group mean has 100×(1 – alpha)% confidence intervals.

- If X is a matrix, then grpstats plots the means and confidence intervals for each column of X.
- If group is a cell array of grouping variables, then grpstats plots the means and confidence intervals for the groups of data in X determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

Examples

Dataset Array Summary Statistics Organized by Group

Load the sample data.

```
load('hospital')
```

The dataset array hospital has 100 observations and 7 variables.

Create a dataset array with only the variables Sex, Age, Weight, and Smoker.

```
dsa = hospital(:,{'Sex','Age','Weight','Smoker'});
```

Sex is a nominal array, with levels Male and Female. The variables Age and Weight have numeric values, and Smoker has logical values.

Compute the mean for the numeric and logical arrays, Age, Weight, and Smoker, grouped by the levels in Sex.

```
statarray = grpstats(dsa,'Sex')
```

```
statarray =
              Sex       GroupCount    mean_Age    mean_Weight    mean_Smoker
    Female    Female    53            37.717      130.47         0.24528
    Male      Male      47            38.915      180.53         0.44681
```

statarray is a dataset array with two rows, corresponding to the levels in Sex. GroupCount is the number of observations in each group. The means of Age, Weight, and Smoker, grouped by Sex, are given in mean_Age, mean_Weight, and mean_Smoker.

Compute the mean for Age and Weight, grouped by the values in Smoker.

```
statarray = grpstats(dsa,'Smoker','mean','DataVars',{'Age','Weight'})
```

```
statarray =
         Smoker    GroupCount    mean_Age    mean_Weight
    0    false     66             37.97      149.91
    1    true      34            38.882      161.94
```

In this case, not all variables in `dsa` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...
                     'DataVars','Weight')
```

```
statarray =
                Sex       Smoker    GroupCount    min_Weight    max_Weight
    Female_0    Female    false     40            111           147
    Female_1    Female    true      13            115           146
    Male_0      Male      false     26            158           194
    Male_1      Male      true      21            164           202
```

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

Specify the names for the columns in the output.

```
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...
          'DataVars','Weight','VarNames',{'Gender','Smoker',...
                    'GroupCount','LowestWeight','HighestWeight'})
```

```
statarray =
                Gender    Smoker    GroupCount    LowestWeight    HighestWeight
    Female_0    Female    false     40            111             147
    Female_1    Female    true      13            115             146
    Male_0      Male      false     26            158             194
    Male_1      Male      true      21            164             202
```

Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Age`, `Weight`, and `Smoker`.

```
dsa = hospital(:,{'Age','Weight','Smoker'});
```

The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, with no grouping.

```
statarray = grpstats(dsa,[],{'mean','min','max'})
```

```
statarray =
           GroupCount    mean_Age    min_Age    max_Age    mean_Weight
    All    100           38.28       25         50         154

           min_Weight    max_Weight    mean_Smoker    min_Smoker    max_Smoker
    All    111           202           0.34           false         true
```

The observation name `All` indicates that all observations in `dsa` were used to compute the summary statistics.

Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

```
load('carsmall')
```

All variables are measured for 100 cars. `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). `Cylinders` has three unique values, `4`, `6`, and `8`, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

```
means = grpstats(Acceleration,Origin)
```

```
means = 6×1

   14.4377
   18.0500
   15.8867
   16.3778
   16.6000
   15.5000
```

`means` is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

```
means = grpstats(Acceleration,{Origin,Cylinders})
```

```
means = 10×1

   17.0818
   16.5267
   11.6406
   18.0500
   15.9143
   15.5000
   16.3375
```

```
   16.7000
   16.6000
   15.5000
```

There are 18 possible combinations of grouping variable values because `Origin` has 6 unique values and `Cylinders` has 3 unique values. Only 10 of the possible combinations appear in the data, so `means` is a 10-by-1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.

```
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},{'mean','gname'})
```

```
means = 10×1

   17.0818
   16.5267
   11.6406
   18.0500
   15.9143
   15.5000
   16.3375
   16.7000
   16.6000
   15.5000

grps = 10x2 cell
    {'USA'    }    {'4'}
    {'USA'    }    {'6'}
    {'USA'    }    {'8'}
    {'France' }    {'4'}
    {'Japan'  }    {'4'}
    {'Japan'  }    {'6'}
    {'Germany'}    {'4'}
    {'Germany'}    {'6'}
    {'Sweden' }    {'4'}
    {'Italy'  }    {'4'}
```

The output `grps` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

Multiple Summary Statistics for a Matrix Organized by Group

Load the sample data.

```
load carsmall
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum and maximum acceleration grouped by country of origin.

```
[grpMin,grpMax,grp] = grpstats(Acceleration,Origin,{'min','max','gname'})
```

```
grpMin = 6×1

    8.0000
   15.3000
   13.9000
   12.2000
   15.7000
   15.5000

grpMax = 6×1

   22.2000
   21.9000
   18.2000
   24.6000
   17.5000
   15.5000

grp = 6x1 cell
    {'USA'    }
    {'France' }
    {'Japan'  }
    {'Germany'}
    {'Sweden' }
    {'Italy'  }
```

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

Plot Prediction Intervals for a New Observation in Each Group

Load the sample data.

```
load('carsmall')
```

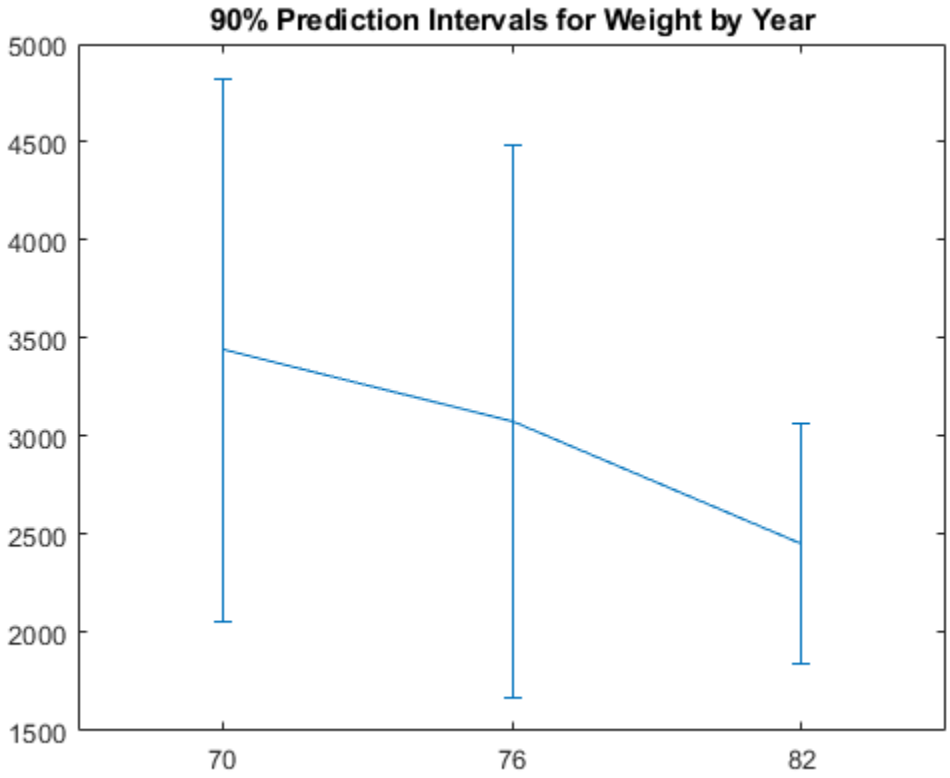
The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, `70`, `76`, and `82`, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```
[means,pred,grp] = grpstats(Weight,Model_Year,...
                      {'mean','predci','gname'},'Alpha',0.1);
```

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```
ngrps = length(grp); % Number of groups
errorbar((1:ngrps)',means,pred(:,2)-means)
xlim([0.5 3.5])
set(gca,'xtick',1:ngrps,'xticklabel',grp)
title('90% Prediction Intervals for Weight by Year')
```



Plot Group Means and Confidence Intervals

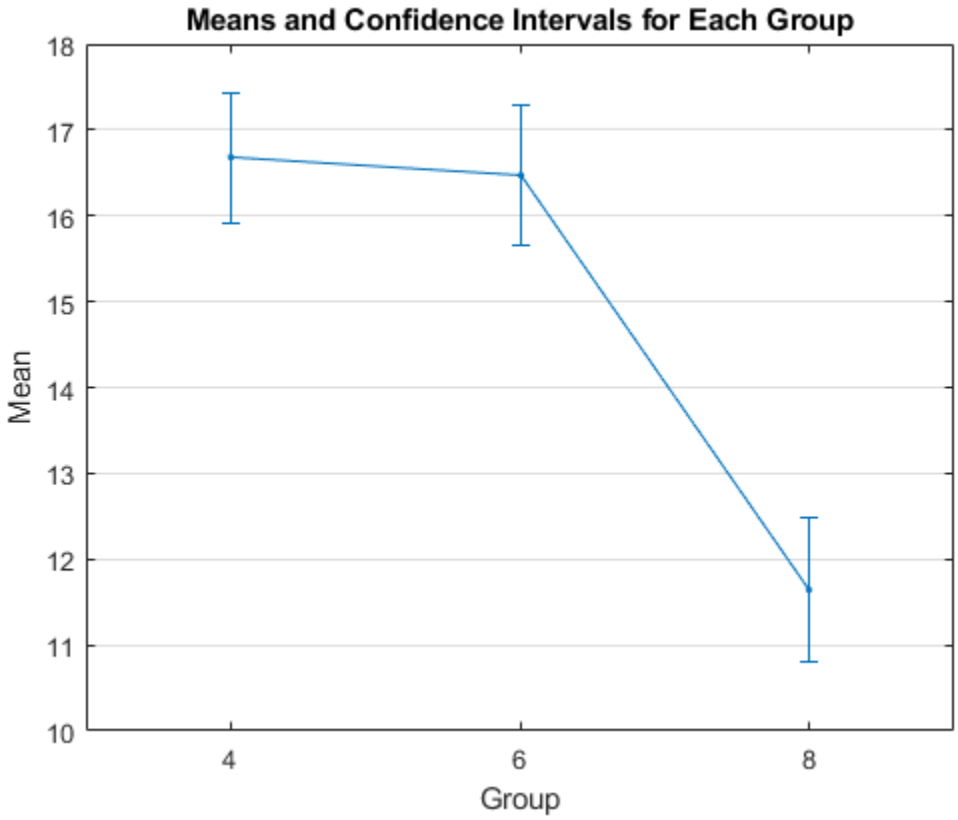
Load the sample data.

```
load('carsmall')
```

The variables `Acceleration` and `Weight` are the acceleration and weight values measured for 100 cars. The variable `Cylinders` is the number of cylinders in each car. The variable `Model_Year` has three unique values, `70`, `76`, and `82`, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by `Cylinders`, with 95% confidence intervals.

```
grpstats(Acceleration,Cylinders,0.05)
```



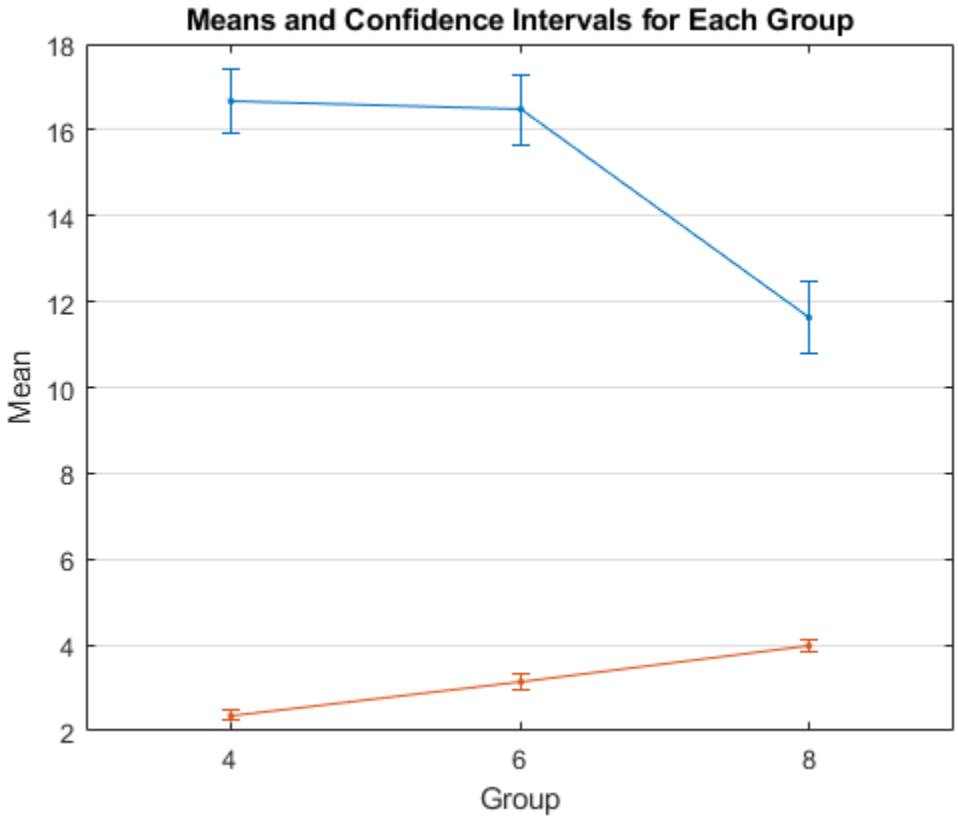
```
ans = 3×1

   16.6706
   16.4765
   11.6406
```

The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by `Cylinders`, and 95% confidence intervals. Scale the `Weight` values by 1000 so the means of `Weight` and `Acceleration` are the same order of magnitude.

```
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```



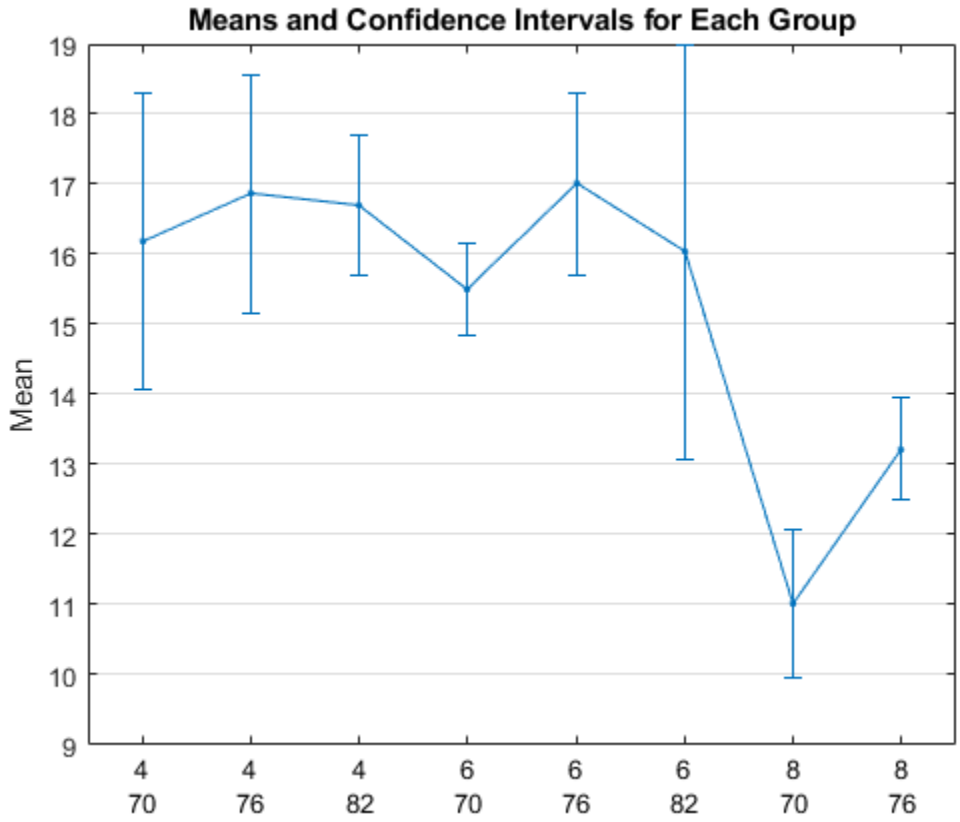
```
ans = 3×2

   16.6706    2.3726
   16.4765    3.1255
   11.6406    3.9703
```

The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both `Cylinders` and `Model_Year`. Specify 95% confidence intervals.

```
grpstats(Acceleration,{Cylinders,Model_Year},0.05)
```



```
ans = 8×1

   16.1875
   16.8667
   16.7036
   15.5000
   17.0000
   16.0333
   11.0217
   13.2222
```

There are nine possible combinations of grouping variable values because there are three unique values in `Cylinders` and three unique values in `Model_Year`. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

Input Arguments

`tbl` — Input data

table | dataset array

Input data, specified as a table or dataset array. `tbl` must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in `tbl` (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument `DataVars` to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

`groupvar` — Identifiers for the grouping variables

character vector | string array | cell array of character vectors | vector of positive integers | logical vector | `[]`

Identifiers for the grouping variables in the input data, `tbl`, specified as one of the following:

Character vector, string array, or cell array of character vectors	Names of the grouping variables
Positive integer or vector of positive integers	Variable numbers of the grouping variables
Vector of logical values with number of elements equal to the number of variables in `tbl`	Logical indicator with value `true` for grouping variables and `false` otherwise
`[]`	No groups (returns summary statistics for all data)

Any variable that is identified by `groupvar` as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, datetime or duration vector, string array, or cell array of character vectors.

For example, consider an input table, `tbl`, with six variables. The fourth variable is named `Gender`. To be a valid grouping variable, the data type of `Gender` might be a string array, a cell array of character vectors, or a nominal array, with the unique values `Male` and `Female`. To specify the variable `Gender` as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(tbl,'Gender')`
- `statarray = grpstats(tbl,4)`
- `statarray = grpstats(tbl,logical([0 0 0 1 0 0]))`

Data Types: `double` | `logical` | `char` | `string` | `cell`

`whichstats` — Type of summary statistics

character vector | string scalar | function handle | string array | cell array of character vectors or function handles

Type of summary statistics to compute, specified as one of the following values.

- Character vector or string scalar specifying the type of summary statistics, as described in this table.

Type	Description
`'mean'`	Mean
`'sem'`	Standard error of the mean
`'numel'`	Count, or number, of non-`NaN` elements
`'gname'`	Group name
`'std'`	Standard deviation

Type	Description
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Range
'meanci'	95% confidence interval for the mean. You can specify different significance levels using the Alpha name-value pair argument.
'predci'	95% prediction interval for a new observation. You can specify different significance levels using the Alpha name-value pair argument.

- Function handle to specify any other type of summary statistics. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time grpstats calls the function handle (even if the output for some groups is empty).
  - If the function accepts a column of data, then the function can return either a scalar value or an *nvals*-by-1 column vector for descriptive statistics of length *nvals* (for example, a confidence interval has length two). If the function accepts a matrix, the function must return either a 1-by-*ncols* row vector or an *nvals*-by-*ncols* matrix, where *ncols* is the number of columns in the input data matrix.
  - For functions that do not compute column-wise statistics, specify the computation direction while specifying the function. For example, to use the sum function, specify the function handle as @(x)sum(x,1) because sum computes column-wise statistics for matrices with two or more rows, but not for single-row matrices.
- String array or a cell array of character vectors or function handles to specify multiple types of summary statistics.

Example: stat1 = grpstats(X,group,'sem')

Example: stat1 = grpstats(X,group,@(x)sum(x,1))

Example: [stat1,stat2,stat3] = grpstats(X,group,{'mean','std',@skewness})

alpha — Significance level
scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify 'meanci' or 'predci' in whichstats, you can use alpha to specify the significance level for the confidence or prediction intervals. If you specify alpha, then grpstats returns 100×(1 – alpha)% confidence or prediction intervals. If you do not specify alpha, then grpstats returns 95% intervals (alpha = 0.05).
- Use alpha with the syntax on page 33-2759 to plot group means and corresponding 100×(1 – alpha)% confidence intervals.

Data Types: double

X — Input data
vector | matrix

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

Data Types: `double` | `single`

`group` — Grouping variable

categorical array | logical or numeric vector | datetime or duration vector | string array | cell array of character vectors | `[]`

Grouping variable, specified as a categorical array, logical or numeric vector, datetime or duration vector, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data `X`. Observations (rows) with the same value of the grouping variable are in the same group. Use `[]` to compute summary statistics for all data, without using groups.

For example, if `Gender` is a string array or cell array of character vectors with values `'Male'` and `'Female'`, you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values `0` for nonsmokers and `1` for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical` | `datetime` | `duration`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DataVars',[1,3,4],'Alpha',0.01` specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

`Alpha` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

When you include `'meanci'` or `'predci'` in `whichstats`, you can use `Alpha` to specify the significance level for confidence or prediction intervals. If you specify the value α, then `grpstats` returns $100\times(1 - \alpha)$% confidence or prediction intervals.

If you do not specify a value for `Alpha`, then `grpstats` returns 95% intervals ($\alpha = 0.05$).

Example: `'Alpha',0.1`

Data Types: `double`

`DataVars` — Variable names or columns
string array | cell array of character vectors | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data `tbl` you want to compute summary statistics for, specified as the comma-separated pair consisting of `'DataVars'` and a string array, cell array of character vectors, vector of positive integers, or logical vector. Use a character vector or string scalar to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (`true` if you want to compute summary statistics, `false` otherwise).

You must specify `DataVars` if there are any variables in `tbl` (other than the grouping variables specified in `groupvar`) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.

Example: `'DataVars',{'Height','Weight'}`

Data Types: `double` | `string` | `cell` | `char`

`VarNames` — Variable names for output
string array | cell array of character vectors

Variable names for the output `statarray`, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input data `tbl`. This prefix corresponds to the summary statistic name.

Example: `'VarNames',{'Gender','GroupCount','MaleMean','FemaleMean'}`

Data Types: `string` | `cell`

Output Arguments

`statarray` — Group summary statistics
table | dataset array

Group summary statistics, returned as a table or a dataset array. If `tbl` is a table, `grpstats` returns `statarray` as a table. If `tbl` is a dataset array, `grpstats` returns `statarray` as a dataset array.

`statarray` contains summary statistic values for the groups of data in `tbl` determined by the levels of the grouping variables specified by `groupvar`. There is a row in `statarray` for each observed value or combination of values in the variables specified by `groupvar`. The output `statarray` contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in `tbl` (other than those specified by `groupvar`), or for only the variables specified using `DataVars`.

The total number of variables in `statarray` is *ngroupvars* + 1 + *ndatavars*×*nstats*, where *ngroupvars* is the number of variables in `groupvar`, *ndatavars* is the number of variables for which summary statistics are computed, and *nstats* is the number of summary statistic types specified in `whichstats`.

`grpstats` assigns default names to the variables in `statarray`, unless you specify variable names using the name-value pair argument `VarNames`.

means — Group means
column vector | array

Group means for the groups of data in the vector or matrix X determined by the levels of group, returned as an *ngroups*-by-*ncols* array. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in X. If X is a vector, then means is a column vector.

stats1,...,statsN — Group summary statistics
column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix X determined by the levels of group, returned as *ngroups*-by-*ncols* arrays. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in X. You must specify an output argument for each type of summary statistic specified in whichstats.

If a summary statistic type in whichstats returns a value of length *nvals* (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an *ngroups*-by-*ncols*-by-*nvals* array.

Algorithms

- grpstats treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- grpstats ignores empty group names.

Alternative Functionality

MATLAB includes the function groupsummary, which also returns group summaries and is recommended when you are working with a table.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If the input data is a tall array, then all grouping variables must also be tall and have the same number of rows as the data.
- The whichstats option cannot be specified as a function handle. In addition to the current built-in options, whichstats can also be:
  - 'Count' — Number of non-NaNs.
  - 'NNZ' — Number of nonzeros and non-NaNs.
  - 'Kurtosis' — Compute kurtosis.
  - 'Skewness' — Compute skewness.
  - 'all-stats' — Compute all summary statistics.
- Group order is not guaranteed to be the same as the in-memory grpstats computation. Specify 'gname' as the whichstats option to return the order of rows of the summary statistics. For

example `[means,grpname] = grpstats(x,bins,{'mean','gname'})` returns the means of groups in `x` in the same order that the groups appear in `grpname`.

- Summary statistics for *nonnumeric* variables return NaNs.
- `grpstats` always operates on the first dimension.
- If the input is a tall table, then the output is also a tall table. However, rather than including row names, the output tall table contains an extra variable `GroupLabel` that contains the same information.

For more information, see “Tall Arrays for Out-of-Memory Data”.

Introduced before R2006a

grpstats

Class: `RepeatedMeasuresModel`

Compute descriptive statistics of repeated measures data by group

Syntax

```
statstbl = grpstats(rm,g)
statstbl = grpstats(rm,g,stats)
```

Description

`statstbl = grpstats(rm,g)` returns the count, mean, and variance for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

`statstbl = grpstats(rm,g,stats)` returns the statistics specified by `stats` for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`g` — Name of grouping factor or factors

character vector | string array | cell array of character vectors

Name of grouping factor or factors, specified as a character vector, string array, or cell array of character vectors.

Example: `'Drug'`

Example: `{'Drug','Sex'}`

Data Types: `char` | `string` | `cell`

`stats` — Statistics to compute

character vector | string scalar | function handle | string array | cell array of multiple character vectors and function handles

Statistics to compute, specified as one of the following:

- Character vector or string scalar specifying the name of the statistics to compute. Names can be one of the following.

Name	Description
`'mean'`	Mean

Name	Description
'sem'	Standard error of the mean
'numel'	Count or number of elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Maximum minus minimum
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.
- A string array or cell array of character vectors and function handles.

Example: `@median`

Example: `@skewness`

Example: `'gname'`

Example: `{'gname','range','predci'}`

Output Arguments

`statstbl` — Statistics values for each group

table

Statistics values for each group, returned as a table.

Examples

Compute Group Statistics

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute group counts, mean, and standard deviation with respect to species.

```
grpstats(rm,'species')
```

```
ans=3×4 table
       species        GroupCount     mean      std
    ______________    __________    ______    ______

    {'setosa'    }       200        2.5355    1.8483
    {'versicolor'}       200         3.573    1.7624
    {'virginica' }       200         4.285    1.9154
```

Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

```
grpstats(rm,'species',{'gname','range','predci'})
```

Statistics for Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors `Group` and `Gender`.

```
GS = grpstats(rm,{'Group','Gender'},{'mean','std',@skewness,@kurtosis})
```

```
GS=6×7 table
    Group    Gender    GroupCount     mean       std      skewness    kurtosis
    _____    ______    __________    _______    ______    ________    ________
```

```
A      Female        40         16.554    21.498     0.35324     3.7807
A      Male          40         9.8335    20.602    -0.38722     2.7834
B      Female        40         11.261    25.779    -0.49177     4.1484
B      Male          40         3.6078    24.646     0.55447     2.7966
C      Female        40        -11.335    27.186      1.7499     6.1429
C      Male          40        -14.028    31.984      1.7362      5.141
```

Tips

- `grpstats` computes results separately for each group. The results do not depend on the fitted repeated measures model. It computes the results on all available data, without omitting entire rows that contain `NaN`s.

See Also

`fitrm` | `plot`

gscatter

Scatter plot by group

Syntax

```
gscatter(x,y,g)
gscatter(x,y,g,clr,sym,siz)
gscatter(x,y,g,clr,sym,siz,doleg)
gscatter(x,y,g,clr,sym,siz,doleg,xnam,ynam)

gscatter(ax,___)

h = gscatter(___)
```

Description

`gscatter(x,y,g)` creates a scatter plot of `x` and `y`, grouped by `g`. The inputs `x` and `y` are vectors of the same size.

`gscatter(x,y,g,clr,sym,siz)` specifies the marker color `clr`, symbol `sym`, and size `siz` for each group.

`gscatter(x,y,g,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph. `gscatter` creates a legend by default.

`gscatter(x,y,g,clr,sym,siz,doleg,xnam,ynam)` specifies the names to use for the x-axis and y-axis labels. If you do not provide `xnam` and `ynam`, and the `x` and `y` inputs are variables with names, then `gscatter` labels the axes with the variable names.

`gscatter(ax,___)` uses the plot axes specified by the axes object `ax`. Specify `ax` as the first input argument followed by any of the input argument combinations in the previous syntaxes.

`h = gscatter(___)` returns graphics handles corresponding to the groups in `g`.

You can pass in `[]` for `clr`, `sym`, `siz`, and `doleg` to use their default values.

Examples

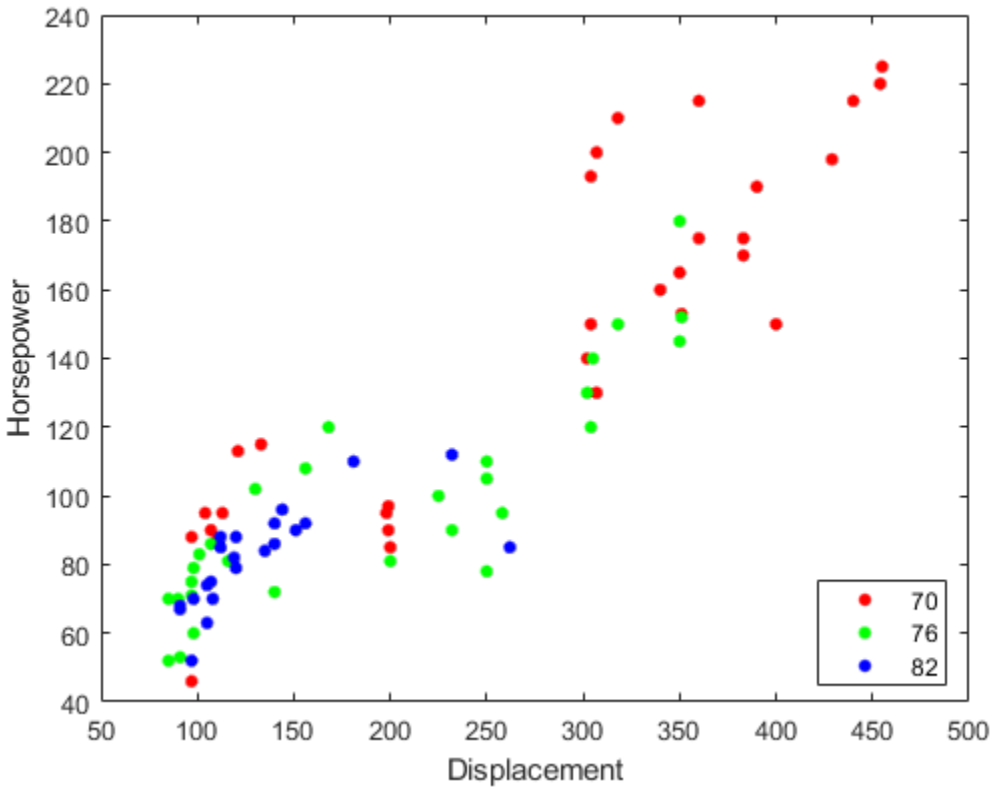
Scatter Plot with Default Settings

Load the `carsmall` data set.

```
load carsmall
```

Plot the `Displacement` values on the x-axis and the `Horsepower` values on the y-axis. `gscatter` uses the variable names as the default labels for the axes. Group the data points by `Model_Year`.

```
gscatter(Displacement,Horsepower,Model_Year)
```



Scatter Plot with One Grouping Variable

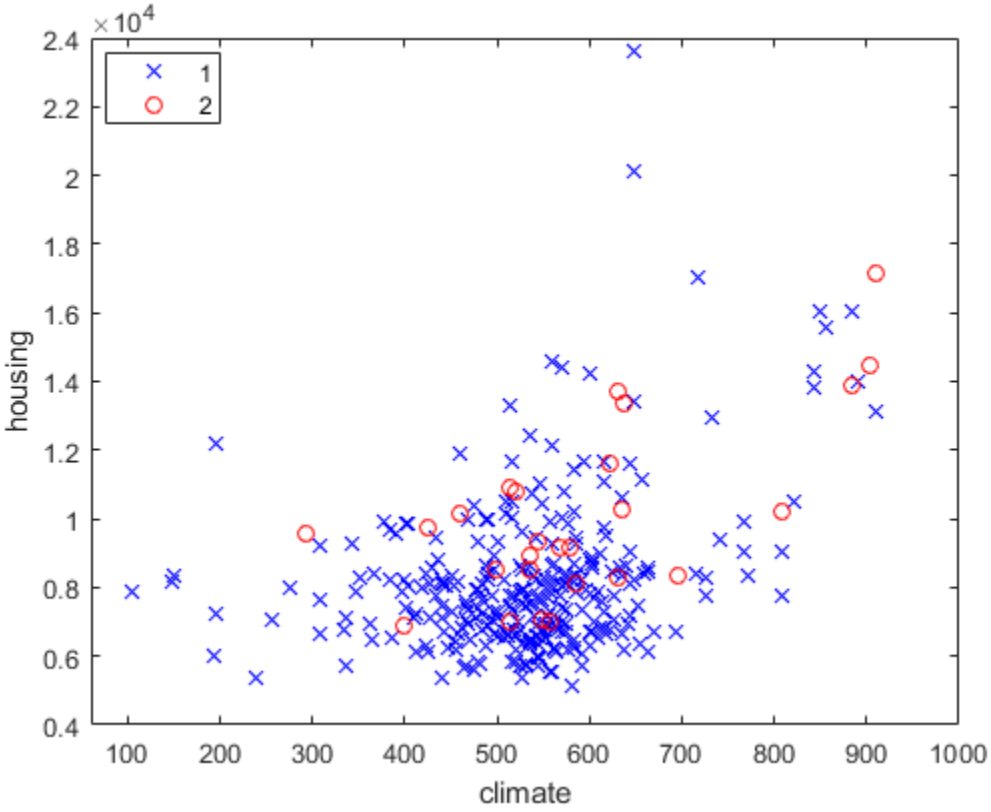
Load the `discrim` data set.

```
load discrim
```

The data set contains ratings of cities according to nine factors such as climate, housing, education, and health. The matrix `ratings` contains the ratings information.

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')
xlabel('climate')
ylabel('housing')
```



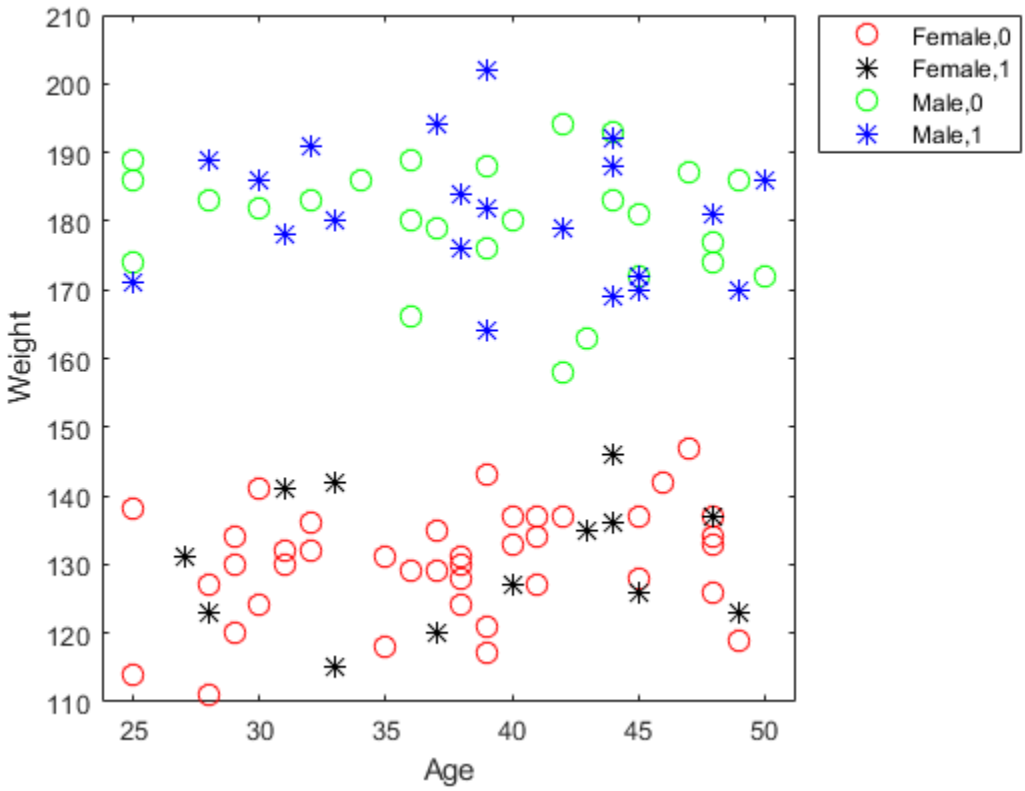
Scatter Plot with Multiple Grouping Variables

Load the `hospital` data set.

```
load hospital
```

Plot the ages and weights of the hospital patients. Group the patients according to their gender and smoker status. Use the `o` symbol to represent nonsmokers and the * symbol to represent smokers.

```
x = hospital.Age;
y = hospital.Weight;
g = {hospital.Sex,hospital.Smoker};
gscatter(x,y,g,'rkgb','o*',8,'on','Age','Weight')
legend('Location','northeastoutside')
```



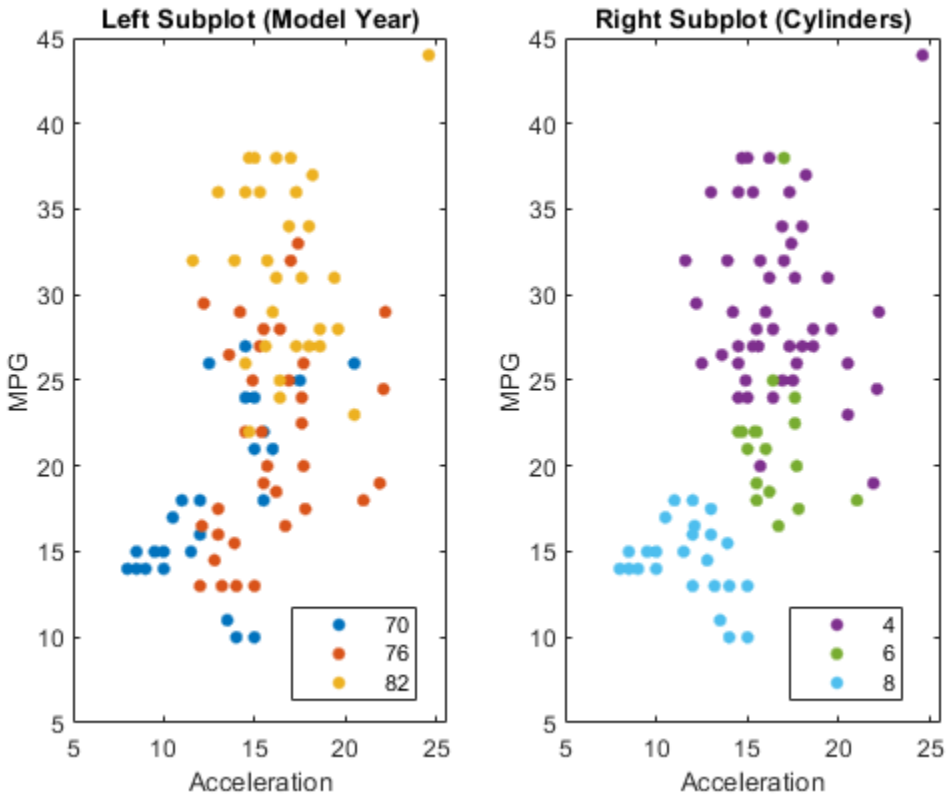
Specify Axes for Scatter Plot

Load the `carsmall` data set. Create a figure with two subplots and return the `axes` objects as `ax1` and `ax2`. Create a scatter plot in each set of axes by referring to the corresponding `Axes` object. In the left subplot, group the data using the `Model_Year` variable. In the right subplot, group the data using the `Cylinders` variable. Add a title to each plot by passing the corresponding `Axes` object to the `title` function.

```
load carsmall
color = lines(6); % Generate color values

ax1 = subplot(1,2,1); % Left subplot
gscatter(ax1,Acceleration,MPG,Model_Year,color(1:3,:))
title(ax1,'Left Subplot (Model Year)')

ax2 = subplot(1,2,2); % Right subplot
gscatter(ax2,Acceleration,MPG,Cylinders,color(4:6,:))
title(ax2,'Right Subplot (Cylinders)')
```



Create and Modify Scatter Plot

Load the `carbig` data set.

```
load carbig
```

Create a scatter plot comparing `Acceleration` to `MPG`. Group data points based on `Origin`.

```
h = gscatter(Acceleration,MPG,Origin)
```

```
h =
  7x1 Line array:

  Line    (USA)
  Line    (France)
  Line    (Japan)
  Line    (Germany)
  Line    (Sweden)
  Line    (Italy)
  Line    (England)
```

Display the `Line` object corresponding to the group labeled `(Japan)`.

```
jgroup = h(3)
```

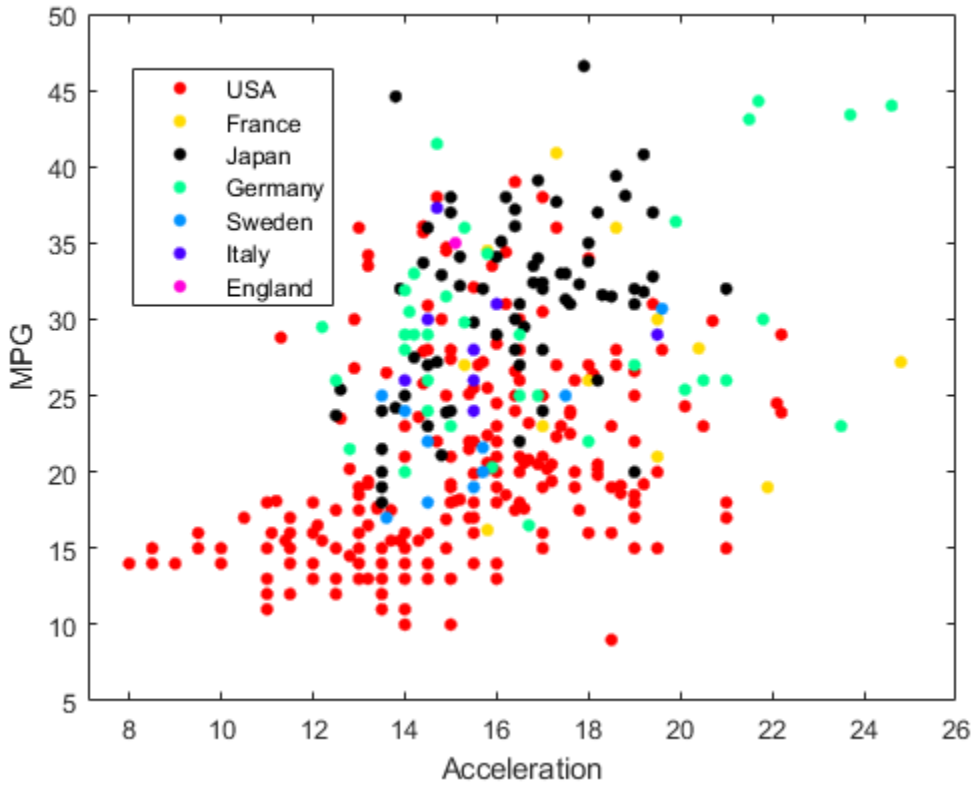
```
jgroup =
  Line (Japan) with properties:

              Color: [0.2857 1 0]
          LineStyle: 'none'
          LineWidth: 0.5000
             Marker: '.'
         MarkerSize: 15
    MarkerFaceColor: 'none'
              XData: [1x79 double]
              YData: [1x79 double]
              ZData: [1x0 double]

  Show all properties
```

Change the marker color for the `Japan` group to black.

```
jgroup.Color = 'k';
```



Input Arguments

x — x-axis values

numeric vector

x-axis values, specified as a numeric vector. `x` must have the same size as `y`.

Data Types: `single` | `double`

y — y-axis values
numeric vector

y-axis values, specified as a numeric vector. `y` must have the same size as `x`.

Data Types: `single` | `double`

g — Grouping variable
categorical vector | logical vector | numeric vector | character array | string array | cell array of character vectors | cell array

Grouping variable, specified as a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors. Alternatively, `g` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group appear on the scatter plot with the same marker color, symbol, and size.

The number of rows in `g` must be equal to the length of `x`.

Example: `species`

Example: `{Cylinders,Origin}`

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

`clr` — Marker colors
character vector or string scalar of colors | matrix of RGB triplet values

Marker colors, specified as either a character vector or string scalar of colors recognized by the `plot` function or a matrix of RGB triplet values. Each RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color, respectively. Each intensity must be in the range [0,1].

This table lists the available color characters and their equivalent RGB triplet values.

Long Name	Short Name	RGB Triplet
Yellow	`'y'`	`[1 1 0]`
Magenta	`'m'`	`[1 0 1]`
Cyan	`'c'`	`[0 1 1]`
Red	`'r'`	`[1 0 0]`
Green	`'g'`	`[0 1 0]`
Blue	`'b'`	`[0 0 1]`
White	`'w'`	`[1 1 1]`
Black	`'k'`	`[0 0 0]`

If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: `'rgb'`

Example: `[0 0 1; 0 0 0]`

Data Types: `char` | `string` | `single` | `double`

`sym` — Marker symbols
`'.'` (default) | character vector or string scalar of symbols

Marker symbols, specified as a character vector or string scalar of symbols recognized by the `plot` function. This table lists the available marker symbols.

Value	Description
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'s'`	Square
`'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'p'`	Five-pointed star (pentagram)
`'h'`	Six-pointed star (hexagram)
`'none'`	No markers

If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: `'o+*v'`

Data Types: `char` | `string`

`siz` — Marker sizes
positive numeric vector

Marker sizes, specified as a positive numeric vector in points. The default value is determined by the number of observations. If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: `[6 12]`

Data Types: `single` | `double`

`doleg` — Option to include legend
`'on'` (default) | `'off'`

Option to include a legend, specified as either `'on'` or `'off'`. By default, the legend is displayed on the graph.

`xnam` — x-axis label
`x` variable name (default) | character vector | string scalar

x-axis label, specified as a character vector or string scalar.

Data Types: `char` | `string`

`ynam` — y-axis label
y variable name (default) | character vector | string scalar

y-axis label, specified as a character vector or string scalar.

Data Types: `char` | `string`

`ax` — Axes for plot
`Axes` object | `UIAxes` object

Axes for the plot, specified as an `Axes` or `UIAxes` object. If you do not specify `ax`, then `gscatter` creates the plot using the current axes. For more information on creating an axes object, see `axes` and `uiaxes`.

Output Arguments

`h` — Graphics handles
array of `Line` objects

Graphics handles, returned as an array of `Line` objects. Each `Line` object corresponds to one of the groups in `g`. You can use dot notation to query and set properties of the line objects. For a list of `Line` object properties, see Chart Line.

Topics
“Create Scatter Plots Using Grouped Data” on page 4-2
“MANOVA” on page 9-49
“Grouping Variables” on page 2-45

Introduced before R2006a

gt

Class: `qrandstream`

Greater than relation for handles

Syntax

```
h1 > h2
```

Description

`h1 > h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = gt(h1, h2)` stores the result in a logical array of the same dimensions.

`eq` | `ge` | `le` | `lt` | `ne` | `qrandstream`

haltonset

Halton quasirandom point set

Description

`haltonset` is a quasirandom point set object that produces points from the Halton sequence. The Halton sequence uses different prime bases in each dimension to fill space in a highly uniform manner.

Creation

Syntax

```
p = haltonset(d)
p = haltonset(d,Name,Value)
```

Description

`p = haltonset(d)` constructs a `d`-dimensional point set `p`, which is a `haltonset` object with default property settings. The input argument `d` corresponds to the `Dimensions` property of `p`.

`p = haltonset(d,Name,Value)` sets properties on page 33-2789 of `p` using one or more name-value pair arguments. Enclose each property name in quotes. For example, `haltonset(5,'Leap',2)` creates a five-dimensional point set from the first point, fourth point, seventh point, tenth point, and so on.

The returned object `p` encapsulates properties of a Halton quasirandom sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of the point set indices (maximum value of 2^{53}). Values of the point set are generated whenever you access `p` using `net` or parenthesis indexing. Values are not stored within `p`.

Properties

`Dimensions` — Number of dimensions

positive integer scalar

This property is read-only.

Number of dimensions of the points in the point set, specified as a positive integer scalar. For example, each point in the point set `p` with `p.Dimensions = 5` has five values.

Use the `d` input argument to specify the number of dimensions when you create a point set using the `haltonset` function.

Leap — Interval between points

`0` (default) | positive integer scalar

Interval between points in the sequence, specified as a positive integer scalar. In other words, the `Leap` property of a point set specifies the number of points in the sequence to leap over and omit for every point taken. The default `Leap` value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the `Leap` values with care. Many `Leap` values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube and, therefore, fail to be a uniform quasirandom point set. For more information, see [1].

One rule for choosing `Leap` values for Halton sets is to set the value to `(n–1)`, where `n` is a prime number that has not been used to generate one of the dimensions. For example, for a `d`-dimensional point set, specify the `(d+1)`th or greater prime number for `n`.

Example: `p = haltonset(2,'Leap',4);` (where `d = 2` and `n = 5`)

Example: `p.Leap = 100;`

`ScrambleMethod` — Settings that control scrambling
`0x0` structure (default) | structure with `Type` and `Options` fields

Settings that control the scrambling of the sequence, specified as a structure with these fields:

- `Type` — A character vector containing the name of the scramble
- `Options` — A cell array of parameter values for the scramble

Use the `scramble` object function to set scrambles. For a list of valid scramble types, see the `type` input argument of `scramble`. An error occurs if you set an invalid scramble type for a given point set.

The `ScrambleMethod` property also accepts an empty matrix as a value. The software then clears all scrambling and sets the property to contain a `0x0` structure.

`Skip` — Number of initial points in sequence to omit
`0` (default) | positive integer scalar

Number of initial points in the sequence to omit from the point set, specified as a positive integer scalar.

Initial points of a sequence sometimes exhibit undesirable properties. For example, the first point is often `(0,0,0,...)`, which can cause the sequence to be unbalanced because the counterpart of the point, `(1,1,1,...)`, never appears. Also, initial points often exhibit correlations among different dimensions, and these correlations disappear later in the sequence.

Example: `p = haltonset(__,'Skip',2e3);`

Example: `p.Skip = 1e3;`

`Type` — Sequence type
`'Halton'` (default)

This property is read-only.

Sequence type on which the quasirandom point set `p` is based, specified as `'Halton'`.

Object Functions

net	Generate quasirandom point set
scramble	Scramble quasirandom point set

You can also use the following MATLAB functions with a `haltonset` object. The software treats the point set object like a matrix of multidimensional points.

length	Length of largest array dimension
size	Array size

Examples

Create Halton Point Set

Generate a three-dimensional Halton point set, skip the first 1000 values, and then retain every 101st point.

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
```

```
p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
               Skip : 1000
               Leap : 100
    ScrambleMethod : none
```

Apply reverse-radix scrambling by using `scramble`.

```
p = scramble(p,'RR2')
```

```
p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
               Skip : 1000
               Leap : 100
    ScrambleMethod : RR2
```

Generate the first four points by using `net`.

```
X0 = net(p,4)
```

```
X0 = 4×3

    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11,:)
```

```
X = 4×3

    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

Tips

- The `Skip` and `Leap` properties are useful for parallel applications. For example, if you have a Parallel Computing Toolbox license, you can partition a sequence of points across N different workers by using the function `labindex`. On each nth worker, set the `Skip` property of the point set to n – 1 and the `Leap` property to N – 1. The following code shows how to partition a sequence across three workers.

```
Nworkers = 3;
p = haltonset(10,'Leap',Nworkers-1);
spmd(Nworkers)
    p.Skip = labindex - 1;

    % Compute something using points 1,4,7...
    % or points 2,5,8... or points 3,6,9...
end
```

Algorithms

Halton Sequence Generation

Consider a default `haltonset` object `p` that contains `d`-dimensional points. Each `p(i,:)` is a point in a Halton sequence. The jth coordinate of the point, `p(i,j)`, is equal to

$$\sum_k a_{ij}(k) b_j^{-k-1}.$$

- b_j is the jth prime.
- The $a_{ij}(k)$ coefficients are nonnegative integers less than b_j such that

$$i - 1 = \sum_{k=0} a_{ij}(k) b_j^k.$$

  In other words, the $a_{ij}(k)$ values are the base b_j digits of the integer i – 1.

For more information, see [1].

“Generating Quasi-Random Numbers” on page 7-12

Introduced in R2008a

harmmean

Harmonic mean

Syntax

```
m = harmmean(X)
m = harmmean(X,'all')
m = harmmean(X,dim)
m = harmmean(X,vecdim)
m = harmmean( ___ ,nanflag)
```

Description

`m = harmmean(X)` calculates the harmonic mean on page 33-2798 of a sample. For vectors, `harmmean(X)` is the harmonic mean of the elements in `X`. For matrices, `harmmean(X)` is a row vector containing the harmonic means of each column. For *N*-dimensional arrays, `harmmean` operates along the first nonsingleton dimension of `X`.

`m = harmmean(X,'all')` returns the harmonic mean of all elements of `X`.

`m = harmmean(X,dim)` takes the harmonic mean along the operating dimension `dim` of `X`.

`m = harmmean(X,vecdim)` returns the harmonic mean over the dimensions specified in the vector `vecdim`. Each element of `vecdim` represents a dimension of the input array `X`. The output `m` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `m`. For example, if `X` is a 2-by-3-by-4 array, then `harmmean(X,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the harmonic mean of the elements on the corresponding page of `X`.

`m = harmmean( ___ ,nanflag)` specifies whether to exclude `NaN` values from the calculation, using any of the input argument combinations in previous syntaxes. By default, `harmmean` includes `NaN` values in the calculation (`nanflag` has the value `'includenan'`). To exclude `NaN` values, set the value of `nanflag` to `'omitnan'`.

Examples

Compare Harmonic and Arithmetic Mean

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a matrix of exponential random numbers with 5 rows and 4 columns.

```
X = exprnd(1,5,4)
```

```
X = 5×4

    0.2049    2.3275    1.8476    1.9527
    0.0989    1.2783    0.0298    0.8633
    2.0637    0.6035    0.0438    0.0880
```

```
    0.0906    0.0434    0.7228    0.2329
    0.4583    0.0357    0.2228    0.0414
```

Compute the harmonic and arithmetic means of the columns of X.

```
harmonic = harmmean(X)
```

```
harmonic = 1×4

    0.1743    0.0928    0.0797    0.1205
```

```
arithmetic = mean(X)
```

```
arithmetic = 1×4

    0.5833    0.8577    0.5734    0.6357
```

The arithmetic mean is greater than the harmonic mean for all the columns of X.

Harmonic Mean of All Values

Find the harmonic mean of all the values in an array.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =
X(:,:,1) =

     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15

X(:,:,2) =

    16    19    22    25    28
    17    20    23    26    29
    18    21    24    27    30
```

Find the harmonic mean of the elements of X.

```
m = harmmean(X,'all')
```

```
m = 7.5094
```

Harmonic Mean Along Specified Dimensions

Find the harmonic mean along different operating dimensions and vectors of dimensions for a multidimensional array.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =
X(:,:,1) =

     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15

X(:,:,2) =

    16    19    22    25    28
    17    20    23    26    29
    18    21    24    27    30
```

Find the harmonic mean of X along the default dimension.

```
hmean1 = harmmean(X)
```

```
hmean1 =
hmean1(:,:,1) =

    1.6364    4.8649    7.9162   10.9392   13.9523

hmean1(:,:,2) =

   16.9607   19.9666   22.9710   25.9743   28.9770
```

By default, harmmean operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the first dimension of X. Therefore, hmean1 is a 1-by-5-by-2 array.

Find the harmonic mean of X along the second dimension.

```
hmean2 = harmmean(X,2)
```

```
hmean2 =
hmean2(:,:,1) =

    3.1852
    5.0641
    6.5693

hmean2(:,:,2) =

   21.1595
   22.1979
```

```
   23.2329
```

`hmean2` is a 3-by-1-by-2 array.

Find the harmonic mean of `X` along the third dimension.

```
hmean3 = harmmean(X,3)
```

```
hmean3 = 3×5

    1.8824    6.6087   10.6207   14.2857   17.7561
    3.5789    8.0000   11.8710   15.4595   18.8837
    5.1429    9.3333   13.0909   16.6154   20.0000
```

`hmean3` is a 3-by-5 array.

Find the harmonic mean of each page of `X` by specifying the first and second dimensions using the `vecdim` input argument.

```
mpage = harmmean(X,[1 2])
```

```
mpage =
mpage(:,:,1) =

    4.5205

mpage(:,:,2) =

   22.1645
```

For example, `mpage(1,1,2)` is the harmonic mean of the elements in `X(:,:,2)`.

Find the harmonic mean of the elements in each `X(i,:,:)` slice by specifying the second and third dimensions.

```
mrow = harmmean(X,[2 3])
```

```
mrow = 3×1

    5.5369
    8.2469
   10.2425
```

For example, `mrow(3)` is the harmonic mean of the elements in `X(3,:,:)` and is equivalent to specifying `harmmean(X(3,:,:),'all')`.

Harmonic Mean Excluding NaN

Create a vector and compute its `harmmean`, excluding `NaN` values.

```
x = 1:10;
x(3) = nan; % Replace the third element of x with a NaN value
n = harmmean(x,'omitnan')
```

```
n = 3.4674
```

If you do not specify `'omitnan'`, then `harmmean(x)` returns `NaN`.

More About

Harmonic Mean

The harmonic mean of a sample `X` is

$$m = \frac{n}{\sum_{i=1}^{n} \frac{1}{x_i}}$$

where n is the number of values in `X`.

Tips

- When `harmmean` computes the harmonic mean of an array containing `0`, the returned value is `0`.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- These input arguments are not supported: `'all'`, `vecdim`, and `nanflag`.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

hazardratio

Estimate Cox model hazard relative to baseline

Syntax

```
hazard = hazardratio(coxMdl,X)
hazard = hazardratio(coxMdl,X,Stratification)
hazard = hazardratio( ___ ,'Baseline',baseline)
```

Description

`hazard = hazardratio(coxMdl,X)` returns the estimated hazard relative to the baseline for a fitted Cox proportional hazards model `coxMdl` using the predictors `X`.

`hazard = hazardratio(coxMdl,X,Stratification)` returns the estimated hazard relative to the baseline using the predictors `X` and stratification levels `Stratification`. The number of rows in `X` and `Stratification` must be the same.

Note When you train `coxMdl` using stratification variables and pass predictor variables `X`, `hazardratio` also requires you to pass stratification variables.

`hazard = hazardratio( ___ ,'Baseline',baseline)` estimates the hazard relative to the supplied baseline using any of the input argument combinations in the previous syntaxes.

Examples

Compute Relative Hazard

Perform a Cox proportional hazards regression on the `lightbulb` data set, which contains simulated lifetimes of light bulbs. The first column of the light bulb data contains the lifetime (in hours) of two different types of bulbs. The second column contains a binary variable indicating whether the bulb is fluorescent or incandescent; 0 indicates the bulb is fluorescent, and 1 indicates it is incandescent. The third column contains the censoring information, where 0 indicates the bulb was observed until failure, and 1 indicates the observation was censored.

Fit a Cox proportional hazards model for the lifetime of the light bulbs, accounting for censoring. The predictor variable is the type of bulb.

```
load lightbulb
coxMdl = fitcox(lightbulb(:,2),lightbulb(:,1), ...
    'Censoring',lightbulb(:,3));
```

View the default baseline for the fitted model.

```
defaultBaseline = coxMdl.Baseline
```

```
defaultBaseline = 0.5000
```

Compute the hazard ratio of an incandescent bulb (1) relative to this baseline.

```
defaultHazard = hazardratio(coxMdl,1)
```

```
defaultHazard = 10.6238
```

Compute the hazard ratio of an incandescent bulb relative to a fluorescent bulb (0).

```
relHazard = hazardratio(coxMdl,1,'Baseline',0)
```

```
relHazard = 112.8646
```

The hazard rate of an incandescent bulb is estimated to be over 100 times the hazard rate of a fluorescent bulb.

Compute Hazard Relative to Different Baseline Values

Create a Cox model from the `readmissiontimes` data. In this data, `0` indicates a male patient, and `1` indicates a female patient.

```
load readmissiontimes
coxMdl = fitcox([Age,Sex,Weight],ReadmissionTime,'Censoring',Censored);
```

Calculate the relative hazard of a 40-year-old man weighing 200 lbs. relative to the baseline hazard.

```
hazard = hazardratio(coxMdl,[40 0 200])
```

```
hazard = 4.3112
```

Calculate the hazard of this same man relative to a 50-year-old woman weighing 150 lbs.

```
hazard2 = hazardratio(coxMdl,[40 0 200],'Baseline',[50 1 150])
```

```
hazard2 = 5.2053
```

Hazard Ratios for Stratified Model

Load the `coxModel` data. (This simulated data is generated in the example “Cox Proportional Hazards Model Object” on page 14-39.) The model named `coxMdl` has three stratification levels (1, 2, and 3) and a predictor `X` with three categorical values (1, 1/20, and 1/100).

```
load coxModel
```

Find the hazard ratio of the predictor value `categorical(1)` and stratification level 3 with respect to the baseline.

```
X = categorical(1);
stratification = 3;
hazard = hazardratio(coxMdl,X,stratification)
```

```
hazard = 12.7096
```

Calculate the ratio with respect to a baseline of 0.

```
hazard = hazardratio(coxMdl,X,stratification,'Baseline',0)
```

```
hazard = 95.5127
```

Calculate the ratio of a `categorical(1/100)` predictor with respect to a baseline of 0.

```
X = categorical(1/100);
hazard = hazardratio(coxMdl,X,stratification,'Baseline',0)
```

```
hazard = 1
```

Input Arguments

`coxMdl` — Fitted Cox proportional hazards model

`CoxModel` object

Fitted Cox proportional hazards model, specified as a `CoxModel` object. Create `coxMdl` using `fitcox`.

`X` — Data for estimating hazard

matrix | table

Data for estimating the hazard, specified as a matrix or table. The data must be the same type as the data used to train `coxMdl`.

Data Types: `double` | `table` | `categorical`

`Stratification` — Stratification level

variable or variables of type used for training

Stratification level, specified as a variable or variables of the same type used for training `coxMdl`. Specify the same number of rows in `Stratification` as in `X`.

Data Types: `single` | `double` | `logical` | `char` | `string` | `table` | `cell` | `categorical`

`baseline` — Baseline hazard

inferred from `coxMdl` (default) | real scalar | real row vector

Baseline hazard, specified as a real scalar or row vector.

- A scalar value applies to all predictors.
- A row vector value must have the same number of entries as the number of predictors.

The returned hazard ratio is relative to the baseline.

Example: `[1 20 100]`

Data Types: `single` | `double`

Output Arguments

`hazard` — Hazard ratio relative to baseline

nonnegative vector

Hazard ratio relative to the baseline, returned as a nonnegative vector. `hazard` gives the factor by which to multiply the baseline hazard, so you can obtain the relative hazard of an individual with predictor values `X` and, if applicable, stratification level `Stratification`.

Topics

“Cox Proportional Hazards Model Object” on page 14-39

Introduced in R2021a

hist3

Bivariate histogram plot

Syntax

```
hist3(X)
hist3(X,'Nbins',nbins)
hist3(X,'Ctrs',ctrs)
hist3(X,'Edges',edges)
hist3(___,Name,Value)
hist3(ax,___)

N = hist3(___)
[N,c] = hist3(___)
```

Description

`hist3(X)` creates a bivariate histogram plot of `X(:,1)` and `X(:,2)` using 10-by-10 equally spaced bins. The `hist3` function displays the bins as 3-D rectangular bars, and the height of each bar indicates the number of elements in the bin.

`hist3(X,'Nbins',nbins)` specifies the number of bins in each dimension of the histogram. This syntax is equivalent to `hist3(X,nbins)`.

`hist3(X,'Ctrs',ctrs)` specifies the centers of the bins in each dimension of the histogram. This syntax is equivalent to `hist3(X,ctrs)`.

`hist3(X,'Edges',edges)` specifies the edges of the bins in each dimension.

`hist3(___,Name,Value)` specifies graphical properties using one or more name-value pair arguments in addition to the input arguments in the previous syntaxes. For example, `'FaceAlpha',0.5` creates a semitransparent histogram. For a list of properties, see Surface Properties.

`hist3(ax,___)` plots into the axes specified by `ax` instead of the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`N = hist3(___)` returns the number of elements in `X` that fall in each bin. This syntax does not create a histogram.

`[N,c] = hist3(___)` also returns the bin centers. This syntax does not create a histogram.

Examples

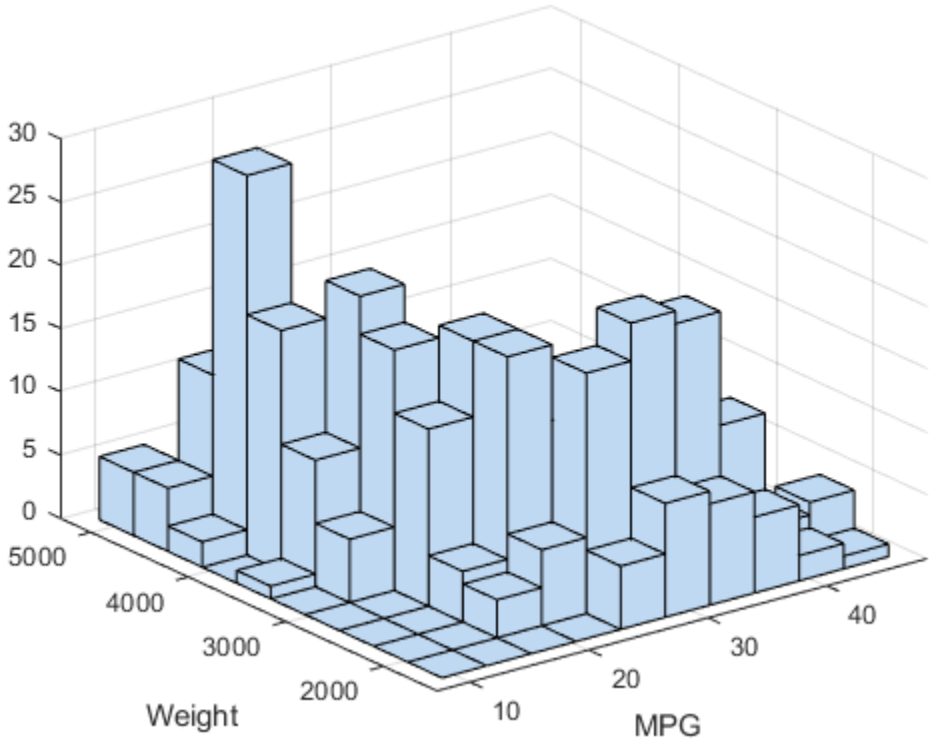
Histogram of Vectors

Load the sample data.

```
load carbig
```

Create a bivariate histogram with the default settings.

```
X = [MPG,Weight];
hist3(X)
xlabel('MPG')
ylabel('Weight')
```



Specify Centers of Histogram Bins

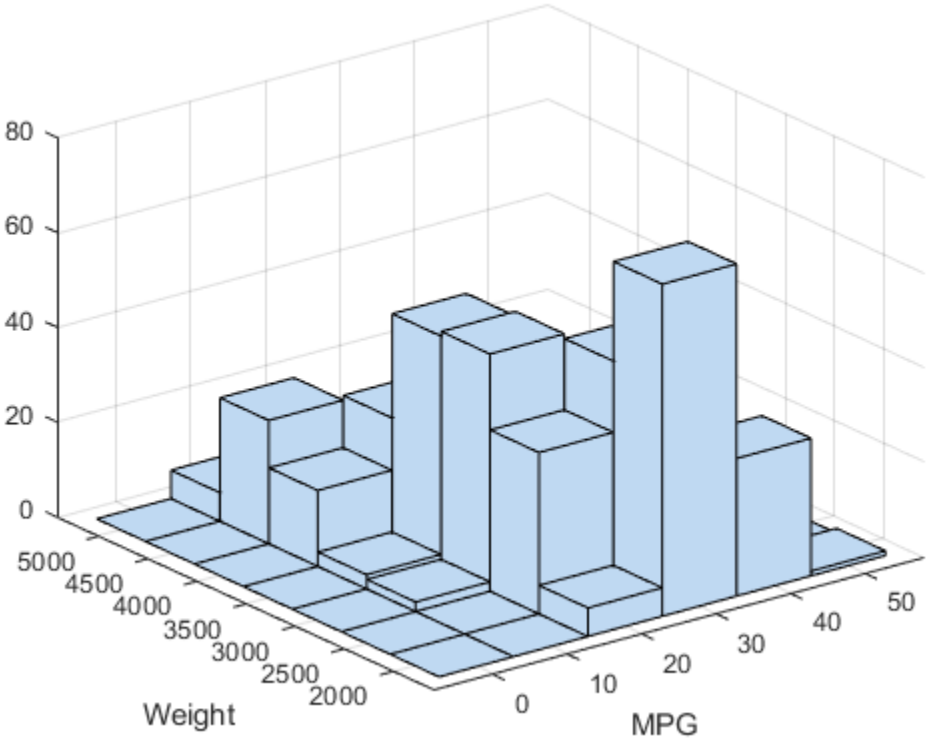
Create a bivariate histogram on the bins specified by the bin centers, and count the number of elements in each bin.

Load the sample data.

```
load carbig
```

Create a bivariate histogram. Specify the centers of the histogram bins using a two-element cell array.

```
X = [MPG,Weight];
hist3(X,'Ctrs',{0:10:50 2000:500:5000})
xlabel('MPG')
ylabel('Weight')
```



Count the number of elements in each bin.

```
N = hist3(X,'Ctrs',{0:10:50 2000:500:5000})
```

```
N = 6×7

     0     0     0     0     0     0     0
     0     0     2     3    16    26     6
     6    34    50    49    27    10     0
    70    49    11     3     0     0     0
    29     4     2     0     0     0     0
     1     0     0     0     0     0     0
```

Color Histogram Bars by Height

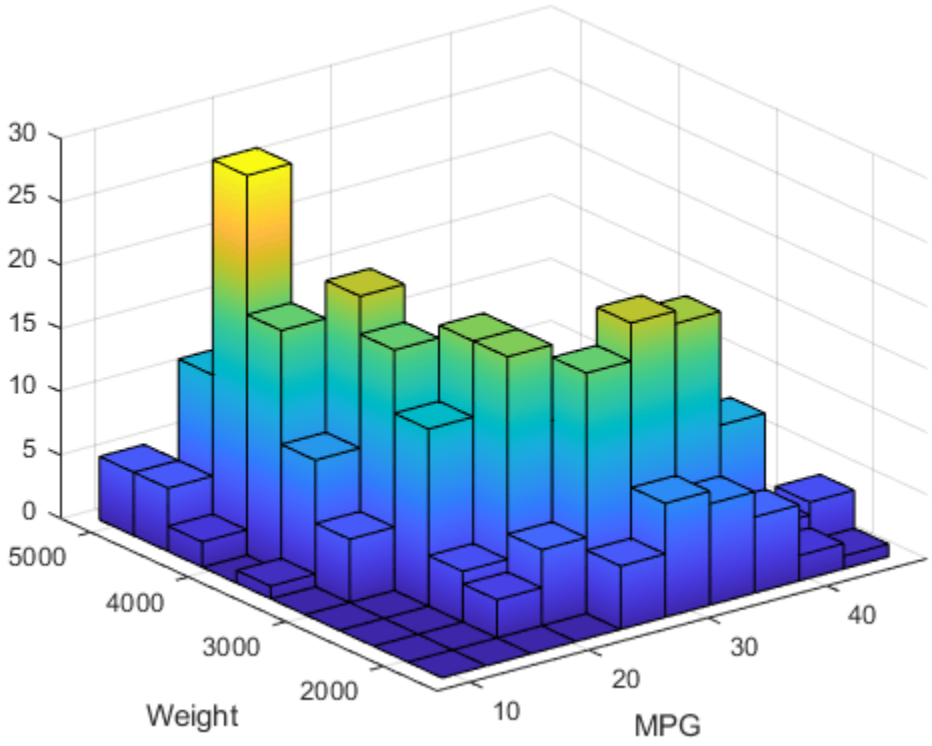
Load the sample data.

```
load carbig
```

Create a bivariate histogram. Specify graphical properties to color the histogram bars by height representing the frequency of the observations.

```
X = [MPG,Weight];
hist3(X,'CDataMode','auto','FaceColor','interp')
```

```
xlabel('MPG')
ylabel('Weight')
```



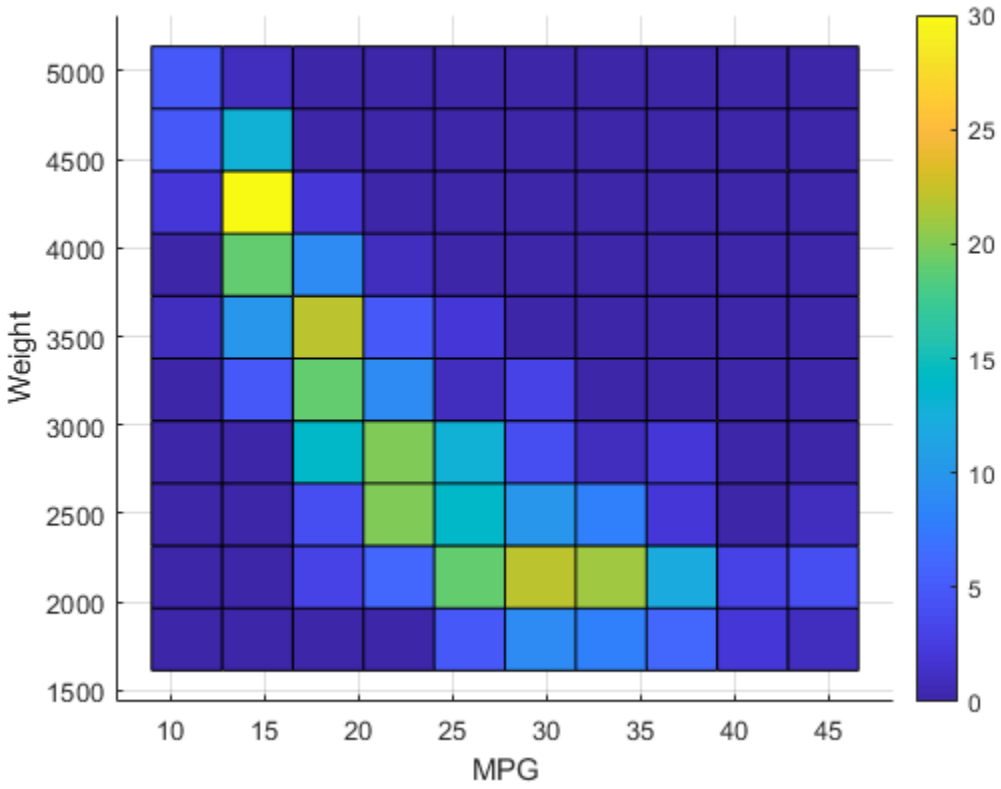
Tiled Histogram View

Load the sample data.

```
load carbig
```

Create a bivariate tiled histogram. Specify graphical properties to color the top surface of the histogram bars by the frequency of the observations. Change the view to two-dimensional.

```
X = [MPG,Weight];
hist3(X,'CdataMode','auto')
xlabel('MPG')
ylabel('Weight')
colorbar
view(2)
```



Adjust Graphical Properties

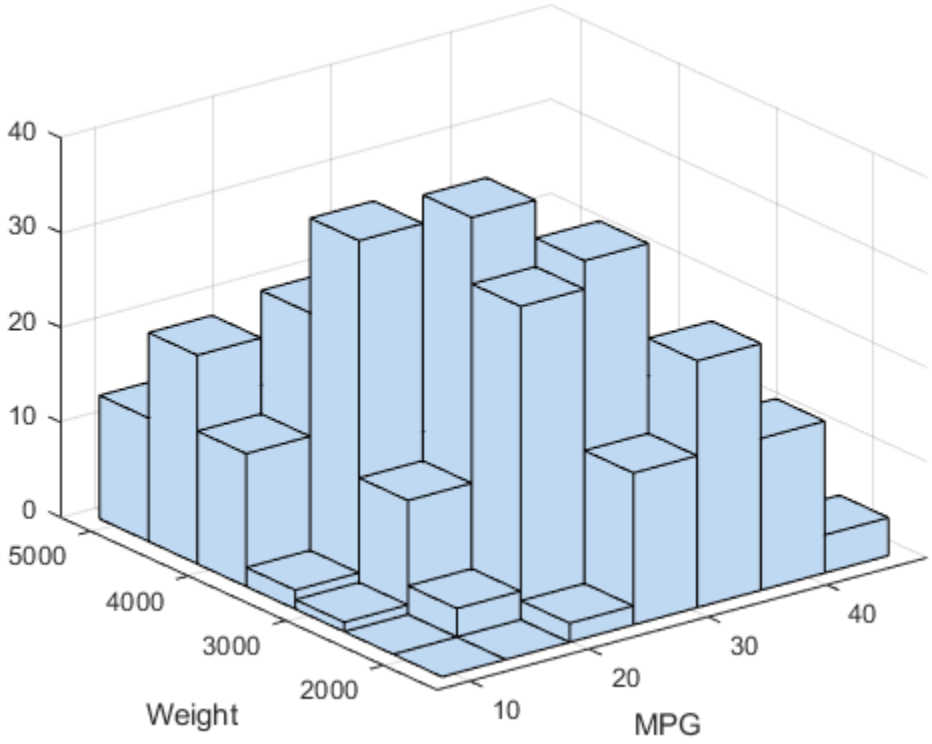
Create a bivariate histogram and adjust its graphical properties by using the handle of the histogram surface object.

Load the sample data.

```
load carbig
```

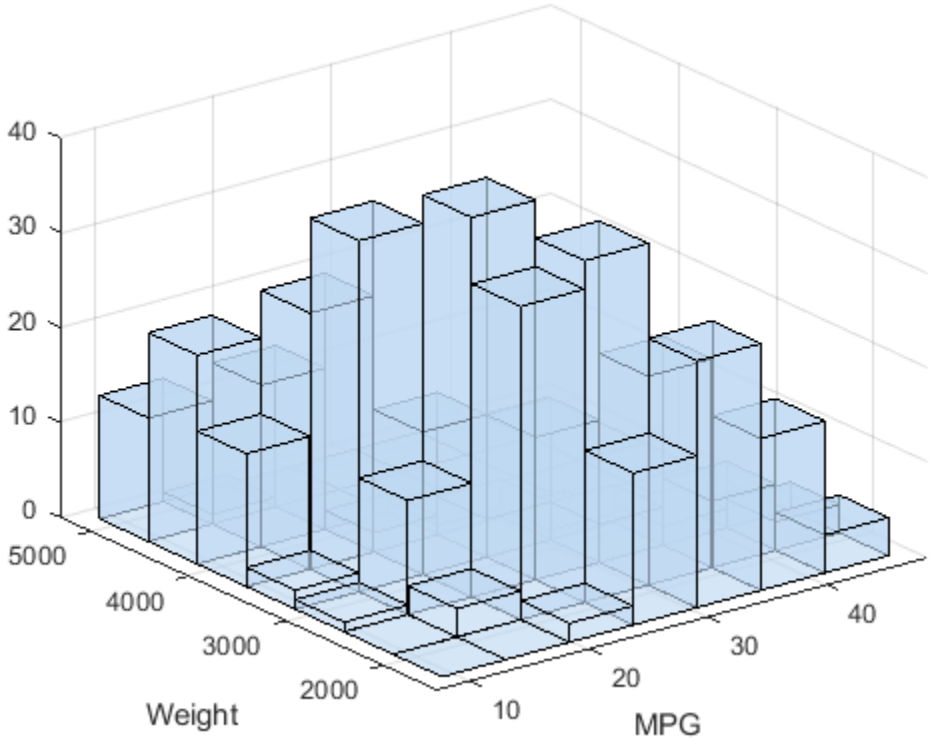
Create a bivariate histogram with 7 bins in each dimension.

```
X = [MPG,Weight];
hist3(X,'Nbins',[7 7])
xlabel('MPG')
ylabel('Weight')
```



The `hist3` function creates a bivariate histogram, which is a type of surface plot. Find the handle of the surface object and adjust the face transparency.

```
s = findobj(gca,'Type','Surface');
s.FaceAlpha = 0.65;
```



Plot Histogram with Intensity Map

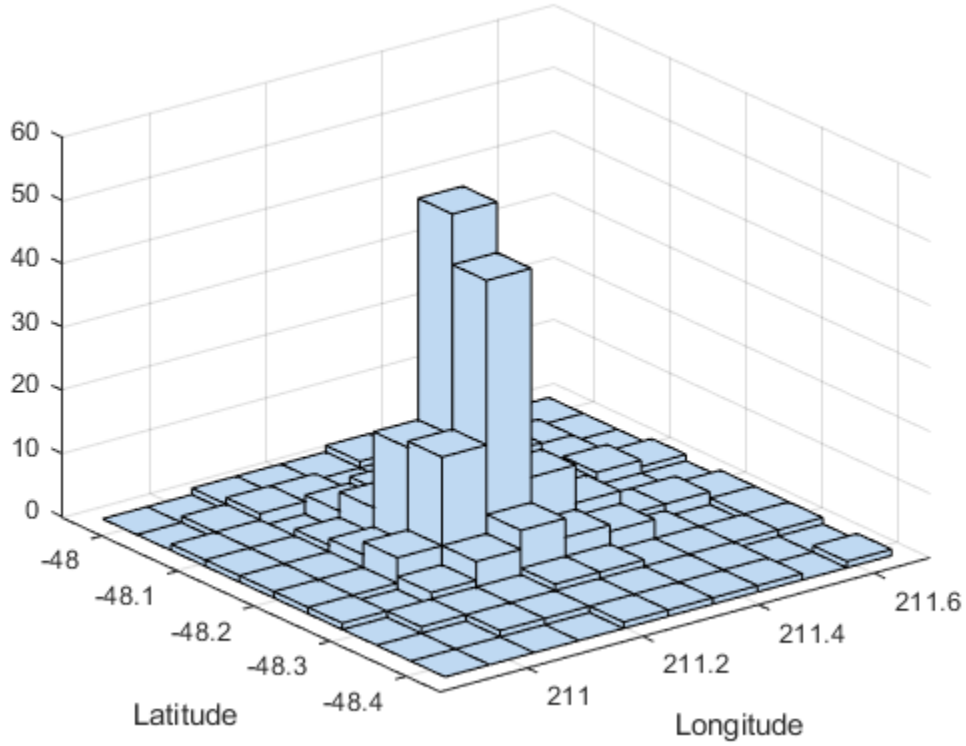
Create a bivariate histogram and add the 2-D projected view of intensities to the histogram.

Load the `seamount` data set (a *seamount* is an underwater mountain). The data set consists of a set of longitude (`x`) and latitude (`y`) locations, and the corresponding `seamount` elevations (`z`) measured at those coordinates. This example uses `x` and `y` to draw a bivariate histogram.

```
load seamount
```

Draw a bivariate histogram.

```
hist3([x,y])
xlabel('Longitude')
ylabel('Latitude')
hold on
```



Count the number of elements in each bin.

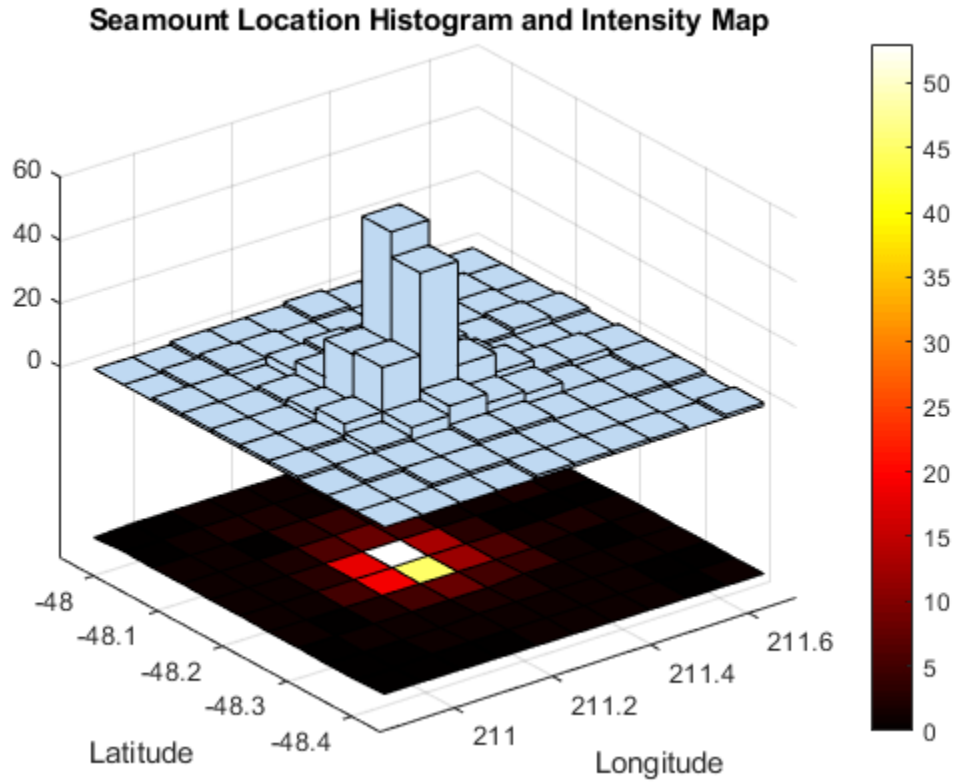
```
N = hist3([x,y]);
```

Generate a grid to draw the 2-D projected view of intensities by using `pcolor`.

```
N_pcolor = N';
N_pcolor(size(N_pcolor,1)+1,size(N_pcolor,2)+1) = 0;
xl = linspace(min(x),max(x),size(N_pcolor,2)); % Columns of N_pcolor
yl = linspace(min(y),max(y),size(N_pcolor,1)); % Rows of N_pcolor
```

Draw the intensity map by using `pcolor`. Set the *z*-level of the intensity map to view the histogram and the intensity map together.

```
h = pcolor(xl,yl,N_pcolor);
colormap('hot') % Change color scheme
colorbar % Display colorbar
h.ZData = -max(N_pcolor(:))*ones(size(N_pcolor));
ax = gca;
ax.ZTick(ax.ZTick < 0) = [];
title('Seamount Location Histogram and Intensity Map');
```



Input Arguments

X — Data to distribute among bins

m-by-2 numeric matrix

Data to distribute among the bins, specified as an *m*-by-2 numeric matrix, where *m* is the number of data points. Corresponding elements in `X(:,1)` and `X(:,2)` specify the *x* and *y* coordinates of 2-D data points.

`hist3` ignores all `NaN` values. Similarly, `hist3` ignores `Inf` and `–Inf` values unless you explicitly specify `Inf` or `–Inf` as a bin edge by using the `edges` input argument.

Data Types: `single` | `double`

nbins — Number of bins

`[10 10]` (default) | two-element vector of positive integers

Number of bins in each dimension, specified as a two-element vector of positive integers. `nbins(1)` specifies the number of bins in the first dimension, and `nbins(2)` specifies the number of bins in the second dimension.

Example: `[10 20]`

Data Types: `single` | `double`

`ctrs` — Bin centers

two-element cell array of numeric vectors

Bin centers in each dimension, specified as a two-element cell array of numeric vectors with monotonically nondecreasing values. `ctrs{1}` and `ctrs{2}` are the positions of the bin centers in the first and second dimensions, respectively.

`hist3` assigns rows of `X` falling outside the range of the grid to the bins along the outer edges of the grid.

Example: `{0:10:100 0:50:500}`

Data Types: `cell`

`edges` — Bin edges

two-element cell array of numeric vectors

Bin edges in each dimension, specified as a two-element cell array of numeric vectors with monotonically nondecreasing values. `edges{1}` and `edges{2}` are the positions of the bin edges in the first and second dimensions, respectively.

The value `X(k,:)` is in the `(i,j)`th bin if `edges{1}(i) ≤ X(k,1) < edges{1}(i+1)` and `edges{2}(j) ≤ X(k,2) < edges{2}(j+1)`.

The last bins in each dimension also include the last (outer) edge. For example, `X(k,:)` falls into the `(I,j)`th bin if `edges{1}(I–1) ≤ X(k,1) ≤ edges{1}(I)` and `edges{2}(j) ≤ X(k,2) < edges{2}(j+1)`, where `I` is the length of `edges{1}`. Also, `X(k,:)` falls into the `(i,J)`th bin if `edges{1}(i) ≤ X(k,1) < edges{1}(i+1)` and `edges{2}(J–1) ≤ X(k,2) ≤ edges{2}(J)`, where `J` is the length of `edges{2}`.

`hist3` does not count rows of `X` falling outside the range of the grid. Use `–Inf` and `Inf` in `edges` to include all non-`NaN` values.

Example: `{0:10:100 0:50:500}`

Data Types: `cell`

`ax` — Target axes

current axes (`gca`) (default) | `Axes` object

Target axes, specified as an axes object. If you do not specify an `Axes` object, then the `hist3` function uses the current axes (`gca`). For details, see Axes Properties.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `hist3(X,'FaceColor','interp','CDataMode','auto')` colors the histogram bars according to the height of the bars.

The graphical properties listed here are only a subset. For a full list, see Surface Properties.

`CDataMode` — Selection mode for vertex colors

`'manual'` (default) | `'auto'`

Selection mode for `CData` (vertex colors), specified as the comma-separated pair consisting of `'CDataMode'` and one of these values:

- `'manual'` — Use manually specified values in the `CData` property. The default color in `CData` is light steel blue corresponding to an RGB triple value of `[0.75 0.85 0.95]`.
- `'auto'` — Use the `ZData` values to set the colors. `ZData` contains the *z*-coordinate data for the eight corners of each bar.

Example: `'CDataMode','auto'`

`EdgeColor` — Edge line color
`[0 0 0]` (default) | `'none'` | `'flat'` | `'interp'` | RGB triplet | hexadecimal color code | color name | short name

Edge line color, specified as the comma-separated pair consisting of `'EdgeColor'` and one of these values:

- `'none'` — Do not draw the edges.
- `'flat'` — Use a different color for each edge based on the values in the `CData` property.
- `'interp'` — Use interpolated coloring for each edge based on the values in the `CData` property.
- RGB triplet, hexadecimal color code, color name, or short name — Use the specified color for all the edges. These values do not use the color values in the `CData` property.

The default color of `[0 0 0]` corresponds to black edges.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
`'red'`	`'r'`	`[1 0 0]`	`'#FF0000'`	
`'green'`	`'g'`	`[0 1 0]`	`'#00FF00'`	
`'blue'`	`'b'`	`[0 0 1]`	`'#0000FF'`	
`'cyan'`	`'c'`	`[0 1 1]`	`'#00FFFF'`	
`'magenta'`	`'m'`	`[1 0 1]`	`'#FF00FF'`	
`'yellow'`	`'y'`	`[1 1 0]`	`'#FFFF00'`	
`'black'`	`'k'`	`[0 0 0]`	`'#000000'`	
`'white'`	`'w'`	`[1 1 1]`	`'#FFFFFF'`	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: `'EdgeColor','blue'`

`FaceAlpha` — Face transparency
1 (default) | scalar in the range `[0,1]` | `'flat'` | `'interp'` | `'texturemap'`

Face transparency, specified as the comma-separated pair consisting of `'FaceAlpha'` and one of these values:

- Scalar in the range `[0,1]` — Use uniform transparency across all the faces. A value of `1` is fully opaque and `0` is completely transparent. Values between `0` and `1` are semitransparent. This option does not use the transparency values in the `AlphaData` property.
- `'flat'` — Use a different transparency for each face based on the values in the `AlphaData` property. The transparency value at the first vertex determines the transparency for the entire face. This value applies only when you specify the `AlphaData` property and set the `FaceColor` property to `'flat'`.
- `'interp'` — Use interpolated transparency for each face based on the values in the `AlphaData` property. The transparency varies across each face by interpolating the values at the vertices. This value applies only when you specify the `AlphaData` property and set the `FaceColor` property to `'interp'`.
- `'texturemap'` — Transform the data in `AlphaData` so that it conforms to the surface.

Example: `'FaceAlpha',0.5`

`FaceColor` — Face color
`'flat'` (default) | `'interp'` | `'none'` | `'texturemap'` | RGB triplet | hexadecimal color code | color name | short name

Face color, specified as the comma-separated pair consisting of `'FaceColor'` and one of these values:

- `'flat'` — Use a different color for each face based on the values in the `CData` property.
- `'interp'` — Use interpolated coloring for each face based on the values in the `CData` property.
- `'none'` — Do not draw the faces.
- `'texturemap'` — Transform the color data in `CData` so that it conforms to the surface.
- RGB triplet, hexadecimal color code, color name, or short name — Use the specified color for all the faces. These values do not use the color values in the `CData` property.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
`'red'`	`'r'`	`[1 0 0]`	`'#FF0000'`	
`'green'`	`'g'`	`[0 1 0]`	`'#00FF00'`	
`'blue'`	`'b'`	`[0 0 1]`	`'#0000FF'`	
`'cyan'`	`'c'`	`[0 1 1]`	`'#00FFFF'`	
`'magenta'`	`'m'`	`[1 0 1]`	`'#FF00FF'`	
`'yellow'`	`'y'`	`[1 1 0]`	`'#FFFF00'`	
`'black'`	`'k'`	`[0 0 0]`	`'#000000'`	
`'white'`	`'w'`	`[1 1 1]`	`'#FFFFFF'`	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
`[0 0.4470 0.7410]`	`'#0072BD'`	
`[0.8500 0.3250 0.0980]`	`'#D95319'`	
`[0.9290 0.6940 0.1250]`	`'#EDB120'`	
`[0.4940 0.1840 0.5560]`	`'#7E2F8E'`	
`[0.4660 0.6740 0.1880]`	`'#77AC30'`	
`[0.3010 0.7450 0.9330]`	`'#4DBEEE'`	
`[0.6350 0.0780 0.1840]`	`'#A2142F'`	

Example: `'FaceColor','interp'`

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and one of the options in this table.

Line Style	Description	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	

Line Style	Description	Resulting Line
':'	Dotted line	.....
'-.'	Dash-dotted line	_._._._.
'none'	No line	No line

Example: 'LineStyle',':'

LineWidth — Line width
0.5 (default) | positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points.

Example: 'LineWidth',0.75

Data Types: single | double

Output Arguments

N — Number of elements in each bin
numeric matrix

Number of elements in X that fall in each bin, returned as a numeric matrix.

c — Bin centers
two-element cell array of numeric vectors

Bin centers in each dimension, returned as a two-element cell array of numeric vectors. c{1} and c{2} are the positions of the bin centers in the first and second dimensions, respectively.

Tips

The hist3 function creates a bivariate histogram, which is a type of surface plot. You can specify surface properties using one or more name-value pair arguments. Also, you can change the appearance of the histogram by changing the surface property values after you create a histogram. Get the handle of the surface object by using s = findobj(gca,'Type','Surface'), and then use s to modify the surface properties. For an example, see “Adjust Graphical Properties” on page 33-2808. For a list of properties, see Surface Properties.

Alternative Functionality

The histogram2 function enables you to create a bivariate histogram using a Histogram2 object. You can use the name-value pair arguments of histogram2 to use normalization ('Normalization'), adjust the width of the bins in each dimension ('BinWidth'), and display the histogram as a rectangular array of tiles instead of 3-D bars ('DisplayStyle').

histfit

Histogram with a distribution fit

Syntax

```
histfit(data)
histfit(data,nbins)
histfit(data,nbins,dist)

histfit(ax, ___ )

h = histfit( ___ )
```

Description

`histfit(data)` plots a histogram of values in `data` using the number of bins equal to the square root of the number of elements in `data` and fits a normal density function.

`histfit(data,nbins)` plots a histogram using `nbins` bins and fits a normal density function.

`histfit(data,nbins,dist)` plots a histogram with `nbins` bins and fits a density function from the distribution specified by `dist`.

`histfit(ax, ___ )` uses the plot axes specified by the `Axes` object `ax`. Specify `ax` as the first input argument followed by any of the input argument combinations in the previous syntaxes.

`h = histfit( ___ )` returns a vector of handles `h`, where `h(1)` is the handle to the histogram and `h(2)` is the handle to the density curve.

Examples

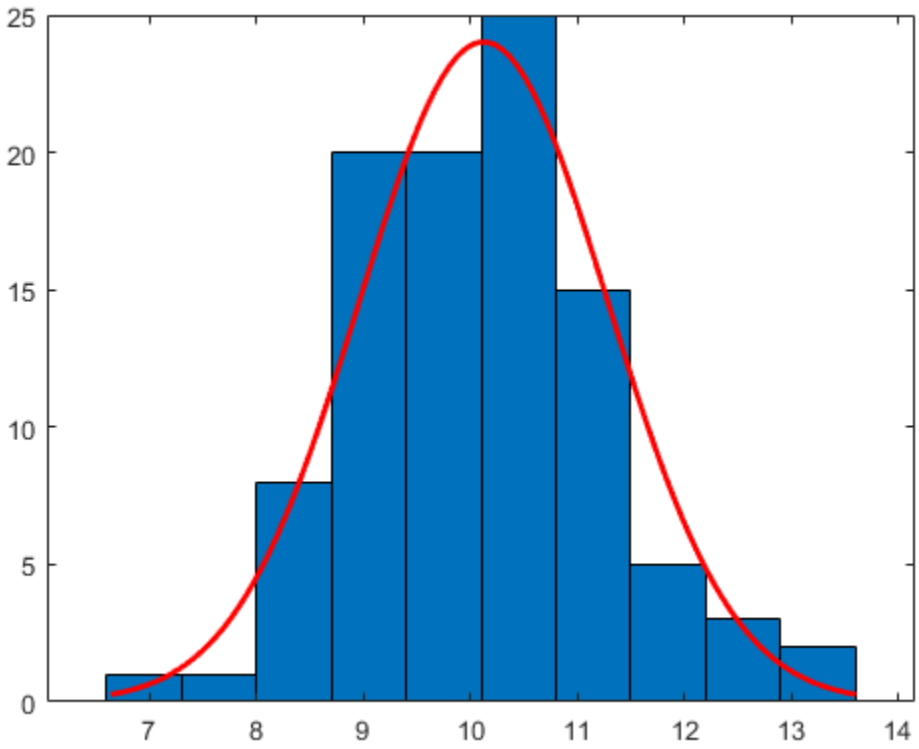
Histogram with a Normal Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
histfit(r)
```



`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

```
pd = fitdist(r,'Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
       mu = 10.1231   [9.89244, 10.3537]
    sigma =  1.1624   [1.02059, 1.35033]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

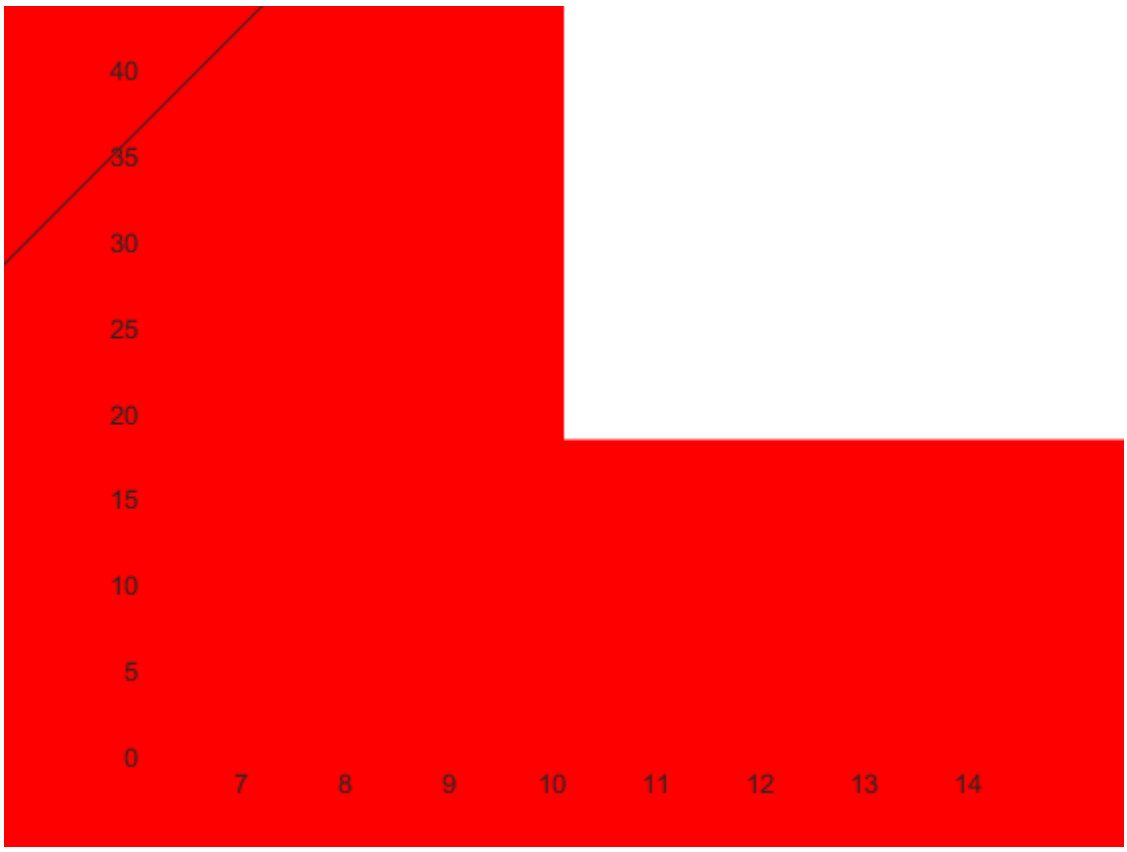
Histogram for a Given Number of Bins

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```
histfit(r,6)
```



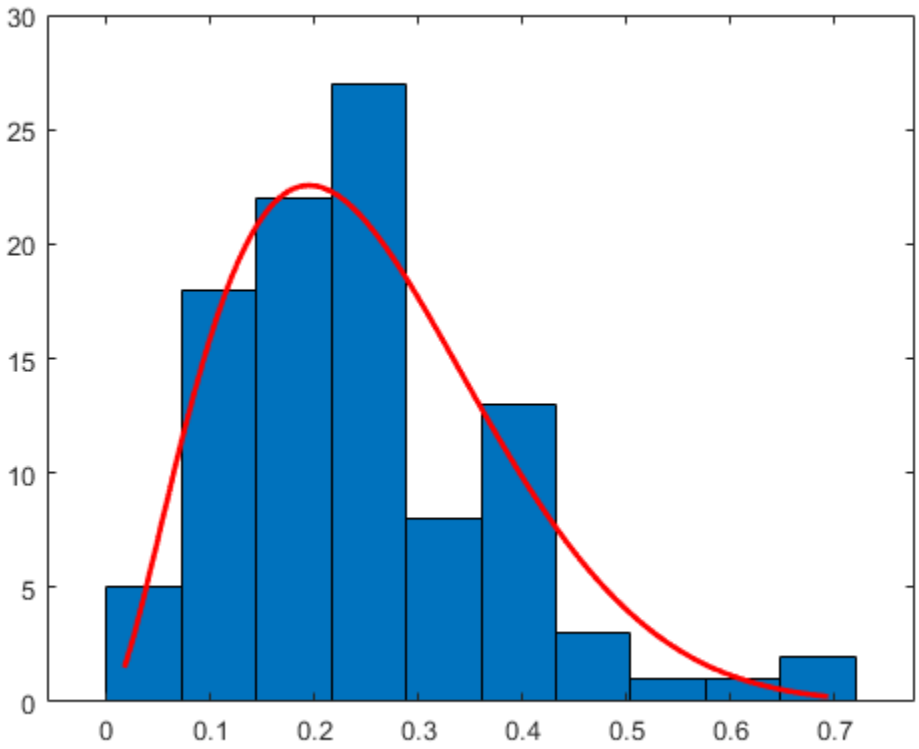
Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default;  % For reproducibility
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```
histfit(b,10,'beta')
```



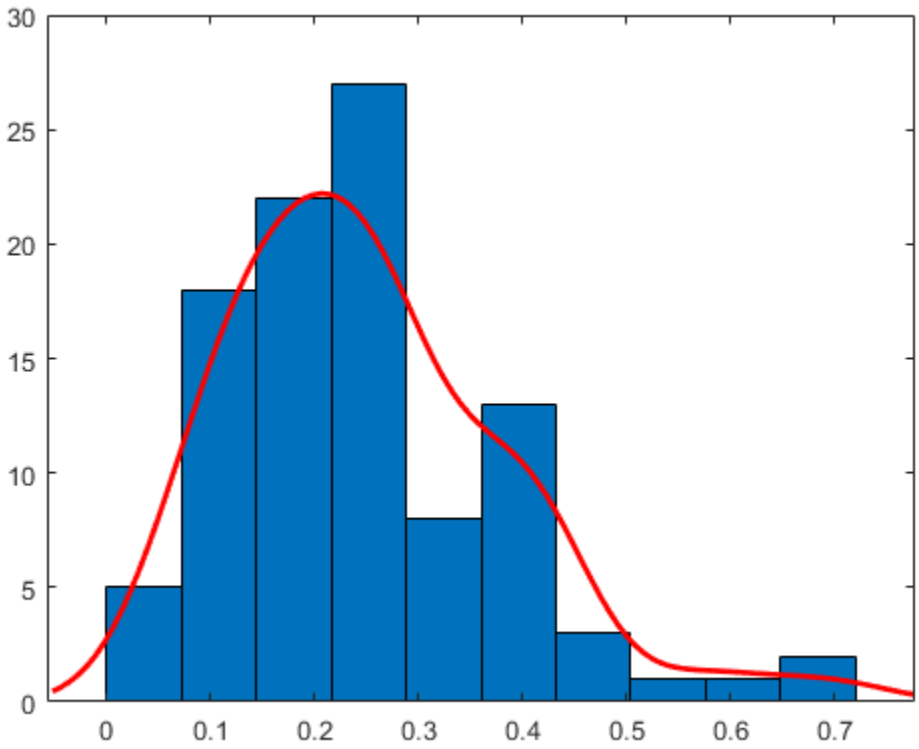
Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default;  % For reproducibility
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```
histfit(b,10,'kernel')
```



Specify Axes for Histogram with Distribution Fit

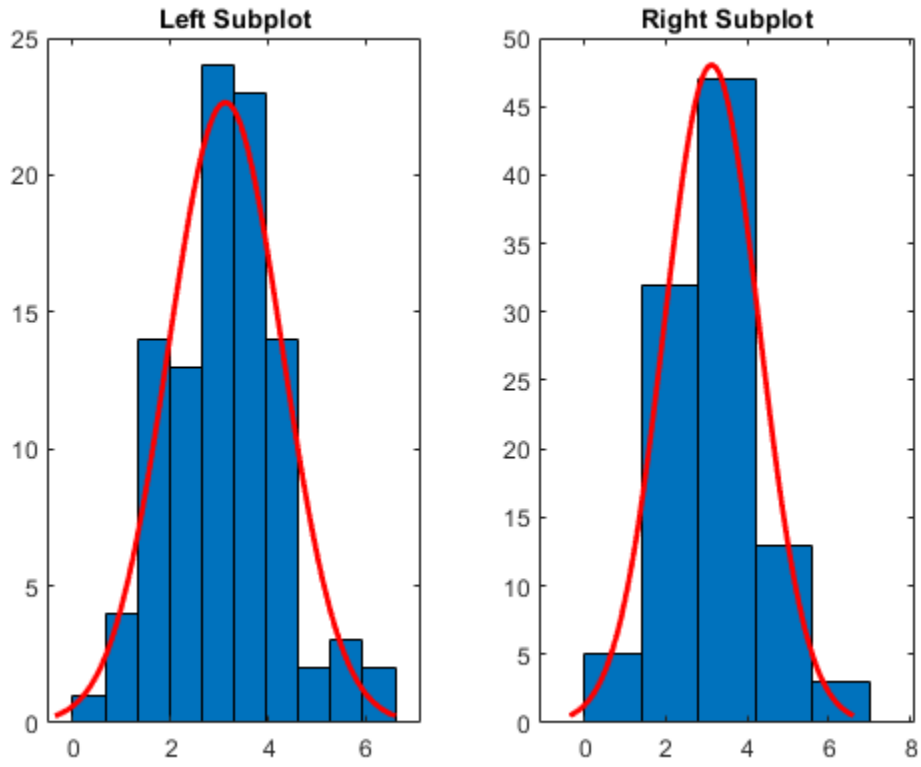
Generate a sample of size `100` from a normal distribution with mean `3` and variance `1`.

```
rng('default') % For reproducibility
r = normrnd(3,1,100,1);
```

Create a figure with two subplots and return the `Axes` objects as `ax1` and `ax2`. Create a histogram with a normal distribution fit in each set of axes by referring to the corresponding `Axes` object. In the left subplot, plot a histogram with 10 bins. In the right subplot, plot a histogram with 5 bins. Add a title to each plot by passing the corresponding `Axes` object to the `title` function.

```
ax1 = subplot(1,2,1); % Left subplot
histfit(ax1,r,10,'normal')
title(ax1,'Left Subplot')

ax2 = subplot(1,2,2); % Right subplot
histfit(ax2,r,5,'normal')
title(ax2,'Right Subplot')
```



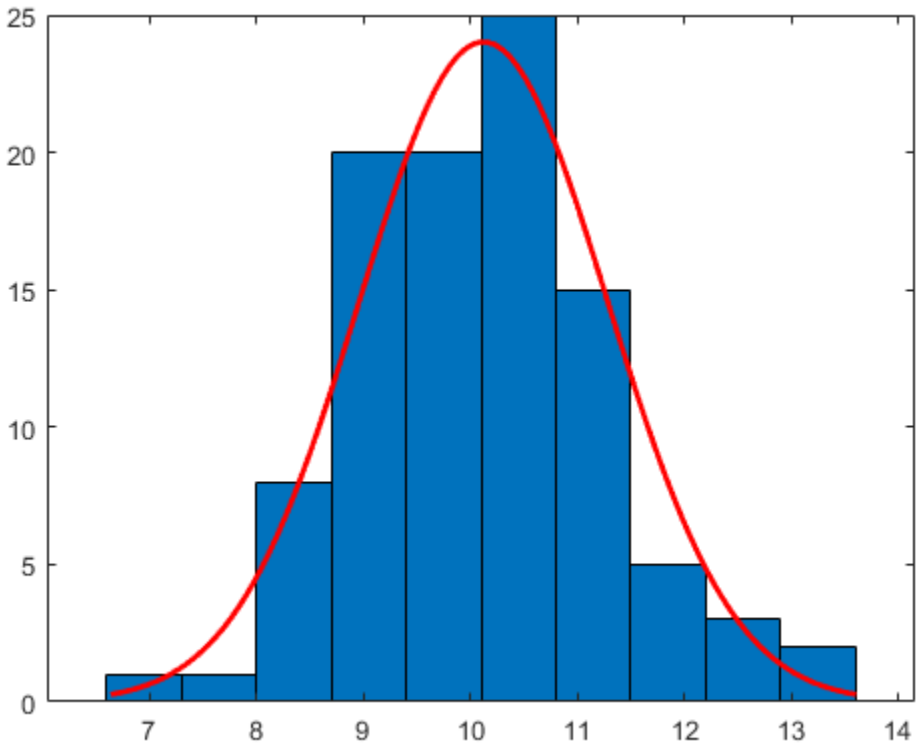
Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default % for reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
h = histfit(r,10,'normal')
```

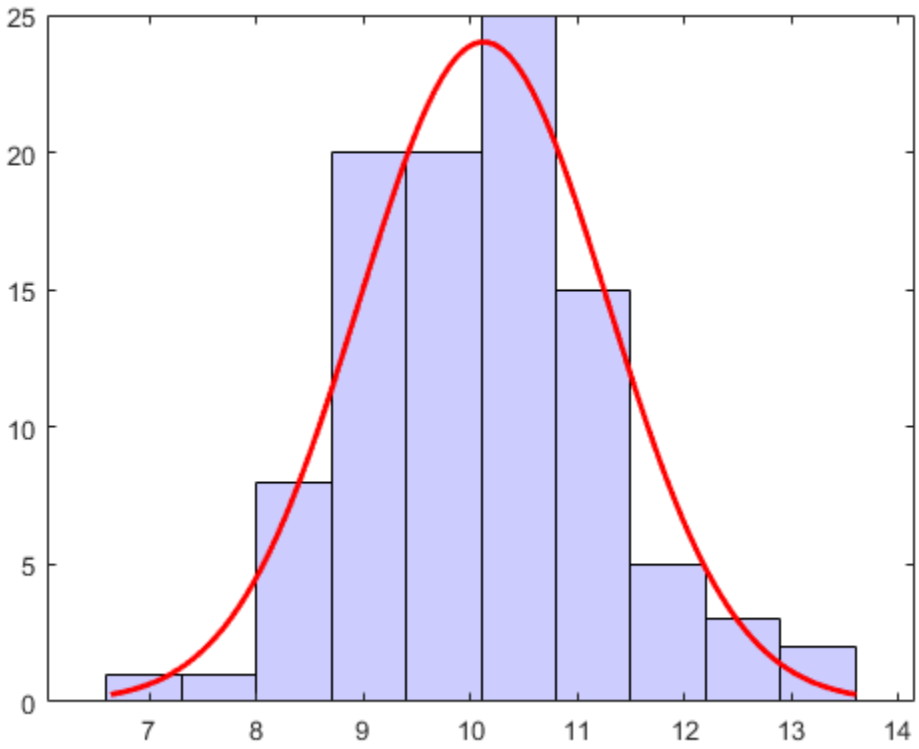


```
h =
  2x1 graphics array:

  Bar
  Line
```

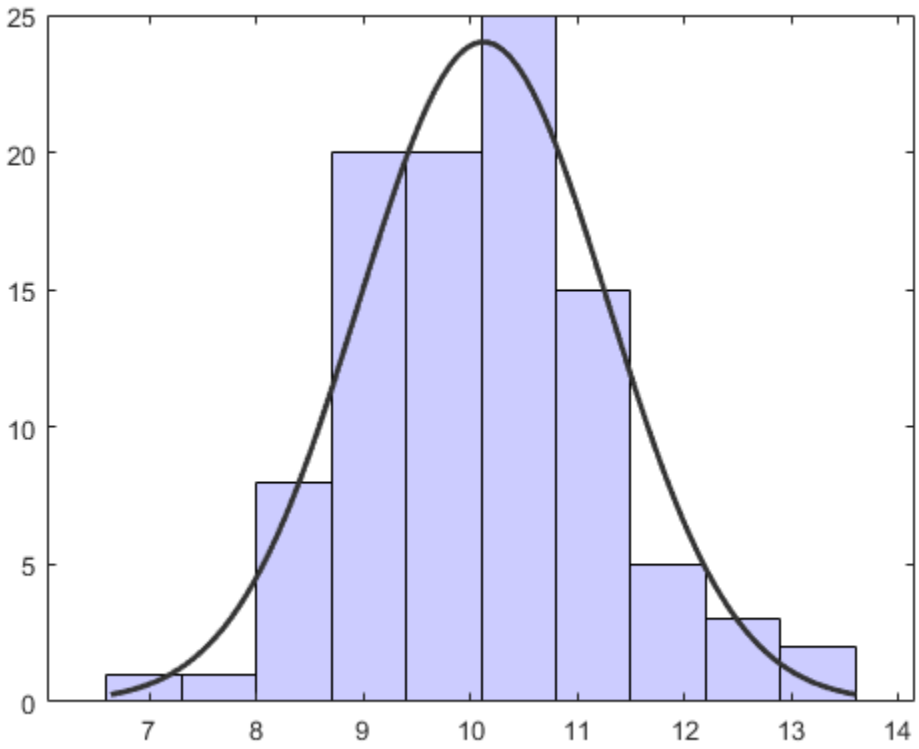
Change the bar colors of the histogram.

```
h(1).FaceColor = [.8 .8 1];
```



Change the color of the density curve.

```
h(2).Color = [.2 .2 .2];
```



Input Arguments

`data` — Input data

vector

Input data, specified as a vector.

Example: `data = [1.5 2.5 4.6 1.2 3.4]`

Example: `data = [1.5 2.5 4.6 1.2 3.4]'`

Data Types: `double` | `single`

`nbins` — Number of bins

positive integer | [ ]

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use [ ] for the default number of bins when fitting a distribution.

Example: `y = histfit(x,8)`

Example: `y = histfit(x,10,'gamma')`

Example: `y = histfit(x,[ ],'weibull')`

Data Types: `double` | `single`

dist — Distribution to fit
'normal' (default) | character vector | string scalar

Distribution to fit to the histogram, specified as a character vector or string scalar. The following table shows the supported distributions.

dist	Description
'beta'	Beta
'birnbaumsaunders'	Birnbaum-Saunders
'burr'	Burr Type XII
'exponential'	Exponential
'extreme value' or 'ev'	Extreme value
'gamma'	Gamma
'generalized extreme value' or 'gev'	Generalized extreme value
'generalized pareto' or 'gp'	Generalized Pareto (threshold 0)
'inversegaussian'	Inverse Gaussian
'logistic'	Logistic
'loglogistic'	Loglogistic
'lognormal'	Lognormal
'nakagami'	Nakagami
'negative binomial' or 'nbin'	Negative binomial
'normal'	Normal
'poisson'	Poisson
'rayleigh'	Rayleigh
'rician'	Rician
'tlocationscale'	t location-scale
'weibull' or 'wbl'	Weibull
'kernel'	Nonparametric kernel-smoothing distribution. The density is evaluated at 100 equally spaced points that cover the range of the data in data. It works best with continuously distributed samples.

ax — Axes for plot
Axes object

Axes for the plot, specified as an Axes object. If you do not specify ax, then histfit creates the plot using the current axes. For more information on creating an Axes object, see axes.

Output Arguments

h — Handles for the plot
plot handle

Handles for the plot, returned as a vector, where `h(1)` is the handle to the histogram, and `h(2)` is the handle to the density curve. `histfit` normalizes the density to match the total area under the curve with that of the histogram.

Algorithms

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

Introduced before R2006a

hmmdecode

Hidden Markov model posterior state probabilities

Syntax

```
PSTATES = hmmdecode(seq,TRANS,EMIS)
[PSTATES,logpseq] = hmmdecode(...)
[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)
hmmdecode(...,'Symbols',SYMBOLS)
```

Description

`PSTATES = hmmdecode(seq,TRANS,EMIS)` calculates the posterior state probabilities, `PSTATES`, of the sequence `seq`, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state *k* at step *i*, given the observed sequence of symbols, `sym`. You specify the model by a transition probability matrix, `TRANS`, and an emissions probability matrix, `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(k,seq)` is the probability that symbol `seq` is emitted from state `k`.

`PSTATES` is an array with the same length as `seq` and one row for each state in the model. The (*i*, *j*)th element of `PSTATES` gives the probability that the model is in state *i* at the *j*th step, given the sequence `seq`.

Note The function `hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `hmmdecode` computes the probabilities in `PSTATES` based on the fact that the model begins in state 1.

`[PSTATES,logpseq] = hmmdecode(...)` returns `logpseq`, the logarithm of the probability of sequence `seq`, given transition matrix `TRANS` and emission matrix `EMIS`.

`[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)` returns the forward and backward probabilities of the sequence scaled by `S`.

`hmmdecode(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers `1` through `N`, where `N` is the number of possible emissions.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
   1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis);
pStates = hmmdecode(seq,trans,emis);
[seq,states] = hmmgenerate(100,trans,emis,...
   'Symbols',{'one','two','three','four','five','six'})
pStates = hmmdecode(seq,trans,emis,...
   'Symbols',{'one','two','three','four','five','six'});
```

See Also

`hmmestimate` | `hmmgenerate` | `hmmtrain` | `hmmviterbi`

Introduced before R2006a

hmmestimate

Hidden Markov model parameter estimates from emissions and states

Syntax

```
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)
```

Description

`[TRANS,EMIS] = hmmestimate(seq,states)` calculates the maximum likelihood estimate of the transition, `TRANS`, and emission, `EMIS`, probabilities of a hidden Markov model for sequence, `seq`, with known states, `states`.

`hmmestimate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array, a string array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

`hmmestimate(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array, a string array, or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

`hmmestimate(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values in the matrix `PSEUDOE`. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size *m*-by-*n*, where *m* is the number of states in the hidden Markov model and *n* is the number of possible emissions. If the $i \to k$ emission does not occur in `seq`, you can set `PSEUDOE(i,k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmestimate(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size *m*-by-*m*, where *m* is the number of states in the hidden Markov model. If the $i \to j$ transition does not occur in `states`, you can set `PSEUDOTR(i,j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence `states`, or the emission might never occur in the sequence `seq`. In either case, the algorithm returns a probability of 0 for the given transition or emission in `TRANS` or `EMIS`. You can compensate for the absence of transition with the `'Pseudotransitions'` and `'Pseudoemissions'` arguments. The simplest way to do this is to set the corresponding entry of `PSEUDOE` or `PSEUDOTR` to `1`. For example, if the transition $i \to j$ does not occur in `states`, set `PSEUDOTR(i,j) = 1`. This forces `TRANS(i,j)` to be positive. If you have an estimate for the expected number of transitions $i \to j$ in a sequence of the same length as `states`, and the actual

number of transitions $i \rightarrow j$ that occur in `seq` is substantially less than what you expect, you can set `PSEUDOTR(i,j)` to the expected number. This increases the value of `TRANS(i,j)`. For transitions that do occur in states with the frequency you expect, set the corresponding entry of `PSEUDOTR` to `0`, which does not increase the corresponding entry of `TRANS`.

If you do not know the sequence of states, use `hmmtrain` to estimate the model parameters.

Examples

```
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
   1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmmestimate(seq,states);
```

`hmmdecode` | `hmmgenerate` | `hmmtrain` | `hmmviterbi`

Introduced before R2006a

hmmgenerate

Hidden Markov model states and emissions

Syntax

```
[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames',STATENAMES)
```

Description

`[seq,states] = hmmgenerate(len,TRANS,EMIS)` takes a known Markov model, specified by transition probability matrix `TRANS` and emission probability matrix `EMIS`, and uses it to generate

- A random sequence `seq` of emission symbols
- A random sequence `states` of states

The length of both `seq` and `states` is `len`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(k,l)` is the probability that symbol `l` is emitted from state `k`.

Note The function `hmmgenerate` begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state i_1, with probability T_{1i_1}, and generates an emission a_{k_l} with probability $E_{i_1k_{1_l}}$. `hmmgenerate` returns i_1 as the first entry of `states`, and a_{k_l} as the first entry of `seq`.

`hmmgenerate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be specified as a numeric array, a string array, or a cell array of character vectors. The default symbols are integers `1` through `N`, where `N` is the number of possible emissions.

`hmmgenerate(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be specified as a numeric array, a string array, or a cell array of character vectors. The default state names are `1` through `M`, where `M` is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of `TRANS`, in the following example, the first entry of the output `states` is be 1 with probability 0.95 and 2 with probability 0.05.

Examples

```
 trans = [0.95,0.05;
          0.10,0.90];
 emis = [1/6 1/6 1/6 1/6 1/6 1/6;
    1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'},...
    'Statenames',{'fair';'loaded'})
```

See Also

hmmdecode | hmmestimate | hmmtrain | hmmviterbi

Introduced before R2006a

hmmtrain

Hidden Markov model parameter estimates from emissions

Syntax

```
[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)
```

Description

`[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)` estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. `seq` can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. `TRGUESS` and `EMITGUESS` are initial estimates of the transition and emission probability matrices. `TRGUESS(i,j)` is the estimated probability of transition from state `i` to state `j`. `EMITGUESS(i,k)` is the estimated probability that symbol `k` is emitted from state `i`.

`hmmtrain(...,'Algorithm',algorithm)` specifies the training algorithm. *`algorithm`* can be either `'BaumWelch'` or `'Viterbi'`. The default algorithm is `'BaumWelch'`.

`hmmtrain(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers `1` through `N`, where `N` is the number of possible emissions.

`hmmtrain(...,'Tolerance',tol)` specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is `1e-4`.

`hmmtrain(...,'Maxiterations',maxiter)` specifies the maximum number of iterations for the estimation process. The default maximum is `100`.

`hmmtrain(...,'Verbose',true)` returns the status of the algorithm at each iteration.

`hmmtrain(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDOE` should be a matrix of size *m*-by-*n*, where *m* is the number of states in the hidden Markov model and *n* is the number of possible emissions. If the *i*→*k* emission does not occur in `seq`, you can set `PSEUDOE(i,k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmtrain(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDOTR` should be a matrix of size *m*-by-*m*, where *m* is the number of states in the hidden Markov model. If the *i*→*j*

transition does not occur in `states`, you can set `PSEUDOTR(i,j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

Tolerance

The input argument `'tolerance'` controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for `tolerance`:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of `'tolerance'` is `1e-6`. Increasing the tolerance decreases the number of steps the `hmmtrain` algorithm executes before it terminates.

`maxiterations`

The maximum number of iterations, `'maxiterations'`, controls the maximum number of steps the algorithm executes before it terminates. If the algorithm executes `maxiter` iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of `'maxiterations'` to make the algorithm reach the desired tolerance before terminating.

Examples

```
trans = [0.95,0.05;
      0.10,0.90];
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;
   1/10, 1/10, 1/10, 1/10, 1/10, 1/2];

seq1 = hmmgenerate(100,trans,emis);
seq2 = hmmgenerate(200,trans,emis);
seqs = {seq1,seq2};
[estTR,estE] = hmmtrain(seqs,trans,emis);
```

hmmviterbi

Hidden Markov model most probable state path

Syntax

```
STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)
```

Description

`STATES = hmmviterbi(seq,TRANS,EMIS)` given a sequence, `seq`, calculates the most likely path through the hidden Markov model specified by transition probability matrix, `TRANS`, and emission probability matrix `EMIS`. `TRANS(i,j)` is the probability of transition from state `i` to state `j`. `EMIS(i,k)` is the probability that symbol `k` is emitted from state `i`.

Note The function `hmmviterbi` begins with the model in state 1 at step 0, prior to the first emission. `hmmviterbi` computes the most likely path based on the fact that the model begins in state 1.

`hmmviterbi(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers `1` through `N`, where `N` is the number of possible emissions.

`hmmviterbi(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array, a string array, or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
   1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis);
estimatedStates = hmmviterbi(seq,trans,emis);

[seq,states] = ...
   hmmgenerate(100,trans,emis,...
               'Statenames',{'fair';'loaded'});
estimatesStates = ...
   hmmviterbi(seq,trans,emis,...
              'Statenames',{'fair';'loaded'});
```

Introduced before R2006a

horzcat

Class: `dataset`

(Not Recommended) Horizontal concatenation for dataset arrays

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = horzcat(ds1, ds2, ...)
```

Description

`ds = horzcat(ds1, ds2, ...)` horizontally concatenates the dataset arrays `ds1, ds2, ...` . You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and `horzcat` includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. `horzcat` concatenates by matching observation names when present, or by position for datasets that do not have observation names.

See Also

`cat` | `vertcat`

hougen

Hougen-Watson model

Syntax

```
yhat = hougen(beta,x)
```

Description

`yhat = hougen(beta,x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

$$\widehat{y} = \frac{\beta_1 x_2 - x_3/\beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

`rsmdemo`

Introduced before R2006a

hygecdf

Hypergeometric cumulative distribution function

Syntax

```
hygecdf(x,M,K,N)
hygecdf(x,M,K,N,'upper')
```

Description

`hygecdf(x,M,K,N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x,M,K,N,'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

$$p = F(x \mid M,K,N) = \sum_{i=0}^{x} \frac{\binom{K}{i}\binom{M-K}{N-i}}{\binom{M}{N}}$$

The result, p, is the probability of drawing up to x of a possible K items in N drawings without replacement from a group of M objects.

Examples

Compute Hypergeometric Distribution CDF

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

```
p = hygecdf(2,100,20,10)
```

```
p = 0.6812
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

```

Description

`hygeinv(P,M,K,N)` returns the smallest integer `X` such that the hypergeometric cdf evaluated at `X` equals or exceeds `P`. You can think of `P` as the probability of observing `X` defective items in `N` drawings without replacement from a group of `M` items where `K` are defective.

Examples

Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```
x = hygeinv(0.99,1000,10,50)
x =
   3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```
x = hygeinv(0.50,1000,10,50)
x =
   0
```

Introduced before R2006a

hygepdf

Hypergeometric probability density function

Syntax

```
Y = hygepdf(X,M,K,N)
```

Description

`Y = hygepdf(X,M,K,N)` computes the hypergeometric pdf at each of the values in `X` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `X`, `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in `M`, `K`, and `N` must all be positive integers, with `N` ≤ `M`. The values in `X` must be less than or equal to all the parameter values.

The hypergeometric pdf is

$$y = f(x \mid M, K, N) = \frac{\binom{K}{x}\binom{M-K}{N-x}}{\binom{M}{N}}$$

The result, y, is the probability of drawing exactly x of a possible K items in n drawings without replacement from a group of M objects.

Examples

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

```
p = hygepdf(0:5,100,20,10)
p =
  0.0951  0.2679  0.3182  0.2092  0.0841  0.0215
```

hygernd

Hypergeometric random numbers

Syntax

```
R = hygernd(M,K,N)
R = hygernd(M,K,N,m,n,...)
R = hygernd(M,K,N,[m,n,...])
```

Description

`R = hygernd(M,K,N)` generates random numbers from the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `R`. A scalar input for `M`, `K`, or `N` is expanded to a constant array with the same dimensions as the other inputs.

`R = hygernd(M,K,N,m,n,...)` or `R = hygernd(M,K,N,[m,n,...])` generates an `m`-by-`n`-by-... array. The `M`, `K`, `N` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
numbers = hygernd(1000,40,50)
numbers =
   1
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

hygestat

Hypergeometric mean and variance

Syntax

```
[MN,V] = hygestat(M,K,N)
```

Description

`[MN,V] = hygestat(M,K,N)` returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `M`, `K`, and `N` must have the same size, which is also the size of `MN` and `V`. A scalar input for `M`, `K`, or `N` is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters `M`, `K`, and `N` is `NK/M`, and the variance is `NK(M-K)(M-N)/[M^2(M-1)]`.

Examples

The hypergeometric distribution approaches the binomial distribution, where `p = K/M`, as `M` goes to infinity.

```
[m,v] = hygestat(10.^(1:4),10.^(0:3),9)
m =
  0.9000  0.9000  0.9000  0.9000
v =
  0.0900  0.7445  0.8035  0.8094

[m,v] = binostat(9,0.1)
m =
  0.9000
v =
  0.8100
```

hyperparameters

Variable descriptions for optimizing a fit function

Syntax

```
VariableDescriptions = hyperparameters(FitFcnName,predictors,response)
VariableDescriptions = hyperparameters(FitFcnName,predictors,response,
LearnerType)
```

Description

`VariableDescriptions = hyperparameters(FitFcnName,predictors,response)` returns the default variables for the given fit function. These are the variables that apply when you set the `OptimizeHyperparameters` name-value pair to `'auto'`.

`VariableDescriptions = hyperparameters(FitFcnName,predictors,response, LearnerType)` returns the variables for an ensemble fit with specified learner type. This syntax applies when `FitFcnName` is `'fitcecoc'`, `'fitcensemble'`, or `'fitrensemble'`.

Examples

Obtain Default Hyperparameters

Obtain the default hyperparameters for the `fitcsvm` classifier.

Load the `ionosphere` data.

```
load ionosphere
```

Obtain the hyperparameters.

```
VariableDescriptions = hyperparameters('fitcsvm',X,Y);
```

Examine all the hyperparameters.

```
for ii = 1:length(VariableDescriptions)
    disp(ii),disp(VariableDescriptions(ii))
end
```

```
     1

  optimizableVariable with properties:

         Name: 'BoxConstraint'
        Range: [1.0000e-03 1000]
         Type: 'real'
    Transform: 'log'
     Optimize: 1

     2
```

```
  optimizableVariable with properties:

        Name: 'KernelScale'
       Range: [1.0000e-03 1000]
        Type: 'real'
   Transform: 'log'
    Optimize: 1

    3

  optimizableVariable with properties:

        Name: 'KernelFunction'
       Range: {'gaussian'  'linear'  'polynomial'}
        Type: 'categorical'
   Transform: 'none'
    Optimize: 0

    4

  optimizableVariable with properties:

        Name: 'PolynomialOrder'
       Range: [2 4]
        Type: 'integer'
   Transform: 'none'
    Optimize: 0

    5

  optimizableVariable with properties:

        Name: 'Standardize'
       Range: {'true'  'false'}
        Type: 'categorical'
   Transform: 'none'
    Optimize: 0
```

Change the `PolynomialOrder` hyperparameter to have a wider range and to be used in an optimization.

```
VariableDescriptions(4).Range = [2,5];
VariableDescriptions(4).Optimize = true;
disp(VariableDescriptions(4))
```

```
  optimizableVariable with properties:

        Name: 'PolynomialOrder'
       Range: [2 5]
        Type: 'integer'
   Transform: 'none'
    Optimize: 1
```

Obtain Ensemble Hyperparameters

Obtain the default hyperparameters for the `fitrensemble` ensemble regression function.

Load the `carsmall` data.

```
load carsmall
```

Use `Horsepower` and `Weight` as predictor variables, and `MPG` as the response variable.

```
X = [Horsepower Weight];
Y = MPG;
```

Obtain the default hyperparameters for a `Tree` learner.

```
VariableDescriptions = hyperparameters('fitrensemble',X,Y,'Tree');
```

Examine all the hyperparameters.

```
for ii = 1:length(VariableDescriptions)
    disp(ii),disp(VariableDescriptions(ii))
end
```

```
     1

  optimizableVariable with properties:

         Name: 'Method'
        Range: {'Bag'  'LSBoost'}
         Type: 'categorical'
    Transform: 'none'
     Optimize: 1

     2

  optimizableVariable with properties:

         Name: 'NumLearningCycles'
        Range: [10 500]
         Type: 'integer'
    Transform: 'log'
     Optimize: 1

     3

  optimizableVariable with properties:

         Name: 'LearnRate'
        Range: [1.0000e-03 1]
         Type: 'real'
    Transform: 'log'
     Optimize: 1

     4

  optimizableVariable with properties:

         Name: 'MinLeafSize'
        Range: [1 50]
         Type: 'integer'
    Transform: 'log'
     Optimize: 1
```

```
    5

  optimizableVariable with properties:

        Name: 'MaxNumSplits'
       Range: [1 99]
        Type: 'integer'
   Transform: 'log'
    Optimize: 0

    6

  optimizableVariable with properties:

        Name: 'NumVariablesToSample'
       Range: [1 2]
        Type: 'integer'
   Transform: 'none'
    Optimize: 0
```

Change the `MaxNumSplits` hyperparameter to have a wider range and to be used in an optimization.

```
VariableDescriptions(5).Range = [1,200];
VariableDescriptions(5).Optimize = true;
disp(VariableDescriptions(5))
```

```
  optimizableVariable with properties:

        Name: 'MaxNumSplits'
       Range: [1 200]
        Type: 'integer'
   Transform: 'log'
    Optimize: 1
```

Input Arguments

`FitFcnName` — Name of fitting function

`'fitcdiscr'` | `'fitcecoc'` | `'fitcensemble'` | `'fitckernel'` | `'fitcknn'` | `'fitclinear'` | `'fitcnb'` | `'fitcsvm'` | `'fitctree'` | `'fitrensemble'` | `'fitrgp'` | `'fitrkernel'` | `'fitrlinear'` | `'fitrsvm'` | `'fitrtree'`

Name of fitting function, specified as one of the listed classification or regression fit function names.

If `FitFcnName` is `'fitcecoc'`, `'fitcensemble'`, or `'fitrensemble'`, then also specify the learner type in the `LearnerType` argument.

Example: `'fitctree'`

`predictors` — Predictor data

matrix with D predictor columns | table with D predictor columns

Predictor data, specified as a matrix with D predictor columns or as a table with D predictor columns, where D is the number of predictors.

Example: `X`

Data Types: `double` | `logical` | `char` | `string` | `table` | `cell` | `categorical` | `datetime`

response — Class labels or numeric response
grouping variable | scalar

Class labels or numeric response, specified as a grouping variable (see “Grouping Variables” on page 2-45) or as a scalar.

Example: `Y`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

LearnerType — Learner type for ensemble fit
`'Discriminant'` | `'Kernel'` | `'KNN'` | `'Linear'` | `'SVM'` | `'Tree'` | template of a listed learner

Learner type for ensemble fit, specified as `'Discriminant'`, `'Kernel'`, `'KNN'`, `'Linear'`, `'SVM'`, `'Tree'`, or a template of a listed learner. Use this argument when `FitFcnName` is `'fitcecoc'`, `'fitcensemble'`, or `'fitrensemble'`.

For `'fitcensemble'` you can use only `'Discriminant'`, `'KNN'`, `'Tree'`, or an associated template.

For `'fitrensemble'`, you can use only `'Tree'` or `templateTree`.

Example: `'Tree'`

Output Arguments

VariableDescriptions — Variable descriptions
vector of `optimizableVariable` objects

Variable descriptions, returned as a vector of `optimizableVariable` objects. The variables have their default parameters set, such as range and variable type. All eligible variables exist in the descriptions, but the variables unused in the `'auto'` setting have their `Optimize` property set to `false`. You can update the variables by using dot notation, as shown in “Examples” on page 33-0 .

See Also
`fitcdiscr` | `fitcecoc` | `fitcensemble` | `fitckernel` | `fitcknn` | `fitclinear` | `fitcnb` | `fitcsvm` | `fitctree` | `fitrensemble` | `fitrgp` | `fitrkernel` | `fitrlinear` | `fitrsvm` | `fitrtree`

Introduced in R2016b

icdf

Package: `prob`

Inverse cumulative distribution function

Syntax

```
x = icdf('name',p,A)
x = icdf('name',p,A,B)
x = icdf('name',p,A,B,C)
x = icdf('name',p,A,B,C,D)

x = icdf(pd,p)
```

Description

`x = icdf('name',p,A)` returns the inverse cumulative distribution function (icdf) for the one-parameter distribution family specified by `'name'` and the distribution parameter `A`, evaluated at the probability values in `p`.

`x = icdf('name',p,A,B)` returns the icdf for the two-parameter distribution family specified by `'name'` and the distribution parameters `A` and `B`, evaluated at the probability values in `p`.

`x = icdf('name',p,A,B,C)` returns the icdf for the three-parameter distribution family specified by `'name'` and the distribution parameters `A`, `B`, and `C`, evaluated at the probability values in `p`.

`x = icdf('name',p,A,B,C,D)` returns the icdf for the four-parameter distribution family specified by `'name'` and the distribution parameters `A`, `B`, `C`, and `D`, evaluated at the probability values in `p`.

`x = icdf(pd,p)` returns the icdf function of the probability distribution object `pd`, evaluated at the probability values in `p`.

Examples

Compute the Normal Distribution icdf

Create a standard normal distribution object with the mean, μ, equal to 0 and the standard deviation, σ, equal to 1.

```
mu = 0;
sigma = 1;
pd = makedist('Normal','mu',mu,'sigma',sigma);
```

Define the input vector p to contain the probability values at which to calculate the icdf.

```
p = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the standard normal distribution at the values in p.

```
x = icdf(pd,p)
```

```
x = 1×5

   -1.2816   -0.6745         0    0.6745    1.2816
```

Each value in *x* corresponds to a value in the input vector *p*. For example, at the value *p* equal to 0.9, the corresponding icdf value *x* is equal to 1.2816.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a standard normal distribution using the same parameter values for μ and σ.

```
x2 = icdf('Normal',p,mu,sigma)
```

```
x2 = 1×5

   -1.2816   -0.6745         0    0.6745    1.2816
```

The icdf values are the same as those computed using the probability distribution object.

Compute the Poisson Distribution icdf

Create a Poisson distribution object with the rate parameter, λ, equal to 2.

```
lambda = 2;
pd = makedist('Poisson','lambda',lambda);
```

Define the input vector *p* to contain the probability values at which to calculate the icdf.

```
p = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the Poisson distribution at the values in *p*.

```
x = icdf(pd,p)
```

```
x = 1×5

     0     1     2     3     4
```

Each value in *x* corresponds to a value in the input vector *p*. For example, at the value *p* equal to 0.9, the corresponding icdf value *x* is equal to 4.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a Poisson distribution using the same value for the rate parameter λ.

```
x2 = icdf('Poisson',p,lambda)
```

```
x2 = 1×5

     0     1     2     3     4
```

The icdf values are the same as those computed using the probability distribution object.

Compute Standard Normal Critical Values

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Determine the critical values at the 5% significance level for a test statistic with a standard normal distribution, by computing the upper and lower 2.5% values.

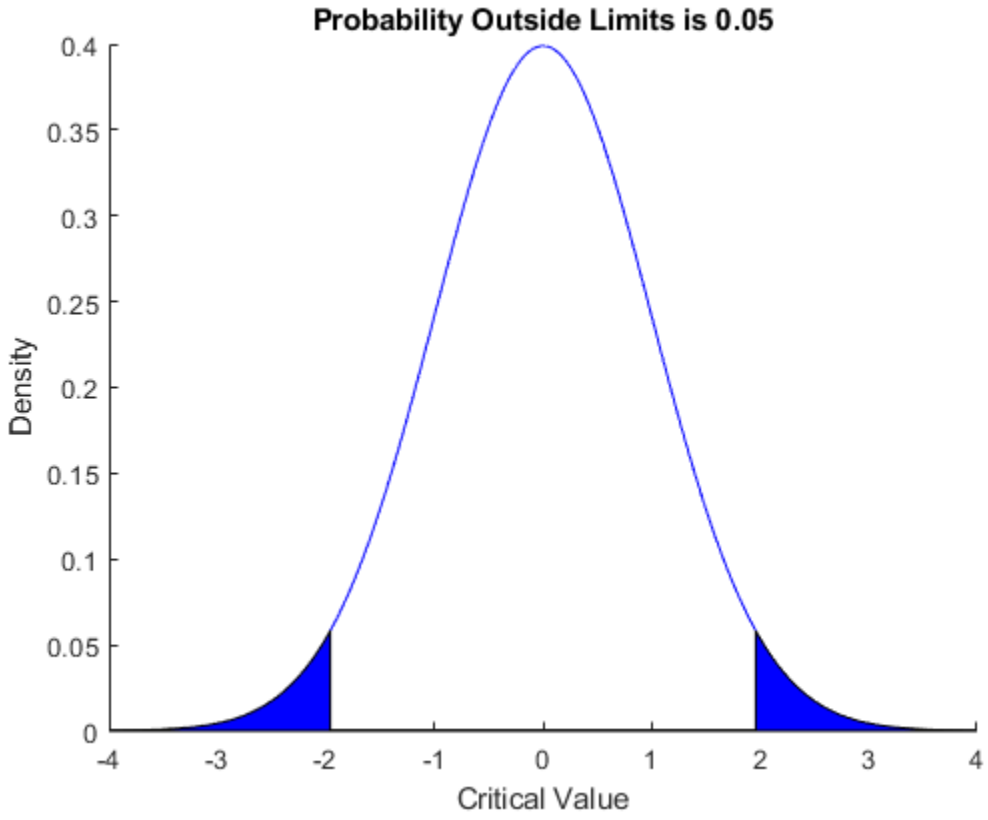
```
x = icdf(pd,[.025,.975])
```

```
x = 1×2

   -1.9600    1.9600
```

Plot the cdf and shade the critical regions.

```
p = normspec(x,0,1,'outside')
```



```
p = 0.0500
```

Input Arguments

`'name'` — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

`'name'`	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D

Example: 'Normal'

p — Probability values at which to evaluate icdf
scalar value | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value, or an array of scalar values in the range [0,1].

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Example: `[0.1,0.25,0.5,0.75,0.9]`

Data Types: `single` | `double`

`A` — First probability distribution parameter
scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`B` — Second probability distribution parameter
scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`C` — Third probability distribution parameter
scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`D` — Fourth probability distribution parameter
scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`pd` — Probability distribution
probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
`makedist`	Create a probability distribution object using specified parameter values.
`fitdist`	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
`paretotails`	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

Output Arguments

x — icdf values

scalar value | array of scalar values

icdf values, returned as a scalar value or an array of scalar values. `x` is the same size as `p` after any necessary scalar expansion. Each element in `x` is the icdf value of the distribution, specified by the corresponding elements in the distribution parameters (`A`, `B`, `C`, and `D`) or specified by the probability distribution object (`pd`), evaluated at the corresponding element in `p`.

Alternative Functionality

`icdf` is a generic function that accepts either a distribution by its name `'name'` or a probability distribution object `pd`. It is faster to use a distribution-specific function, such as `norminv` for the normal distribution and `binoinv` for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-14.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `'name'` must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 32-82.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

inconsistent

Inconsistency coefficient

Syntax

```
Y = inconsistent(Z)
Y = inconsistent(Z,d)
```

Description

`Y = inconsistent(Z)` returns the inconsistency coefficient for each link of the hierarchical cluster tree `Z` generated by the `linkage` function. `inconsistent` calculates the inconsistency coefficient for each link by comparing its height with the average height of other links at the same level of the hierarchy. The larger the coefficient, the greater the difference between the objects connected by the link. For more information, see “Algorithms” on page 33-2867.

`Y = inconsistent(Z,d)` returns the inconsistency coefficient for each link in the tree `Z` by searching to a depth `d` below each link.

Examples

Inconsistency Coefficient Calculation

Examine an inconsistency coefficient calculation for a hierarchical cluster tree.

Load the `examgrades` data set.

```
load examgrades
```

Create a hierarchical cluster tree.

```
Z = linkage(grades);
```

Create a matrix of inconsistency coefficient information using `inconsistent`. Examine the information for the 84th link.

```
Y = inconsistent(Z);
Y(84,:)
```

```
ans = 1×4

    7.2741    0.3624    3.0000    0.5774
```

The fourth column of `Y` contains the inconsistency coefficient, which is computed using the mean in the first column of `Y` and the standard deviation in the second column of `Y`.

Because the rows of `Y` correspond to the rows of `Z`, examine the 84th link in `Z`.

```
Z(84,:)
```

```
ans = 1×3

  190.0000  203.0000    7.4833
```

The 84th link connects the 190th and 203rd clusters in the tree and has a height of `7.4833`. The 190th cluster corresponds to the link of index 190 − 120 = 70, where 120 is the number of observations. The 203rd cluster corresponds to the 83rd link.

By default, `inconsistent` uses two levels of the tree to compute `Y`. Therefore, it uses only the 70th, 83rd, and 84th links to compute the inconsistency coefficient for the 84th link. Compare the values in `Y(84,:)` with the corresponding computations by using the link heights in `Z`.

```
mean84 = mean([Z(70,3) Z(83,3) Z(84,3)])
```

```
mean84 = 7.2741
```

```
std84 = std([Z(70,3) Z(83,3) Z(84,3)])
```

```
std84 = 0.3624
```

```
inconsistent84 = (Z(84,3)-mean84)/std84
```

```
inconsistent84 = 0.5774
```

Compute Inconsistency Coefficient

Create the sample data.

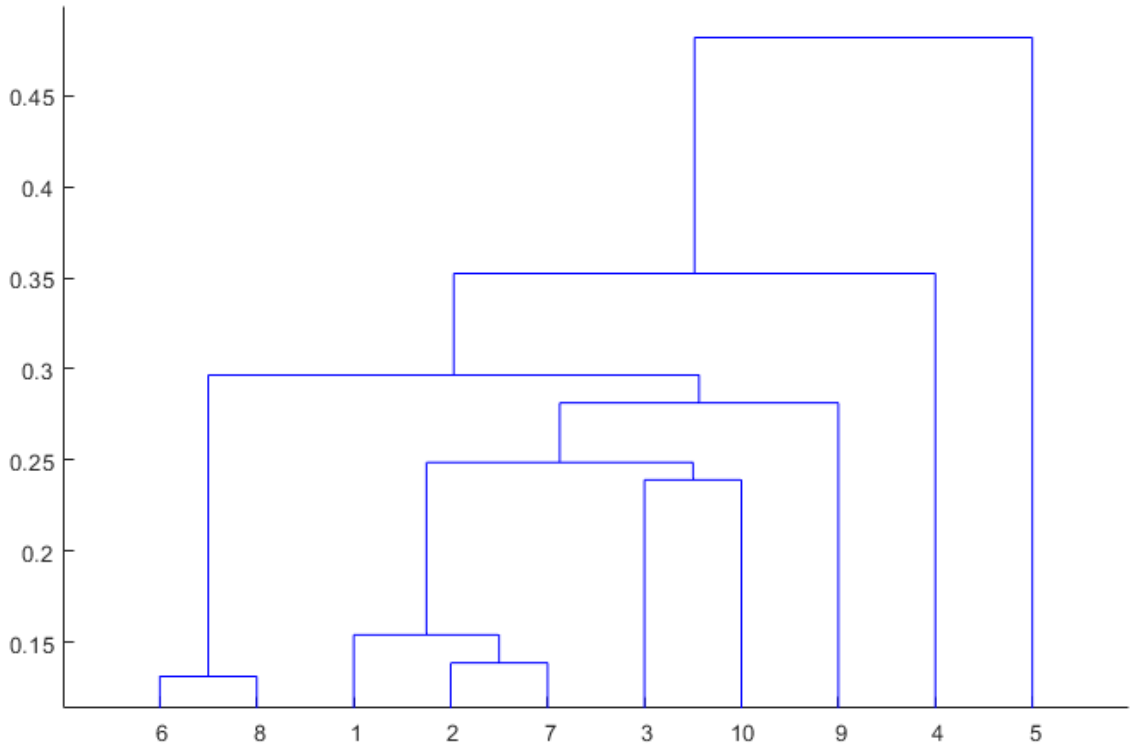
```
X = gallery('uniformdata',[10 2],12);
Y = pdist(X);
```

Generate the hierarchical cluster tree.

```
Z = linkage(Y,'single');
```

Generate a dendrogram plot of the hierarchical cluster tree.

```
dendrogram(Z)
```



Compute the inconsistency coefficient for each link in the cluster tree Z to depth 3.

```
W = inconsistent(Z,3)
```

```
W = 9×4

    0.1313         0    1.0000         0
    0.1386         0    1.0000         0
    0.1463    0.0109    2.0000    0.7071
    0.2391         0    1.0000         0
    0.1951    0.0568    4.0000    0.9425
    0.2308    0.0543    4.0000    0.9320
    0.2395    0.0748    4.0000    0.7636
    0.2654    0.0945    4.0000    0.9203
    0.3769    0.0950    3.0000    1.1040
```

Input Arguments

Z — Agglomerative hierarchical cluster tree

numeric matrix

Agglomerative hierarchical cluster tree, specified as a numeric matrix returned by `linkage`. Z is an (m – 1)-by-3 matrix, where m is the number of observations. Columns 1 and 2 of Z contain cluster

indices linked in pairs to form a binary tree. `Z(I,3)` contains the linkage distances between the two clusters merged in row `Z(I,:)`.

Data Types: `single` | `double`

d — Depth
2 (default) | positive integer scalar

Depth, specified as a positive integer scalar. For each link k, `inconsistent` calculates the corresponding inconsistency coefficient using all the links in the tree within `d` levels below k.

Data Types: `single` | `double`

Output Arguments

Y — Inconsistency coefficient information
numeric matrix

Inconsistency coefficient information, returned as an (m – 1)-by-4 matrix, where the (m – 1) rows correspond to the rows of `Z`. This table describes the columns of `Y`.

Column	Description
1	Mean of the heights of all the links included in the calculation
2	Standard deviation of the heights of all the links included in the calculation
3	Number of links included in the calculation
4	Inconsistency coefficient

Data Types: `double`

Algorithms

For each link k, the inconsistency coefficient is calculated as

$$Y(k,4) = (Z(k,3) - Y(k,1))/Y(k,2),$$

where `Y` is the inconsistency coefficient information for links in the hierarchical cluster tree `Z`.

For links that have no further links below them, the inconsistency coefficient is set to 0.

increaseB

Class: `clustering.evaluation.GapEvaluation`
Package: `clustering.evaluation`

Increase reference data sets

Syntax

```
eva_out = increaseB(eva,nref)
```

Description

`eva_out = increaseB(eva,nref)` returns a gap criterion clustering evaluation object `eva_out` that uses the same evaluation criteria as the input object `eva` and an additional number of reference data sets as specified by `nref`.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

nref — Number of additional reference data sets

positive integer value

Number of additional reference data sets, specified as a positive integer value.

Output Arguments

eva_out — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. `eva_out` contains evaluation data obtained using the reference data sets from the input object `eva` plus a number of additional reference data sets as specified in `nref`.

`increaseB` updates the `B` property of the input object `eva` to reflect the increase in the number of reference data sets used to compute the gap criterion values. `increaseB` also updates the `CriterionValues` property with gap criterion values computed using the total number of reference data sets. `increaseB` might also update the `OptimalK` and `OptimalY` properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

Examples

Evaluate Clustering Solutions Using Additional Reference Data

Create a gap clustering evaluation object using `evalclusters`, then use `increaseB` to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

```
rng('default') % For reproducibility
eva = evalclusters(meas,'kmeans','gap','klist',1:5,'B',50)
```

```
eva =
  GapEvaluation with properties:

    NumObservations: 150
         InspectedK: [1 2 3 4 5]
    CriterionValues: [0.0870 0.5822 0.8766 1.0007 1.0465]
           OptimalK: 4
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is four.

The value of the `B` property of `eva` shows 50 reference data sets.

```
eva.B
```

```
ans = 50
```

Increase the number of reference data sets by 100, for a total of 150 sets.

```
eva = increaseB(eva,100)
```

```
eva =
  GapEvaluation with properties:

    NumObservations: 150
         InspectedK: [1 2 3 4 5]
    CriterionValues: [0.0794 0.5850 0.8738 1.0034 1.0508]
           OptimalK: 5
```

The returned results now indicate that the optimal number of clusters is five.

The value of the `B` property of `eva` now shows 150 reference data sets.

```
eva.B
```

```
ans = 150
```

`evalclusters`

interactionplot

Interaction plot for grouped data

Syntax

```
interactionplot(Y,GROUP)
interactionplot(Y,GROUP,'varnames',VARNAMES)
[h,AX,bigax] = interactionplot(...)
```

Description

`interactionplot(Y,GROUP)` displays the two-factor interaction plot for the group means of matrix `Y` with groups defined by entries in `GROUP`, which can be a cell array or a matrix. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `Y` is a vector, the rows give the means of each entry in `GROUP`. If `GROUP` is a cell array, then each cell of `GROUP` must contain a grouping variable that is a categorical variable, numeric vector, character matrix, string array, or single-column cell array of character vectors. If `GROUP` is a matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position (*i*,*j*) is the interaction of the two variables whose names are given at row diagonal (*i*,*i*) and column diagonal (*j*,*j*), respectively.

`interactionplot(Y,GROUP,'varnames',VARNAMES)` displays the interaction plot with user-specified grouping variable names `VARNAMES`. `VARNAMES` is a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are `'X1'`, `'X2'`, ...

`[h,AX,bigax] = interactionplot(...)` returns a handle `h` to the figure window, a matrix `AX` of handles to the subplot axes, and a handle `bigax` to the big (invisible) axes framing the subplots.

Examples

Display Interaction Plots

Randomly generate data for a response variable `y` .

```
rng default;     % For reproducibility
y = randn(1000,1);
```

Randomly generate data for four three-level factors.

```
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```
interactionplot(y,group,'varnames',{'A','B','C','D'})
```

Introduced in R2006b

intersect

Class: `dataset`

(Not Recommended) Set intersection for dataset array observations

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( ___ )
```

Description

`C = intersect(A,B)` for `dataset` arrays `A` and `B` returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are in sorted order.

`C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observations in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, then those values are taken from the first occurrence.

`C = intersect(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = intersect( ___ )` also returns index vectors `iA` and `iB` such that `C = A(iA,:)` and `C = B(iB,:)`. If there are repeated observations in `A` or `B`, then `intersect` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

`A,B`

Input dataset arrays.

`vars`

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables in `A` and `B` that `intersect` considers.

Specify `vars` as `[]` to use its default value of all variables.

`setOrder`

Flag indicating the sorting order for the observations in `C`. The possible values of `setOrder` are:

`'sorted'`	Observations in `C` are in sorted order (default).
`'stable'`	Observations in `C` are in the same order that they appear in `A`.

Output Arguments

`C`

Dataset array with the common set of observations in `A` and `B`, with repetitions removed. `C` is in sorted order (by default), or the order specified by `setOrder`.

`iA`

Index vector, indicating the observations in `A` that are common to `B`. The vector `iA` contains the index to the first occurrence of any repeated observations in `A`.

`iB`

Index vector, indicating the observations in `B` that are common to `A`. The vector `iB` contains the index to the first occurrence of any repeated observations in `B`.

Examples

Intersection of Two Dataset Arrays

Load sample data.

```
A = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall.xlsx'));
B = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall.xlsx'),'Sh
```

Return the intersection and index vectors.

```
[C,iA,iB] = intersect(A,B);
```

```
C =

    id              name          sex        age    wgt    smoke
    'TRW-072'       'WHITE'       'm'        39     202    1
```

There is one observation in common between `A` and `B`.

Find the observation in the original dataset arrays.

```
A(iA,:)
```

```
ans =

    id              name          sex        age    wgt    smoke
    'TRW-072'       'WHITE'       'm'        39     202    1
```

```
B(iB,:)
```

```
ans =

    id              name          sex        age    wgt    smoke
    'TRW-072'       'WHITE'       'm'        39     202    1
```

Topics

“Merge Dataset Arrays” on page 2-85
“Dataset Arrays” on page 2-112

invpred

Inverse prediction

Syntax

```
X0 = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)
```

Description

`X0 = invpred(X,Y,Y0)` accepts vectors `X` and `Y` of the same length, fits a simple regression, and returns the estimated value `X0` for which the height of the line is equal to `Y0`. The output, `X0`, has the same size as `Y0`, and `Y0` can be an array of any size.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0)` also computes 95% inverse prediction intervals. `DXLO` and `DXUP` define intervals with lower bound `X0–DXLO` and upper bound `X0+DXUP`. Both `DXLO` and `DXUP` have the same size as `Y0`.

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to `-Inf` or `+Inf`, and some may extend over the entire real line.

`[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)` specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

Name	Value
`'alpha'`	A value between 0 and 1 specifying a confidence level of `100*(1-alpha)`%. Default is `alpha=0.05` for 95% confidence.
`'predopt'`	Either `'observation'`, the default value to compute the intervals for `X0` at which a new observation could equal `Y0`, or `'curve'` to compute intervals for the `X0` value at which the curve is equal to `Y0`.

Examples

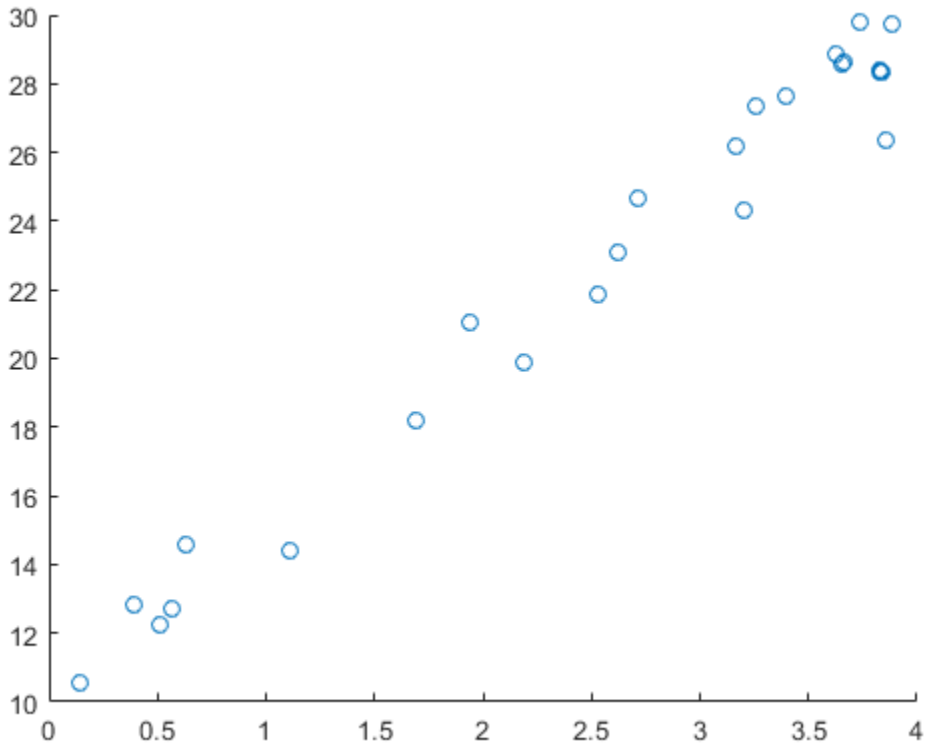
Inverse Prediction

Generate sample data.

```
x = 4*rand(25,1);
y = 10 + 5*x + randn(size(x));
```

Make a scatterplot of the data.

```
scatter(x,y)
```



Predict the *x* value for a given *y* value of 20.

```
x0 = invpred(x,y,20)
```

```
x0 = 1.9967
```

`polyconf` | `polyfit` | `polytool` | `polyval`

Introduced before R2006a

iqr

Package: `prob`

Interquartile range

Syntax

```
r = iqr(x)
r = iqr(x,'all')
r = iqr(x,dim)
r = iqr(x,vecdim)

r = iqr(pd)
```

Description

`r = iqr(x)` returns the interquartile range of the values in `x`.

- If `x` is a vector, then `r` is the difference between the 75th and the 25th percentiles of the data contained in `x`.
- If `x` is a matrix, then `r` is a row vector containing the difference between the 75th and the 25th percentiles of the sample data in each column of `x`.
- If `x` is a multidimensional array, then `iqr` operates along the first nonsingleton dimension of `x`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`r = iqr(x,'all')` returns the interquartile range of all the values in `x`.

`r = iqr(x,dim)` returns the interquartile range along the dimension of `x` specified by `dim`.

`r = iqr(x,vecdim)` returns the interquartile range over the dimensions specified by `vecdim`. For example, if `x` is a matrix, then `iqr(x,[1 2])` is the interquartile range of all the elements of `x` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`r = iqr(pd)` returns the interquartile range of the probability distribution `pd`.

Examples

Compute the Interquartile Range

Generate a 4-by-4 matrix of random data from a normal distribution with parameter values μ equal to 10 and σ equal to 1.

```
rng default  % For reproducibility
x = normrnd(10,1,4)
```

```
x = 4×4

   10.5377   10.3188   13.5784   10.7254
   11.8339    8.6923   12.7694    9.9369
```

```
    7.7412    9.5664    8.6501   10.7147
   10.8622   10.3426   13.0349    9.7950
```

Compute the interquartile range for each column of data.

```
r = iqr(x)
```

```
r = 1×4

    2.2086    1.2013    2.5969    0.8541
```

Compute the interquartile range for each row of data.

```
r2 = iqr(x,2)
```

```
r2 = 4×1

    1.7237
    2.9870
    1.9449
    1.8797
```

Compute Interquartile Range of Multidimensional Array

Compute the interquartile range of a multidimensional array over multiple dimensions by specifying the `'all'` and `vecdim` input arguments.

Create a 3-by-4-by-2 array `X`.

```
X = reshape(1:24,[3 4 2])
```

```
X =
X(:,:,1) =

     1     4     7    10
     2     5     8    11
     3     6     9    12

X(:,:,2) =

    13    16    19    22
    14    17    20    23
    15    18    21    24
```

Compute the interquartile range of all the values in `X`.

```
rall = iqr(X,'all')
```

```
rall = 12
```

Compute the interquartile range of each page of `X`. Specify the first and second dimensions as the operating dimensions along which the interquartile range is calculated.

```
rpage = iqr(X,[1 2])
```

```
rpage =
rpage(:,:,1) =

     6

rpage(:,:,2) =

     6
```

For example, `rpage(1,1,1)` is the interquartile range of all the elements in `X(:,:,1)`.

Compute the interquartile range of the elements in each `X(i,:,:)` slice by specifying the second and third dimensions as the operating dimensions.

```
rrow = iqr(X,[2 3])
```

```
rrow = 3×1

    12
    12
    12
```

For example, `rrow(3)` is the interquartile range of all the elements in `X(3,:,:)`.

Compute the Normal Distribution Interquartile Range

Create a standard normal distribution object with the mean, μ, equal to 0 and the standard deviation, σ, equal to 1.

```
pd = makedist('Normal','mu',0,'sigma',1);
```

Compute the interquartile range of the standard normal distribution.

```
r = iqr(pd)
```

```
r = 1.3490
```

The returned value is the difference between the 75th and the 25th percentile values for the distribution. This is equivalent to computing the difference between the inverse cumulative distribution function (icdf) values at the probabilities y equal to 0.75 and 0.25.

```
r2 = icdf(pd,0.75) - icdf(pd,0.25)
```

```
r2 = 1.3490
```

Interquartile Range of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```
r = iqr(pd)
```

```
r = 11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```
y = icdf(pd,[0.25,0.75])
```

```
y = 1×2

   69.1266   80.8900
```

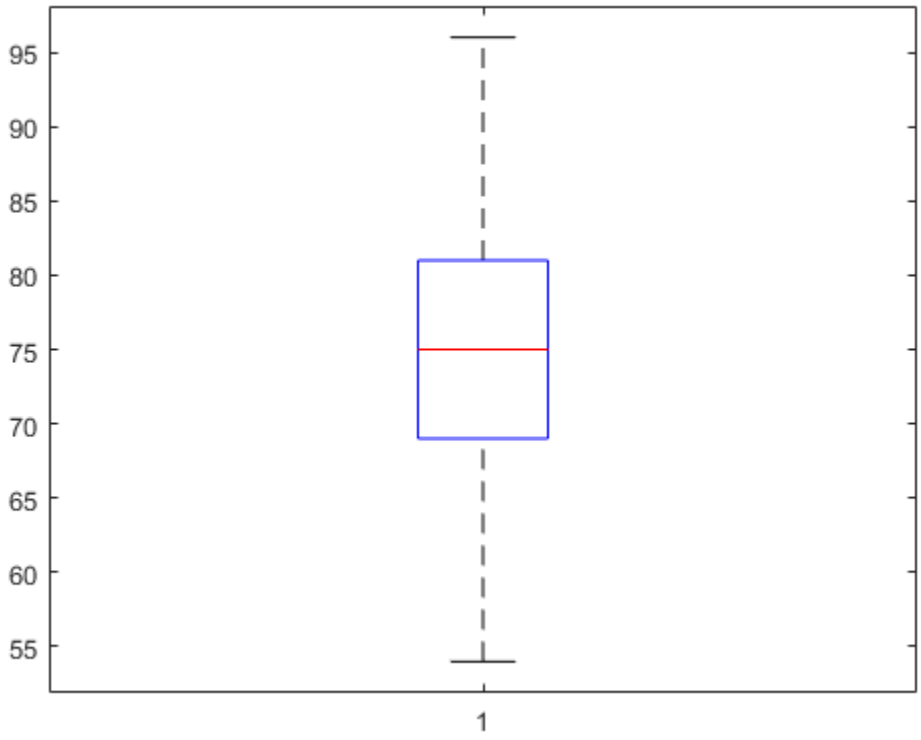
Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```
y(2)-y(1)
```

```
ans = 11.7634
```

Use `boxplot` to visualize the interquartile range.

```
boxplot(x)
```



The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

Input Arguments

`x` — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double`

`dim` — Dimension

positive integer value

Dimension along which the interquartile range is calculated, specified as a positive integer. For example, for a matrix `x`, when `dim` is equal to 1, `iqr` returns the interquartile range for the columns of `x`. When `dim` is equal to 2, `iqr` returns the interquartile range for the rows of `x`. For *n*-dimensional arrays, `iqr` operates along the first nonsingleton dimension of `x`.

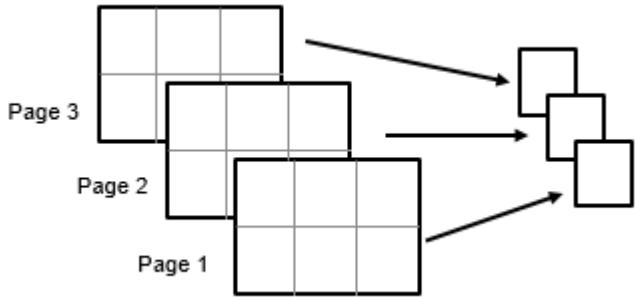
Data Types: `single` | `double`

`vecdim` — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `x`. The output `r` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `x` and `r`.

For example, if `x` is a 2-by-3-by-3 array, then `iqr(x,[1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the interquartile range of the elements on the corresponding page of `x`.



Data Types: `single` | `double`

pd — Probability distribution
probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
`makedist`	Create a probability distribution object using specified parameter values.
`fitdist`	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

r — Interquartile range values
scalar | vector | matrix | multidimensional array

Interquartile range values, returned as a scalar, vector, matrix, or multidimensional array.

- If you input an array `x`, then the dimensions of `r` depend on whether the `'all'`, `dim`, or `vecdim` input arguments are specified. Each interquartile range value in `r` is the difference between the 75th and the 25th percentiles of the specified data contained in `x`.
- If you input a probability distribution `pd`, then the scalar value of `r` is the difference between the values of the 75th and 25th percentiles of the probability distribution.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- These input arguments are not supported: `'all'` and `vecdim`.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see "Automatic dimension restriction" (MATLAB Coder).
- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see "Code Generation for Probability Distribution Objects" on page 32-82.

For more information on code generation, see "Introduction to Code Generation" on page 32-2 and "General Code Generation Workflow" on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- These input arguments are not supported: `'all'`, `vecdim`, and `pd`.

For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

Introduced before R2006a

incrementalClassificationLinear

Binary classification linear model for incremental learning

Description

`incrementalClassificationLinear` creates an `incrementalClassificationLinear` model object, which represents a binary classification linear model for incremental learning. Supported learners include support vector machine (SVM) and logistic regression.

Unlike other Statistics and Machine Learning Toolbox model objects, `incrementalClassificationLinear` can be called directly. Also, you can specify learning options such as performance metrics configurations, parameter values, and the objective solver, before fitting the model to data. After you create an `incrementalClassificationLinear` object, it is prepared for incremental learning on page 33-2906.

`incrementalClassificationLinear` is best suited for incremental learning. For a traditional approach to training an SVM or linear model for binary classification (such as creating a model by fitting it to data, performing cross-validation, tuning hyperparameters, and so on), see `fitcsvm` or `fitclinear`. For multiclass incremental learning using the naive Bayes algorithm, see `incrementalClassificationNaiveBayes`.

Creation

You can create an `incrementalClassificationLinear` model object in several ways:

- **Call the function directly** — Configure incremental learning options, or specify initial values for linear model parameters and hyperparameters, by calling `incrementalClassificationLinear` directly. This approach is best when you do not have data yet or you want to start incremental learning immediately.
- **Convert a traditionally trained model** — To initialize a binary classification linear model for incremental learning using the model coefficients and hyperparameters of a trained SVM or binary classification linear model object, you can convert the traditionally trained model to an `incrementalClassificationLinear` model object by passing it to the `incrementalLearner` function. This table contains links to the appropriate reference pages.

Convertible Model Object	Conversion Function
`ClassificationSVM` or `CompactClassificationSVM`	`incrementalLearner`
`ClassificationLinear`	`incrementalLearner`

- **Call an incremental learning function** — `fit`, `updateMetrics`, and `updateMetricsAndFit` accept a configured `incrementalClassificationLinear` model object and data as input, and return an `incrementalClassificationLinear` model object updated with information learned from the input model and data.

Syntax

```
Mdl = incrementalClassificationLinear()
Mdl = incrementalClassificationLinear(Name,Value)
```

Description

`Mdl = incrementalClassificationLinear()` returns a default binary classification linear model object for incremental learning, `Mdl`. Properties of a default model contain placeholders for unknown model parameters. You must train a default model before you can track its performance or generate predictions from it.

`Mdl = incrementalClassificationLinear(Name,Value)` sets properties on page 33-2889 and additional options using name-value pair arguments. Enclose each name in quotes. For example, `incrementalClassificationLinear('Beta',[0.1 0.3],'Bias',1,'MetricsWarmupPeriod',100)` sets the vector of linear model coefficients β to `[0.1 0.3]`, the bias β_0 to `1`, and the metrics warm-up period to `100`.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Standardize',true` standardizes the predictor data using the predictor means and standard deviations estimated during the estimation period.

`Metrics` — Model performance metrics to track during incremental learning
`"classiferror"` (default) | string vector | function handle | cell vector | structure array | `"binodeviance"` | `"exponential"` | `"hinge"` | `"logit"` | `"quadratic"` | ...

Model performance metrics to track during incremental learning, specified as a built-in loss function name, string vector of names, function handle (`@metricName`), structure array of function handles, or cell vector of names, function handles, or structure arrays.

When `Mdl` is warm (see IsWarm), `updateMetrics` and `updateMetricsAndFit` track performance metrics in the Metrics property of `Mdl`.

The following table lists the built-in loss function names. You can specify more than one by using a string vector.

Name	Description
`"binodeviance"`	Binomial deviance
`"classiferror"`	Classification error
`"exponential"`	Exponential
`"hinge"`	Hinge
`"logit"`	Logistic
`"quadratic"`	Quadratic

For more details on the built-in loss functions, see `loss`.

Example: `'Metrics',["classiferror" "hinge"]`

To specify a custom function that returns a performance metric, use function handle notation. The function must have this form:

```
metric = customMetric(C,S)
```

- The output argument `metric` is an *n*-by-1 numeric vector, where each element is the loss of the corresponding observation in the data processed by the incremental learning functions during a learning cycle.
- You select the function name (`customMetric`).
- `C` is an *n*-by-2 logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in the `ClassNames` property. Create `C` by setting `C(p,q) = 1`, if observation *p* is in class *q*, for each observation in the specified data. Set the other element in row *p* to `0`.
- `S` is an *n*-by-2 numeric matrix of predicted classification scores. `S` is similar to the `Score` output of `predict`, where rows correspond to observations in the data and the column order corresponds to the class order in the `ClassNames` property. `S(p,q)` is the classification score of observation *p* being classified in class *q*.

To specify multiple custom metrics and assign a custom name to each, use a structure array. To specify a combination of built-in and custom metrics, use a cell vector.

Example: `'Metrics',struct('Metric1',@customMetric1,'Metric2',@customMetric2)`

Example: `'Metrics',{@customMetric1 @customeMetric2 'logit' struct('Metric3',@customMetric3)}`

`updateMetrics` and `updateMetricsAndFit` store specified metrics in a table in the `Metrics` property. The data type of `Metrics` determines the row names of the table.

`'Metrics'` Value Data Type	Description of `Metrics` Property Row Name	Example
String or character vector	Name of corresponding built-in metric	Row name for `"classiferror"` is `"ClassificationError"`
Structure array	Field name	Row name for `struct('Metric1',@customMetric1)` is `"Metric1"`
Function handle to function stored in a program file	Name of function	Row name for `@customMetric` is `"customMetric"`
Anonymous function	`CustomMetric_`*j*, where *j* is metric *j* in `Metrics`	Row name for `@(C,S)customMetric(C,S)...` is `CustomMetric_1`

For more details on performance metrics options, see “Performance Metrics” on page 33-2909.

Data Types: `char` | `string` | `struct` | `cell` | `function_handle`

`Standardize` — Flag to standardize predictor data
`'auto'` (default) | `false` | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and a value in this table.

Value	Description
`'auto'`	`incrementalClassificationLinear` determines whether the predictor variables need to be standardized. See “Standardize Data” on page 33-2908.
`true`	The software standardizes the predictor data. For more details, see “Standardize Data” on page 33-2908.
`false`	The software does not standardize the predictor data.

Example: `'Standardize',true`

Data Types: `logical` | `char` | `string`

Properties

You can set most properties by using name-value pair argument syntax only when you call `incrementalClassificationLinear` directly. You can set some properties when you call `incrementalLearner` to convert a traditionally trained model. You cannot set the properties `FittedLoss`, `NumTrainingObservations`, `Mu`, `Sigma`, `SolverOptions`, and `IsWarm`.

Classification Model Parameters

`Beta` — Linear model coefficients β

numeric vector

This property is read-only.

Linear model coefficients β, specified as a `NumPredictors`-by-1 numeric vector.

If you convert a traditionally trained model to create `Mdl`, `Beta` is specified by the value of the `Beta` property of the traditionally trained model. Otherwise, by default, `Beta` is `zeros(NumPredictors,1)`.

Data Types: `single` | `double`

`Bias` — Model intercept β_0

numeric scalar

This property is read-only.

Model intercept β_0, or bias term, specified as a numeric scalar.

If you convert a traditionally trained model to create `Mdl`, `Bias` is specified by the value of the `Bias` property of the traditionally trained model. Otherwise, by default, `Bias` is `0`.

Data Types: `single` | `double`

`ClassNames` — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used in training the model, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `incrementalClassificationLinear` stores a specified string vector as a cell array of character vectors. `ClassNames` and the response data must have the same data type.

- If you convert a traditionally trained model to create `Mdl`, `ClassNames` is the `ClassNames` property of the traditionally trained model.
- Otherwise, incremental fitting functions infer `ClassNames` during training.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

`FittedLoss` — Loss function used to fit linear model
`'hinge'` | `'logit'`

This property is read-only.

Loss function used to fit the linear model, specified as `'hinge'` or `'logit'`.

Value	Algorithm	Loss Function	`Learner` Value
`'hinge'`	Support vector machine	Hinge: $\ell[y, f(x)] = \max [0, 1 - yf(x)]$	`'svm'`
`'logit'`	Logistic regression	Deviance (logistic): $\ell[y, f(x)] = \log \{1 + \exp[-yf(x)]\}$	`'logistic'`

`Learner` — Linear classification model type
`'logistic'` | `'svm'`

This property is read-only.

Linear classification model type, specified as `'logistic'` or `'svm'`.

In the following table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Loss Function	`FittedLoss` Value
`'logistic'`	Logistic regression	Deviance (logistic): $\ell[y, f(x)] = \log \{1 + \exp[-yf(x)]\}$	`'logit'`
`'svm'`	Support vector machine	Hinge: $\ell[y, f(x)] = \max [0, 1 - yf(x)]$	`'hinge'`

If you convert a traditionally trained model to create `Mdl`, `Learner` is the learner of the traditionally trained model.

- If the traditionally trained model is `ClassificationSVM` or `CompactClassificationSVM`, `Learner` is `'svm'`.

- If the traditionally trained model is `ClassificationLinear`, `Learner` is the value of the `Learner` property of the traditionally trained model.

`NumPredictors` — Number of predictor variables
`0` (default) | nonnegative numeric scalar

This property is read-only.

Number of predictor variables, specified as a nonnegative numeric scalar.

If you convert a traditionally trained model to create `Mdl`, `NumPredictors` is specified by the congruent property of the traditionally trained model. Otherwise, incremental fitting functions infer `NumPredictors` from the predictor data during training.

Data Types: `double`

`NumTrainingObservations` — Number of observations fit to incremental model
`0` (default) | nonnegative numeric scalar

This property is read-only.

Number of observations fit to the incremental model `Mdl`, specified as a nonnegative numeric scalar. `NumTrainingObservations` increases when you pass `Mdl` and training data to `fit` or `updateMetricsAndFit`.

Note If you convert a traditionally trained model to create `Mdl`, `incrementalClassificationLinear` does not add the number of observations fit to the traditionally trained model to `NumTrainingObservations`.

Data Types: `double`

`Prior` — Prior class probabilities
numeric vector | `'empirical'` | `'uniform'`

This property is read-only.

Prior class probabilities, specified as a value in this table. You can set this property using name-value pair argument syntax, but `incrementalClassificationLinear` always stores a numeric vector.

Value	Description
`'empirical'`	Incremental learning functions infer prior class probabilities from the observed class relative frequencies in the response data during incremental training (after the estimation period `EstimationPeriod`).
`'uniform'`	For each class, the prior probability is $1/K$, where K is the number of classes.
numeric vector	Custom, normalized prior probabilities. The order of the elements of `Prior` corresponds to the elements of the `ClassNames` property.

- If you convert a traditionally trained model to create `Mdl`, `incrementalClassificationLinear` uses the `Prior` property of the traditionally trained model.
- Otherwise, `Prior` is `'empirical'`.

Data Types: `single` | `double`

`ScoreTransform` — Score transformation function
character vector | string scalar | function handle

This property is read-only.

Score transformation function describing how incremental learning functions transform raw response values, specified as a character vector, string scalar, or function handle. `incrementalClassificationLinear` stores the specified value as a character vector or function handle.

This table describes the available built-in functions for score transformation.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function that you define, enter its function handle; for example, `'ScoreTransform',@`*`function`*, where:

- *`function`* accepts an n-by-K matrix (the original scores) and returns a matrix of the same size (the transformed scores).
- n is the number of observations, and row j of the matrix contains the class scores of observation j.
- K is the number of classes `numel(ClassNames)`, and column k is class `ClassNames(`*`k`*`)`.

By default:

- If you convert a traditionally trained model to create `Mdl`, `ScoreTransform` is specified by the congruent property of the traditionally trained model. For example, if the `ScoreTransform` property of the traditionally trained model is a score-to-posterior-probability transformation function, as computed by `fitPosterior` or `fitSVMPosterior`, `Mdl.ScoreTransform` contains an anonymous function.

- `ScoreTransform` is `'none'` when `Learner` is `'svm'`.
- `ScoreTransform` is `'logit'` when `Learner` is `'logistic'`.

Data Types: `char` | `function_handle`

Training Parameters

`EstimationPeriod` — Number of observations processed to estimate hyperparameters

nonnegative integer

This property is read-only.

Number of observations processed by the incremental model to estimate hyperparameters before training or tracking performance metrics, specified as a nonnegative integer.

Note

- If `Mdl` is prepared for incremental learning (all hyperparameters required for training are specified), `incrementalClassificationLinear` forces `'EstimationPeriod'` to `0`.
- If `Mdl` is not prepared for incremental learning, `incrementalClassificationLinear` sets `'EstimationPeriod'` to `1000`.

For more details, see “Estimation Period” on page 33-2907.

Data Types: `single` | `double`

`FitBias` — Linear model intercept inclusion flag

`true` | `false`

This property is read-only.

Linear model intercept inclusion flag, specified as `true` or `false`.

Value	Description
`true`	`incrementalClassificationLinear` includes the bias term β_0 in the linear model, which incremental fitting functions fit to data.
`false`	`incrementalClassificationLinear` sets $\beta_0 = 0$.

If `Bias` ≠ 0, `FitBias` must be `true`. In other words, `incrementalClassificationLinear` does not support an equality constraint on β_0.

If you convert a traditionally trained linear classification model (`ClassificationLinear`) to create `Mdl`, `FitBias` is specified by the value of the `ModelParameters.FitBias` property of the traditionally trained model.

Data Types: `logical`

`Mu` — Predictor means

vector of numeric values | `[]`

This property is read-only.

Predictor means, specified as a numeric vector.

If `Mu` is an empty array `[]` and you specify `'Standardize',true`, incremental fitting functions set `Mu` to the predictor variable means estimated during the estimation period specified by `EstimationPeriod`.

You cannot specify `Mu` directly.

Data Types: `single` | `double`

`Sigma` — Predictor standard deviations
vector of numeric values | `[]`

This property is read-only.

Predictor standard deviations, specified as a numeric vector.

If `Sigma` is an empty array `[]` and you specify `'Standardize',true`, incremental fitting functions set `Sigma` to the predictor variable standard deviations estimated during the estimation period specified by `EstimationPeriod`.

You cannot specify `Sigma` directly.

Data Types: `single` | `double`

`Solver` — Objective function minimization technique
`'scale-invariant'` (default) | `'sgd'` | `'asgd'`

This property is read-only.

Objective function minimization technique, specified as a value in this table.

Value	Description	Notes
`'scale-invariant'`	Adaptive scale-invariant solver for incremental learning on page 33-2907 [1]	• This algorithm is parameter free and can adapt to differences in predictor scales. Try this algorithm before using SGD or ASGD. • To shuffle incoming batches before the `fit` function fits the model, set `Shuffle` to `true`.
`'sgd'`	Stochastic gradient descent (SGD) [3][2]	• To train effectively with SGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Parameters” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.
`'asgd'`	Average stochastic gradient descent (ASGD) [4]	• To train effectively with ASGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Parameters” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.

If you convert a traditionally trained linear model for binary classification (`ClassificationLinear`) to create `Mdl`, whose `ModelParameters.Solver` property is `'sgd'` or `'asgd'`, `Solver` is specified by the `ModelParameters.Solver` property of the traditionally trained model.

Data Types: `char` | `string`

`SolverOptions` — Objective solver configurations

structure array

This property is read-only.

Objective solver configurations, specified as a structure array. The fields of `SolverOptions` are properties specific to the specified solver `Solver`.

Data Types: `struct`

SGD and ASGD Solver Parameters

`BatchSize` — Mini-batch size

positive integer

This property is read-only.

Mini-batch size, specified as a positive integer. At each iteration during training, `incrementalClassificationLinear` uses `min(BatchSize,numObs)` observations to compute the subgradient, where `numObs` is the number of observations in the training data passed to `fit` or `updateMetricsAndFit`.

If you convert a traditionally trained linear model for binary classification (`ClassificationLinear`) to create `Mdl`, whose `ModelParameters.Solver` property is `'sgd'` or `'asgd'`, `BatchSize` is specified by the `ModelParameters.BatchSize` property of the traditionally trained model. Otherwise, the default is `10`.

Data Types: `single` | `double`

`Lambda` — Ridge (*L*2) regularization term strength

nonnegative scalar

This property is read-only.

Ridge (*L*2) regularization term strength, specified as a nonnegative scalar.

If you convert a traditionally trained linear model for binary classification with a ridge penalty (`ClassificationLinear` object with property `Regularization` equal to `'ridge (L2)'`) to create `Mdl`, `Lambda` is specified by the value of the `Lambda` property of the traditionally trained model. Otherwise, the default is `1e-5`.

Data Types: `double` | `single`

`LearnRate` — Learning rate

`'auto'` | positive scalar

This property is read-only.

Learning rate, specified as `'auto'` or a positive scalar. `LearnRate` controls the optimization step size by scaling the objective subgradient.

When you specify `'auto'`:

- If `EstimationPeriod` is `0`, the initial learning rate is `0.7`.
- If `EstimationPeriod` > `0`, the initial learning rate is `1/sqrt(1+max(sum(X.^2,obsDim)))`, where `obsDim` is `1` if the observations compose the columns of the predictor data, and `2` otherwise. `fit` and `updateMetricsAndFit` set the value when you pass the model and training data to either.

If you convert a traditionally trained linear model for binary classification (`ClassificationLinear`) to create `Mdl`, whose `ModelParameters.Solver` property is `'sgd'` or `'asgd'`, `LearnRate` is specified by the `ModelParameters.LearnRate` property of the traditionally trained model.

The `LearnRateSchedule` property determines the learning rate for subsequent learning cycles.

Data Types: `single` | `double` | `char` | `string`

`LearnRateSchedule` — Learning rate schedule
`'decaying'` (default) | `'constant'`

This property is read-only.

Learning rate schedule, specified as a value in this table, where `LearnRate` specifies the initial learning rate γ_0.

Value	Description
`'constant'`	The learning rate is γ_0 for all learning cycles.
`'decaying'`	The learning rate at learning cycle t is $$\gamma_t = \frac{\gamma_0}{(1+\lambda\gamma_0 t)^c}.$$ • λ is the value of `Lambda`. • If `Solver` is `'sgd'`, then $c = 1$. • If `Solver` is `'asgd'`, then c is 0.75 [4].

If you convert a traditionally trained linear model for binary classification (`ClassificationLinear`) to create `Mdl`, whose `ModelParameters.Solver` property is `'sgd'` or `'asgd'`, `LearnRate` is `'decaying'`.

Data Types: `char` | `string`

Adaptive Scale-Invariant Solver Options

`Shuffle` — Flag for shuffling observations in batch
`true` (default) | `false`

This property is read-only.

Flag for shuffling the observations in the batch at each learning cycle, specified as a value in this table.

Value	Description
`true`	The software shuffles observations in each incoming batch of data before processing the set. This action reduces bias induced by the sampling scheme.
`false`	The software processes the data in the order received.

Data Types: `logical`

Performance Metrics Parameters

`IsWarm` — Flag indicating whether model tracks performance metrics

`false` | `true`

This property is read-only.

Flag indicating whether the incremental model tracks performance metrics, specified as `false` or `true`. The incremental model `Mdl` is warm (`IsWarm` becomes `true`) after incremental fitting functions fit `MetricsWarmupPeriod` observations to the incremental model (that is, `EstimationPeriod` + `MetricsWarmupPeriod` observations).

Value	Description
`true`	The incremental model `Mdl` is warm. Consequently, `updateMetrics` and `updateMetricsAndFit` track performance metrics in the `Metrics` property of `Mdl`.
`false`	`updateMetrics` and `updateMetricsAndFit` do not track performance metrics.

Data Types: `logical`

`Metrics` — Model performance metrics

table

This property is read-only.

Model performance metrics updated during incremental learning by `updateMetrics` and `updateMetricsAndFit`, specified as a table with two columns and *m* rows, where *m* is the number of metrics specified by the `'Metrics'` name-value pair argument.

The columns of `Metrics` are labeled `Cumulative` and `Window`.

- **`Cumulative`**: Element *j* is the model performance, as measured by metric *j*, from the time the model became warm (IsWarm is 1).
- **`Window`**: Element *j* is the model performance, as measured by metric *j*, evaluated over all observations within the window specified by the `MetricsWindowSize` property. The software updates `Window` after it processes `MetricsWindowSize` observations.

Rows are labeled by the specified metrics. For details, see `'Metrics'`.

Data Types: `table`

`MetricsWarmupPeriod` — Number of observations fit before tracking performance metrics
`1000` (default) | nonnegative integer

This property is read-only.

Number of observations the incremental model must be fit to before it tracks performance metrics in its `Metrics` property, specified as a nonnegative integer.

For more details, see “Performance Metrics” on page 33-2909.

Data Types: `single` | `double`

`MetricsWindowSize` — Number of observations to use to compute window performance metrics
`200` (default) | positive integer

This property is read-only.

Number of observations to use to compute window performance metrics, specified as a positive integer.

For more details on performance metrics options, see “Performance Metrics” on page 33-2909.

Data Types: `single` | `double`

Object Functions

fit	Train linear model for incremental learning
updateMetricsAndFit	Update performance metrics in linear model for incremental learning given new data and train model
updateMetrics	Update performance metrics in linear model for incremental learning given new data
loss	Loss of linear model for incremental learning on batch of data
predict	Predict responses for new observations from linear model for incremental learning

Examples

Create Incremental Learner Without Any Prior Information

Create a default incremental linear SVM model for binary classification.

```
Mdl = incrementalClassificationLinear()
```

```
Mdl =
  incrementalClassificationLinear

            IsWarm: 0
           Metrics: [1x2 table]
        ClassNames: [1x0 double]
    ScoreTransform: 'none'
              Beta: [0x1 double]
              Bias: 0
           Learner: 'svm'
```

```
  Properties, Methods
```

`Mdl` is an `incrementalClassificationLinear` model object. All its properties are read-only.

`Mdl` must be fit to data before you can use it to perform any other operations.

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
n = numel(actid);
rng(1); % For reproducibility
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Walking, Running, or Dancing. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = Y > 2;
```

Fit the incremental model to the training data by using the `updateMetricsAndfit` function. Simulate a data stream by processing chunks of 50 observations at a time. At each iteration:

- Process 50 observations.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store β_1, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = zeros(nchunk,1);

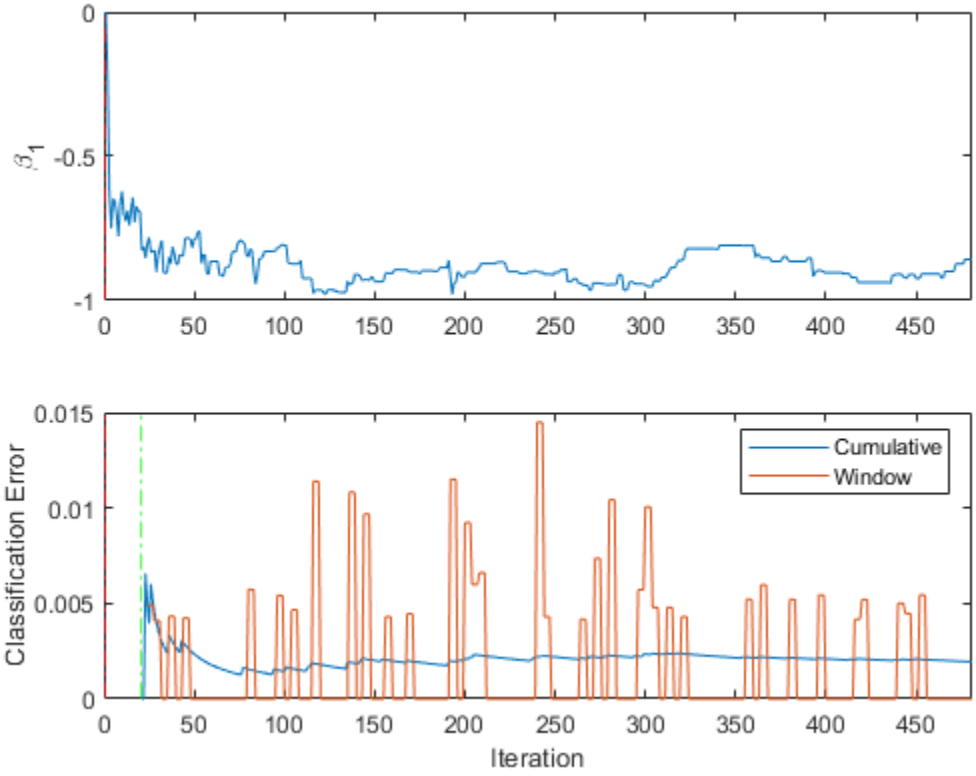
% Incremental learning
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetricsAndFit(Mdl,X(idx,:),Y(idx));
    ce{j,:} = Mdl.Metrics{"ClassificationError",:};
    beta1(j + 1) = Mdl.Beta(1);
end
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and β_1 evolved during training, plot them on separate subplots.

```
figure;
subplot(2,1,1)
```

```
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xline(Mdl.EstimationPeriod/numObsPerChunk,'r-.');
subplot(2,1,2)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
xline(Mdl.EstimationPeriod/numObsPerChunk,'r-.');
xline((Mdl.EstimationPeriod + Mdl.MetricsWarmupPeriod)/numObsPerChunk,'g-.');
legend(h,ce.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit β_1 during all incremental learning iterations
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations.

Configure Incremental Learning Options

Prepare an incremental binary SVM learner by specifying a metrics warm-up period, during which the `updateMetricsAndFit` function only fits the model. Specify a metrics window size of 500

observations. Train the model by using SGD, and adjust the SGD batch size, learning rate, and regularization parameter.

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
n = numel(actid);
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Waling, Running, or Dancing. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = Y > 2;
```

Create an incremental linear model for binary classification. Configure the model as follows:

- Specify that the incremental fitting functions process the raw (unstandardized) predictor data.
- Specify the SGD solver.
- Assume that a ridge regularization parameter value of 0.001, SGD batch size of 20, and learning rate of 0.002 work well for the problem.
- Specify a metrics warm-up period of 5000 observations.
- Specify a metrics window size of 500 observations.
- Track the classification and hinge error metrics to measure the performance of the model.

```
Mdl = incrementalClassificationLinear('Standardize',false,...
    'Solver','sgd','Lambda',0.001,'BatchSize',20,'LearnRate',0.002,...
    'MetricsWarmupPeriod',5000,'MetricsWindowSize',500,...
    'Metrics',{'classiferror' 'hinge'})
```

```
Mdl =
  incrementalClassificationLinear

            IsWarm: 0
           Metrics: [2x2 table]
        ClassNames: [1x0 double]
    ScoreTransform: 'none'
              Beta: [0x1 double]
              Bias: 0
           Learner: 'svm'

  Properties, Methods
```

`Mdl` is an `incrementalClassificationLinear` model object configured for incremental learning.

Fit the incremental model to the rest of the data by using the `updateMetricsAndfit` function. At each iteration:

- Simulate a data stream by processing a chunk of 50 observations. Note that chunk size is different from SGD batch size.

- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the estimated coefficient β_{10}, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

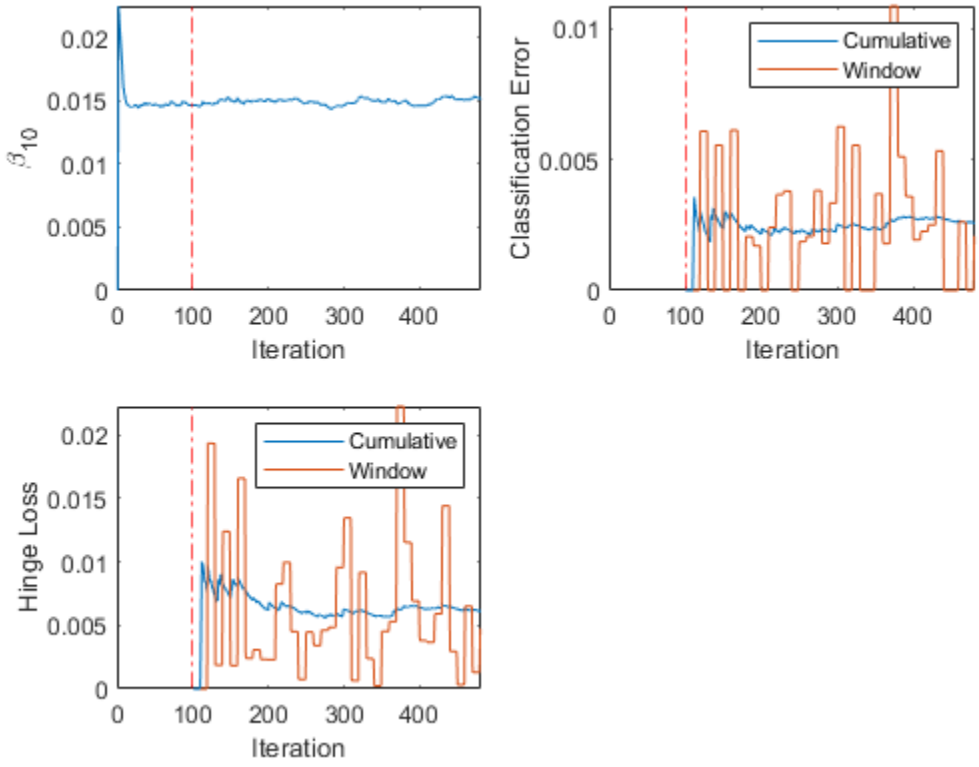
```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
hinge = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta10 = zeros(nchunk,1);

% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetricsAndFit(Mdl,X(idx,:),Y(idx));
    ce{j,:} = Mdl.Metrics{"ClassificationError",:};
    hinge{j,:} = Mdl.Metrics{"HingeLoss",:};
    beta10(j + 1) = Mdl.Beta(10);
end
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and β_{10} evolved during training, plot them on separate subplots.

```
figure;
subplot(2,2,1)
plot(beta10)
ylabel('\beta_{10}')
xlim([0 nchunk]);
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
subplot(2,2,2)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,ce.Properties.VariableNames)
xlabel('Iteration')
subplot(2,2,3)
h = plot(hinge.Variables);
xlim([0 nchunk]);
ylabel('Hinge Loss')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,hinge.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit β_{10} during all incremental learning iterations
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations (10 iterations).

Convert Traditionally Trained Model to Incremental Learner

Train a linear model for binary classification by using `fitclinear`, convert it to an incremental learner, track its performance, and fit it to streaming data. Carry over training options from traditional to incremental learning.

Load and Preprocess Data

Load the human activity data set. Randomly shuffle the data. Orient the observations of the predictor data in columns.

```
load humanactivity
rng(1); % For reproducibility
n = numel(actid);
idx = randsample(n,n);
```

```
X = feat(idx,:)';
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Walking, Running, or Dancing. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = Y > 2;
```

Suppose that the data collected when the subject was idle (`Y = false`) has double the quality than when the subject was moving. Create a weight variable that attributes 2 to observations collected from an idle subject, and 1 to a moving subject.

```
W = ones(n,1) + ~Y;
```

Train Linear Model for Binary Classification

Fit a linear model for binary classification to a random sample of half the data.

```
idxtt = randsample([true false],n,true);
TTMdl = fitclinear(X(:,idxtt),Y(idxtt),'ObservationsIn','columns',...
    'Weights',W(idxtt))
```

```
TTMdl =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [60x1 double]
              Bias: -0.1107
            Lambda: 8.2967e-05
           Learner: 'svm'

  Properties, Methods
```

`TTMdl` is a `ClassificationLinear` model object representing a traditionally trained linear model for binary classification.

Convert Trained Model

Convert the traditionally trained classification model to a binary classification linear model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalClassificationLinear

             IsWarm: 1
            Metrics: [1x2 table]
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [60x1 double]
              Bias: -0.1107
           Learner: 'svm'
```

```
  Properties, Methods
```

Separately Track Performance Metrics and Fit Model

Perform incremental learning on the rest of the data by using the `updateMetrics` and `fit` functions. Simulate a data stream by processing 50 observations at a time. At each iteration:

1. Call `updateMetrics` to update the cumulative and window classification error of the model given the incoming chunk of observations. Overwrite the previous incremental model to update the losses in the `Metrics` property. Note that the function does not fit the model to the chunk of data—the chunk is "new" data for the model. Specify that the observations are oriented in columns, and specify the observation weights.
2. Call `fit` to fit the model to the incoming chunk of observations. Overwrite the previous incremental model to update the model parameters. Specify that the observations are oriented in columns, and specify the observation weights.
3. Store the classification error and first estimated coefficient β_1.

```
% Preallocation
idxil = ~idxtt;
nil = sum(idxil);
numObsPerChunk = 50;
nchunk = floor(nil/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = [IncrementalMdl.Beta(1); zeros(nchunk,1)];
Xil = X(:,idxil);
Yil = Y(idxil);
Wil = W(idxil);

% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetrics(IncrementalMdl,Xil(:,idx),Yil(idx),...
        'ObservationsIn','columns','Weights',Wil(idx));
    ce{j,:} = IncrementalMdl.Metrics{"ClassificationError",:};
    IncrementalMdl = fit(IncrementalMdl,Xil(:,idx),Yil(idx),'ObservationsIn','columns',...
        'Weights',Wil(idx));
    beta1(j + 1) = IncrementalMdl.Beta(end);
end
```

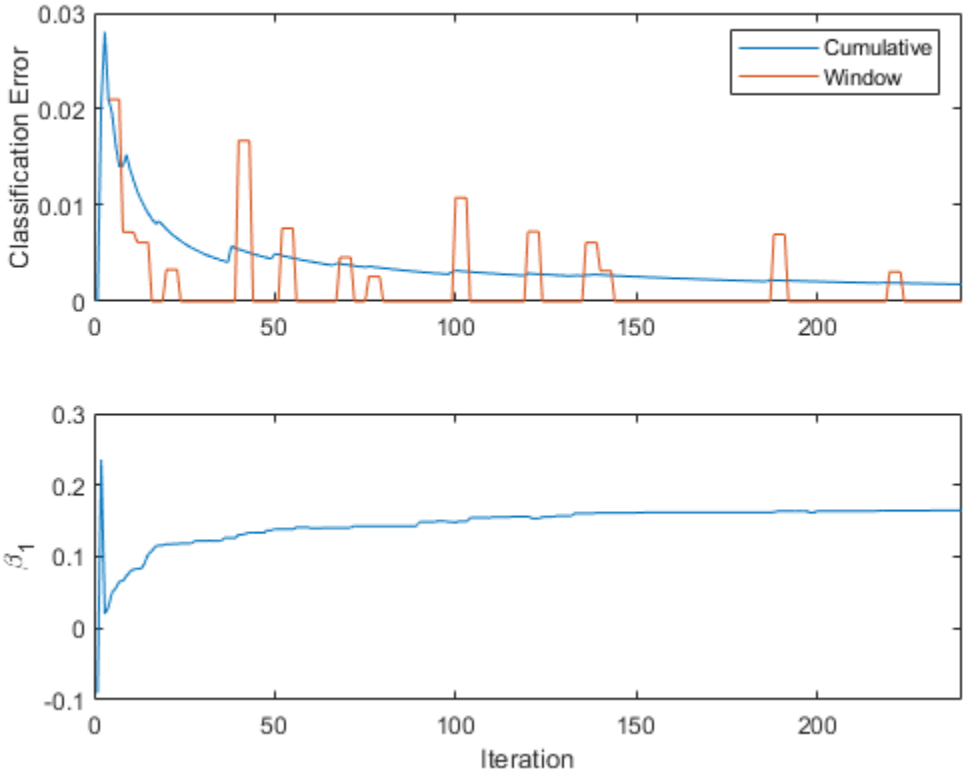
`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream.

Alternatively, you can use `updateMetricsAndFit` to update performance metrics of the model given a new chunk of data, and then fit the model to the data.

Plot a trace plot of the performance metrics and estimated coefficient β_1.

```
figure;
subplot(2,1,1)
h = plot(ce.Variables);
xlim([0 nchunk]);
```

```
ylabel('Classification Error')
legend(h,ce.Properties.VariableNames)
subplot(2,1,2)
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xlabel('Iteration')
```



The cumulative loss is stable and decreases gradually, whereas the window loss jumps.

β_1 changes abruptly at first, then gradually levels off as `fit` processes more chunks.

More About

Incremental Learning

Incremental learning, or online learning, is a branch of machine learning concerned with processing incoming data from a data stream, possibly given little to no knowledge of the distribution of the predictor variables, aspects of the prediction or objective function (including tuning parameter values), or whether the observations are labeled. Incremental learning differs from traditional machine learning, where enough labeled data is available to fit to a model, perform cross-validation to tune hyperparameters, and infer the predictor distribution.

Given incoming observations, an incremental learning model processes data in any of the following ways, but usually in this order:

- Predict labels.
- Measure the predictive performance.
- Check for structural breaks or drift in the model.
- Fit the model to the incoming observations.

Adaptive Scale-Invariant Solver for Incremental Learning

The adaptive scale-invariant solver for incremental learning, introduced in [1], is a gradient-descent-based objective solver for training linear predictive models. The solver is hyperparameter free, insensitive to differences in predictor variable scales, and does not require prior knowledge of the distribution of the predictor variables. These characteristics make it well suited to incremental learning.

The standard SGD and ASGD solvers are sensitive to differing scales among the predictor variables, resulting in models that can perform poorly. To achieve better accuracy using SGD and ASGD, you can standardize the predictor data, and tune the regularization and learning rate parameters can require tuning. For traditional machine learning, enough data is available to enable hyperparameter tuning by cross-validation and predictor standardization. However, for incremental learning, enough data might not be available (for example, observations might be available only one at a time) and the distribution of the predictors might be unknown. These characteristics make parameter tuning and predictor standardization difficult or impossible to do during incremental learning.

The incremental fitting functions for classification `fit` and `updateMetricsAndFit` use the more aggressive ScInOL2 version of the algorithm.

Tips

- After creating a model, you can generate C/C++ code that performs incremental learning on a data stream. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

Estimation Period

During the estimation period, incremental fitting functions `fit` and `updateMetricsAndFit` use the first incoming `EstimationPeriod` observations to estimate (tune) hyperparameters required for incremental training. This table describes the hyperparameters and when they are estimated or tuned. Estimation occurs only when `EstimationPeriod` is positive.

Hyperparameter	Model Property	Use	Hyperparameters Estimated
Predictor means and standard deviations	`Mu` and `Sigma`	Standardize predictor data	When both these conditions apply: • Incremental fitting functions are configured to standardize predictor data (see “Standardize Data” on page 33-2908). • `Mdl.Mu` and `Mdl.Sigma` are empty arrays `[]`.

Hyperparameter	Model Property	Use	Hyperparameters Estimated
Learning rate	LearnRate	Adjust solver step size	When both these conditions apply: • The solver is SGD or ASGD (see Solver). • You do not set the `'LearnRate'` name-value pair argument.

The functions fit only the last estimation period observation to the incremental model, and they do not use any of the observations to track the performance of the model. At the end of the estimation period, the functions update the properties that store the hyperparameters.

Standardize Data

If incremental learning functions are configured to standardize predictor variables, they do so using the means and standard deviations stored in the `Mu` and `Sigma` properties of the incremental learning model `Mdl`.

- When you set `'Standardize',true` and a positive estimation period (see EstimationPeriod), and `Mdl.Mu` and `Mdl.Sigma` are empty, incremental fitting functions estimate means and standard deviations using the estimation period observations.
- When you set `'Standardize','auto'` (the default), the following conditions apply:
  - If you create `incrementalClassificationLinear` by converting a traditionally trained binary linear SVM model (`ClassificationSVM` or `CompactClassificationSVM`), and the `Mu` and `Sigma` properties of the traditionally trained model are empty arrays `[]`, incremental learning functions do not standardize predictor variables. If the `Mu` and `Sigma` properties of the traditionally trained model are nonempty, incremental learning functions standardize the predictor variables using the specified means and standard deviations. Incremental fitting functions do not estimate new means and standard deviations, regardless of the length of the estimation period.
  - If you create `incrementalClassificationLinear` by converting a linear classification model (`ClassificationLinear`), incremental learning functions do not standardize the data, regardless of the length of the estimation period.
  - If you do not convert a traditionally trained model, incremental learning functions standardize the predictor data only when you specify an SGD solver (see `Solver`) and a positive estimation period (see EstimationPeriod).
- When incremental fitting functions estimate predictor means and standard deviations, the functions compute weighted means and weighted standard deviations using the estimation period observations. Specifically, the functions standardize predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

  - x_j is predictor j, and x_{jk} is observation k of predictor j in the estimation period.
  - $\mu_j^* = \frac{1}{\sum_k w_k^*} \sum_k w_k^* x_{jk}$.
  - $\left(\sigma_j^*\right)^2 = \frac{1}{\sum_k w_k^*} \sum_k w_k^* \left(x_{jk} - \mu_j^*\right)^2$.

- $w_j^* = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_k$,

  - p_k is the prior probability of class k (`Prior` property of the incremental model).
  - w_j is observation weight j.

Performance Metrics

- The `updateMetrics` and `updateMetricsAndFit` functions track model performance metrics (`'Metrics'`) from new data when the incremental model is warm (IsWarm property). An incremental model is warm after `fit` or `updateMetricsAndFit` fit the incremental model to MetricsWarmupPeriod observations, which is the metrics warm-up period.

  If EstimationPeriod > 0, the functions estimate hyperparameters before fitting the model to data. Therefore, the functions must process an additional `EstimationPeriod` observations before the model starts the metrics warm-up period.
- The `Metrics` property of the incremental model stores two forms of each performance metric as variables (columns) of a table, `Cumulative` and `Window`, with individual metrics in rows. When the incremental model is warm, `updateMetrics` and `updateMetricsAndFit` update the metrics at the following frequencies:

  - `Cumulative` — The functions compute cumulative metrics since the start of model performance tracking. The functions update metrics every time you call the functions and base the calculation on the entire supplied data set.
  - `Window` — The functions compute metrics based on all observations within a window determined by the MetricsWindowSize name-value pair argument. `MetricsWindowSize` also determines the frequency at which the software updates `Window` metrics. For example, if `MetricsWindowSize` is 20, the functions compute metrics based on the last 20 observations in the supplied data (`X((end − 20 + 1):end,:)` and `Y((end − 20 + 1):end)`).

    Incremental functions that track performance metrics within a window use the following process:

    1. For each specified metric, store a buffer of length `MetricsWindowSize` and a buffer of observation weights.
    2. Populate elements of the metrics buffer with the model performance based on batches of incoming observations, and store corresponding observations weights in the weights buffer.
    3. When the buffer is filled, overwrite `Mdl.Metrics.Window` with the weighted average performance in the metrics window. If the buffer is overfilled when the function processes a batch of observations, the latest incoming `MetricsWindowSize` observations enter the buffer, and the earliest observations are removed from the buffer. For example, suppose `MetricsWindowSize` is 20, the metrics buffer has 10 values from a previously processed batch, and 15 values are incoming. To compose the length 20 window, the functions use the measurements from the 15 incoming observations and the latest 5 measurements from the previous batch.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- All object functions on page 33-2898 of an `incrementalClassificationLinear` model object support code generation.
- If you configure `Mdl` to shuffle data (see Solver and Shuffle), the `fit` function randomly shuffles each incoming batch of observations before it fits the model to the batch. The order of the shuffled observations might not match the order generated by MATLAB.
- When you generate code that loads or creates an `incrementalClassificationLinear` model object, the following restrictions apply.
  - `Mdl` cannot represent a converted SVM model configured to return posterior probabilities as scores.
  - The `ClassNames` property must contain all expected class names.
  - The `NumPredictors` property must reflect the number of predictor variables.

For more information, see “Introduction to Code Generation” on page 32-2.

incrementalClassificationNaiveBayes

Naive Bayes classification model for incremental learning

Description

`incrementalClassificationNaiveBayes` creates an `incrementalClassificationNaiveBayes` model object, which represents a naive Bayes multiclass classification model for incremental learning. `incrementalClassificationNaiveBayes` supports normally distributed predictor variables.

Unlike other Statistics and Machine Learning Toolbox model objects, `incrementalClassificationNaiveBayes` can be called directly. Also, you can specify learning options such as performance metrics configurations and prior class probabilities before fitting the model to data. After you create an `incrementalClassificationNaiveBayes` object, it is prepared for incremental learning on page 33-2932.

`incrementalClassificationNaiveBayes` is best suited for incremental learning. For a traditional approach to training a naive Bayes model for multiclass classification (such as creating a model by fitting it to data, performing cross-validation, tuning hyperparameters, and so on), see `fitcnb`.

Creation

You can create an `incrementalClassificationNaiveBayes` model object in several ways:

- **Call the function directly** — Configure incremental learning options, or specify learner-specific options, by calling `incrementalClassificationNaiveBayes` directly. This approach is best when you do not have data yet or you want to start incremental learning immediately. You must specify the maximum number of classes or all class names expected in the response data during incremental learning.
- **Convert a traditionally trained model** — To initialize a naive Bayes classification model for incremental learning using the model parameters of a trained naive Bayes model object, you can convert the traditionally trained model to an `incrementalClassificationNaiveBayes` model object by passing it to the `incrementalLearner` function.
- **Call an incremental learning function** — `fit`, `updateMetrics`, and `updateMetricsAndFit` accept a configured `incrementalClassificationNaiveBayes` model object and data as input, and return an `incrementalClassificationNaiveBayes` model object updated with information learned from the input model and data.

Syntax

```
Mdl = incrementalClassificationNaiveBayes('MaxNumClasses',MaxNumClasses)
Mdl = incrementalClassificationNaiveBayes('ClassNames',ClassNames)
Mdl = incrementalClassificationNaiveBayes(___,Name,Value)
```

Description

`Mdl = incrementalClassificationNaiveBayes('MaxNumClasses',MaxNumClasses)` returns a default naive Bayes classification model object for incremental learning, `Mdl`, where `MaxNumClasses` is the maximum number of classes expected in the response data during incremental learning. Properties of a default model contain placeholders for unknown model parameters. You must train a default model before you can track its performance or generate predictions from it.

`Mdl = incrementalClassificationNaiveBayes('ClassNames',ClassNames)` specifies all class names `ClassNames` expected in the response data during incremental learning, and sets the `ClassNames` property.

`Mdl = incrementalClassificationNaiveBayes( ___ ,Name,Value)` uses any of the input-argument combinations in the previous syntaxes to set properties on page 33-2916 and additional options using name-value pair arguments . Enclose each name in quotes. For example, `incrementalClassificationNaiveBayes('MaxNumClasses',5,'MetricsWarmupPeriod',100)` sets the maximum number of classes expected in the response data to `5`, and sets the metrics warm-up period to `100`.

Input Arguments

`MaxNumClasses` — Maximum number of classes

positive integer

Maximum number of classes expected in the response data during incremental learning, specified as a positive integer.

If you do not specify `MaxNumClasses`, you must specify the `ClassNames` argument. In that case, `MaxNumClasses` is the number of class names in `ClassNames`.

Example: `'MaxNumClasses',5`

Data Types: `single` | `double`

`ClassNames` — All unique class labels

categorical array | character array | string vector | logical vector | numeric vector | cell array of character vectors

All unique class labels expected in the response data during incremental learning, specified as a categorical or character array; logical, numeric, or string vector, or cell array of character vectors. `ClassNames` and the response data must have the same data type. `ClassNames` sets the `ClassNames` property.

`ClassNames` specifies the order of any input or output argument dimension that corresponds to the class order. For example, set `'ClassNames'` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`

If you do not specify `ClassNames`, you must specify the `MaxNumClasses` argument. In that case, the software infers the `MaxNumClasses` `ClassNames` from the data during incremental learning.

Example: `'ClassNames',["virginica" "setosa" "versicolor"}`

Data Types: `single` | `double` | `logical` | `string` | `char` | `cell` | `categorical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NumPredictors',4,'Prior',[0.3 0.3 0.4]` specifies 4 variables in the predictor data and a prior class probability distribution of `[0.3 0.3 0.4]`.

`Cost` — Cost of misclassifying an observation
square matrix | structure array

Cost of misclassifying an observation, specified as a value in this table, where are `MaxNumClasses` is the number of classes in the `ClassNames` property:

Value	Description
`MaxNumClasses`-by-`MaxNumClasses` numeric matrix	`Cost(i,j)` is the cost of classifying an observation into class `j` when its true class is `i`. In other words, the rows correspond to the true class and the columns correspond to the predicted class. For example, `Cost = [0 2;1 0]` applies double the penalty for misclassifying `ClassNames(1)` than for misclassifying `ClassNames(2)`.
Structure array	A structure array having two fields: • `ClassNames` containing the class names, the same value as `ClassNames` • `ClassificationCosts` containing the cost matrix, as previously described.

If you specify `Cost`, you must also specify the `ClassNames` argument. `Cost` sets the `Cost` property.

The default is a `MaxNumClasses`-by-`MaxNumClasses` matrix, where `Cost(`i`,`j`) = 1` for all $i \neq j$, and `Cost(`i`,`j`) = 0` for all $i = j$.

Example: `'Cost',struct('ClassNames',{'b','g'},'ClassificationCosts',[0 2; 1 0])`

Data Types: `single` | `double` | `struct`

`Metrics` — Model performance metrics to track during incremental learning
`"mincost"` (default) | `"classiferror"` | string vector | function handle | cell vector | structure array | `"binodeviance"` | `"exponential"` | `"hinge"` | `"logit"` | `"quadratic"` | ...

Model performance metrics to track during incremental learning, in addition to minimal expected misclassification cost, specified as a built-in loss function name, string vector of names, function handle (`@metricName`), structure array of function handles, or cell vector of names, function handles, or structure arrays.

When `Mdl` is warm (see IsWarm), `updateMetrics` and `updateMetricsAndFit` track performance metrics in the Metrics property of `Mdl`.

The following table lists the built-in loss function names. You can specify more than one by using a string vector.

Name	Description
`"binodeviance"`	Binomial deviance
`"classiferror"`	Misclassification error rate
`"exponential"`	Exponential
`"hinge"`	Hinge
`"logit"`	Logistic
`'"mincost"`	Minimal expected misclassification cost (for classification scores that are posterior probabilities). `incrementalClassificationNaiveBayes` always tracks this metric.
`"quadratic"`	Quadratic

For more details on the built-in loss functions, see `loss`.

Example: `'Metrics',["classiferror" "logit"]`

To specify a custom function that returns a performance metric, use function handle notation. The function must have this form:

```
metric = customMetric(C,S,Cost)
```

- The output argument `metric` is an *n*-by-1 numeric vector, where each element is the loss of the corresponding observation in the data processed by the incremental learning functions during a learning cycle.
- You select the function name (`customMetric`).
- `C` is an *n*-by-*K* logical matrix with rows indicating the class to which the corresponding observation belongs, where *K* is the number of classes. The column order corresponds to the class order in the `ClassNames` property. Create `C` by setting `C(p,q) = 1`, if observation *p* is in class *q*, for each observation in the specified data. Set the other element in row *p* to `0`.
- `S` is an *n*-by-*K* numeric matrix of predicted classification scores. `S` is similar to the `Posterior` output of `predict`, where rows correspond to observations in the data and the column order corresponds to the class order in the `ClassNames` property. `S(p,q)` is the classification score of observation *p* being classified in class *q*.
- `Cost` is a *K*-by-*K* numeric matrix of misclassification costs. See the `'Cost'` name-value argument.

To specify multiple custom metrics and assign a custom name to each, use a structure array. To specify a combination of built-in and custom metrics, use a cell vector.

Example: `'Metrics',struct('Metric1',@customMetric1,'Metric2',@customMetric2)`

Example: `'Metrics',{@customMetric1 @customeMetric2 'logit' struct('Metric3',@customMetric3)}`

`updateMetrics` and `updateMetricsAndFit` store specified metrics in a table in the `Metrics` property. The data type of `Metrics` determines the row names of the table.

'Metrics' Value Data Type	Description of Metrics Property Row Name	Example
String or character vector	Name of corresponding built-in metric	Row name for "classiferror" is "ClassificationError"
Structure array	Field name	Row name for struct('Metric1',@customMetric1) is "Metric1"
Function handle to function stored in a program file	Name of function	Row name for @customMetric is "customMetric"
Anonymous function	CustomMetric_*j*, where *j* is metric *j* in Metrics	Row name for @(C,S,Cost)customMetric(C,S,Cost)... is CustomMetric_1

For more details on performance metrics options, see “Performance Metrics” on page 33-2932.

Data Types: char | string | struct | cell | function_handle

Properties

You can set most properties by using name-value pair argument syntax only when you call incrementalClassificationNaiveBayes directly. You can set some properties when you call incrementalLearner to convert a traditionally trained model. You cannot set the properties DistributionParameters, IsWarm, and NumTrainingObservations.

Classification Model Parameters

Cost — Cost of misclassifying an observation

square numeric matrix

This property is read-only.

Cost of misclassifying an observation, specified as a MaxNumClasses-by-MaxNumClasses numeric matrix.

If you specify the 'Cost' name-value argument, its value sets Cost. If you specify a structure array, Cost is the value of the ClassificationCosts field.

If you convert a traditionally trained model to create Mdl, Cost is the Cost property of the traditionally trained model.

Data Types: single | double

ClassNames — All unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

All unique class labels expected in the response data during incremental learning, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors.

- If you specify the MaxNumClasses argument, the software infers ClassNames during incremental learning.

- If you specify the `ClassNames` argument, `incrementalClassificationNaiveBayes` stores your specification in `ClassNames`. If you specify a string vector, `incrementalClassificationNaiveBayes` stores it as a cell array of character vectors instead.
- If you convert a traditionally trained model to create `Mdl`, `ClassNames` is the `ClassNames` property of the traditionally trained model.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

`NumPredictors` — Number of predictor variables
`0` (default) | nonnegative numeric scalar

This property is read-only.

Number of predictor variables, specified as a nonnegative numeric scalar.

If you convert a traditionally trained model to create `Mdl`, `NumPredictors` is specified by the congruent property of the traditionally trained model. Otherwise, incremental fitting functions infer `NumPredictors` from the predictor data during training.

Data Types: `double`

`NumTrainingObservations` — Number of observations fit to incremental model
`0` (default) | nonnegative numeric scalar

This property is read-only.

Number of observations fit to the incremental model `Mdl`, specified as a nonnegative numeric scalar. `NumTrainingObservations` increases when you pass `Mdl` and training data to `fit` or `updateMetricsAndFit`.

Note If you convert a traditionally trained model to create `Mdl`, `incrementalClassificationNaiveBayes` does not add the number of observations fit to the traditionally trained model to `NumTrainingObservations`.

Data Types: `double`

`Prior` — Prior class probabilities
numeric vector | `'empirical'` | `'uniform'`

This property is read-only.

Prior class probabilities, specified as a value in this table. You can set this property using name-value pair argument syntax, but `incrementalClassificationNaiveBayes` always stores a numeric vector.

Value	Description
`'empirical'`	Incremental learning functions infer prior class probabilities from the observed class relative frequencies in the response data during incremental training.

Value	Description
`'uniform'`	For each class, the prior probability is 1/*K*, where *K* is the number of classes.
numeric vector	Custom, normalized prior probabilities. The order of the elements of `Prior` corresponds to the elements of the `ClassNames` property.

- If you convert a traditionally trained model to create `Mdl`, `incrementalClassificationNaiveBayes` uses the `Prior` property of the traditionally trained model.
- Otherwise, `Prior` is `'empirical'`.

Data Types: `single` | `double`

`ScoreTransform` — Score transformation function
`'none'` (default) | string scalar | character vector | function handle

This property is read-only.

Score transformation function describing how incremental learning functions transform raw response values, specified as a character vector, string scalar, or function handle. `incrementalClassificationNaiveBayes` stores the specified value as a character vector or function handle.

This table describes the available built-in functions for score transformation.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function that you define, enter its function handle; for example, `'ScoreTransform',@`*`function`*, where:

- *`function`* accepts an *n*-by-*K* matrix (the original scores) and returns a matrix of the same size (the transformed scores).
- *n* is the number of observations, and row *j* of the matrix contains the class scores of observation *j*.
- *K* is the number of classes, and column *k* is class `ClassNames(`*`k`*`)`.

If you convert a traditionally trained model to create `Mdl`, `ScoreTransform` is specified by the congruent property of the traditionally trained model.

The default `'none'` specifies returning posterior class probabilities.

Data Types: `char` | `function_handle`

Training Parameters

`DistributionNames` — Predictor distributions

`'normal'` (default) | cell array of character vectors

This property is read-only.

Predictor distributions, specified as `'normal'` or a 1-by-`NumPredictors` cell array with all cells containing `'normal'`. The conditional distribution $P(x_j|c_k)$ is normal (Gaussian), for $j = 1, \ldots,$`NumPredictors` and each $k \in$ `ClassNames`.

Data Types: `char` | `string` | `cell`

`DistributionParameters` — Distribution parameter estimates

cell array

This property is read-only.

Distribution parameter estimates, specified as a cell array. `DistributionParameters` is a K-by-`NumPredictors` cell array, where K is the number of classes and cell (k,j) contains the distribution parameter estimates for instances of predictor j in class k. The order of the rows corresponds to the order of the classes in the property `ClassNames`, and the order of the columns corresponds to the order of the predictors in the predictor data.

If class k has no observations for predictor j, then `DistributionParameters{`k`,`j`}` is empty (`[]`).

Because all predictor distributions, specified by the `DistributionNames` property, are `'normal'`, each cell of `DistributionParameters` is a 2-by-1 numeric vector, where the first element is the sample mean and the second element is the sample standard deviation.

Data Types: `cell`

Performance Metrics Parameters

`IsWarm` — Flag indicating whether model tracks performance metrics

`false` | `true`

Flag indicating whether the incremental model tracks performance metrics, specified as `false` or `true`.

The incremental model `Mdl` is warm (`IsWarm` becomes `true`) when incremental fitting functions perform both of the following actions:

- Fit the incremental model to `MetricsWarmupPeriod` observations.
- Process `MaxNumClasses` classes or all class names specified by the `ClassNames` name-value argument.

Value	Description
`true`	The incremental model `Mdl` is warm. Consequently, `updateMetrics` and `updateMetricsAndFit` track performance metrics in the `Metrics` property of `Mdl`.
`false`	`updateMetrics` and `updateMetricsAndFit` do not track performance metrics.

Data Types: `logical`

`Metrics` — Model performance metrics
table

This property is read-only.

Model performance metrics updated during incremental learning by `updateMetrics` and `updateMetricsAndFit`, specified as a table with two columns and *m* rows, where *m* is the number of metrics specified by the `'Metrics'` name-value pair argument.

The columns of `Metrics` are labeled `Cumulative` and `Window`.

- **`Cumulative`**: Element *j* is the model performance, as measured by metric *j*, from the time the model became warm (IsWarm is `1`).
- **`Window`**: Element *j* is the model performance, as measured by metric *j*, evaluated over all observations within the window specified by the `MetricsWindowSize` property. The software updates `Window` after it processes `MetricsWindowSize` observations.

Rows are labeled by the specified metrics. For details, see `'Metrics'`.

Data Types: `table`

`MetricsWarmupPeriod` — Number of observations fit before tracking performance metrics
`1000` (default) | nonnegative integer

This property is read-only.

Number of observations the incremental model must be fit to before it tracks performance metrics in its `Metrics` property, specified as a nonnegative integer.

For more details, see “Performance Metrics” on page 33-2932.

Data Types: `single` | `double`

`MetricsWindowSize` — Number of observations to use to compute window performance metrics
`200` (default) | positive integer

This property is read-only.

Number of observations to use to compute window performance metrics, specified as a positive integer.

For more details on performance metrics options, see “Performance Metrics” on page 33-2932.

Data Types: `single` | `double`

Object Functions

fit	Train naive Bayes classification model for incremental learning
updateMetricsAndFit	Update performance metrics in naive Bayes classification model for incremental learning given new data and train model
updateMetrics	Update performance metrics in naive Bayes classification model for incremental learning given new data
logp	Log unconditional probability density of naive Bayes classification model for incremental learning
loss	Loss of naive Bayes classification model for incremental learning on batch of data
predict	Predict responses for new observations from naive Bayes classification model for incremental learning

Examples

Create Incremental Learner With Little Prior Information

To create a naive Bayes classification model for incremental learning, the least amount of information you must specify is the maximum number of classes that you expect the model to experience (`'MaxNumClasses'` name-value argument). As you fit the model to incoming batches of data by using an incremental fitting function, the model collects newly experienced classes in its `ClassNames` property. If the specified expected maximum number of classes is inaccurate, one of the following alternatives occurs:

- Before an incremental fitting function experiences the expected maximum number of classes, the model is cold. Consequently, the `updateMetrics` and `updateMetricsAndFit` functions do not measure performance metrics.
- If the number of classes exceeds the maximum expected, the incremental fitting function issues an error.

This example shows how to create a naive Bayes classification model for incremental learning when you know only the expected maximum number of classes in the data. Also, the example illustrates the consequences when incremental fitting functions experience all expected classes early and late in the sample.

For this example, consider training a device to predict whether a subject is sitting, standing, walking, running, or dancing based on biometric data measured on the subject. Therefore, the device has a maximum of 5 classes from which to choose.

Experience Expected Maximum Number of Classes Early in Sample

Create an incremental naive Bayes learner for multiclass learning. Specify a maximum of 5 classes in the data.

```
MdlEarly = incrementalClassificationNaiveBayes('MaxNumClasses',5)
```

```
MdlEarly =
  incrementalClassificationNaiveBayes

                  IsWarm: 0
                 Metrics: [1×2 table]
              ClassNames: [1×0 double]
          ScoreTransform: 'none'
```

```
         DistributionNames: 'normal'
    DistributionParameters: {}

  Properties, Methods
```

`MdlEarly` is an `incrementalClassificationNaiveBayes` model object. All its properties are read-only.

`MdlEarly` must be fit to data before you can use it to perform any other operations.

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
n = numel(actid);
rng(1); % For reproducibility
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Fit the incremental model to the training data by using the `updateMetricsAndfit` function. Simulate a data stream by processing chunks of 50 observations at a time. At each iteration:

- Process 50 observations.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store μ_{11} (the mean of the first predictor variable in the first class), the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
mc = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mu1 = zeros(nchunk,1);

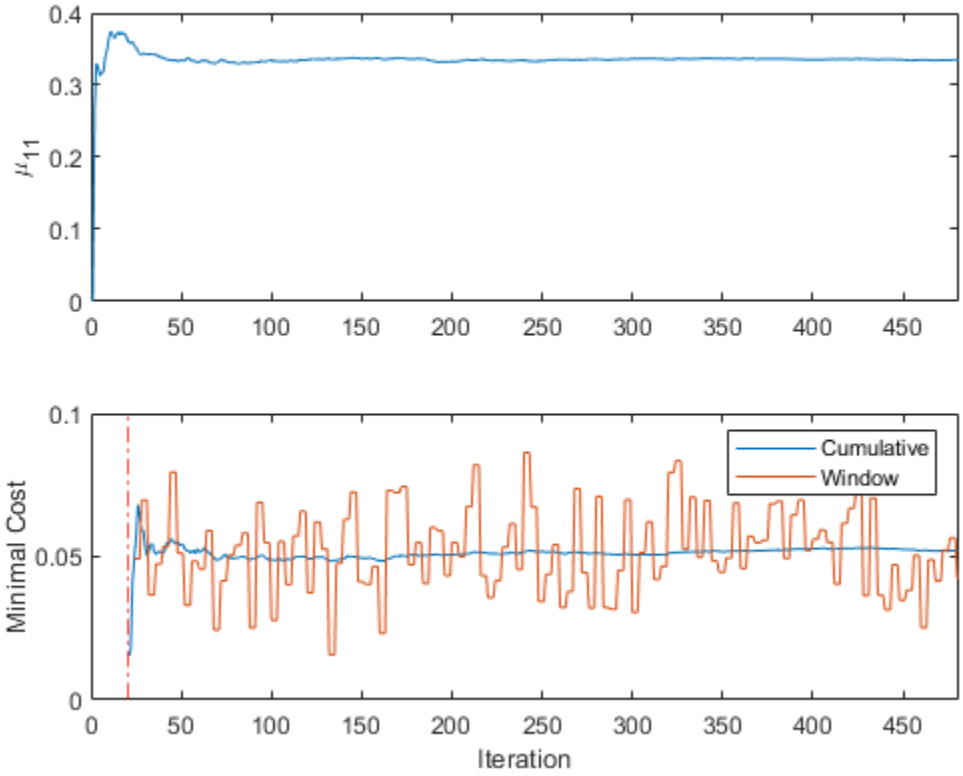
% Incremental learning
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    MdlEarly = updateMetricsAndFit(MdlEarly,X(idx,:),Y(idx));
    mc{j,:} = MdlEarly.Metrics{"MinimalCost",:};
    mu1(j + 1) = MdlEarly.DistributionParameters{1,1}(1);
end
```

`MdlEarly` is an `incrementalClassificationNaiveBayes` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and μ_{11} evolved during training, plot them on separate subplots.

```
figure;
subplot(2,1,1)
```

```
plot(mu1)
ylabel('\mu_{11}')
xlim([0 nchunk]);
subplot(2,1,2)
h = plot(mc.Variables);
xlim([0 nchunk]);
ylabel('Minimal Cost')
xline(MdlEarly.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mc.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit μ_{11} during all incremental learning iterations
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations.

Experience Expected Maximum Number of Classes Late in Sample

Create a different naive Bayes model for incremental learning for the objective.

```
MdlLate = incrementalClassificationNaiveBayes('MaxNumClasses',5)
```

```
MdlLate =
  incrementalClassificationNaiveBayes
```

```
                  IsWarm: 0
                 Metrics: [1×2 table]
              ClassNames: [1×0 double]
          ScoreTransform: 'none'
       DistributionNames: 'normal'
  DistributionParameters: {}

  Properties, Methods
```

Move all observations labeled with class 5 to the end of the sample.

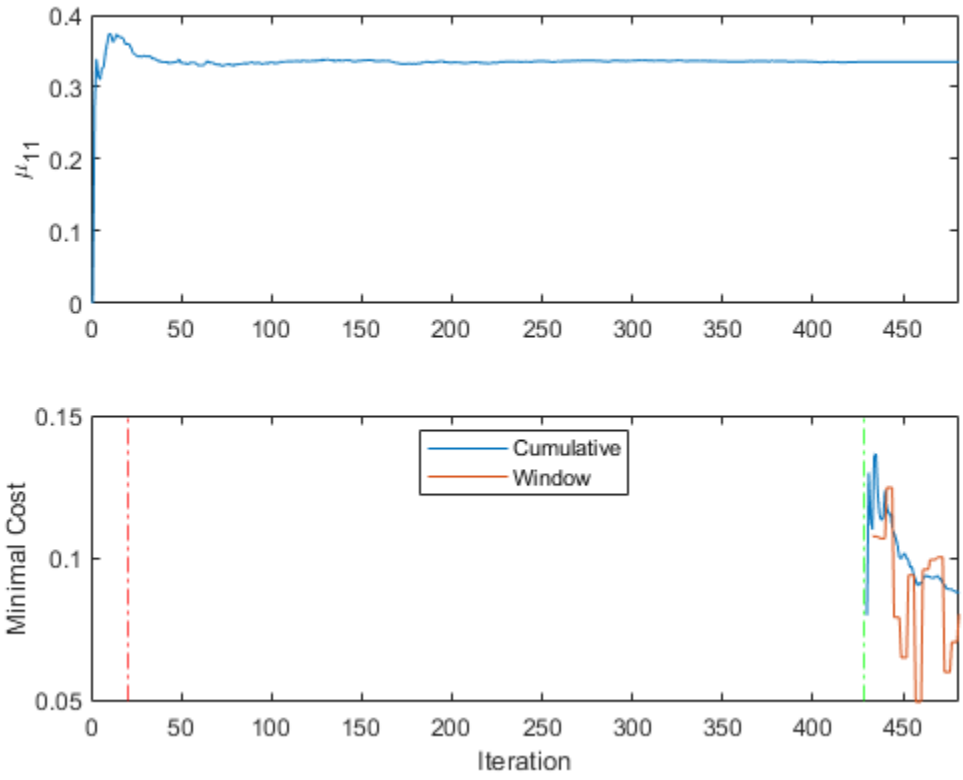
```
idx5 = Y == 5;
Xnew = [X(~idx5,:); X(idx5,:)];
Ynew = [Y(~idx5) ;Y(idx5)];
```

Fit the incremental model and plot results, as performed previously.

```
mcnew = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mu1new = zeros(nchunk,1);

for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    MdlLate = updateMetricsAndFit(MdlLate,Xnew(idx,:),Ynew(idx));
    mcnew{j,:} = MdlLate.Metrics{"MinimalCost",:};
    mu1new(j + 1) = MdlLate.DistributionParameters{1,1}(1);
end

figure;
subplot(2,1,1)
plot(mu1new)
ylabel('\mu_{11}')
xlim([0 nchunk]);
subplot(2,1,2)
h = plot(mcnew.Variables);
xlim([0 nchunk]);
ylabel('Minimal Cost')
xline(MdlLate.MetricsWarmupPeriod/numObsPerChunk,'r-.');
xline(sum(~idx5)/numObsPerChunk,'g-.');
legend(h,mcnew.Properties.VariableNames,'Location','best')
xlabel('Iteration')
```



The `updateMetricsAndFit` function trains throughout incremental learning, but the function starts tracking performance metrics after the model has been fit to all expected number of classes (the green vertical line in the bottom subplot).

Specify All Class Names

This example shows how to create an incremental naive Bayes learner when you know all the class names in the data.

Consider training a device to predict whether a subject is sitting, standing, walking, running, or dancing based on biometric data measured on the subject, and you know the class names map 1 through 5 to an activity.

Create an incremental naive Bayes learner for multiclass learning. Specify the class names.

```
classnames = 1:5;
Mdl = incrementalClassificationNaiveBayes('ClassNames',classnames)
```

```
Mdl =
  incrementalClassificationNaiveBayes

                  IsWarm: 0
                 Metrics: [1x2 table]
              ClassNames: [1 2 3 4 5]
          ScoreTransform: 'none'
```

```
        DistributionNames: 'normal'
    DistributionParameters: {5x0 cell}

  Properties, Methods
```

`Mdl` is an `incrementalClassificationNaiveBayes` model object. All its properties are read-only.

`Mdl` must be fit to data before you can use it to perform any other operations.

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
n = numel(actid);
rng(1); % For reproducibility
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Fit the incremental model to the training data by using the `updateMetricsAndfit` function. Simulate a data stream by processing chunks of 50 observations at a time. At each iteration:

- Process 50 observations.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.

```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);

% Incremental learning
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetricsAndFit(Mdl,X(idx,:),Y(idx));
end
```

Configure Incremental Learning Options

In addition to specifying the maximum number of class names, prepare an incremental naive Bayes learner by specifying a metrics warm-up period, during which the `updateMetricsAndFit` function only fits the model. Specify a metrics window size of 500 observations.

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
n = numel(actid);
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Create an incremental linear model for binary classification. Configure the model as follows:

- Specify a metrics warm-up period of 5000 observations.
- Specify a metrics window size of 500 observations.
- Track the classification error and minimal cost to measure the performance of the model.

```
Mdl = incrementalClassificationNaiveBayes('MaxNumClasses',5,'MetricsWarmupPeriod',5000,...
    'MetricsWindowSize',500,'Metrics',["classiferror" "mincost"])
```

```
Mdl =
  incrementalClassificationNaiveBayes

                   IsWarm: 0
                  Metrics: [2x2 table]
               ClassNames: [1x0 double]
           ScoreTransform: 'none'
        DistributionNames: 'normal'
    DistributionParameters: {}

  Properties, Methods
```

`Mdl` is an `incrementalClassificationNaiveBayes` model object configured for incremental learning.

Fit the incremental model to the rest of the data by using the `updateMetricsAndfit` function. At each iteration:

- Simulate a data stream by processing a chunk of 50 observations.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store σ_{11} (the standard deviation of the first predictor variable in the first class), the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

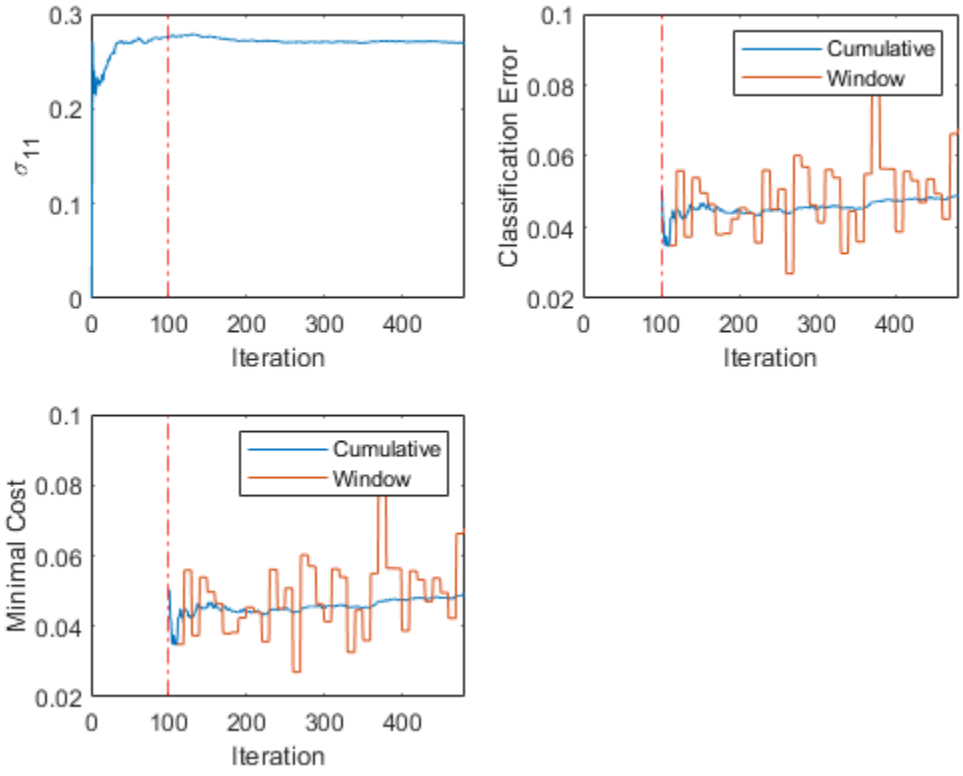
```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mc = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
sigma11 = zeros(nchunk,1);

% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetricsAndFit(Mdl,X(idx,:),Y(idx));
    ce{j,:} = Mdl.Metrics{"ClassificationError",:};
    mc{j,:} = Mdl.Metrics{"MinimalCost",:};
    sigma11(j + 1) = Mdl.DistributionParameters{1,1}(2);
end
```

`IncrementalMdl` is an `incrementalClassificationNaiveBayes` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and σ_{11} evolved during training, plot them on separate subplots.

```
figure;
subplot(2,2,1)
plot(sigma11)
ylabel('\sigma_{11}')
xlim([0 nchunk]);
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
subplot(2,2,2)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,ce.Properties.VariableNames)
xlabel('Iteration')
subplot(2,2,3)
h = plot(mc.Variables);
xlim([0 nchunk]);
ylabel('Minimal Cost')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mc.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit σ_{11} during all incremental learning iterations

- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations (10 iterations).

Convert Traditionally Trained Model to Incremental Learner

Train a naive Bayes model for multiclass classification by using `fitcnb`, convert it to an incremental learner, track its performance, and fit it to streaming data. Carry over training options from traditional to incremental learning.

Load and Preprocess Data

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
rng(1); % For reproducibility
n = numel(actid);
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Suppose that the data collected when the subject was idle (`Y > 2`) has double the quality than when the subject was moving. Create a weight variable that attributes 2 to observations collected from an idle subject, and 1 to a moving subject.

```
W = ones(n,1) + (Y < 3);
```

Train Naive Bayes Model

Fit a naive Bayes model for multiclass classification to a random sample of half the data.

```
idxtt = randsample([true false],n,true);
TTMdl = fitcnb(X(idxtt,:),Y(idxtt),'Weights',W(idxtt))
```

```
TTMdl =
  ClassificationNaiveBayes
              ResponseName: 'Y'
     CategoricalPredictors: []
                ClassNames: [1 2 3 4 5]
           ScoreTransform: 'none'
          NumObservations: 12053
         DistributionNames: {1x60 cell}
    DistributionParameters: {5x60 cell}

  Properties, Methods
```

`TTMdl` is a `ClassificationNaiveBayes` model object representing a traditionally trained naive Bayes model.

Convert Trained Model

Convert the traditionally trained naive Bayes model to a naive Bayes classification model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalClassificationNaiveBayes

                   IsWarm: 1
                  Metrics: [1x2 table]
               ClassNames: [1 2 3 4 5]
           ScoreTransform: 'none'
        DistributionNames: {1x60 cell}
   DistributionParameters: {5x60 cell}

  Properties, Methods
```

Separately Track Performance Metrics and Fit Model

Perform incremental learning on the rest of the data by using the `updateMetrics` and `fit` functions. Simulate a data stream by processing 50 observations at a time. At each iteration:

1. Call `updateMetrics` to update the cumulative and window classification error of the model given the incoming chunk of observations. Overwrite the previous incremental model to update the losses in the `Metrics` property. Note that the function does not fit the model to the chunk of data—the chunk is "new" data for the model. Specify the observation weights.
2. Call `fit` to fit the model to the incoming chunk of observations. Overwrite the previous incremental model to update the model parameters. Specify the observation weights.
3. Store the minimal cost and mean of the first predictor variable of the first class μ_{11}.

```
% Preallocation
idxil = ~idxtt;
nil = sum(idxil);
numObsPerChunk = 50;
nchunk = floor(nil/numObsPerChunk);
mc = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mu11 = [IncrementalMdl.DistributionParameters{1,1}(1); zeros(nchunk,1)];
Xil = X(idxil,:);
Yil = Y(idxil);
Wil = W(idxil);

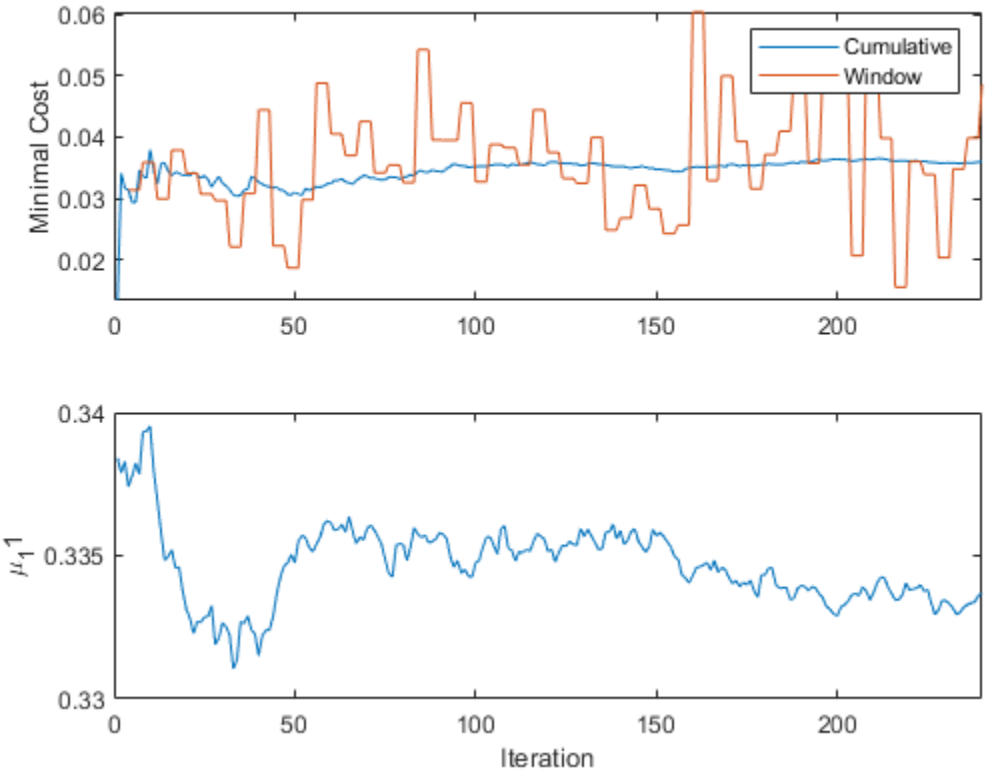
% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetrics(IncrementalMdl,Xil(idx,:),Yil(idx),...
        'Weights',Wil(idx));
    mc{j,:} = IncrementalMdl.Metrics{"MinimalCost",:};
    IncrementalMdl = fit(IncrementalMdl,Xil(idx,:),Yil(idx),'Weights',Wil(idx));
    mu11(j + 1) = IncrementalMdl.DistributionParameters{1,1}(1);
end
```

`IncrementalMdl` is an `incrementalClassificationNaiveBayes` model object trained on all the data in the stream.

Alternatively, you can use `updateMetricsAndFit` to update performance metrics of the model given a new chunk of data, and then fit the model to the data.

Plot a trace plot of the performance metrics and estimated coefficient μ_{11}.

```
figure;
subplot(2,1,1)
h = plot(mc.Variables);
xlim([0 nchunk]);
ylabel('Minimal Cost')
legend(h,mc.Properties.VariableNames)
subplot(2,1,2)
plot(mu11)
ylabel('\mu_11')
xlim([0 nchunk]);
xlabel('Iteration')
```



The cumulative loss is stable and decreases gradually, whereas the window loss jumps.

μ_{11} changes abruptly at first, then gradually levels off as `fit` processes more chunks.

More About

Incremental Learning

Incremental learning, or online learning, is a branch of machine learning concerned with processing incoming data from a data stream, possibly given little to no knowledge of the distribution of the predictor variables, aspects of the prediction or objective function (including tuning parameter values), or whether the observations are labeled. Incremental learning differs from traditional machine learning, where enough labeled data is available to fit to a model, perform cross-validation to tune hyperparameters, and infer the predictor distribution.

Given incoming observations, an incremental learning model processes data in any of the following ways, but usually in this order:

- Predict labels.
- Measure the predictive performance.
- Check for structural breaks or drift in the model.
- Fit the model to the incoming observations.

Algorithms

Performance Metrics

- The `updateMetrics` and `updateMetricsAndFit` functions track model performance metrics (`'Metrics'`) from new data when the incremental model is warm (`IsWarm` property). An incremental model is warm when `fit` or `updateMetricsAndFit` perform both of the following actions:
  - Fit the incremental model to MetricsWarmupPeriod observations, which is the metrics warm-up period.
  - Process `MaxNumClasses` classes or all class names specified by the `ClassNames` name-value argument.
- The `Metrics` property of the incremental model stores two forms of each performance metric as variables (columns) of a table, `Cumulative` and `Window`, with individual metrics in rows. When the incremental model is warm, `updateMetrics` and `updateMetricsAndFit` update the metrics at the following frequencies:
  - `Cumulative` — The functions compute cumulative metrics since the start of model performance tracking. The functions update metrics every time you call the functions and base the calculation on the entire supplied data set.
  - `Window` — The functions compute metrics based on all observations within a window determined by the MetricsWindowSize name-value pair argument. `MetricsWindowSize` also determines the frequency at which the software updates `Window` metrics. For example, if `MetricsWindowSize` is 20, the functions compute metrics based on the last 20 observations in the supplied data (`X((end − 20 + 1):end,:)` and `Y((end − 20 + 1):end)`).

    Incremental functions that track performance metrics within a window use the following process:

1. For each specified metric, store a buffer of length `MetricsWindowSize` and a buffer of observation weights.
2. Populate elements of the metrics buffer with the model performance based on batches of incoming observations, and store corresponding observation weights in the weights buffer.
3. When the buffer is filled, overwrite `Mdl.Metrics.Window` with the weighted average performance in the metrics window. If the buffer is overfilled when the function processes a batch of observations, the latest incoming `MetricsWindowSize` observations enter the buffer, and the earliest observations are removed from the buffer. For example, suppose `MetricsWindowSize` is 20, the metrics buffer has 10 values from a previously processed batch, and 15 values are incoming. To compose the length 20 window, the functions use the measurements from the 15 incoming observations and the latest 5 measurements from the previous batch.

Introduced in R2021a

incrementalLearner

Convert linear model for binary classification to incremental learner

Syntax

```
IncrementalMdl = incrementalLearner(Mdl)
IncrementalMdl = incrementalLearner(Mdl,Name,Value)
```

Description

`IncrementalMdl = incrementalLearner(Mdl)` returns a binary classification linear model for incremental learning on page 33-2948, `IncrementalMdl`, using the hyperparameters and coefficients of the traditionally trained linear model for binary classification, `Mdl`. Because its property values reflect the knowledge gained from `Mdl`, `IncrementalMdl` can predict labels given new observations, and it is warm, meaning that its predictive performance is tracked.

`IncrementalMdl = incrementalLearner(Mdl,Name,Value)` uses additional options specified by one or more name-value pair arguments. Some options require you to train `IncrementalMdl` before its predictive performance is tracked. For example, `'MetricsWarmupPeriod',50,'MetricsWindowSize',100` specifies a preliminary incremental training period of 50 observations before performance metrics are tracked, and specifies processing 100 observations before updating the performance metrics.

Examples

Convert Traditionally Trained Model to Incremental Learner

Train a linear classification model for binary learning by using `fitclinear`, and then convert it to an incremental learner.

Load and Preprocess Data

Load the human activity data set.

```
load humanactivity
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: `Sitting`, `Standing`, `Walking`, `Running`, or `Dancing`. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = actid > 2;
```

Train Linear Classification Model

Fit a linear classification model to the entire data set.

```
TTMdl = fitclinear(feat,Y)
```

```
TTMdl =
  ClassificationLinear
```

```
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [60x1 double]
              Bias: -0.2005
            Lambda: 4.1537e-05
           Learner: 'svm'

  Properties, Methods
```

`TTMdl` is a `ClassificationLinear` model object representing a traditionally trained linear classification model.

Convert Trained Model

Convert the traditionally trained linear classification model to a binary classification linear model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalClassificationLinear

             IsWarm: 1
            Metrics: [1x2 table]
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [60x1 double]
              Bias: -0.2005
           Learner: 'svm'

  Properties, Methods
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object prepared for incremental learning using SVM.

- The `incrementalLearner` function Initializes the incremental learner by passing learned coefficients to it, along with other information `TTMdl` extracted from the training data.
- `IncrementalMdl` is warm (`IsWarm` is `1`), which means that incremental learning functions can start tracking performance metrics.
- The `incrementalLearner` function trains the model using the adaptive scale-invariant solver, whereas `fitclinear` trained `TTMdl` using the BFGS solver.

Predict Responses

An incremental learner created from converting a traditionally trained model can generate predictions without further processing.

Predict classification scores for all observations using both models.

```
[~,ttscores] = predict(TTMdl,feat);
[~,ilscores] = predict(IncrementalMdl,feat);
compareScores = norm(ttscores(:,1) - ilscores(:,1))
```

```
compareScores = 0
```

The difference between the scores generated by the models is 0.

Specify SGD Solver and Standardize Predictor Data

If you train a linear classification model using the SGD or ASGD solver, `incrementalLearner` preserves the solver, linear model type, and associated hyperparameter values when it converts the linear classification model.

Load the human activity data set.

```
load humanactivity
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Waling, Running, or Dancing. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = actid > 2;
```

Randomly split the data in half: the first half for training a model traditionally, and the second half for incremental learning.

```
n = numel(Y);
rng(1) % For reproducibility
cvp = cvpartition(n,'Holdout',0.5);
idxtt = training(cvp);
idxil = test(cvp);

% First half of data
Xtt = feat(idxtt,:);
Ytt = Y(idxtt);

% Second half of data
Xil = feat(idxil,:);
Yil = Y(idxil);
```

Create a set of 11 logarithmically spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6,-0.5,11);
```

Because the variables are on different scales, use implicit expansion to standardize the predictor data.

```
Xtt = (Xtt - mean(Xtt))./std(Xtt);
```

Tune the L2 regularization parameter by applying 5-fold cross-validation. Specify the standard SGD solver.

```
TTCVMdl = fitclinear(Xtt,Ytt,'KFold',5,'Learner','logistic',...
    'Solver','sgd','Lambda',Lambda);
```

`TTCVMdl` is a `ClassificationPartitionedLinear` model representing the five models created during cross-validation (see `TTCVMdl.Trained`). The cross-validation procedure includes training with each specified regularization value.

Compute the cross-validated classification error for each model and regularization.

```
cvloss = kfoldLoss(TTCVMdl)
```

```
cvloss = 1×11

    0.0054    0.0039    0.0034    0.0033    0.0030    0.0027    0.0027    0.0031    0.0036    0.0
```

`cvloss` contains the test-sample classification loss for each regularization value in `Lamba`.

Select the regularization value that minimizes the classification error. Train the model again using the selected regularization value.

```
[~,idxmin] = min(cvloss);
TTMdl = fitclinear(Xtt,Ytt,'Learner','logistic','Solver','sgd',...
    'Lambda',Lambda(idxmin));
```

`TTMdl` is a `ClassificationLinear` model.

Convert the traditionally trained linear classification model to a binary classification linear model for incremental learning. Specify the standard SGD solver. Prepare incremental learning functions to standardize the predictors. This action requires an initial period for estimating the predictor means and standard deviations. Specify an estimation period of `2000` observations (the default is `1000` when predictor moments are required).

```
IncrementalMdl = incrementalLearner(TTMdl,'Standardize',true,'EstimationPeriod',2000);
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object. `incrementalLearner` passes the solver and regularization strength, among other information learned from training `TTMdl`, to `IncrementalMdl`.

Fit the incremental model to the second half of the data by using the `fit` function. At each iteration:

- Simulate a data stream by processing 10 observations at a time.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store β_1 to see how it evolves during training.

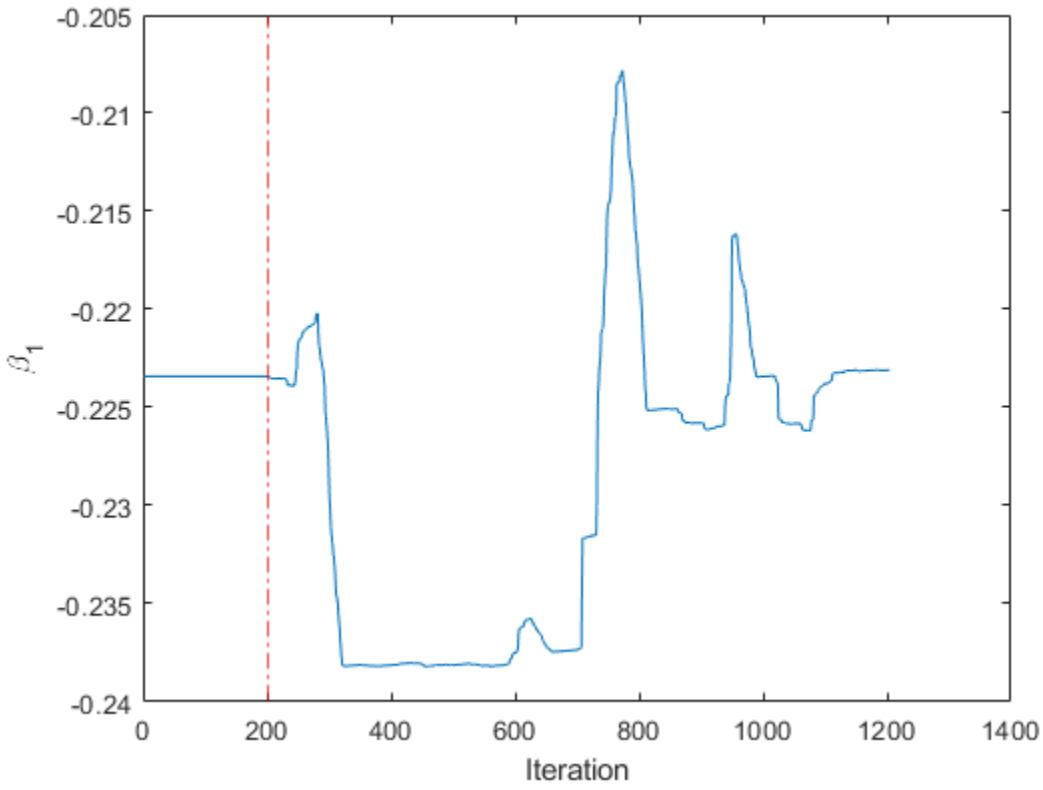
```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 10;
nchunk = floor(nil/numObsPerChunk);
learnrate = [IncrementalMdl.LearnRate; zeros(nchunk,1)];
beta1 = [IncrementalMdl.Beta(1); zeros(nchunk,1)];

% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = fit(IncrementalMdl,Xil(idx,:),Yil(idx));
    beta1(j + 1) = IncrementalMdl.Beta(1);
end
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream.

Plot β_1 to see how it evolved.

```
plot(beta1)
ylabel('\beta_1')
xline(IncrementalMdl.EstimationPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
```



Because `fit` does not fit the model to the streaming data during the estimation period, β_1 is constant for the first 200 iterations (2000 observations). Then, β_1 changes abruptly during incremental fitting.

Configure Performance Metric Options

Use a trained linear classification model to initialize an incremental learner. Prepare the incremental learner by specifying a metrics warm-up period, during which the `updateMetricsAndFit` function only fits the model. Specify a metrics window size of 500 observations.

Load the human activity data set.

```
load humanactivity
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Walking, Running, and Dancing. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = actid > 2;
```

Because the data set is grouped by activity, shuffle it for simplicity. Then, randomly split the data in half: the first half for training a model traditionally, and the second half for incremental learning.

```
n = numel(Y);

rng(1) % For reproducibility
cvp = cvpartition(n,'Holdout',0.5);
idxtt = training(cvp);
idxil = test(cvp);
shuffidx = randperm(n);
X = feat(shuffidx,:);
Y = Y(shuffidx);

% First half of data
Xtt = X(idxtt,:);
Ytt = Y(idxtt);

% Second half of data
Xil = X(idxil,:);
Yil = Y(idxil);
```

Fit a linear classification model to the first half of the data.

```
TTMdl = fitclinear(Xtt,Ytt);
```

Convert the traditionally trained linear classification model to a binary classification linear model for incremental learning. Specify the following:

- A performance metrics warm-up period of 2000 observations
- A metrics window size of 500 observations
- Use of classification error and hinge loss to measure the performance of the model

```
IncrementalMdl = incrementalLearner(TTMdl,'MetricsWarmupPeriod',2000,'MetricsWindowSize',500,...
    'Metrics',["classiferror" "hinge"]);
```

Fit the incremental model to the second half of the data by using the `updateMetricsAndFit` function. At each iteration:

- Simulate a data stream that processing a chunk of 20 observations.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store β_1, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 20;
nchunk = ceil(nil/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
hinge = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = zeros(nchunk,1);

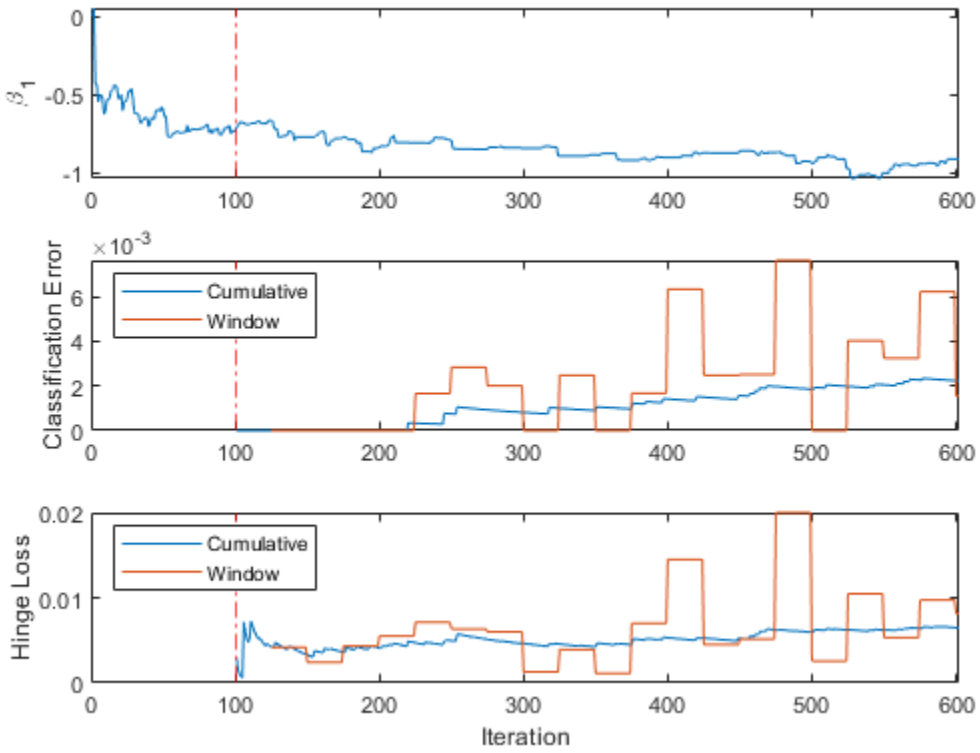
% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
```

```
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetricsAndFit(IncrementalMdl,Xil(idx,:),Yil(idx));
    ce{j,:} = IncrementalMdl.Metrics{"ClassificationError",:};
    hinge{j,:} = IncrementalMdl.Metrics{"HingeLoss",:};
    beta1(j + 1) = IncrementalMdl.Beta(1);
end
```

`IncrementalMdl` is an `incrementalClassificationLinear` model trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and β_1 evolved during training, plot them on separate subplots.

```
figure;
subplot(3,1,1)
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
subplot(3,1,2)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,ce.Properties.VariableNames,'Location','northwest')
subplot(3,1,3)
h = plot(hinge.Variables);
xlim([0 nchunk]);
ylabel('Hinge Loss')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,hinge.Properties.VariableNames,'Location','northwest')
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit β_1 during all incremental learning iterations.
- Compute the performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations (25 iterations).

Input Arguments

`Mdl` — Traditionally trained linear model for binary classification

`ClassificationLinear` model object

Traditionally trained linear model for binary classification, specified as a `ClassificationLinear` model object returned by `fitclinear`.

Note

- If `Mdl.Lambda` is a numeric vector, you must select the model corresponding to one regularization strength in the regularization path by using `selectModels`.
- Incremental learning functions support only numeric input predictor data. If `Mdl` was fit to categorical data, use `dummyvar` to convert each categorical variable to a numeric matrix of

dummy variables, and concatenate all dummy variable matrices and any other numeric predictors. For more details, see “Dummy Variables” on page 2-48.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Solver','scale-invariant','MetricsWindowSize',100` specifies the adaptive scale-invariant solver for objective optimization, and specifies processing 100 observations before updating the performance metrics.

General Options

`Solver` — Objective function minimization technique

`'scale-invariant'` (default) | `'sgd'` | `'asgd'`

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a value in this table.

Value	Description	Notes
`'scale-invariant'`	Adaptive scale-invariant solver for incremental learning on page 33-2948 [1]	• This algorithm is parameter free and can adapt to differences in predictor scales. Try this algorithm before using SGD or ASGD. • To shuffle incoming batches before the `fit` function fits the model, set `Shuffle` to `true`.
`'sgd'`	Stochastic gradient descent (SGD) [3][2]	• To train effectively with SGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Options” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.
`'asgd'`	Average stochastic gradient descent (ASGD) [4]	• To train effectively with ASGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Options” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.

Example: `'Solver','sgd'`

Data Types: `char` | `string`

`EstimationPeriod` — Number of observations processed to estimate hyperparameters

nonnegative integer

Number of observations processed by the incremental model to estimate hyperparameters before training or tracking performance metrics, specified as the comma-separated pair consisting of `'EstimationPeriod'` and a nonnegative integer.

Note

- If `Mdl` is prepared for incremental learning (all hyperparameters required for training are specified), `incrementalLearner` forces `'EstimationPeriod'` to `0`.
- If `Mdl` is not prepared for incremental learning, `incrementalLearner` sets `'EstimationPeriod'` to `1000`.

For more details, see “Estimation Period” on page 33-2948.

Example: `'EstimationPeriod',100`

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictor data

`false` (default) | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and a value in this table.

Value	Description
`true`	The software standardizes the predictor data. For more details, see “Standardize Data” on page 33-2949.
`false`	The software does not standardize the predictor data.

Example: `'Standardize',true`

Data Types: `logical`

SGD and ASGD Solver Options

`BatchSize` — Mini-batch size

positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration during training, `incrementalLearner` uses `min(BatchSize,numObs)` observations to compute the subgradient, where `numObs` is the number of observations in the training data passed to `fit` or `updateMetricsAndFit`.

- If `Mdl.ModelParameters.Solver` is `'sgd'` or `'asgd'`, you cannot set `'BatchSize'`. Instead, `incrementalLearner` sets `'BatchSize'` to `Mdl.ModelParameters.BatchSize`.
- Otherwise, `BatchSize` is `10`.

Example: `'BatchSize',1`

Data Types: `single` | `double`

`Lambda` — Ridge (*L*2) regularization term strength

nonnegative scalar

Ridge (*L*2) regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

When `Mdl.Regularization` is `'ridge (L2)'`:

- If `Mdl.ModelParameters.Solver` is `'sgd'` or `'asgd'`, you cannot set `'Lambda'`. Instead, `incrementalLearner` sets `'Lambda'` to `Mdl.Lambda`.
- Otherwise, `Lambda` is `1e-5`.

Note `incrementalLearner` does not support lasso regularization. If `Mdl.Regularization` is `'lasso (L1)'`, `incrementalLearner` uses ridge regularization instead, and sets the `'Solver'` name-value pair argument to `'scale-invariant'` by default.

Example: `'Lambda',0.01`

Data Types: `single` | `double`

`LearnRate` — Learning rate
`'auto'` | positive scalar

Learning rate, specified as the comma-separated pair consisting of `'LearnRate'` and `'auto'` or a positive scalar. `LearnRate` controls the optimization step size by scaling the objective subgradient.

- If `Mdl.ModelParameters.Solver` is `'sgd'` or `'asgd'`, you cannot set `'LearnRate'`. Instead, `incrementalLearner` sets `'LearnRate'` to `Mdl.ModelParameters.LearnRate`.
- Otherwise, `LearnRate` is `'auto'`.

For `'auto'`:

- If `EstimationPeriod` is `0`, the initial learning rate is `0.7`.
- If `EstimationPeriod` > `0`, the initial learning rate is `1/sqrt(1+max(sum(X.^2,obsDim)))`, where `obsDim` is `1` if the observations compose the columns of the predictor data, and `2` otherwise. `fit` and `updateMetricsAndFit` set the value when you pass the model and training data to either function.

The name-value pair argument `'LearnRateSchedule'` determines the learning rate for subsequent learning cycles.

Example: `'LearnRate',0.001`

Data Types: `single` | `double` | `char` | `string`

`LearnRateSchedule` — Learning rate schedule
`'decaying'` (default) | `'constant'`

Learning rate schedule, specified as the comma-separated pair consisting of `'LearnRateSchedule'` and a value in this table, where `LearnRate` specifies the initial learning rate γ_0.

Value	Description
`'constant'`	The learning rate is γ_0 for all learning cycles.

Value	Description
`'decaying'`	The learning rate at learning cycle t is $$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$ • λ is the value of `Lambda`. • If `Solver` is `'sgd'`, then $c = 1$. • If `Solver` is `'asgd'`, then c is 0.75 [4].

If `Mdl.ModelParameters.Solver` is `'sgd'` or `'asgd'`, you cannot set `'LearnRateSchedule'`.

Example: `'LearnRateSchedule','constant'`

Data Types: `char` | `string`

Adaptive Scale-Invariant Solver Options

`Shuffle` — Flag for shuffling observations in batch

`true` (default) | `false`

Flag for shuffling the observations in the batch at each iteration, specified as the comma-separated pair consisting of `'Shuffle'` and a value in this table.

Value	Description
`true`	The software shuffles observations in each incoming batch of data before processing the set. This action reduces bias induced by the sampling scheme.
`false`	The software processes the data in the order received.

Example: `'Shuffle',false`

Data Types: `logical`

Performance Metrics Options

`Metrics` — Model performance metrics to track during incremental learning

`"classiferror"` (default) | string vector | function handle | cell vector | structure array | `"binodeviance"` | `"exponential"` | `"hinge"` | `"logit"` | `"quadratic"` | ...

Model performance metrics to track during incremental learning with the `updateMetrics` or `updateMetricsAndFit` function, specified as a built-in loss function name, string vector of names, function handle (`@metricName`), structure array of function handles, or cell vector of names, function handles, or structure arrays.

The following table lists the built-in loss function names. You can specify more than one by using a string vector.

Name	Description
`"binodeviance"`	Binomial deviance

Name	Description
"classiferror"	Classification error
"exponential"	Exponential
"hinge"	Hinge
"logit"	Logistic
"quadratic"	Quadratic

For more details on the built-in loss functions, see `loss`.

Example: `'Metrics',["classiferror" "hinge"]`

To specify a custom function that returns a performance metric, use function handle notation. The function must have this form:

```
metric = customMetric(C,S)
```

- The output argument `metric` is an *n*-by-1 numeric vector, where each element is the loss of the corresponding observation in the data by processing the incremental learning functions during a learning cycle.
- You specify the function name (`customMetric`).
- `C` is an *n*-by-2 logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`. Create `C` by setting `C(p,q) = 1`, if observation *p* is in class *q*, for each observation in the specified data. Set the other element in row *p* to `0`.
- `S` is an *n*-by-2 numeric matrix of predicted classification scores. `S` is similar to the `score` output of `predict`, where rows correspond to observations in the data and the column order corresponds to the class order in `Mdl.ClassNames`. `S(p,q)` is the classification score of observation *p* being classified in class *q*.

To specify multiple custom metrics and assign a custom name to each, use a structure array. To specify a combination of built-in and custom metrics, use a cell vector.

Example: `'Metrics',struct('Metric1',@customMetric1,'Metric2',@customMetric2)`

Example: `'Metrics',{@customMetric1 @customeMetric2 'logit' struct('Metric3',@customMetric3)}`

`updateMetrics` and `updateMetricsAndFit` store specified metrics in a table in the property `IncrementalMdl.Metrics`. The data type of `Metrics` determines the row names of the table.

'Metrics' Value Data Type	Description of Metrics Property Row Name	Example
String or character vector	Name of corresponding built-in metric	Row name for `"classiferror"` is `"ClassificationError"`
Structure array	Field name	Row name for `struct('Metric1',@customMetric1)` is `"Metric1"`
Function handle to function stored in a program file	Name of function	Row name for `@customMetric` is `"customMetric"`

'Metrics' Value Data Type	Description of Metrics Property Row Name	Example
Anonymous function	`CustomMetric_j`, where `j` is metric `j` in `Metrics`	Row name for `@(C,S)customMetric(C,S)...` is `CustomMetric_1`

For more details on performance metrics options, see “Performance Metrics” on page 33-2950.

Data Types: `char` | `string` | `struct` | `cell` | `function_handle`

`MetricsWarmupPeriod` — Number of observations fit before tracking performance metrics
`0` (default) | nonnegative integer | ...

Number of observations the incremental model must be fit to before it tracks performance metrics in its `Metrics` property, specified as the comma-separated pair consisting of `'MetricsWarmupPeriod'` and a nonnegative integer. The incremental model is warm after incremental fitting functions fit `MetricsWarmupPeriod` observations to the incremental model (`EstimationPeriod` + `MetricsWarmupPeriod` observations).

For more details on performance metrics options, see “Performance Metrics” on page 33-2950.

Data Types: `single` | `double`

`MetricsWindowSize` — Number of observations to use to compute window performance metrics
`200` (default) | positive integer | ...

Number of observations to use to compute window performance metrics, specified as a positive integer.

For more details on performance metrics options, see “Performance Metrics” on page 33-2950.

Data Types: `single` | `double`

Output Arguments

`IncrementalMdl` — Binary classification linear model for incremental learning
`incrementalClassificationLinear` model object

Binary classification linear model for incremental learning, returned as an `incrementalClassificationLinear` model object. `IncrementalMdl` is also configured to generate predictions given new data (see `predict`).

To initialize `IncrementalMdl` for incremental learning, `incrementalLearner` passes the values of the `Mdl` properties in this table to congruent properties of `IncrementalMdl`.

Property	Description
`Beta`	Linear model coefficients, a numeric vector
`Bias`	Model intercept, a numeric scalar
`ClassNames`	Class labels for binary classification, a two-element list
`ModelParameters.FitBias`	Linear model intercept inclusion flag

Property	Description
`Learner`	Linear classification model type
`Prior`	Prior class label distribution, a numeric vector

More About

Incremental Learning

Incremental learning, or online learning, is a branch of machine learning concerned with processing incoming data from a data stream, possibly given little to no knowledge of the distribution of the predictor variables, aspects of the prediction or objective function (including tuning parameter values), or whether the observations are labeled. Incremental learning differs from traditional machine learning, where enough labeled data is available to fit to a model, perform cross-validation to tune hyperparameters, and infer the predictor distribution.

Given incoming observations, an incremental learning model processes data in any of the following ways, but usually in this order:

- Predict labels.
- Measure the predictive performance.
- Check for structural breaks or drift in the model.
- Fit the model to the incoming observations.

Adaptive Scale-Invariant Solver for Incremental Learning

The adaptive scale-invariant solver for incremental learning, introduced in [1], is a gradient-descent-based objective solver for training linear predictive models. The solver is hyperparameter free, insensitive to differences in predictor variable scales, and does not require prior knowledge of the distribution of the predictor variables. These characteristics make it well suited to incremental learning.

The standard SGD and ASGD solvers are sensitive to differing scales among the predictor variables, resulting in models that can perform poorly. To achieve better accuracy using SGD and ASGD, you can standardize the predictor data, and tune the regularization and learning rate parameters can require tuning. For traditional machine learning, enough data is available to enable hyperparameter tuning by cross-validation and predictor standardization. However, for incremental learning, enough data might not be available (for example, observations might be available only one at a time) and the distribution of the predictors might be unknown. These characteristics make parameter tuning and predictor standardization difficult or impossible to do during incremental learning.

The incremental fitting functions for classification `fit` and `updateMetricsAndFit` use the more aggressive ScInOL2 version of the algorithm.

Algorithms

Estimation Period

During the estimation period, incremental fitting functions `fit` and `updateMetricsAndFit` use the first incoming `EstimationPeriod` observations to estimate (tune) hyperparameters required for incremental training. This table describes the hyperparameters and when they are estimated or tuned.

Hyperparameter	Model Property	Use	Hyperparameters Estimated
Predictor means and standard deviations	`Mu` and `Sigma`	Standardize predictor data	When you set `'Standardize',true` (see "Standardize Data" on page 33-2949)
Learning rate	`LearnRate`	Adjust solver step size	When both of these conditions apply: • You change the solver of `Mdl` to SGD or ASGD (see `Solver`). • You do not set the `'LearnRate'` name-value pair argument.

The functions fit only the last estimation period observation to the incremental model, and they do not use any of the observations to track the performance of the model. At the end of the estimation period, the functions update the properties that store the hyperparameters.

Standardize Data

If incremental learning functions are configured to standardize predictor variables, they do so using the means and standard deviations stored in the `Mu` and `Sigma` properties of the incremental learning model `IncrementalMdl`.

- When you set `'Standardize',true`, and `IncrementalMdl.Mu` and `IncrementalMdl.Sigma` are empty, the following conditions apply:
  - If the estimation period is positive (see the `EstimationPeriod` property of `IncrementalMdl`), incremental fitting functions estimate means and standard deviations using the estimation period observations.
  - If the estimation period is 0, `incrementalLearner` forces the estimation period to `1000`. Consequently, incremental fitting functions estimate new predictor variable means and standard deviations during the forced estimation period.
- When incremental fitting functions estimate predictor means and standard deviations, the functions compute weighted means and weighted standard deviations using the estimation period observations. Specifically, the functions standardize predictor j (x_j) using

  $$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

  where
  - x_j is predictor j, and x_{jk} is observation k of predictor j in the estimation period.
  - $\mu_j^* = \frac{1}{\sum_k w_k^*} \sum_k w_k^* x_{jk}$.
  - $\left(\sigma_j^*\right)^2 = \frac{1}{\sum_k w_k^*} \sum_k w_k^* \left(x_{jk} - \mu_j^*\right)^2$.
  - $w_j^* = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_k$, where

- p_k is the prior probability of class k (`Prior` property of the incremental model).
- w_j is observation weight j.

Performance Metrics

- The `updateMetrics` and `updateMetricsAndFit` functions are incremental learning functions that track model performance metrics (`'Metrics'`) from new data when the incremental model is warm (`IsWarm` property). An incremental model is warm after `fit` or `updateMetricsAndFit` fit the incremental model to `'MetricsWarmupPeriod'` observations, which is the metrics warm-up period.

  If `'EstimationPeriod'` > 0, the functions estimate hyperparameters before fitting the model to data. Therefore, the functions must process an additional `EstimationPeriod` observations before the model starts the metrics warm-up period.
- The `Metrics` property of the incremental model stores two forms of each performance metric as variables (columns) of a table, `Cumulative` and `Window`, with individual metrics in rows. When the incremental model is warm, `updateMetrics` and `updateMetricsAndFit` update the metrics at the following frequencies:

  - `Cumulative` — The functions compute cumulative metrics since the start of model performance tracking. The functions update metrics every time you call the functions and base the calculation on the entire supplied data set.
  - `Window` — The functions compute metrics based on all observations within a window determined by the `'MetricsWindowSize'` name-value pair argument. `'MetricsWindowSize'` also determines the frequency at which the software updates `Window` metrics. For example, if `MetricsWindowSize` is 20, the functions compute metrics based on the last 20 observations in the supplied data (`X((end − 20 + 1):end,:)` and `Y((end − 20 + 1):end)`).

    Incremental functions that track performance metrics within a window use the following process:

    1. For each specified metric, store a buffer of length `MetricsWindowSize` and a buffer of observation weights.
    2. Populate elements of the metrics buffer with the model performance based on batches of incoming observations, and store corresponding observations weights in the weights buffer.
    3. When the buffer is filled, overwrite `IncrementalMdl.Metrics.Window` with the weighted average performance in the metrics window. If the buffer is overfilled when the function processes a batch of observations, the latest incoming `MetricsWindowSize` observations enter the buffer, and the earliest observations are removed from the buffer. For example, suppose `MetricsWindowSize` is 20, the metrics buffer has 10 values from a previously processed batch, and 15 values are incoming. To compose the length 20 window, the functions use the measurements from the 15 incoming observations and the latest 5 measurements from the previous batch.

Introduced in R2020b

incrementalLearner

Convert naive Bayes classification model to incremental learner

Syntax

```
IncrementalMdl = incrementalLearner(Mdl)
IncrementalMdl = incrementalLearner(Mdl,Name,Value)
```

Description

`IncrementalMdl = incrementalLearner(Mdl)` returns a naive Bayes classification model for incremental learning on page 33-2959, `IncrementalMdl`, using the hyperparameters of the traditionally trained naive Bayes classification model, `Mdl`. Because its property values reflect the knowledge gained from `Mdl`, `IncrementalMdl` can predict labels given new observations, and it is warm, meaning that its predictive performance is tracked.

`IncrementalMdl = incrementalLearner(Mdl,Name,Value)` uses additional options specified by one or more name-value pair arguments. Some options require you to train `IncrementalMdl` before its predictive performance is tracked. For example, `'MetricsWarmupPeriod',50,'MetricsWindowSize',100` specifies a preliminary incremental training period of 50 observations before performance metrics are tracked, and specifies processing 100 observations before updating the performance metrics.

Examples

Convert Traditionally Trained Model to Incremental Learner

Train a naive Bayes model by using `fitcnb`, and then convert it to an incremental learner.

Load and Preprocess Data

Load the human activity data set.

```
load humanactivity
```

For details on the data set, enter `Description` at the command line.

Train Naive Bayes Model

Fit a naive Bayes classification model to the entire data set.

```
TTMdl = fitcnb(feat,actid);
```

`TTMdl` is a `ClassificationNaiveBayes` model object representing a traditionally trained naive Bayes classification model.

Convert Trained Model

Convert the traditionally trained naive Bayes classification model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalClassificationNaiveBayes

                   IsWarm: 1
                  Metrics: [1x2 table]
              ClassNames: [1 2 3 4 5]
          ScoreTransform: 'none'
        DistributionNames: {1x60 cell}
   DistributionParameters: {5x60 cell}

  Properties, Methods
```

`IncrementalMdl` is an `incrementalClassificationNaiveBayes` model object prepared for incremental learning using naive Bayes classification.

- The `incrementalLearner` function Initializes the incremental learner by passing learned conditional predictor distribution parameters to it, along with other information `TTMdl` extracted from the training data.
- `IncrementalMdl` is warm (`IsWarm` is `1`), which means that incremental learning functions can track performance metrics and make predictions.

Predict Responses

An incremental learner created from converting a traditionally trained model can generate predictions without further processing.

Predict classification scores (class posterior probabilities) for all observations using both models.

```
[~,ttscores] = predict(TTMdl,feat);
[~,ilcores] = predict(IncrementalMdl,feat);
compareScores = norm(ttscores - ilcores)
```

```
compareScores = 0
```

The difference between the scores generated by the models is 0.

Configure Performance Metric Options

Use a trained naive Bayes model to initialize an incremental learner. Prepare the incremental learner by specifying a metrics warm-up period, during which the `updateMetricsAndFit` function only fits the model. Specify a metrics window size of 500 observations.

Load the human activity data set.

```
load humanactivity
```

For details on the data set, enter `Description` at the command line

Randomly split the data in half: the first half for training a model traditionally, and the second half for incremental learning.

```
n = numel(actid);
```

```
rng(1) % For reproducibility
cvp = cvpartition(n,'Holdout',0.5);
idxtt = training(cvp);
idxil = test(cvp);

% First half of data
Xtt = feat(idxtt,:);
Ytt = actid(idxtt);

% Second half of data
Xil = feat(idxil,:);
Yil = actid(idxil);
```

Fit a naive Bayes model to the first half of the data.

```
TTMdl = fitcnb(Xtt,Ytt);
```

Convert the traditionally trained naive Bayes model to a naive Bayes classification model for incremental learning. Specify the following:

- A performance metrics warm-up period of 2000 observations
- A metrics window size of 500 observations
- Use of classification error and minimal cost to measure the performance of the model

```
IncrementalMdl = incrementalLearner(TTMdl,'MetricsWarmupPeriod',2000,'MetricsWindowSize',500,...
    'Metrics',["classiferror" "hinge"]);
```

Fit the incremental model to the second half of the data by using the `updateMetricsAndfit` function. At each iteration:

- Simulate a data stream by processing 20 observations at a time.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the mean of the second predictor within the first class μ_{12}, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 20;
nchunk = ceil(nil/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mc = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mu12 = zeros(nchunk,1);

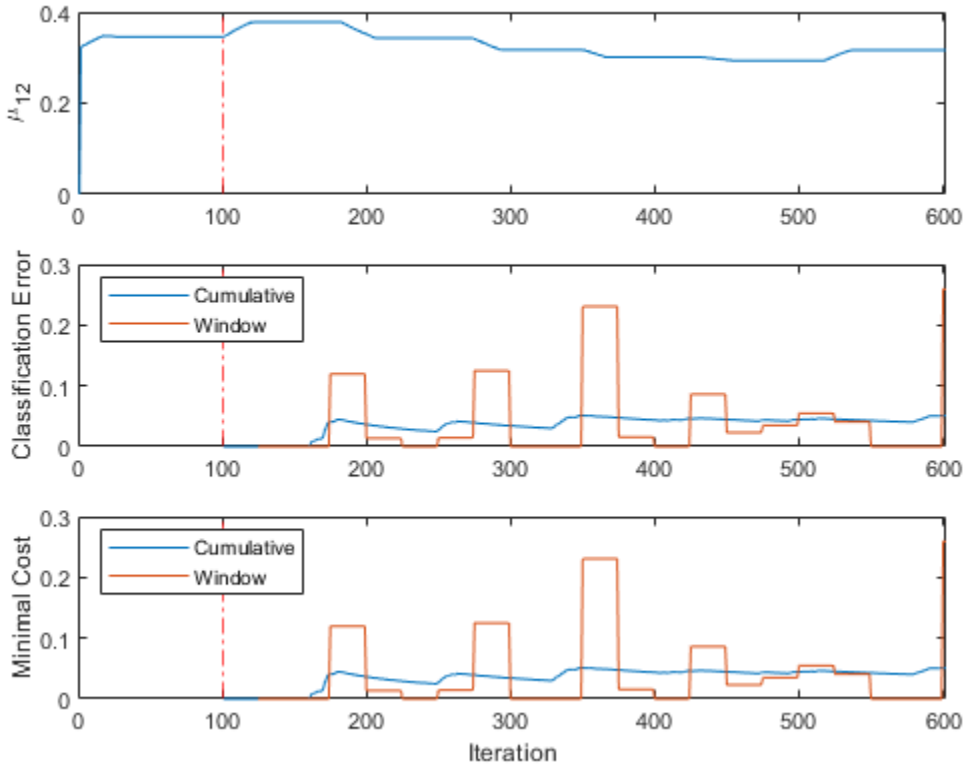
% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetricsAndFit(IncrementalMdl,Xil(idx,:),Yil(idx));
    ce{j,:} = IncrementalMdl.Metrics{"ClassificationError",:};
    mc{j,:} = IncrementalMdl.Metrics{"MinimalCost",:};
    mu12(j + 1) = IncrementalMdl.DistributionParameters{1,2}(1);
end
```

`IncrementalMdl` is an `incrementalClassificationNaiveBayes` model object trained on all the data in the stream. During incremental learning and after the model is warmed up,

`updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and μ_{12} evolved during training, plot them on separate subplots.

```
figure;
subplot(3,1,1)
plot(mu12)
ylabel('\mu_{12}')
xlim([0 nchunk]);
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
subplot(3,1,2)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,ce.Properties.VariableNames,'Location','northwest')
subplot(3,1,3)
h = plot(mc.Variables);
xlim([0 nchunk]);
ylabel('Minimal Cost')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mc.Properties.VariableNames,'Location','northwest')
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit μ_{12} during all incremental learning iterations.
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations (25 iterations).

Because the data is ordered by activity, the mean and performance metrics periodically change abruptly.

Input Arguments

`Mdl` — Traditionally trained naive Bayes model for multiclass classification

`ClassificationNaiveBayes` model object

Traditionally trained naive Bayes model for multiclass classification, specified as a `ClassificationNaiveBayes` model object returned by `fitcnb`. The conditional distribution of each predictor variable, as stored in `Mdl.DistributionNames`, must be normal.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Metrics',["classiferror" "mincost"],'MetricsWindowSize',100` specifies tracking the misclassification rate and minimal cost, and specifies processing 100 observations before updating the performance metrics.

`Metrics` — Model performance metrics to track during incremental learning

`"mincost"` (default) | `"classiferror"` | string vector | function handle | cell vector | structure array | `"binodeviance"` | `"exponential"` | `"hinge"` | `"logit"` | `"quadratic"` | ...

Model performance metrics to track during incremental learning with the `updateMetrics` or `updateMetricsAndFit` function, specified as a built-in loss function name, string vector of names, function handle (`@metricName`), structure array of function handles, or cell vector of names, function handles, or structure arrays.

The following table lists the built-in loss function names. You can specify more than one by using a string vector.

Name	Description
`"binodeviance"`	Binomial deviance
`"classiferror"`	Classification error
`"exponential"`	Exponential
`"hinge"`	Hinge
`"logit"`	Logistic
`'"mincost"`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)

Name	Description
`"quadratic"`	Quadratic

For more details on the built-in loss functions, see `loss`.

Example: `'Metrics',["classiferror" "mincost"]`

To specify a custom function that returns a performance metric, use function handle notation. The function must have this form:

```
metric = customMetric(C,S,Cost)
```

- The output argument `metric` is an *n*-by-1 numeric vector, where each element is the loss of the corresponding observation in the data processed by the incremental learning functions during a learning cycle.
- You select the function name (`customMetric`).
- `C` is an *n*-by-*K* logical matrix with rows indicating the class to which the corresponding observation belongs, where *K* is the number of classes. The column order corresponds to the class order in the `ClassNames` property. Create `C` by setting `C(p,q) = 1`, if observation *p* is in class *q*, for each observation in the specified data. Set the other element in row *p* to `0`.
- `S` is an *n*-by-*K* numeric matrix of predicted classification scores. `S` is similar to the `Score` output of `predict`, where rows correspond to observations in the data and the column order corresponds to the class order in the `ClassNames` property. `S(p,q)` is the classification score of observation *p* being classified in class *q*.
- `Cost` is a *K*-by-*K* numeric matrix of misclassification costs. See the `'Cost'` name-value argument.

To specify multiple custom metrics and assign a custom name to each, use a structure array. To specify a combination of built-in and custom metrics, use a cell vector.

Example: `'Metrics',struct('Metric1',@customMetric1,'Metric2',@customMetric2)`

Example: `'Metrics',{@customMetric1 @customeMetric2 'logit' struct('Metric3',@customMetric3)}`

`updateMetrics` and `updateMetricsAndFit` store specified metrics in a table in the property `IncrementalMdl.Metrics`. The data type of `Metrics` determines the row names of the table.

`'Metrics'` Value Data Type	Description of `Metrics` Property Row Name	Example
String or character vector	Name of corresponding built-in metric	Row name for `"classiferror"` is `"ClassificationError"`
Structure array	Field name	Row name for `struct('Metric1',@customMetric1)` is `"Metric1"`
Function handle to function stored in a program file	Name of function	Row name for `@customMetric` is `"customMetric"`
Anonymous function	`CustomMetric_`*j*, where *j* is metric *j* in `Metrics`	Row name for `@(C,S,Cost)customMetric(C,S,Cost)...` is `CustomMetric_1`

For more details on performance metrics options, see “Performance Metrics” on page 33-2959.

Data Types: `char` | `string` | `struct` | `cell` | `function_handle`

`MetricsWarmupPeriod` — Number of observations fit before tracking performance metrics
`1000` (default) | nonnegative integer

This property is read-only.

Number of observations the incremental model must be fit to before it tracks performance metrics in its `Metrics` property, specified as a nonnegative integer.

For more details, see “Performance Metrics” on page 33-2959.

Data Types: `single` | `double`

`MetricsWindowSize` — Number of observations to use to compute window performance metrics
`200` (default) | positive integer

This property is read-only.

Number of observations to use to compute window performance metrics, specified as a positive integer.

For more details on performance metrics options, see “Performance Metrics” on page 33-2959.

Data Types: `single` | `double`

Output Arguments

`IncrementalMdl` — Naive Bayes classification for incremental learning
`incrementalClassificationNaiveBayes` model object

Naive Bayes classification model for incremental learning, returned as an `incrementalClassificationNaiveBayes` model object. `IncrementalMdl` is also configured to generate predictions given new data (see `predict`).

To initialize `IncrementalMdl` for incremental learning, `incrementalLearner` passes the values of the properties of `Mdl` in this table to congruent properties of `IncrementalMdl`.

Property	Description
`ClassNames`	Class labels for binary classification, a list of names
`Cost`	Misclassification costs, a numeric matrix
`DistributionNames`	Names of the conditional distributions of the predictor variables, a cell array in which each cell contains `'normal`
`DistributionParameters`	Parameter values of the conditional distributions of the predictor variables, a cell array of length 2 numeric vectors (for details, see `DistributionParameters`)
`Prior`	Prior class label distribution, a numeric vector
`ScoreTransform`	Score transformation function, a name or function handle.
`Y`	Class labels supplied to `fitcnb` to compute per class weights for incremental learning, stored as an array of labels (see `Y`)

More About

Incremental Learning

Incremental learning, or online learning, is a branch of machine learning concerned with processing incoming data from a data stream, possibly given little to no knowledge of the distribution of the predictor variables, aspects of the prediction or objective function (including tuning parameter values), or whether the observations are labeled. Incremental learning differs from traditional machine learning, where enough labeled data is available to fit to a model, perform cross-validation to tune hyperparameters, and infer the predictor distribution.

Given incoming observations, an incremental learning model processes data in any of the following ways, but usually in this order:

- Predict labels.
- Measure the predictive performance.
- Check for structural breaks or drift in the model.
- Fit the model to the incoming observations.

Algorithms

Performance Metrics

- The `updateMetrics` and `updateMetricsAndFit` functions track model performance metrics (`'Metrics'`) from new data when the incremental model is warm (`IsWarm` property). An incremental model is warm when `fit` or `updateMetricsAndFit` perform both of the following actions:
  - Fit the incremental model to MetricsWarmupPeriod observations, which is the metrics warm-up period.
  - Process `MaxNumClasses` classes or all class names specified by the `ClassNames` name-value argument.
- The `Metrics` property of the incremental model stores two forms of each performance metric as variables (columns) of a table, `Cumulative` and `Window`, with individual metrics in rows. When the incremental model is warm, `updateMetrics` and `updateMetricsAndFit` update the metrics at the following frequencies:
  - `Cumulative` — The functions compute cumulative metrics since the start of model performance tracking. The functions update metrics every time you call the functions and base the calculation on the entire supplied data set.
  - `Window` — The functions compute metrics based on all observations within a window determined by the MetricsWindowSize name-value pair argument. `MetricsWindowSize` also determines the frequency at which the software updates `Window` metrics. For example, if `MetricsWindowSize` is 20, the functions compute metrics based on the last 20 observations in the supplied data (`X((end − 20 + 1):end,:)` and `Y((end − 20 + 1):end)`).

    Incremental functions that track performance metrics within a window use the following process:

    1. For each specified metric, store a buffer of length `MetricsWindowSize` and a buffer of observation weights.

2. Populate elements of the metrics buffer with the model performance based on batches of incoming observations, and store corresponding observation weights in the weights buffer.
3. When the buffer is filled, overwrite `Mdl.Metrics.Window` with the weighted average performance in the metrics window. If the buffer is overfilled when the function processes a batch of observations, the latest incoming `MetricsWindowSize` observations enter the buffer, and the earliest observations are removed from the buffer. For example, suppose `MetricsWindowSize` is 20, the metrics buffer has 10 values from a previously processed batch, and 15 values are incoming. To compose the length 20 window, the functions use the measurements from the 15 incoming observations and the latest 5 measurements from the previous batch.

Introduced in R2021a

incrementalLearner

Convert binary classification support vector machine (SVM) model to incremental learner

Syntax

```
IncrementalMdl = incrementalLearner(Mdl)
IncrementalMdl = incrementalLearner(Mdl,Name,Value)
```

Description

`IncrementalMdl = incrementalLearner(Mdl)` returns a binary classification linear model for incremental learning on page 33-2974, `IncrementalMdl`, using the hyperparameters and coefficients of the traditionally trained linear SVM model for binary classification, `Mdl`. Because its property values reflect the knowledge gained from `Mdl`, `IncrementalMdl` can predict labels given new observations, and it is warm, meaning that its predictive performance is tracked.

`IncrementalMdl = incrementalLearner(Mdl,Name,Value)` uses additional options specified by one or more name-value pair arguments. Some options require you to train `IncrementalMdl` before its predictive performance is tracked. For example, `'MetricsWarmupPeriod',50,'MetricsWindowSize',100` specifies a preliminary incremental training period of 50 observations before performance metrics are tracked, and specifies processing 100 observations before updating the performance metrics.

Examples

Convert Traditionally Trained Model to Incremental Learner

Train an SVM model by using `fitcsvm`, and then convert it to an incremental learner.

Load and Preprocess Data

Load the human activity data set.

```
load humanactivity
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: `Sitting`, `Standing`, `Walking`, `Running`, or `Dancing`. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = actid > 2;
```

Train SVM Model

Fit an SVM model to the entire data set. Discard the support vectors (`Alpha`) from the model so that the software uses the linear coefficients (`Beta`) for prediction.

```
TTMdl = fitcsvm(feat,Y);
TTMdl = discardSupportVectors(TTMdl)
```

```
TTMdl =
  ClassificationSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: [0 1]
           ScoreTransform: 'none'
          NumObservations: 24075
                     Beta: [60x1 double]
                     Bias: -6.4221
         KernelParameters: [1x1 struct]
           BoxConstraints: [24075x1 double]
          ConvergenceInfo: [1x1 struct]
          IsSupportVector: [24075x1 logical]
                   Solver: 'SMO'

  Properties, Methods
```

`TTMdl` is a `ClassificationSVM` model object representing a traditionally trained SVM model.

Convert Trained Model

Convert the traditionally trained SVM model to a binary classification linear model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalClassificationLinear

            IsWarm: 1
           Metrics: [1x2 table]
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [60x1 double]
              Bias: -6.4221
           Learner: 'svm'

  Properties, Methods
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object prepared for incremental learning using SVM.

- The `incrementalLearner` function Initializes the incremental learner by passing learned coefficients to it, along with other information `TTMdl` extracted from the training data.
- `IncrementalMdl` is warm (`IsWarm` is `1`), which means that incremental learning functions can start tracking performance metrics.
- The `incrementalLearner` function specifies to train the model using the adaptive scale-invariant solver, whereas `fitcsvm` trained `TTMdl` using the `SMO` solver.

Predict Responses

An incremental learner created from converting a traditionally trained model can generate predictions without further processing.

Predict classification scores for all observations using both models.

```
[~,ttscores] = predict(TTMdl,feat);
[~,ilcores] = predict(IncrementalMdl,feat);
compareScores = norm(ttscores(:,1) - ilcores(:,1))
```

```
compareScores = 0
```

The difference between the scores generated by the models is 0.

Specify SGD Solver and Standardize Predictor Data

The default solver is the adaptive scale-invariant solver. If you specify this solver, you do not need to tune any parameters for training. However, if you specify either the standard SGD or ASGD solver instead, you can also specify an estimation period, during which the incremental fitting functions tune the learning rate.

Load the human activity data set.

```
load humanactivity
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: `Sitting`, `Standing`, `Walking`, `Running`, and `Dancing`. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = actid > 2;
```

Randomly split the data in half: the first half have for training a model traditionally, and the second half for incremental learning.

```
n = numel(Y);

rng(1) % For reproducibility
cvp = cvpartition(n,'Holdout',0.5);
idxtt = training(cvp);
idxil = test(cvp);

% First half of data
Xtt = feat(idxtt,:);
Ytt = Y(idxtt);

% Second half of data
Xil = feat(idxil,:);
Yil = Y(idxil);
```

Fit an SVM model to the first half of the data. Standardize the predictor data by setting `'Standardize',true`.

```
TTMdl = fitcsvm(Xtt,Ytt,'Standardize',true);
```

The `Mu` and `Sigma` properties of `TTMdl` contain the predictor data sample means and standard deviations, respectively.

Suppose that the distribution of the predictors is not expected to change in the future. Convert the traditionally trained SVM model to a binary classification linear model for incremental learning.

Specify the standard SGD solver and an estimation period of `2000` observations (the default is `1000` when a learning rate is required).

```
IncrementalMdl = incrementalLearner(TTMdl,'Solver','sgd','EstimationPeriod',2000);
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object. Because the predictor data of `TTMdl` is standardized (`TTMdl.Mu` and `TTMdl.Sigma` are nonempty), `incrementalLearner` prepares incremental learning functions to standardize supplied predictor data by using the previously learned moments (stored in `IncrementalMdl.Mu` and `IncrementalMdl.Sigma`).

Fit the incremental model to the second half of the data by using the `fit` function. At each iteration:

- Simulate a data stream by processing 10 observations at a time.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the learning rate and β_1 to see how the coefficients and learning rate evolve during training.

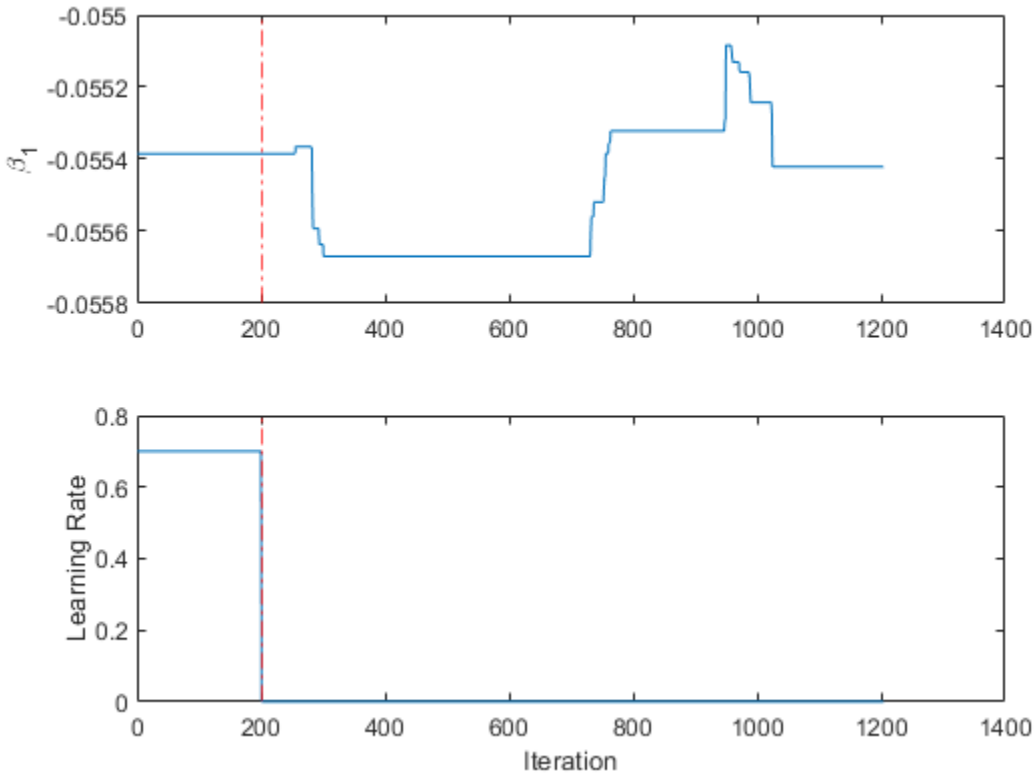
```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 10;
nchunk = floor(nil/numObsPerChunk);
learnrate = [IncrementalMdl.LearnRate; zeros(nchunk,1)];
beta1 = [IncrementalMdl.Beta(1); zeros(nchunk,1)];

% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = fit(IncrementalMdl,Xil(idx,:),Yil(idx));
    beta1(j + 1) = IncrementalMdl.Beta(1);
    learnrate(j + 1) = IncrementalMdl.LearnRate;
end
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream.

To see how the learning rate and β_1 evolved during training, plot them on separate subplots.

```
subplot(2,1,1)
plot(beta1)
ylabel('\beta_1')
xline(IncrementalMdl.EstimationPeriod/numObsPerChunk,'r-.');
subplot(2,1,2)
plot(learnrate)
ylabel('Learning Rate')
xline(IncrementalMdl.EstimationPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
```



The learning rate jumps to its auto-tuned value after the estimation period.

Because `fit` does not fit the model to the streaming data during the estimation period, β_1 is constant for the first 200 iterations (2000 observations). Then, β_1 changes during incremental fitting.

Configure Performance Metric Options

Use a trained SVM model to initialize an incremental learner. Prepare the incremental learner by specifying a metrics warm-up period, during which the `updateMetricsAndFit` function only fits the model. Specify a metrics window size of 500 observations.

Load the human activity data set.

```
load humanactivity
```

For details on the data set, enter `Description` at the command line

Responses can be one of five classes: `Sitting`, `Standing`, `Walking`, `Running`, and `Dancing`. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = actid > 2;
```

Because the data set is grouped by activity, shuffle it to reduce bias. Then, randomly split the data in half: the first half for training a model traditionally, and the second half for incremental learning.

```
n = numel(Y);

rng(1) % For reproducibility
cvp = cvpartition(n,'Holdout',0.5);
idxtt = training(cvp);
idxil = test(cvp);
shuffidx = randperm(n);
X = feat(shuffidx,:);
Y = Y(shuffidx);

% First half of data
Xtt = X(idxtt,:);
Ytt = Y(idxtt);

% Second half of data
Xil = X(idxil,:);
Yil = Y(idxil);
```

Fit an SVM model to the first half of the data.

```
TTMdl = fitcsvm(Xtt,Ytt);
```

Convert the traditionally trained SVM model to a binary classification linear model for incremental learning. Specify the following:

- A performance metrics warm-up period of 2000 observations
- A metrics window size of 500 observations
- Use of classification error and hinge loss to measure the performance of the model

```
IncrementalMdl = incrementalLearner(TTMdl,'MetricsWarmupPeriod',2000,'MetricsWindowSize',500,...
    'Metrics',["classiferror" "hinge"]);
```

Fit the incremental model to the second half of the data by using the `updateMetricsAndfit` function. At each iteration:

- Simulate a data stream by processing 20 observations at a time.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store β_1, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 20;
nchunk = ceil(nil/numObsPerChunk);
ce = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
hinge = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = zeros(nchunk,1);

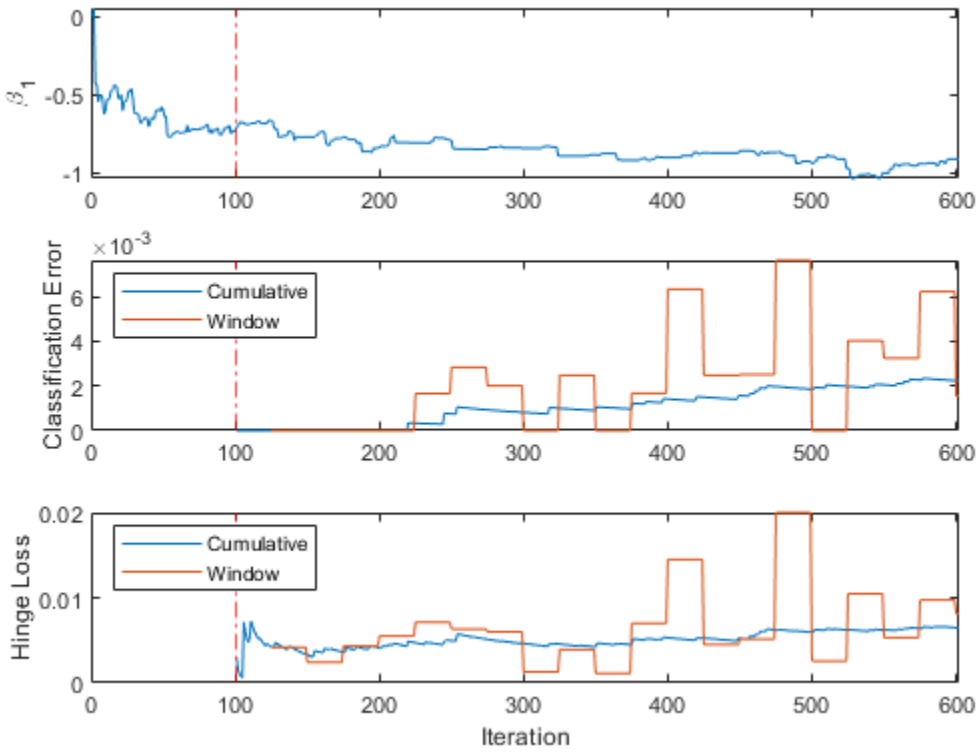
% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetricsAndFit(IncrementalMdl,Xil(idx,:),Yil(idx));
    ce{j,:} = IncrementalMdl.Metrics{"ClassificationError",:};
    hinge{j,:} = IncrementalMdl.Metrics{"HingeLoss",:};
```

```
    beta1(j + 1) = IncrementalMdl.Beta(1);
end
```

`IncrementalMdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and β_1 evolved during training, plot them on separate subplots.

```
figure;
subplot(3,1,1)
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
subplot(3,1,2)
h = plot(ce.Variables);
xlim([0 nchunk]);
ylabel('Classification Error')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,ce.Properties.VariableNames,'Location','northwest')
subplot(3,1,3)
h = plot(hinge.Variables);
xlim([0 nchunk]);
ylabel('Hinge Loss')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,hinge.Properties.VariableNames,'Location','northwest')
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit β_1 during all incremental learning iterations.
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations (25 iterations).

Input Arguments

`Mdl` — Traditionally trained linear SVM model for binary classification

`ClassificationSVM` model object | `CompactClassificationSVM` model object

Traditionally trained linear SVM model for binary classification, specified as a model object returned by its training or processing function.

Model Object	Training or Processing Function
`ClassificationSVM`	`fitcsvm`
`CompactClassificationSVM`	`fitcsvm` or `compact`

Note

Incremental learning functions support only numeric input predictor data. If `Mdl` was fit to categorical data, use `dummyvar` to convert each categorical variable to a numeric matrix of dummy variables, and concatenate all dummy variable matrices and any other numeric predictors. For more details, see “Dummy Variables” on page 2-48.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Solver','scale-invariant','MetricsWindowSize',100` specifies the adaptive scale-invariant solver for objective optimization, and specifies processing 100 observations before updating the performance metrics.

General Options

`Solver` — Objective function minimization technique
`'scale-invariant'` (default) | `'sgd'` | `'asgd'`

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a value in this table.

Value	Description	Notes
`'scale-invariant'`	Adaptive scale-invariant solver for incremental learning on page 33-2974 [1]	• This algorithm is parameter free and can adapt to differences in predictor scales. Try this algorithm before using SGD or ASGD. • To shuffle incoming batches before the `fit` function fits the model, set `Shuffle` to `true`.
`'sgd'`	Stochastic gradient descent (SGD) [3][2]	• To train effectively with SGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Options” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.
`'asgd'`	Average stochastic gradient descent (ASGD) [4]	• To train effectively with ASGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Options” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.

Example: `'Solver','sgd'`

Data Types: `char` | `string`

`EstimationPeriod` — Number of observations processed to estimate hyperparameters
nonnegative integer

Number of observations processed by the incremental model to estimate hyperparameters before training or tracking performance metrics, specified as the comma-separated pair consisting of `'EstimationPeriod'` and a nonnegative integer.

Note

- If `Mdl` is prepared for incremental learning (all hyperparameters required for training are specified), `incrementalLearner` forces `'EstimationPeriod'` to `0`.
- If `Mdl` is not prepared for incremental learning, `incrementalLearner` sets `'EstimationPeriod'` to `1000`.

For more details, see "Estimation Period" on page 33-2975.

Example: `'EstimationPeriod',100`

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictor data

`'auto'` (default) | `false` | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and a value in this table.

Value	Description
`'auto'`	`incrementalLearner` determines whether the predictor variables need to be standardized. See "Standardize Data" on page 33-2975.
`true`	The software standardizes the predictor data.
`false`	The software does not standardize the predictor data.

Under some conditions, `incrementalLearner` can override your specification. For more details, see "Standardize Data" on page 33-2975.

Example: `'Standardize',true`

Data Types: `logical` | `char` | `string`

SGD and ASGD Solver Options

`BatchSize` — Mini-batch size

`10` (default) | positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration during training, `incrementalLearner` uses `min(BatchSize,numObs)` observations to compute the subgradient, where `numObs` is the number of observations in the training data passed to `fit` or `updateMetricsAndFit`.

Example: `'BatchSize',1`

Data Types: `single` | `double`

`Lambda` — Ridge (L^2) regularization term strength

`1e-5` (default) | nonnegative scalar

Ridge (L^2) regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

Example: `'Lambda',0.01`

Data Types: `single` | `double`

`LearnRate` — Learning rate

`'auto'` (default) | positive scalar

Learning rate, specified as the comma-separated pair consisting of `'LearnRate'` and `'auto'` or a positive scalar. `LearnRate` controls the optimization step size by scaling the objective subgradient.

For `'auto'`:

- If `EstimationPeriod` is `0`, the initial learning rate is `0.7`.
- If `EstimationPeriod` > `0`, the initial learning rate is `1/sqrt(1+max(sum(X.^2,obsDim)))`, where `obsDim` is `1` if the observations compose the columns of the predictor data, and `2` otherwise. `fit` and `updateMetricsAndFit` set the value when you pass the model and training data to either function.

The name-value pair argument `'LearnRateSchedule'` determines the learning rate for subsequent learning cycles.

Example: `'LearnRate',0.001`

Data Types: `single` | `double` | `char` | `string`

`LearnRateSchedule` — Learning rate schedule

`'decaying'` (default) | `'constant'`

Learning rate schedule, specified as the comma-separated pair consisting of `'LearnRateSchedule'` and a value in this table, where `LearnRate` specifies the initial learning rate γ_0.

Value	Description
`'constant'`	The learning rate is γ_0 for all learning cycles.
`'decaying'`	The learning rate at learning cycle t is $$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$ • λ is the value of `Lambda`. • If `Solver` is `'sgd'`, then $c = 1$. • If `Solver` is `'asgd'`, then c is 0.75 [4].

Example: `'LearnRateSchedule','constant'`

Data Types: `char` | `string`

Adaptive Scale-Invariant Solver Options

`Shuffle` — Flag for shuffling observations in batch

`true` (default) | `false`

Flag for shuffling the observations in the batch at each iteration, specified as the comma-separated pair consisting of `'Shuffle'` and a value in this table.

Value	Description
`true`	The software shuffles observations in each incoming batch of data before processing the set. This action reduces bias induced by the sampling scheme.
`false`	The software processes the data in the order received.

Example: `'Shuffle',false`

Data Types: `logical`

Performance Metrics Options

`Metrics` — Model performance metrics to track during incremental learning
`"classiferror"` (default) | string vector | function handle | cell vector | structure array | `"binodeviance"` | `"exponential"` | `"hinge"` | `"logit"` | `"quadratic"` | ...

Model performance metrics to track during incremental learning with the `updateMetrics` or `updateMetricsAndFit` function, specified as a built-in loss function name, string vector of names, function handle (`@metricName`), structure array of function handles, or cell vector of names, function handles, or structure arrays.

The following table lists the built-in loss function names. You can specify more than one by using a string vector.

Name	Description
`"binodeviance"`	Binomial deviance
`"classiferror"`	Classification error
`"exponential"`	Exponential
`"hinge"`	Hinge
`"logit"`	Logistic
`"quadratic"`	Quadratic

For more details on the built-in loss functions, see `loss`.

Example: `'Metrics',["classiferror" "hinge"]`

To specify a custom function that returns a performance metric, use function handle notation. The function must have this form:

```
metric = customMetric(C,S)
```

- The output argument `metric` is an *n*-by-1 numeric vector, where each element is the loss of the corresponding observation in the data by processing the incremental learning functions during a learning cycle.
- You specify the function name (`customMetric`).
- `C` is an *n*-by-2 logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`. Create `C` by setting `C(`*p*`,`*q*`) = 1`, if observation *p* is in class *q*, for each observation in the specified data. Set the other element in row *p* to `0`.

- `S` is an *n*-by-2 numeric matrix of predicted classification scores. `S` is similar to the `score` output of `predict`, where rows correspond to observations in the data and the column order corresponds to the class order in `Mdl.ClassNames`. `S(p,q)` is the classification score of observation *p* being classified in class *q*.

To specify multiple custom metrics and assign a custom name to each, use a structure array. To specify a combination of built-in and custom metrics, use a cell vector.

Example: `'Metrics',struct('Metric1',@customMetric1,'Metric2',@customMetric2)`

Example: `'Metrics',{@customMetric1 @customeMetric2 'logit' struct('Metric3',@customMetric3)}`

`updateMetrics` and `updateMetricsAndFit` store specified metrics in a table in the property `IncrementalMdl.Metrics`. The data type of `Metrics` determines the row names of the table.

`'Metrics'` Value Data Type	Description of `Metrics` Property Row Name	Example
String or character vector	Name of corresponding built-in metric	Row name for `"classiferror"` is `"ClassificationError"`
Structure array	Field name	Row name for `struct('Metric1',@customMetric1)` is `"Metric1"`
Function handle to function stored in a program file	Name of function	Row name for `@customMetric` is `"customMetric"`
Anonymous function	`CustomMetric_`*j*, where *j* is metric *j* in `Metrics`	Row name for `@(C,S)customMetric(C,S)...` is `CustomMetric_1`

For more details on performance metrics options, see “Performance Metrics” on page 33-2976.

Data Types: `char` | `string` | `struct` | `cell` | `function_handle`

`MetricsWarmupPeriod` — Number of observations fit before tracking performance metrics
`0` (default) | nonnegative integer | ...

Number of observations the incremental model must be fit to before it tracks performance metrics in its `Metrics` property, specified as the comma-separated pair consisting of `'MetricsWarmupPeriod'` and a nonnegative integer. The incremental model is warm after incremental fitting functions fit `MetricsWarmupPeriod` observations to the incremental model (`EstimationPeriod` + `MetricsWarmupPeriod` observations).

For more details on performance metrics options, see “Performance Metrics” on page 33-2976.

Data Types: `single` | `double`

`MetricsWindowSize` — Number of observations to use to compute window performance metrics
`200` (default) | positive integer | ...

Number of observations to use to compute window performance metrics, specified as a positive integer.

For more details on performance metrics options, see “Performance Metrics” on page 33-2976.

Data Types: `single` | `double`

Output Arguments

`IncrementalMdl` — Binary classification linear model for incremental learning
`incrementalClassificationLinear` model object

Binary classification linear model for incremental learning, returned as an `incrementalClassificationLinear` model object. `IncrementalMdl` is also configured to generate predictions given new data (see `predict`).

To initialize `IncrementalMdl` for incremental learning, `incrementalLearner` passes the values of the `Mdl` properties in this table to congruent properties of `IncrementalMdl`.

Property	Description
`Beta`	Linear model coefficients, a numeric vector
`Bias`	Model intercept, a numeric scalar
`ClassNames`	Class labels for binary classification, two-element list
`Mu`	Predictor variable means, a numeric vector
`Prior`	Prior class label distribution, a numeric vector
`Sigma`	Predictor variable standard deviations, a numeric vector

More About

Incremental Learning

Incremental learning, or online learning, is a branch of machine learning concerned with processing incoming data from a data stream, possibly given little to no knowledge of the distribution of the predictor variables, aspects of the prediction or objective function (including tuning parameter values), or whether the observations are labeled. Incremental learning differs from traditional machine learning, where enough labeled data is available to fit to a model, perform cross-validation to tune hyperparameters, and infer the predictor distribution.

Given incoming observations, an incremental learning model processes data in any of the following ways, but usually in this order:

- Predict labels.
- Measure the predictive performance.
- Check for structural breaks or drift in the model.
- Fit the model to the incoming observations.

Adaptive Scale-Invariant Solver for Incremental Learning

The adaptive scale-invariant solver for incremental learning, introduced in [1], is a gradient-descent-based objective solver for training linear predictive models. The solver is hyperparameter free, insensitive to differences in predictor variable scales, and does not require prior knowledge of the distribution of the predictor variables. These characteristics make it well suited to incremental learning.

The standard SGD and ASGD solvers are sensitive to differing scales among the predictor variables, resulting in models that can perform poorly. To achieve better accuracy using SGD and ASGD, you can standardize the predictor data, and tune the regularization and learning rate parameters can require tuning. For traditional machine learning, enough data is available to enable hyperparameter tuning by cross-validation and predictor standardization. However, for incremental learning, enough data might not be available (for example, observations might be available only one at a time) and the distribution of the predictors might be unknown. These characteristics make parameter tuning and predictor standardization difficult or impossible to do during incremental learning.

The incremental fitting functions for classification `fit` and `updateMetricsAndFit` use the more aggressive ScInOL2 version of the algorithm.

Algorithms

Estimation Period

During the estimation period, incremental fitting functions `fit` and `updateMetricsAndFit` use the first incoming `EstimationPeriod` observations to estimate (tune) hyperparameters required for incremental training. This table describes the hyperparameters and when they are estimated or tuned.

Hyperparameter	Model Property	Use	Hyperparameters Estimated
Predictor means and standard deviations	`Mu` and `Sigma`	Standardize predictor data	When both these conditions apply: • When you set `'Standardize',true` (see "Standardize Data" on page 33-2975) • `IncrementalMdl.Mu` and `IncrementalMdl.Sigma` are empty arrays `[]`.
Learning rate	`LearnRate`	Adjust solver step size	When both of these conditions apply: • You change the solver of `Mdl` to SGD or ASGD (see `Solver`). • You do not set the `'LearnRate'` name-value pair argument.

The functions fit only the last estimation period observation to the incremental model, and they do not use any of the observations to track the performance of the model. At the end of the estimation period, the functions update the properties that store the hyperparameters.

Standardize Data

If incremental learning functions are configured to standardize predictor variables, they do so using the means and standard deviations stored in the `Mu` and `Sigma` properties of the incremental learning model `IncrementalMdl`.

- If you standardized the predictor data when you trained the input model `Mdl` by using `fitcsvm`, the following conditions apply:
  - `incrementalLearner` passes the means in `Mdl.Mu` and standard deviations in `Mdl.Sigma` to the congruent incremental learning model properties.

  - Incremental learning functions always standardize the predictor data, regardless of the value of the `'Standardize'` name-value pair argument.
- When you set `'Standardize',true`, and `IncrementalMdl.Mu` and `IncrementalMdl.Sigma` are empty, the following conditions apply:
  - If the estimation period is positive (see the `EstimationPeriod` property of `IncrementalMdl`), incremental fitting functions estimate means and standard deviations using the estimation period observations.
  - If the estimation period is 0, `incrementalLearner` forces the estimation period to `1000`. Consequently, incremental fitting functions estimate new predictor variable means and standard deviations during the forced estimation period.
- When you set `'Standardize','auto'` (the default), the following conditions apply.
  - If `IncrementalMdl.Mu` and `IncrementalMdl.Sigma` are empty, incremental learning functions do not standardize predictor variables.
  - Otherwise, incremental learning functions standardize the predictor variables using their means and standard deviations in `IncrementalMdl.Mu` and `IncrementalMdl.Sigma`, respectively. Incremental fitting functions do not estimate new means and standard deviations regardless of the length of the estimation period.
- When incremental fitting functions estimate predictor means and standard deviations, the functions compute weighted means and weighted standard deviations using the estimation period observations. Specifically, the functions standardize predictor j (x_j) using

  $$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

  where
  - x_j is predictor j, and x_{jk} is observation k of predictor j in the estimation period.
  - $\mu_j^* = \frac{1}{\sum_k w_k^*} \sum_k w_k^* x_{jk}$.
  - $\left(\sigma_j^*\right)^2 = \frac{1}{\sum_k w_k^*} \sum_k w_k^* \left(x_{jk} - \mu_j^*\right)^2$.
  - $w_j^* = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_k$, where
    - p_k is the prior probability of class k (`Prior` property of the incremental model).
    - w_j is observation weight j.

Performance Metrics

- The `updateMetrics` and `updateMetricsAndFit` functions are incremental learning functions that track model performance metrics (`'Metrics'`) from new data when the incremental model is warm (`IsWarm` property). An incremental model is warm after `fit` or `updateMetricsAndFit` fit the incremental model to `'MetricsWarmupPeriod'` observations, which is the metrics warm-up period.

If `'EstimationPeriod'` > 0, the functions estimate hyperparameters before fitting the model to data. Therefore, the functions must process an additional `EstimationPeriod` observations before the model starts the metrics warm-up period.

- The `Metrics` property of the incremental model stores two forms of each performance metric as variables (columns) of a table, `Cumulative` and `Window`, with individual metrics in rows. When the incremental model is warm, `updateMetrics` and `updateMetricsAndFit` update the metrics at the following frequencies:

  - `Cumulative` — The functions compute cumulative metrics since the start of model performance tracking. The functions update metrics every time you call the functions and base the calculation on the entire supplied data set.
  - `Window` — The functions compute metrics based on all observations within a window determined by the `'MetricsWindowSize'` name-value pair argument. `'MetricsWindowSize'` also determines the frequency at which the software updates `Window` metrics. For example, if `MetricsWindowSize` is 20, the functions compute metrics based on the last 20 observations in the supplied data (`X((end − 20 + 1):end,:)` and `Y((end − 20 + 1):end)`).

    Incremental functions that track performance metrics within a window use the following process:

    1. For each specified metric, store a buffer of length `MetricsWindowSize` and a buffer of observation weights.
    2. Populate elements of the metrics buffer with the model performance based on batches of incoming observations, and store corresponding observations weights in the weights buffer.
    3. When the buffer is filled, overwrite `IncrementalMdl.Metrics.Window` with the weighted average performance in the metrics window. If the buffer is overfilled when the function processes a batch of observations, the latest incoming `MetricsWindowSize` observations enter the buffer, and the earliest observations are removed from the buffer. For example, suppose `MetricsWindowSize` is 20, the metrics buffer has 10 values from a previously processed batch, and 15 values are incoming. To compose the length 20 window, the functions use the measurements from the 15 incoming observations and the latest 5 measurements from the previous batch.

Introduced in R2020b

incrementalLearner

Convert support vector machine (SVM) regression model to incremental learner

Syntax

```
IncrementalMdl = incrementalLearner(Mdl)
IncrementalMdl = incrementalLearner(Mdl,Name,Value)
```

Description

`IncrementalMdl = incrementalLearner(Mdl)` returns a linear regression model for incremental learning on page 33-2992, `IncrementalMdl`, using the hyperparameters and coefficients of the traditionally trained linear SVM model for regression, `Mdl`. Because its property values reflect the knowledge gained from `Mdl`, `IncrementalMdl` can predict labels given new observations, and it is warm, meaning that its predictive performance is tracked.

`IncrementalMdl = incrementalLearner(Mdl,Name,Value)` uses additional options specified by one or more name-value pair arguments. Some options require you to train `IncrementalMdl` before its predictive performance is tracked. For example, `'MetricsWarmupPeriod',50,'MetricsWindowSize',100` specifies a preliminary incremental training period of 50 observations before performance metrics are tracked, and specifies processing 100 observations before updating the performance metrics.

Examples

Convert Traditionally Trained Model to Incremental Learner

Train an SVM regression model by using `fitrsvm`, and then convert it to an incremental learner.

Load and Preprocess Data

Load the 2015 NYC housing data set. For more details on the data, see NYC Open Data.

```
load NYCHousing2015
```

Extract the response variable `SALEPRICE` from the table. For numerical stability, scale `SALEPRICE` by `1e6`.

```
Y = NYCHousing2015.SALEPRICE/1e6;
NYCHousing2015.SALEPRICE = [];
```

Create dummy variable matrices from the categorical predictors.

```
catvars = ["BOROUGH" "BUILDINGCLASSCATEGORY" "NEIGHBORHOOD"];
dumvarstbl = varfun(@(x)dummyvar(categorical(x)),NYCHousing2015,...
    'InputVariables',catvars);
dumvarmat = table2array(dumvarstbl);
NYCHousing2015(:,catvars) = [];
```

Treat all other numeric variables in the table as linear predictors of sales price. Concatenate the matrix of dummy variables to the rest of the predictor data.

```
idxnum = varfun(@isnumeric,NYCHousing2015,'OutputFormat','uniform');
X = [dumvarmat NYCHousing2015{:,idxnum}];
```

Train SVM Regression Model

Fit an SVM regression model to 5000 randomly drawn observations from the data set. Discard the support vectors (`Alpha`) from the model so that the software uses linear coefficients (`Beta`) for prediction.

```
N = numel(Y);
n = 5000;
rng(1); % For reproducibility
idx = randsample(N,n);

TTMdl = fitrsvm(X(idx,:),Y(idx));
TTMdl = discardSupportVectors(TTMdl)
```

```
TTMdl =
  RegressionSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
                     Beta: [312x1 double]
                     Bias: 64.5811
         KernelParameters: [1x1 struct]
          NumObservations: 5000
           BoxConstraints: [5000x1 double]
          ConvergenceInfo: [1x1 struct]
          IsSupportVector: [5000x1 logical]
                   Solver: 'SMO'

  Properties, Methods
```

`TTMdl` is a `RegressionSVM` model object representing a traditionally trained SVM regression model.

Convert Trained Model

Convert the traditionally trained SVM regression model to a linear regression model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalRegressionLinear

               IsWarm: 1
              Metrics: [1x2 table]
    ResponseTransform: 'none'
                 Beta: [312x1 double]
                 Bias: 64.5811
              Learner: 'svm'

  Properties, Methods
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object prepared for incremental learning using SVM.

- The `incrementalLearner` function Initializes the incremental learner by passing learned coefficients to it, along with other information `TTMdl` extracted from the training data.
- `IncrementalMdl` is warm (`IsWarm` is `1`), which means that incremental learning functions can start tracking performance metrics.
- The `incrementalLearner` function trains the model using the adaptive scale-invariant solver, whereas `fitrsvm` trained `TTMdl` using the SMO solver.

Predict Responses

An incremental learner created from converting a traditionally trained model can generate predictions without further processing.

Predict sales prices for all observations using both models.

```
ttyfit = predict(TTMdl,X);
ilyfit = predict(IncrementalMdl,X);
compareyfit = norm(ttyfit - ilyfit)
```

```
compareyfit = 0
```

The difference between the fitted values generated by the models is 0.

Specify SGD Solver

The default solver is the adaptive scale-invariant solver. If you specify this solver, you do not need to tune any parameters for training. However, if you specify either the standard SGD or ASGD solver instead, you can also specify an estimation period, during which the incremental fitting functions tune the learning rate.

Load and shuffle the 2015 NYC housing data set. For more details on the data, see NYC Open Data.

```
load NYCHousing2015

rng(1) % For reproducibility
n = size(NYCHousing2015,1);
shuffidx = randsample(n,n);
NYCHousing2015 = NYCHousing2015(shuffidx,:);
```

Extract the response variable `SALEPRICE` from the table. For numerical stability, scale `SALEPRICE` by `1e6`.

```
Y = NYCHousing2015.SALEPRICE/1e6;
NYCHousing2015.SALEPRICE = [];
```

Create dummy variable matrices from the categorical predictors.

```
catvars = ["BOROUGH" "BUILDINGCLASSCATEGORY" "NEIGHBORHOOD"];
dumvarstbl = varfun(@(x)dummyvar(categorical(x)),NYCHousing2015,...
    'InputVariables',catvars);
dumvarmat = table2array(dumvarstbl);
NYCHousing2015(:,catvars) = [];
```

Treat all other numeric variables in the table as linear predictors of sales price. Concatenate the matrix of dummy variables to the rest of the predictor data.

```
idxnum = varfun(@isnumeric,NYCHousing2015,'OutputFormat','uniform');
X = [dumvarmat NYCHousing2015{:,idxnum}];
```

Randomly partition the data into 5% and 95% sets: the first set for training a model traditionally, and the second set for incremental learning.

```
cvp = cvpartition(n,'Holdout',0.95);
idxtt = training(cvp);
idxil = test(cvp);

% 5% set for traditional training
Xtt = X(idxtt,:);
Ytt = Y(idxtt);

% 95% set for incremental learning
Xil = X(idxil,:);
Yil = Y(idxil);
```

Fit an SVM regression model to 5% of the data.

```
TTMdl = fitrsvm(Xtt,Ytt);
```

Convert the traditionally trained SVM regression model to a linear regression model for incremental learning. Specify the standard SGD solver and an estimation period of `2e4` observations (the default is `1000` when a learning rate is required).

```
IncrementalMdl = incrementalLearner(TTMdl,'Solver','sgd','EstimationPeriod',2e4);
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object.

Fit the incremental model to the rest of the data by using the `fit` function. At each iteration:

- Simulate a data stream by processing 10 observations at a time.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the learning rate and β_1 to see how the coefficients and learning rate evolve during training.

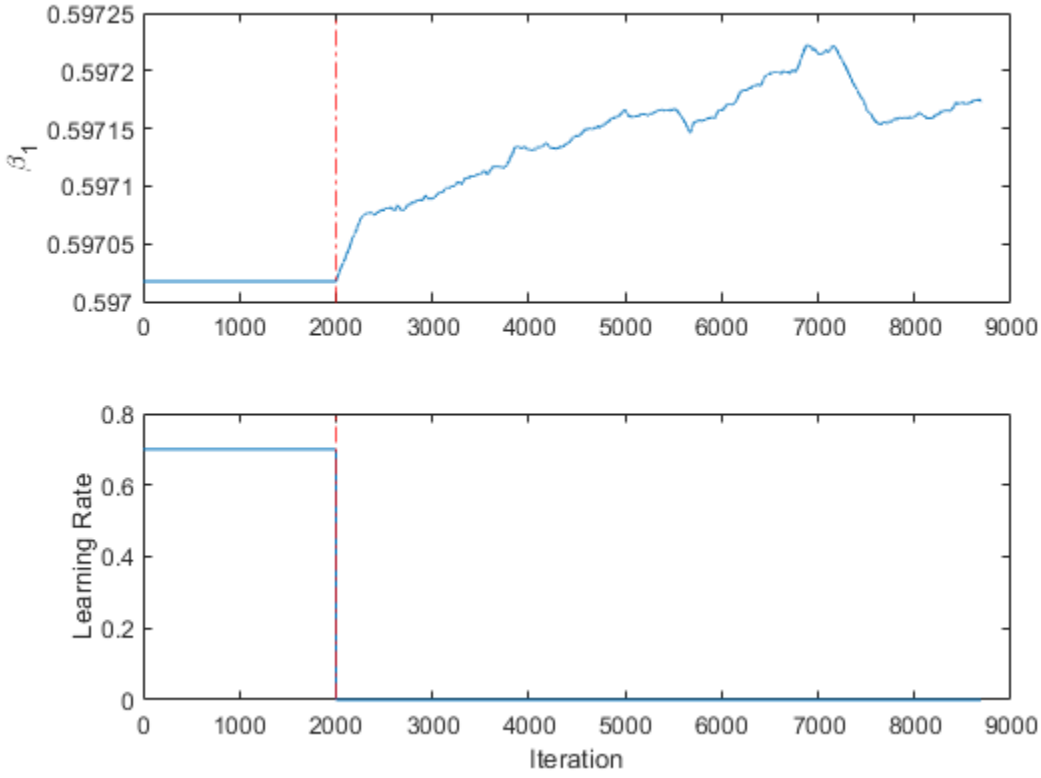
```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 10;
nchunk = floor(nil/numObsPerChunk);
learnrate = [IncrementalMdl.LearnRate; zeros(nchunk,1)];
beta1 = [IncrementalMdl.Beta(1); zeros(nchunk,1)];

% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = fit(IncrementalMdl,Xil(idx,:),Yil(idx));
    beta1(j + 1) = IncrementalMdl.Beta(1);
    learnrate(j + 1) = IncrementalMdl.LearnRate;
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream.

To see how the learning rate and β_1 evolved during training, plot them on separate subplots.

```
subplot(2,1,1)
plot(beta1)
hold on
ylabel('\beta_1')
xline(IncrementalMdl.EstimationPeriod/numObsPerChunk,'r-.');
subplot(2,1,2)
plot(learnrate)
ylabel('Learning Rate')
xline(IncrementalMdl.EstimationPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
```



The learning rate jumps to its auto-tuned value after the estimation period.

Because `fit` does not fit the model to the streaming data during the estimation period, β_1 is constant for the first 2000 iterations (20,000 observations). Then, β_1 changes slightly as `fit` fits the model to each new chunk of 10 observations.

Configure Performance Metric Options

Use a trained SVM regression model to initialize an incremental learner. Prepare the incremental learner by specifying a metrics warm-up period, during which the `updateMetricsAndFit` function only fits the model. Specify a metrics window size of 500 observations.

Load the robot arm data set.

```
load robotarm
```

For details on the data set, enter `Description` at the command line.

Randomly partition the data into 5% and 95% sets: the first set for training a model traditionally, and the second set for incremental learning.

```
n = numel(ytrain);

rng(1) % For reproducibility
cvp = cvpartition(n,'Holdout',0.95);
idxtt = training(cvp);
idxil = test(cvp);

% 5% set for traditional training
Xtt = Xtrain(idxtt,:);
Ytt = ytrain(idxtt);

% 95% set for incremental learning
Xil = Xtrain(idxil,:);
Yil = ytrain(idxil);
```

Fit an SVM regression model to the first set.

```
TTMdl = fitrsvm(Xtt,Ytt);
```

Convert the traditionally trained SVM regression model to a linear regression model for incremental learning. Specify the following:

- A performance metrics warm-up period of 2000 observations.
- A metrics window size of 500 observations.
- Use of epsilon insensitive loss, MSE, and mean absolute error (MAE) to measure the performance of the model. The software supports epsilon insensitive loss and MSE. Create an anonymous function that measures the absolute error of each new observation. Create a structure array containing the name `MeanAbsoluteError` and its corresponding function.

```
maefcn = @(z,zfit)abs(z - zfit);
maemetric = struct("MeanAbsoluteError",maefcn);
IncrementalMdl = incrementalLearner(TTMdl,'MetricsWarmupPeriod',2000,'MetricsWindowSize',500,...
    'Metrics',{'epsiloninsensitive' 'mse' maemetric});
```

Fit the incremental model to the rest of the data by using the `updateMetricsAndfit` function. At each iteration:

- Simulate a data stream by processing 50 observations at a time.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the estimated coefficient β_{10}, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

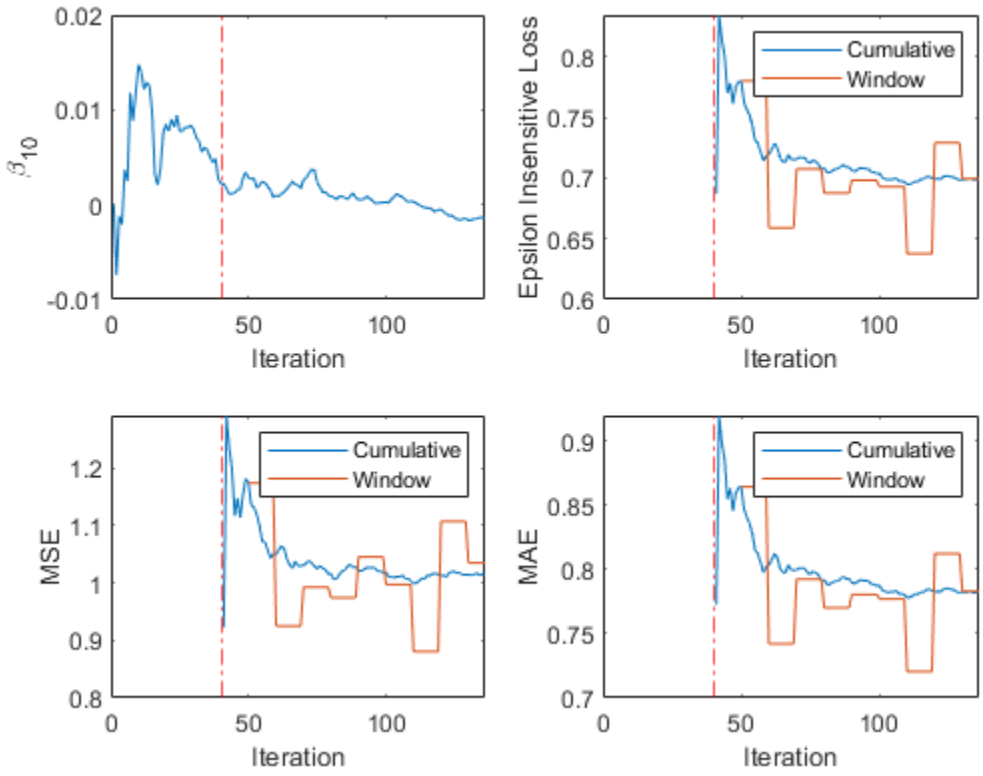
```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 50;
nchunk = floor(nil/numObsPerChunk);
ei = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mse = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mae = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = zeros(nchunk,1);

% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetricsAndFit(IncrementalMdl,Xil(idx,:),Yil(idx));
    ei{j,:} = IncrementalMdl.Metrics{"EpsilonInsensitiveLoss",:};
    mse{j,:} = IncrementalMdl.Metrics{"MeanSquaredError",:};
    mae{j,:} = IncrementalMdl.Metrics{"MeanAbsoluteError",:};
    beta1(j + 1) = IncrementalMdl.Beta(10);
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and β_{10} evolved during training, plot them on separate subplots.

```
figure;
subplot(2,2,1)
plot(beta1)
ylabel('\beta_{10}')
xlim([0 nchunk]);
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
subplot(2,2,2)
h = plot(ei.Variables);
xlim([0 nchunk]);
ylabel('Epsilon Insensitive Loss')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,ei.Properties.VariableNames)
xlabel('Iteration')
subplot(2,2,3)
h = plot(mse.Variables);
xlim([0 nchunk]);
ylabel('MSE')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mse.Properties.VariableNames)
xlabel('Iteration')
subplot(2,2,4)
h = plot(mae.Variables);
xlim([0 nchunk]);
ylabel('MAE')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mae.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit β_{10} during all incremental learning iterations.
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations.

Input Arguments

`Mdl` — Traditionally trained linear SVM model for regression

`RegressionSVM` model object | `CompactRegressionSVM` model object

Traditionally trained linear SVM model for regression, specified as a model object returned by its training or processing function.

Model Object	Training or Processing Function
`RegressionSVM`	`fitrsvm`
`CompactRegressionSVM`	`fitrsvm` or `compact`

Note

Incremental learning functions support only numeric input predictor data. If `Mdl` was fit to categorical data, use `dummyvar` to convert each categorical variable to a numeric matrix of dummy variables, and concatenate all dummy variable matrices and any other numeric predictors. For more details, see “Dummy Variables” on page 2-48.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Solver','scale-invariant','MetricsWindowSize',100` specifies the adaptive scale-invariant solver for objective optimization, and specifies processing 100 observations before updating the performance metrics.

General Options

`Solver` — Objective function minimization technique
`'scale-invariant'` (default) | `'sgd'` | `'asgd'`

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a value in this table.

Value	Description	Notes
`'scale-invariant'`	Adaptive scale-invariant solver for incremental learning on page 33-2992 [1]	• This algorithm is parameter free and can adapt to differences in predictor scales. Try this algorithm before using SGD or ASGD. • To shuffle incoming batches before the `fit` function fits the model, set `Shuffle` to `true`.
`'sgd'`	Stochastic gradient descent (SGD) [3][2]	• To train effectively with SGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Options” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.
`'asgd'`	Average stochastic gradient descent (ASGD) [4]	• To train effectively with ASGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Options” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.

Example: `'Solver','sgd'`

Data Types: `char` | `string`

`EstimationPeriod` — Number of observations processed to estimate hyperparameters
nonnegative integer

Number of observations processed by the incremental model to estimate hyperparameters before training or tracking performance metrics, specified as the comma-separated pair consisting of `'EstimationPeriod'` and a nonnegative integer.

Note

- If `Mdl` is prepared for incremental learning (all hyperparameters required for training are specified), `incrementalLearner` forces `'EstimationPeriod'` to `0`.
- If `Mdl` is not prepared for incremental learning, `incrementalLearner` sets `'EstimationPeriod'` to `1000`.

For more details, see “Estimation Period” on page 33-2993.

Example: `'EstimationPeriod',100`

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictor data

`'auto'` (default) | `false` | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and a value in this table.

Value	Description
`'auto'`	`incrementalLearner` determines whether the predictor variables need to be standardized. See “Standardize Data” on page 33-2993.
`true`	The software standardizes the predictor data.
`false`	The software does not standardize the predictor data.

Under some conditions, `incrementalLearner` can override your specification. For more details, see “Standardize Data” on page 33-2993.

Example: `'Standardize',true`

Data Types: `logical` | `char` | `string`

SGD and ASGD Solver Options

`BatchSize` — Mini-batch size

`10` (default) | positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration during training, `incrementalLearner` uses `min(BatchSize,numObs)` observations to compute the subgradient, where `numObs` is the number of observations in the training data passed to `fit` or `updateMetricsAndFit`.

Example: `'BatchSize',1`

Data Types: `single` | `double`

`Lambda` — Ridge (L^2) regularization term strength

`1e-5` (default) | nonnegative scalar

Ridge (L^2) regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

Example: `'Lambda',0.01`

Data Types: `single` | `double`

`LearnRate` — Learning rate
`'auto'` (default) | positive scalar

Learning rate, specified as the comma-separated pair consisting of `'LearnRate'` and `'auto'` or a positive scalar. `LearnRate` controls the optimization step size by scaling the objective subgradient.

For `'auto'`:

- If `EstimationPeriod` is `0`, the initial learning rate is `0.7`.
- If `EstimationPeriod` > `0`, the initial learning rate is `1/sqrt(1+max(sum(X.^2,obsDim)))`, where `obsDim` is `1` if the observations compose the columns of the predictor data, and `2` otherwise. `fit` and `updateMetricsAndFit` set the value when you pass the model and training data to either function.

The name-value pair argument `'LearnRateSchedule'` determines the learning rate for subsequent learning cycles.

Example: `'LearnRate',0.001`

Data Types: `single` | `double` | `char` | `string`

`LearnRateSchedule` — Learning rate schedule
`'decaying'` (default) | `'constant'`

Learning rate schedule, specified as the comma-separated pair consisting of `'LearnRateSchedule'` and a value in this table, where `LearnRate` specifies the initial learning rate γ_0.

Value	Description
`'constant'`	The learning rate is γ_0 for all learning cycles.
`'decaying'`	The learning rate at learning cycle t is $$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$ • λ is the value of `Lambda`. • If `Solver` is `'sgd'`, then $c = 1$. • If `Solver` is `'asgd'`, then c is 0.75 [4].

Example: `'LearnRateSchedule','constant'`

Data Types: `char` | `string`

Adaptive Scale-Invariant Solver Options

`Shuffle` — Flag for shuffling observations in batch
`true` (default) | `false`

Flag for shuffling the observations in the batch at each iteration, specified as the comma-separated pair consisting of `'Shuffle'` and a value in this table.

Value	Description
`true`	The software shuffles observations in each incoming batch of data before processing the set. This action reduces bias induced by the sampling scheme.
`false`	The software processes the data in the order received.

Example: `'Shuffle',false`

Data Types: `logical`

Performance Metrics Options

`Metrics` — Model performance metrics to track during incremental learning
`"epsiloninsensitive"` (default) | string vector | function handle | cell vector | structure array | `"mse"` | ...

Model performance metrics to track during incremental learning with `updateMetrics` and `updateMetricsAndFit`, specified as the comma-separated pair consisting of `'Metrics'` and a built-in loss function name, string vector of names, function handle (`@metricName`), structure array of function handles, or cell vector of names, function handles, or structure arrays.

The following table lists the built-in loss function names. You can specify more than one by using a string vector.

Name	Description
`"epsiloninsensitive"`	Epsilon insensitive loss
`"mse"`	Weighted mean squared error

For more details on the built-in loss functions, see `loss`.

Example: `'Metrics',["epsiloninsensitive" "mse"]`

To specify a custom function that returns a performance metric, use function handle notation. The function must have this form:

```
metric = customMetric(Y,YFit)
```

- The output argument `metric` is an *n*-by-1 numeric vector, where each element is the loss of the corresponding observation in the data processed by the incremental learning functions during a learning cycle.
- You select the function name (`customMetric`).
- `Y` is a length *n* numeric vector of observed responses, where *n* is the sample size.
- `YFit` is a length *n* numeric vector of corresponding predicted responses.

To specify multiple custom metrics and assign a custom name to each, use a structure array. To specify a combination of built-in and custom metrics, use a cell vector.

Example: `'Metrics',struct('Metric1',@customMetric1,'Metric2',@customMetric2)`

Example: `'Metrics',{@customMetric1 @customeMetric2 'mse' struct('Metric3',@customMetric3)}`

`updateMetrics` and `updateMetricsAndFit` store specified metrics in a table in the property `IncrementalMdl.Metrics`. The data type of `Metrics` determines the row names of the table.

`'Metrics'` Value Data Type	Description of `Metrics` Property Row Name	Example
String or character vector	Name of corresponding built-in metric	Row name for `"epsiloninsensitive"` is `"EpsilonInsensitiveLoss"`
Structure array	Field name	Row name for `struct('Metric1',@customMetric1)` is `"Metric1"`
Function handle to function stored in a program file	Name of function	Row name for `@customMetric` is `"customMetric"`
Anonymous function	`CustomMetric_`*j*, where *j* is metric *j* in `Metrics`	Row name for `@(Y,YFit)customMetric(Y,YFit)...` is `CustomMetric_1`

For more details on performance metrics options, see “Performance Metrics” on page 33-2994.

Data Types: `char` | `string` | `struct` | `cell` | `function_handle`

`MetricsWarmupPeriod` — Number of observations fit before tracking performance metrics
`0` (default) | nonnegative integer | ...

Number of observations the incremental model must be fit to before it tracks performance metrics in its `Metrics` property, specified as the comma-separated pair consisting of `'MetricsWarmupPeriod'` and a nonnegative integer. The incremental model is warm after incremental fitting functions fit `MetricsWarmupPeriod` observations to the incremental model (`EstimationPeriod` + `MetricsWarmupPeriod` observations).

For more details on performance metrics options, see “Performance Metrics” on page 33-2994.

Data Types: `single` | `double`

`MetricsWindowSize` — Number of observations to use to compute window performance metrics
`200` (default) | positive integer | ...

Number of observations to use to compute window performance metrics, specified as a positive integer.

For more details on performance metrics options, see “Performance Metrics” on page 33-2994.

Data Types: `single` | `double`

Output Arguments

`IncrementalMdl` — Linear regression model for incremental learning
`incrementalRegressionLinear` model object

Linear regression model for incremental learning, returned as an `incrementalRegressionLinear` model object. `IncrementalMdl` is also configured to generate predictions given new data (see `predict`).

To initialize `IncrementalMdl` for incremental learning, `incrementalLearner` passes the values of the `Mdl` properties in this table to congruent properties of `IncrementalMdl`.

Property	Description
`Beta`	Linear model coefficients, a numeric vector
`Bias`	Model intercept, a numeric scalar
`Epsilon`	Half the width of the epsilon insensitive band, a nonnegative scalar
`Mu`	Predictor variable means, a numeric vector
`Sigma`	Predictor variable standard deviations, a numeric vector

More About

Incremental Learning

Incremental learning, or online learning, is a branch of machine learning concerned with processing incoming data from a data stream, possibly given little to no knowledge of the distribution of the predictor variables, aspects of the prediction or objective function (including tuning parameter values), or whether the observations are labeled. Incremental learning differs from traditional machine learning, where enough labeled data is available to fit to a model, perform cross-validation to tune hyperparameters, and infer the predictor distribution.

Given incoming observations, an incremental learning model processes data in any of the following ways, but usually in this order:

- Predict labels.
- Measure the predictive performance.
- Check for structural breaks or drift in the model.
- Fit the model to the incoming observations.

Adaptive Scale-Invariant Solver for Incremental Learning

The adaptive scale-invariant solver for incremental learning, introduced in [1], is a gradient-descent-based objective solver for training linear predictive models. The solver is hyperparameter free, insensitive to differences in predictor variable scales, and does not require prior knowledge of the distribution of the predictor variables. These characteristics make it well suited to incremental learning.

The standard SGD and ASGD solvers are sensitive to differing scales among the predictor variables, resulting in models that can perform poorly. To achieve better accuracy using SGD and ASGD, you can standardize the predictor data, and tune the regularization and learning rate parameters can require tuning. For traditional machine learning, enough data is available to enable hyperparameter tuning by cross-validation and predictor standardization. However, for incremental learning, enough data might not be available (for example, observations might be available only one at a time) and the distribution of the predictors might be unknown. These characteristics make parameter tuning and predictor standardization difficult or impossible to do during incremental learning.

The incremental fitting functions for regression `fit` and `updateMetricsAndFit` use the more conservative ScInOL1 version of the algorithm.

Algorithms

Estimation Period

During the estimation period, incremental fitting functions `fit` and `updateMetricsAndFit` use the first incoming `EstimationPeriod` observations to estimate (tune) hyperparameters required for incremental training. This table describes the hyperparameters and when they are estimated or tuned.

Hyperparameter	Model Property	Use	Hyperparameters Estimated
Predictor means and standard deviations	`Mu` and `Sigma`	Standardize predictor data	When both these conditions apply: • When you set `'Standardize',true` (see "Standardize Data" on page 33-2993) • `IncrementalMdl.Mu` and `IncrementalMdl.Sigma` are empty arrays `[]`.
Learning rate	`LearnRate`	Adjust solver step size	When both of these conditions apply: • You change the solver of `Mdl` to SGD or ASGD (see `Solver`). • You do not set the `'LearnRate'` name-value pair argument.

The functions fit only the last estimation period observation to the incremental model, and they do not use any of the observations to track the performance of the model. At the end of the estimation period, the functions update the properties that store the hyperparameters.

Standardize Data

If incremental learning functions are configured to standardize predictor variables, they do so using the means and standard deviations stored in the `Mu` and `Sigma` properties of the incremental learning model `IncrementalMdl`.

- If you standardized the predictor data when you trained the input model `Mdl` by using `fitrsvm`, the following conditions apply:
  - `incrementalLearner` passes the means in `Mdl.Mu` and standard deviations in `Mdl.Sigma` to the congruent incremental learning model properties.
  - Incremental learning functions always standardize the predictor data, regardless of the value of the `'Standardize'` name-value pair argument.
- When you set `'Standardize',true`, and `IncrementalMdl.Mu` and `IncrementalMdl.Sigma` are empty, the following conditions apply:
  - If the estimation period is positive (see the `EstimationPeriod` property of `IncrementalMdl`), incremental fitting functions estimate means and standard deviations using the estimation period observations.

- If the estimation period is 0, `incrementalLearner` forces the estimation period to `1000`. Consequently, incremental fitting functions estimate new predictor variable means and standard deviations during the forced estimation period.

- If you set `'Standardize','auto'` (the default), the following conditions apply.
  - If `IncrementalMdl.Mu` and `IncrementalMdl.Sigma` are empty, incremental learning functions do not standardize predictor variables.
  - Otherwise, incremental learning functions standardize the predictor variables using their means and standard deviations in `IncrementalMdl.Mu` and `IncrementalMdl.Sigma`, respectively. Incremental fitting functions do not estimate new means and standard deviations regardless of the length of the estimation period.
- When incremental fitting functions estimate predictor means and standard deviations, the functions compute weighted means and weighted standard deviations using the estimation period observations. Specifically, the functions standardize predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

  - x_j is predictor j, and x_{jk} is observation k of predictor j in the estimation period.
  - $\mu_j^* = \frac{1}{\sum_k w_k}\sum_k w_k x_{jk}$.
  - $\left(\sigma_j^*\right)^2 = \frac{1}{\sum_k w_k}\sum_k w_k\left(x_{jk} - \mu_j^*\right)^2$.
  - w_j is observation weight j.

Performance Metrics

- The `updateMetrics` and `updateMetricsAndFit` functions are incremental learning functions that track model performance metrics (`'Metrics'`) from new data when the incremental model is warm (`IsWarm` property). An incremental model is warm after `fit` or `updateMetricsAndFit` fit the incremental model to `'MetricsWarmupPeriod'` observations, which is the metrics warm-up period.

  If `'EstimationPeriod'` > 0, the functions estimate hyperparameters before fitting the model to data. Therefore, the functions must process an additional `EstimationPeriod` observations before the model starts the metrics warm-up period.
- The `Metrics` property of the incremental model stores two forms of each performance metric as variables (columns) of a table, `Cumulative` and `Window`, with individual metrics in rows. When the incremental model is warm, `updateMetrics` and `updateMetricsAndFit` update the metrics at the following frequencies:
  - `Cumulative` — The functions compute cumulative metrics since the start of model performance tracking. The functions update metrics every time you call the functions and base the calculation on the entire supplied data set.
  - `Window` — The functions compute metrics based on all observations within a window determined by the `'MetricsWindowSize'` name-value pair argument. `'MetricsWindowSize'` also determines the frequency at which the software updates `Window` metrics. For example, if `MetricsWindowSize` is 20, the functions compute metrics based on

the last 20 observations in the supplied data (`X((end – 20 + 1):end,:)` and `Y((end – 20 + 1):end)`).

Incremental functions that track performance metrics within a window use the following process:

1. For each specified metric, store a buffer of length `MetricsWindowSize` and a buffer of observation weights.
2. Populate elements of the metrics buffer with the model performance based on batches of incoming observations, and store corresponding observations weights in the weights buffer.
3. When the buffer is filled, overwrite `IncrementalMdl.Metrics.Window` with the weighted average performance in the metrics window. If the buffer is overfilled when the function processes a batch of observations, the latest incoming `MetricsWindowSize` observations enter the buffer, and the earliest observations are removed from the buffer. For example, suppose `MetricsWindowSize` is 20, the metrics buffer has 10 values from a previously processed batch, and 15 values are incoming. To compose the length 20 window, the functions use the measurements from the 15 incoming observations and the latest 5 measurements from the previous batch.

Introduced in R2020b

incrementalLearner

Convert linear regression model to incremental learner

Syntax

```
IncrementalMdl = incrementalLearner(Mdl)
IncrementalMdl = incrementalLearner(Mdl,Name,Value)
```

Description

`IncrementalMdl = incrementalLearner(Mdl)` returns a linear regression model for incremental learning on page 33-3009, `IncrementalMdl`, using the hyperparameters and coefficients of the traditionally trained linear regression model `Mdl`. Because its property values reflect the knowledge gained from `Mdl`, `IncrementalMdl` can predict labels given new observations, and it is warm, meaning that its predictive performance is tracked.

`IncrementalMdl = incrementalLearner(Mdl,Name,Value)` uses additional options specified by one or more name-value pair arguments. Some options require you to train `IncrementalMdl` before its predictive performance is tracked. For example, `'MetricsWarmupPeriod',50,'MetricsWindowSize',100` specifies a preliminary incremental training period of 50 observations before performance metrics are tracked, and specifies processing 100 observations before updating the performance metrics.

Examples

Convert Traditionally Trained Model to Incremental Learner

Train a linear regression model by using `fitrlinear`, and then convert it to an incremental learner.

Load and Preprocess Data

Load the 2015 NYC housing data set. For more details on the data, see NYC Open Data.

```
load NYCHousing2015
```

Extract the response variable `SALEPRICE` from the table. For numerical stability, scale `SALEPRICE` by `1e6`.

```
Y = NYCHousing2015.SALEPRICE/1e6;
NYCHousing2015.SALEPRICE = [];
```

Create dummy variable matrices from the categorical predictors.

```
catvars = ["BOROUGH" "BUILDINGCLASSCATEGORY" "NEIGHBORHOOD"];
dumvarstbl = varfun(@(x)dummyvar(categorical(x)),NYCHousing2015,...
    'InputVariables',catvars);
dumvarmat = table2array(dumvarstbl);
NYCHousing2015(:,catvars) = [];
```

Treat all other numeric variables in the table as linear predictors of sales price. Concatenate the matrix of dummy variables to the rest of the predictor data.

```
idxnum = varfun(@isnumeric,NYCHousing2015,'OutputFormat','uniform');
X = [dumvarmat NYCHousing2015{:,idxnum}];
```

Train Linear Regression Model

Fit an linear regression model to the entire data set.

```
TTMdl = fitrlinear(X,Y)
```

```
TTMdl =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [312x1 double]
                 Bias: 0.0956
               Lambda: 1.0935e-05
              Learner: 'svm'

  Properties, Methods
```

`TTMdl` is a `RegressionLinear` model object representing a traditionally trained linear regression model.

Convert Trained Model

Convert the traditionally trained linear regression model to a linear regression model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalRegressionLinear

               IsWarm: 1
              Metrics: [1x2 table]
    ResponseTransform: 'none'
                 Beta: [312x1 double]
                 Bias: 0.0956
              Learner: 'svm'

  Properties, Methods
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object prepared for incremental learning using SVM.

- The `incrementalLearner` function Initializes the incremental learner by passing learned coefficients to it, along with other information `TTMdl` extracted from the training data.
- `IncrementalMdl` is warm (`IsWarm` is `1`), which means that incremental learning functions can start tracking performance metrics.
- The `incrementalLearner` function trains the model using the adaptive scale-invariant solver, whereas `fitrlinear` trained `TTMdl` using the dual SGD solver.

Predict Responses

An incremental learner created from converting a traditionally trained model can generate predictions without further processing.

Predict sales prices for all observations using both models.

```
ttyfit = predict(TTMdl,X);
ilyfit = predict(IncrementalMdl,X);
compareyfit = norm(ttyfit - ilyfit)
```

```
compareyfit = 0
```

The difference between the fitted values generated by the models is 0.

Specify SGD Solver

The default solver is the adaptive scale-invariant solver. If you specify this solver, you do not need to tune any parameters for training. However, if you specify either the standard SGD or ASGD solver instead, you can also specify an estimation period, during which the incremental fitting functions tune the learning rate.

Load and shuffle the 2015 NYC housing data set. For more details on the data, see NYC Open Data.

```
load NYCHousing2015

rng(1) % For reproducibility
n = size(NYCHousing2015,1);
shuffidx = randsample(n,n);
NYCHousing2015 = NYCHousing2015(shuffidx,:);
```

Extract the response variable `SALEPRICE` from the table. For numerical stability, scale `SALEPRICE` by `1e6`.

```
Y = NYCHousing2015.SALEPRICE/1e6;
NYCHousing2015.SALEPRICE = [];
```

Create dummy variable matrices from the categorical predictors.

```
catvars = ["BOROUGH" "BUILDINGCLASSCATEGORY" "NEIGHBORHOOD"];
dumvarstbl = varfun(@(x)dummyvar(categorical(x)),NYCHousing2015,...
    'InputVariables',catvars);
dumvarmat = table2array(dumvarstbl);
NYCHousing2015(:,catvars) = [];
```

Treat all other numeric variables in the table as linear predictors of sales price. Concatenate the matrix of dummy variables to the rest of the predictor data.

```
idxnum = varfun(@isnumeric,NYCHousing2015,'OutputFormat','uniform');
X = [dumvarmat NYCHousing2015{:,idxnum}];
```

Randomly partition the data into 5% and 95% sets: the first set for training a model traditionally, and the second set for incremental learning.

```
cvp = cvpartition(n,'Holdout',0.95);
idxtt = training(cvp);
```

```
idxil = test(cvp);

% 5% set for traditional training
Xtt = X(idxtt,:);
Ytt = Y(idxtt);

% 95% set for incremental learning
Xil = X(idxil,:);
Yil = Y(idxil);
```

Fit a linear regression model to 5% of the data.

```
TTMdl = fitrlinear(Xtt,Ytt);
```

Convert the traditionally trained linear regression model to a linear regression model for incremental learning. Specify the standard SGD solver and an estimation period of `2e4` observations (the default is `1000` when a learning rate is required).

```
IncrementalMdl = incrementalLearner(TTMdl,'Solver','sgd','EstimationPeriod',2e4);
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object.

Fit the incremental model to the rest of the data by using the `fit` function. At each iteration:

- Simulate a data stream by processing 10 observations at a time.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the learning rate and β_1 to see how the coefficients and learning rate evolve during training.

```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 10;
nchunk = floor(nil/numObsPerChunk);
learnrate = [IncrementalMdl.LearnRate; zeros(nchunk,1)];
beta1 = [IncrementalMdl.Beta(1); zeros(nchunk,1)];

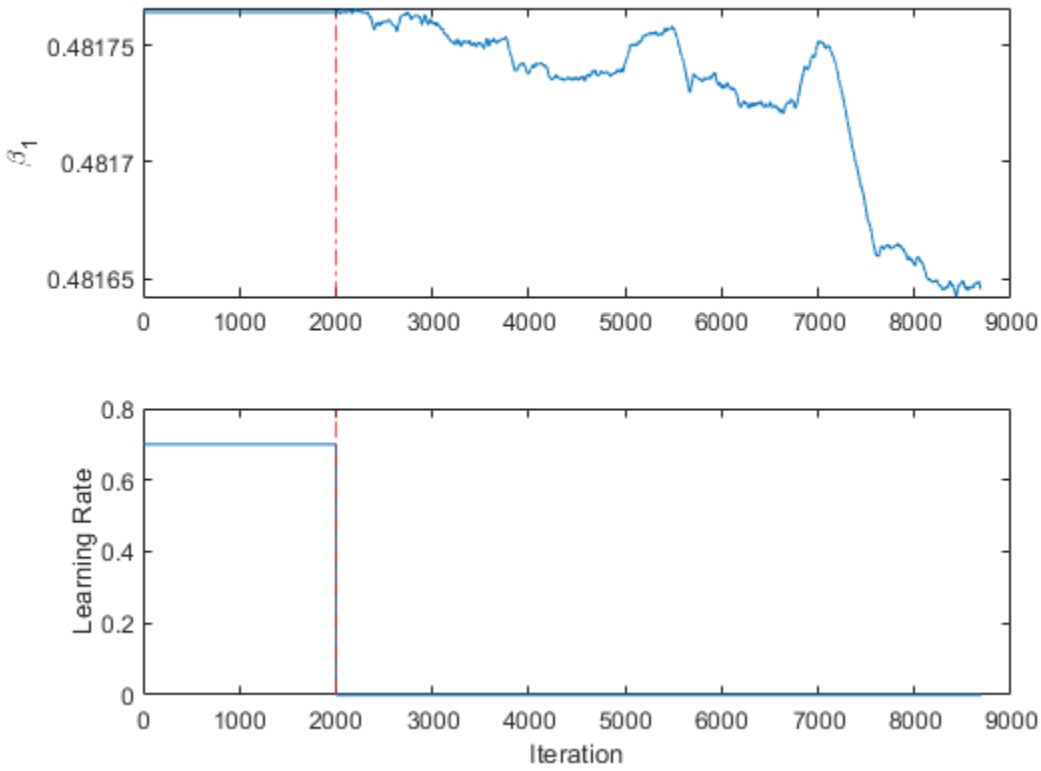
% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = fit(IncrementalMdl,Xil(idx,:),Yil(idx));
    beta1(j + 1) = IncrementalMdl.Beta(1);
    learnrate(j + 1) = IncrementalMdl.LearnRate;
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream.

To see how the learning rate and β_1 evolved during training, plot them on separate subplots.

```
subplot(2,1,1)
plot(beta1)
hold on
ylabel('\beta_1')
xline(IncrementalMdl.EstimationPeriod/numObsPerChunk,'r-.');
subplot(2,1,2)
plot(learnrate)
```

```
ylabel('Learning Rate')
xline(IncrementalMdl.EstimationPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
```



The learning rate jumps to its auto-tuned value after the estimation period.

Because `fit` does not fit the model to the streaming data during the estimation period, β_1 is constant for the first 2000 iterations (20,000 observations). Then, β_1 changes slightly as `fit` fits the model to each new chunk of 10 observations.

Configure Performance Metric Options

Use a trained linear regression model to initialize an incremental learner. Prepare the incremental learner by specifying a metrics warm-up period, during which the `updateMetricsAndFit` function only fits the model. Specify a metrics window size of 500 observations.

Load the robot arm data set.

```
load robotarm
```

For details on the data set, enter `Description` at the command line.

Randomly partition the data into 5% and 95% sets: the first set for training a model traditionally, and the second set for incremental learning.

```
n = numel(ytrain);

rng(1) % For reproducibility
cvp = cvpartition(n,'Holdout',0.95);
idxtt = training(cvp);
idxil = test(cvp);

% 5% set for traditional training
Xtt = Xtrain(idxtt,:);
Ytt = ytrain(idxtt);

% 95% set for incremental learning
Xil = Xtrain(idxil,:);
Yil = ytrain(idxil);
```

Fit a linear regression model to the first set.

```
TTMdl = fitrlinear(Xtt,Ytt);
```

Convert the traditionally trained linear regression model to a linear regression model for incremental learning. Specify all of the following:

- A performance metrics warm-up period of 2000 observations.
- A metrics window size of 500 observations.
- Use of epsilon insensitive loss, MSE, and mean absolute error (MAE) to measure the performance of the model. The software supports epsilon insensitive loss and MSE. Create an anonymous function that measures the absolute error of each new observation. Create a structure array containing the name `MeanAbsoluteError` and its corresponding function.

```
maefcn = @(z,zfit)abs(z - zfit);
maemetric = struct("MeanAbsoluteError",maefcn);
IncrementalMdl = incrementalLearner(TTMdl,'MetricsWarmupPeriod',2000,'MetricsWindowSize',500,...
    'Metrics',{'epsiloninsensitive' 'mse' maemetric});
```

Fit the incremental model to the rest of the data by using the `updateMetricsAndFit` function. At each iteration:

- Simulate a data stream by processing 50 observations at a time.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store β_1, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

```
% Preallocation
nil = numel(Yil);
numObsPerChunk = 50;
nchunk = floor(nil/numObsPerChunk);
ei = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mse = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mae = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = zeros(nchunk,1);

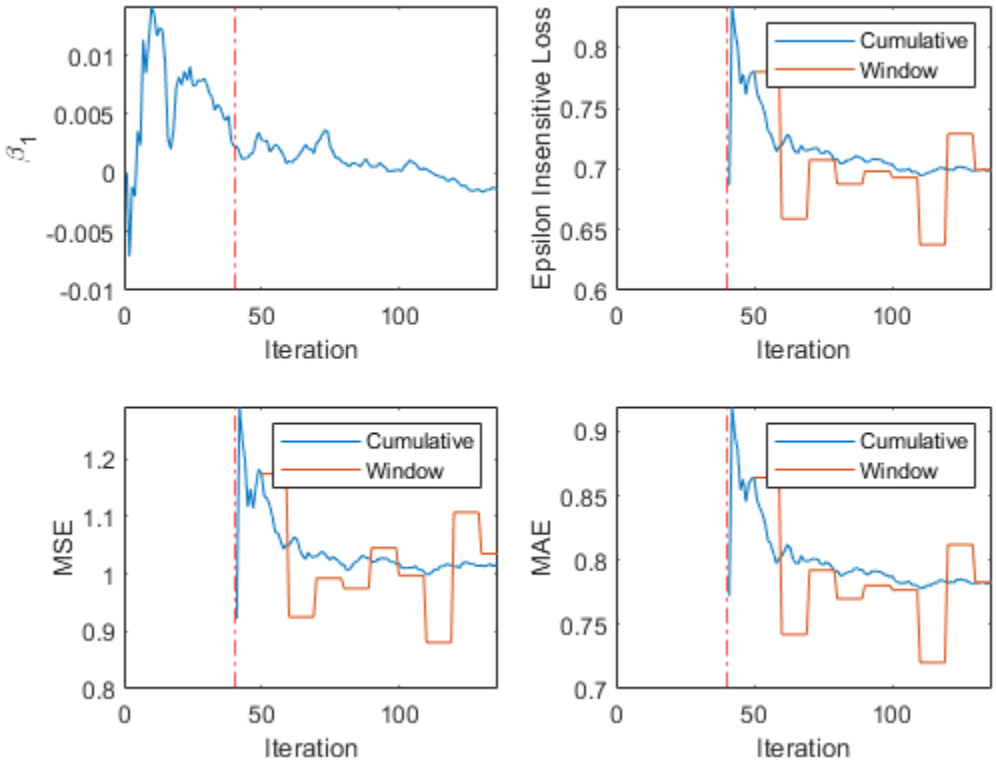
% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
```

```
    IncrementalMdl = updateMetricsAndFit(IncrementalMdl,Xil(idx,:),Yil(idx));
    ei{j,:} = IncrementalMdl.Metrics{"EpsilonInsensitiveLoss",:};
    mse{j,:} = IncrementalMdl.Metrics{"MeanSquaredError",:};
    mae{j,:} = IncrementalMdl.Metrics{"MeanAbsoluteError",:};
    beta1(j + 1) = IncrementalMdl.Beta(10);
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and β_1 evolved during training, plot them on separate subplots.

```
figure;
subplot(2,2,1)
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
subplot(2,2,2)
h = plot(ei.Variables);
xlim([0 nchunk]);
ylabel('Epsilon Insensitive Loss')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,ei.Properties.VariableNames)
xlabel('Iteration')
subplot(2,2,3)
h = plot(mse.Variables);
xlim([0 nchunk]);
ylabel('MSE')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mse.Properties.VariableNames)
xlabel('Iteration')
subplot(2,2,4)
h = plot(mae.Variables);
xlim([0 nchunk]);
ylabel('MAE')
xline(IncrementalMdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mae.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit β_1 during all incremental learning iterations.
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations.

Input Arguments

`Mdl` — Traditionally trained linear regression model

`RegressionLinear` model object

Traditionally trained linear regression model, specified as a `RegressionLinear` model object returned by `fitrlinear`.

Note

- If `Mdl.Lambda` is a numeric vector, you must select the model corresponding to one regularization strength in the regularization path by using `selectModels`.
- Incremental learning functions support only numeric input predictor data. If `Mdl` was fit to categorical data, use `dummyvar` to convert each categorical variable to a numeric matrix of

dummy variables, and concatenate all dummy variable matrices and any other numeric predictors. For more details, see “Dummy Variables” on page 2-48.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Solver','scale-invariant','MetricsWindowSize',100` specifies the adaptive scale-invariant solver for objective optimization, and specifies processing 100 observations before updating the performance metrics.

General Options

`Solver` — Objective function minimization technique
`'scale-invariant'` (default) | `'sgd'` | `'asgd'`

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a value in this table.

Value	Description	Notes
`'scale-invariant'`	Adaptive scale-invariant solver for incremental learning on page 33-3010 [1]	• This algorithm is parameter free and can adapt to differences in predictor scales. Try this algorithm before using SGD or ASGD. • To shuffle incoming batches before the `fit` function fits the model, set `Shuffle` to `true`.
`'sgd'`	Stochastic gradient descent (SGD) [3][2]	• To train effectively with SGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Options” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.
`'asgd'`	Average stochastic gradient descent (ASGD) [4]	• To train effectively with ASGD, standardize the data and specify adequate values for hyperparameters using options listed in “SGD and ASGD Solver Options” on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.

Example: `'Solver','sgd'`

Data Types: `char` | `string`

`EstimationPeriod` — Number of observations processed to estimate hyperparameters
nonnegative integer

Number of observations processed by the incremental model to estimate hyperparameters before training or tracking performance metrics, specified as the comma-separated pair consisting of `'EstimationPeriod'` and a nonnegative integer.

Note

- If `Mdl` is prepared for incremental learning (all hyperparameters required for training are specified), `incrementalLearner` forces `'EstimationPeriod'` to `0`.
- If `Mdl` is not prepared for incremental learning, `incrementalLearner` sets `'EstimationPeriod'` to `1000`.

For more details, see “Estimation Period” on page 33-3010.

Example: `'EstimationPeriod',100`

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictor data

`false` (default) | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and a value in this table.

Value	Description
`true`	The software standardizes the predictor data. For more details, see “Standardize Data” on page 33-3011.
`false`	The software does not standardize the predictor data.

Example: `'Standardize',true`

Data Types: `logical`

SGD and ASGD Solver Options

`BatchSize` — Mini-batch size

positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration during training, `incrementalLearner` uses `min(BatchSize,numObs)` observations to compute the subgradient, where `numObs` is the number of observations in the training data passed to `fit` or `updateMetricsAndFit`.

- If `Mdl.ModelParameters.Solver` is `'sgd'` or `'asgd'`, you cannot set `'BatchSize'`. Instead, `incrementalLearner` sets `'BatchSize'` to `Mdl.ModelParameters.BatchSize`.
- Otherwise, `BatchSize` is `10`.

Example: `'BatchSize',1`

Data Types: `single` | `double`

`Lambda` — Ridge (*L*2) regularization term strength

nonnegative scalar

Ridge (*L*2) regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

When `Mdl.Regularization` is `'ridge (L2)'`:

- If `Mdl.ModelParameters.Solver` is `'sgd'` or `'asgd'`, you cannot set `'Lambda'`. Instead, `incrementalLearner` sets `'Lambda'` to `Mdl.Lambda`.
- Otherwise, `Lambda` is `1e-5`.

Note `incrementalLearner` does not support lasso regularization. If `Mdl.Regularization` is `'lasso (L1)'`, `incrementalLearner` uses ridge regularization instead, and sets the `'Solver'` name-value pair argument to `'scale-invariant'` by default.

Example: `'Lambda',0.01`

Data Types: `single` | `double`

`LearnRate` — Learning rate
`'auto'` | positive scalar

Learning rate, specified as the comma-separated pair consisting of `'LearnRate'` and `'auto'` or a positive scalar. `LearnRate` controls the optimization step size by scaling the objective subgradient.

- If `Mdl.ModelParameters.Solver` is `'sgd'` or `'asgd'`, you cannot set `'LearnRate'`. Instead, `incrementalLearner` sets `'LearnRate'` to `Mdl.ModelParameters.LearnRate`.
- Otherwise, `LearnRate` is `'auto'`.

For `'auto'`:

- If `EstimationPeriod` is `0`, the initial learning rate is `0.7`.
- If `EstimationPeriod` > `0`, the initial learning rate is `1/sqrt(1+max(sum(X.^2,obsDim)))`, where `obsDim` is `1` if the observations compose the columns of the predictor data, and `2` otherwise. `fit` and `updateMetricsAndFit` set the value when you pass the model and training data to either function.

The name-value pair argument `'LearnRateSchedule'` determines the learning rate for subsequent learning cycles.

Example: `'LearnRate',0.001`

Data Types: `single` | `double` | `char` | `string`

`LearnRateSchedule` — Learning rate schedule
`'decaying'` (default) | `'constant'`

Learning rate schedule, specified as the comma-separated pair consisting of `'LearnRateSchedule'` and a value in this table, where `LearnRate` specifies the initial learning rate γ_0.

Value	Description
`'constant'`	The learning rate is γ_0 for all learning cycles.

Value	Description
`'decaying'`	The learning rate at learning cycle t is $$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$ • λ is the value of `Lambda`. • If `Solver` is `'sgd'`, then $c = 1$. • If `Solver` is `'asgd'`, then c is 0.75 [4].

If `Mdl.ModelParameters.Solver` is `'sgd'` or `'asgd'`, you cannot set `'LearnRateSchedule'`.

Example: `'LearnRateSchedule','constant'`

Data Types: `char` | `string`

Adaptive Scale-Invariant Solver Options

`Shuffle` — Flag for shuffling observations in batch

`true` (default) | `false`

Flag for shuffling the observations in the batch at each iteration, specified as the comma-separated pair consisting of `'Shuffle'` and a value in this table.

Value	Description
`true`	The software shuffles observations in each incoming batch of data before processing the set. This action reduces bias induced by the sampling scheme.
`false`	The software processes the data in the order received.

Example: `'Shuffle',false`

Data Types: `logical`

Performance Metrics Options

`Metrics` — Model performance metrics to track during incremental learning

`"epsiloninsensitive"` | `"mse"` | string vector | function handle | cell vector | structure array | ...

Model performance metrics to track during incremental learning with `updateMetrics` and `updateMetricsAndFit`, specified as the comma-separated pair consisting of `'Metrics'` and a built-in loss function name, string vector of names, function handle (`@metricName`), structure array of function handles, or cell vector of names, function handles, or structure arrays.

The following table lists the built-in loss function names and which learners, specified in `Mdl.Learner`, support them. You can specify more than one loss function by using a string vector.

Name	Description	Learners Supporting Metric
`"epsiloninsensitive"`	Epsilon insensitive loss	`'svm'`
`"mse"`	Weighted mean squared error	`'svm'` and `'leastsquares'`

For more details on the built-in loss functions, see `loss`.

Example: `'Metrics',["epsiloninsensitive" "mse"]`

To specify a custom function that returns a performance metric, use function handle notation. The function must have this form:

```
metric = customMetric(Y,YFit)
```

- The output argument `metric` is an *n*-by-1 numeric vector, where each element is the loss of the corresponding observation in the data processed by the incremental learning functions during a learning cycle.
- You specify the function name (`customMetric`).
- `Y` is a length *n* numeric vector of observed responses, where *n* is the sample size.
- `YFit` is a length *n* numeric vector of corresponding predicted responses.

To specify multiple custom metrics and assign a custom name to each, use a structure array. To specify a combination of built-in and custom metrics, use a cell vector.

Example: `'Metrics',struct('Metric1',@customMetric1,'Metric2',@customMetric2)`

Example: `'Metrics',{@customMetric1 @customeMetric2 'mse' struct('Metric3',@customMetric3)}`

`updateMetrics` and `updateMetricsAndFit` store specified metrics in a table in the property `IncrementalMdl.Metrics`. The data type of `Metrics` determines the row names of the table.

`'Metrics'` Value Data Type	Description of `Metrics` Property Row Name	Example
String or character vector	Name of corresponding built-in metric	Row name for `"epsiloninsensitive"` is `"EpsilonInsensitiveLoss"`
Structure array	Field name	Row name for `struct('Metric1',@customMetric1)` is `"Metric1"`
Function handle to function stored in a program file	Name of function	Row name for `@customMetric` is `"customMetric"`
Anonymous function	`CustomMetric_`*j*, where *j* is metric *j* in `Metrics`	Row name for `@(Y,YFit)customMetric(Y,YFit)...` is `CustomMetric_1`

By default:

- `Metrics` is `"epsiloninsensitive"` if `Mdl.Learner` is `'svm'`.
- `Metrics` is `"mse"` if `Mdl.Learner` is `'leastsquares'`.

For more details on performance metrics options, see “Performance Metrics” on page 33-3011.

Data Types: `char` | `string` | `struct` | `cell` | `function_handle`

`MetricsWarmupPeriod` — Number of observations fit before tracking performance metrics
`0` (default) | nonnegative integer | ...

Number of observations the incremental model must be fit to before it tracks performance metrics in its `Metrics` property, specified as the comma-separated pair consisting of `'MetricsWarmupPeriod'` and a nonnegative integer. The incremental model is warm after incremental fitting functions fit `MetricsWarmupPeriod` observations to the incremental model (`EstimationPeriod` + `MetricsWarmupPeriod` observations).

For more details on performance metrics options, see “Performance Metrics” on page 33-3011.

Data Types: `single` | `double`

`MetricsWindowSize` — Number of observations to use to compute window performance metrics
`200` (default) | positive integer | ...

Number of observations to use to compute window performance metrics, specified as a positive integer.

For more details on performance metrics options, see “Performance Metrics” on page 33-3011.

Data Types: `single` | `double`

Output Arguments

`IncrementalMdl` — Linear regression model for incremental learning
`incrementalRegressionLinear` model object

Linear regression model for incremental learning, returned as an `incrementalRegressionLinear` model object. `IncrementalMdl` is also configured to generate predictions given new data (see `predict`).

To initialize `IncrementalMdl` for incremental learning, `incrementalLearner` passes the values of the `Mdl` properties in this table to congruent properties of `IncrementalMdl`.

Property	Description
`Beta`	Linear model coefficients, a numeric vector
`Bias`	Model intercept, a numeric scalar
`Epsilon`	Half the width of the epsilon insensitive band, a nonnegative scalar
`Learner`	Linear regression model type
`ModelParameters.FitBias`	Linear model intercept inclusion flag
`Mu`	Predictor variable means, a numeric vector
`Sigma`	Predictor variable standard deviations, a numeric vector

More About

Incremental Learning

Incremental learning, or online learning, is a branch of machine learning concerned with processing incoming data from a data stream, possibly given little to no knowledge of the distribution of the predictor variables, aspects of the prediction or objective function (including tuning parameter values), or whether the observations are labeled. Incremental learning differs from traditional

machine learning, where enough labeled data is available to fit to a model, perform cross-validation to tune hyperparameters, and infer the predictor distribution.

Given incoming observations, an incremental learning model processes data in any of the following ways, but usually in this order:

- Predict labels.
- Measure the predictive performance.
- Check for structural breaks or drift in the model.
- Fit the model to the incoming observations.

Adaptive Scale-Invariant Solver for Incremental Learning

The adaptive scale-invariant solver for incremental learning, introduced in [1], is a gradient-descent-based objective solver for training linear predictive models. The solver is hyperparameter free, insensitive to differences in predictor variable scales, and does not require prior knowledge of the distribution of the predictor variables. These characteristics make it well suited to incremental learning.

The standard SGD and ASGD solvers are sensitive to differing scales among the predictor variables, resulting in models that can perform poorly. To achieve better accuracy using SGD and ASGD, you can standardize the predictor data, and tune the regularization and learning rate parameters can require tuning. For traditional machine learning, enough data is available to enable hyperparameter tuning by cross-validation and predictor standardization. However, for incremental learning, enough data might not be available (for example, observations might be available only one at a time) and the distribution of the predictors might be unknown. These characteristics make parameter tuning and predictor standardization difficult or impossible to do during incremental learning.

The incremental fitting functions for regression `fit` and `updateMetricsAndFit` use the more conservative ScInOL1 version of the algorithm.

Algorithms

Estimation Period

During the estimation period, incremental fitting functions `fit` and `updateMetricsAndFit` use the first incoming `EstimationPeriod` observations to estimate (tune) hyperparameters required for incremental training. This table describes the hyperparameters and when they are estimated or tuned.

Hyperparameter	Model Property	Use	Hyperparameters Estimated
Predictor means and standard deviations	`Mu` and `Sigma`	Standardize predictor data	When you set `'Standardize',true` (see “Standardize Data” on page 33-3011)
Learning rate	`LearnRate`	Adjust solver step size	When both of these conditions apply: • You change the solver of `Mdl` to SGD or ASGD (see `Solver`). • You do not set the `'LearnRate'` name-value pair argument.

The functions fit only the last estimation period observation to the incremental model, and they do not use any of the observations to track the performance of the model. At the end of the estimation period, the functions update the properties that store the hyperparameters.

Standardize Data

If incremental learning functions are configured to standardize predictor variables, they do so using the means and standard deviations stored in the `Mu` and `Sigma` properties of the incremental learning model `IncrementalMdl`.

- When you set `'Standardize',true`, and `IncrementalMdl.Mu` and `IncrementalMdl.Sigma` are empty, the following conditions apply:
  - If the estimation period is positive (see the `EstimationPeriod` property of `IncrementalMdl`), incremental fitting functions estimate means and standard deviations using the estimation period observations.
  - If the estimation period is 0, `incrementalLearner` forces the estimation period to `1000`. Consequently, incremental fitting functions estimate new predictor variable means and standard deviations during the forced estimation period.
- When incremental fitting functions estimate predictor means and standard deviations, the functions compute weighted means and weighted standard deviations using the estimation period observations. Specifically, the functions standardize predictor j (x_j) using

  $$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

  where
  - x_j is predictor j, and x_{jk} is observation k of predictor j in the estimation period.
  - $\mu_j^* = \frac{1}{\sum_k w_k}\sum_k w_k x_{jk}$.
  - $\left(\sigma_j^*\right)^2 = \frac{1}{\sum_k w_k}\sum_k w_k\left(x_{jk} - \mu_j^*\right)^2$.
  - w_j is observation weight j.

Performance Metrics

- The `updateMetrics` and `updateMetricsAndFit` functions are incremental learning functions that track model performance metrics (`'Metrics'`) from new data when the incremental model is warm (`IsWarm` property). An incremental model is warm after `fit` or `updateMetricsAndFit` fit the incremental model to `'MetricsWarmupPeriod'` observations, which is the metrics warm-up period.

  If `'EstimationPeriod'` > 0, the functions estimate hyperparameters before fitting the model to data. Therefore, the functions must process an additional `EstimationPeriod` observations before the model starts the metrics warm-up period.
- The `Metrics` property of the incremental model stores two forms of each performance metric as variables (columns) of a table, `Cumulative` and `Window`, with individual metrics in rows. When the incremental model is warm, `updateMetrics` and `updateMetricsAndFit` update the metrics at the following frequencies:

- `Cumulative` — The functions compute cumulative metrics since the start of model performance tracking. The functions update metrics every time you call the functions and base the calculation on the entire supplied data set.
- `Window` — The functions compute metrics based on all observations within a window determined by the `'MetricsWindowSize'` name-value pair argument. `'MetricsWindowSize'` also determines the frequency at which the software updates `Window` metrics. For example, if `MetricsWindowSize` is 20, the functions compute metrics based on the last 20 observations in the supplied data (`X((end − 20 + 1):end,:)` and `Y((end − 20 + 1):end)`).

  Incremental functions that track performance metrics within a window use the following process:

  1. For each specified metric, store a buffer of length `MetricsWindowSize` and a buffer of observation weights.
  2. Populate elements of the metrics buffer with the model performance based on batches of incoming observations, and store corresponding observations weights in the weights buffer.
  3. When the buffer is filled, overwrite `IncrementalMdl.Metrics.Window` with the weighted average performance in the metrics window. If the buffer is overfilled when the function processes a batch of observations, the latest incoming `MetricsWindowSize` observations enter the buffer, and the earliest observations are removed from the buffer. For example, suppose `MetricsWindowSize` is 20, the metrics buffer has 10 values from a previously processed batch, and 15 values are incoming. To compose the length 20 window, the functions use the measurements from the 15 incoming observations and the latest 5 measurements from the previous batch.

incrementalRegressionLinear

Linear regression model for incremental learning

Description

`incrementalRegressionLinear` creates an `incrementalRegressionLinear` model object, which represents an incremental linear model for regression problems. Supported learners include support vector machine (SVM) and least squares.

Unlike other Statistics and Machine Learning Toolbox model objects, `incrementalRegressionLinear` can be called directly. Also, you can specify learning options, such as performance metrics configurations, parameter values, and the objective solver, before fitting the model to data. After you create an `incrementalRegressionLinear` object, it is prepared for incremental learning on page 33-3034.

`incrementalRegressionLinear` is best suited for incremental learning. For a traditional approach to training an SVM or linear regression model (such as creating a model by fitting it to data, performing cross-validation, tuning hyperparameters, and so on), see `fitrsvm` or `fitrlinear`.

Creation

You can create an `incrementalRegressionLinear` model object in several ways:

- **Call the function directly** — Configure incremental learning options, or specify initial values for linear model parameters and hyperparameters, by calling `incrementalRegressionLinear` directly. This approach is best when you do not have data yet or you want to start incremental learning immediately.
- **Convert a traditionally trained model** — To initialize an linear regression model for incremental learning using the model coefficients and hyperparameters of a trained SVM or linear regression model object, you can convert the traditionally trained model to an `incrementalRegressionLinear` model object by passing it to the `incrementalLearner` function. This table contains links to the appropriate reference pages.

Convertible Model Object	Conversion Function
`RegressionSVM` or `CompactRegressionSVM`	`incrementalLearner`
`RegressionLinear`	`incrementalLearner`

- **Call an incremental learning function** — `fit`, `updateMetrics`, and `updateMetricsAndFit` accept a configured `incrementalRegressionLinear` model object and data as input, and return an `incrementalRegressionLinear` model object updated with information learned from the input model and data.

Syntax

```
Mdl = incrementalRegressionLinear()
Mdl = incrementalRegressionLinear(Name,Value)
```

Description

`Mdl = incrementalRegressionLinear()` returns a default incremental linear model object for regression `Mdl`. Properties of a default model contain placeholders for unknown model parameters. You must train a default model before you can track its performance or generate predictions from it.

`Mdl = incrementalRegressionLinear(Name,Value)` sets properties on page 33-3017 and additional options using name-value pair arguments. Enclose each name in quotes. For example, `incrementalRegressionLinear('Beta',[0.1 0.3],'Bias',1,'MetricsWarmupPeriod',100)` sets the vector of linear model coefficients β to `[0.1 0.3]`, the bias β_0 to `1`, and the metrics warm-up period to `100`.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Standardize',true` standardizes the predictor data using the predictor means and standard deviations estimated during the estimation period.

`Metrics` — Model performance metrics to track during incremental learning
`"epsiloninsensitive"` | `"mse"` | string vector | function handle | cell vector | structure array | ...

Model performance metrics to track during incremental learning, specified as the comma-separated pair consisting of `'Metrics'` and a built-in loss function name, string vector of names, function handle (`@metricName`), structure array of function handles, or cell vector of names, function handles, or structure arrays.

When `Mdl` is warm (see IsWarm), `updateMetrics` and `updateMetricsAndFit` track performance metrics in the Metrics property of `Mdl`.

The following table lists the built-in loss-function names and which learners, specified in `Mdl.Learner`, support them. You can specify more than one loss function by using a string vector.

Name	Description	Learners Supporting Metric
`"epsiloninsensitive"`	Epsilon insensitive loss	`'svm'`
`"mse"`	Weighted mean squared error	`'svm'` and `'leastsquares'`

For more details on the built-in loss functions, see `loss`.

Example: `'Metrics',["epsiloninsensitive" "mse"]`

To specify a custom function that returns a performance metric, use function handle notation. The function must have this form:

```
metric = customMetric(Y,YFit)
```

- The output argument `metric` is an *n*-by-1 numeric vector, where each element is the loss of the corresponding observation in the data processed by the incremental learning functions during a learning cycle.
- You select the function name (`customMetric`).

- `Y` is a length *n* numeric vector of observed responses, where *n* is the sample size.
- `YFit` is a length *n* numeric vector of corresponding predicted responses.

To specify multiple custom metrics and assign a custom name to each, use a structure array. To specify a combination of built-in and custom metrics, use a cell vector.

Example: `'Metrics',struct('Metric1',@customMetric1,'Metric2',@customMetric2)`

Example: `'Metrics',{@customMetric1 @customeMetric2 'mse' struct('Metric3',@customMetric3)}`

`updateMetrics` and `updateMetricsAndFit` store specified metrics in a table in the property `Metrics`. The data type of `Metrics` determines the row names of the table.

`'Metrics'` Value Data Type	Description of `Metrics` Property Row Name	Example
String or character vector	Name of corresponding built-in metric	Row name for `"epsiloninsensitive"` is `"EpsilonInsensitiveLoss"`
Structure array	Field name	Row name for `struct('Metric1',@customMetric1)` is `"Metric1"`
Function handle to function stored in a program file	Name of function	Row name for `@customMetric` is `"customMetric"`
Anonymous function	`CustomMetric_`*j*, where *j* is metric *j* in `Metrics`	Row name for `@(Y,YFit)customMetric(Y,YFit)...` is `CustomMetric_1`

By default:

- `Metrics` is `"epsiloninsensitive"` if `Mdl.Learner` is `'svm'`.
- `Metrics` is `"mse"` if `Mdl.Learner` is `'leastsquares'`.

For more details on performance metrics options, see “Performance Metrics” on page 33-3037.

Data Types: `char` | `string` | `struct` | `cell` | `function_handle`

`Standardize` — Flag to standardize predictor data
`'auto'` (default) | `false` | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and a value in this table.

Value	Description
`'auto'`	`incrementalRegressionLinear` determines whether the predictor variables need to be standardized. See “Standardize Data” on page 33-3036.

Value	Description
`true`	The software standardizes the predictor data. For more details, see “Standardize Data” on page 33-3036.
`false`	The software does not standardize the predictor data.

Example: `'Standardize',true`

Data Types: `logical` | `char` | `string`

Properties

You can set most properties by using name-value pair argument syntax only when you call `incrementalRegressionLinear`. You can set some properties when you call `incrementalLearner` to convert a traditionally trained model. You cannot set the properties `FittedLoss`, `NumTrainingObservations`, `Mu`, `Sigma`, `SolverOptions` , and `IsWarm`.

Regression Model Parameters

`Beta` — Linear model coefficients β

numeric vector

This property is read-only.

Linear model coefficients β, specified as a `NumPredictors`-by-1 numeric vector.

If you convert a traditionally trained model to create `Mdl`, `Beta` is specified by the value of the `Beta` property of the traditionally trained model. Otherwise, by default, `Beta` is `zeros(NumPredictors,1)`.

Data Types: `single` | `double`

`Bias` — Model intercept β_0

numeric scalar

This property is read-only.

Model intercept β_0, or bias term, specified as a numeric scalar.

If you convert a traditionally trained model to create `Mdl`, `Bias` is specified by the value of the `Bias` property of the traditionally trained model. Otherwise, by default, `Bias` is `0`.

Data Types: `single` | `double`

`Epsilon` — Half of the width of epsilon insensitive band

`'auto'` | nonnegative scalar

This property is read-only.

Half of the width of the epsilon insensitive-band, specified as `'auto'` or a nonnegative scalar.

If you specify `'auto'` when you call `incrementalRegressionLinear`, incremental fitting functions estimate `Epsilon` during the estimation period, specified by EstimationPeriod, using this procedure:

- If `iqr(Y)` ≠ 0, `Epsilon` is `iqr(Y)/13.49`, where `Y` is the estimation period response data.
- If `iqr(Y)` = 0 or before you fit `Mdl` to data, `Epsilon` is `0.1`.

If you convert a traditionally trained SVM regression model to create `Mdl` (`Learner` is `'svm'`), `Epsilon` is specified by the value of the `Epsilon` property of the traditionally trained model.

If `Learner` is `'leastsquares'`, you cannot set `Epsilon` and its value is `NaN`.

Data Types: `single` | `double`

`FittedLoss` — Loss function used to fit linear model
`'epsiloninsensitive'` | `'mse'`

This property is read-only.

Loss function used to fit the linear model, specified as `'epsiloninsensitive'` or `'mse'`.

Value	Algorithm	Loss function	`Learner` Value
`'epsiloninsensitive'`	Support vector machine regression	Epsilon insensitive: $\ell[y, f(x)] = \max[0, \lvert y - f(x)\rvert - \varepsilon]$	`'svm'`
`'mse'`	Linear regression through ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	`'leastsquares'`

`Learner` — Linear regression model type
`'leastsquares'` | `'svm'`

This property is read-only.

Linear regression model type, specified as `'leastsquares'` or `'svm'`.

In the following table, $f(x) = x\beta + b$.

- β is `Beta`.
- x is an observation from p predictor variables.
- β_0 is `Bias`.

Value	Algorithm	Loss function	`FittedLoss` Value
`'leastsquares'`	Linear regression through ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	`'mse'`
`'svm'`	Support vector machine regression	Epsilon insensitive: $\ell[y, f(x)] = \max[0, \lvert y - f(x)\rvert - \varepsilon]$	`'epsiloninsensitive'`

If you convert a traditionally trained model to create `Mdl`, `Learner` is the learner of the traditionally trained model.

- If the traditionally trained model is `CompactRegressionSVM` or `RegressionSVM`, `Learner` is `'svm'`.

- If the traditionally trained model is `RegressionLinear`, `Learner` is the value of the `Learner` property of the traditionally trained model.

`NumPredictors` — Number of predictor variables
`0` (default) | nonnegative numeric scalar

This property is read-only.

Number of predictor variables, specified as a nonnegative numeric scalar.

If you convert a traditionally trained model to create `Mdl`, `NumPredictors` is specified by the congruent property of the traditionally trained model. Otherwise, incremental fitting functions infer `NumPredictors` from the predictor data during training.

Data Types: `double`

`NumTrainingObservations` — Number of observations fit to incremental model
`0` (default) | nonnegative numeric scalar

This property is read-only.

Number of observations fit to the incremental model `Mdl`, specified as a nonnegative numeric scalar. `NumTrainingObservations` increases when you pass `Mdl` and training data to `fit` or `updateMetricsAndFit`.

Note If you convert a traditionally trained model to create `Mdl`, `incrementalRegressionLinear` does not add the number of observations fit to the traditionally trained model to `NumTrainingObservations`.

Data Types: `double`

`ResponseTransform` — Response transformation function
`'none'` | function handle

This property is read-only.

Response transformation function, specified as `'none'` or a function handle. `ResponseTransform` describes how incremental learning functions transform raw response values.

For a MATLAB function or a function that you define, enter its function handle; for example, `'ResponseTransform',@`*`function`*, where *`function`* accepts an *n*-by-1 vector (the original responses) and returns a vector of the same length (the transformed responses).

- If you convert a traditionally trained model to create `Mdl`, `ResponseTransform` is specified by the congruent property of the traditionally trained model.
- Otherwise, `ResponseTransform` is `'none'`.

Data Types: `char` | `function_handle`

Training Parameters

`EstimationPeriod` — Number of observations processed to estimate hyperparameters
nonnegative integer

This property is read-only.

Number of observations processed by the incremental model to estimate hyperparameters before training or tracking performance metrics, specified as a nonnegative integer.

Note

- If `Mdl` is prepared for incremental learning (all hyperparameters required for training are specified), `incrementalRegressionLinear` forces `'EstimationPeriod'` to `0`.
- If `Mdl` is not prepared for incremental learning, `incrementalRegressionLinear` sets `'EstimationPeriod'` to `1000`.

For more details, see “Estimation Period” on page 33-3035.

Data Types: `single` | `double`

FitBias — Linear model intercept inclusion flag

`true` | `false`

This property is read-only.

Linear model intercept inclusion flag, specified as `true` or `false`.

Value	Description
`true`	`incrementalRegressionLinear` includes the bias term β_0 in the linear model, which incremental fitting functions fit to data.
`false`	`incrementalRegressionLinear` sets $\beta_0 = 0$.

If `Bias` $\neq 0$, `FitBias` must be `true`. In other words, `incrementalRegressionLinear` does not support an equality constraint on β_0.

If you convert a traditionally trained linear regression model (`RegressionLinear`) to create `Mdl`, `FitBias` is specified by the value of the `ModelParameters.FitBias` property of the traditionally trained model.

Data Types: `logical`

Mu — Predictor means

vector of numeric values | `[]`

This property is read-only.

Predictor means, specified as a numeric vector.

If `Mu` is an empty array `[]` and you specify `'Standardize',true`, incremental fitting functions set `Mu` to the predictor variable means estimated during the estimation period specified by `EstimationPeriod`.

You cannot specify `Mu` directly.

Data Types: `single` | `double`

`Sigma` — Predictor standard deviations

vector of numeric values | `[]`

This property is read-only.

Predictor standard deviations, specified as a numeric vector.

If `Sigma` is an empty array `[]` and you specify `'Standardize',true`, incremental fitting functions set `Sigma` to the predictor variable standard deviations estimated during the estimation period specified by `EstimationPeriod`.

You cannot specify `Sigma` directly.

Data Types: `single` | `double`

`Shuffle` — Flag for shuffling observations in batch

`true` (default) | `false`

This property is read-only.

Flag for shuffling the observations in the batch at each learning cycle, specified as a value in this table.

Value	Description
`true`	The software shuffles observations in each incoming batch of data before processing the set. This action reduces bias induced by the sampling scheme.
`false`	The software processes the data in the order received.

Data Types: `logical`

`Solver` — Objective function minimization technique

`'scale-invariant'` (default) | `'sgd'` | `'asgd'`

This property is read-only.

Objective function minimization technique, specified as a value in this table.

Value	Description	Notes
`'scale-invariant'`	Adaptive scale-invariant solver for incremental learning on page 33-3035 [1]	• This algorithm is parameter free and can adapt to differences in predictor scales. Try this algorithm before using SGD or ASGD. • To shuffle incoming batches before the `fit` function fits the model, set `Shuffle` to `true`.

Value	Description	Notes
`'sgd'`	Stochastic gradient descent (SGD) [3][2]	• To train effectively with SGD, standardize the data and specify adequate values for hyperparameters using options listed in "SGD and ASGD Solver Parameters" on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.
`'asgd'`	Average stochastic gradient descent (ASGD) [4]	• To train effectively with ASGD, standardize the data and specify adequate values for hyperparameters using options listed in "SGD and ASGD Solver Parameters" on page 33-0 . • The `fit` function always shuffles an incoming batch of data before fitting the model.

If you convert a traditionally trained linear regression model (`RegressionLinear`) to create `Mdl`, whose `ModelParameters.Solver` property is `'sgd'` or `'asgd'`, `Solver` is specified by the `ModelParameters.Solver` property of the traditionally trained model.

Data Types: `char` | `string`

`SolverOptions` — Objective solver configurations
structure array

This property is read-only.

Objective solver configurations, specified as a structure array. The fields of `SolverOptions` are properties specific to the specified solver `Solver`.

Data Types: `struct`

SGD and ASGD Solver Parameters

`BatchSize` — Mini-batch size
positive integer

This property is read-only.

Mini-batch size, specified as a positive integer. At each iteration during training, `incrementalRegressionLinear` uses `min(BatchSize,numObs)` observations to compute the subgradient, where `numObs` is the number of observations in the training data passed to `fit` or `updateMetricsAndFit`.

If you convert a traditionally trained linear regression model (`RegressionLinear`) to create `Mdl`, whose `ModelParameters.Solver` property is `'sgd'` or `'asgd'`, `BatchSize` is specified by the `ModelParameters.BatchSize` property of the traditionally trained model. Otherwise, the default is `10`.

Data Types: `single` | `double`

`Lambda` — Ridge (*L*2) regularization term strength
nonnegative scalar

This property is read-only.

Ridge ($L2$) regularization term strength, specified as a nonnegative scalar.

If you convert a traditionally trained linear model for ridge regression (`RegressionLinear` object with the `Regularization` property equal to `'ridge (L2)'`) to create `Mdl`, `Lambda` is specified by the value of the `Lambda` property of the traditionally trained model. Otherwise, the default is `1e-5`.

Data Types: `double` | `single`

`LearnRate` — Learning rate
`'auto'` | positive scalar

This property is read-only.

Learning rate, specified as `'auto'` or a positive scalar. `LearnRate` controls the optimization step size by scaling the objective subgradient.

When you specify `'auto'`:

- If `EstimationPeriod` is `0`, the initial learning rate is `0.7`.
- If `EstimationPeriod` > `0`, the initial learning rate is `1/sqrt(1+max(sum(X.^2,obsDim)))`, where `obsDim` is `1` if the observations compose the columns of the predictor data, and `2` otherwise. `fit` and `updateMetricsAndFit` set the value when you pass the model and training data to either.

If you convert a traditionally trained linear regression model (`RegressionLinear`) to create `Mdl`, whose `ModelParameters.Solver` property is `'sgd'` or `'asgd'`, `LearnRate` is specified by the `ModelParameters.LearnRate` property of the traditionally trained model.

The `LearnRateSchedule` property determines the learning rate for subsequent learning cycles.

Example: `'LearnRate',0.001`

Data Types: `single` | `double` | `char` | `string`

`LearnRateSchedule` — Learning rate schedule
`'decaying'` (default) | `'constant'`

This property is read-only.

Learning rate schedule, specified as a value in this table, where `LearnRate` specifies the initial learning rate γ_0.

Value	Description
`'constant'`	The learning rate is γ_0 for all learning cycles.

Value	Description

`'decaying'`	The learning rate at learning cycle t is
	$$\gamma_t = \frac{\gamma_0}{(1+\lambda\gamma_0 t)^c}.$$
	• λ is the value of `Lambda`.
	• If `Solver` is `'sgd'`, $c = 1$.
	• If `Solver` is `'asgd'`:
	  • $c = 2/3$ if `Learner` is `'leastsquares'`
	  • $c = 3/4$ if `Learner` is `'svm'` [4]

If you convert a traditionally trained linear regression model (`RegressionLinear`) to create `Mdl`, whose `ModelParameters.Solver` property is `'sgd'` or `'asgd'`, `LearnRate` is `'decaying'`.

Data Types: `char` | `string`

Adaptive Scale-Invariant Solver Options

`Shuffle` — Flag for shuffling observations in batch

`true` (default) | `false`

This property is read-only.

Flag for shuffling the observations in the batch at each learning cycle, specified as a value in this table.

Value	Description
`true`	The software shuffles observations in each incoming batch of data before processing the set. This action reduces bias induced by the sampling scheme.
`false`	The software processes the data in the order received.

Data Types: `logical`

Performance Metrics Parameters

`IsWarm` — Flag indicating whether model tracks performance metrics

`false` | `true`

This property is read-only.

Flag indicating whether the incremental model tracks performance metrics, specified as `false` or `true`. The incremental model `Mdl` is warm (`IsWarm` becomes `true`) after incremental fitting functions fit `MetricsWarmupPeriod` observations to the incremental model (that is, `EstimationPeriod` + `MetricsWarmupPeriod` observations).

Value	Description
`true`	The incremental model `Mdl` is warm. Consequently, `updateMetrics` and `updateMetricsAndFit` track performance metrics in the `Metrics` property of `Mdl`.
`false`	`updateMetrics` and `updateMetricsAndFit` do not track performance metrics.

Data Types: `logical`

`Metrics` — Model performance metrics
table

This property is read-only.

Model performance metrics updated during incremental learning by `updateMetrics` and `updateMetricsAndFit`, specified as a table with two columns and *m* rows, where *m* is the number of metrics specified by the `'Metrics'` name-value pair argument.

The columns of `Metrics` are labeled `Cumulative` and `Window`.

- **`Cumulative`**: Element *j* is the model performance, as measured by metric *j*, from the time the model became warm (IsWarm is `1`).
- **`Window`**: Element *j* is the model performance, as measured by metric *j*, evaluated over all observations within the window specified by the `MetricsWindowSize` property. The software updates `Window` after it processes `MetricsWindowSize` observations.

Rows are labeled by the specified metrics. For details, see `'Metrics'`.

Data Types: `table`

`MetricsWarmupPeriod` — Number of observations fit before tracking performance metrics
`1000` (default) | nonnegative integer

This property is read-only.

Number of observations the incremental model must be fit to before it tracks performance metrics in its `Metrics` property, specified as a nonnegative integer.

For more details, see “Performance Metrics” on page 33-3037.

Data Types: `single` | `double`

`MetricsWindowSize` — Number of observations to use to compute window performance metrics
`200` (default) | positive integer

This property is read-only.

Number of observations to use to compute window performance metrics, specified as a positive integer.

For more details on performance metrics options, see “Performance Metrics” on page 33-3037.

Data Types: `single` | `double`

Object Functions

fit	Train linear model for incremental learning
updateMetricsAndFit	Update performance metrics in linear model for incremental learning given new data and train model
updateMetrics	Update performance metrics in linear model for incremental learning given new data
loss	Loss of linear model for incremental learning on batch of data
predict	Predict responses for new observations from linear model for incremental learning

Examples

Create Incremental Learner Without Any Prior Information

Create a default incremental linear model for regression.

```
Mdl = incrementalRegressionLinear()
```

```
Mdl =
  incrementalRegressionLinear

               IsWarm: 0
              Metrics: [1x2 table]
    ResponseTransform: 'none'
                 Beta: [0x1 double]
                 Bias: 0
              Learner: 'svm'

  Properties, Methods
```

```
Mdl.EstimationPeriod
```

```
ans = 1000
```

`Mdl` is an `incrementalRegressionLinear` model object. All its properties are read-only.

`Mdl` must be fit to data before you can use it to perform any other operations. The software sets the estimation period to 1000 because half the width of the epsilon insensitive band `Epsilon` is unknown. You can set `Epsilon` to a positive floating point scalar by using the `'Epsilon'` name-value pair argument. This action results in a default estimation period of 0.

Load the robot arm data set.

```
load robotarm
```

For details on the data set, enter `Description` at the command line.

Fit the incremental model to the training data by using the `updateMetricsAndfit` function. To simulate a data stream fit the model in chunks of 50 observations at a time. At each iteration:

- Process 50 observations.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.

- Store β_1, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

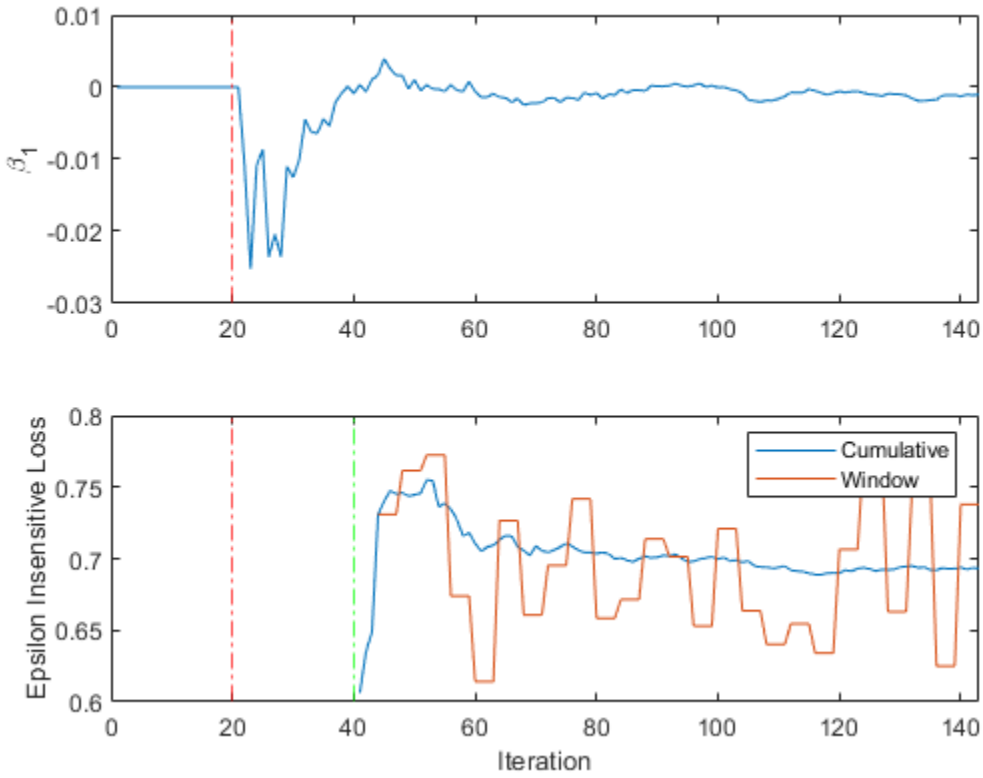
```
% Preallocation
n = numel(ytrain);
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ei = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta1 = zeros(nchunk,1);

% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetricsAndFit(Mdl,Xtrain(idx,:),ytrain(idx));
    ei{j,:} = Mdl.Metrics{"EpsilonInsensitiveLoss",:};
    beta1(j + 1) = Mdl.Beta(1);
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream. While `updateMetricsAndFit` processes the first 1000 observations, it stores a buffer to estimate `Epsilon`; the function does not fit the coefficients until after this estimation period. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and β_1 evolved during training, plot them on separate subplots.

```
figure;
subplot(2,1,1)
plot(beta1)
ylabel('\beta_1')
xlim([0 nchunk]);
xline(Mdl.EstimationPeriod/numObsPerChunk,'r-.');
subplot(2,1,2)
h = plot(ei.Variables);
xlim([0 nchunk]);
ylabel('Epsilon Insensitive Loss')
xline(Mdl.EstimationPeriod/numObsPerChunk,'r-.');
xline((Mdl.EstimationPeriod + Mdl.MetricsWarmupPeriod)/numObsPerChunk,'g-.');
legend(h,ei.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- After the estimation period (first 20 iterations), fit β_1 during all incremental learning iterations.
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations (4 iterations).

Configure Incremental Learning Options

Prepare an incremental regression learner by specifying a metrics warm-up period, during which the `updateMetricsAndFit` function only fits the model. Specify a metrics window size of 500 observations. Train the model by using SGD, and adjust the SGD batch size, learning rate, and regularization parameter.

Load the robot arm data set.

```
load robotarm
n = numel(ytrain);
```

For details on the data set, enter `Description` at the command line.

Create an incremental linear model for regression. Configure the model as follows:

- Specify the SGD solver.
- Assume that a ridge regularization parameter value of 0.001, SGD batch size of 20, learning rate of 0.002, and half the width of the epsilon insensitive band for SVM of 0.05 work well for the problem.
- Specify that the incremental fitting functions process the raw (unstandardized) predictor data.
- Specify a metrics warm-up period of 1000 observations.
- Specify a metrics window size of 500 observations.
- Track the epsilon insensitive loss, MSE, and mean absolute error (MAE) to measure the performance of the model. The software supports epsilon insensitive loss and MSE. Create an anonymous function that measures the absolute error of each new observation. Create a structure array containing the name `MeanAbsoluteError` and its corresponding function.

```
maefcn = @(z,zfit)abs(z - zfit);
maemetric = struct("MeanAbsoluteError",maefcn);

Mdl = incrementalRegressionLinear('Epsilon',0.05,...
    'Solver','sgd','Lambda',0.001,'BatchSize',20,'LearnRate',0.002,...
    'Standardize',false,...
    'MetricsWarmupPeriod',1000,'MetricsWindowSize',500,...
    'Metrics',{'epsiloninsensitive' 'mse' maemetric})
```

```
Mdl =
  incrementalRegressionLinear

               IsWarm: 0
              Metrics: [3x2 table]
    ResponseTransform: 'none'
                 Beta: [0x1 double]
                 Bias: 0
              Learner: 'svm'

  Properties, Methods
```

`Mdl` is an `incrementalRegressionLinear` model object configured for incremental learning without an estimation period.

Fit the incremental model to the data by using `updateMetricsAndfit` function. At each iteration:

- Simulate a data stream by processing a chunk of 50 observations. Note that chunk size is different from SGD batch size.
- Overwrite the previous incremental model with a new one fitted to the incoming observation.
- Store the estimated coefficient β_{10}, the cumulative metrics, and the window metrics to see how they evolve during incremental learning.

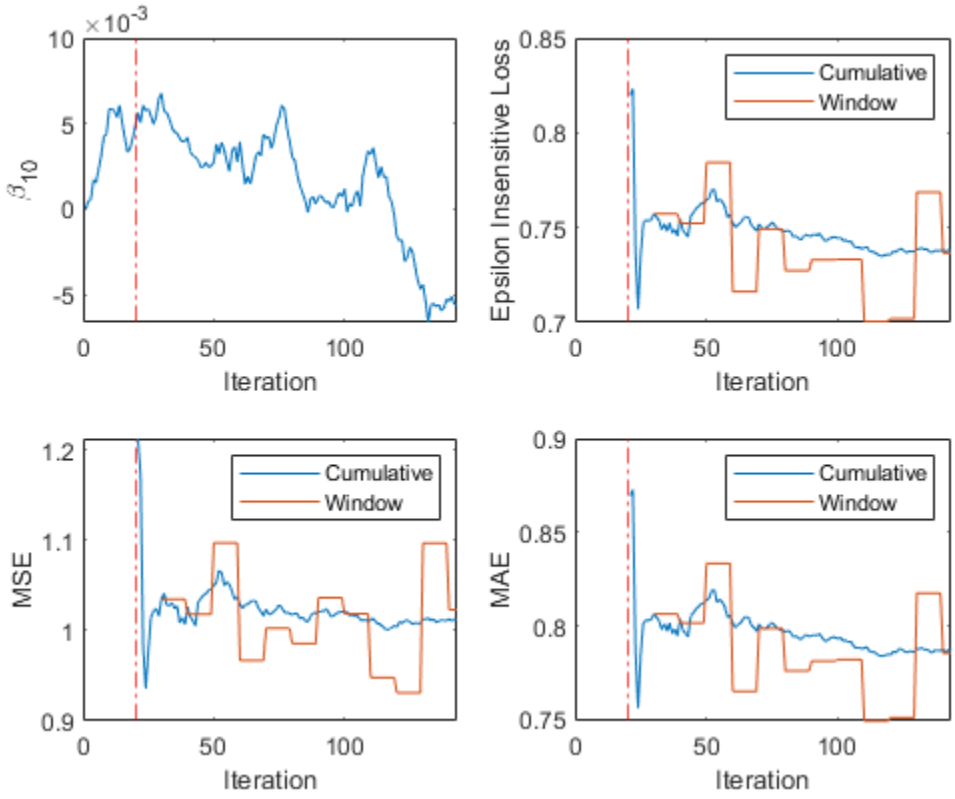
```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ei = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mse = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
mae = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta10 = zeros(nchunk,1);
```

```
% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetricsAndFit(Mdl,Xtrain(idx,:),ytrain(idx));
    ei{j,:} = Mdl.Metrics{"EpsilonInsensitiveLoss",:};
    mse{j,:} = Mdl.Metrics{"MeanSquaredError",:};
    mae{j,:} = Mdl.Metrics{"MeanAbsoluteError",:};
    beta10(j + 1) = Mdl.Beta(10);
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetricsAndFit` checks the performance of the model on the incoming observation, and then fits the model to that observation.

To see how the performance metrics and β_{10} evolved during training, plot them on separate subplots.

```
figure;
subplot(2,2,1)
plot(beta10)
ylabel('\beta_{10}')
xlim([0 nchunk]);
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
subplot(2,2,2)
h = plot(ei.Variables);
xlim([0 nchunk]);
ylabel('Epsilon Insensitive Loss')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,ei.Properties.VariableNames)
xlabel('Iteration')
subplot(2,2,3)
h = plot(mse.Variables);
xlim([0 nchunk]);
ylabel('MSE')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mse.Properties.VariableNames)
xlabel('Iteration')
subplot(2,2,4)
h = plot(mae.Variables);
xlim([0 nchunk]);
ylabel('MAE')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(h,mae.Properties.VariableNames)
xlabel('Iteration')
```



The plot suggests that `updateMetricsAndFit` does the following:

- Fit β_{10} during all incremental learning iterations.
- Compute performance metrics after the metrics warm-up period only.
- Compute the cumulative metrics during each iteration.
- Compute the window metrics after processing 500 observations (10 iterations).

Convert Traditionally Trained Model to Incremental Learner

Train a linear regression model by using `fitrlinear`, convert it to an incremental learner, track its performance, and fit it to streaming data. Carry over training options from traditional to incremental learning.

Load and Preprocess Data

Load the 2015 NYC housing data set, and shuffle the data. For more details on the data, see NYC Open Data.

```
load NYCHousing2015
rng(1); % For reproducibility
n = size(NYCHousing2015,1);
idxshuff = randsample(n,n);
NYCHousing2015 = NYCHousing2015(idxshuff,:);
```

Suppose that the data collected from Manhattan (`BOROUGH = 1`) was collected using a new method that doubles its quality. Create a weight variable that attributes `2` to observations collected from Manhattan, and `1` to all other observations.

```
NYCHousing2015.W = ones(n,1) + (NYCHousing2015.BOROUGH == 1);
```

Extract the response variable `SALEPRICE` from the table. For numerical stability, scale `SALEPRICE` by `1e6`.

```
Y = NYCHousing2015.SALEPRICE/1e6;
NYCHousing2015.SALEPRICE = [];
```

Create dummy variable matrices from the categorical predictors.

```
catvars = ["BOROUGH" "BUILDINGCLASSCATEGORY" "NEIGHBORHOOD"];
dumvarstbl = varfun(@(x)dummyvar(categorical(x)),NYCHousing2015,...
    'InputVariables',catvars);
dumvarmat = table2array(dumvarstbl);
NYCHousing2015(:,catvars) = [];
```

Treat all other numeric variables in the table as linear predictors of sales price. Concatenate the matrix of dummy variables to the rest of the predictor data. Transpose the resulting predictor matrix.

```
idxnum = varfun(@isnumeric,NYCHousing2015,'OutputFormat','uniform');
X = [dumvarmat NYCHousing2015{:,idxnum}]';
```

Train Linear Regression Model

Fit a linear regression model to a random sample of half the data.

```
idxtt = randsample([true false],n,true);
TTMdl = fitrlinear(X(:,idxtt),Y(idxtt),'ObservationsIn','columns',...
    'Weights',NYCHousing2015.W(idxtt))
```

```
TTMdl =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [313x1 double]
                 Bias: 0.1116
               Lambda: 2.1977e-05
              Learner: 'svm'

  Properties, Methods
```

`TTMdl` is a `RegressionLinear` model object representing a traditionally trained linear regression model.

Convert Trained Model

Convert the traditionally trained linear regression model to a linear regression model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalRegressionLinear
```

```
              IsWarm: 1
             Metrics: [1x2 table]
    ResponseTransform: 'none'
                Beta: [313x1 double]
                Bias: 0.1116
             Learner: 'svm'

  Properties, Methods
```

Separately Track Performance Metrics and Fit Model

Perform incremental learning on the rest of the data by using the `updateMetrics` and `fit` functions. Simulate a data stream by processing 500 observations at a time. At each iteration:

1. Call `updateMetrics` to update the cumulative and window epsilon insensitive loss of the model given the incoming chunk of observations. Overwrite the previous incremental model to update the losses in the `Metrics` property. Note that the function does not fit the model to the chunk of data—the chunk is "new" data for the model. Specify that the observations are oriented in columns, and specify the observation weights.
2. Call `fit` to fit the model to the incoming chunk of observations. Overwrite the previous incremental model to update the model parameters. Specify that the observations are oriented in columns, and specify the observation weights.
3. Store the losses and last estimated coefficient β_{313}.

```
% Preallocation
idxil = ~idxtt;
nil = sum(idxil);
numObsPerChunk = 500;
nchunk = floor(nil/numObsPerChunk);
ei = array2table(zeros(nchunk,2),'VariableNames',["Cumulative" "Window"]);
beta313 = [IncrementalMdl.Beta(end); zeros(nchunk,1)];
Xil = X(:,idxil);
Yil = Y(idxil);
Wil = NYCHousing2015.W(idxil);

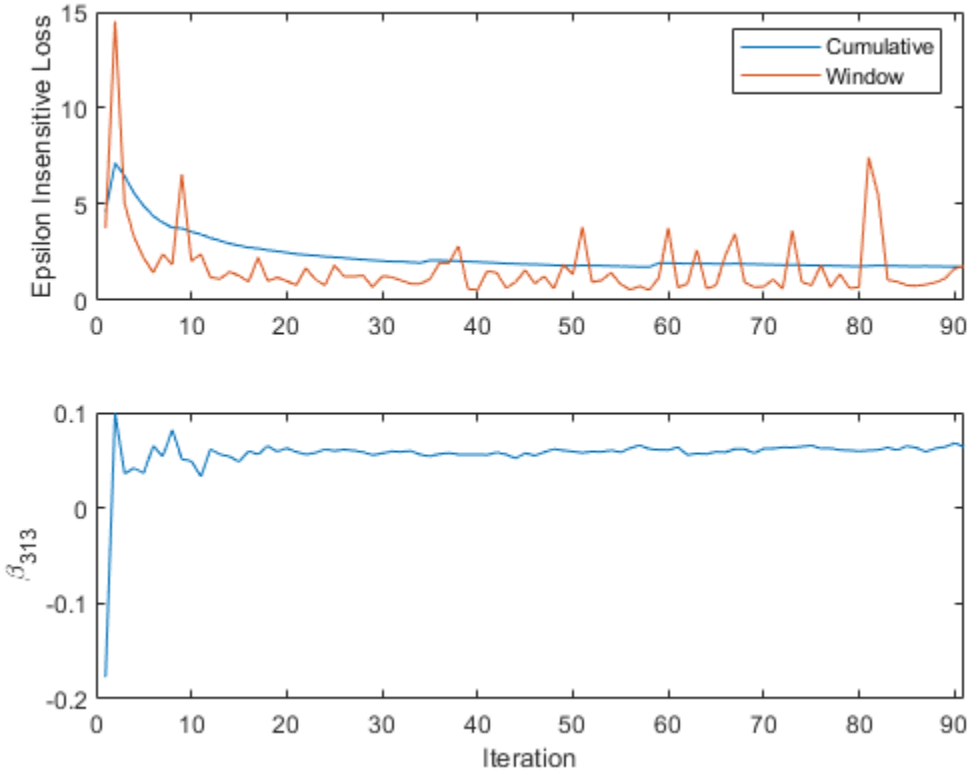
% Incremental fitting
for j = 1:nchunk
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    IncrementalMdl = updateMetrics(IncrementalMdl,Xil(:,idx),Yil(idx),...
        'ObservationsIn','columns','Weights',Wil(idx));
    ei{j,:} = IncrementalMdl.Metrics{"EpsilonInsensitiveLoss",:};
    IncrementalMdl = fit(IncrementalMdl,Xil(:,idx),Yil(idx),'ObservationsIn','columns',...
        'Weights',Wil(idx));
    beta313(j + 1) = IncrementalMdl.Beta(end);
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream.

Alternatively, you can use `updateMetricsAndFit` to update performance metrics of the model given a new chunk of data, and then fit the model to the data.

Plot a trace plot of the performance metrics and estimated coefficient β_{313}.

```
figure;
subplot(2,1,1)
h = plot(ei.Variables);
xlim([0 nchunk]);
ylabel('Epsilon Insensitive Loss')
legend(h,ei.Properties.VariableNames)
subplot(2,1,2)
plot(beta313)
ylabel('\beta_{313}')
xlim([0 nchunk]);
xlabel('Iteration')
```



The cumulative loss gradually changes with each iteration (chunk of 500 observations), whereas the window loss jumps. Because the metrics window is 200 by default, `updateMetrics` measures the performance based on the latest 200 observations in each 500 observation chunk.

β_{313} changes abruptly, then levels off as `fit` processes chunks of observations.

More About

Incremental Learning

Incremental learning, or online learning, is a branch of machine learning concerned with processing incoming data from a data stream, possibly given little to no knowledge of the distribution of the

predictor variables, aspects of the prediction or objective function (including tuning parameter values), or whether the observations are labeled. Incremental learning differs from traditional machine learning, where enough labeled data is available to fit to a model, perform cross-validation to tune hyperparameters, and infer the predictor distribution.

Given incoming observations, an incremental learning model processes data in any of the following ways, but usually in this order:

- Predict labels.
- Measure the predictive performance.
- Check for structural breaks or drift in the model.
- Fit the model to the incoming observations.

Adaptive Scale-Invariant Solver for Incremental Learning

The adaptive scale-invariant solver for incremental learning, introduced in [1], is a gradient-descent-based objective solver for training linear predictive models. The solver is hyperparameter free, insensitive to differences in predictor variable scales, and does not require prior knowledge of the distribution of the predictor variables. These characteristics make it well suited to incremental learning.

The standard SGD and ASGD solvers are sensitive to differing scales among the predictor variables, resulting in models that can perform poorly. To achieve better accuracy using SGD and ASGD, you can standardize the predictor data, and tune the regularization and learning rate parameters can require tuning. For traditional machine learning, enough data is available to enable hyperparameter tuning by cross-validation and predictor standardization. However, for incremental learning, enough data might not be available (for example, observations might be available only one at a time) and the distribution of the predictors might be unknown. These characteristics make parameter tuning and predictor standardization difficult or impossible to do during incremental learning.

The incremental fitting functions for regression `fit` and `updateMetricsAndFit` use the more conservative ScInOL1 version of the algorithm.

Tips

- After creating a model, you can generate C/C++ code that performs incremental learning on a data stream. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

Estimation Period

During the estimation period, incremental fitting functions `fit` and `updateMetricsAndFit` use the first incoming `EstimationPeriod` observations to estimate (tune) hyperparameters required for incremental training. This table describes the hyperparameters and when they are estimated or tuned. Estimation occurs only when `EstimationPeriod` is positive.

Hyperparameter	Model Property	Use	Hyperparameters Estimated
Predictor means and standard deviations	`Mu` and `Sigma`	Standardize predictor data	When both these conditions apply: • Incremental fitting functions are configured to standardize predictor data (see "Standardize Data" on page 33-3036). • `Mdl.Mu` and `Mdl.Sigma` are empty arrays `[]`.
Learning rate	LearnRate	Adjust solver step size	When both these conditions apply: • The solver is SGD or ASGD (see Solver). • You do not set the `'LearnRate'` name-value pair argument.
Half the width of the epsilon insensitive band	Epsilon	Control number of support vectors	When both these conditions apply: • The learner is SVM (see Learner). • You do not set the `'Epsilon'` name-value pair argument.

The functions fit only the last estimation period observation to the incremental model, and they do not use any of the observations to track the performance of the model. At the end of the estimation period, the functions update the properties that store the hyperparameters.

Standardize Data

If incremental learning functions are configured to standardize predictor variables, they do so using the means and standard deviations stored in the `Mu` and `Sigma` properties of the incremental learning model `Mdl`.

- When you set `'Standardize',true` and a positive estimation period (see EstimationPeriod), and `Mdl.Mu` and `Mdl.Sigma` are empty, incremental fitting functions estimate means and standard deviations using the estimation period observations.
- When you set `'Standardize','auto'` (the default), the following conditions apply.
  - If you create `incrementalRegressionLinear` by converting a traditionally trained SVM regression model (`CompactRegressionSVM` or `RegressionSVM`), and the `Mu` and `Sigma` properties of the model being converted are empty arrays `[]`, incremental learning functions do not standardize predictor variables. If the `Mu` and `Sigma` properties of the model being converted are nonempty, incremental learning functions standardize the predictor variables using the specified means and standard deviations. Incremental fitting functions do not estimate new means and standard deviations regardless of the length of the estimation period.
  - If you create `incrementalRegressionLinear` by converting a linear regression model (`RegressionLinear`), incremental learning functions does not standardize the data regardless of the length of the estimation period.
  - If you do not convert a traditionally trained model, incremental learning functions standardize the predictor data only when you specify an SGD solver (see `Solver`) and a positive estimation period (see EstimationPeriod).

- When incremental fitting functions estimate predictor means and standard deviations, the functions compute weighted means and weighted standard deviations using the estimation period observations. Specifically, the functions standardize predictor j (x_j) using

  $$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

  - x_j is predictor j, and x_{jk} is observation k of predictor j in the estimation period.
  - $\mu_j^* = \frac{1}{\sum_k w_k} \sum_k w_k x_{jk}$.
  - $\left(\sigma_j^*\right)^2 = \frac{1}{\sum_k w_k} \sum_k w_k \left(x_{jk} - \mu_j^*\right)^2$.
  - w_j is observation weight j.

Performance Metrics

- The `updateMetrics` and `updateMetricsAndFit` functions track model performance metrics (`'Metrics'`) from new data when the incremental model is warm (IsWarm property). An incremental model is warm after `fit` or `updateMetricsAndFit` fit the incremental model to MetricsWarmupPeriod observations, which is the metrics warm-up period.

  If EstimationPeriod > 0, the functions estimate hyperparameters before fitting the model to data. Therefore, the functions must process an additional `EstimationPeriod` observations before the model starts the metrics warm-up period.
- The `Metrics` property of the incremental model stores two forms of each performance metric as variables (columns) of a table, `Cumulative` and `Window`, with individual metrics in rows. When the incremental model is warm, `updateMetrics` and `updateMetricsAndFit` update the metrics at the following frequencies:

  - `Cumulative` — The functions compute cumulative metrics since the start of model performance tracking. The functions update metrics every time you call the functions and base the calculation on the entire supplied data set.
  - `Window` — The functions compute metrics based on all observations within a window determined by the MetricsWindowSize name-value pair argument. `MetricsWindowSize` also determines the frequency at which the software updates `Window` metrics. For example, if `MetricsWindowSize` is 20, the functions compute metrics based on the last 20 observations in the supplied data (`X((end − 20 + 1):end,:)` and `Y((end − 20 + 1):end)`).

    Incremental functions that track performance metrics within a window use the following process:

    1. For each specified metric, store a buffer of length `MetricsWindowSize` and a buffer of observation weights.
    2. Populate elements of the metrics buffer with the model performance based on batches of incoming observations, and store corresponding observations weights in the weights buffer.
    3. When the buffer is filled, overwrite `Mdl.Metrics.Window` with the weighted average performance in the metrics window. If the buffer is overfilled when the function processes a batch of observations, the latest incoming `MetricsWindowSize` observations enter the

buffer, and the earliest observations are removed from the buffer. For example, suppose `MetricsWindowSize` is 20, the metrics buffer has 10 values from a previously processed batch, and 15 values are incoming. To compose the length 20 window, the functions use the measurements from the 15 incoming observations and the latest 5 measurements from the previous batch.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- All object functions on page 33-3026 of an `incrementalRegressionLinear` model object support code generation.
- If you configure `Mdl` to shuffle data (see Solver and Shuffle), the `fit` function randomly shuffles each incoming batch of observations before it fits the model to the batch. The order of the shuffled observations might not match the order generated by MATLAB.
- When you generate code that loads or creates an `incrementalRegressionLinear` model object, the `NumPredictors` property must reflect the number of predictor variables.

For more information, see “Introduction to Code Generation” on page 32-2.

Introduced in R2020b

isempty

Class: `dataset`

(Not Recommended) True for empty dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
tf = isempty(A)
```

Description

`tf = isempty(A)` returns true (`1`) if `A` is an empty dataset and false (`0`) otherwise. An empty array has no elements, that is `prod(size(A))==0`.

See Also

`size`

islevel

(Not Recommended) Determine if levels are in nominal or ordinal array

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” data type instead.

Syntax

```
tf = islevel(levels,A)
```

Description

`tf = islevel(levels,A)` returns a logical array indicating which of the levels in `levels` correspond to a level in the nominal or ordinal array `A`.

Input Arguments

`A` — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

`levels` — Levels to test

character vector | string array | cell array of character vectors | 2-D character matrix

Levels to test, specified as a character vector, string array, cell array of character vectors, or 2-D character matrix.

Data Types: `char` | `string` | `cell`

Output Arguments

`tf` — Level indicator

logical array

Level indicator, returned as a logical array of the same size as `levels`. `tf` has the value `1` (true) when the corresponding element of `levels` is the label of a level in the nominal or ordinal array `A`, even if the level contains no elements. Otherwise, `tf` has the value `0` (false).

See Also

`isequal` | `ismember` | `nominal` | `ordinal`

Introduced in R2007a

ismember

Class: `dataset`

(Not Recommended) Dataset array elements that are members of set

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
LiA = ismember(A,B)
LiA = ismember(A,B,vars)
[LiA,LocB] = ismember( ___ )
```

Description

`LiA = ismember(A,B)` for `dataset` arrays `A` and `B` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value `1` (true) in the elements that correspond to observations in `A` that are also present in `B`, and `0` (false) otherwise.

`LiA = ismember(A,B,vars)` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value `1` (true) in the elements that correspond to observations in `A` that are also present in `B` for the variables specified in `vars` only, and `0` (false) otherwise.

`[LiA,LocB] = ismember( ___ )` also returns a vector the same length as `A` containing the index to the first observation in `B` that corresponds to each observation in `A`, or `0` if there is no such observation. You can use any of the previous input arguments.

Input Arguments

`A`

Query dataset array, containing the observations to be found in `B`.

`B`

Set dataset array. When an observation in `A` is found in `B`, for all variables or only those variables specified in `vars`, the corresponding element of `LiA` is `1`.

`vars`

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates which variables to match observations on in `A` and `B`.

Output Arguments

`LiA`

Vector of logical values the same length as `A`. `LiA` has value `1` (true) when the corresponding observation in `A` is present in `B`. Otherwise, `LiA` has value `0` (false).

If you specify `vars`, `LiA` has value `1` when the corresponding observation in `A` is present in `B` for the variables in `vars` only.

`LocB`

Vector the same length as `A` containing the index to the first observation in `B` that corresponds to each observation in `A`, for all variables or only those variables specified in `vars`.

Examples

Find Observations That Are Members of a Dataset Array

Load sample data.

```
load('hospital')
B = hospital(1:50,1:5);
```

This set dataset array, `B`, has 50 observations on 5 variables.

Specify a query dataset array.

```
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

```
A =
                LastName             Sex       Age    Weight    Smoker
    YLN-495    {'COLEMAN'  }        Male      39     188       false
    LQW-768    {'TAYLOR'   }        Female    31     132       false
    DGC-290    {'BUTLER'   }        Male      38     184       true

Class: `dataset`

(Not Recommended) Find dataset array elements with missing values

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
I = ismissing(ds)
I = ismissing(ds,Name,Value)
```

Description

`I = ismissing(ds)` returns a logical array that indicates which elements in the dataset array, `ds`, contain a missing value. By default, `ismissing` recognizes `NaN` as a missing value in numeric variables, `''` as a missing value in character variables, and `<undefined>` as a missing value in categorical arrays.

- `ds2 = ds(~any(I,2),:)` creates a new dataset array containing only the complete observations in `ds`.
- `ds2 = ds(:,~any(I,1))` creates a new dataset array containing only the variables from `ds` with no missing values.

`I = ismissing(ds,Name,Value)` returns missing value indices with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ds`

`dataset` array

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`NumericTreatAsMissing`

Vector of numeric values to treat as missing value indicators in floating point `ds` variables. `ismissing` always treats a `NaN` value as a missing value.

Default:

`StringTreatAsMissing`

Character vector, string array, or cell array of character vectors to treat as missing value indicators in character `ds` variables. `ismissing` always treats `''` as a missing value.

Output Arguments

`I`

Logical array indicating which elements in `ds` contain a missing value. `I` is the same size as `ds`, with value `1` for elements that contain a missing value.

“Dataset Arrays” on page 2-112

isvalid

Class: `qrandstream`

Test handle validity

Syntax

```
tf = isvalid(h)
```

Description

`tf = isvalid(h)` performs an element-wise check for validity on the handle elements of `h`. The result is a logical array of the same dimensions as `h`, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

`delete` | `qrandstream`

iwishrnd

Inverse Wishart random numbers

Syntax

```
W = iwishrnd(Tau,df)
W = iwishrnd(Tau,df,DI)
[W,DI] = iwishrnd(Tau,df)
```

Description

`W = iwishrnd(Tau,df)` generates a random matrix `W` from the inverse Wishart distribution with parameters `Tau` and `df`. The inverse of `W` has the Wishart distribution with covariance matrix `Sigma = inv(Tau)` and with `df` degrees of freedom. `Tau` is a symmetric and positive definite matrix.

`W = iwishrnd(Tau,df,DI)` expects `DI` to be the transpose of the inverse of the Cholesky factor of `Tau`, so that `DI'*DI = inv(Tau)`, where `inv` is the MATLAB inverse function. `DI` is lower-triangular and the same size as `Tau`. If you call `iwishrnd` multiple times using the same value of `Tau`, it is more efficient to supply `DI` instead of computing it each time.

`[W,DI] = iwishrnd(Tau,df)` returns `DI` so you can use it as an input in future calls to `iwishrnd`.

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter `tau` so that the mean of the output matrix is `Tau/(df-d-1)` where `d` is the dimension of `Tau`.

Introduced before R2006a

jackknife

Jackknife sampling

Syntax

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

Description

`jackstat = jackknife(jackfun,X)` draws jackknife data samples from the `n`-by-`p` data array `X`, computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of `X` as one data sample, so there are `n` data samples. Each of the `n` rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with `@`. Row `i` of `jackstat` contains the results for the sample consisting of `X` with the `i`th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If `X` is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set `'Options'` as a structure you create with `statset`. `jackknife` uses the following field in the structure:

`'UseParallel'`	If `true`, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, then computation occurs in serial mode. Default is `false`, meaning serial computation.

Examples

Estimate the bias of the MLE variance estimator of random samples taken from the vector `y` using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var,y,1);
n = length(y);
```

```
bias = -sigma^2/n % known bias formula
jbias = (n-1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =
   -0.2500

jbias =
   -0.3378
```

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

jbtest

Jarque-Bera test

Syntax

```
h = jbtest(x)
h = jbtest(x,alpha)
h = jbtest(x,alpha,mctol)
[h,p] = jbtest(___)
[h,p,jbstat,critval] = jbtest(___)
```

Description

`h = jbtest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test on page 33-3054. The alternative hypothesis is that it does not come from such a distribution. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, and `0` otherwise.

`h = jbtest(x,alpha)` returns a test decision for the null hypothesis at the significance level specified by `alpha`.

`h = jbtest(x,alpha,mctol)` returns a test decision based on a *p*-value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error on page 33-3054 less than or equal to `mctol`.

`[h,p] = jbtest(___)` also returns the *p*-value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,jbstat,critval] = jbtest(___)` also returns the test statistic `jbstat` and the critical value `critval` for the test.

Examples

Test for a Normal Distribution

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage, in miles per gallon (`MPG`), follows a normal distribution across different makes of cars.

```
h = jbtest(MPG)
```

```
h = 1
```

The returned value of `h = 1` indicates that `jbtest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at a Different Significance Level

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```
[h,p] = jbtest(MPG,0.01)
```

```
h = 1
```

```
p = 0.0022
```

The returned value of `h = 1`, and the returned *p*-value less than `α = 0.01` indicate that `jbtest` rejects the null hypothesis.

Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact *p*-value.

```
[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)
```

```
h = 1
```

```
p = 0.0022
```

```
jbstat = 18.2275
```

```
critval = 5.8461
```

The returned value of `h = 1` indicates that `jbtest` rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, `jbstat`, is larger than the critical value, `critval`, which indicates rejection of the null hypothesis.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector. `jbtest` treats `NaN` values in `x` as missing values and ignores them.

Data Types: `single` | `double`

alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use `mctol`.

Example: `0.01`

Data Types: `single` | `double`

`mctol` — Maximum Monte Carlo standard error
nonnegative scalar value

Maximum Monte Carlo standard error on page 33-3054 for the *p*-value, `p`, specified as a nonnegative scalar value. If you specify a value for `mctol`, `jbtest` computes a Monte Carlo approximation for `p` directly, rather than interpolating into a table of precomputed values. `jbtest` chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for `p` less than `mctol`.

If you specify a value for `mctol`, you must also specify a value for `alpha`. You can specify `alpha` as `[]` to use the default value of 0.05.

Example: `0.0001`

Data Types: `single` | `double`

Output Arguments

`h` — Hypothesis test result
`1` | `0`

Hypothesis test result, returned as `1` or `0`.

- If `h = 1`, this indicates the rejection of the null hypothesis at the `alpha` significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the `alpha` significance level.

`p` — *p*-value
scalar value in the range (0,1)

p-value of the test, returned as a scalar value in the range (0,1). `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

`jbtest` warns when `p` is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use `mctol` to compute a more accurate *p*-value.

`jbstat` — Test statistic
nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

`critval` — Critical value
nonnegative scalar value

Critical value for the Jarque-Bera test at the `alpha` significance level, returned as a nonnegative scalar value. If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000,

`jbtest` looks up the critical value for the test in a table of precomputed values. If you use `mctol`, `jbtest` determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when `jbstat > critval`.

More About

Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

$$JB = \frac{n}{6}\left(s^2 + \frac{(k-3)^2}{4}\right),$$

where n is the sample size, s is the sample skewness, and k is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p-value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\widehat{p})(1-\widehat{p})}{\text{mcreps}}},$$

where $\widehat{p}$ is the estimated p-value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed. `jbtest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for $\widehat{p}$ less than the value specified for `mctol`.

Algorithms

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see `lillietest`) for small samples. `jbtest`, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

Introduced before R2006a

johnsrnd

Johnson system random numbers

Syntax

```
r = johnsrnd(quantiles,m,n)
r = johnsrnd(quantiles)
[r,type] = johnsrnd(...)
[r,type,coefs] = johnsrnd(...)
```

Description

`r = johnsrnd(quantiles,m,n)` returns an `m`-by-`n` matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by `quantiles`. `quantiles` is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles [–1.5 –0.5 0.5 1.5]. In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities [0.067 0.309 0.691 0.933]. `quantiles` may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

Note Because `r` is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

`r = johnsrnd(quantiles)` returns a scalar value.

`r = johnsrnd(quantiles,m,n,...)` or `r = johnsrnd(quantiles,[m,n,...])` returns an `m`-by-`n`-by-... array.

`[r,type] = johnsrnd(...)` returns the type of the specified distribution within the Johnson system. `type` is `'SN'`, `'SL'`, `'SB'`, or `'SU'`. Set `m` and `n` to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- `'SN'` — Identity transformation (normal distribution on page B-119)
- `'SL'` — Exponential transformation (lognormal distribution on page B-88)
- `'SB'` — Logistic transformation (bounded)
- `'SU'` — Hyperbolic sine transformation (unbounded)

`[r,type,coefs] = johnsrnd(...)` returns coefficients `coefs` of the transformation that defines the distribution. `coefs` is `[gamma, eta, epsilon, lambda]`. If `z` is a standard normal random variable and `h` is one of the transformations defined above, `r = lambda*h((z-gamma)/eta) +epsilon` is a random variate from the distribution type corresponding to `h`.

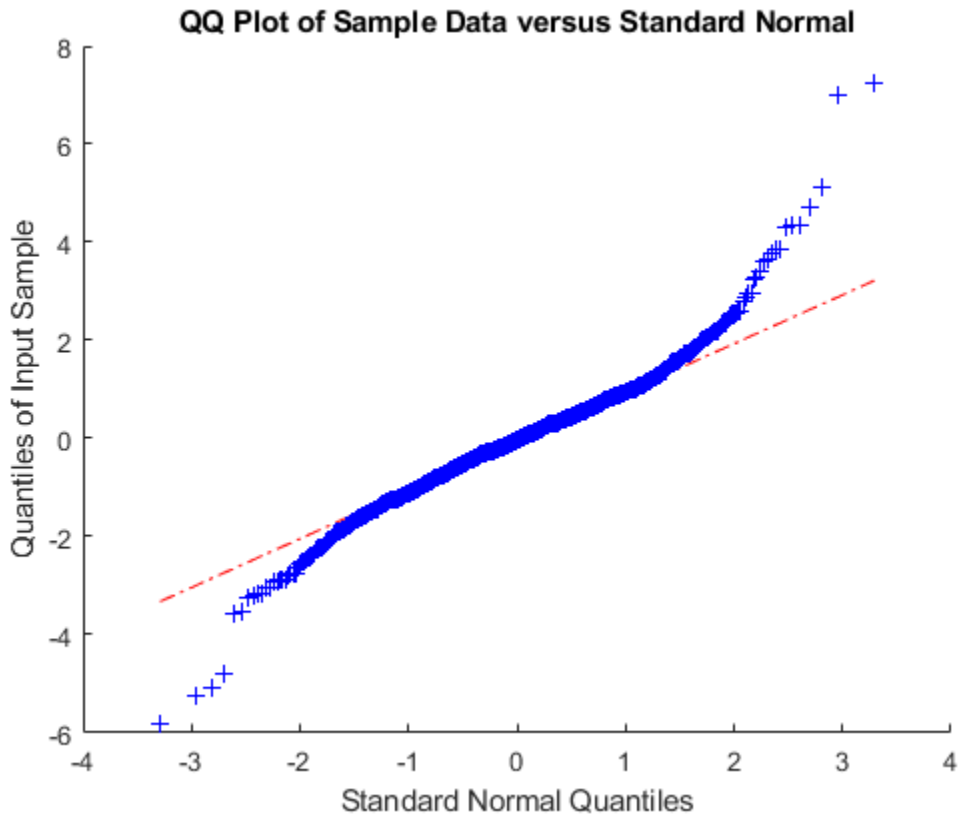
Examples

Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

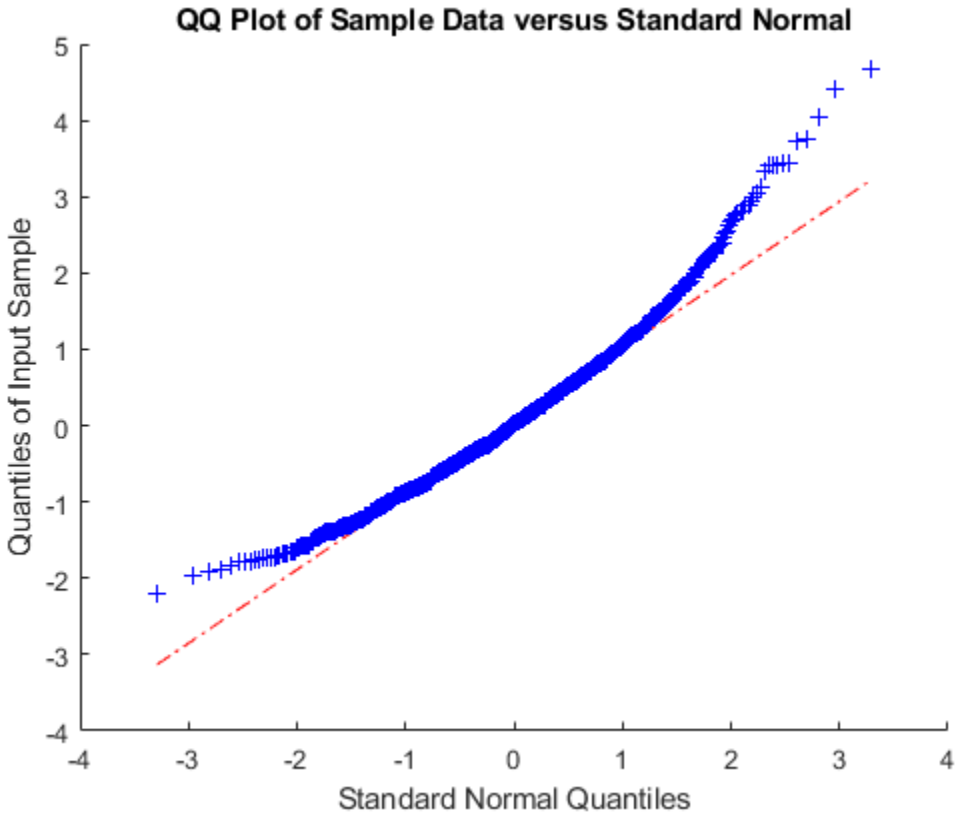
Generate random values with longer tails than a standard normal.

```
rng default;  % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```



Generate random values skewed to the right.

```
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```



Generate random values that match some sample data well in the right-hand tail.

```
load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]
```

```
ans = 2×4

   16.7000   18.2086   19.5376   21.7263
   16.6986   18.2220   19.9078   22.0918
```

Determine the distribution type and the coefficients.

```
[r,type,coefs] = johnsrnd([qnorm;q],0)
```

```
r =

     []

type =
'SU'

coefs = 1×4

    1.0920    0.5829   18.4382    1.4494
```

Introduced in R2006a

join

Class: `dataset`

(Not Recommended) Merge dataset array observations

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,val1,param2,val2,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)
```

Description

`C = join(A,B)` creates a dataset array `C` by merging observations from the two dataset arrays `A` and `B`. `join` performs the merge by first finding *key variables*, that is, pairs of dataset variables, one in `A` and one in `B`, that share the same name. Each observation in `B` must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from `A`. `join` then uses these key variables to define a many-to-one correspondence between observations in `A` and those in `B`. `join` uses this correspondence to replicate the observations in `B` and combine them with the observations in `A` to create `C`.

`C = join(A,B,keys)` performs the merge using the variables specified by `keys` as the key variables in both `A` and `B`. `keys` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

`C` contains one observation for each observation in `A`. Variables in `C` include all of the variables from `A`, as well as one variable corresponding to each variable in `B` (except for the keys from `B`). If `A` and `B` contain variables with identical names, `join` adds the suffix `'_left'` and `'_right'` to the corresponding variables in `C`.

`C = join(A,B,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control how the dataset variables in `A` and `B` are used in the merge. Parameters are:

- `'Keys'` — Specifies the variables to use as keys in both `A` and `B`.
- `'LeftKeys'` — Specifies the variables to use as keys in `A`.
- `'RightKeys'` — Specifies the variables to use as keys in `B`.

You may provide either the `'Keys'` parameter, or both the `'LeftKeys'` and `'RightKeys'` parameters. The value for these parameters is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. `'LeftKeys'` or `'RightKeys'` must both specify the same number of key variables, and `join` pairs the left and right keys in the order specified.

- `'LeftVars'` — Specifies which variables from `A` to include in `C`. By default, `join` includes all variables from `A`.
- `'RightVars'` — Specifies which variables from `B` to include in `C`. By default, `join` includes all variables from `B` except the key variables.

You can use `'LeftVars'` or `'RightVars'` to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

`[C,IB] = join(...)` returns an index vector `IB`, where `join` constructs `C` by horizontally concatenating `A(:,LeftVars)` and `B(IB,RightVars)`. `join` can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between `A` and `B`, and allow unmatched observations in either `A` or `B`.

`C = join(A,B,'Type',TYPE,...)` performs the join operation specified by `TYPE`. `TYPE` is one of `'inner'`, `'leftouter'`, `'rightouter'`, `'fullouter'`, or `'outer'` (which is a synonym for `'fullouter'`). For an inner join, `C` only contains observations corresponding to a combination of key values that occurred in both `A` and `B`. For a left (or right) outer join, `C` also contains observations corresponding to keys in `A` (or `B`) that did not match any in `B` (or `A`). Variables in `C` taken from `A` (or `B`) contain null values in those observations. A full outer join is equivalent to a left and right outer join. `C` contains variables corresponding to the key variables from both `A` and `B`, and `join` sorts the observations in `C` by the key values.

For inner and outer joins, `C` contains variables corresponding to the key variables from both `A` and `B` by default, as well as all the remaining variables. `join` sorts the observations in the result `C` by the key values.

`C = join(A,B,'Type',TYPE,'MergeKeys',true,...)` includes a single variable in `C` for each key variable pair from `A` and `B`, rather than including two separate variables. For outer joins, `join` creates the single variable by merging the key values from `A` and `B`, taking values from `A` where a corresponding observation exists in `A`, and from `B` otherwise. Setting the `'MergeKeys'` parameter to `true` overrides inclusion or exclusion of any key variables specified via the `'LeftVars'` or `'RightVars'` parameter. Setting the `'MergeKeys'` parameter to `false` is equivalent to not passing in the `'MergeKeys'` parameter.

`[C,IA,IB] = join(A,B,'Type',TYPE,...)` returns index vectors `IA` and `IB` indicating the correspondence between observations in `C` and those in `A` and `B`. For an inner join, `join` constructs `C` by horizontally concatenating `A(IA,LeftVars)` and `B(IB,RightVars)`. For an outer join, `IA` or `IB` may also contain zeros, indicating the observations in `C` that do not correspond to observations in `A` or `B`, respectively.

Examples

Create a dataset array from Fisher's iris data:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
               {meas,'SL','SW','PL','PW'},...
               'ObsNames',NameObs);
```

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```
snames = nominal({'setosa';'versicolor';'virginica'});
CC = dataset({snames,'species'},{[38;108;70],'cc'})
CC =
    species       cc
    setosa         38
    versicolor    108
    virginica      70
```

Broadcast the data in `CC` to the rows of `iris` using the key variable `species` in each dataset:

```
iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =
           species       SL     SW     PL     PW     cc
 Obs1      setosa        5.1    3.5    1.4    0.2     38
 Obs2      setosa        4.9      3    1.4    0.2     38
 Obs51     versicolor      7    3.2    4.7    1.4    108
 Obs52     versicolor    6.4    3.2    4.5    1.5    108
 Obs101    virginica     6.3    3.3      6    2.5     70
 Obs102    virginica     5.8    2.7    5.1    1.9     70
```

Create two datasets and join them using the `'MergeKeys'` flag:

```
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'}',[1 2 3 11 17]',...
   'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'}',[4 5 6 7]',...
   'VarNames',{'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
   'MergeKeys',true)

% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...
   'MergeKeys',true)

a =

    Key1       Var1
    'a'         1
    'b'         2
    'c'         3
    'e'        11
    'h'        17
```

```
b =

    Key1       Var2
    'a'        4
    'b'        5
    'd'        6
    'e'        7

couter =

    Key1_left    Var1    Key1_right    Var2
    'a'            1     'a'             4

KDTreeSearcher

Create *K*d-tree nearest neighbor searcher

Description

`KDTreeSearcher` model objects store the results of a nearest neighbor search that uses the *K*d-tree algorithm. Results include the training data, distance metric and its parameters, and maximum number of data points in each leaf node (that is, the bucket size). The *K*d-tree algorithm partitions an *n*-by-*K* data set by recursively splitting *n* points in *K*-dimensional space into a binary tree.

Once you create a `KDTreeSearcher` model object, you can search the stored tree to find all neighboring points to the query data by performing a nearest neighbor search using `knnsearch` or a radius search using `rangesearch`. The *K*d-tree algorithm is more efficient than the exhaustive search algorithm when *K* is small (that is, $K \leq 10$), the training and query sets are not sparse, and the training and query sets have many observations.

Creation

Use either the `createns` function or the `KDTreeSearcher` function (described here) to create a `KDTreeSearcher` model object. Both functions use the same syntax except that the `createns` function has the `'NSMethod'` name-value pair argument, which you use to choose the nearest neighbor search method. The `createns` function also creates an `ExhaustiveSearcher` object. Specify `'NSMethod','kdtree'` to create a `KDTreeSearcher` object. The default is `'kdtree'` if *K* ≤ 10, the training data is not sparse, and the distance metric is Euclidean, city block, Chebychev, or Minkowski.

Syntax

```
Mdl = KDTreeSearcher(X)
Mdl = KDTreeSearcher(X,Name,Value)
```

Description

`Mdl = KDTreeSearcher(X)` grows a default *K*d-tree (`Mdl`) using the *n*-by-*K* numeric matrix of training data (`X`).

`Mdl = KDTreeSearcher(X,Name,Value)` specifies additional options using one or more name-value pair arguments. You can specify the maximum number of data points in each leaf node (that is, the bucket size) and the distance metric, and set the distance metric parameter (`DistParameter`) property. For example, `KDTreeSearcher(X,'Distance','minkowski','BucketSize',10)` specifies to use the Minkowski distance when searching for nearest neighbors and to use `10` for the bucket size. To specify `DistParameter`, use the `P` name-value pair argument.

Input Arguments

`X` — Training data
numeric matrix

Training data that grows the *K*d-tree, specified as a numeric matrix. `X` has *n* rows, each corresponding to an observation (that is, an instance or example), and *K* columns, each corresponding to a predictor (that is, a feature).

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distance','minkowski','P',3,'BucketSize',10` specifies to use the following when searching for nearest neighbors: the Minkowski distance, `3` for the Minkowski distance metric exponent, and `10` for the bucket size.

`Distance` — Distance metric

`'euclidean'` (default) | `'chebychev'` | `'cityblock'` | `'minkowski'`

Distance metric used when you call `knnsearch` or `rangesearch` to find nearest neighbors for future query points, specified as the comma-separated pair consisting of `'Distance'` and one of these values.

Value	Description
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'cityblock'`	City block distance.
`'euclidean'`	Euclidean distance.
`'minkowski'`	Minkowski distance. The default exponent is 2. To specify a different exponent, use the `'P'` name-value pair argument.

For more details, see “Distance Metrics” on page 18-12.

The software does not use the distance metric for creating a `KDTreeSearcher` model object, so you can alter the distance metric by using dot notation after creating the object.

Example: `'Distance','minkowski'`

`P` — Exponent for Minkowski distance metric

`2` (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. This argument is valid only if `'Distance'` is `'minkowski'`.

Example: `'P',3`

Data Types: `single` | `double`

`BucketSize` — Maximum number of data points in each leaf node

`50` (default) | positive integer

Maximum number of data points in each leaf node of the *K*d-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer.

Example: `'BucketSize',10`

Data Types: `single` | `double`

Properties

X — Training data
numeric matrix

This property is read-only.

Training data that grows the *K*d-tree, specified as a numeric matrix. `X` has *n* rows, each corresponding to an observation (that is, an instance or example), and *K* columns, each corresponding to a predictor (that is, a feature).

The input argument `X` of `createns` or `KDTreeSearcher` sets this property.

Data Types: `single` | `double`

`Distance` — Distance metric
`'chebychev'` | `'cityblock'` | `'minkowski'`

Distance metric used when you call `knnsearch` or `rangesearch` to find nearest neighbors for future query points, specified as `'chebychev'`, `'cityblock'`, `'euclidean'`, or `'minkowski'`.

The `'Distance'` name-value pair argument of `createns` or `KDTreeSearcher` sets this property.

The software does not use the distance metric for creating a `KDTreeSearcher` model object, so you can alter it by using dot notation.

`DistParameter` — Distance metric parameter values
`[]` | positive scalar

Distance metric parameter values, specified as empty (`[]`) or a positive scalar.

If `Distance` is `'minkowski'`, then `DistParameter` is the exponent in the Minkowski distance formula. Otherwise, `DistParameter` is `[]`, indicating that the specified distance metric formula has no parameters.

The `'P'` name-value pair argument of `createns` or `KDTreeSearcher` sets this property.

You can alter `DistParameter` by using dot notation, for example, `Mdl.DistParameter = PNew`, where `PNew` is a positive scalar.

Data Types: `single` | `double`

`BucketSize` — Maximum number of data points in each leaf node
positive integer

This property is read-only.

Maximum number of data points in each leaf node of the *K*d-tree, specified as a positive integer.

The `'BucketSize'` name-value pair argument of `createns` or `KDTreeSearcher` sets this property.

Data Types: `single` | `double`

Object Functions

knnsearch Find k-nearest neighbors using searcher object

rangesearch Find all neighbors within specified distance using searcher object

Examples

Grow Default *K*d-Tree

Grow a four-dimensional *K*d-tree that uses the Euclidean distance.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n = 150
```

```
k = 4
```

`X` has 150 observations and 4 predictors.

Grow a four-dimensional *K*d-tree using the entire data set as training data.

```
Mdl1 = KDTreeSearcher(X)
```

```
Mdl1 =
  KDTreeSearcher with properties:

       BucketSize: 50
         Distance: 'euclidean'
    DistParameter: []
                X: [150x4 double]
```

`Mdl1` is a `KDTreeSearcher` model object, and its properties appear in the Command Window. The object contains information about the grown four-dimensional *K*d-tree, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can grow a *K*d-tree by using `createns`.

```
Mdl2 = createns(X)
```

```
Mdl2 =
  KDTreeSearcher with properties:

       BucketSize: 50
         Distance: 'euclidean'
    DistParameter: []
                X: [150x4 double]
```

`Mdl2` is also a `KDTreeSearcher` model object, and it is equivalent to `Mdl1`. Because `X` has four columns and the default distance metric is Euclidean, `createns` creates a `KDTreeSearcher` model by default.

To find the nearest neighbors in `X` to a batch of query data, pass the `KDTreeSearcher` model object and the query data to `knnsearch` or `rangesearch`.

Specify the Minkowski Distance for Nearest Neighbor Search

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris
X = meas(:,[3 4]); % Predictors
```

Grow a two-dimensional *K*d-tree using `createns` and the training data. Specify the Minkowski distance metric.

```
Mdl = createns(X,'Distance','Minkowski')
```

```
Mdl =
  KDTreeSearcher with properties:

       BucketSize: 50
         Distance: 'minkowski'
    DistParameter: 2
                X: [150x2 double]
```

Because `X` has two columns and the distance metric is Minkowski, `createns` creates a `KDTreeSearcher` model object by default.

Access properties of `Mdl` by using dot notation. For example, use `Mdl.DistParameter` to access the Minkowski distance exponent.

```
Mdl.DistParameter
```

```
ans = 2
```

You can pass query data and `Mdl` to:

- `knnsearch` to find indices and distances of nearest neighbors
- `rangesearch` to find indices of all nearest neighbors within a distance that you specify

Alter Properties of `KDTreeSearcher` Model

Create a `KDTreeSearcher` model object and alter the `Distance` property by using dot notation.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

Grow a default four-dimensional *K*d-tree using the entire data set as training data.

```
Mdl = KDTreeSearcher(X)
```

```
Mdl =
  KDTreeSearcher with properties:
```

```
       BucketSize: 50
         Distance: 'euclidean'
    DistParameter: []
                X: [150x4 double]
```

Specify that the neighbor searcher use the Minkowski metric to compute the distances between the training and query data.

```
Mdl.Distance = 'minkowski'
```

```
Mdl =
  KDTreeSearcher with properties:

       BucketSize: 50
         Distance: 'minkowski'
    DistParameter: 2
                X: [150x4 double]
```

You can pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data based on the Minkowski distance.

Search for Nearest Neighbors of Query Data Using Minkowski Distance

Grow a *K*d-tree nearest neighbor searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find *k*-nearest neighbors.

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional *K*d-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```
Mdl = createns(X,'Distance','minkowski')
```

```
Mdl =
  KDTreeSearcher with properties:

       BucketSize: 50
         Distance: 'minkowski'
    DistParameter: 2
                X: [145x4 double]
```

Because `X` has four columns and the distance metric is Minkowski, `createns` creates a `KDTreeSearcher` model object by default. The Minkowski distance exponent is `2` by default.

Find the indices of the training data (`Mdl.X`) that are the two nearest neighbors of each point in the query data (`Q`).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

```
IdxNN = 5×2

    17     4
     6     2
     1    12
    89    66
   124   100
```

Each row of `IdxNN` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, based on the Minkowski distance, the second nearest neighbor of `Q(3,:)` is `X(12,:)`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations: The `knnsearch` and `rangesearch` functions support code generation.

For more information, see “Introduction to Code Generation” on page 32-2 and “Code Generation for Nearest Neighbor Searcher” on page 32-19.

Introduced in R2010a

kfoldEdge

Package: `classreg.learning.partition`

Classification edge for cross-validated ECOC model

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 33-3076 obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using an ECOC model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Edge

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the edges.

```
edge = kfoldEdge(CVMdl)
```

```
edge = 0.4825
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode','individual'` in `kfoldEdge`.

Display Individual Edges for Each Cross-Validation Fold

The classification edge is a relative measure of classifier quality. To determine which folds perform poorly, display the edges for each fold.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Use 8-fold cross-validation, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the classification edge for each fold.

```
edges = kfoldEdge(CVMdl,'Mode','individual')
```

```
edges = 8×1

    0.4792
    0.4872
    0.4259
    0.5302
    0.5064
    0.4575
    0.4860
    0.4687
```

The edges have similar magnitudes across folds. Folds that perform poorly have small edges relative to the other folds.

To return the average classification edge across the folds that perform well, specify the `'Folds'` name-value pair argument.

Select ECOC Model Features by Comparing Cross-Validation Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define the following two data sets.

- `fullX` contains all the predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

For each predictor set, train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedECOC` models. By default, the software implements 10-fold cross-validation.

Estimate the edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
```

```
fullEdge = 0.4825
```

```
partEdge = kfoldEdge(PCVMdl)
```

```
partEdge = 0.4951
```

The two models have comparable edges.

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`.
- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldEdge(CVMdl,'BinaryLoss','hinge')` specifies `'hinge'` as the binary learner loss function.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3259.

Example: `'Decoding','lossbased'`

`Folds` — Fold indices for prediction
`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from `1` to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`Mode` — Aggregation level for output
`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
`'average'`	The output is a scalar average over all folds.

Value	Description
`'individual'`	The output is a vector of length *k* containing one value per fold, where *k* is the number of folds.

Example: `'Mode','individual'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

edge — Classification edge
numeric scalar | numeric column vector

Classification edge on page 33-3076, returned as a numeric scalar or numeric column vector.

If `Mode` is `'average'`, then `edge` is the average classification edge over all folds. Otherwise, `edge` is a *k*-by-1 numeric column vector containing the classification edge for each fold, where *k* is the number of folds.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same

scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldEdge

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification ensemble `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitcensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`folds`

Indices of folds ranging from `1` to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

`mode`

Character vector or string scalar representing the meaning of the output `edge`:

- `'average'` — `edge` is a scalar value, the average over all folds.
- `'individual'` — `edge` is a vector of length `ens.KFold` with one element per fold.
- `'cumulative'` — `edge` is a vector of length `min(ens.NTrainedPerFold)` in which element `J` is obtained by averaging values across all folds for weak learners `1:J` in each fold.

Default: `'average'`

Output Arguments

E

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

Compute K-Fold Edge of Held-Out Observations

Compute the k-fold edge for an ensemble trained on the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Learners',t);
```

Create a cross-validated ensemble from `ens` and find the classification edge.

```
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
E = kfoldEdge(cvens)
```

```
E = 3.2033
```

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from –∞ to ∞.
- `Bag` scores range from `0` to `1`.

kfoldEdge

Package: `classreg.learning.partition`

Classification edge for cross-validated kernel classification model

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 33-3085 obtained by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using a model trained on training-fold observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds or the aggregation level.

Examples

Estimate *k*-Fold Cross-Validation Edge

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```
CVMdl =
  ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
           ResponseName: 'Y'
        NumObservations: 351
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'b'  'g'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the cross-validated classification edge.

```
edge = kfoldEdge(CVMdl)
```

```
edge = 1.5585
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode','individual'` in `kfoldEdge`.

Feature Selection Using *k*-Fold Edges

Perform feature selection by comparing *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Randomly choose half of the predictor variables.

```
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Cross-validate two binary kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```
CVMdl = fitckernel(X,Y,'CrossVal','on');
PCVMdl = fitckernel(X(:,idxPart),Y,'CrossVal','on');
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedKernel` models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the *k*-fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
```

```
fullEdge = 1.5142
```

```
partEdge = kfoldEdge(PCVMdl)
```

```
partEdge = 1.8910
```

Based on the *k*-fold edges, the classifier that uses half of the predictors is the better model.

Input Arguments

`CVMdl` — Cross-validated, binary kernel classification model

`ClassificationPartitionedKernel` model object

Cross-validated, binary kernel classification model, specified as a `ClassificationPartitionedKernel` model object. You can create a

`ClassificationPartitionedKernel` model by using `fitckernel` and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, `kfoldEdge` applies the same data used to cross-validate the kernel classification model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldEdge(CVMdl,'Mode','individual')` returns the classification edge for each fold.

`Folds` — Fold indices for prediction

`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from `1` to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`Mode` — Aggregation level for output

`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
`'average'`	The output is a scalar average over all folds.
`'individual'`	The output is a vector of length *k* containing one value per fold, where *k* is the number of folds.

Example: `'Mode','individual'`

Output Arguments

edge — Classification edge

numeric scalar | numeric column vector

Classification edge on page 33-3085, returned as a numeric scalar or numeric column vector.

If `Mode` is `'average'`, then `edge` is the average classification edge over all folds. Otherwise, `edge` is a *k*-by-1 numeric column vector containing the classification edge for each fold, where *k* is the number of folds.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and –1 otherwise. $f(x)$ is the positive-class classification score for the observation x. The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the `'logit'` score transformation to the raw classification scores (see `ScoreTransform`).

kfoldEdge

Package: `classreg.learning.partition`

Classification edge for cross-validated kernel ECOC model

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 33-3090 obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using a model trained on training-fold observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Edge

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

```
CVMdl =
  ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
           ResponseName: 'Y'
        NumObservations: 150
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'setosa'  'versicolor'  'virginica'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the cross-validated classification edges.

```
edge = kfoldEdge(CVMdl)
```

```
edge = 0.4145
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode','individual'` in `kfoldEdge`.

Feature Selection Using *k*-Fold Edges

Perform feature selection by comparing *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Randomly choose half of the predictor variables.

```
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Cross-validate two ECOC models composed of kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on');
PCVMdl = fitcecoc(X(:,idxPart),Y,'Learners','kernel','CrossVal','on');
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedKernelECOC` models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the *k*-fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
```

```
fullEdge = 0.4092
```

```
partEdge = kfoldEdge(PCVMdl)
```

```
partEdge = 0.4161
```

Based on the *k*-fold edges, the two classifiers are comparable.

Input Arguments

`CVMdl` — Cross-validated kernel ECOC model

`ClassificationPartitionedKernelECOC` model

Cross-validated kernel ECOC model, specified as a `ClassificationPartitionedKernelECOC` model. You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitcecoc` and specifying these name-value pair arguments:

- `'Learners'`– Set the value to `'kernel'`, a template object returned by `templateKernel`, or a cell array of such template objects.
- One of the arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldEdge(CVMdl,'BinaryLoss','hinge')` specifies `'hinge'` as the binary learner loss function.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

where:

- `M` is the *K*-by-*L* coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by-*L* row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- *K* is the number of classes.
- *L* is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3090.

Example: `'Decoding','lossbased'`

`Folds` — Fold indices for prediction
`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from `1` to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`Mode` — Aggregation level for output
`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
`'average'`	The output is a scalar average over all folds.
`'individual'`	The output is a vector of length *k* containing one value per fold, where *k* is the number of folds.

Example: `'Mode','individual'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

edge — Classification edge
numeric scalar | numeric column vector

Classification edge on page 33-3090, returned as a numeric scalar or numeric column vector.

If `Mode` is `'average'`, then `edge` is the average classification edge over all folds. Otherwise, `edge` is a *k*-by-1 numeric column vector containing the classification edge for each fold, where *k* is the number of folds.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or $(-\infty,\infty)$	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'logit'`	Logistic	$(-\infty,\infty)$	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Introduced in R2018b

kfoldEdge

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl,Name,Value)
```

Description

`e = kfoldEdge(CVMdl)` returns the cross-validated classification edges on page 33-3098 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMdl`.

`e = kfoldEdge(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the edge calculation.

Input Arguments

`CVMdl` — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, kfoldEdge applies the same data used to cross-validate the linear classification model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Folds` — Fold indices to use for classification-score prediction

`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from `1` through `CVMdl.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

Mode — Edge aggregation level
`'average'` (default) | `'individual'`

Edge aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
`'average'`	Returns classification edges averaged over all folds
`'individual'`	Returns classification edges for each fold

Example: `'Mode','individual'`

Output Arguments

e — Cross-validated classification edges
numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges on page 33-3098, returned as a numeric scalar, vector, or matrix.

Let L be the number of regularization strengths in the cross-validated models (that is, L is `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then `e` is a 1-by-L vector. `e(`j`)` is the average classification edge over all folds of the cross-validated model that uses regularization strength j.
- Otherwise, `e` is an F-by-L matrix. `e(`i`,`j`)` is the classification edge for fold i of the cross-validated model that uses regularization strength j.

To estimate `e`, `kfoldEdge` uses the data that created `CVMdl` (see `X` and `Y`).

Examples

Estimate *k*-Fold Cross-Validation Edge

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the out-of-fold edges.

```
e = kfoldEdge(CVMdl)
```

```
e = 8.1243
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode','individual'` in `kfoldEdge`.

Feature Selection Using *k*-fold Edges

One way to perform feature selection is to compare *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Edge” on page 33-3094.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

```
CVMdl = fitclinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
PCVMdl = fitclinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedLinear` models.

Estimate the *k*-fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
```

```
fullEdge = 16.5629
```

```
partEdge = kfoldEdge(PCVMdl)
```

```
partEdge = 13.9030
```

Based on the *k*-fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using *k*-fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k-fold edges.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Edge” on page 33-3094.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^{1}.

```
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
  ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
        NumObservations: 31572
                  KFold: 5
              Partition: [1x1 cvpartition]
             ClassNames: [0 1]
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedLinear` model. Because `fitclinear` implements 5-fold cross-validation, `CVMdl` contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the edges for each fold and regularization strength.

```
eFolds = kfoldEdge(CVMdl,'Mode','individual')
```

```
eFolds = 5×11

    0.9958    0.9958    0.9958    0.9958    0.9958    0.9924    0.9769    0.9204    0.8424    0.8
    0.9991    0.9991    0.9991    0.9991    0.9991    0.9938    0.9777    0.9177    0.8263    0.8
    0.9992    0.9992    0.9992    0.9992    0.9992    0.9942    0.9779    0.9210    0.8255    0.8
    0.9974    0.9974    0.9974    0.9974    0.9974    0.9931    0.9773    0.9131    0.8422    0.8
```

```
    0.9976    0.9976    0.9976    0.9976    0.9976    0.9942    0.9783    0.9197    0.8390    0.8
```

`eFolds` is a 5-by-11 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in `Lambda`. You can use `eFolds` to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

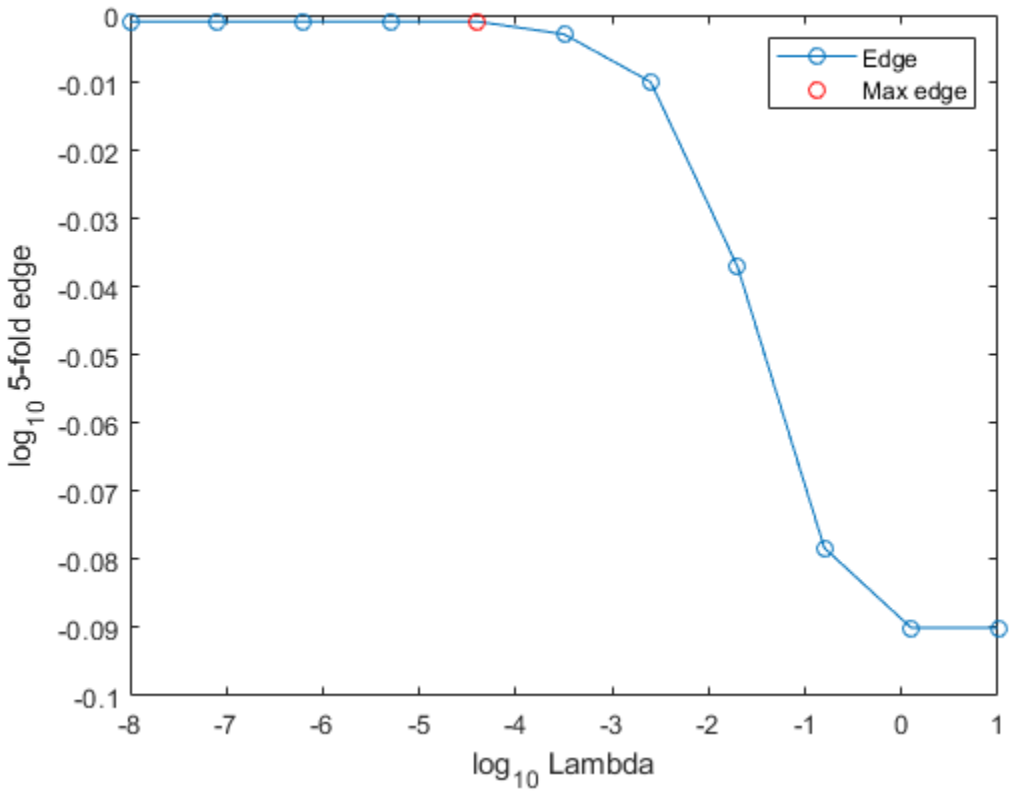
```
e = kfoldEdge(CVMdl)
```

```
e = 1×11

    0.9978    0.9978    0.9978    0.9978    0.9978    0.9936    0.9776    0.9184    0.8351    0.8
```

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

```
figure;
plot(log10(Lambda),log10(e),'-o')
[~, maxEIdx] = max(e);
maxLambda = Lambda(maxEIdx);
hold on
plot(log10(maxLambda),log10(e(maxEIdx)),'ro');
ylabel('log_{10} 5-fold edge')
xlabel('log_{10} Lambda')
legend('Edge','Max edge')
hold off
```



Several values of `Lambda` yield similarly high edges. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and –1 otherwise. $f(x)$ is the positive-class classification score for the observation x. The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For linear classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j, β_j is the estimated column vector of coefficients (the model property `Beta(:,j)`) and b_j is the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the `'logit'` score transformation to the raw classification scores (see `ScoreTransform`).

Introduced in R2016a

kfoldEdge

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl,Name,Value)
```

Description

`e = kfoldEdge(CVMdl)` returns the cross-validated classification edges on page 33-3108 obtained by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMdl`.

`e = kfoldEdge(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme, which folds to use for the edge calculation, or verbosity level.

Input Arguments

`CVMdl` — Cross-validated, ECOC model composed of linear classification models

`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model using `fitcecoc` and by:

1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
2. Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, kfoldEdge applies the same data used to cross-validate the ECOC model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3259.

Example: `'Decoding','lossbased'`

`Folds` — Fold indices to use for classification-score prediction
`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from `1` through `CVMdl.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`Mode` — Edge aggregation level
`'average'` (default) | `'individual'`

Edge aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
`'average'`	Returns classification edges averaged over all folds
`'individual'`	Returns classification edges for each fold

Example: `'Mode','individual'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

e — Cross-validated classification edges

numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges on page 33-3108, returned as a numeric scalar, vector, or matrix.

Let L be the number of regularization strengths in the cross-validated models (that is, L is `numel(CVMdl.Trained{1}.BinaryLearners{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then `e` is a 1-by-L vector. `e(j)` is the average classification edge over all folds of the cross-validated model that uses regularization strength j.
- Otherwise, `e` is a F-by-L matrix. `e(i,j)` is the classification edge for fold i of the cross-validated model that uses regularization strength j.

Examples

Estimate *k*-Fold Cross-Validation Edge

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in `Y` that are not `'simulink'`, `'dsp'`, or `'comm'`.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the out-of-fold edges.

```
e = kfoldEdge(CVMdl)
```

```
e = 0.7232
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode','individual'` in `kfoldEdge`.

Feature Selection Using *k*-fold Edges

One way to perform feature selection is to compare *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Edge” on page 33-3103, and orient the predictor data so that observations correspond to columns.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains a 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies to optimize the objective function using SpaRSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```
CVMdl = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
PCVMdl = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedLinearECOC` models.

Estimate the *k*-fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
```

```
fullEdge = 0.3090
```

```
partEdge = kfoldEdge(PCVMdl)
```

```
partEdge = 0.2617
```

Based on the *k*-fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using *k*-fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k-fold edges.

Load the NLP data set. Preprocess the data as in “Feature Selection Using k-fold Edges” on page 33-3103.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 8 logarithmically-spaced regularization strengths from 10^{-8} through 10^{1}.

```
Lambda = logspace(-8,1,8);
```

Create a linear classification model template that specifies to use logistic regression with a lasso penalty, use each of the regularization strengths, optimize the objective function using SpaRSA, and reduce the tolerance on the gradient of the objective function to `1e-8`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```
rng(10) % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```
CVMdl =
  ClassificationPartitionedLinearECOC
    CrossValidatedModel: 'LinearECOC'
           ResponseName: 'Y'
        NumObservations: 31572
                  KFold: 5
              Partition: [1x1 cvpartition]
             ClassNames: [comm    dsp    simulink    others]
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model.

Estimate the edges for each fold and regularization strength.

```
eFolds = kfoldEdge(CVMdl,'Mode','individual')
```

```
eFolds = 5×8

    0.5533    0.5553    0.5554    0.5541    0.4948    0.2930    0.1044    0.0855
    0.5249    0.5261    0.5265    0.5266    0.4796    0.2948    0.1063    0.0867
    0.5316    0.5323    0.5326    0.5322    0.4792    0.2888    0.1039    0.0868
    0.5375    0.5392    0.5402    0.5364    0.4835    0.2918    0.1018    0.0853
    0.5502    0.5560    0.5585    0.5575    0.4947    0.2929    0.1026    0.0849
```

`eFolds` is a 5-by-8 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in `Lambda`. You can use `eFolds` to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

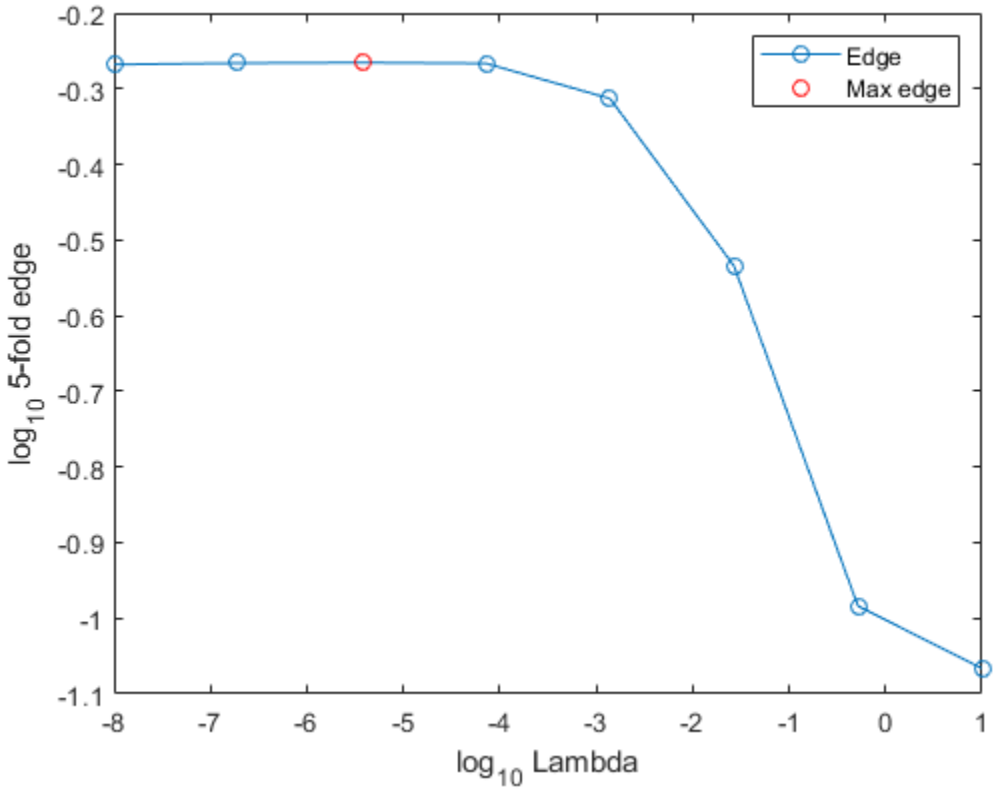
```
e = kfoldEdge(CVMdl)
```

```
e = 1×8

    0.5395    0.5418    0.5426    0.5414    0.4863    0.2923    0.1038    0.0859
```

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

```
figure
plot(log10(Lambda),log10(e),'-o')
[~, maxEIdx] = max(e);
maxLambda = Lambda(maxEIdx);
hold on
plot(log10(maxLambda),log10(e(maxEIdx)),'ro')
ylabel('log_{10} 5-fold edge')
xlabel('log_{10} Lambda')
legend('Edge','Max edge')
hold off
```



Several values of `Lambda` yield similarly high edges. Greater regularization strength values lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

```
LambdaFinal = Lambda(4);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',LambdaFinal,'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or $(-\infty,\infty)$	$[1 - \text{sign}(y_js_j)]/2$

Value	Description	Score Domain	$g(y_j,s_j)$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_j s_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_j s_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldEdge

Package: `classreg.learning.partition`

Classification edge for cross-validated classification model

Syntax

```
E = kfoldEdge(CVMdl)
E = kfoldEdge(CVMdl,Name,Value)
```

Description

`E = kfoldEdge(CVMdl)` returns the classification edge on page 33-3114 obtained by the cross-validated classification model `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using a classifier trained on training-fold observations. `CVMdl.X` and `CVMdl.Y` contain both sets of observations.

`E = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value arguments. For example, specify the folds to use or specify to compute the classification edge for each individual fold.

Examples

Estimate *k*-fold Edge of Classifier

Compute the *k*-fold edge for a model trained on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
tree = fitctree(meas,species);
```

Cross-validate the classifier using 10-fold cross-validation.

```
cvtree = crossval(tree);
```

Compute the *k*-fold edge.

```
edge = kfoldEdge(cvtree)
```

```
edge = 0.8578
```

Compute K-Fold Edge of Held-Out Observations

Compute the k-fold edge for an ensemble trained on the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Learners',t);
```

Create a cross-validated ensemble from `ens` and find the classification edge.

```
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
E = kfoldEdge(cvens)
```

```
E = 3.2033
```

Input Arguments

`CVMdl` — Cross-validated partitioned classifier

`ClassificationPartitionedModel` object | `ClassificationPartitionedEnsemble` object | `ClassificationPartitionedGAM` object

Cross-validated partitioned classifier, specified as a `ClassificationPartitionedModel`, `ClassificationPartitionedEnsemble`, or `ClassificationPartitionedGAM` object. You can create the object in two ways:

- Pass a trained classification model listed in the following table to its `crossval` object function.
- Train a classification model using a function listed in the following table and specify one of the cross-validation name-value arguments for the function.

Classification Model	Function
`ClassificationDiscriminant`	`fitcdiscr`
`ClassificationEnsemble`	`fitcensemble`
`ClassificationGAM`	`fitcgam`
`ClassificationKNN`	`fitcknn`
`ClassificationNaiveBayes`	`fitcnb`
`ClassificationNeuralNetwork`	`fitcnet`
`ClassificationSVM`	`fitcsvm`
`ClassificationTree`	`fitctree`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldEdge(CVMdl,'Folds',[1 2 3 5])` specifies to use the first, second, third, and fifth folds to compute the classification edge, but to exclude the fourth fold.

`Folds` — Fold indices to use

`1:CVMdl.KFold` (default) | positive integer vector

Fold indices to use, specified as a positive integer vector. The elements of `Folds` must be within the range from `1` to `CVMdl.KFold`.

The software uses only the folds specified in `Folds`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`IncludeInteractions` — Flag to include interaction terms
`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `CVMdl` is `ClassificationPartitionedGAM`.

The default value is `true` if the models in `CVMdl` (`CVMdl.Trained`) contain interaction terms. The value must be `false` if the models do not contain interaction terms.

Example: `'IncludeInteractions',false`

Data Types: `logical`

`Mode` — Aggregation level for output
`'average'` (default) | `'individual'` | `'cumulative'`

Aggregation level for the output, specified as `'average'`, `'individual'`, or `'cumulative'`.

Value	Description
`'average'`	The output is a scalar average over all folds.
`'individual'`	The output is a vector of length k containing one value per fold, where k is the number of folds.

Value	Description

`'cumulative'`	**Note** If you want to specify this value, `CVMdl` must be a `ClassificationPartitionedEnsemble` object or `ClassificationPartitionedGAM` object.
	
	• If `CVMdl` is `ClassificationPartitionedEnsemble`, then the output is a vector of length `min(CVMdl.NumTrainedPerFold)`. Each element `j` is an average over all folds that the function obtains by using ensembles trained with weak learners `1:j`.
	• If `CVMdl` is `ClassificationPartitionedGAM`, then the output value depends on the `IncludeInteractions` value.
	  • If `IncludeInteractions` is `false`, then `L` is a `(1 + min(NumTrainedPerFold.PredictorTrees))`-by-1 numeric column vector. The first element of `L` is an average over all folds that is obtained only the intercept (constant) term. The `(j + 1)`th element of `L` is an average obtained using the intercept term and the first `j` predictor trees per linear term.
	  • If `IncludeInteractions` is `true`, then `L` is a `(1 + min(NumTrainedPerFold.InteractionTrees))`-by-1 numeric column vector. The first element of `L` is an average over all folds that is obtained using the intercept (constant) term and all predictor trees per linear term. The `(j + 1)`th element of `L` is an average obtained using the intercept term, all predictor trees per linear term, and the first `j` interaction trees per interaction term.

Example: `'Mode','individual'`

Output Arguments

E — Classification edge

numeric scalar | numeric column vector

Classification edge on page 33-3114, returned as a numeric scalar or numeric column vector.

- If `Mode` is `'average'`, then `E` is the average classification edge over all folds.
- If `Mode` is `'individual'`, then `E` is a *k*-by-1 numeric column vector containing the classification edge for each fold, where *k* is the number of folds.
- If `Mode` is `'cumulative'` and `CVMdl` is `ClassificationPartitionedEnsemble`, then `E` is a `min(CVMdl.NumTrainedPerFold)`-by-1 numeric column vector. Each element `j` is the average classification edge over all folds that the function obtains by using ensembles trained with weak learners `1:j`.
- If `Mode` is `'cumulative'` and `CVMdl` is `ClassificationPartitionedGAM`, then the output value depends on the `IncludeInteractions` value.
  - If `IncludeInteractions` is `false`, then `L` is a `(1 + min(NumTrainedPerFold.PredictorTrees))`-by-1 numeric column vector. The first

element of `L` is the average classification edge over all folds that is obtained using only the intercept (constant) term. The `(j + 1)`th element of `L` is the average edge obtained using the intercept term and the first `j` predictor trees per linear term.

- If `IncludeInteractions` is `true`, then `L` is a `(1 + min(NumTrainedPerFold.InteractionTrees))`-by-1 numeric column vector. The first element of `L` is the average classification edge over all folds that is obtained using the intercept (constant) term and all predictor trees per linear term. The `(j + 1)`th element of `L` is the average edge obtained using the intercept term, all predictor trees per linear term, and the first `j` interaction trees per interaction term.

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class. The classification margin for multiclass classification is the difference between the classification score for the true class and the maximal score for the false classes.

If the margins are on the same scale (that is, the score values are based on the same score transformation), then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Algorithms

`kfoldEdge` computes the classification edge as described in the corresponding `edge` object function. For a model-specific description, see the appropriate `edge` function reference page in the following table.

Model Type	edge Function
Discriminant analysis classifier	`edge`
Ensemble classifier	`edge`
Generalized additive model classifier	`edge`
k-nearest neighbor classifier	`edge`
Naive Bayes classifier	`edge`
Neural network classifier	`edge`
Support vector machine classifier	`edge`
Binary decision tree for multiclass classification	`edge`

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports *k*-nearest neighbor and SVM model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`ClassificationPartitionedModel` | `kfoldLoss` | `kfoldMargin` | `kfoldPredict` | `kfoldfun`

Introduced in R2011a

kfoldfun

Package: `classreg.learning.partition`

Cross-validate function using cross-validated ECOC model

Syntax

```
vals = kfoldfun(CVMdl,fun)
```

Description

`vals = kfoldfun(CVMdl,fun)` cross-validates the function `fun` by applying `fun` to the data stored in the cross-validated ECOC model `CVMdl`. You must pass `fun` as a function handle.

Examples

Estimate Classification Error Using Custom Loss Function

Train a multiclass ECOC classifier, and then cross-validate the model using a custom *k*-fold loss function.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation.

Compute the classification error (proportion of misclassified observations) for the validation-fold observations.

```
L = kfoldLoss(CVMdl)
```

```
L = 0.0400
```

Examine the result when the cost of misclassifying a flower as `versicolor` is `10` and the cost of any other error is `1`. Write a function named `noversicolor` that assigns a cost of `1` for general misclassification and a cost of `10` for misclassifying a flower as `versicolor`.

If you use the live script file for this example, the `noversicolor` function is already included at the end of the file. Otherwise, you need to create this function at the end of your .m file or add it as a file on the MATLAB path.

Compute the mean misclassification error with the `noversicolor` cost.

```
foldLoss = kfoldfun(CVMdl,@noversicolor);
mean(foldLoss)
```

```
ans = 0.0667
```

This code creates the function `noversicolor`.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
% noversicolor: Example custom cross-validation function that assigns a cost of
%   10 for misclassifying versicolor irises and a cost of 1 for misclassifying
%   the other irises. This example function requires the fisheriris data
%   set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = single(cost/numel(Ytest)); % Average error
end
```

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model.

`fun` — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has this syntax:

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` is the set of training weights for observations.
- `Xtest` and `Ytest` are the validation data, with associated weights `Wtest`.
- The returned value `testvals` must have the same size across all folds.

Data Types: `function_handle`

Output Arguments

`vals` — Cross-validation results

numeric matrix

Cross-validation results, returned as a numeric matrix. `vals` corresponds to the arrays of the `testvals` output, concatenated vertically over all the folds. For example, if `testvals` from every fold is a numeric vector of length *n*, `kfoldfun` returns a `KFold`-by-*n* numeric matrix with one row per fold.

Introduced in R2014b

kfoldfun

Package: `classreg.learning.partition`

Cross-validate function for classification

Syntax

```
vals = kfoldfun(CVMdl,fun)
```

Description

`vals = kfoldfun(CVMdl,fun)` cross-validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Examples

Estimate Classification Loss Using Custom Loss Function

Train a classification tree classifier, and then cross-validate it using a custom *k*-fold loss function.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
Mdl = fitctree(meas,species);
```

`Mdl` is a `ClassificationTree` model.

Cross-validate `Mdl` using the default 10-fold cross-validation. Compute the classification error (proportion of misclassified observations) for the validation-fold observations.

```
rng(1); % For reproducibility
CVMdl = crossval(Mdl);
L = kfoldLoss(CVMdl,'LossFun','classiferror')
```

```
L = 0.0467
```

Examine the result when the cost of misclassifying a flower as `versicolor` is `10`, and the cost of any other misclassification is `1`. Create the custom function `noversicolor` (shown at the end of this example). This function attributes a cost of `10` for misclassifying a flower as `versicolor`, and a cost of `1` for any other misclassification.

Compute the mean misclassification error with the `noversicolor` cost.

```
mean(kfoldfun(CVMdl,@noversicolor))
```

```
ans = 0.2267
```

This code creates the function `noversicolor`.

```
function averageCost = noversicolor(CMP,~,~,~,Xtest,Ytest,~)
% noversicolor Example custom cross-validation function
%    Attributes a cost of 10 for misclassifying versicolor irises, and 1 for
%    the other irises.  This example function requires the fisheriris data
%    set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Input Arguments

`CVMdl` — Cross-validated model

`ClassificationPartitionedModel` object | `ClassificationPartitionedEnsemble` object | `ClassificationPartitionedGAM` object

Cross-validated model, specified as a `ClassificationPartitionedModel` object, `ClassificationPartitionedEnsemble` object, or `ClassificationPartitionedGAM` object.

`fun` — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax:

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` must have the same size across all folds.

Data Types: `function_handle`

Output Arguments

`vals` — Cross-validation results

numeric matrix

Cross-validation results, returned as a numeric matrix. `vals` contains the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

See Also

`ClassificationPartitionedModel` | `kfoldEdge` | `kfoldLoss` | `kfoldMargin` | `kfoldPredict`

Introduced in R2011a

kfoldfun

Package: `classreg.learning.partition`

Cross-validate function for regression

Syntax

```
vals = kfoldfun(CVMdl,fun)
```

Description

`vals = kfoldfun(CVMdl,fun)` cross-validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Examples

Estimate Regression Loss Using Custom Loss Function

Train a regression tree model, and then cross-validate it using a custom *k*-fold loss function.

Load the `imports-85` data set. Train a regression tree using a subset of the data.

```
load imports-85
Mdl = fitrtree(X(:,[4 5]),X(:,16),...
    'PredictorNames',{'Length','Width'},...
    'ResponseName','Price');
```

Cross-validate the regression tree, and obtain the mean squared error.

```
CVMdl = crossval(Mdl);
L = kfoldLoss(CVMdl)
```

```
L = 1.9167e+07
```

Examine the error when you use a simple averaging of training responses instead of predictions in the calculation.

```
f = @(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
```

```
f = function_handle with value:
    @(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)mean((Ytest-mean(Ytrain)).^2)
```

```
mean(kfoldfun(CVMdl,f))
```

```
ans = 6.3586e+07
```

Input Arguments

`CVMdl` — Cross-validated model

`RegressionPartitionedModel` object | `RegressionPartitionedEnsemble` object | `RegressionPartitionedGAM` object | `RegressionPartitionedSVM` object

Cross-validated model, specified as a `RegressionPartitionedModel` object, `RegressionPartitionedEnsemble` object, `RegressionPartitionedGAM` object, or `RegressionPartitionedSVM` object.

`fun` — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax:

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` must have the same size across all folds.

Data Types: `function_handle`

Output Arguments

`vals` — Cross-validation results

numeric matrix

Cross-validation results, returned as a numeric matrix. `vals` contains the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

See Also

Introduced in R2011a

kfoldLoss

Package: `classreg.learning.partition`

Classification loss for cross-validated ECOC model

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

Examples

Determine *k*-Fold Cross-Validation Loss

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

Estimate the average classification error.

```
L = kfoldLoss(CVMdl)
```

```
L = 0.0400
```

The average classification error for the folds is 4%.

Alternatively, you can obtain the per-fold losses by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Display Individual Losses for Each Cross-Validation Fold

The classification loss is a measure of classifier quality. To determine which folds perform poorly, display the losses for each fold.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Use 8-fold cross-validation, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the average classification loss across all folds and the losses for each fold.

```
loss = kfoldLoss(CVMdl)
```

```
loss = 0.0333
```

```
losses = kfoldLoss(CVMdl,'Mode','individual')
```

```
losses = 8×1

    0.0556
    0.0526
    0.1579
         0
         0
         0
         0
         0
```

The third fold misclassifies a much higher percentage of observations than any other fold.

Return the average classification loss for the folds that perform well by specifying the `'Folds'` name-value pair argument.

```
newloss = kfoldLoss(CVMdl,'Folds',[1:2 4:8])
```

```
newloss = 0.0153
```

The total classification loss decreases by approximately half its original size.

Consider adjusting parameters of the binary classifiers or the coding design to see if performance for all folds improves.

Determine ECOC Model Quality Using Custom Cross-Validation Loss

In addition to knowing whether a model generally classifies observations correctly, you can determine how well the model classifies an observation into its predicted class. One way to determine this type of model quality is to pass a custom loss function to `kfoldLoss`.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y)  % Class order
```

```
classOrder = 3x1 categorical
     setosa
     versicolor
     virginica
```

```
rng(1) % For reproducibility
```

Train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

Create a custom function that takes the minimal loss for each observation, then averages the minimal losses for all observations. `S` corresponds to the `NegLoss` output of `kfoldPredict`.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the cross-validated custom loss.

```
kfoldLoss(CVMdl,'LossFun',lossfun)
```

```
ans = 0.0101
```

The average minimal binary loss for the validation-fold observations is `0.0101`.

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`.
- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

`BinaryLoss` — Binary learner loss function
`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.

- *K* is the number of classes.
- *L* is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3259.

Example: `'Decoding','lossbased'`

`Folds` — Fold indices for prediction
`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from `1` to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`LossFun` — Loss function
`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'classiferror'` or a function handle.

- Specify the built-in function `'classiferror'`. In this case, the loss function is the classification error on page 33-3130.
- Or, specify your own function using function handle notation.

  Assume that *n* is the number of observations in the training data (`CVMdl.NumObservations`) and *K* is the number of classes (`numel(CVMdl.ClassNames)`). Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

  - The output argument `lossvalue` is a scalar.
  - You specify the function name (*`lossfun`*).
  - `C` is an *n*-by-*K* logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `CVMdl.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set every element of row `p` to `0`.
  - `S` is an *n*-by-*K* numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMdl.ClassNames`. The input `S` resembles the output argument `NegLoss` of `kfoldPredict`.
  - `W` is an *n*-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to `1`.
  - `Cost` is a *K*-by-*K* numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

  Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `string` | `function_handle`

`Mode` — Aggregation level for output
`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
`'average'`	The output is a scalar average over all folds.
`'individual'`	The output is a vector of length *k* containing one value per fold, where *k* is the number of folds.

Example: `'Mode','individual'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.

- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`loss` — Classification loss
numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

If `Mode` is `'average'`, then `loss` is the average classification loss over all folds. Otherwise, `loss` is a *k*-by-1 numeric column vector containing the classification loss for each fold, where *k* is the number of folds.

More About

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).

- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

kfoldLoss

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(ens)
L = kfoldLoss(ens,Name,Value)
```

Description

`L = kfoldLoss(ens)` returns loss obtained by cross-validated classification model `ens`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitcensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`folds`

Indices of folds ranging from `1` to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

`lossfun`

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal

Value	Description
'exponential'	Exponential loss
'hinge'	Hinge loss
'logit'	Logistic loss
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic loss

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (ens.Method is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', GentleBoost, or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

  ```
  ens.ScoreTransform = 'doublelogit';
  ```

- For all other ensemble methods, the software does not support posterior probabilities as classification scores.

- Specify your own function using function handle notation.

  Suppose that n be the number of observations in X and K be the number of distinct classes (numel(ens.ClassNames), ens is the input model). Your function must have this signature

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  where:

  - The output argument lossvalue is a scalar.
  - You choose the function name (*lossfun*).
  - C is an n-by-K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in ens.ClassNames.

    Construct C by setting C(p,q) = 1 if observation p is in class q, for each row. Set all other elements of row p to 0.
  - S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in ens.ClassNames. S is a matrix of classification scores, similar to the output of predict.
  - W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes them to sum to 1.
  - Cost is a *K*-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) - eye(K) specifies a cost of 0 for correct classification, and 1 for misclassification.

  Specify your function using 'LossFun',@*lossfun*.

For more details on loss functions, see “Classification Loss” on page 33-3135.

Default: 'classiferror'

mode

A character vector or string scalar for determining the output of `kfoldLoss`:

- `'average'` — `L` is a scalar, the loss averaged over all folds.
- `'individual'` — `L` is a vector of length `ens.KFold`, where each entry is the loss for a fold.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'average'`

Output Arguments

L

Loss, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Cross-Validated Classification Error

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble of 100 decision trees using AdaBoostM1. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Cross-validate the ensemble using 10-fold cross-validation.

```
cvens = crossval(ens);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvens)
```

```
L = 0.0655
```

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.

- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of $K – 1$ zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\hat{y}_j \neq y_j\right\}.$ $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.

Loss Function	Value of LossFun	Equation
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $$L = -\sum_{j=1}^{n}\frac{\tilde{w}_j \log(m_j)}{Kn},$$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).

kfoldLoss

Package: `classreg.learning.partition`

Classification loss for cross-validated kernel classification model

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss on page 33-3144 obtained by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations.

By default, `kfoldLoss` returns the classification error.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the classification loss function, number of folds, or aggregation level.

Examples

Estimate *k*-Fold Cross-Validation Classification Error

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```
CVMdl =
  ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
           ResponseName: 'Y'
        NumObservations: 351
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'b'  'g'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the cross-validated classification loss. By default, the software computes the classification error.

```
loss = kfoldLoss(CVMdl)
```

```
loss = 0.0940
```

Alternatively, you can obtain the per-fold classification errors by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Specify Custom Classification Loss

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```
CVMdl =
  ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
           ResponseName: 'Y'
        NumObservations: 351
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'b'  'g'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j - w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j, y_j is the response j (–1 for the negative class and 1 otherwise), and f_j is the raw classification score of observation j.

```
linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);
```

Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `'LossFun'` name-value pair argument.

Estimate the cross-validated classification loss using the linear loss function.

```
loss = kfoldLoss(CVMdl,'LossFun',linearloss)
```

```
loss = -0.7792
```

Input Arguments

`CVMdl` — Cross-validated, binary kernel classification model

`ClassificationPartitionedKernel` model object

Cross-validated, binary kernel classification model, specified as a `ClassificationPartitionedKernel` model object. You can create a `ClassificationPartitionedKernel` model by using `fitckernel` and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, `kfoldLoss` applies the same data used to cross-validate the kernel classification model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

`Folds` — Fold indices for prediction

`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from `1` to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`LossFun` — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding value.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal

Value	Description
'exponential'	Exponential loss
'hinge'	Hinge loss
'logit'	Logistic loss
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic loss

'mincost' is appropriate for classification scores that are posterior probabilities. For kernel classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see kfoldPredict).

- Specify your own function by using function handle notation.

  Assume that n is the number of observations in X, and K is the number of distinct classes (numel(CVMdl.ClassNames), where CVMdl is the input model). Your function must have this signature:

  lossvalue = *lossfun*(C,S,W,Cost)

  - The output argument lossvalue is a scalar.
  - You specify the function name (*lossfun*).
  - C is an n-by-K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames.

    Construct C by setting C(p,q) = 1, if observation p is in class q, for each row. Set all other elements of row p to 0.
  - S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in CVMdl.ClassNames. S is a matrix of classification scores, similar to the output of kfoldPredict.
  - W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes the weights to sum to 1.
  - Cost is a K-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) – eye(K) specifies a cost of 0 for correct classification, and 1 for misclassification.

Example: 'LossFun',@*lossfun*

Data Types: char | string | function_handle

Mode — Aggregation level for output
'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

Value	Description
'average'	The output is a scalar average over all folds.

Value	Description
`'individual'`	The output is a vector of length k containing one value per fold, where k is the number of folds.

Example: `'Mode','individual'`

Output Arguments

`loss` — Classification loss

numeric scalar | numeric column vector

Classification loss on page 33-3144, returned as a numeric scalar or numeric column vector.

If `Mode` is `'average'`, then `loss` is the average classification loss over all folds. Otherwise, `loss` is a k-by-1 numeric column vector containing the classification loss for each fold, where k is the number of folds.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Suppose the following:

- L is the weighted average classification loss.
- n is the sample size.
- y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
- $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so that they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

This table describes the supported loss functions that you can specify by using the `'LossFun'` name-value argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$

Loss Function	Value of LossFun	Equation
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$. $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).

Introduced in R2018b

kfoldLoss

Package: `classreg.learning.partition`

Classification loss for cross-validated kernel ECOC model

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations. `kfoldLoss` applies the same data used to create `CVMdl` (see `fitcecoc`).

By default, `kfoldLoss` returns the classification error on page 33-3153.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the classification loss function, number of folds, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Classification Error

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

```
CVMdl =
  ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
           ResponseName: 'Y'
        NumObservations: 150
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'setosa'  'versicolor'  'virginica'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the cross-validated classification loss. By default, the software computes the classification error.

```
loss = kfoldLoss(CVMdl)
```

```
loss = 0.0333
```

Alternatively, you can obtain the per-fold classification errors by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Determine Model Quality Using Custom Cross-Validation Loss

In addition to knowing whether a model generally classifies observations correctly, you can determine how well the model classifies an observation into its predicted class. One way to determine this type of model quality is to pass a custom loss function to `kfoldLoss`.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
rng(1) % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

```
CVMdl =
  ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
           ResponseName: 'Y'
        NumObservations: 150
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'setosa'  'versicolor'  'virginica'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Create a custom function that takes the minimal loss for each observation, then averages the minimal losses for all observations. `S` corresponds to the `NegLoss` output of `kfoldPredict`.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the cross-validated custom loss.

```
kfoldLoss(CVMdl,'LossFun',lossfun)
```

```
ans = 0.0199
```

The average minimal binary loss for the validation-fold observations is about 0.02.

Input Arguments

`CVMdl` — Cross-validated kernel ECOC model

`ClassificationPartitionedKernelECOC` model

Cross-validated kernel ECOC model, specified as a `ClassificationPartitionedKernelECOC` model. You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitcecoc` and specifying these name-value pair arguments:

- `'Learners'` – Set the value to `'kernel'`, a template object returned by `templateKernel`, or a cell array of such template objects.
- One of the arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$

Value	Description	Score Domain	$g(y_j,s_j)$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3153.

Example: `'Decoding','lossbased'`

`Folds` — Fold indices for prediction
`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from `1` to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`LossFun` — Loss function
`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'classiferror'` or a function handle.

- Specify the built-in function `'classiferror'`. In this case, the loss function is the classification error on page 33-3153.
- Or, specify your own function using function handle notation.

  Assume that *n* is the number of observations in the training data (`CVMdl.NumObservations`) and *K* is the number of classes (`numel(CVMdl.ClassNames)`). Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

  - The output argument `lossvalue` is a scalar.
  - You specify the function name (*`lossfun`*).
  - `C` is an *n*-by-*K* logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `CVMdl.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set every element of row `p` to `0`.
  - `S` is an *n*-by-*K* numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMdl.ClassNames`. The input `S` resembles the output argument `NegLoss` of `kfoldPredict`.
  - `W` is an *n*-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to `1`.
  - `Cost` is a *K*-by-*K* numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

  Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `string` | `function_handle`

`Mode` — Aggregation level for output
`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
`'average'`	The output is a scalar average over all folds.
`'individual'`	The output is a vector of length *k* containing one value per fold, where *k* is the number of folds.

Example: `'Mode','individual'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`loss` — Classification loss
numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

If `Mode` is `'average'`, then `loss` is the average classification loss over all folds. Otherwise, `loss` is a *k*-by-1 numeric column vector containing the classification loss for each fold, where *k* is the number of folds.

More About

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).

- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Introduced in R2018b

kfoldLoss

Classification loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated classification losses on page 33-3162 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldLoss` estimates the classification loss for observations that it holds out when it trains using all other observations.

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the classification-loss function.

Input Arguments

`CVMdl` — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, kfoldLoss applies the same data used to cross-validate the linear classification model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Folds` — Fold indices to use for classification-score prediction

`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from `1` through `CVMdl.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

LossFun — Loss function
`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  `'mincost'` is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `predict`).
- Specify your own function using function handle notation.

  Let `n` be the number of observations in `X` and `K` be the number of distinct classes (`numel(Mdl.ClassNames)`, `Mdl` is the input model). Your function must have this signature

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  where:

  - The output argument `lossvalue` is a scalar.
  - You choose the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to `1`.
  - `Cost` is a *K*-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification, and `1` for misclassification.

  Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `string` | `function_handle`

`Mode` — Loss aggregation level
`'average'` (default) | `'individual'`

Loss aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
`'average'`	Returns losses averaged over all folds
`'individual'`	Returns losses for each fold

Example: `'Mode','individual'`

Output Arguments

`L` — Cross-validated classification losses
numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses on page 33-3162, returned as a numeric scalar, vector, or matrix. The interpretation of `L` depends on `LossFun`.

Let *R* be the number of regularizations strengths is the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and *F* be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then `L` is a 1-by-*R* vector. `L(j)` is the average classification loss over all folds of the cross-validated model that uses regularization strength *j*.
- Otherwise, `L` is an *F*-by-*R* matrix. `L(i,j)` is the classification loss for fold *i* of the cross-validated model that uses regularization strength *j*.

To estimate `L`, `kfoldLoss` uses the data that created `CVMdl` (see `X` and `Y`).

Examples

Estimate *k*-Fold Cross-Validation Classification Error

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the out-of-fold, classification error rates.

```
ce = kfoldLoss(CVMdl)
```

```
ce = 7.6017e-04
```

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in "Estimate k-Fold Cross-Validation Classification Error" on page 33-3158, and transpose the predictor data.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Cross-validate a binary, linear classification model using 5-fold cross-validation. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','KFold',5,...
    'ObservationsIn','columns');
CMdl = CVMdl.Trained{1};
```

`CVMdl` is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `ClassificationLinear` models that the software trained using the training set of each fold.

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j - w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j, y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j. Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LossFun` name-value pair argument. Because the function does not use classification cost, use ~ to have `kfoldLoss` ignore its position.

```
linearloss = @(C,S,W,~)sum(-W.*sum(S.*C,2))/sum(W);
```

Estimate the average cross-validated classification loss using the linear loss function. Also, obtain the loss for each fold.

```
ce = kfoldLoss(CVMdl,'LossFun',linearloss)
```

```
ce = -8.0982
```

```
ceFold = kfoldLoss(CVMdl,'LossFun',linearloss,'Mode','individual')
```

```
ceFold = 5×1

   -8.3165
   -8.7633
   -7.4342
   -8.0423
   -7.9347
```

Find Good Lasso Penalty Using *k*-fold Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 33-3159.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{0.5}$.

```
Lambda = logspace(-6,-0.5,11);
```

Cross-validate binary, linear classification models using 5-fold cross-validation, and that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'KFold',5,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
  ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
        NumObservations: 31572
                  KFold: 5
              Partition: [1x1 cvpartition]
             ClassNames: [0 1]
         ScoreTransform: 'none'

  Properties, Methods
```

Extract a trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  ClassificationLinear
```

```
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'logit'
              Beta: [34023x11 double]
              Bias: [1x11 double]
            Lambda: [1x11 double]
           Learner: 'logistic'

  Properties, Methods
```

`Mdl1` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMdl);
```

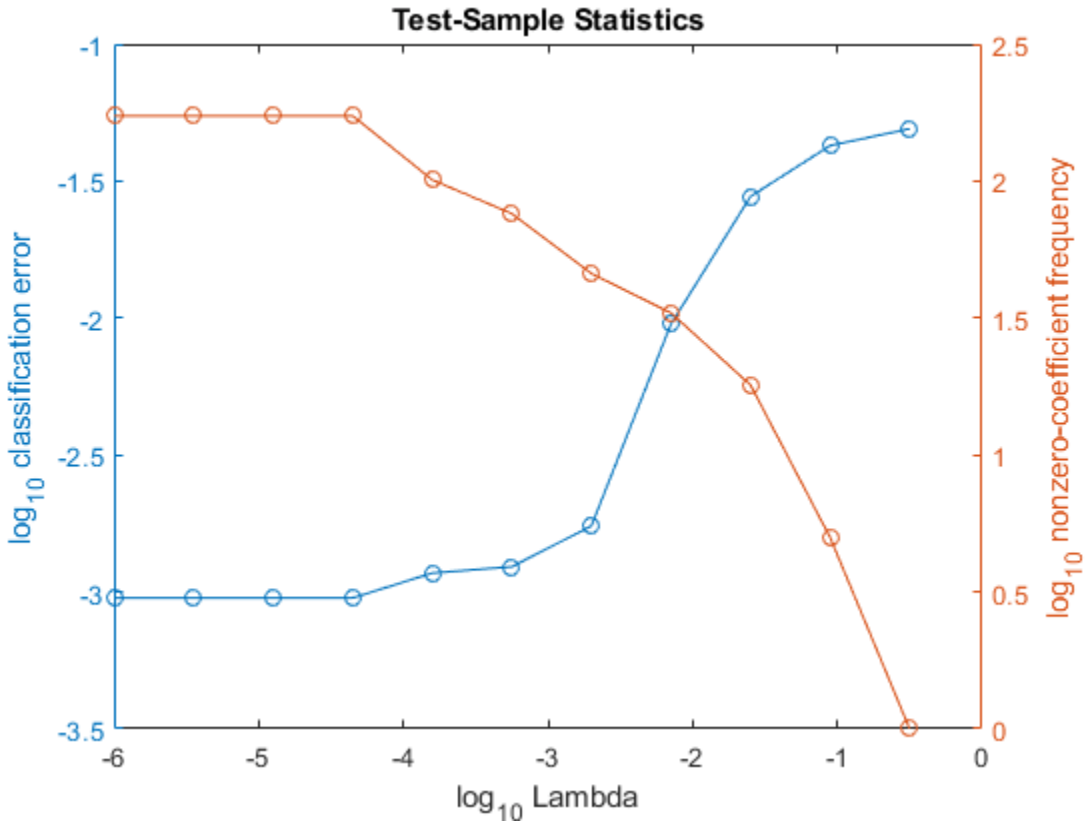
Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
```



Choose the indexes of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:

- y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
- $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.

- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\hat{y}_j \neq y_j\right\}.$ $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn},$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.

Loss Function	Value of LossFun	Equation
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = (f(X_j)'C)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\hat{y}_j = \underset{k=1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j (1 - m_j)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).

`ClassificationLinear` | `ClassificationPartitionedLinear` | `kfoldPredict` | `loss`

Introduced in R2016a

kfoldLoss

Classification loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated classification error on page 33-3175 rates estimated by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldLoss` estimates the classification error rate for observations that it holds out when it trains using all other observations. `kfoldLoss` applies the same data used create `CVMdl` (see `fitcecoc`).

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme, which folds to use for the loss calculation, or verbosity level.

Input Arguments

`CVMdl` — Cross-validated, ECOC model composed of linear classification models

`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model using `fitcecoc` and by:

1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
2. Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, kfoldLoss applies the same data used to cross-validate the ECOC model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3259.

Example: `'Decoding','lossbased'`

`Folds` — Fold indices to use for classification-score prediction
`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from `1` through `CVMdl.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`LossFun` — Loss function
`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle or `'classiferror'`.

You can:

- Specify the built-in function `'classiferror'`, then the loss function is the classification error on page 33-3175.
- Specify your own function using function handle notation.

  For what follows, `n` is the number of observations in the training data (`CVMdl.NumObservations`) and `K` is the number of classes (`numel(CVMdl.ClassNames)`). Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

  - The output argument `lossvalue` is a scalar.
  - You choose the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `CVMdl.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set every element of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMdl.ClassNames`. `S` resembles the output argument `NegLoss` of `kfoldPredict`.
  - `W` is an `n`-by-`1` numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to `1`.
  - `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

  Specify your function using `'LossFun',@lossfun`.

Data Types: `function_handle` | `char` | `string`

`Mode` — Loss aggregation level
`'average'` (default) | `'individual'`

Loss aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
`'average'`	Returns losses averaged over all folds
`'individual'`	Returns losses for each fold

Example: `'Mode','individual'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`L` — Cross-validated classification losses
numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses on page 33-3175, returned as a numeric scalar, vector, or matrix. The interpretation of `L` depends on `LossFun`.

Let R be the number of regularizations strengths is the cross-validated models (`CVMdl.Trained{1}.BinaryLearners{1}.Lambda`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then `L` is a 1-by-R vector. `L(`j`)` is the average classification loss over all folds of the cross-validated model that uses regularization strength j.
- Otherwise, `L` is a F-by-R matrix. `L(`i`,`j`)` is the classification loss for fold i of the cross-validated model that uses regularization strength j.

Examples

Estimate *k*-Fold Cross-Validation Classification Error

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation.

Estimate the average of the out-of-fold classification error rates.

```
ce = kfoldLoss(CVMdl)
```

```
ce = 0.0958
```

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Specify Custom Classification Loss

Load the NLP data set. Transpose the predictor data.

```
load nlpdata
X = X';
```

For simplicity, use the label 'others' for all observations in Y that are not `'simulink'`, `'dsp'`, or `'comm'`.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMdl1 = CVMdl.Trained{1}
```

```
CMdl1 =
  CompactClassificationECOC
      ResponseName: 'Y'
        ClassNames: [comm    dsp    simulink    others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
      CodingMatrix: [4x6 double]
```

```
  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `CompactClassificationECOC` models that the software trained using the training set of each fold.

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations. Because the function does not use the class-identifier matrix (`C`), observation weights (`W`), and classification cost (`Cost`), use `~` to have `kfoldLoss` ignore its their positions.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Estimate the average cross-validated classification loss using the minimal loss per observation function. Also, obtain the loss for each fold.

```
ce = kfoldLoss(CVMdl,'LossFun',lossfun)
```

```
ce = 0.0243
```

```
ceFold = kfoldLoss(CVMdl,'LossFun',lossfun,'Mode','individual')
```

```
ceFold = 5×1

    0.0244
    0.0255
    0.0248
    0.0240
    0.0226
```

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in `Y` that are not `'simulink'`, `'dsp'`, or `'comm'`.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-7} through 10^{-2}.

```
Lambda = logspace(-7,-2,11);
```

Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in `Lambda`, train using SpaRSA, and lower the tolerance on the gradient of the objective function to `1e-8`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model.

Dissect `CVMdl`, and each model within it.

```
numECOCModels = numel(CVMdl.Trained)
```

```
numECOCModels = 5
```

```
ECOCMdl1 = CVMdl.Trained{1}
```

```
ECOCMdl1 =
  CompactClassificationECOC
      ResponseName: 'Y'
        ClassNames: [comm    dsp    simulink    others]
    ScoreTransform: 'none'
    BinaryLearners: {6×1 cell}
      CodingMatrix: [4×6 double]

  Properties, Methods
```

```
numCLModels = numel(ECOCMdl1.BinaryLearners)
```

```
numCLModels = 6
```

```
CLMdl1 = ECOCMdl1.BinaryLearners{1}
```

```
CLMdl1 =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [-1 1]
    ScoreTransform: 'logit'
              Beta: [34023×11 double]
              Bias: [-0.3169 -0.3169 -0.3168 -0.3168 -0.3168 -0.3167 -0.1725 -0.0805 -0.1762 -0.1
            Lambda: [1.0000e-07 3.1623e-07 1.0000e-06 3.1623e-06 1.0000e-05 3.1623e-05 1.0000e-04
           Learner: 'logistic'

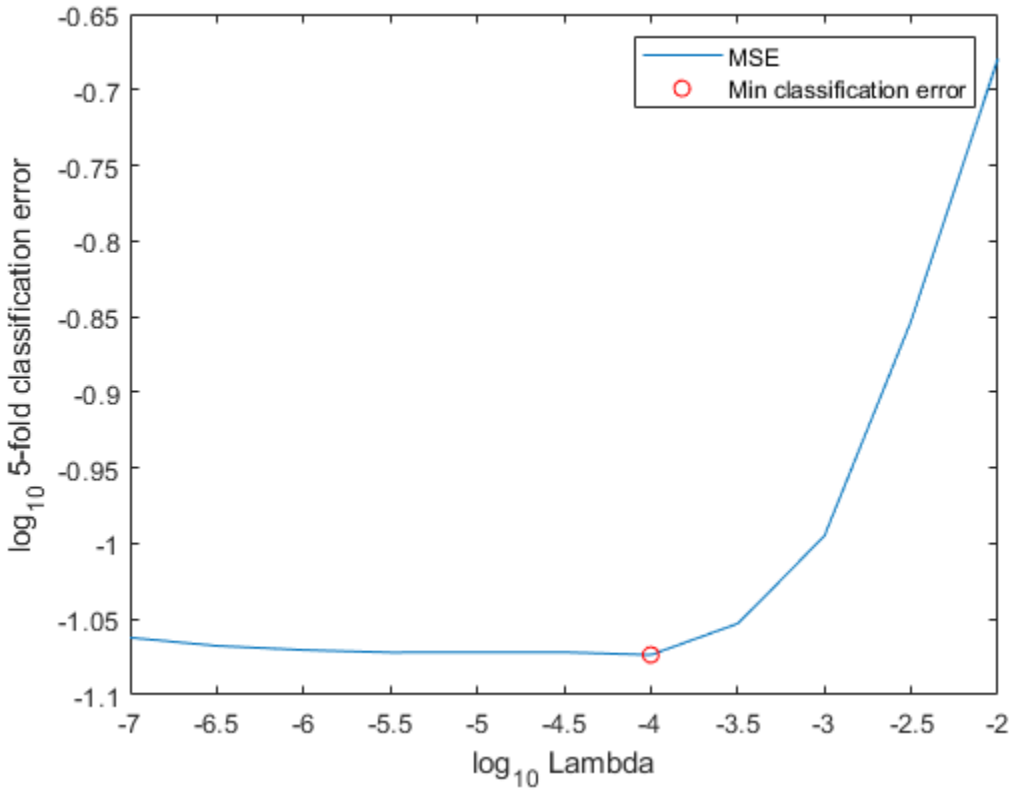
  Properties, Methods
```

Because `fitcecoc` implements 5-fold cross-validation, `CVMdl` contains a 5-by-1 cell array of `CompactClassificationECOC` models that the software trains on each fold. The `BinaryLearners` property of each `CompactClassificationECOC` model contains the `ClassificationLinear`

models. The number of `ClassificationLinear` models within each compact ECOC model depends on the number of distinct labels and coding design. Because `Lambda` is a sequence of regularization strengths, you can think of `CLMdl1` as 11 models, one for each regularization strength in `Lambda`.

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.

```
ce = kfoldLoss(CVMdl);
figure;
plot(log10(Lambda),log10(ce))
[~,minCEIdx] = min(ce);
minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda),log10(ce(minCEIdx)),'ro');
ylabel('log_{10} 5-fold classification error')
xlabel('log_{10} Lambda')
legend('MSE','Min classification error')
hold off
```



Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',minLambda,'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016a

kfoldLoss

Package: `classreg.learning.partition`

Classification loss for cross-validated classification model

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

`L = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated classification model `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a classifier trained on training-fold observations. `CVMdl.X` and `CVMdl.Y` contain both sets of observations.

`L = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value arguments. For example, you can specify a custom loss function.

Examples

Estimate Cross-Validated Classification Error

Load the `ionosphere` data set.

```
load ionosphere
```

Grow a classification tree.

```
tree = fitctree(X,Y);
```

Cross-validate the classification tree using 10-fold cross-validation.

```
cvtree = crossval(tree);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvtree)
```

```
L = 0.1083
```

Estimate Cross-Validated Classification Error

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble of 100 decision trees using AdaBoostM1. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Cross-validate the ensemble using 10-fold cross-validation.

```
cvens = crossval(ens);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvens)
```

```
L = 0.0655
```

Find Optimal Number of Trees for GAM Using `kfoldLoss`

Train a cross-validated generalized additive model (GAM) with 10 folds. Then, use `kfoldLoss` to compute cumulative cross-validation classification errors (misclassification rate in decimal). Use the errors to determine the optimal number of trees per predictor (linear term for predictor) and the optimal number of trees per interaction term.

Alternatively, you can find optimal values of `fitcgam` name-value arguments by using the `bayesopt` function. For an example, see “Optimize Cross-Validated GAM Using bayesopt” on page 33-1693.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Create a cross-validated GAM by using the default cross-validation option. Specify the `'CrossVal'` name-value argument as `'on'`. Specify to include all available interaction terms whose *p*-values are not greater than 0.05.

```
rng('default') % For reproducibility
CVMdl = fitcgam(X,Y,'CrossVal','on','Interactions','all','MaxPValue',0.05);
```

If you specify `'Mode'` as `'cumulative'` for `kfoldLoss`, then the function returns cumulative errors, which are the average errors across all folds obtained using the same number of trees for each fold. Display the number of trees for each fold.

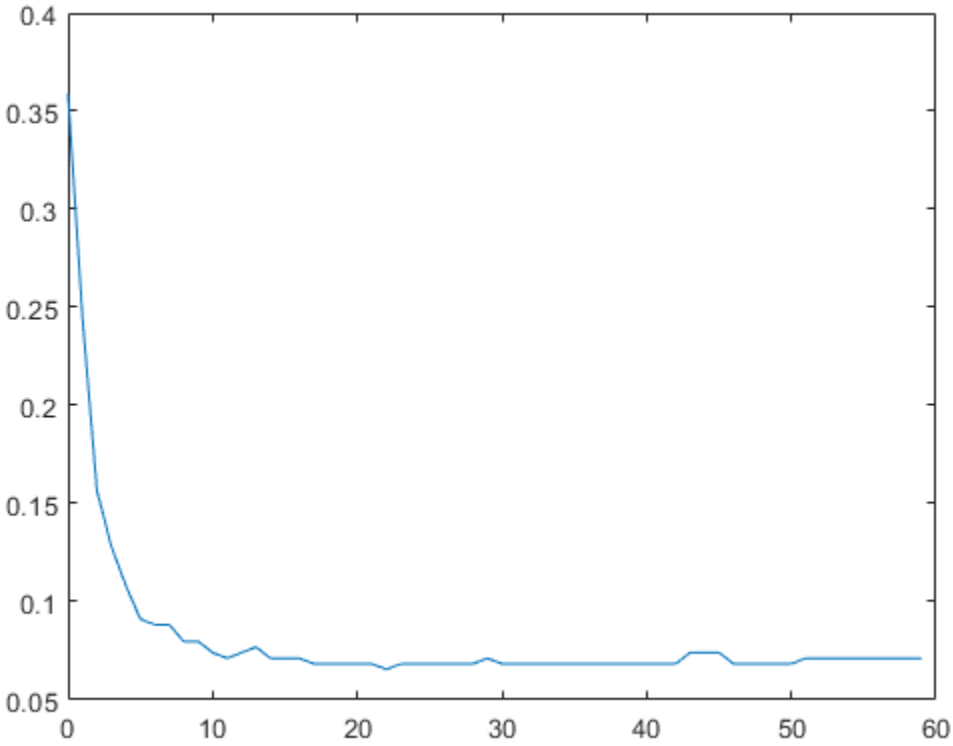
```
CVMdl.NumTrainedPerFold
```

```
ans = struct with fields:
      PredictorTrees: [65 64 59 61 60 66 65 62 64 61]
    InteractionTrees: [1 2 2 2 2 1 2 2 2 2]
```

`kfoldLoss` can compute cumulative errors using up to 59 predictor trees and one interaction tree.

Plot the cumulative, 10-fold cross-validated, classification error (misclassification rate in decimal). Specify `'IncludeInteractions'` as `false` to exclude interaction terms from the computation.

```
L_noInteractions = kfoldLoss(CVMdl,'Mode','cumulative','IncludeInteractions',false);
figure
plot(0:min(CVMdl.NumTrainedPerFold.PredictorTrees),L_noInteractions)
```



The first element of `L_noInteractions` is the average error over all folds obtained using only the intercept (constant) term. The (`J`+1)th element of `L_noInteractions` is the average error obtained using the intercept term and the first `J` predictor trees per linear term. Plotting the cumulative loss allows you to monitor how the error changes as the number of predictor trees in GAM increases.

Find the minimum error and the number of predictor trees used to achieve the minimum error.

```
[M,I] = min(L_noInteractions)
```

```
M = 0.0655
```

```
I = 23
```

The GAM achieves the minimum error when it includes 22 predictor trees.

Compute the cumulative classification error using both linear terms and interaction terms.

```
L = kfoldLoss(CVMdl,'Mode','cumulative')
```

```
L = 2×1

    0.0712
    0.0712
```

The first element of L is the average error over all folds obtained using the intercept (constant) term and all predictor trees per linear term. The second element of L is the average error obtained using the intercept term, all predictor trees per linear term, and one interaction tree per interaction term. The error does not decrease when interaction terms are added.

If you are satisfied with the error when the number of predictor trees is 22, you can create a predictive model by training the univariate GAM again and specifying 'NumTreesPerPredictor',22 without cross-validation.

Input Arguments

CVMdl — Cross-validated partitioned classifier

ClassificationPartitionedModel object | ClassificationPartitionedEnsemble object | ClassificationPartitionedGAM object

Cross-validated partitioned classifier, specified as a ClassificationPartitionedModel, ClassificationPartitionedEnsemble, or ClassificationPartitionedGAM object. You can create the object in two ways:

- Pass a trained classification model listed in the following table to its crossval object function.
- Train a classification model using a function listed in the following table and specify one of the cross-validation name-value arguments for the function.

Classification Model	Function
ClassificationDiscriminant	fitcdiscr
ClassificationEnsemble	fitcensemble
ClassificationGAM	fitcgam
ClassificationKNN	fitcknn
ClassificationNaiveBayes	fitcnb
ClassificationNeuralNetwork	fitcnet
ClassificationSVM	fitcsvm
ClassificationTree	fitctree

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: kfoldLoss(CVMdl,'Folds',[1 2 3 5]) specifies to use the first, second, third, and fifth folds to compute the classification loss, but to exclude the fourth fold.

Folds — Fold indices to use

1:CVMdl.KFold (default) | positive integer vector

Fold indices to use, specified as a positive integer vector. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`IncludeInteractions` — Flag to include interaction terms
`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `CVMdl` is `ClassificationPartitionedGAM`.

The default value is `true` if the models in `CVMdl` (`CVMdl.Trained`) contain interaction terms. The value must be `false` if the models do not contain interaction terms.

Data Types: `logical`

`LossFun` — Loss function
`'classiferror'` | `'binodeviance'` | `'crossentropy'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as a built-in loss function name or a function handle. The default loss function depends on the model type of `CVMdl`.

- The default value is `'classiferror'` if the model type is an ensemble, generalized additive model, neural network, or support vector machine classifier.
- The default value is `'mincost'` if the model type is a discriminant analysis, *k*-nearest neighbor, naive Bayes, or tree classifier.

`'classiferror'` and `'mincost'` are equivalent when you use the default cost matrix. See “Algorithms” on page 33-3187 for more information.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'crossentropy'`	Cross-entropy loss (for neural networks only)
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  `'mincost'` is appropriate for classification scores that are posterior probabilities. The `predict` and `kfoldPredict` functions of discriminant analysis, generalized additive model, *k*-nearest neighbor, naive Bayes, neural network, and tree classifiers return such scores by default.

  - For ensemble models that use `'Bag'` or `'Subspace'` methods, classification scores are posterior probabilities by default. For ensemble models that use `'AdaBoostM1'`,

'AdaBoostM2', GentleBoost, or 'LogitBoost' methods, you can use posterior probabilities as classification scores by specifying the double-logit score transform. For example, enter:

```
CVMdl.ScoreTransform = 'doublelogit';
```

For all other ensemble methods, the software does not support posterior probabilities as classification scores.

- For SVM models, you can specify to use posterior probabilities as classification scores by setting 'FitPosterior',true when you cross-validate the model using fitcsvm.

- Specify your own function using function handle notation.

  Suppose that n is the number of observations in the training data (CVMdl.NumObservations) and K is the number of classes (numel(CVMdl.ClassNames)). Your function must have the signature lossvalue = *lossfun*(C,S,W,Cost), where:

  - The output argument lossvalue is a scalar.
  - You specify the function name (*lossfun*).
  - C is an n-by-K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames.

    Construct C by setting C(p,q) = 1 if observation p is in class q, for each row. Set all other elements of row p to 0.
  - S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in CVMdl.ClassNames. The input S resembles the output argument score of kfoldPredict.
  - W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes its elements to sum to 1.
  - Cost is a K-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) – eye(K) specifies a cost of 0 for correct classification, and 1 for misclassification.

  Specify your function using 'LossFun',@*lossfun*.

For more details on loss functions, see “Classification Loss” on page 33-3184.

Example: 'LossFun','hinge'

Data Types: char | string | function_handle

Mode — Aggregation level for output

'average' (default) | 'individual' | 'cumulative'

Aggregation level for the output, specified as 'average', 'individual', or 'cumulative'.

Value	Description
'average'	The output is a scalar average over all folds.
'individual'	The output is a vector of length *k* containing one value per fold, where *k* is the number of folds.

Value	Description

`'cumulative'`	**Note** If you want to specify this value, `CVMdl` must be a `ClassificationPartitionedEnsemble` object or `ClassificationPartitionedGAM` object.
	
	• If `CVMdl` is `ClassificationPartitionedEnsemble`, then the output is a vector of length `min(CVMdl.NumTrainedPerFold)`. Each element `j` is an average over all folds that the function obtains by using ensembles trained with weak learners `1:j`.
	• If `CVMdl` is `ClassificationPartitionedGAM`, then the output value depends on the `IncludeInteractions` value.
	  • If `IncludeInteractions` is `false`, then `L` is a `(1 + min(NumTrainedPerFold.PredictorTrees))`-by-1 numeric column vector. The first element of `L` is an average over all folds that is obtained only the intercept (constant) term. The `(j + 1)`th element of `L` is an average obtained using the intercept term and the first `j` predictor trees per linear term.
	  • If `IncludeInteractions` is `true`, then `L` is a `(1 + min(NumTrainedPerFold.InteractionTrees))`-by-1 numeric column vector. The first element of `L` is an average over all folds that is obtained using the intercept (constant) term and all predictor trees per linear term. The `(j + 1)`th element of `L` is an average obtained using the intercept term, all predictor trees per linear term, and the first `j` interaction trees per interaction term.

Example: `'Mode','individual'`

Output Arguments

L — Classification loss

numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

- If `Mode` is `'average'`, then `L` is the average classification loss over all folds.
- If `Mode` is `'individual'`, then `L` is a *k*-by-1 numeric column vector containing the classification loss for each fold, where *k* is the number of folds.
- If `Mode` is `'cumulative'` and `CVMdl` is `ClassificationPartitionedEnsemble`, then `L` is a `min(CVMdl.NumTrainedPerFold)`-by-1 numeric column vector. Each element `j` is the average classification loss over all folds that the function obtains by using ensembles trained with weak learners `1:j`.
- If `Mode` is `'cumulative'` and `CVMdl` is `ClassificationPartitionedGAM`, then the output value depends on the `IncludeInteractions` value.
  - If `IncludeInteractions` is `false`, then `L` is a `(1 + min(NumTrainedPerFold.PredictorTrees))`-by-1 numeric column vector. The first

element of `L` is the average classification loss over all folds that is obtained using only the intercept (constant) term. The `(j + 1)`th element of `L` is the average loss obtained using the intercept term and the first `j` predictor trees per linear term.

- If `IncludeInteractions` is `true`, then `L` is a `(1 + min(NumTrainedPerFold.InteractionTrees))`-by-1 numeric column vector. The first element of `L` is the average classification loss over all folds that is obtained using the intercept (constant) term and all predictor trees per linear term. The `(j + 1)`th element of `L` is the average loss obtained using the intercept term, all predictor trees per linear term, and the first `j` interaction trees per interaction term.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

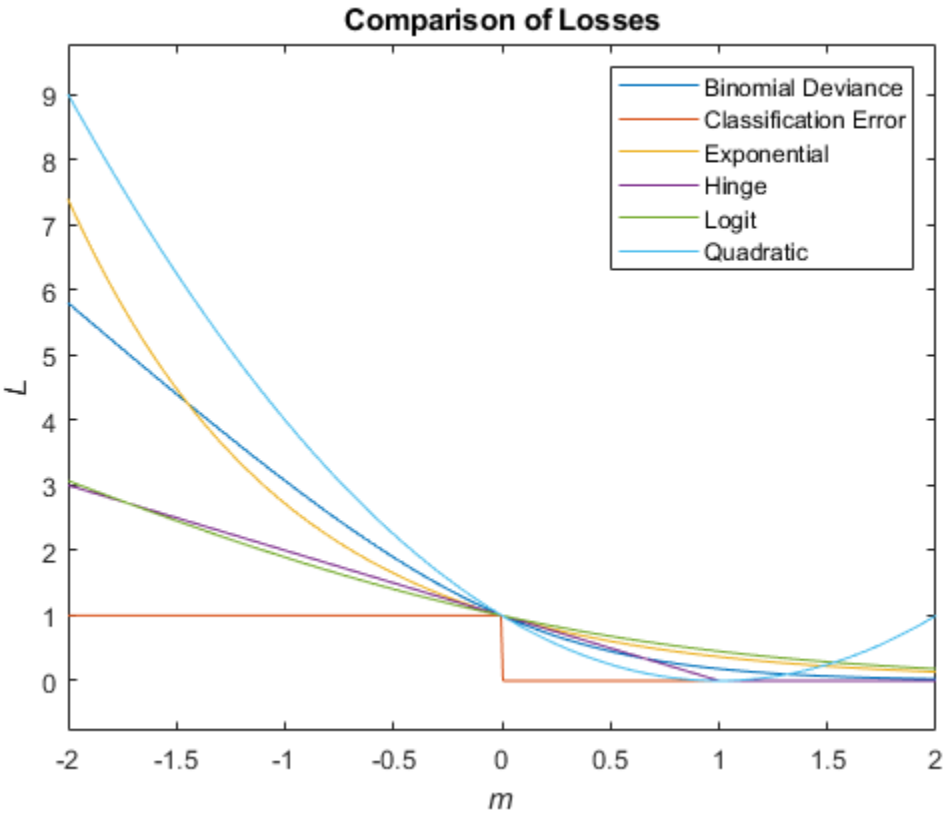
$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\{1 + \exp[-2m_j]\}$.
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$. $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn}$, where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



Algorithms

`kfoldLoss` computes the classification loss as described in the corresponding `loss` object function. For a model-specific description, see the appropriate `loss` function reference page in the following table.

Model Type	`loss` Function
Discriminant analysis classifier	`loss`
Ensemble classifier	`loss`
Generalized additive model classifier	`loss`
k-nearest neighbor classifier	`loss`
Naive Bayes classifier	`loss`
Neural network classifier	`loss`
Support vector machine classifier	`loss`
Binary decision tree for multiclass classification	`loss`

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports *k*-nearest neighbor and SVM model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Examine Quality of KNN Classifier” on page 18-28

Introduced in R2011a

kfoldLoss

Cross-validation loss of partitioned regression ensemble

Syntax

```
L = kfoldLoss(cvens)
L = kfoldLoss(cvens,Name,Value)
```

Description

`L = kfoldLoss(cvens)` returns the cross-validation loss of `cvens`.

`L = kfoldLoss(cvens,Name,Value)` returns cross-validation loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`cvens`

Object of class `RegressionPartitionedEnsemble`. Create `obj` with `fitrensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`folds`

Indices of folds ranging from `1` to `cvens.KFold`. Use only these folds for predictions.

Default: `1:cvens.KFold`

`lossfun`

Function handle for loss function, or `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

`mode`

Method for computing cross-validation loss.

- `'average'` — `L` is a scalar value, the average loss over all folds.
- `'individual'` — `L` is a vector with one element per fold.
- `'cumulative'` — `L` is a vector with a length of minimum number of observations used for training in each fold. Each element in the vector `L` is obtained by taking the average of loss across all folds.

Default: `'average'`

Output Arguments

`L`

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Find Cross-Validation Loss for Regression Ensemble

Find the cross-validation loss for a regression ensemble of the `carsmall` data.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of regression trees.

```
rens = fitrensemble(X,MPG);
```

Create a cross-validated ensemble from `rens` and find the k-fold cross-validation loss.

```
rng(10,'twister') % For reproducibility
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

```
L = 28.7114
```

See Also

`RegressionPartitionedEnsemble` | `kfoldPredict` | `loss`

kfoldLoss

Regression loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated mean squared error (MSE) obtained by the cross-validated, linear regression model `CVMdl`. That is, for every fold, `kfoldLoss` estimates the regression loss for observations that it holds out when it trains using all other observations.

`L` contains a regression loss for each regularization strength in the linear regression models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the regression-loss function.

Input Arguments

`CVMdl` — Cross-validated, linear regression model

`RegressionPartitionedLinear` model object

Cross-validated, linear regression model, specified as a `RegressionPartitionedLinear` model object. You can create a `RegressionPartitionedLinear` model using `fitrlinear` and specifying any of the one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, kfoldLoss applies the same data used to cross-validate the linear regression model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Folds` — Fold indices to use for response prediction

`1:CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for response prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from `1` through `CVMdl.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

LossFun — Loss function
'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar. Also, in the table, $f(x) = x\beta + b$.
  - β is a vector of p coefficients.
  - x is an observation from p predictor variables.
  - b is the scalar bias.

Value	Description
'epsiloninsensitive'	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, \lvert y - f(x)\rvert - \varepsilon]$
'mse'	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

  'epsiloninsensitive' is appropriate for SVM learners only.
- Specify your own function using function handle notation.

  Let n be the number of observations in X. Your function must have this signature

  `lossvalue = lossfun(Y,Yhat,W)`

  where:

  - The output argument lossvalue is a scalar.
  - You choose the function name (*lossfun*).
  - Y is an n-dimensional vector of observed responses. kfoldLoss passes the input argument Y in for Y.
  - Yhat is an n-dimensional vector of predicted responses, which is similar to the output of predict.
  - W is an n-by-1 numeric vector of observation weights.

  Specify your function using 'LossFun',@*lossfun*.

Data Types: char | string | function_handle

Mode — Loss aggregation level
'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns losses averaged over all folds
'individual'	Returns losses for each fold

Example: 'Mode','individual'

Output Arguments

L — Cross-validated regression losses

numeric scalar | numeric vector | numeric matrix

Cross-validated regression losses, returned as a numeric scalar, vector, or matrix. The interpretation of `L` depends on `LossFun`.

Let R be the number of regularizations strengths is the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then `L` is a 1-by-R vector. `L(`j`)` is the average regression loss over all folds of the cross-validated model that uses regularization strength j.
- Otherwise, `L` is an F-by-R matrix. `L(`i`,`j`)` is the regression loss for fold i of the cross-validated model that uses regularization strength j.

To estimate `L`, `kfoldLoss` uses the data that created `CVMdl` (see `X` and `Y`).

Examples

Estimate *k*-Fold Mean Squared Error

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \ldots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model using SVM learners.

```
rng(1); % For reproducibility
CVMdl = fitrlinear(X,Y,'CrossVal','on');
```

`CVMdl` is a `RegressionPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the test-sample MSEs.

```
mse = kfoldLoss(CVMdl)
```

```
mse = 0.1735
```

Alternatively, you can obtain the per-fold MSEs by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Specify Custom Regression Loss

Simulate data as in “Estimate k-Fold Mean Squared Error” on page 33-3193.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training
```

Cross-validate a linear regression model using 10-fold cross-validation. Optimize the objective function using SpaRSA.

```
CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns',...
    'Solver','sparsa');
```

`CVMdl` is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 10-by-1 cell array holding `RegressionLinear` models that the software trained using the training set.

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum w_j} \sum_{j=1}^{n} w_j \ell_j ,$$

where

$$\ell_j = \begin{cases} 0.5\widehat{e}_j^2; & |\widehat{e}_j| \le 1 \\ |\widehat{e}_j| - 0.5; & |\widehat{e}_j| > 1 \end{cases}.$$

$\widehat{e}_j$ is the residual for observation j. Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `'LossFun'` name-value pair argument.

```
huberloss = @(Y,Yhat,W)sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...
    ((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/sum(W);
```

Estimate the average Huber loss over the folds. Also, obtain the Huber loss for each fold.

```
mseAve = kfoldLoss(CVMdl,'LossFun',huberloss)
```

```
mseAve = -0.4447
```

```
mseFold = kfoldLoss(CVMdl,'LossFun',huberloss,'Mode','individual')
```

```
mseFold = 10×1

   -0.4454
   -0.4473
   -0.4452
   -0.4469
   -0.4434
```

```
   -0.4427
   -0.4471
   -0.4430
   -0.4438
   -0.4426
```

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \ldots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1}.

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpaRSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');

numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

`CVMdl` is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, `CVMdl` contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 = 
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x15 double]
```

```
                Bias: [1x15 double]
              Lambda: [1x15 double]
             Learner: 'leastsquares'

  Properties, Methods
```

`Mdl1` is a `RegressionLinear` model object. `fitrlinear` constructed `Mdl1` by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 15 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

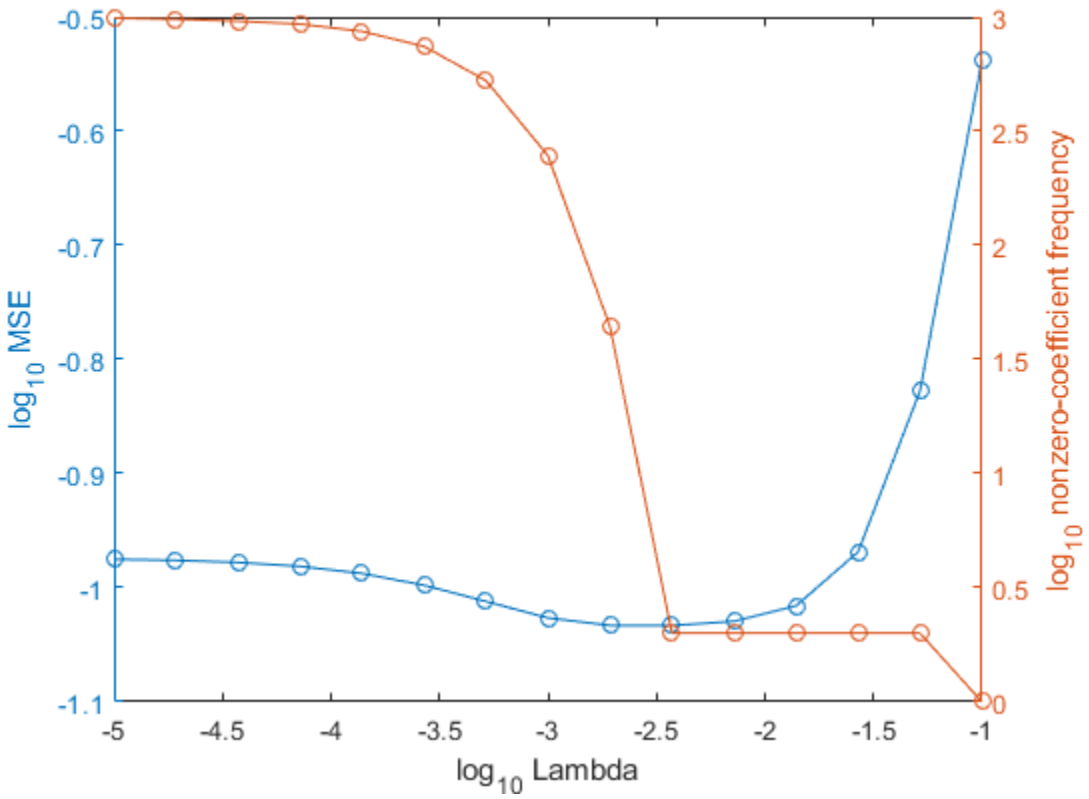
```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```



Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, `Lambda(10)`).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x1 double]
                 Bias: -0.0050
               Lambda: 0.0037
              Learner: 'leastsquares'

  Properties, Methods
```

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2×1

   100
   200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1

    1.0051
    1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

`RegressionLinear` | `RegressionPartitionedLinear` | `kfoldPredict` | `loss`

Introduced in R2016a

kfoldLoss

Package: `classreg.learning.partition`

Loss for cross-validated partitioned regression model

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

`L = kfoldLoss(CVMdl)` returns the loss (mean squared error) obtained by the cross-validated regression model `CVMdl`. For every fold, `kfoldLoss` computes the loss for validation-fold observations using a model trained on training-fold observations. `CVMdl.X` and `CVMdl.Y` contain both sets of observations.

`L = kfoldLoss(CVMdl,Name,Value)` returns the loss with additional options specified by one or more name-value arguments. For example, you can specify a custom loss function.

Examples

Find Cross-Validation Loss for Regression Ensemble

Find the cross-validation loss for a regression ensemble of the `carsmall` data.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of regression trees.

```
rens = fitrensemble(X,MPG);
```

Create a cross-validated ensemble from `rens` and find the k-fold cross-validation loss.

```
rng(10,'twister') % For reproducibility
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

```
L = 28.7114
```

Display Individual Losses for Each Cross-Validation Fold

The mean squared error (MSE) is a measure of model quality. Examine the MSE for each fold of a cross-validated regression model.

Load the `carsmall` data set. Specify the predictor `X` and the response data `Y`.

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
Y = MPG;
```

Train a cross-validated regression tree model. By default, the software implements 10-fold cross-validation.

```
rng('default') % For reproducibility
CVMdl = fitrtree(X,Y,'CrossVal','on');
```

Compute the MSE for each fold. Visualize the distribution of the loss values by using a box plot. Notice that none of the values is an outlier.

```
losses = kfoldLoss(CVMdl,'Mode','individual')
```

```
losses = 10×1

   42.5072
   20.3995
   22.3737

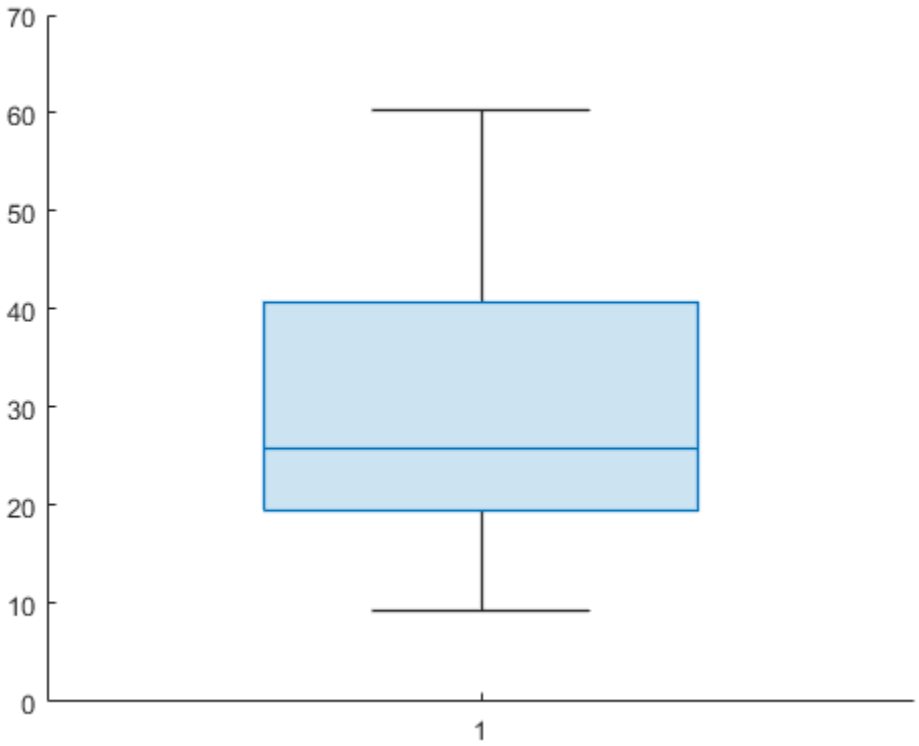
    9.2060
   29.0788
   16.3386
```

```
boxchart(losses)
```



Find Optimal Number of Trees for GAM Using `kfoldLoss`

Train a cross-validated generalized additive model (GAM) with 10 folds. Then, use `kfoldLoss` to compute the cumulative cross-validation regression loss (mean squared errors). Use the errors to determine the optimal number of trees per predictor (linear term for predictor) and the optimal number of trees per interaction term.

Alternatively, you can find optimal values of `fitrgam` name-value arguments by using the `bayesopt` function. For an example, see “Optimize Cross-Validated GAM Using bayesopt” on page 33-2120.

Load the `patients` data set.

```
load patients
```

Create a table that contains the predictor variables (`Age`, `Diastolic`, `Smoker`, `Weight`, `Gender`, and `SelfAssessedHealthStatus`) and the response variable (`Systolic`).

```
tbl = table(Age,Diastolic,Smoker,Weight,Gender,SelfAssessedHealthStatus,Systolic);
```

Create a cross-validated GAM by using the default cross-validation option. Specify the `'CrossVal'` name-value argument as `'on'`. Also, specify to include 5 interaction terms.

```
rng('default') % For reproducibility
CVMdl = fitrgam(tbl,'Systolic','CrossVal','on','Interactions',5);
```

If you specify `'Mode'` as `'cumulative'` for `kfoldLoss`, then the function returns cumulative errors, which are the average errors across all folds obtained using the same number of trees for each fold. Display the number of trees for each fold.

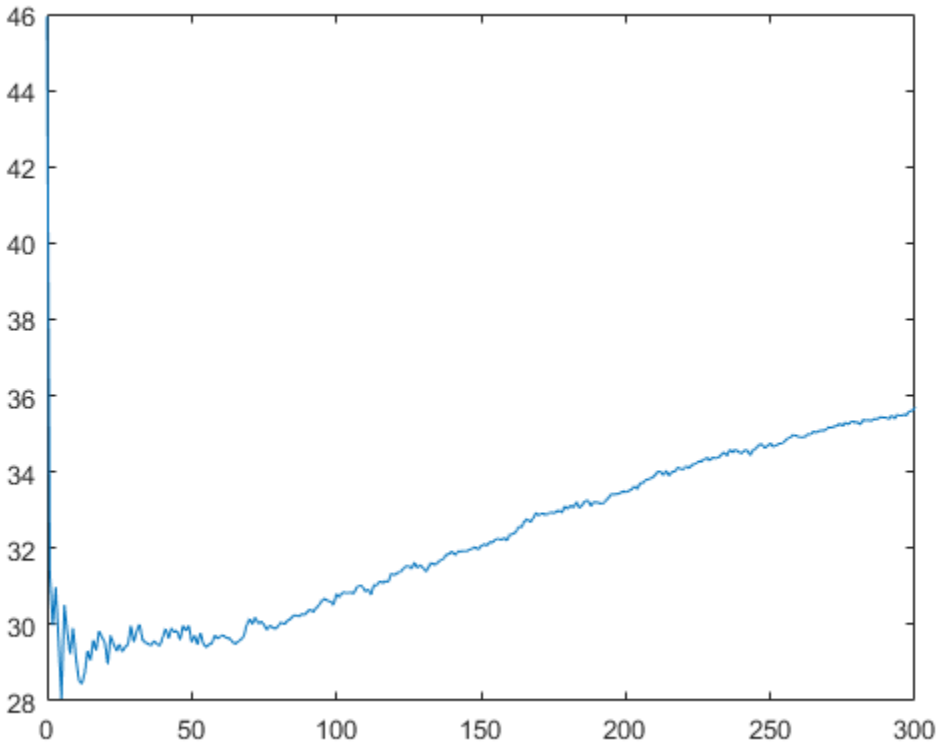
```
CVMdl.NumTrainedPerFold
```

```
ans = struct with fields:
      PredictorTrees: [300 300 300 300 300 300 300 300 300 300]
    InteractionTrees: [76 100 100 100 100 42 100 100 59 100]
```

`kfoldLoss` can compute cumulative errors using up to 300 predictor trees and 42 interaction trees.

Plot the cumulative, 10-fold cross-validated, mean squared errors. Specify `'IncludeInteractions'` as `false` to exclude interaction terms from the computation.

```
L_noInteractions = kfoldLoss(CVMdl,'Mode','cumulative','IncludeInteractions',false);
figure
plot(0:min(CVMdl.NumTrainedPerFold.PredictorTrees),L_noInteractions)
```



The first element of `L_noInteractions` is the average error over all folds obtained using only the intercept (constant) term. The (`J`+1)th element of `L_noInteractions` is the average error obtained using the intercept term and the first `J` predictor trees per linear term. Plotting the cumulative loss allows you to monitor how the error changes as the number of predictor trees in the GAM increases.

Find the minimum error and the number of predictor trees used to achieve the minimum error.

```
[M,I] = min(L_noInteractions)
```

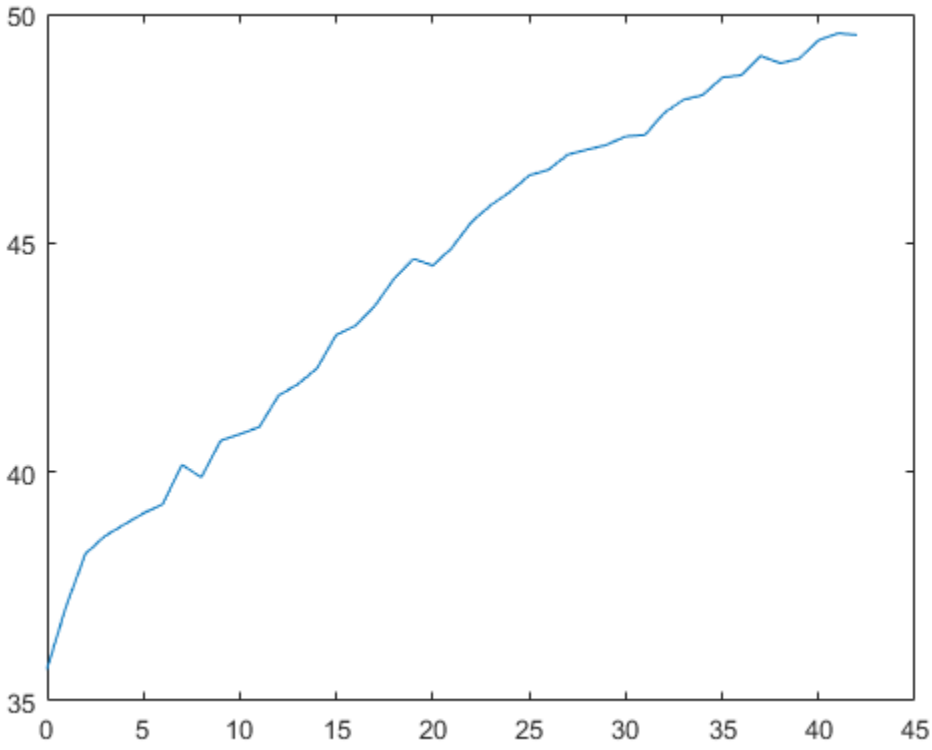
```
M = 28.0506

I = 6
```

The GAM achieves the minimum error when it includes 5 predictor trees.

Compute the cumulative mean squared error using both linear terms and interaction terms.

```
L = kfoldLoss(CVMdl,'Mode','cumulative');
figure
plot(0:min(CVMdl.NumTrainedPerFold.InteractionTrees),L)
```



The first element of `L` is the average error over all folds obtained using the intercept (constant) term and all predictor trees per linear term. The (`J`+1)th element of `L` is the average error obtained using the intercept term, all predictor trees per linear term, and the first `J` interaction trees per interaction term. The plot shows that the error increases when interaction terms are added.

If you are satisfied with the error when the number of predictor trees is 5, you can create a predictive model by training the univariate GAM again and specifying `'NumTreesPerPredictor',5` without cross-validation.

Input Arguments

`CVMdl` — Cross-validated partitioned regression model

`RegressionPartitionedModel` object | `RegressionPartitionedEnsemble` object | `RegressionPartitionedGAM` object | `RegressionPartitionedSVM` object

Cross-validated partitioned regression model, specified as a `RegressionPartitionedModel`, `RegressionPartitionedEnsemble`, `RegressionPartitionedGAM`, or `RegressionPartitionedSVM` object. You can create the in two ways:

- Pass a trained regression model listed in the following table to its `crossval` object function.
- Train a regression model using a function listed in the following table and specify one of the cross-validation name-value arguments for the function.

Regression Model	Function
`RegressionEnsemble`	`fitrensemble`
`RegressionGAM`	`fitrgam`
`RegressionGP`	`fitrgp`
`RegressionNeuralNetwork`	`fitrnet`
`RegressionSVM`	`fitrsvm`
`RegressionTree`	`fitrtree`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 2 3 5])` specifies to use the first, second, third, and fifth folds to compute the mean squared error, but to exclude the fourth fold.

`Folds` — Fold indices to use
`1:CVMdl.KFold` (default) | positive integer vector

Fold indices to use, specified as a positive integer vector. The elements of `Folds` must be within the range from `1` to `CVMdl.KFold`.

The software uses only the folds specified in `Folds`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

`IncludeInteractions` — Flag to include interaction terms
`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `CVMdl` is `RegressionPartitionedGAM`.

The default value is `true` if the models in `CVMdl` (`CVMdl.Trained`) contain interaction terms. The value must be `false` if the models do not contain interaction terms.

Example: `'IncludeInteractions',false`

Data Types: `logical`

`LossFun` — Loss function
`'mse'` (default) | function handle

Loss function, specified as `'mse'` or a function handle.

- Specify the built-in function `'mse'`. In this case, the loss function is the mean squared error.
- Specify your own function using function handle notation.

  Assume that *n* is the number of observations in the training data (`CVMdl.NumObservations`). Your function must have the signature `lossvalue = lossfun(Y,Yfit,W)`, where:

  - The output argument `lossvalue` is a scalar.
  - You specify the function name (*`lossfun`*).
  - `Y` is an *n*-by-1 numeric vector of observed responses.
  - `Yfit` is an *n*-by-1 numeric vector of predicted responses.
  - `W` is an *n*-by-1 numeric vector of observation weights.

  Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `string` | `function_handle`

`Mode` — Aggregation level for output
`'average'` (default) | `'individual'` | `'cumulative'`

Aggregation level for the output, specified as `'average'`, `'individual'`, or `'cumulative'`.

Value	Description
`'average'`	The output is a scalar average over all folds.
`'individual'`	The output is a vector of length *k* containing one value per fold, where *k* is the number of folds.

Value	Description

`'cumulative'`	**Note** If you want to specify this value, `CVMdl` must be a `RegressionPartitionedEnsemble` object or `RegressionPartitionedGAM` object.
	
	• If `CVMdl` is `RegressionPartitionedEnsemble`, then the output is a vector of length `min(CVMdl.NumTrainedPerFold)`. Each element `j` is an average over all folds that the function obtains by using ensembles trained with weak learners `1:j`.
	• If `CVMdl` is `RegressionPartitionedGAM`, then the output value depends on the `IncludeInteractions` value.
	  • If `IncludeInteractions` is `false`, then `L` is a `(1 + min(NumTrainedPerFold.PredictorTrees))`-by-1 numeric column vector. The first element of `L` is an average over all folds that is obtained using only the intercept (constant) term. The `(j + 1)`th element of `L` is an average obtained using the intercept term and the first `j` predictor trees per linear term.
	  • If `IncludeInteractions` is `true`, then `L` is a `(1 + min(NumTrainedPerFold.InteractionTrees))`-by-1 numeric column vector. The first element of `L` is an average over all folds that is obtained using the intercept (constant) term and all predictor trees per linear term. The `(j + 1)`th element of `L` is an average obtained using the intercept term, all predictor trees per linear term, and the first `j` interaction trees per interaction term.

Example: `'Mode','individual'`

Output Arguments

L — Loss

numeric scalar | numeric column vector

Loss, returned as a numeric scalar or numeric column vector.

By default, the loss is the mean squared error between the validation-fold observations and the predictions made with a regression model trained on the training-fold observations.

- If `Mode` is `'average'`, then `L` is the average loss over all folds.
- If `Mode` is `'individual'`, then `L` is a *k*-by-1 numeric column vector containing the loss for each fold, where *k* is the number of folds.
- If `Mode` is `'cumulative'` and `CVMdl` is `RegressionPartitionedEnsemble`, then `L` is a `min(CVMdl.NumTrainedPerFold)`-by-1 numeric column vector. Each element `j` is the average loss over all folds that the function obtains using ensembles trained with weak learners `1:j`.
- If `Mode` is `'cumulative'` and `CVMdl` is `RegressionPartitionedGAM`, then the output value depends on the `IncludeInteractions` value.

- If `IncludeInteractions` is `false`, then `L` is a `(1 + min(NumTrainedPerFold.PredictorTrees))`-by-1 numeric column vector. The first element of `L` is the average loss over all folds that is obtained using only the intercept (constant) term. The `(j + 1)`th element of `L` is the average loss obtained using the intercept term and the first `j` predictor trees per linear term.
- If `IncludeInteractions` is `true`, then `L` is a `(1 + min(NumTrainedPerFold.InteractionTrees))`-by-1 numeric column vector. The first element of `L` is the average loss over all folds that is obtained using the intercept (constant) term and all predictor trees per linear term. The `(j + 1)`th element of `L` is the average loss obtained using the intercept term, all predictor trees per linear term, and the first `j` interaction trees per interaction term.

Alternative Functionality

If you want to compute the cross-validated loss of a tree model, you can avoid constructing a `RegressionPartitionedModel` object by calling `cvloss`. Creating a cross-validated tree object can save you time if you plan to examine it more than once.

Introduced in R2011a

kfoldMargin

Package: `classreg.learning.partition`

Classification margins for cross-validated ECOC model

Syntax

```
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

Description

`margin = kfoldMargin(CVMdl)` returns classification margins on page 33-3213 obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldMargin` computes classification margins for validation-fold observations using an ECOC model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more name-value pair arguments. For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Margins

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

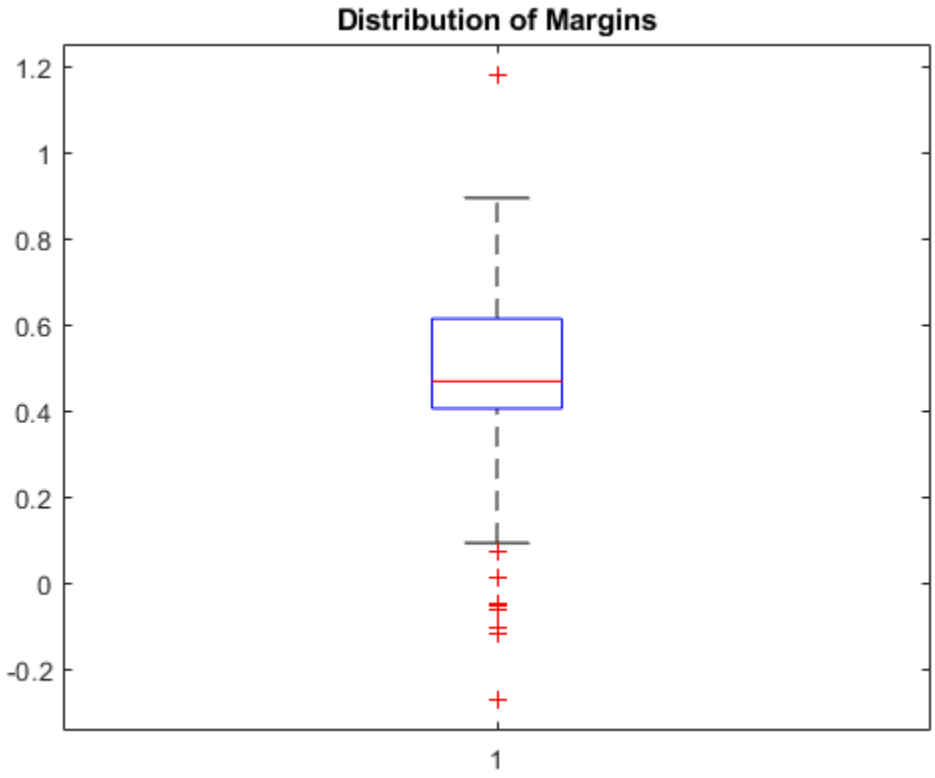
```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

Estimate the margins for validation-fold observations. Display the distribution of the margins using a boxplot.

```
margin = kfoldMargin(CVMdl);

boxplot(margin)
title('Distribution of Margins')
```



Select ECOC Model Features by Comparing Cross-Validation Margins

One way to perform feature selection is to compare cross-validation margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define the following two data sets.

- `fullX` contains all the predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

For each predictor set, train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

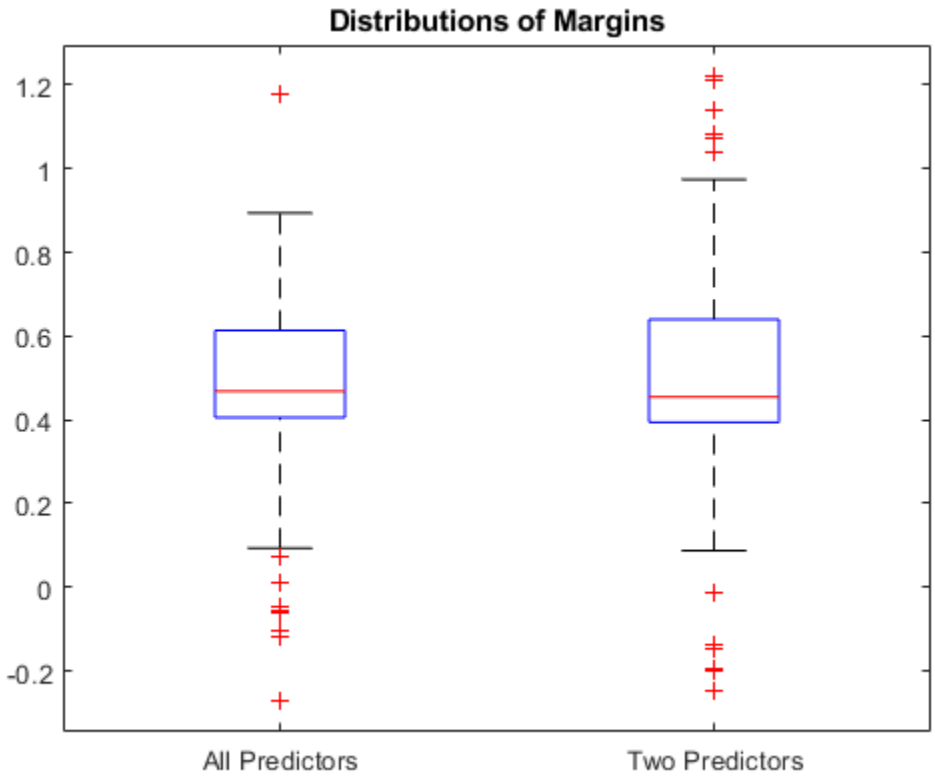
```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedECOC` models. By default, the software implements 10-fold cross-validation.

Estimate the margins for each classifier. Use loss-based decoding for aggregating the binary learner results. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = kfoldMargin(CVMdl,'Decoding','lossbased');
partMargins = kfoldMargin(PCVMdl,'Decoding','lossbased');

boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'})
title('Distributions of Margins')
```



The margin distributions are approximately the same.

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`.
- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldMargin(CVMdl,'Verbose',1)` specifies to display diagnostic messages in the Command Window.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.

- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- *K* is the number of classes.
- *L* is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3259.

Example: `'Decoding','lossbased'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`margin` — Classification margins

numeric vector

Classification margins on page 33-3213, returned as a numeric vector. `margin` is an *n*-by-1 vector, where each row is the margin of the corresponding observation and *n* is the number of observations (`size(CVMdl.X,1)`).

More About

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldMargin

Package: `classreg.learning.partition`

Classification margins for cross-validated kernel classification model

Syntax

```
margin = kfoldMargin(CVMdl)
```

Description

`margin = kfoldMargin(CVMdl)` returns the classification margins on page 33-3219 obtained by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldMargin` computes the classification margins for validation-fold observations using a model trained on training-fold observations.

Examples

Estimate *k*-Fold Cross-Validation Margins

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled as either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```
CVMdl =
  ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
           ResponseName: 'Y'
        NumObservations: 351
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'b'  'g'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the classification margins for validation-fold observations.

```
m = kfoldMargin(CVMdl);
size(m)
```

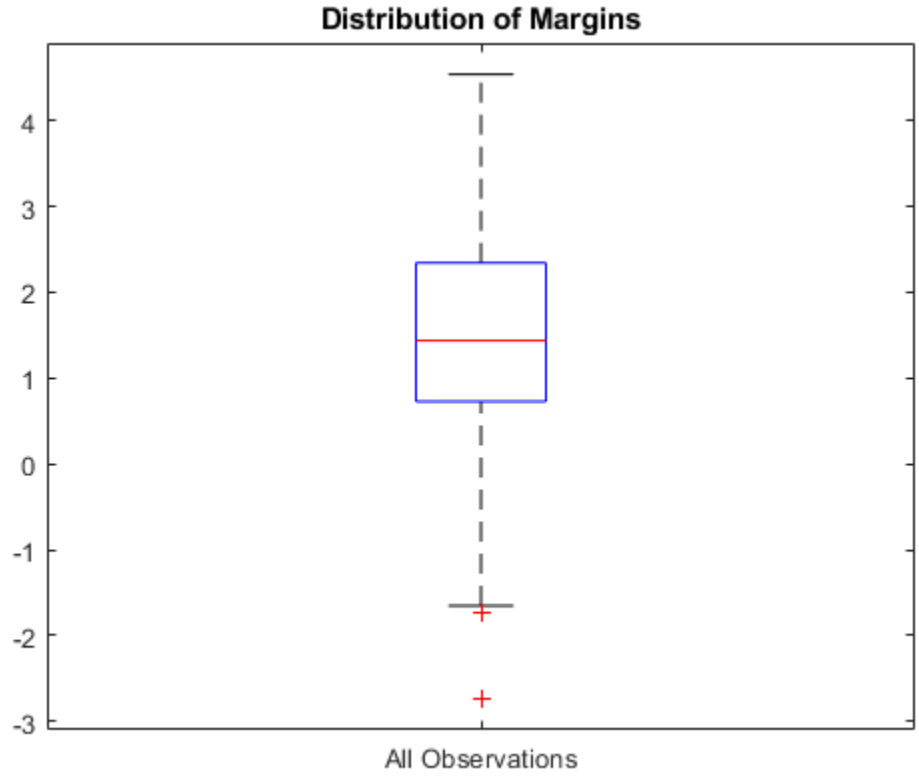
```
ans = 1×2

   351     1
```

`m` is a 351-by-1 vector. `m(j)` is the classification margin for observation `j`.

Plot the k-fold margins using a boxplot.

```
boxplot(m,'Labels','All Observations')
title('Distribution of Margins')
```



Feature Selection Using *k*-Fold Margins

Perform feature selection by comparing *k*-fold margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Randomly choose 10% of the predictor variables.

```
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));
```

Cross-validate two binary kernel classification models: one that uses all of the predictors, and one that uses 10% of the predictors.

```
CVMdl = fitckernel(X,Y,'CrossVal','on');
PCVMdl = fitckernel(X(:,idxPart),Y,'CrossVal','on');
```

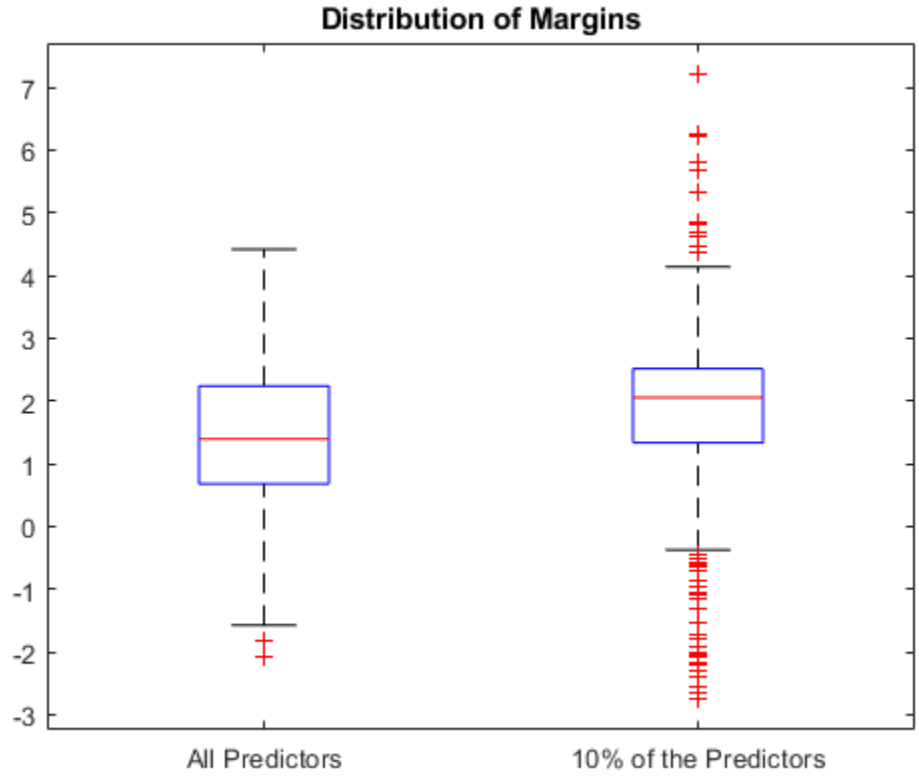
`CVMdl` and `PCVMdl` are `ClassificationPartitionedKernel` models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the *k*-fold margins for each classifier.

```
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);
```

Plot the distribution of the margin sets using box plots.

```
boxplot([fullMargins partMargins], ...
    'Labels',{'All Predictors','10% of the Predictors'});
title('Distribution of Margins')
```



The quartiles of the `PCVMdl` margin distribution are situated higher than the quartiles of the `CVMdl` margin distribution, indicating that the `PCVMdl` model is the better classifier.

Input Arguments

`CVMdl` — Cross-validated, binary kernel classification model

`ClassificationPartitionedKernel` model object

Cross-validated, binary kernel classification model, specified as a `ClassificationPartitionedKernel` model object. You can create a `ClassificationPartitionedKernel` model by using `fitckernel` and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, `kfoldMargin` applies the same data used to cross-validate the kernel classification model (`X` and `Y`).

Output Arguments

`margin` — Classification margins

numeric vector

Classification margins on page 33-3219, returned as a numeric vector. `margin` is an *n*-by-1 vector, where each row is the margin of the corresponding observation and *n* is the number of observations (`size(CVMdl.Y,1)`).

More About

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and –1 otherwise. $f(x)$ is the positive-class classification score for the observation x. The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the `'logit'` score transformation to the raw classification scores (see `ScoreTransform`).

kfoldMargin

Package: `classreg.learning.partition`

Classification margins for cross-validated kernel ECOC model

Syntax

```
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

Description

`margin = kfoldMargin(CVMdl)` returns the classification margins on page 33-3226 obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldMargin` computes the classification margins for validation-fold observations using a model trained on training-fold observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more name-value pair arguments. For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Margins

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

```
CVMdl =
  ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
           ResponseName: 'Y'
        NumObservations: 150
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'setosa'  'versicolor'  'virginica'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the classification margins for validation-fold observations.

```
m = kfoldMargin(CVMdl);
size(m)
```

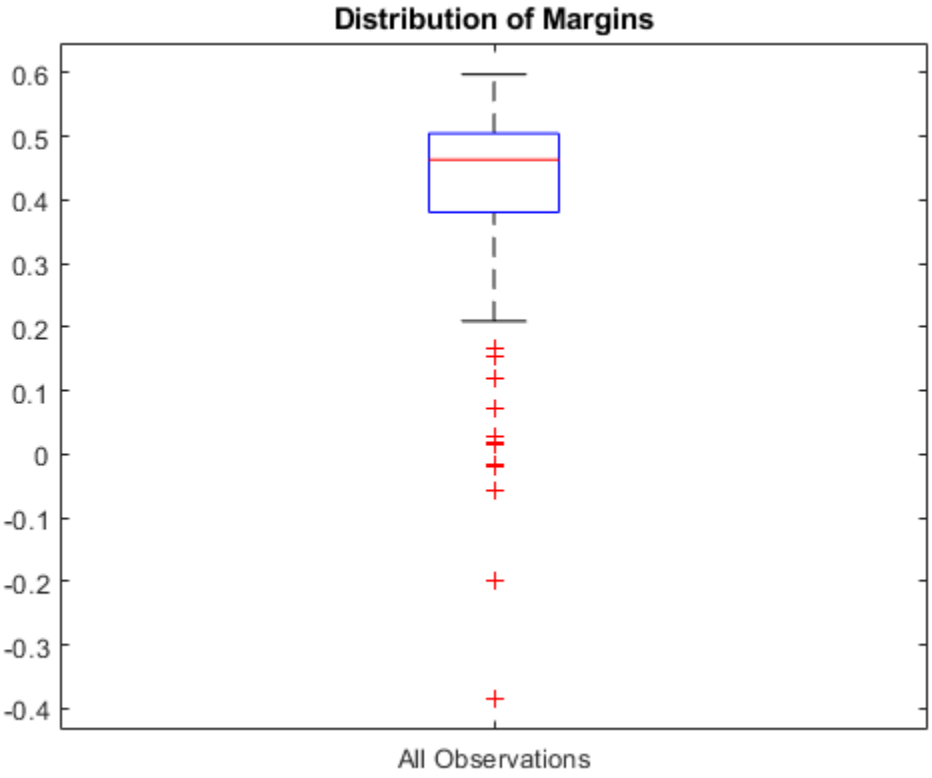
```
ans = 1×2

   150     1
```

`m` is a 150-by-1 vector. `m(j)` is the classification margin for observation `j`.

Plot the k-fold margins using a boxplot.

```
boxplot(m,'Labels','All Observations')
title('Distribution of Margins')
```



Feature Selection Using *k*-Fold Margins

Perform feature selection by comparing *k*-fold margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Randomly choose half of the predictor variables.

```
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Cross-validate two ECOC models composed of kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on');
PCVMdl = fitcecoc(X(:,idxPart),Y,'Learners','kernel','CrossVal','on');
```

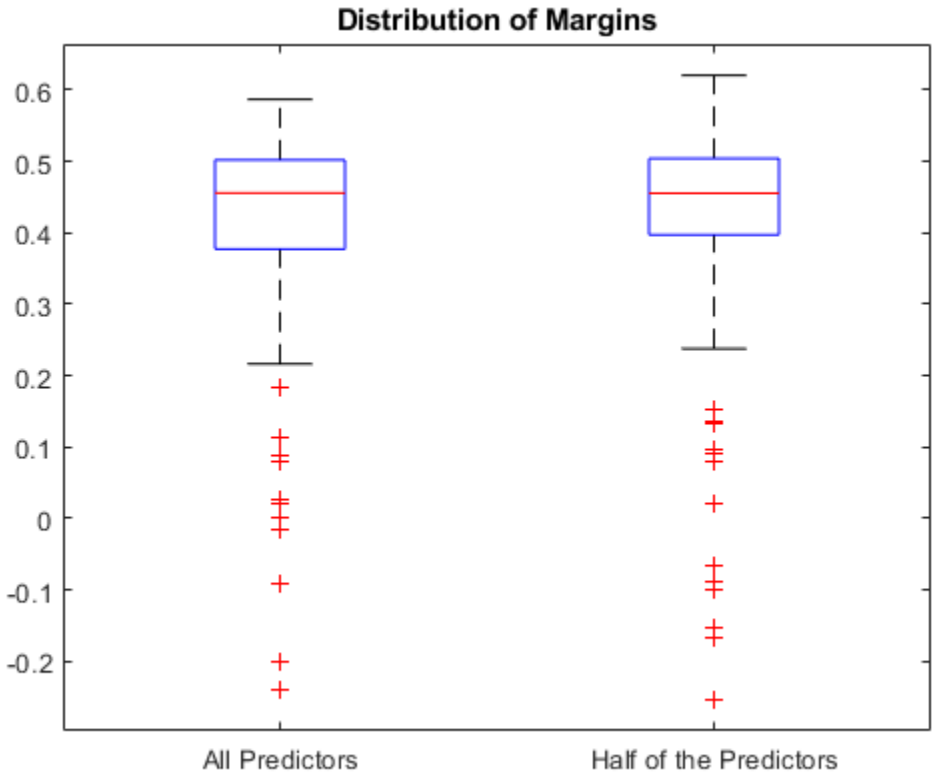
`CVMdl` and `PCVMdl` are `ClassificationPartitionedKernelECOC` models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the *k*-fold margins for each classifier.

```
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);
```

Plot the distribution of the margin sets using box plots.

```
boxplot([fullMargins partMargins], ...
    'Labels',{'All Predictors','Half of the Predictors'});
title('Distribution of Margins')
```



The `PCVMdl` margin distribution is similar to the `CVMdl` margin distribution.

Input Arguments

`CVMdl` — Cross-validated kernel ECOC model

`ClassificationPartitionedKernelECOC` model

Cross-validated kernel ECOC model, specified as a `ClassificationPartitionedKernelECOC` model. You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitcecoc` and specifying these name-value pair arguments:

- `'Learners'`– Set the value to `'kernel'`, a template object returned by `templateKernel`, or a cell array of such template objects.
- One of the arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldMargin(CVMdl,'Verbose',1)` specifies to display diagnostic messages in the Command Window.

`BinaryLoss` — Binary learner loss function
`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.
- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3226.

Example: `'Decoding','lossbased'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`margin` — Classification margins
numeric vector

Classification margins on page 33-3226, returned as a numeric vector. `margin` is an *n*-by-1 vector, where each row is the margin of the corresponding observation and *n* is the number of observations (`size(CVMdl.Y,1)`).

More About

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

`ClassificationPartitionedKernelECOC` | `fitcecoc`

Introduced in R2018b

kfoldMargin

Classification margins for observations not used in training

Syntax

```
m = kfoldMargin(CVMdl)
```

Description

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins on page 33-3235 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

Input Arguments

`CVMdl` — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, kfoldMargin applies the same data used to cross-validate the linear classification model (`X` and `Y`).

Output Arguments

`m` — Cross-validated classification margins

numeric vector | numeric matrix

Cross-validated classification margins on page 33-3235, returned as a numeric vector or matrix.

`m` is *n*-by-*L*, where *n* is the number of observations in the data that created `CVMdl` (see `X` and `Y`) and *L* is the number of regularization strengths in `CVMdl` (that is, `numel(CVMdl.Trained{1}.Lambda)`).

`m(i,j)` is the cross-validated classification margin of observation *i* using the linear classification model that has regularization strength `CVMdl.Trained{1}.Lambda(j)`.

Data Types: `single` | `double`

Examples

Estimate *k*-Fold Cross-Validation Margins

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the cross-validated margins.

```
m = kfoldMargin(CVMdl);
size(m)
```

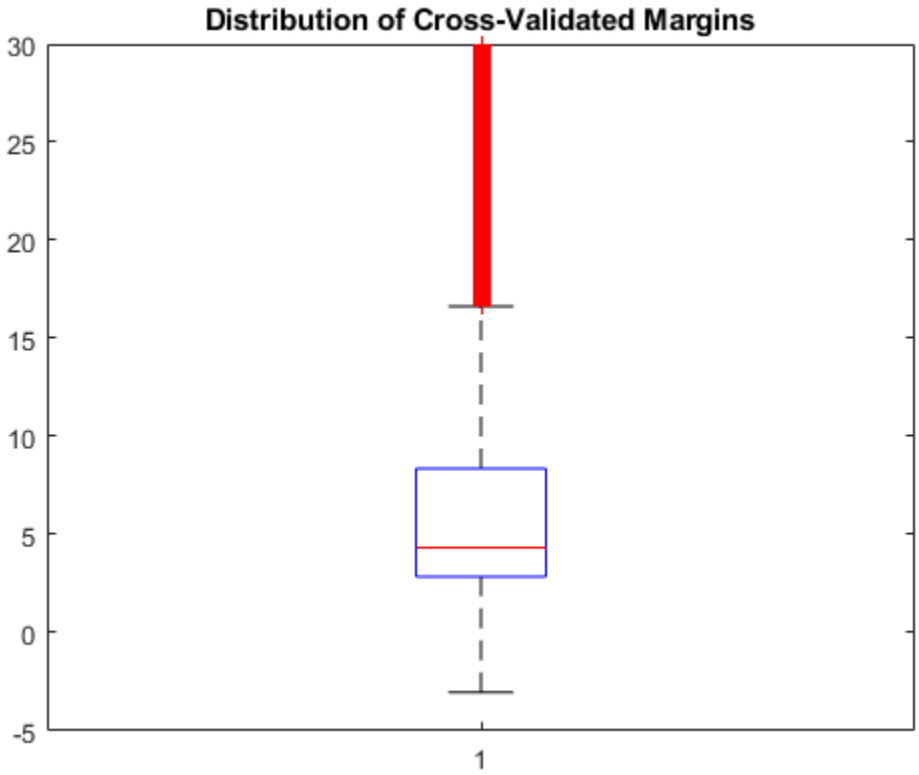
```
ans = 1×2

       31572           1
```

`m` is a 31572-by-1 vector. `m(j)` is the average of the out-of-fold margins for observation `j`.

Plot the *k*-fold margins using box plots.

```
figure;
boxplot(m);
h = gca;
h.YLim = [-5 30];
title('Distribution of Cross-Validated Margins')
```



Feature Selection Using *k*-fold Margins

One way to perform feature selection is to compare *k*-fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Margins” on page 33-3229.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpaRSA, and indicate that observations correspond to columns.

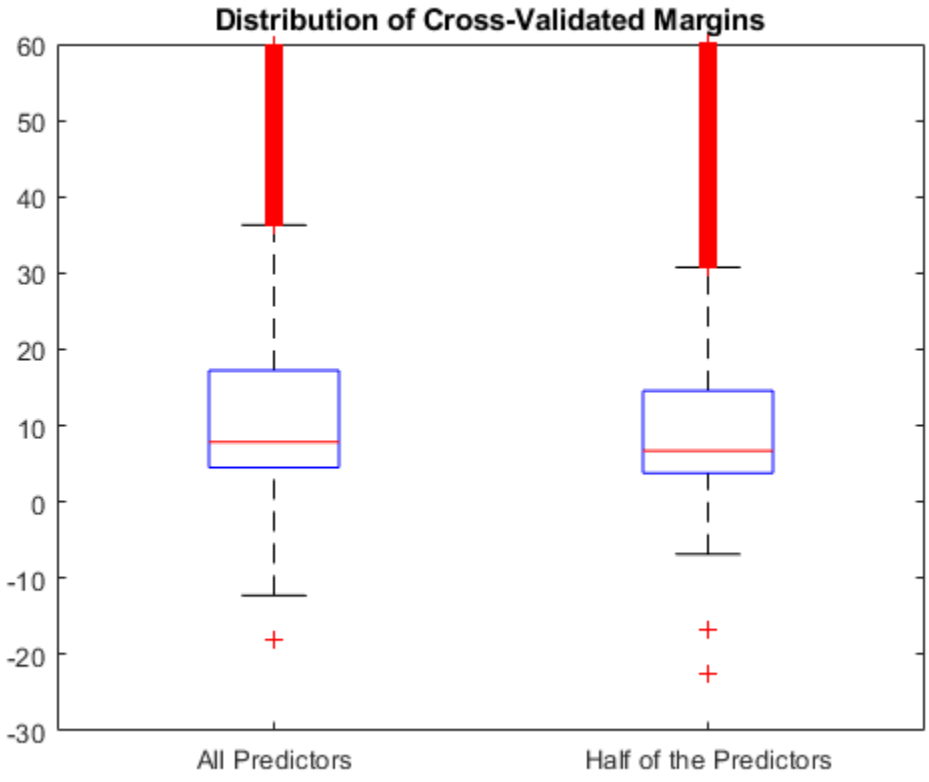
```
CVMdl = fitclinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
PCVMdl = fitclinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedLinear` models.

Estimate the *k*-fold margins for each classifier. Plot the distribution of the *k*-fold margins sets using box plots.

```
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-30 60];
title('Distribution of Cross-Validated Margins')
```



The distributions of the margins of the two classifiers are similar.

Find Good Lasso Penalty Using *k*-fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of *k*-fold margins.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Margins” on page 33-3229.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^{1}.

```
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5, ...
    'Learner','logistic','Solver','sparsa','Regularization','lasso', ...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
  ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
        NumObservations: 31572
                  KFold: 5
              Partition: [1x1 cvpartition]
             ClassNames: [0 1]
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedLinear` model. Because `fitclinear` implements 5-fold cross-validation, `CVMdl` contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the *k*-fold margins for each regularization strength.

```
m = kfoldMargin(CVMdl);
size(m)
```

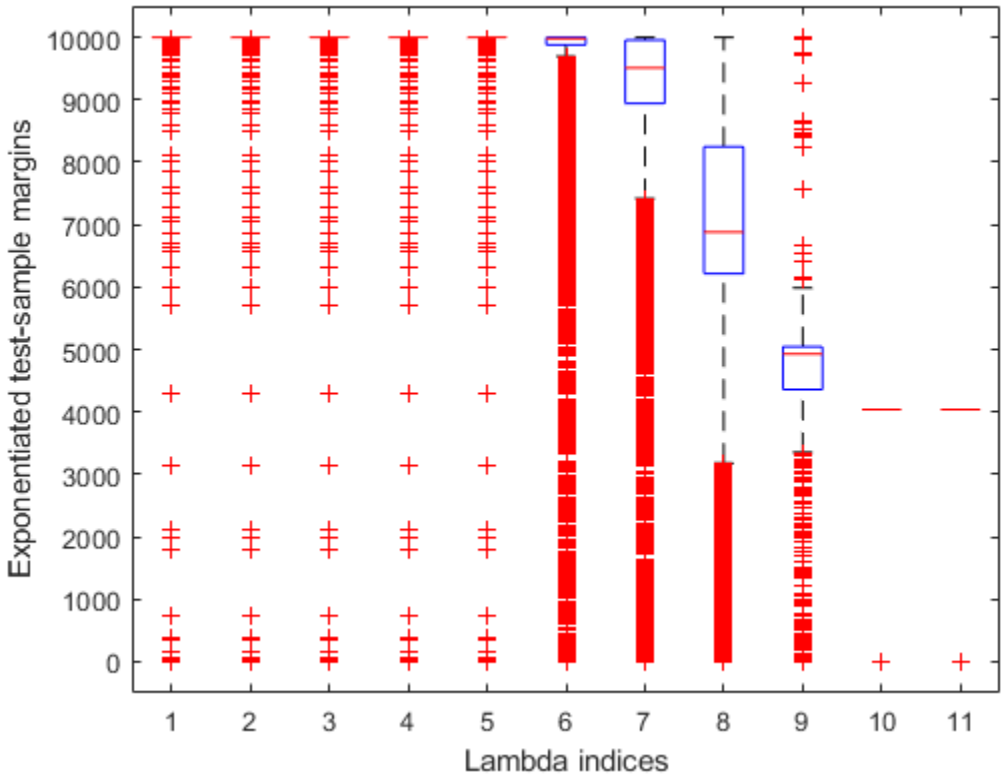
```
ans = 1×2

       31572          11
```

`m` is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the *k*-fold margins for each regularization strength. Because logistic regression scores are in [0,1], margins are in [-1,1]. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```
figure
boxplot(10000.^m)
ylabel('Exponentiated test-sample margins')
xlabel('Lambda indices')
```



Several values of `Lambda` yield *k*-fold margin distributions that are compacted near 10000. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the *k*-fold margin distributions start decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the desired regularization strength.

```
MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns', ...
    'Learner','logistic','Solver','sparsa','Regularization','lasso', ...
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and –1 otherwise. $f(x)$ is the positive-class classification score for the observation x. The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For linear classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j, β_j is the estimated column vector of coefficients (the model property `Beta(:,j)`) and b_j is the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the `'logit'` score transformation to the raw classification scores (see `ScoreTransform`).

Introduced in R2016a

kfoldMargin

Classification margins for observations not used in training

Syntax

```
m = kfoldMargin(CVMdl)
m = kfoldMargin(CVMdl,Name,Value)
```

Description

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins on page 33-3245 obtained by `CVMdl`, which is a cross-validated, error-correcting output codes (ECOC) model composed of linear classification models. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

`m = kfoldMargin(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme or verbosity level.

Input Arguments

`CVMdl` — Cross-validated, ECOC model composed of linear classification models

`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model using `fitcecoc` and by:

1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
2. Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, kfoldMargin applies the same data used to cross-validate the ECOC model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3259.

Example: `'Decoding','lossbased'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`m` — Cross-validated classification margins
numeric vector | numeric matrix

Cross-validated classification margins on page 33-3245, returned as a numeric vector or matrix.

`m` is *n*-by-*L*, where *n* is the number of observations in `X` and *L* is the number of regularization strengths in `Mdl` (that is, `numel(Mdl.Lambda)`).

`m(i,j)` is the cross-validated classification margin of observation *i* using the ECOC model, composed of linear classification models, that has regularization strength `Mdl.Lambda(j)`.

Examples

Estimate *k*-Fold Cross-Validation Margins

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in `Y` that are not `'simulink'`, `'dsp'`, or `'comm'`.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the *k*-fold margins.

```
m = kfoldMargin(CVMdl);
size(m)
```

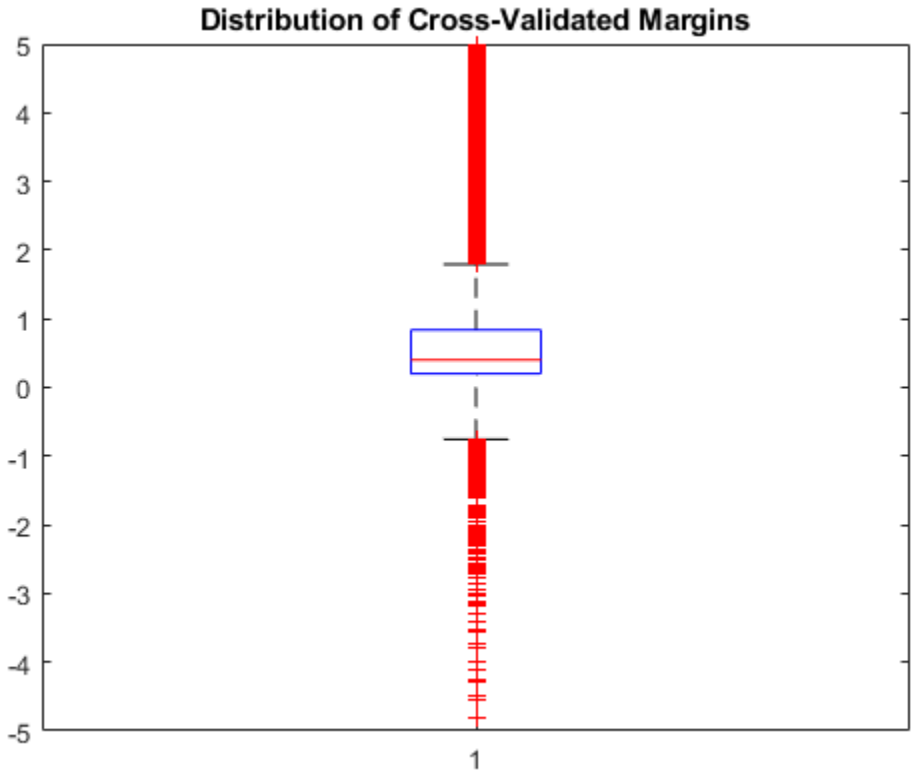
```
ans = 1×2

       31572           1
```

`m` is a 31572-by-1 vector. `m(j)` is the average of the out-of-fold margins for observation `j`.

Plot the *k*-fold margins using box plots.

```
figure;
boxplot(m);
h = gca;
h.YLim = [-5 5];
title('Distribution of Cross-Validated Margins')
```



Feature Selection Using *k*-fold Margins

One way to perform feature selection is to compare *k*-fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Margins” on page 33-3238, and orient the predictor data so that observations correspond to columns.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

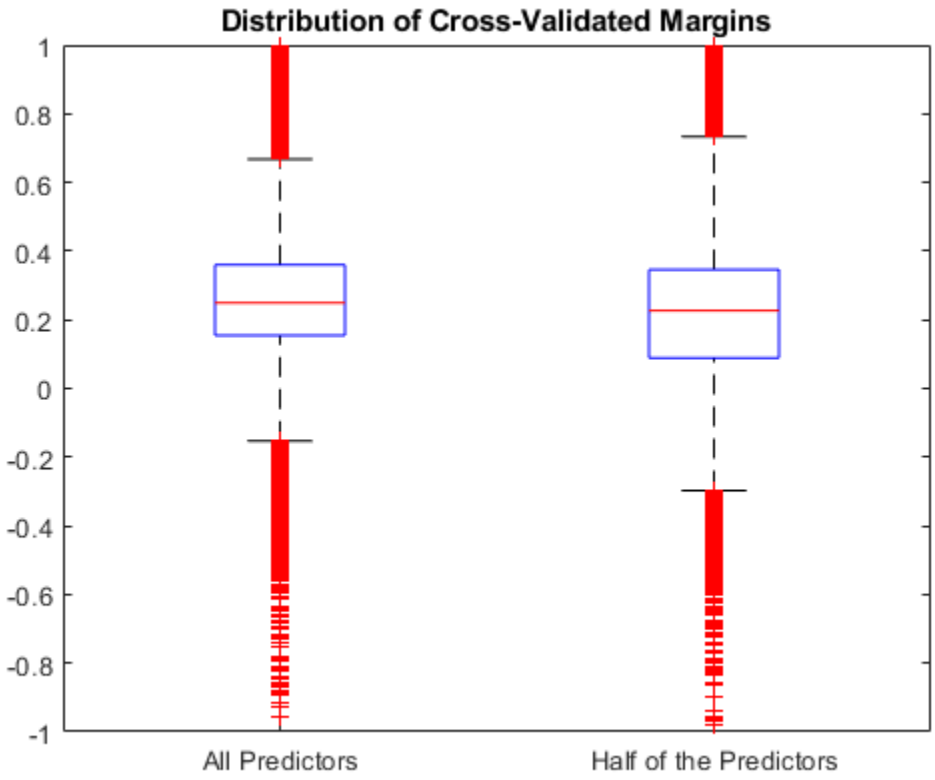
```
CVMdl = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
PCVMdl = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedLinearECOC` models.

Estimate the *k*-fold margins for each classifier. Plot the distribution of the *k*-fold margins sets using box plots.

```
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-1 1];
title('Distribution of Cross-Validated Margins')
```



The distributions of the *k*-fold margins of the two classifiers are similar.

Find Good Lasso Penalty Using *k*-fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of *k*-fold margins.

Load the NLP data set. Preprocess the data as in “Feature Selection Using k-fold Margins” on page 33-3240.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^{1}.

```
Lambda = logspace(-8,1,11);
```

Create a linear classification model template that specifies using logistic regression with a lasso penalty, using each of the regularization strengths, optimizing the objective function using SpaRSA, and reducing the tolerance on the gradient of the objective function to `1e-8`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```
CVMdl =
  ClassificationPartitionedLinearECOC
    CrossValidatedModel: 'LinearECOC'
           ResponseName: 'Y'
        NumObservations: 31572
                  KFold: 5
              Partition: [1x1 cvpartition]
             ClassNames: [comm    dsp    simulink    others]
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model.

Estimate the *k*-fold margins for each regularization strength. The scores for logistic regression are in [0,1]. Apply the quadratic binary loss.

```
m = kfoldMargin(CVMdl,'BinaryLoss','quadratic');
size(m)
```

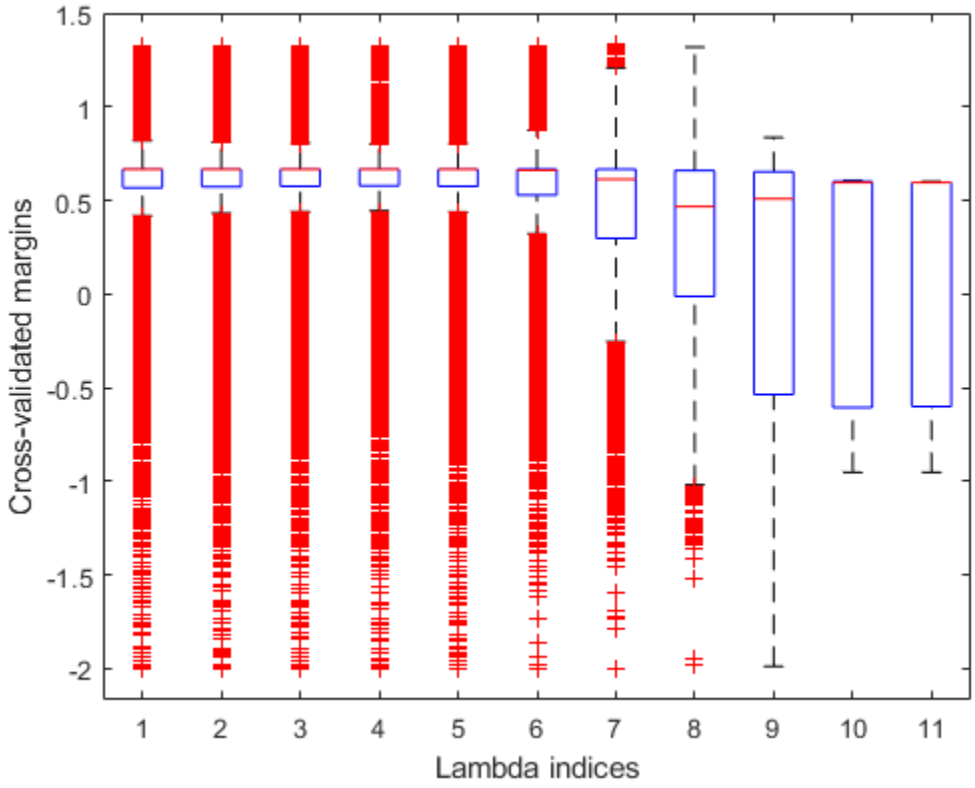
```
ans = 1×2

       31572          11
```

`m` is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the *k*-fold margins for each regularization strength.

```
figure;
boxplot(m)
ylabel('Cross-validated margins')
xlabel('Lambda indices')
```



Several values of `Lambda` yield similarly high margin distribution centers with low spreads. Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the margin distribution center starts decreasing and spread starts increasing.

```
LambdaFinal = Lambda(5);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda(5),'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or $(-\infty,\infty)$	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'logit'`	Logistic	$(-\infty,\infty)$	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldMargin

Package: `classreg.learning.partition`

Classification margins for cross-validated classification model

Syntax

```
M = kfoldMargin(CVMdl)
M = kfoldMargin(CVMdl,'IncludeInteractions',includeInteractions)
```

Description

`M = kfoldMargin(CVMdl)` returns classification margins on page 33-3248 obtained by the cross-validated classification model `CVMdl`. For every fold, `kfoldMargin` computes classification margins for validation-fold observations using a classifier trained on training-fold observations. `CVMdl.X` and `CVMdl.Y` contain both sets of observations.

`M = kfoldMargin(CVMdl,'IncludeInteractions',includeInteractions)` specifies whether to include interaction terms in computations. This syntax applies only to generalized additive models.

Examples

Estimate *k*-fold Margins of Classifier

Find the *k*-fold margins for an ensemble that classifies the `ionosphere` data.

Load the `ionosphere` data set.

```
load ionosphere
```

Create a template tree stump.

```
t = templateTree('MaxNumSplits',1);
```

Train a classification ensemble of decision trees. Specify `t` as the weak learner.

```
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Cross-validate the classifier using 10-fold cross-validation.

```
cvens = crossval(Mdl);
```

Compute the k-fold margins. Display summary statistics for the margins.

```
m = kfoldMargin(cvens);
marginStats = table(min(m),mean(m),max(m),...
    'VariableNames',{'Min','Mean','Max'})
```

```
marginStats=1×3 table
      Min       Mean      Max
```

```
    _______    _______    _______

    -11.312    7.3236     23.517
```

Input Arguments

`CVMdl` — Cross-validated partitioned classifier

`ClassificationPartitionedModel` object | `ClassificationPartitionedEnsemble` object | `ClassificationPartitionedGAM` object

Cross-validated partitioned classifier, specified as a `ClassificationPartitionedModel`, `ClassificationPartitionedEnsemble`, or `ClassificationPartitionedGAM` object. You can create the object in two ways:

- Pass a trained classification model listed in the following table to its `crossval` object function.
- Train a classification model using a function listed in the following table and specify one of the cross-validation name-value arguments for the function.

Classification Model	Function
`ClassificationDiscriminant`	`fitcdiscr`
`ClassificationEnsemble`	`fitcensemble`
`ClassificationGAM`	`fitcgam`
`ClassificationKNN`	`fitcknn`
`ClassificationNaiveBayes`	`fitcnb`
`ClassificationNeuralNetwork`	`fitcnet`
`ClassificationSVM`	`fitcsvm`
`ClassificationTree`	`fitctree`

`includeInteractions` — Flag to include interaction terms

`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `CVMdl` is `ClassificationPartitionedGAM`.

The default value is `true` if the models in `CVMdl` (`CVMdl.Trained`) contain interaction terms. The value must be `false` if the models do not contain interaction terms.

Data Types: `logical`

Output Arguments

`M` — Classification margins

numeric vector

Classification margins on page 33-3248, returned as a numeric vector. `M` is an *n*-by-1 vector, where each row is the margin of the corresponding observation and *n* is the number of observations. (*n* is `size(CVMdl.X,1)` when observations are in rows.)

If you use a holdout validation technique to create `CVMdl` (that is, if `CVMdl.KFold` is `1`), then `M` has `NaN` values for training-fold observations.

More About

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class. The classification margin for multiclass classification is the difference between the classification score for the true class and the maximal score for the false classes.

If the margins are on the same scale (that is, the score values are based on the same score transformation), then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Algorithms

`kfoldMargin` computes classification margins as described in the corresponding `margin` object function. For a model-specific description, see the appropriate `margin` function reference page in the following table.

Model Type	`margin` Function
Discriminant analysis classifier	`margin`
Ensemble classifier	`margin`
Generalized additive model classifier	`margin`
k-nearest neighbor classifier	`margin`
Naive Bayes classifier	`margin`
Neural network classifier	`margin`
Support vector machine classifier	`margin`
Binary decision tree for multiclass classification	`margin`

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports *k*-nearest neighbor and SVM model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also

`ClassificationPartitionedModel` | `kfoldEdge` | `kfoldLoss` | `kfoldPredict` | `kfoldfun`

Introduced in R2011a

kfoldPredict

Package: `classreg.learning.partition`

Classify observations in cross-validated ECOC model

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(___)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(___)
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for observations that it holds out during training. `CVMdl.X` contains both sets of observations.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict(___)` additionally returns negated values of the average binary loss per class (`NegLoss`) for validation-fold observations and positive-class scores (`PBScore`) for validation-fold observations classified by each binary learner, using any of the input argument combinations in the previous syntaxes.

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`[label,NegLoss,PBScore,Posterior] = kfoldPredict(___)` additionally returns posterior class probability estimates for validation-fold observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',1` when training the cross-validated ECOC model using `fitcecoc`. Otherwise, `kfoldPredict` throws an error.

Examples

Predict *k*-Fold Cross-Validation Labels

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
```

```
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

Predict the validation-fold labels. Print a random subset of true and predicted labels.

```
labels = kfoldPredict(CVMdl);
idx = randsample(numel(labels),10);
table(Y(idx),labels(idx),...
    'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans=10×2 table
    TrueLabels    PredictedLabels
    __________    _______________

    setosa          setosa
    versicolor      versicolor
    setosa          setosa
    virginica       virginica
    versicolor      versicolor
    setosa          setosa
    virginica       virginica
    virginica       virginica
    setosa          setosa
    setosa          setosa
```

`CVMdl` correctly labels the validation-fold observations with indices `idx`.

Predict Cross-Validation Labels Using Custom Binary Loss Function

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
K = numel(classOrder);  % Number of classes
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Alternatively, you can specify an anonymous binary loss function. In this case, create a function handle (`customBL`) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 validation-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);

idx = randsample(numel(label),10);
classOrder
```

```
classOrder = 3x1 categorical
     setosa
     versicolor
     virginica
```

```
table(Y(idx),label(idx),NegLoss(idx,:),'VariableNames',...
    {'TrueLabel','PredictedLabel','NegLoss'})
```

```
ans=10×3 table
    TrueLabel     PredictedLabel                NegLoss
    __________    ______________    ____________________________________

    setosa          versicolor      0.37141       2.1296       -4.001
    versicolor      versicolor      -1.2166      0.36678     -0.65021
    setosa          versicolor      0.23932       2.0793      -3.8186
    virginica       virginica       -1.9151     -0.19953      0.61467
    versicolor      versicolor      -1.3745      0.45532     -0.58077
    setosa          versicolor      0.20061       2.2774       -3.978
    virginica       versicolor      -1.4926     0.090706    -0.098127
    virginica       virginica       -1.7667     -0.13466      0.40134
    setosa          versicolor      0.20011       1.9111      -3.6112
    setosa          versicolor      0.16118       1.9679      -3.6291
```

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.

Estimate Cross-Validation Posterior Probabilities

Load Fisher's iris data set. Use the petal dimensions as the predictor data X. Specify the response data Y and the order of the classes in Y.

```
load fisheriris
X = meas(:,3:4);
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train and cross-validate an ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (returned by `kfoldPredict`) using the `'FitPosterior'` name-value pair argument. Specify the class order.

```
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on','FitPosterior',true,...
    'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross-validation.

Predict the validation-fold class posterior probabilities. Use 10 random initial values for the Kullback-Leibler algorithm.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl,'NumKLInitializations',10);
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all the binary learners compute posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10);
CVMdl.ClassNames
```

```
ans = 3x1 categorical
     setosa
     versicolor
     virginica
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10×3 table
    TrueLabel     PredLabel                  Posterior
    __________    __________    ___________________________________

    versicolor    versicolor     0.0086404       0.98243     0.0089302
    versicolor    virginica     2.2197e-14       0.12437       0.87563
    setosa        setosa             0.999    0.00022837    0.00076884
    versicolor    versicolor    2.2194e-14       0.98916      0.010845
```

```
    virginica     virginica       0.012316      0.012923       0.97476
    virginica     virginica      0.0015569     0.0015636       0.99688
    virginica     virginica      0.0042886     0.0043547       0.99136
    setosa        setosa             0.999    0.00028329    0.00071382
    virginica     virginica      0.0094736     0.0098247        0.9807
    setosa        setosa             0.999    0.00013558    0.00086196
```

The columns of `Posterior` correspond to the class order of `CVMdl.ClassNames`.

Estimate Cross-Validation Posterior Probabilities Using Parallel Computing

Train a multiclass ECOC model and estimate the posterior probabilities using parallel computing.

Load the `arrhythmia` data set. Examine the response data `Y`.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
     15        5      1.11%
     16       22      4.87%
```

```
n = numel(Y);
K = numel(unique(Y));
```

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of the options are empty (`[]`). The software uses default values for all empty options during training.

Because the response variable contains many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparserandom');
```

Train and cross-validate an ECOC model using parallel computing. Fit posterior probabilities (returned by `kfoldPredict`).

```
pool = parpool;                       % Invokes workers

Starting parallel pool (parpool) using the 'local' profile ...
connected to 6 workers.

options = statset('UseParallel',1);
CVMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',1,'CrossVal','on');

Warning: One or more folds do not contain points from all the groups.
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

The pool invokes six workers, although the number of workers might vary among systems. Because some classes have low relative frequency, one or more folds most likely do not contain observations from all classes.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of validation-fold observations.

```
[~,~,~,posterior] = kfoldPredict(CVMdl,'Options',options);
idx = randsample(n,10);
table(idx,Y(idx),posterior(idx,1),...
    'VariableNames',{'OOFSampleIndex','TrueLabel','PosteriorNoArrhythmia'})

ans=10×3 table
    OOFSampleIndex    TrueLabel    PosteriorNoArrhythmia
    ______________    _________    _____________________

         202              1                0.8438
         243              1                0.9435
          18              1               0.81198
          49              6              0.090154
         234              1                0.61625
         315              1                0.97187
```

Input Arguments

`CVMdl` — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`.
- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldPredict(CVMdl,'PosteriorMethod','qp')` specifies to estimate multiclass posterior probabilities by solving a least-squares problem using quadratic programming.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3259.

Example: `'Decoding','lossbased'`

`NumKLInitializations` — Number of random initial values
`0` (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer scalar.

If you do not request the fourth output argument (`Posterior`) and set `'PosteriorMethod','kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 33-3260.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.

- Specify `'Options',statset('UseParallel',true)`.

`PosteriorMethod` — Posterior probability estimation method
`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 33-3260.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 33-3261.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`label` — Predicted class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type and number of rows as `CVMdl.Y`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`NegLoss` — Negated average binary losses
numeric matrix

Negated average binary losses, returned as a numeric matrix. `NegLoss` is an n-by-K matrix, where n is the number of observations (`size(CVMdl.X,1)`) and K is the number of unique classes (`size(CVMdl.ClassNames,1)`).

`PBScore` — Positive-class scores
numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an *n*-by-*L* matrix, where *n* is the number of observations (`size(CVMdl.X,1)`) and *L* is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`Posterior` — Posterior class probabilities
numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an *n*-by-*K* matrix, where *n* is the number of observations (`size(CVMdl.X,1)`) and *K* is the number of unique classes (`size(CVMdl.ClassNames,1)`).

You must set `'FitPosterior',1` when training the cross-validated ECOC model using `fitcecoc` in order to request `Posterior`. Otherwise, the software throws an error.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j)}{\sum_{j=1}^{L} \left|m_{kj}\right|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k,j) of the coding design matrix M.
- I is the indicator function.
- $\widehat{p}_k$ is the class posterior probability estimate for class k of an observation, $k = 1,...,K$.
- r_j is the positive-class posterior probability for binary learner j. That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r,\widehat{r}) = \sum_{j=1}^{L} w_j\left[r_j\log\frac{r_j}{\widehat{r}_j} + (1-r_j)\log\frac{1-r_j}{1-\widehat{r}_j}\right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j.

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i.

The software minimizes the divergence iteratively. The first step is to choose initial values $\widehat{p}_k^{(0)};\ k = 1, ..., K$ for the class posterior probabilities.

- If you do not specify `'NumKLIterations'`, then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ.
  - $\widehat{p}_k^{(0)} = 1/K;\ k = 1, ..., K$.
  - $\widehat{p}_k^{(0)};\ k = 1, ..., K$ is the solution of the system

    $$M_{01}\widehat{p}^{(0)} = r,$$

    where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-279. The software uses `lsqnonneg` to solve the system.
- If you specify `'NumKLIterations',c`, where `c` is a natural number, then the software does the following to choose the set $\widehat{p}_k^{(0)};\ k = 1, ..., K$, and selects the set that minimizes Δ.
  - The software tries both sets of deterministic initial values as described previously.
  - The software randomly generates `c` vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t, the software completes these steps:

1 Compute

$$\widehat{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \widehat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \widehat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

2 Estimate the next class posterior probability using

$$\widehat{p}_k^{(t+1)} = \widehat{p}_k^{(t)} \frac{\sum_{j=1}^{L} w_j \left[r_j I\left(m_{kj} = +1\right) + \left(1 - r_j\right) I\left(m_{kj} = -1\right) \right]}{\sum_{j=1}^{L} w_j \left[\widehat{r}_j^{(t)} I\left(m_{kj} = +1\right) + \left(1 - \widehat{r}_j^{(t)}\right) I\left(m_{kj} = -1\right) \right]}.$$

3 Normalize $\widehat{p}_k^{(t+1)};\ k = 1, ..., K$ so that they sum to 1.

4 Check for convergence.

For more details, see [Hastie et al.] on page 18-280 and [Zadrozny] on page 18-281.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1 Estimate the positive-class posterior probabilities, r_j, for binary learners $j = 1,...,L$.

2 Using the relationship between r_j and $\widehat{p}_k$ [Wu et al.] on page 18-281, minimize

$$\sum_{j=1}^{L}\left[-r_j\sum_{k=1}^{K}\widehat{p}_k I\left(m_{kj}=-1\right)+\left(1-r_j\right)\sum_{k=1}^{K}\widehat{p}_k I\left(m_{kj}=+1\right)\right]^2$$

with respect to $\widehat{p}_k$ and the restrictions

$$0\le\widehat{p}_k\le 1$$

$$\sum_k\widehat{p}_k=1.$$

The software performs minimization using `quadprog`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldPredict

Package: `classreg.learning.partition`

Classify observations in cross-validated kernel classification model

Syntax

```
label = kfoldPredict(CVMdl)
[label,score] = kfoldPredict(CVMdl)
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a model trained on training-fold observations.

`[label,score] = kfoldPredict(CVMdl)` also returns classification scores on page 33-3268 for both classes.

Examples

Classify Observations Using Cross-Validation

Classify observations using a cross-validated, binary kernel classifier, and display the confusion matrix for the resulting classification.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
rng(1); % For reproducibility
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```
CVMdl =
  ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
           ResponseName: 'Y'
        NumObservations: 351
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'b'  'g'}
         ScoreTransform: 'none'

  Properties, Methods
```

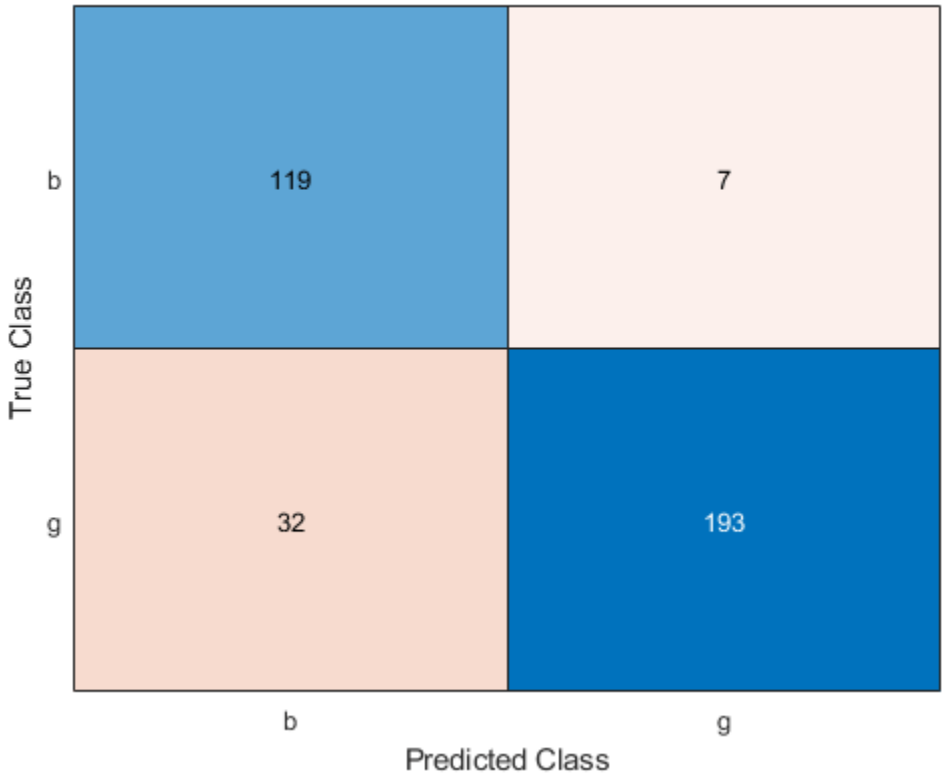
`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Classify the observations that `fitckernel` does not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Construct a confusion matrix to compare the true classes of the observations to their predicted labels.

```
C = confusionchart(Y,label);
```



The `CVMdl` model misclassifies 32 good (`'g'`) radar returns as being bad (`'b'`) and misclassifies 7 bad radar returns as being good.

Estimate *k*-Fold Cross-Validation Posterior Class Probabilities

Estimate posterior class probabilities using a cross-validated, binary kernel classifier, and determine the quality of the model by plotting a receiver operating characteristic (ROC) curve. Cross-validated kernel classification models return posterior probabilities for logistic regression learners only.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data. Specify the class order, and fit logistic regression learners.

```
rng(1); % For reproducibility
CVMdl = fitckernel(X,Y,'Crossval','on', ...
    'ClassNames',{'b','g'},'Learner','logistic')
```

```
CVMdl =
  ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
           ResponseName: 'Y'
        NumObservations: 351
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'b'  'g'}
         ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Predict the posterior class probabilities for the observations that `fitckernel` does not use in training the folds.

```
[~,posterior] = kfoldPredict(CVMdl);
```

The output `posterior` is a matrix with two columns and `n` rows, where `n` is the number of observations. Column `i` contains posterior probabilities of `CVMdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the area under the curve (AUC). Specify that the second class is the positive class.

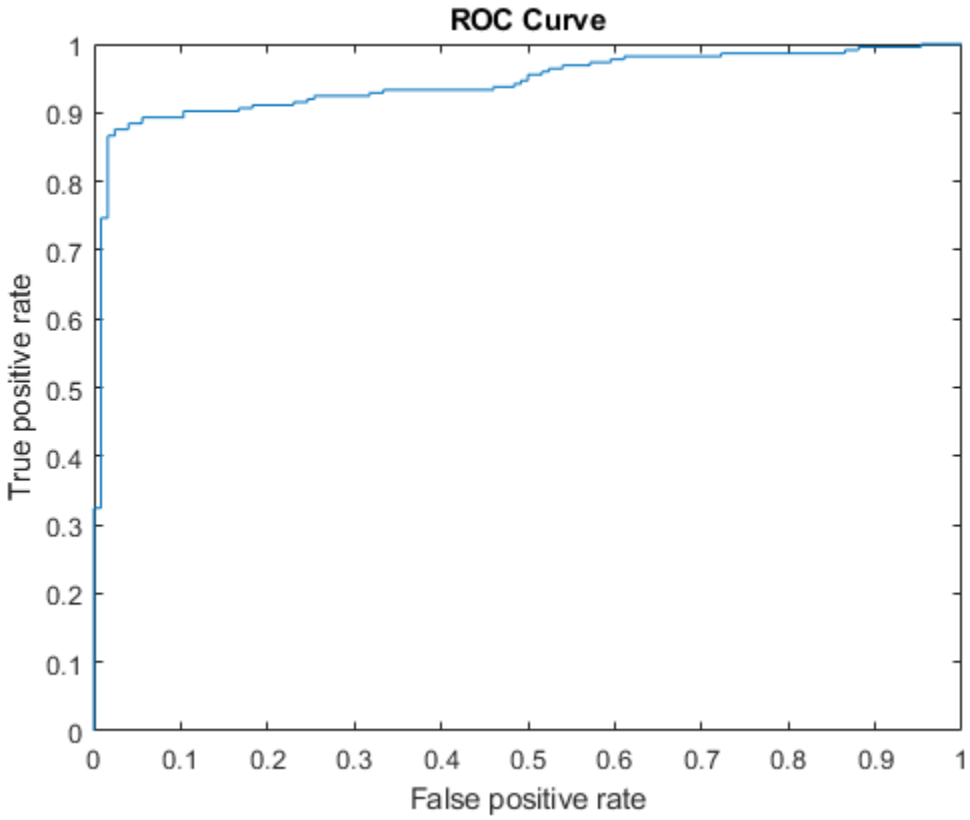
```
[fpr,tpr,~,auc] = perfcurve(Y,posterior(:,2),CVMdl.ClassNames(2));
auc
```

```
auc = 0.9441
```

The AUC is close to `1`, which indicates that the model predicts labels well.

Plot an ROC curve.

```
plot(fpr,tpr)
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
```



Input Arguments

`CVMdl` — Cross-validated, binary kernel classification model

`ClassificationPartitionedKernel` model object

Cross-validated, binary kernel classification model, specified as a `ClassificationPartitionedKernel` model object. You can create a `ClassificationPartitionedKernel` model by using `fitckernel` and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the kernel classification model (`X` and `Y`).

Output Arguments

`label` — Predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

`label` has *n* rows, where *n* is the number of observations in `X`, and has the same data type as the observed class labels (`Y`) used to train `CVMdl`. (The software treats string arrays as cell arrays of character vectors.)

`kfoldPredict` classifies observations into the class yielding the highest score.

`score` — Classification scores
numeric array

Classification scores on page 33-3268, returned as an *n*-by-2 numeric array, where *n* is the number of observations in `X`. `score(i,j)` is the score for classifying observation `i` into class `j`. The order of the classes is stored in `CVMdl.ClassNames`.

If `CVMdl.Trained{1}.Learner` is `'logistic'`, then classification scores are posterior probabilities.

More About

Classification Score

For kernel classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b\,.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the `'logit'` score transformation to the raw classification scores (see `ScoreTransform`).

`ClassificationPartitionedKernel` | `fitckernel`

Introduced in R2018b

kfoldPredict

Package: `classreg.learning.partition`

Classify observations in cross-validated kernel ECOC model

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict( ___ )
[label,NegLoss,PBScore,Posterior] = kfoldPredict( ___ )
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a model trained on training-fold observations. `kfoldPredict` applies the same data used to create `CVMdl` (see `fitcecoc`).

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict( ___ )` additionally returns negated values of the average binary loss per class (`NegLoss`) for validation-fold observations and positive-class scores (`PBScore`) for validation-fold observations classified by each binary learner, using any of the input argument combinations in the previous syntaxes.

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`[label,NegLoss,PBScore,Posterior] = kfoldPredict( ___ )` additionally returns posterior class probability estimates for validation-fold observations (`Posterior`).

To obtain posterior class probabilities, the kernel classification binary learners must be logistic regression models. Otherwise, `kfoldPredict` throws an error.

Examples

Classify Observations Using Cross-Validation

Classify observations using a cross-validated, multiclass kernel ECOC classifier, and display the confusion matrix for the resulting classification.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
```

```
CVMdl =
  ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
           ResponseName: 'Y'
        NumObservations: 150
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'setosa'  'versicolor'  'virginica'}
         ScoreTransform: 'none'

  Properties, Methods
```

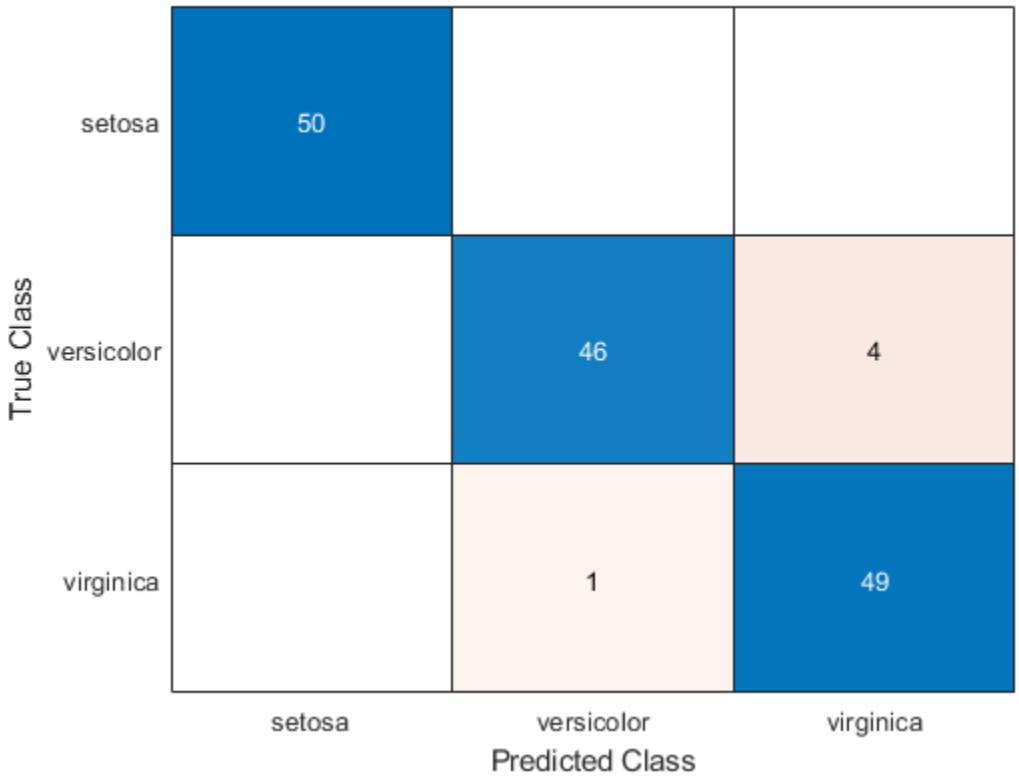
`CVMdl` is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Classify the observations that `fitcecoc` does not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Construct a confusion matrix to compare the true classes of the observations to their predicted labels.

```
C = confusionchart(Y,label);
```



The `CVMdl` model misclassifies four `'versicolor'` irises as `'virginica'` irises and misclassifies one `'virginica'` iris as a `'versicolor'` iris.

Predict Cross-Validation Labels Using Custom Binary Loss

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model of kernel classification models using 5-fold cross-validation.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','KFold',5)
```

```
CVMdl =
  ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
           ResponseName: 'Y'
        NumObservations: 150
                  KFold: 5
              Partition: [1x1 cvpartition]
             ClassNames: {'setosa'  'versicolor'  'virginica'}
```

```
          ScoreTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedKernelECOC` model. It contains the property `Trained`, which is a 5-by-1 cell array of `CompactClassificationECOC` models.

By default, the kernel classification models that compose the `CompactClassificationECOC` models use SVMs. SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function. In this case, create a function handle (`customBL`) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);

idx = randsample(numel(label),10);
table(Y(idx),label(idx),NegLoss(idx,1),NegLoss(idx,2),NegLoss(idx,3),...
    'VariableNames',[{'True'};{'Predicted'};...
    unique(CVMdl.ClassNames)])
```

```
ans=10×5 table
         True           Predicted        setosa     versicolor    virginica
    ________________    ____________    ________    __________    _________

    {'setosa'    }    {'setosa'    }     0.20926     -0.84572     -0.86354
    {'setosa'    }    {'setosa'    }     0.16144     -0.90572     -0.75572
    {'virginica' }    {'versicolor'}    -0.83532     -0.12157     -0.54311
    {'virginica' }    {'virginica' }    -0.97235     -0.69759      0.16994
    {'virginica' }    {'virginica' }    -0.89441     -0.69937     0.093778
    {'virginica' }    {'virginica' }    -0.86774     -0.47297     -0.15929
    {'setosa'    }    {'setosa'    }     -0.1026     -0.69671     -0.70069
    {'setosa'    }    {'setosa'    }      0.1001     -0.89163     -0.70848
    {'virginica' }    {'virginica' }     -1.0106     -0.52919     0.039829
    {'versicolor'}    {'versicolor'}     -1.0298     0.027354     -0.49757
```

The cross-validated model correctly predicts the labels for 9 of the 10 random observations.

Estimate *k*-Fold Cross-Validation Posterior Class Probabilities

Estimate posterior class probabilities using a cross-validated, multiclass kernel ECOC classification model. Kernel classification models return posterior probabilities for logistic regression learners only.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Create a kernel template for the binary kernel classification models. Specify to fit logistic regression learners.

```
t = templateKernel('Learner','logistic')
```

```
t =
Fit template for classification Kernel.

                      Type: 'classification'
```

`t` is a kernel template. Most of its properties are empty. When training an ECOC classifier using the template, the software sets the applicable properties to their default values.

Cross-validate an ECOC model using the kernel template.

```
rng('default'); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on')
```

```
CVMdl =
  ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
           ResponseName: 'Y'
        NumObservations: 150
                  KFold: 10
              Partition: [1x1 cvpartition]
             ClassNames: {'setosa'  'versicolor'  'virginica'}
         ScoreTransform: 'none'
```

```
  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross-validation.

Predict the validation-fold class posterior probabilities.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl);
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display the posterior probabilities for 10 randomly selected observations.

```
idx = randsample(size(X,1),10);
CVMdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10×3 table

    {'setosa'    }    {'setosa'    }     0.42448     0.21181     0.36371
    {'virginica' }    {'virginica' }    0.082705      0.1428      0.7745
```

The columns of `Posterior` correspond to the class order of `CVMdl.ClassNames`.

Input Arguments

`CVMdl` — Cross-validated kernel ECOC model

`ClassificationPartitionedKernelECOC` model

Cross-validated kernel ECOC model, specified as a `ClassificationPartitionedKernelECOC` model. You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitcecoc` and specifying these name-value pair arguments:

- `'Learners'` – Set the value to `'kernel'`, a template object returned by `templateKernel`, or a cell array of such template objects.

- One of the arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldPredict(CVMdl,'PosteriorMethod','qp')` specifies to estimate multiclass posterior probabilities by solving a least-squares problem using quadratic programming.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.

- L is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3278.

Example: `'Decoding','lossbased'`

`NumKLInitializations` — Number of random initial values
`0` (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer scalar.

If you do not request the fourth output argument (`Posterior`) and set `'PosteriorMethod','kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 33-3279.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`PosteriorMethod` — Posterior probability estimation method
`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 33-3279.

- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 33-3280.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`label` — Predicted class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type and number of rows as `CVMdl.Y`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`NegLoss` — Negated average binary losses
numeric matrix

Negated average binary losses, returned as a numeric matrix. `NegLoss` is an *n*-by-*K* matrix, where *n* is the number of observations (`size(CVMdl.Y,1)`) and *K* is the number of unique classes (`size(CVMdl.ClassNames,1)`).

`PBScore` — Positive-class scores
numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an *n*-by-*L* matrix, where *n* is the number of observations (`size(CVMdl.Y,1)`) and *L* is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`Posterior` — Posterior class probabilities
numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an n-by-K matrix, where n is the number of observations (`size(CVMdl.Y,1)`) and K is the number of unique classes (`size(CVMdl.ClassNames,1)`).

To return posterior probabilities, each kernel classification binary learner must have its `Learner` property set to `'logistic'`. Otherwise, the software throws an error.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or $(-\infty,\infty)$	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$

Value	Description	Score Domain	$g(y_j,s_j)$
`'linear'`	Linear	(–∞,∞)	$(1 - y_j s_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k,j) of the coding design matrix M.
- I is the indicator function.
- $\widehat{p}_k$ is the class posterior probability estimate for class k of an observation, $k = 1,...,K$.
- r_j is the positive-class posterior probability for binary learner j. That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r,\widehat{r}) = \sum_{j=1}^{L} w_j \left[r_j \log\frac{r_j}{\widehat{r}_j} + (1 - r_j)\log\frac{1 - r_j}{1 - \widehat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j.

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i.

The software minimizes the divergence iteratively. The first step is to choose initial values $\widehat{p}_k^{(0)};\ k = 1,...,K$ for the class posterior probabilities.

- If you do not specify `'NumKLIterations'`, then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ.
  - $\widehat{p}_k^{(0)} = 1/K;\ k = 1,...,K$.
  - $\widehat{p}_k^{(0)};\ k = 1,...,K$ is the solution of the system

$$M_{01}\hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-279. The software uses `lsqnonneg` to solve the system.

- If you specify `'NumKLIterations',c`, where `c` is a natural number, then the software does the following to choose the set $\hat{p}_k^{(0)};\ k = 1,\ldots,K$, and selects the set that minimizes Δ.
  - The software tries both sets of deterministic initial values as described previously.
  - The software randomly generates `c` vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t, the software completes these steps:

1 Compute

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

2 Estimate the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^{L} w_j \left[r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1) \right]}{\sum_{j=1}^{L} w_j \left[\hat{r}_j^{(t)} I(m_{kj} = +1) + \left(1 - \hat{r}_j^{(t)}\right) I(m_{kj} = -1) \right]}.$$

3 Normalize $\hat{p}_k^{(t+1)};\ k = 1,\ldots,K$ so that they sum to 1.

4 Check for convergence.

For more details, see [Hastie et al.] on page 18-280 and [Zadrozny] on page 18-281.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1 Estimate the positive-class posterior probabilities, r_j, for binary learners $j = 1,\ldots,L$.

2 Using the relationship between r_j and $\hat{p}_k$ [Wu et al.] on page 18-281, minimize

$$\sum_{j=1}^{L} \left[-r_j \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^{K} \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to $\hat{p}_k$ and the restrictions

$$0 \le \hat{p}_k \le 1$$

$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using `quadprog`.

Introduced in R2018b

kfoldPredict

Predict labels for observations not used for training

Syntax

```
Label = kfoldPredict(CVMdl)
[Label,Score] = kfoldPredict(CVMdl)
```

Description

`Label = kfoldPredict(CVMdl)` returns cross-validated class labels predicted by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains using all other observations.

`Label` contains predicted class labels for each regularization strength in the linear classification models that compose `CVMdl`.

`[Label,Score] = kfoldPredict(CVMdl)` also returns cross-validated classification scores on page 33-3289 for both classes. `Score` contains classification scores for each regularization strength in `CVMdl`.

Input Arguments

`CVMdl` — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, kfoldPredict applies the same data used to cross-validate the linear classification model (`X` and `Y`).

Output Arguments

`Label` — Cross-validated, predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an n-by-L array of the same data type as the observed class labels (see `Y`) used to create `CVMdl`. (The software treats string arrays as cell arrays of character vectors.) n is the number of observations in the predictor data (see `X`) and L is the number of regularization strengths in `CVMdl.Trained{1}.Lambda`. That is, `Label(`i`,`j`)` is the predicted class label for observation i using the linear classification model that has regularization strength `CVMdl.Trained{1}.Lambda(`j`)`.

If `Y` is a character array and $L > 1$, then `Label` is a cell array of class labels.

`Score` — Cross-validated classification scores
numeric array

Cross-validated classification scores on page 33-3289, returned as an n-by-2-by-L numeric array. n is the number of observations in the predictor data that created `CVMdl` (see `X`) and L is the number of regularization strengths in `CVMdl.Trained{1}.Lambda`. `Score(`i`,`k`,`j`)` is the score for classifying observation i into class k using the linear classification model that has regularization strength `CVMdl.Trained{1}.Lambda(`j`)`. `CVMdl.ClassNames` stores the order of the classes.

If `CVMdl.Trained{1}.Learner` is `'logistic'`, then classification scores are posterior probabilities.

Examples

Predict *k*-fold Cross-Validation Labels

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model using the entire data set, which can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'CrossVal','on');
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [34023x1 double]
              Bias: -1.0008
            Lambda: 3.5193e-05
           Learner: 'svm'

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Predict labels for the observations that `fitclinear` did not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Because there is one regularization strength in `Mdl1`, `label` is a column vector of predictions containing as many rows as observations in `X`.

Construct a confusion matrix.

```
ConfusionTrain = confusionchart(Ystats,label);
```

The model misclassifies 15 `'stats'` documentation pages as being outside of the Statistics and Machine Learning Toolbox documentation, and misclassifies nine pages as `'stats'` pages.

Estimate *k*-fold Cross-Validation Posterior Class Probabilities

Linear classification models return posterior probabilities for logistic regression learners only.

Load the NLP data set and preprocess it as in “Predict k-fold Cross-Validation Labels” on page 33-3283. Transpose the predictor data matrix.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Cross-validate binary, linear classification models using 5-fold cross-validation. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'KFold',5,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','GradientTolerance',1e-8);
```

Predict the posterior class probabilities for observations not used to train each fold.

```
[~,posterior] = kfoldPredict(CVMdl);
CVMdl.ClassNames
```

```
ans = 2x1 logical array

   0
   1
```

Because there is one regularization strength in `CVMdl`, `posterior` is a matrix with 2 columns and rows equal to the number of observations. Column *i* contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the AUC. Specify that the second class is the positive class.

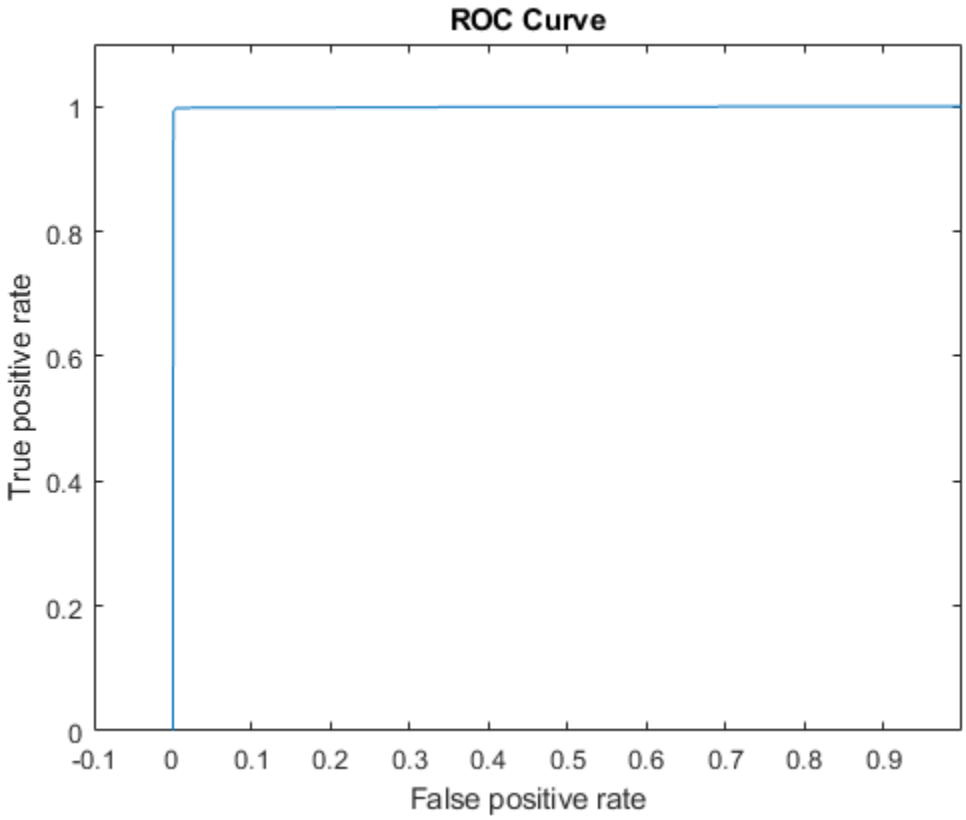
```
[fpr,tpr,~,auc] = perfcurve(Ystats,posterior(:,2),CVMdl.ClassNames(2));
auc
```

```
auc = 0.9990
```

The AUC is `0.9990`, which indicates a model that predicts well.

Plot an ROC curve.

```
figure;
plot(fpr,tpr)
h = gca;
h.XLim(1) = -0.1;
h.YLim(2) = 1.1;
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
```



The ROC curve indicates that the model classifies almost perfectly.

Find Good Lasso Penalty Using Cross-Validated AUC

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare cross-validated AUC values.

Load the NLP data set. Preprocess the data as in “Estimate k-fold Cross-Validation Posterior Class Probabilities” on page 33-3284.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

There are 9471 observations in the test sample.

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6,-0.5,11);
```

Cross-validate a binary, linear classification models that use each of the regularization strengths and 5-fold cross-validation. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
rng(10) % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns', ...
    'KFold',5,'Learner','logistic','Solver','sparsa', ...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)

CVMdl =
  ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
        NumObservations: 31572
                  KFold: 5
              Partition: [1x1 cvpartition]
             ClassNames: [0 1]
         ScoreTransform: 'none'

  Properties, Methods

Mdl1 = CVMdl.Trained{1}

Mdl1 =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'logit'
              Beta: [34023x11 double]
              Bias: [1x11 double]
            Lambda: [1x11 double]
           Learner: 'logistic'

  Properties, Methods
```

`Mdl1` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 11 models, one for each regularization strength in `Lambda`.

Predict the cross-validated labels and posterior class probabilities.

```
[label,posterior] = kfoldPredict(CVMdl);
CVMdl.ClassNames;
[n,K,L] = size(posterior)

n = 31572

K = 2

L = 11

posterior(3,1,5)

ans = 1.0000
```

`label` is a 31572-by-11 matrix of predicted labels. Each column corresponds to the predicted labels of the model trained using the corresponding regularization strength. `posterior` is a 31572-by-2-by-11 matrix of posterior class probabilities. Columns correspond to classes and pages correspond to regularization strengths. For example, `posterior(3,1,5)` indicates that the posterior probability

that the first class (label `0`) is assigned to observation 3 by the model that uses `Lambda(5)` as a regularization strength is 1.0000.

For each model, compute the AUC. Designate the second class as the positive class.

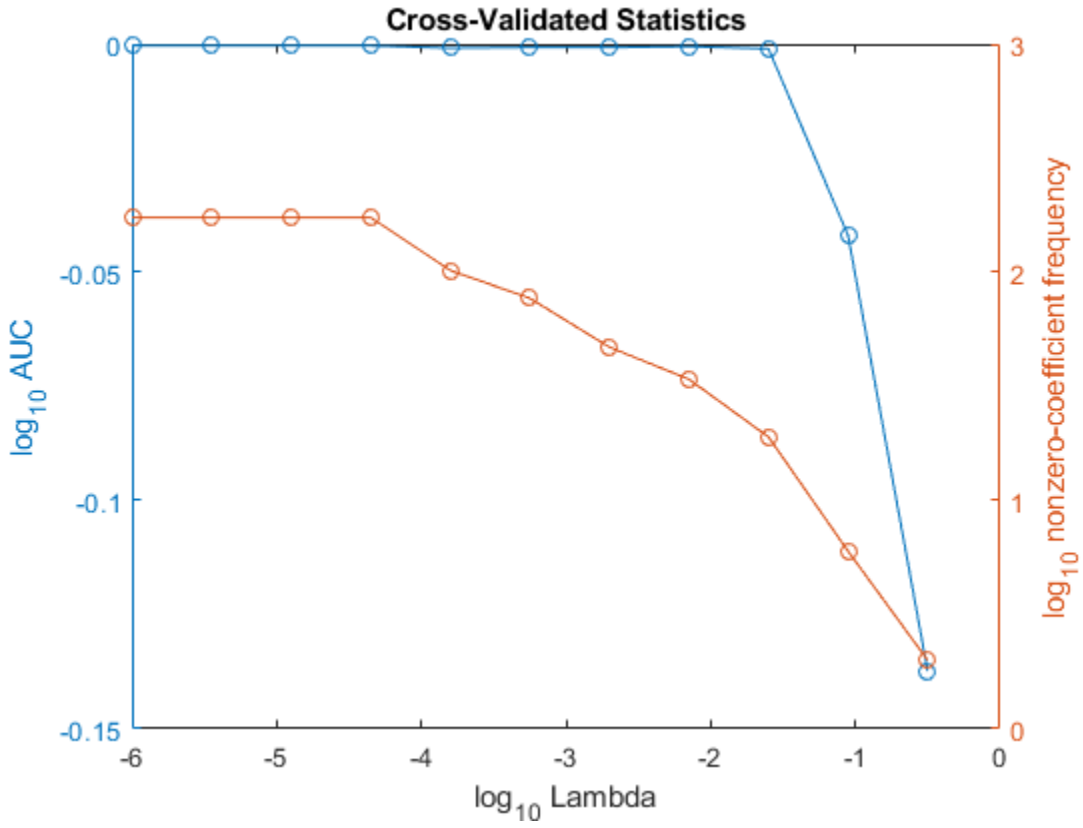
```
auc = 1:numel(Lambda);  % Preallocation
for j = 1:numel(Lambda)
    [~,~,~,auc(j)] = perfcurve(Ystats,posterior(:,2,j),CVMdl.ClassNames(2));
end
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you trained the model. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns', ...
    'Learner','logistic','Solver','sparsa','Regularization','lasso', ...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(auc), ...
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} AUC')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Cross-Validated Statistics')
hold off
```



Choose the index of the regularization strength that balances predictor variable sparsity and high AUC. In this case, a value between 10^{-3} to 10^{-1} should suffice.

```
idxFinal = 9;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Classification Score

For linear classification models, the raw classification score for classifying the observation x, a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j, β_j is the estimated column vector of coefficients (the model property `Beta(:,j)`) and b_j is the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the `'logit'` score transformation to the raw classification scores (see `ScoreTransform`).

Introduced in R2016a

kfoldPredict

Predict labels for observations not used for training

Syntax

```
Label = kfoldPredict(CVMdl)
Label = kfoldPredict(CVMdl,Name,Value)
[Label,NegLoss,PBScore] = kfoldPredict( ___ )
[Label,NegLoss,PBScore,Posterior] = kfoldPredict( ___ )
```

Description

`Label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains using all other observations. `kfoldPredict` applies the same data used create `CVMdl` (see `fitcecoc`).

Also, `Label` contains class labels for each regularization strength in the linear classification models that compose `CVMdl`.

`Label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[Label,NegLoss,PBScore] = kfoldPredict( ___ )` additionally returns, for held-out observations and each regularization strength:

- Negated values of the average binary loss per class (`NegLoss`).
- Positive-class scores (`PBScore`) for each binary learner.

`[Label,NegLoss,PBScore,Posterior] = kfoldPredict( ___ )` additionally returns posterior class probability estimates for held-out observations and for each regularization strength. To return posterior probabilities, the linear classification model learners must be logistic regression models.

Input Arguments

`CVMdl` — Cross-validated, ECOC model composed of linear classification models

`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model using `fitcecoc` and by:

1. Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
2. Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, kfoldPredict applies the same data used to cross-validate the ECOC model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`BinaryLoss` — Binary learner loss function
`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set {-1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or $(-\infty,\infty)$	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$
`'logit'`	Logistic	$(-\infty,\infty)$	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` should have this form

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - K is the number of classes.
  - L is the number of binary learners.

  For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3259.

Example: `'Decoding','lossbased'`

`NumKLInitializations` — Number of random initial values
`0` (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer.

To use this option, you must:

- Return the fourth output argument (`Posterior`).
- The linear classification models that compose the ECOC models must use logistic regression learners (that is, `CVMdl.Trained{1}.BinaryLearners{1}.Learner` must be `'logistic'`).
- `PosteriorMethod` must be `'kl'`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 33-3301.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`PosteriorMethod` — Posterior probability estimation method
`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- To use this option, you must return the fourth output argument (`Posterior`) and the linear classification models that compose the ECOC models must use logistic regression learners (that is, `CVMdl.Trained{1}.BinaryLearners{1}.Learner` must be `'logistic'`).

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 33-3301.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 33-3302.

Example: `'PosteriorMethod','qp'`

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`Label` — Cross-validated, predicted class labels
categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an *n*-by-*L* array of the same data type as the observed class labels (`Y`) used to create `CVMdl`. (The software treats string arrays as cell arrays of character vectors.) *n* is the number of observations in the predictor data (`X`) and *L* is the number of regularization strengths in the linear classification models that compose the cross-validated ECOC model. That is, `Label(i,j)` is the predicted class label for observation `i` using the ECOC model of linear classification models that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

If `Y` is a character array and $L > 1$, then `Label` is a cell array of class labels.

The software assigns the predicted label corresponding to the class with the largest, negated, average binary loss (`NegLoss`), or, equivalently, the smallest average binary loss.

`NegLoss` — Cross-validated, negated, average binary losses
numeric array

Cross-validated, negated, average binary losses, returned as an *n*-by-*K*-by-*L* numeric matrix or array. *K* is the number of distinct classes in the training data and columns correspond to the classes in `CVMdl.ClassNames`. For *n* and *L*, see `Label`. `NegLoss(i,k,j)` is the negated, average binary loss for classifying observation `i` into class `k` using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLoss{1}.Lambda(j)`.

`PBScore` — Cross-validated, positive-class scores
numeric array

Cross-validated, positive-class scores, returned as an *n*-by-*B*-by-*L* numeric array. *B* is the number of binary learners in the cross-validated ECOC model and columns correspond to the binary learners in `CVMdl.Trained{1}.BinaryLearners`. For *n* and *L*, see `Label`. `PBScore(i,b,j)` is the positive-class score of binary learner *b* for classifying observation `i` into its positive class, using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

If the coding matrix varies across folds (that is, if the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

`Posterior` — Cross-validated posterior class probabilities
numeric array

Cross-validated posterior class probabilities, returned as an *n*-by-*K*-by-*L* numeric array. For dimension definitions, see `NegLoss`. `Posterior(i,k,j)` is the posterior probability for classifying observation `i` into class *k* using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

To return posterior probabilities, `CVMdl.Trained{1}.BinaryLearner{1}.Learner` must be `'logistic'`.

Examples

Predict *k*-fold Cross-Validation Labels

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation.

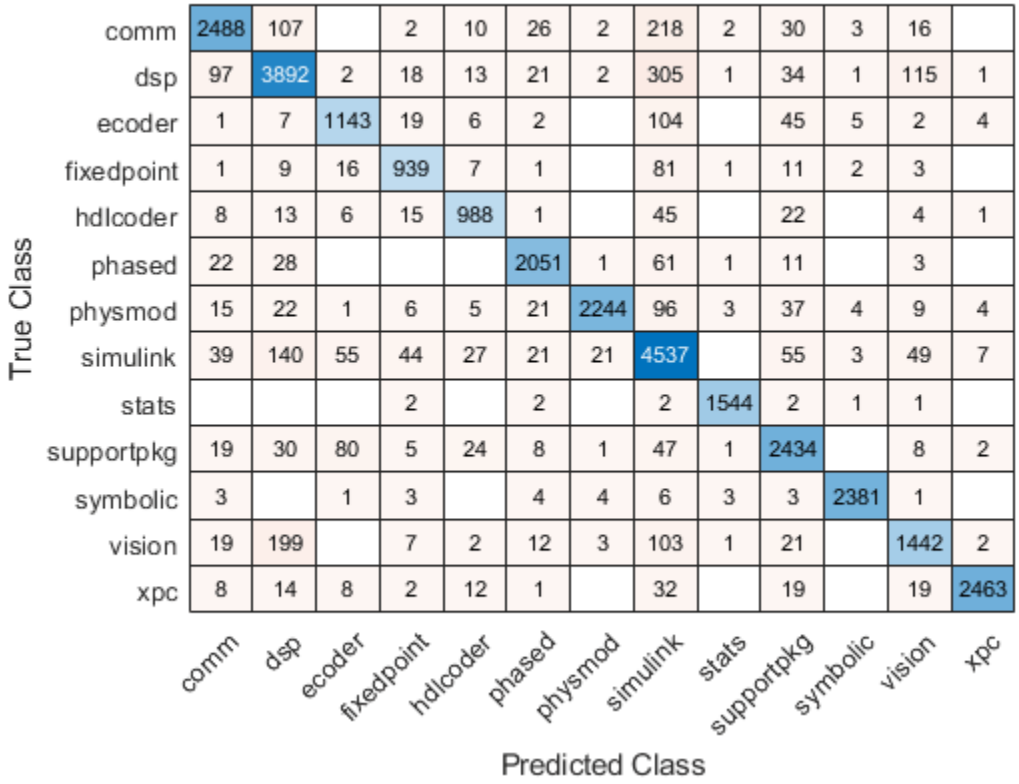
Predict labels for the observations that `fitcecoc` did not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Because there is one regularization strength in `CVMdl`, `label` is a column vector of predictions containing as many rows as observations in `X`.

Construct a confusion matrix.

```
cm = confusionchart(Y,label);
```



Specify Custom Binary Loss

Load the NLP data set. Transpose the predictor data.

```
load nlpdata
X = X';
```

For simplicity, use the label 'others' for all observations in Y that are not `'simulink'`, `'dsp'`, or `'comm'`.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMdl1 = CVMdl.Trained{1}
```

```
CMdl1 =
  CompactClassificationECOC
```

```
      ResponseName: 'Y'
        ClassNames: [comm    dsp    simulink    others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
      CodingMatrix: [4x6 double]

  Properties, Methods
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `CompactClassificationECOC` models that the software trained using the training set of each fold.

By default, the linear classification models that compose the ECOC models use SVMs. SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);

idx = randsample(numel(label),10);
table(Y(idx),label(idx),NegLoss(idx,1),NegLoss(idx,2),NegLoss(idx,3),...
    NegLoss(idx,4),'VariableNames',[{'True'};{'Predicted'};...
    categories(CVMdl.ClassNames)])
```

```
ans=10×6 table
      True      Predicted      comm         dsp       simulink    others
    ________    _________    _________    ________    ________    _______

    others      others          -1.2319     -1.0488    0.048758     1.6175
    simulink    simulink        -16.407     -12.218      21.531     11.218
    dsp         dsp             -0.7387    -0.11534    -0.88466    -0.2613
    others      others          -0.1251     -0.8749    -0.99766    0.14517
    dsp         dsp              2.5867      6.4187     -3.5867    -4.4165
    others      others        -0.025358     -1.2287    -0.97464    0.19747
    others      others          -2.6725    -0.56708    -0.51092     2.7453
    others      others          -1.1605    -0.88321    -0.11679    0.43504
    others      others          -1.9511     -1.3175     0.24735    0.95111
    simulink    others           -7.848     -5.8203      4.8203     6.8457
```

The software predicts the label based on the maximum negated loss.

Estimate Posterior Class Probabilities

ECOC models composed of linear classification models return posterior probabilities for logistic regression learners only. This example requires the Parallel Computing Toolbox™ and the Optimization Toolbox™

Load the NLP data set and preprocess the data as in “Specify Custom Binary Loss” on page 33-3296.

```
load nlpdata
X = X';
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 5 logarithmically-spaced regularization strengths from 10^{-5} through $10^{-0.5}$.

```
Lambda = logspace(-6,-0.5,5);
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA and to use logistic regression learners.

```
t = templateLinear('Solver','sparsa','Learner','logistic','Lambda',Lambda);
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns, and to use parallel computing.

```
rng(1); % For reproducibility
Options = statset('UseParallel',true);
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns',...
    'Options',Options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Predict the cross-validated posterior class probabilities. Specify to use parallel computing and to estimate posterior probabilities using quadratic programming.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl,'Options',Options,...
    'PosteriorMethod','qp');
size(label)
label(3,4)
size(Posterior)
Posterior(3,:,4)
```

```
ans =

       31572           5

ans =

  categorical

     others

ans =
```

```
       31572           4           5

ans =

    0.0285    0.0373    0.1714    0.7627
```

Because there are five regularization strengths:

- `label` is a 31572-by-5 categorical array. `label(3,4)` is the predicted, cross-validated label for observation 3 using the model trained with regularization strength `Lambda(4)`.
- `Posterior` is a 31572-by-4-by-5 matrix. `Posterior(3,:,4)` is the vector of all estimated, posterior class probabilities for observation 3 using the model trained with regularization strength `Lambda(4)`. The order of the second dimension corresponds to `CVMdl.ClassNames`. Display a random set of 10 posterior class probabilities.

Display a random sample of cross-validated labels and posterior probabilities for the model trained using `Lambda(4)`.

```
idx = randsample(size(label,1),10);
table(Y(idx),label(idx,4),Posterior(idx,1,4),Posterior(idx,2,4),...
    Posterior(idx,3,4),Posterior(idx,4,4),...
    'VariableNames',[{'True'};{'Predicted'};categories(CVMdl.ClassNames)])
```

```
ans =

  10×6 table

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).

- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k,j) of the coding design matrix M.
- I is the indicator function.
- $\widehat{p}_k$ is the class posterior probability estimate for class k of an observation, $k = 1,...,K$.
- r_j is the positive-class posterior probability for binary learner j. That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r,\widehat{r}) = \sum_{j=1}^{L} w_j \left[r_j \log\frac{r_j}{\widehat{r}_j} + (1-r_j)\log\frac{1-r_j}{1-\widehat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j.

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i.

The software minimizes the divergence iteratively. The first step is to choose initial values $\widehat{p}_k^{(0)};\ k = 1,...,K$ for the class posterior probabilities.

- If you do not specify `'NumKLIterations'`, then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ.
  - $\widehat{p}_k^{(0)} = 1/K;\ k = 1,...,K$.
  - $\widehat{p}_k^{(0)};\ k = 1,...,K$ is the solution of the system

    $$M_{01}\widehat{p}^{(0)} = r,$$

    where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-279. The software uses `lsqnonneg` to solve the system.
- If you specify `'NumKLIterations',c`, where `c` is a natural number, then the software does the following to choose the set $\widehat{p}_k^{(0)};\ k = 1,...,K$, and selects the set that minimizes Δ.
  - The software tries both sets of deterministic initial values as described previously.
  - The software randomly generates `c` vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t, the software completes these steps:

1 Compute

$$\widehat{r}_j^{(t)} = \frac{\sum_{k=1}^{K} \widehat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^{K} \widehat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

2 Estimate the next class posterior probability using

$$\widehat{p}_k^{(t+1)} = \widehat{p}_k^{(t)} \frac{\sum_{j=1}^{L} w_j \left[r_j I\left(m_{kj} = +1\right) + \left(1 - r_j\right) I\left(m_{kj} = -1\right) \right]}{\sum_{j=1}^{L} w_j \left[\widehat{r}_j^{(t)} I\left(m_{kj} = +1\right) + \left(1 - \widehat{r}_j^{(t)}\right) I\left(m_{kj} = -1\right) \right]}.$$

3 Normalize $\widehat{p}_k^{(t+1)};\ k = 1, \ldots, K$ so that they sum to 1.

4 Check for convergence.

For more details, see [Hastie et al.] on page 18-280 and [Zadrozny] on page 18-281.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1 Estimate the positive-class posterior probabilities, r_j, for binary learners $j = 1,\ldots,L$.

2 Using the relationship between r_j and $\widehat{p}_k$ [Wu et al.] on page 18-281, minimize

$$\sum_{j=1}^{L} \left[-r_j \sum_{k=1}^{K} \widehat{p}_k I\left(m_{kj} = -1\right) + \left(1 - r_j\right) \sum_{k=1}^{K} \widehat{p}_k I\left(m_{kj} = +1\right) \right]^2$$

with respect to $\widehat{p}_k$ and the restrictions

$$0 \le \widehat{p}_k \le 1$$

$$\sum_k \widehat{p}_k = 1.$$

The software performs minimization using `quadprog`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016a

kfoldPredict

Package: `classreg.learning.partition`

Classify observations in cross-validated classification model

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,'IncludeInteractions',includeInteractions)
[label,Score] = kfoldPredict( ___ )
[label,Score,Cost] = kfoldPredict(CVMdl)
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated classifier `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a classifier trained on training-fold observations. `CVMdl.X` and `CVMdl.Y` contain both sets of observations.

`label = kfoldPredict(CVMdl,'IncludeInteractions',includeInteractions)` specifies whether to include interaction terms in computations. This syntax applies only to generalized additive models.

`[label,Score] = kfoldPredict( ___ )` additionally returns the predicted classification scores for validation-fold observations using a classifier trained on training-fold observations, with any of the input argument in the previous syntaxes.

`[label,Score,Cost] = kfoldPredict(CVMdl)` additionally returns the expected misclassification costs for discriminant analysis, *k*-nearest neighbor, naive Bayes, and tree classifiers.

Examples

Create Confusion Matrix Using Cross-Validation Predictions

Create a confusion matrix using the 10-fold cross-validation predictions of a discriminant analysis model.

Load the `fisheriris` data set. `X` contains flower measurements for 150 different flowers, and `y` lists the species, or class, for each flower. Create a variable `order` that specifies the order of the classes.

```
load fisheriris
X = meas;
y = species;
order = unique(y)
```

```
order = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

Create a 10-fold cross-validated discriminant analysis model by using the `fitcdiscr` function. By default, `fitcdiscr` ensures that training and test sets have roughly the same proportions of flower species. Specify the order of the flower classes.

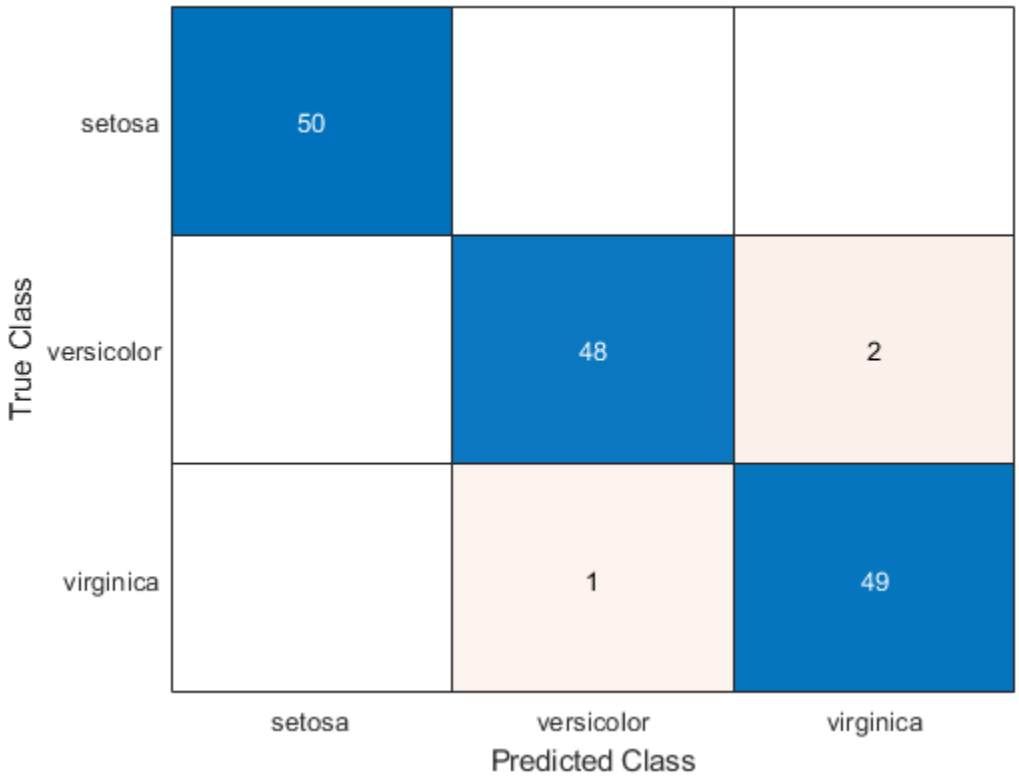
```
cvmdl = fitcdiscr(X,y,'KFold',10,'ClassNames',order);
```

Predict the species of the test set flowers.

```
predictedSpecies = kfoldPredict(cvmdl);
```

Create a confusion matrix that compares the true class values to the predicted class values.

```
confusionchart(y,predictedSpecies)
```



Estimate Cross-Validation Predictions from Ensemble

Find the cross-validation predictions for a model based on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of classification trees using AdaBoostM2. Specify tree stumps as the weak learners.

```
rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Cross-validate the trained ensemble using 10-fold cross-validation.

```
CVMdl = crossval(Mdl);
```

Estimate cross-validation predicted labels and scores.

```
[elabel,escore] = kfoldPredict(CVMdl);
```

Display the maximum and minimum scores of each class.

```
max(escore)
```

```
ans = 1×3

    9.3862    8.9871   10.1866
```

```
min(escore)
```

```
ans = 1×3

    0.0018    3.8359    0.9573
```

Input Arguments

`CVMdl` — Cross-validated partitioned classifier

`ClassificationPartitionedModel` object | `ClassificationPartitionedEnsemble` object | `ClassificationPartitionedGAM` object

Cross-validated partitioned classifier, specified as a `ClassificationPartitionedModel`, `ClassificationPartitionedEnsemble`, or `ClassificationPartitionedGAM` object. You can create the object in two ways:

- Pass a trained classification model listed in the following table to its `crossval` object function.
- Train a classification model using a function listed in the following table and specify one of the cross-validation name-value arguments for the function.

Classification Model	Function
`ClassificationDiscriminant`	`fitcdiscr`
`ClassificationEnsemble`	`fitcensemble`
`ClassificationGAM`	`fitcgam`
`ClassificationKNN`	`fitcknn`
`ClassificationNaiveBayes`	`fitcnb`
`ClassificationNeuralNetwork`	`fitcnet`
`ClassificationSVM`	`fitcsvm`
`ClassificationTree`	`fitctree`

`includeInteractions` — Flag to include interaction terms
`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `CVMdl` is `ClassificationPartitionedGAM`.

The default value is `true` if the models in `CVMdl` (`CVMdl.Trained`) contain interaction terms. The value must be `false` if the models do not contain interaction terms.

Data Types: `logical`

Output Arguments

`label` — Predicted class labels
categorical vector | logical vector | numeric vector | character array | cell array of character vectors

Predicted class labels, returned as a categorical vector, logical vector, numeric vector, character array, or cell array of character vectors. `label` has the same data type and number of rows as `CVMdl.Y`. Each entry of `label` corresponds to the predicted class label for the corresponding observation in `CVMdl.X`.

If you use a holdout validation technique to create `CVMdl` (that is, if `CVMdl.KFold` is `1`), then ignore the `label` values for training-fold observations. These values match the class with the highest frequency.

`Score` — Classification scores
numeric matrix

Classification scores, returned as an *n*-by-*K* matrix, where *n* is the number of observations (`size(CVMdl.X,1)` when observations are in rows) and *K* is the number of unique classes (`size(CVMdl.ClassNames,1)`). The classification score `Score(i,j)` represents the confidence that the `i`th observation belongs to class `j`.

If you use a holdout validation technique to create `CVMdl` (that is, if `CVMdl.KFold` is `1`), then `Score` has `NaN` values for training-fold observations.

`Cost` — Expected misclassification costs
numeric matrix

Expected misclassification costs, returned as an *n*-by-*K* matrix, where *n* is the number of observations (`size(CVMdl.X,1)` when observations are in rows) and *K* is the number of unique classes (`size(CVMdl.ClassNames,1)`). The value `Cost(i,j)` is the average misclassification cost of predicting that the `i`th observation belongs to class `j`.

Note If you want to return this output argument, `CVMdl` must be a discriminant analysis, *k*-nearest neighbor, naive Bayes, or tree classifier.

If you use a holdout validation technique to create `CVMdl` (that is, if `CVMdl.KFold` is `1`), then `Cost` has `NaN` values for training-fold observations.

Algorithms

`kfoldPredict` computes predictions as described in the corresponding `predict` object function. For a model-specific description, see the appropriate `predict` function reference page in the following table.

Model Type	`predict` Function
Discriminant analysis classifier	`predict`
Ensemble classifier	`predict`
Generalized additive model classifier	`predict`
k-nearest neighbor classifier	`predict`
Naive Bayes classifier	`predict`
Neural network classifier	`predict`
Support vector machine classifier	`predict`
Binary decision tree for multiclass classification	`predict`

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports *k*-nearest neighbor and SVM model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2011a

kfoldPredict

Predict responses for observations not used for training

Syntax

```
YHat = kfoldPredict(CVMdl)
```

Description

`YHat = kfoldPredict(CVMdl)` returns cross-validated predicted responses by the cross-validated linear regression model `CVMdl`. That is, for every fold, `kfoldPredict` predicts responses for observations that it holds out when it trains using all other observations.

`YHat` contains predicted responses for each regularization strength in the linear regression models that compose `CVMdl`.

Input Arguments

`CVMdl` — Cross-validated, linear regression model

`RegressionPartitionedLinear` model object

Cross-validated, linear regression model, specified as a `RegressionPartitionedLinear` model object. You can create a `RegressionPartitionedLinear` model using `fitrlinear` and specifying any of the one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, kfoldPredict applies the same data used to cross-validate the linear regression model (`X` and `Y`).

Output Arguments

`YHat` — Cross-validated predicted responses

numeric array

Cross-validated predicted responses, returned as an n-by-L numeric array. n is the number of observations in the predictor data that created `CVMdl` (see `X`) and L is the number of regularization strengths in `CVMdl.Trained{1}.Lambda`. `YHat(`i`,`j`)` is the predicted response for observation i using the linear regression model that has regularization strength `CVMdl.Trained{1}.Lambda(`j`)`.

The predicted response using the model with regularization strength j is $\widehat{y}_j = x\beta_j + b_j$.

- x is an observation from the predictor data matrix `X`, and is row vector.
- β_j is the estimated column vector of coefficients. The software stores this vector in `Mdl.Beta(:,`j`)`.
- b_j is the estimated, scalar bias, which the software stores in `Mdl.Bias(`j`)`.

Examples

Predict Cross-Validated Responses

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = x_1, \ldots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model.

```
CVMdl = fitrlinear(X,Y,'CrossVal','on')
```

```
CVMdl =
  RegressionPartitionedLinear
    CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
        NumObservations: 10000
                  KFold: 10
              Partition: [1x1 cvpartition]
      ResponseTransform: 'none'

  Properties, Methods
```

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x1 double]
                 Bias: 0.0107
               Lambda: 1.1111e-04
              Learner: 'svm'

  Properties, Methods
```

By default, `fitrlinear` implements 10-fold cross-validation. `CVMdl` is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 10-by-1 cell array holding 10 `RegressionLinear` models that the software trained using the training set.

Predict responses for observations that `fitrlinear` did not use in training the folds.

```
yHat = kfoldPredict(CVMdl);
```

Because there is one regularization strength in `Mdl`, `yHat` is a numeric vector.

Predict for Models Containing Several Regularization Strengths

Simulate 10000 observations as in “Predict Cross-Validated Responses” on page 33-3309.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1}.

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Specify using least squares with a lasso penalty and optimizing the objective function using SpaRSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

`CVMdl` is a `RegressionPartitionedLinear` model. Its `Trained` property contains a 5-by-1 cell array of trained `RegressionLinear` models, each one holds out a different fold during training. Because `fitrlinear` trained using 15 regularization strengths, you can think of each `RegressionLinear` model as 15 models.

Predict cross-validated responses.

```
YHat = kfoldPredict(CVMdl);
size(YHat)
```

```
ans = 1×2

       10000          15
```

```
YHat(2,:)
```

```
ans = 1×15

   -1.7338   -1.7332   -1.7319   -1.7299   -1.7266   -1.7239   -1.7135   -1.7210   -1.7324   -1.7
```

`YHat` is a 10000-by-15 matrix. `YHat(2,:)` is the cross-validated response for observation 2 using the model regularized with all 15 regularization values.

See Also

`RegressionLinear` | `RegressionPartitionedLinear` | `fitrlinear` | `predict`

Introduced in R2016a

kfoldPredict

Package: `classreg.learning.partition`

Predict responses for observations in cross-validated regression model

Syntax

```
yfit = kfoldPredict(CVMdl)
yfit = kfoldPredict(CVMdl,'IncludeInteractions',includeInteractions)
```

Description

`yfit = kfoldPredict(CVMdl)` returns responses predicted by the cross-validated regression model `CVMdl`. For every fold, `kfoldPredict` predicts the responses for validation-fold observations using a model trained on training-fold observations. `CVMdl.X` and `CVMdl.Y` contain both sets of observations.

`yfit = kfoldPredict(CVMdl,'IncludeInteractions',includeInteractions)` specifies whether to include interaction terms in computations. This syntax applies only to generalized additive models.

Examples

Compute Cross-Validation Loss Manually

When you create a cross-validated regression model, you can compute the mean squared error (MSE) by using the `kfoldLoss` object function. Alternatively, you can predict responses for validation-fold observations using `kfoldPredict` and compute the MSE manually.

Load the `carsmall` data set. Specify the predictor data `X` and the response data `Y`.

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
Y = MPG;
```

Train a cross-validated regression tree model. By default, the software implements 10-fold cross-validation.

```
rng('default') % For reproducibility
CVMdl = fitrtree(X,Y,'CrossVal','on');
```

Compute the 10-fold cross-validation MSE by using `kfoldLoss`.

```
L = kfoldLoss(CVMdl)
```

```
L = 29.4963
```

Predict the responses `yfit` by using the cross-validated regression model. Compute the mean squared error between `yfit` and the true responses `CVMdl.Y`. The computed MSE matches the loss value returned by `kfoldLoss`.

```
yfit = kfoldPredict(CVMdl);
mse = mean((yfit - CVMdl.Y).^2)
```

```
mse = 29.4963
```

Input Arguments

`CVMdl` — Cross-validated partitioned regression model

`RegressionPartitionedModel` object | `RegressionPartitionedEnsemble` object | `RegressionPartitionedGAM` object | `RegressionPartitionedSVM` object

Cross-validated partitioned regression model, specified as a `RegressionPartitionedModel`, `RegressionPartitionedEnsemble`, `RegressionPartitionedGAM`, or `RegressionPartitionedSVM` object. You can create the in two ways:

- Pass a trained regression model listed in the following table to its `crossval` object function.
- Train a regression model using a function listed in the following table and specify one of the cross-validation name-value arguments for the function.

Regression Model	Function
`RegressionEnsemble`	`fitrensemble`
`RegressionGAM`	`fitrgam`
`RegressionGP`	`fitrgp`
`RegressionNeuralNetwork`	`fitrnet`
`RegressionSVM`	`fitrsvm`
`RegressionTree`	`fitrtree`

`includeInteractions` — Flag to include interaction terms

`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `CVMdl` is `RegressionPartitionedGAM`.

The default value is `true` if the models in `CVMdl` (`CVMdl.Trained`) contain interaction terms. The value must be `false` if the models do not contain interaction terms.

Data Types: `logical`

Output Arguments

`yfit` — Predicted responses

numeric vector

Predicted responses, returned as an *n*-by-1 numeric vector, where *n* is the number of observations. (*n* is `size(CVMdl.X,1)` when observations are in rows.) Each entry of `yfit` corresponds to the predicted response for the corresponding row of `CVMdl.X`.

If you use a holdout validation technique to create `CVMdl` (that is, if `CVMdl.KFold` is `1`), then `yfit` has `NaN` values for training-fold observations.

`RegressionPartitionedEnsemble` | `RegressionPartitionedGAM` | `RegressionPartitionedModel` | `RegressionPartitionedSVM` | `kfoldLoss`

Introduced in R2011a

kmeans

k-means clustering

Syntax

```
idx = kmeans(X,k)
idx = kmeans(X,k,Name,Value)
[idx,C] = kmeans( ___ )
[idx,C,sumd] = kmeans( ___ )
[idx,C,sumd,D] = kmeans( ___ )
```

Description

`idx = kmeans(X,k)` performs *k*-means clustering on page 33-3329 to partition the observations of the *n*-by-*p* data matrix `X` into `k` clusters, and returns an *n*-by-1 vector (`idx`) containing cluster indices of each observation. Rows of `X` correspond to points and columns correspond to variables.

By default, `kmeans` uses the squared Euclidean distance metric and the *k*-means++ algorithm on page 33-3329 for cluster center initialization.

`idx = kmeans(X,k,Name,Value)` returns the cluster indices with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the cosine distance, the number of times to repeat the clustering using new initial values, or to use parallel computing.

`[idx,C] = kmeans( ___ )` returns the `k` cluster centroid locations in the `k`-by-*p* matrix `C`.

`[idx,C,sumd] = kmeans( ___ )` returns the within-cluster sums of point-to-centroid distances in the `k`-by-1 vector `sumd`.

`[idx,C,sumd,D] = kmeans( ___ )` returns distances from each point to every centroid in the *n*-by-`k` matrix `D`.

Examples

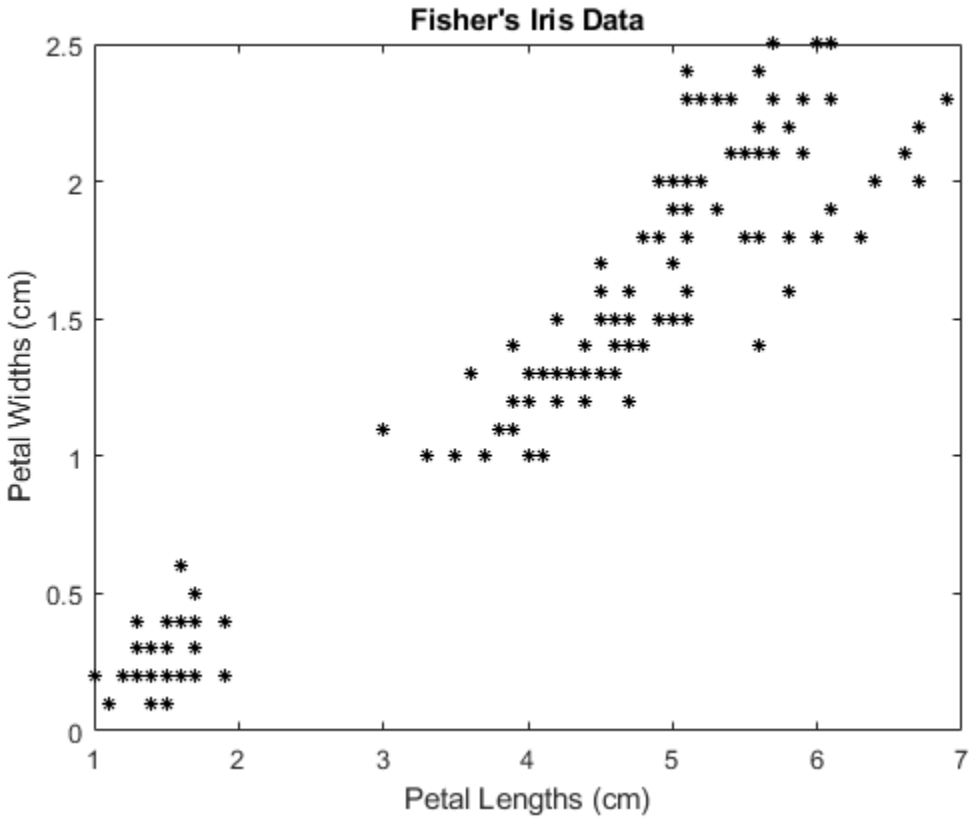
Train a *k*-Means Clustering Algorithm

Cluster data using *k*-means clustering, then plot the cluster regions.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);

figure;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
```



The larger cluster seems to be split into a lower variance region and a higher variance region. This might indicate that the larger cluster is two, overlapping clusters.

Cluster the data. Specify $k = 3$ clusters.

```
rng(1); % For reproducibility
[idx,C] = kmeans(X,3);
```

`idx` is a vector of predicted cluster indices corresponding to the observations in `X`. `C` is a 3-by-2 matrix containing the final centroid locations.

Use `kmeans` to compute the distance from each centroid to points on a grid. To do this, pass the centroids (`C`) and points on a grid to `kmeans`, and implement one iteration of the algorithm.

```
x1 = min(X(:,1)):0.01:max(X(:,1));
x2 = min(X(:,2)):0.01:max(X(:,2));
[x1G,x2G] = meshgrid(x1,x2);
XGrid = [x1G(:),x2G(:)]; % Defines a fine grid on the plot

idx2Region = kmeans(XGrid,3,'MaxIter',1,'Start',C);

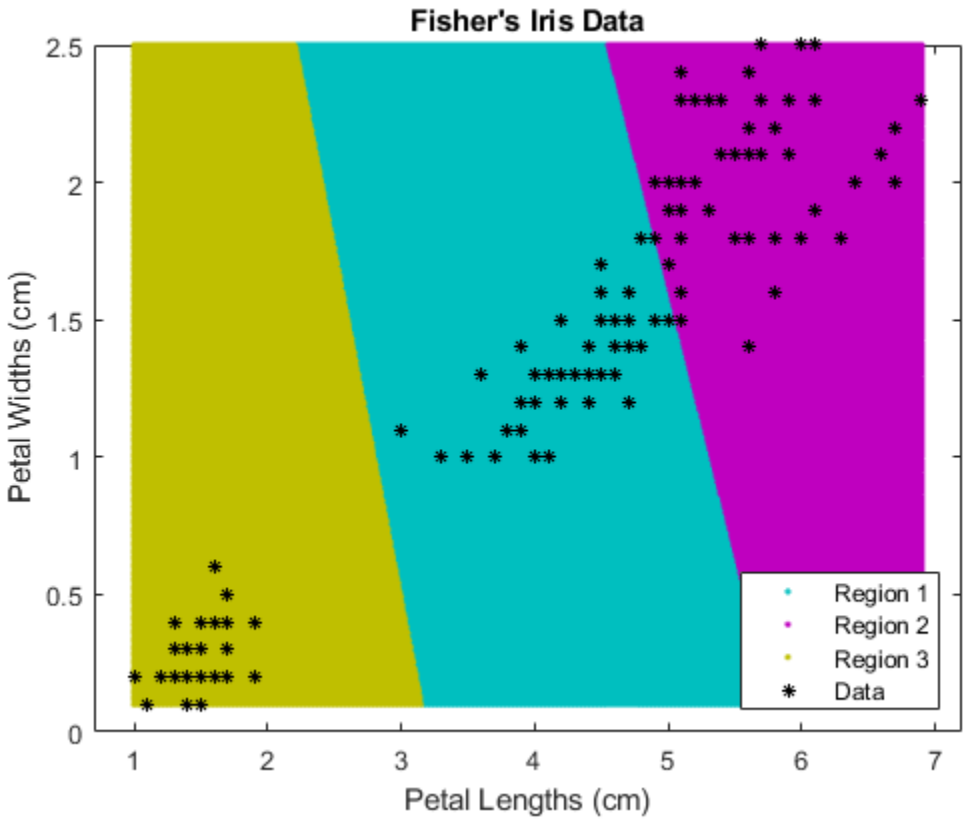
Warning: Failed to converge in 1 iterations.

    % Assigns each node in the grid to the closest centroid
```

`kmeans` displays a warning stating that the algorithm did not converge, which you should expect since the software only implemented one iteration.

Plot the cluster regions.

```
figure;
gscatter(XGrid(:,1),XGrid(:,2),idx2Region,...
    [0,0.75,0.75;0.75,0,0.75;0.75,0.75,0],'..');
hold on;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
legend('Region 1','Region 2','Region 3','Data','Location','SouthEast');
hold off;
```

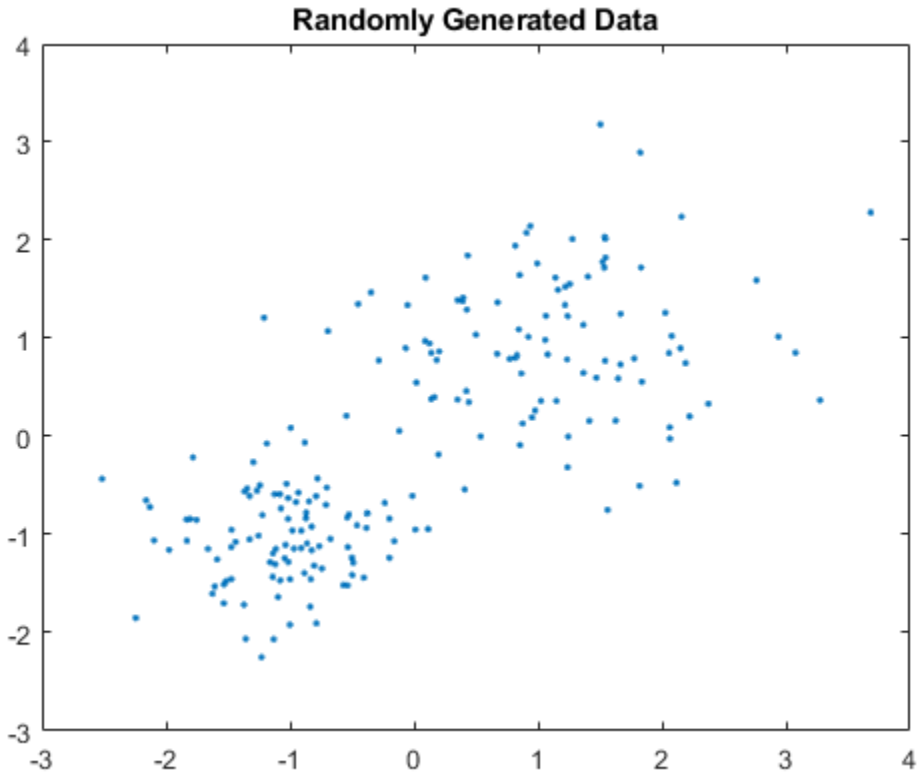


Partition Data into Two Clusters

Randomly generate the sample data.

```
rng default; % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
    randn(100,2)*0.5-ones(100,2)];

figure;
plot(X(:,1),X(:,2),'.');
title 'Randomly Generated Data';
```



There appears to be two clusters in the data.

Partition the data into two clusters, and choose the best arrangement out of five initializations. Display the final output.

```
opts = statset('Display','final');
[idx,C] = kmeans(X,2,'Distance','cityblock',...
    'Replicates',5,'Options',opts);
```

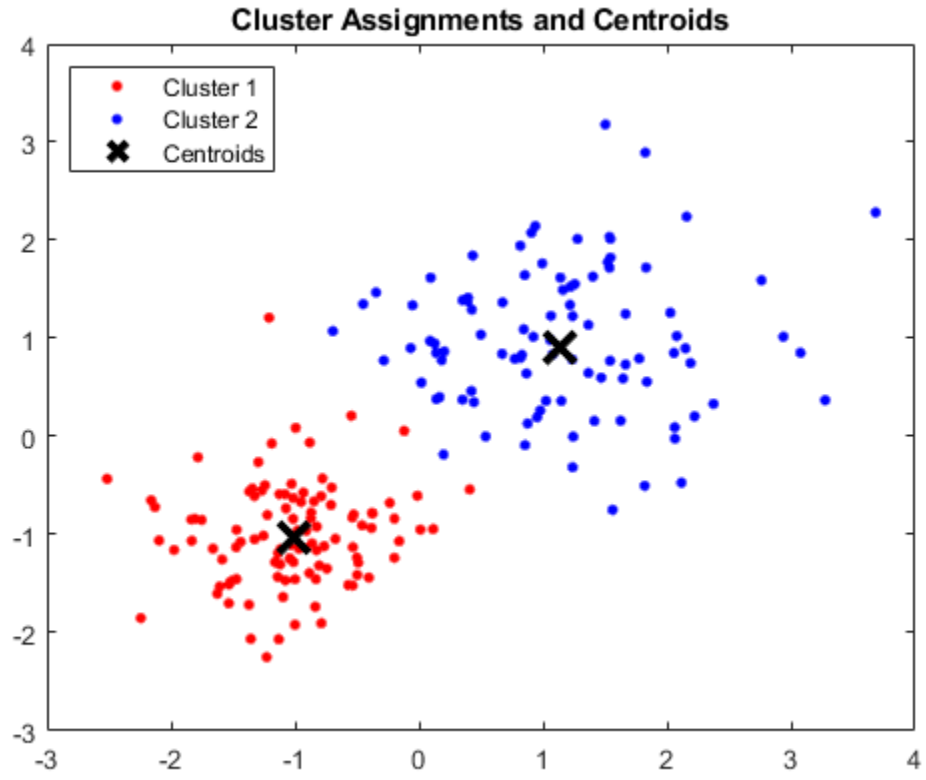
```
Replicate 1, 3 iterations, total sum of distances = 201.533.
Replicate 2, 5 iterations, total sum of distances = 201.533.
Replicate 3, 3 iterations, total sum of distances = 201.533.
Replicate 4, 3 iterations, total sum of distances = 201.533.
Replicate 5, 2 iterations, total sum of distances = 201.533.
Best total sum of distances = 201.533
```

By default, the software initializes the replicates separately using *k*-means++.

Plot the clusters and the cluster centroids.

```
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',12)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',12)
plot(C(:,1),C(:,2),'kx',...
     'MarkerSize',15,'LineWidth',3)
legend('Cluster 1','Cluster 2','Centroids',...
       'Location','NW')
```

```
title 'Cluster Assignments and Centroids'
hold off
```



You can determine how well separated the clusters are by passing `idx` to `silhouette`.

Cluster Data Using Parallel Computing

Clustering large data sets might take time, particularly if you use online updates (set by default). If you have a Parallel Computing Toolbox ™ license and you set the options for parallel computing, then `kmeans` runs each clustering task (or replicate) in parallel. And, if `Replicates`>1, then parallel computing decreases time to convergence.

Randomly generate a large data set from a Gaussian mixture model.

```
Mu = bsxfun(@times,ones(20,30),(1:20)'); % Gaussian mixture mean
rn30 = randn(30,30);
Sigma = rn30'*rn30; % Symmetric and positive-definite covariance
Mdl = gmdistribution(Mu,Sigma); % Define the Gaussian mixture distribution

rng(1); % For reproducibility
X = random(Mdl,10000);
```

`Mdl` is a 30-dimensional `gmdistribution` model with 20 components. `X` is a 10000-by-30 matrix of data generated from `Mdl`.

Specify the options for parallel computing.

```
stream = RandStream('mlfg6331_64');  % Random number stream
options = statset('UseParallel',1,'UseSubstreams',1,...
    'Streams',stream);
```

The input argument `'mlfg6331_64'` of `RandStream` specifies to use the multiplicative lagged Fibonacci generator algorithm. `options` is a structure array with fields that specify options for controlling estimation.

Cluster the data using *k*-means clustering. Specify that there are $k = 20$ clusters in the data and increase the number of iterations. Typically, the objective function contains local minima. Specify 10 replicates to help find a lower, local minimum.

```
tic; % Start stopwatch timer
[idx,C,sumd,D] = kmeans(X,20,'Options',options,'MaxIter',10000,...
    'Display','final','Replicates',10);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
connected to 6 workers.
Replicate 5, 72 iterations, total sum of distances = 7.73161e+06.
Replicate 1, 64 iterations, total sum of distances = 7.72988e+06.
Replicate 3, 68 iterations, total sum of distances = 7.72576e+06.
Replicate 4, 84 iterations, total sum of distances = 7.72696e+06.
Replicate 6, 82 iterations, total sum of distances = 7.73006e+06.
Replicate 7, 40 iterations, total sum of distances = 7.73451e+06.
Replicate 2, 194 iterations, total sum of distances = 7.72953e+06.
Replicate 9, 105 iterations, total sum of distances = 7.72064e+06.
Replicate 10, 125 iterations, total sum of distances = 7.72816e+06.
Replicate 8, 70 iterations, total sum of distances = 7.73188e+06.
Best total sum of distances = 7.72064e+06
```

```
toc % Terminate stopwatch timer
```

```
Elapsed time is 61.915955 seconds.
```

The Command Window indicates that six workers are available. The number of workers might vary on your system. The Command Window displays the number of iterations and the terminal objective function value for each replicate. The output arguments contain the results of replicate 9 because it has the lowest total sum of distances.

Assign New Data to Existing Clusters and Generate C/C++ Code

`kmeans` performs *k*-means clustering to partition data into *k* clusters. When you have a new data set to cluster, you can create new clusters that include the existing data and the new data by using `kmeans`. The `kmeans` function supports C/C++ code generation, so you can generate code that accepts training data and returns clustering results, and then deploy the code to a device. In this workflow, you must pass training data, which can be of considerable size. To save memory on the device, you can separate training and prediction by using `kmeans` and `pdist2`, respectively.

Use `kmeans` to create clusters in MATLAB® and use `pdist2` in the generated code to assign new data to existing clusters. For code generation, define an entry-point function that accepts the cluster centroid positions and the new data set, and returns the index of the nearest cluster. Then, generate code for the entry-point function.

Generating C/C++ code requires MATLAB® Coder™.

Perform *k*-Means Clustering

Generate a training data set using three distributions.

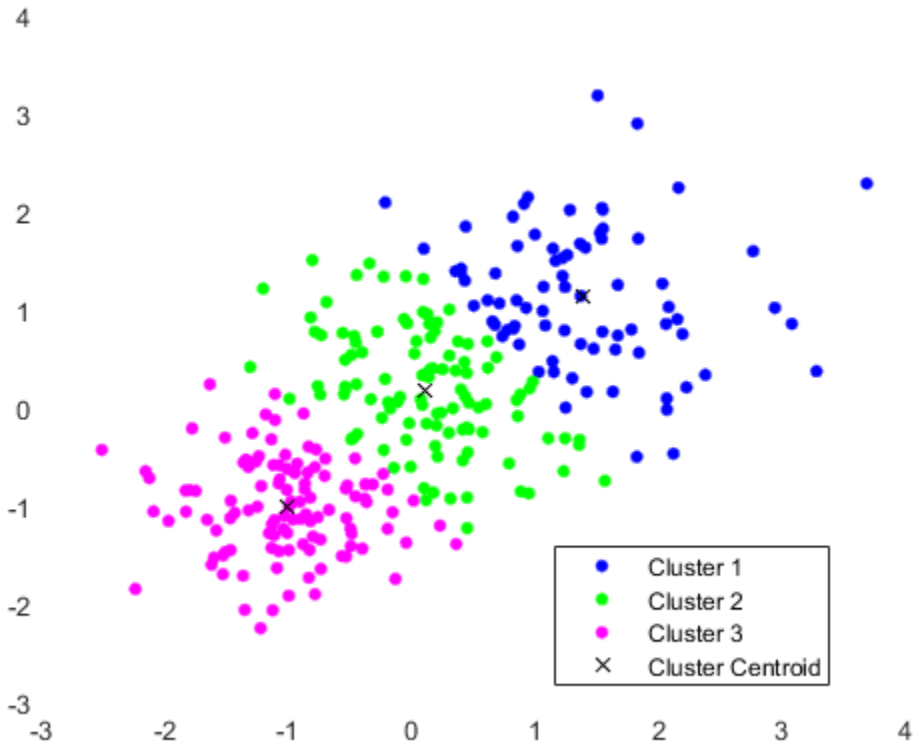
```
rng('default') % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.5-ones(100,2);
     randn(100,2)*0.75];
```

Partition the training data into three clusters by using `kmeans`.

```
[idx,C] = kmeans(X,3);
```

Plot the clusters and the cluster centroids.

```
figure
gscatter(X(:,1),X(:,2),idx,'bgm')
hold on
plot(C(:,1),C(:,2),'kx')
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid')
```



Assign New Data to Existing Clusters

Generate a test data set.

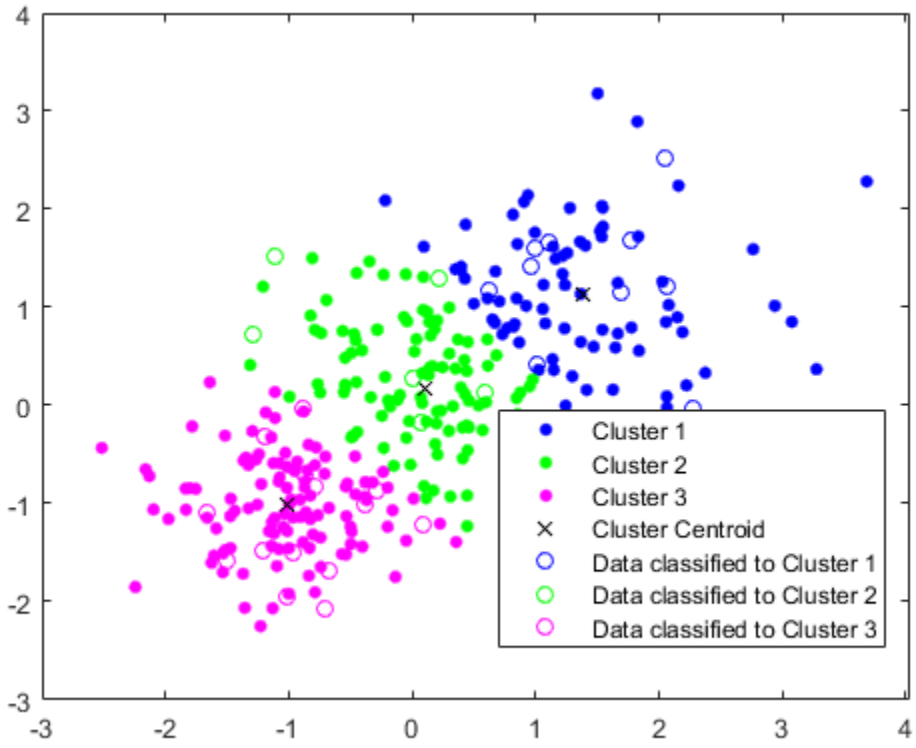
```
Xtest = [randn(10,2)*0.75+ones(10,2);
    randn(10,2)*0.5-ones(10,2);
    randn(10,2)*0.75];
```

Classify the test data set using the existing clusters. Find the nearest centroid from each test data point by using `pdist2`.

```
[~,idx_test] = pdist2(C,Xtest,'euclidean','Smallest',1);
```

Plot the test data and label the test data using `idx_test` by using `gscatter`.

```
gscatter(Xtest(:,1),Xtest(:,2),idx_test,'bgm','ooo')
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid', ...
    'Data classified to Cluster 1','Data classified to Cluster 2', ...
    'Data classified to Cluster 3')
```



Generate Code

Generate C code that assigns new data to the existing clusters. Note that generating C/C++ code requires MATLAB® Coder™.

Define an entry-point function named `findNearestCentroid` that accepts centroid positions and new data, and then find the nearest cluster by using `pdist2`.

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation.

```
type findNearestCentroid % Display contents of findNearestCentroid.m

function idx = findNearestCentroid(C,X) %#codegen
[~,idx] = pdist2(C,X,'euclidean','Smallest',1); % Find the nearest centroid
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate code by using `codegen` (MATLAB Coder). Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and array size of the inputs of `findNearestCentroid`, pass a MATLAB expression that represents the set of values with a certain data type and array size by using the `-args` option. For details, see “Specify Variable-Size Arguments for Code Generation” on page 32-45.

```
codegen findNearestCentroid -args {C,Xtest}

Code generation successful.
```

`codegen` generates the MEX function `findNearestCentroid_mex` with a platform-dependent extension.

Verify the generated code.

```
myIndx = findNearestCentroid(C,Xtest);
myIndex_mex = findNearestCentroid_mex(C,Xtest);
verifyMEX = isequal(idx_test,myIndx,myIndex_mex)

verifyMEX = logical
   1
```

`isequal` returns logical 1 (`true`), which means all the inputs are equal. The comparison confirms that the `pdist2` function, the `findNearestCentroid` function, and the MEX function return the same index.

You can also generate optimized CUDA® code using GPU Coder™.

```
cfg = coder.gpuConfig('mex');
codegen -config cfg findNearestCentroid -args {C,Xtest}
```

For more information on code generation, see “General Code Generation Workflow” on page 32-5. For more information on GPU coder, see “Get Started with GPU Coder” (GPU Coder) and “Supported Functions” (GPU Coder).

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of `X` correspond to observations, and the columns correspond to variables.

If `X` is a numeric vector, then `kmeans` treats it as an *n*-by-1 data matrix, regardless of its orientation.

The software treats NaNs in X as missing data and removes any row of X that contains at least one NaN. Removing rows of X reduces the sample size. The kmeans function returns NaN for the corresponding value in the output argument idx.

Data Types: single | double

k — Number of clusters
positive integer

Number of clusters in the data, specified as a positive integer.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Distance','cosine','Replicates',10,'Options',statset('UseParallel',1) specifies the cosine distance, 10 replicate clusters at different starting values, and to use parallel computing.

Display — Level of output to display
'off' (default) | 'final' | 'iter'

Level of output to display in the Command Window, specified as the comma-separated pair consisting of 'Display' and one of the following options:

- 'final' — Displays results of the final iteration
- 'iter' — Displays results of each iteration
- 'off' — Displays nothing

Example: 'Display','final'

Distance — Distance metric
'sqeuclidean' (default) | 'cityblock' | 'cosine' | 'correlation' | 'hamming'

Distance metric, in p-dimensional space, used for minimization, specified as the comma-separated pair consisting of 'Distance' and 'sqeuclidean', 'cityblock', 'cosine', 'correlation', or 'hamming'.

kmeans computes centroid clusters differently for the supported distance metrics. This table summarizes the available distance metrics. In the formulae, x is an observation (that is, a row of X) and c is a centroid (a row vector).

Distance Metric	Description	Formula
'sqeuclidean'	Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.	$d(x,c) = (x-c)(x-c)'$

Distance Metric	Description	Formula
`'cityblock'`	Sum of absolute differences, i.e., the $L1$ distance. Each centroid is the component-wise median of the points in that cluster.	$d(x,c) = \sum_{j=1}^{p} \left\lvert x_j - c_j \right\rvert$
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors). Each centroid is the mean of the points in that cluster, after normalizing those points to unit Euclidean length.	$d(x,c) = 1 - \frac{xc'}{\sqrt{(xx')(cc')}}$
`'correlation'`	One minus the sample correlation between points (treated as sequences of values). Each centroid is the component-wise mean of the points in that cluster, after centering and normalizing those points to zero mean and unit standard deviation.	$d(x,c) = 1 - \frac{\left(x-\overrightarrow{\bar{x}}\right)\left(c-\overrightarrow{\bar{c}}\right)'}{\sqrt{\left(x-\overrightarrow{\bar{x}}\right)\left(x-\overrightarrow{\bar{x}}\right)'}\sqrt{\left(c-\overrightarrow{\bar{c}}\right)\left(c-\overrightarrow{\bar{c}}\right)'}},$ where • $\overrightarrow{\bar{x}} = \frac{1}{p}\left(\sum_{j=1}^{p} x_j\right)\overrightarrow{1}_p$ • $\overrightarrow{\bar{c}} = \frac{1}{p}\left(\sum_{j=1}^{p} c_j\right)\overrightarrow{1}_p$ • $\overrightarrow{1}_p$ is a row vector of p ones.
`'hamming'`	This metric is only suitable for binary data. It is the proportion of bits that differ. Each centroid is the component-wise median of points in that cluster.	$d(x,y) = \frac{1}{p}\sum_{j=1}^{p} I\{x_j \neq y_j\},$ where I is the indicator function.

Example: `'Distance','cityblock'`

`EmptyAction` — Action to take if cluster loses all member observations
`'singleton'` (default) | `'error'` | `'drop'`

Action to take if a cluster loses all its member observations, specified as the comma-separated pair consisting of `'EmptyAction'` and one of the following options.

Value	Description
`'error'`	Treat an empty cluster as an error.

Value	Description
'drop'	Remove any clusters that become empty. kmeans sets the corresponding return values in C and D to NaN.
'singleton'	Create a new cluster consisting of the one point furthest from its centroid (default).

Example: 'EmptyAction','error'

MaxIter — Maximum number of iterations
100 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer.

Example: 'MaxIter',1000

Data Types: double | single

OnlinePhase — Online update flag
'off' (default) | 'on'

Online update flag, specified as the comma-separated pair consisting of 'OnlinePhase' and 'off' or 'on'.

If OnlinePhase is on, then kmeans performs an online update phase in addition to a batch update phase. The online phase can be time consuming for large data sets, but guarantees a solution that is a local minimum of the distance criterion. In other words, the software finds a partition of the data in which moving any single point to a different cluster increases the total sum of distances.

Example: 'OnlinePhase','on'

Options — Options for controlling iterative algorithm for minimizing fitting criteria
[] (default) | structure array returned by statset

Options for controlling the iterative algorithm for minimizing the fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by statset. Supported fields of the structure array specify options for controlling the iterative algorithm.

This table summarizes the supported fields. Note that the supported fields require Parallel Computing Toolbox.

Field	Description
`'Streams'`	A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `kmeans` uses the default stream or streams. If you specify `Streams`, use a single object except when all of the following conditions exist: • You have an open parallel pool. • `UseParallel` is `true`. • `UseSubstreams` is `false`. In this case, use a cell array the same size as the parallel pool. If a parallel pool is not open, then `Streams` must supply a single random number stream.
`'UseParallel'`	• If `true` and `Replicates` > 1, then `kmeans` implements the *k*-means algorithm on each replicate in parallel. • If Parallel Computing Toolbox is not installed, then computation occurs in serial mode. The default is `false`, indicating serial computation.
`'UseSubstreams'`	Set to `true` to compute in parallel in a reproducible fashion. The default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.

To ensure more predictable results, use `parpool` and explicitly create a parallel pool before invoking `kmeans` and setting `'Options',statset('UseParallel',1)`.

Example: `'Options',statset('UseParallel',1)`

Data Types: `struct`

`Replicates` — Number of times to repeat clustering using new initial cluster centroid positions
1 (default) | positive integer

Number of times to repeat clustering using new initial cluster centroid positions, specified as the comma-separated pair consisting of `'Replicates'` and an integer. `kmeans` returns the solution with the lowest `sumd`.

You can set `'Replicates'` implicitly by supplying a 3-D array as the value for the `'Start'` name-value pair argument.

Example: `'Replicates',5`

Data Types: `double` | `single`

`Start` — Method for choosing initial cluster centroid positions
`'plus'` (default) | `'cluster'` | `'sample'` | `'uniform'` | numeric matrix | numeric array

Method for choosing initial cluster centroid positions (or seeds), specified as the comma-separated pair consisting of `'Start'` and `'cluster'`, `'plus'`, `'sample'`, `'uniform'`, a numeric matrix, or a numeric array. This table summarizes the available options for choosing seeds.

Value	Description
`'cluster'`	Perform a preliminary clustering phase on a random 10% subsample of `X` when the number of observations in the subsample is greater than `k`. This preliminary phase is itself initialized using `'sample'`. If the number of observations in the random 10% subsample is less than `k`, then the software selects `k` observations from `X` at random.
`'plus'` (default)	Select `k` seeds by implementing the *k*-means++ algorithm on page 33-3329 for cluster center initialization.
`'sample'`	Select `k` observations from `X` at random.
`'uniform'`	Select `k` points uniformly at random from the range of `X`. Not valid with the Hamming distance.
numeric matrix	`k`-by-*p* matrix of centroid starting locations. The rows of `Start` correspond to seeds. The software infers `k` from the first dimension of `Start`, so you can pass in `[]` for `k`.
numeric array	`k`-by-*p*-by-*r* array of centroid starting locations. The rows of each page correspond to seeds. The third dimension invokes replication of the clustering routine. Page *j* contains the set of seeds for replicate *j*. The software infers the number of replicates (specified by the `'Replicates'` name-value pair argument) from the size of the third dimension.

Example: `'Start','sample'`

Data Types: `char` | `string` | `double` | `single`

Output Arguments

`idx` — Cluster indices

numeric column vector

Cluster indices, returned as a numeric column vector. `idx` has as many rows as `X`, and each row indicates the cluster assignment of the corresponding observation.

`C` — Cluster centroid locations

numeric matrix

Cluster centroid locations, returned as a numeric matrix. `C` is a `k`-by-*p* matrix, where row *j* is the centroid of cluster *j*.

`sumd` — Within-cluster sums of point-to-centroid distances
numeric column vector

Within-cluster sums of point-to-centroid distances, returned as a numeric column vector. `sumd` is a `k`-by-1 vector, where element *j* is the sum of point-to-centroid distances within cluster *j*. By default, `kmeans` uses the squared Euclidean distance (see `'Distance'` metrics).

`D` — Distances from each point to every centroid
numeric matrix

Distances from each point to every centroid, returned as a numeric matrix. `D` is an *n*-by-`k` matrix, where element (*j*,*m*) is the distance from observation *j* to centroid *m*. By default, `kmeans` uses the squared Euclidean distance (see `'Distance'` metrics).

More About

k-Means Clustering

k-means clustering, or Lloyd's algorithm [2], is an iterative, data-partitioning algorithm that assigns *n* observations to exactly one of *k* clusters defined by centroids, where *k* is chosen before the algorithm starts.

The algorithm proceeds as follows:

1. Choose *k* initial cluster centers (centroid). For example, choose *k* observations at random (by using `'Start','sample'`) or use the *k*-means ++ algorithm on page 33-3329 for cluster center initialization (the default).
2. Compute point-to-cluster-centroid distances of all observations to each centroid.
3. There are two ways to proceed (specified by `OnlinePhase`):
   - Batch update — Assign each observation to the cluster with the closest centroid.
   - Online update — Individually assign observations to a different centroid if the reassignment decreases the sum of the within-cluster, sum-of-squares point-to-cluster-centroid distances.

   For more details, see "Algorithms" on page 33-3330.
4. Compute the average of the observations in each cluster to obtain *k* new centroid locations.
5. Repeat steps 2 through 4 until cluster assignments do not change, or the maximum number of iterations is reached.

k-means++ Algorithm

The *k*-means++ algorithm uses an heuristic to find centroid seeds for *k*-means clustering. According to Arthur and Vassilvitskii [1], *k*-means++ improves the running time of Lloyd's algorithm, and the quality of the final solution.

The *k*-means++ algorithm chooses seeds as follows, assuming the number of clusters is *k*.

1. Select an observation uniformly at random from the data set, *X*. The chosen observation is the first centroid, and is denoted c_1.
2. Compute distances from each observation to c_1. Denote the distance between c_j and the observation m as $d(x_m, c_j)$.

3 Select the next centroid, c_2 at random from X with probability

$$\frac{d^2(x_m, c_1)}{\sum_{j=1}^{n} d^2(x_j, c_1)}.$$

4 To choose center j:

   a Compute the distances from each observation to each centroid, and assign each observation to its closest centroid.

   b For $m = 1,...,n$ and $p = 1,...,j - 1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, c_p)}{\sum_{\{h;\, x_h \in C_p\}} d^2(x_h, c_p)},$$

   where C_p is the set of all observations closest to centroid c_p and x_m belongs to C_p.

   That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

5 Repeat step 4 until k centroids are chosen.

Arthur and Vassilvitskii [1] demonstrate, using a simulation study for several cluster orientations, that k-means++ achieves faster convergence to a lower sum of within-cluster, sum-of-squares point-to-cluster-centroid distances than Lloyd's algorithm.

Algorithms

- `kmeans` uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all `k` clusters.

  1 This first phase uses batch updates, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum. That is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.

  2 This second phase uses online updates, where points are individually reassigned if doing so reduces the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during this phase consists of one pass though all the points. This phase converges to a local minimum, although there might be other local minima with lower total sum of distances. In general, finding the global minimum is solved by an exhaustive choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.

- If `Replicates` = $r > 1$ and `Start` is `plus` (the default), then the software selects r possibly different sets of seeds according to the k-means++ algorithm on page 33-3329.
- If you enable the `UseParallel` option in `Options` and `Replicates` > 1, then each worker selects seeds and clusters in parallel.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
  - `idx = kmeans(X,k)`
  - `[idx,C] = kmeans(X,k)`
  - `[idx,C,sumd] = kmeans(X,k)`
  - `[___] = kmeans(___,Name,Value)`
- Supported name-value pair arguments, and any differences, are:
  - `'Display'` — Default value is `'iter'`.
  - `'MaxIter'`
  - `'Options'` — Supports only the `'TolFun'` field of the structure array created by `statset`. The default value of `'TolFun'` is `1e-4`. The `kmeans` function uses the value of `'TolFun'` as the termination tolerance for the within-cluster sums of point-to-centroid distances. For example, you can specify `'Options',statset('TolFun',1e-8)`.
  - `'Replicates'`
  - `'Start'` — Supports only `'plus'`, `'sample'`, and a numeric array.

For more information, see “Tall Arrays for Out-of-Memory Data”.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- If the `Start` method uses random selections, the initial centroid cluster positions might not match MATLAB.
- If the number of rows in `X` is fixed, code generation does not remove rows of `X` that contain a `NaN`.
- The cluster centroid locations in `C` can have a different order than in MATLAB. In this case, the cluster indices in `idx` have corresponding differences.

- If you provide `Display`, its value must be `'off'`.
- If you provide `Streams`, it must be empty and `UseSubstreams` must be `false`.
- When you set the `UseParallel` option to `true`:
  - Some computations can execute in parallel even when `Replicates` is `1`. For large data sets, when `Replicates` is `1`, consider setting the `UseParallel` option to `true`.
  - `kmeans` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms. Loops that run in parallel can be faster than loops that run on a single thread. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see `https://www.mathworks.com/support/compilers/current_release/`.
- To save memory on the device to which you deploy generated code, you can separate training and prediction by using `kmeans` and `pdist2`, respectively. Use `kmeans` to create clusters in MATLAB and use `pdist2` in the generated code to assign new data to existing clusters. For code generation, define an entry-point function that accepts the cluster centroid positions and the new data set, and returns the index of the nearest cluster. Then, generate code for the entry-point function. For an example, see “Assign New Data to Existing Clusters and Generate C/C++ Code” on page 33-3320.
- Starting in R2020a, `kmeans` returns integer-type (`int32`) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for stricter single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

kmedoids

k-medoids clustering

Syntax

```
idx = kmedoids(X,k)
idx = kmedoids(X,k,Name,Value)
[idx,C] = kmedoids( ___ )
[idx,C,sumd] = kmedoids( ___ )
[idx,C,sumd,D] = kmedoids( ___ )
[idx,C,sumd,D,midx] = kmedoids( ___ )
[idx,C,sumd,D,midx,info] = kmedoids( ___ )
```

Description

`idx = kmedoids(X,k)` performs “k-medoids Clustering” on page 33-3345 to partition the observations of the *n*-by-*p* matrix `X` into `k` clusters, and returns an *n*-by-1 vector `idx` containing cluster indices of each observation. Rows of `X` correspond to points and columns correspond to variables. By default, `kmedoids` uses squared Euclidean distance metric and the *k*-means++ algorithm on page 33-3329 for choosing initial cluster medoid positions.

`idx = kmedoids(X,k,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[idx,C] = kmedoids( ___ )` returns the `k` cluster medoid locations in the *k*-by-*p* matrix `C`.

`[idx,C,sumd] = kmedoids( ___ )` returns the within-cluster sums of point-to-medoid distances in the *k*-by-1 vector `sumd`.

`[idx,C,sumd,D] = kmedoids( ___ )` returns distances from each point to every medoid in the *n*-by-*k* matrix `D`.

`[idx,C,sumd,D,midx] = kmedoids( ___ )` returns the indices `midx` such that `C = X(midx,:)`. `midx` is a *k*-by-1 vector.

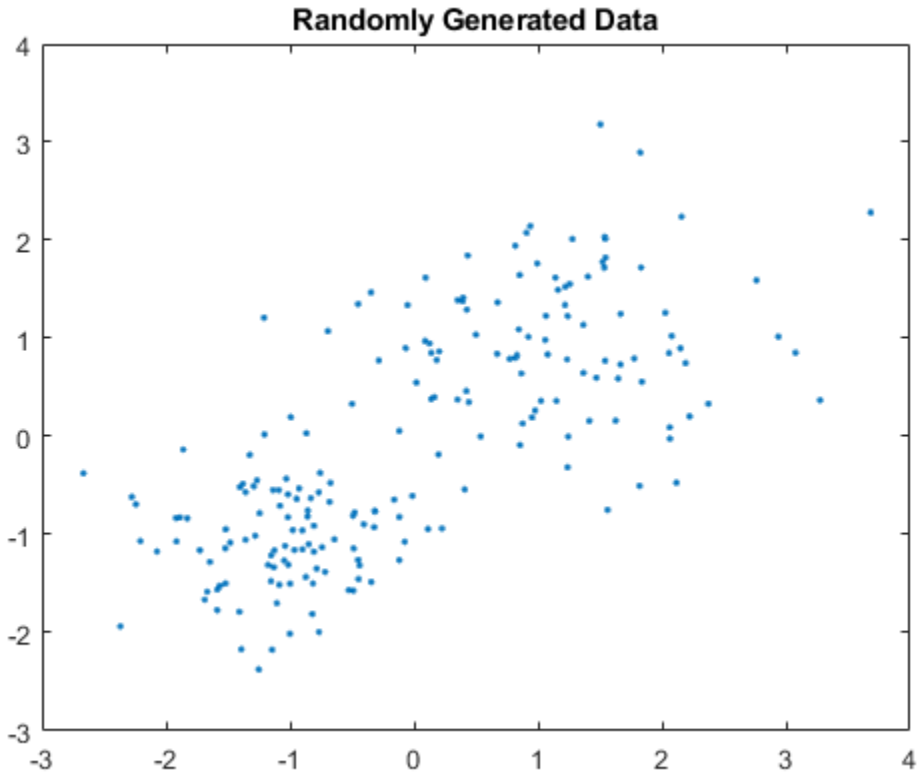
`[idx,C,sumd,D,midx,info] = kmedoids( ___ )` returns a structure `info` with information about the options used by the algorithm when executed.

Examples

Group Data into Two Clusters

Randomly generate data.

```
rng('default'); % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
    randn(100,2)*0.55-ones(100,2)];
figure;
plot(X(:,1),X(:,2),'.');
title('Randomly Generated Data');
```



Group data into two clusters using `kmedoids`. Use the `cityblock` distance metric.

```
opts = statset('Display','iter');
[idx,C,sumd,d,midx,info] = kmedoids(X,2,'Distance','cityblock','Options',opts);
```

```
   rep        iter             sum
     1           1         209.856
     1           2         209.856
Best total sum of distances = 209.856
```

`info` is a struct that contains information about how the algorithm was executed. For example, `bestReplicate` field indicates the replicate that was used to produce the final solution. In this example, the replicate number 1 was used since the default number of replicates is 1 for the default algorithm, which is `pam` in this case.

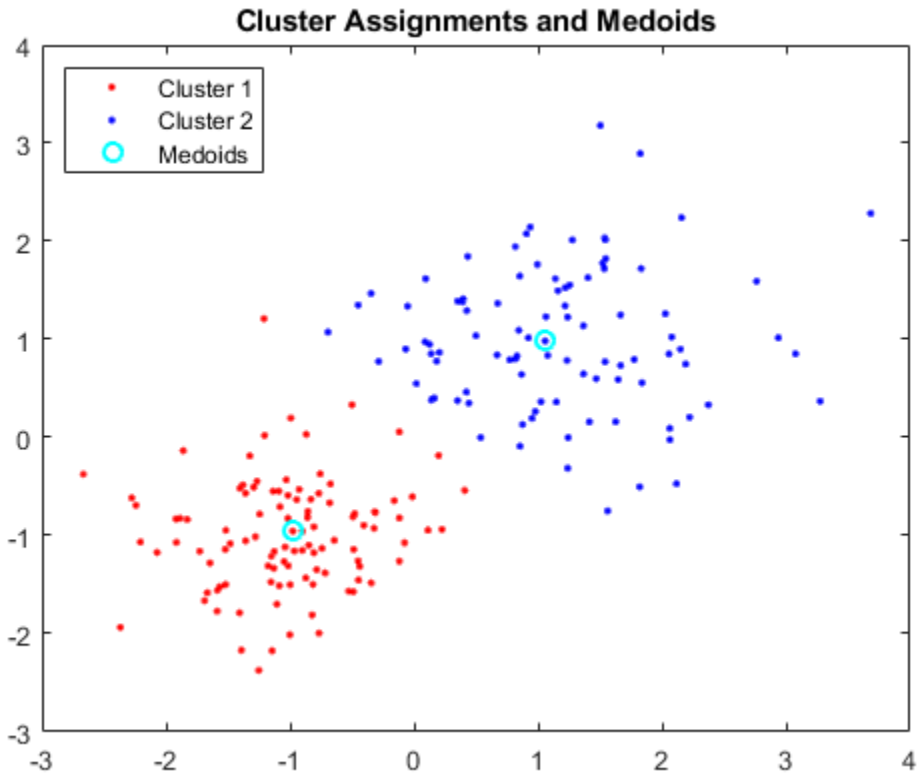
```
info
```

```
info = struct with fields:
        algorithm: 'pam'
            start: 'plus'
         distance: 'cityblock'
       iterations: 2
    bestReplicate: 1
```

Plot the clusters and the cluster medoids.

```
figure;
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',7)
```

```
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',7)
plot(C(:,1),C(:,2),'co',...
     'MarkerSize',7,'LineWidth',1.5)
legend('Cluster 1','Cluster 2','Medoids',...
       'Location','NW');
title('Cluster Assignments and Medoids');
hold off
```



Cluster Categorical Data Using k-Medoids

This example uses "Mushroom" data set [3][4][5] [6][7] from the UCI machine learning archive [7], described in http://archive.ics.uci.edu/ml/datasets/Mushroom. The data set includes 22 predictors for 8,124 observations of various mushrooms. The predictors are categorical data types. For example, cap shape is categorized with features of `'b'` for bell-shaped cap and `'c'` for conical. Mushroom color is also categorized with features of `'n'` for brown, and `'p'` for pink. The data set also includes a classification for each mushroom of either edible or poisonous.

Since the features of the mushroom data set are categorical, it is not possible to define the mean of several data points, and therefore the widely-used *k*-means clustering algorithm cannot be meaningfully applied to this data set. *k*-medoids is a related algorithm that partitions data into *k* distinct clusters, by finding medoids that minimize the sum of dissimilarities between points in the data and their nearest medoid.

The medoid of a set is a member of that set whose average dissimilarity with the other members of the set is the smallest. Similarity can be defined for many types of data that do not allow a mean to be calculated, allowing *k*-medoids to be used for a broader range of problems than *k*-means.

Using *k*-medoids, this example clusters the mushrooms into two groups, based on the predictors provided. It then explores the relationship between those clusters and the classifications of the mushrooms as either edible or poisonous.

This example assumes that you have downloaded the "Mushroom" data set [3][4][5] [6][7] from the UCI database (http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/) and saved it in your current directory as a text file named agaricus-lepiota.txt. There is no column headers in the data, so `readtable` uses the default variable names.

```
clear all
data = readtable('agaricus-lepiota.txt','ReadVariableNames',false);
```

Display the first 5 mushrooms with their first few features.

```
data(1:5,1:10)
```

```
ans =

    Var1    Var2    Var3    Var4    Var5    Var6    Var7    Var8    Var9    Var10
    ____    ____    ____    ____    ____    ____    ____    ____    ____    _____

    'p'     'x'     's'     'n'     't'     'p'     'f'     'c'     'n'     'k'
    'e'     'x'     's'     'y'     't'     'a'     'f'     'c'     'b'     'k'
    'e'     'b'     's'     'w'     't'     'l'     'f'     'c'     'b'     'n'
    'p'     'x'     'y'     'w'     't'     'p'     'f'     'c'     'n'     'n'
    'e'     'x'     's'     'g'     'f'     'n'     'f'     'w'     'b'     'k'
```

Extract the first column, labeled data for edible and poisonous groups. Then delete the column.

```
labels = data(:,1);
labels = categorical(labels{:,:});
data(:,1) = [];
```

Store the names of predictors (features), which are described in http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/agaricus-lepiota.names.

```
VarNames = {'cap_shape' 'cap_surface' 'cap_color' 'bruises' 'odor' ...
    'gill_attachment' 'gill_spacing' 'gill_size' 'gill_color' ...
    'stalk_shape' 'stalk_root' 'stalk_surface_above_ring' ...
    'stalk_surface_below_ring' 'stalk_color_above_ring' ...
    'stalk_color_below_ring' 'veil_type' 'veil_color' 'ring_number' ....
    'ring_type' 'spore_print_color' 'population' 'habitat'};
```

Set the variable names.

```
data.Properties.VariableNames = VarNames;
```

There are a total of 2480 missing values denoted as `'?'`.

```
sum(char(data{:,:}) == '?')
```

```
ans =

        2480
```

Based on the inspection of the data set and its description, the missing values belong only to the 11th variable (`stalk_root`). Remove the column from the table.

```
data(:,11) = [];
```

`kmedoids` only accepts numeric data. You need to cast the categories you have into numeric type. The distance function you will use to define the dissimilarity of the data will be based on the double representation of the categorical data.

```
cats = categorical(data{:,:});
data = double(cats);
```

`kmedoids` can use any distance metric supported by pdist2 to cluster. For this example you will cluster the data using the Hamming distance because this is an appropriate distance metric for categorical data as illustrated below. The Hamming distance between two vectors is the percentage of the vector components that differ. For instance, consider these two vectors.

```
v1 = [1 0 2 1];
```

```
v2 = [1 1 2 1];
```

They are equal in the 1st, 3rd and 4th coordinate. Since 1 of the 4 coordinates differ, the Hamming distance between these two vectors is .25.

You can use the function `pdist2` to measure the Hamming distance between the first and second row of data, the numerical representation of the categorical mushroom data. The value .2857 means that 6 of the 21 features of the mushroom differ.

```
pdist2(data(1,:),data(2,:),'hamming')
```

```
ans =

    0.2857
```

In this example, you're clustering the mushroom data into two clusters based on features to see if the clustering corresponds to edibility. The `kmedoids` function is guaranteed to converge to a local minima of the clustering criterion; however, this may not be a global minimum for the problem. It is a good idea to cluster the problem a few times using the `'replicates'` parameter. When `'replicates'` is set to a value, *n*, greater than 1, the k-medoids algorithm is run *n* times, and the best result is returned.

To run `kmedoids` to cluster data into 2 clusters, based on the Hamming distance and to return the best result of 3 replicates, you run the following.

```
rng('default'); % For reproducibility
[IDX, C, SUMD, D, MIDX, INFO] = kmedoids(data,2,'distance','hamming','replicates',3);
```

Let's assume that mushrooms in the predicted group 1 are poisonous and group 2 are all edible. To determine the performance of clustering results, calculate how many mushrooms in group 1 are indeed poisonous and group 2 are edible based on the known labels. In other words, calculate the number of false positives, false negatives, as well as true positives and true negatives.

Construct a confusion matrix (or matching matrix), where the diagonal elements represent the number of true positives and true negatives, respectively. The off-diagonal elements represent false negatives and false positives, respectively. For convenience, use the `confusionmat` function, which calculates a confusion matrix given known labels and predicted labels. Get the predicted label

information from the IDX variable. IDX contains values of 1 and 2 for each data point, representing poisonous and edible groups, respectively.

```
predLabels = labels; % Initialize a vector for predicted labels.
predLabels(IDX==1) = categorical({'p'}); % Assign group 1 to be poisonous.
predLabels(IDX==2) = categorical({'e'}); % Assign group 2 to be edible.
confMatrix = confusionmat(labels,predLabels)
```

```
confMatrix =

        4176          32
         816        3100
```

Out of 4208 edible mushrooms, 4176 were correctly predicted to be in group 2 (edible group), and 32 were incorrectly predicted to be in group 1 (poisonous group). Similarly, out of 3916 poisonous mushrooms, 3100 were correctly predicted to be in group 1 (poisonous group), and 816 were incorrectly predicted to be in group 2 (edible group).

Given this confusion matrix, calculate the accuracy, which is the proportion of true results (both true positives and true negatives) against the overall data, and precision, which is the proportion of the true positives against all the positive results (true positives and false positives).

```
accuracy = (confMatrix(1,1)+confMatrix(2,2))/(sum(sum(confMatrix)))
```

```
accuracy =

    0.8956
```

```
precision = confMatrix(1,1) / (confMatrix(1,1)+confMatrix(2,1))
```

```
precision =

    0.8365
```

The results indicated that applying the k-medoids algorithm to the categorical features of mushrooms resulted in clusters that were associated with edibility.

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of X correspond to observations, and the columns correspond to variables.

k — Number of medoids

positive integer

Number of medoids in the data, specified as a positive integer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example:
`'Distance','euclidean','Replicates',3,'Options',statset('UseParallel',1)`
specifies Euclidean distance, three replicate medoids at different starting values, and to use parallel computing.

`Algorithm` — Algorithm to find medoids
`'pam'` | `'small'` | `'clara'` | `'large'`

Algorithm to find medoids, specified as the comma-separated pair consisting of `'Algorithm'` and `'pam'`, `'small'`, `'clara'`, or `'large'`. The default algorithm depends on the number of rows of `X`.

- If the number of rows of `X` is less than 3000, `'pam'` is the default algorithm.
- If the number of rows is between 3000 and 10000, `'small'` is the default algorithm.
- For all other cases, `'large'` is the default algorithm.

You can override the default choice by explicitly stating the algorithm. This table summarizes the available algorithms.

Algorithm	Description
`'pam'`	Partitioning Around Medoids (PAM) is the classical algorithm for solving the *k*-medoids problem described in [1]. After applying the initialization function to select initial medoid positions, the program performs the swap-step of the PAM algorithm, that is, it searches over all possible swaps between medoids and non-medoids to see if the sum of medoid to cluster member distances goes down. You can specify which initialization function to use via the `'Start'` name-value pair argument. The algorithm proceeds as follows. **1** Build-step: Each of *k* clusters is associated with a potential medoid. This assignment is performed using a technique specified by the `'Start'` name-value pair argument. **2** Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid. The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met. The algorithm can produce better solutions than the other algorithms in some situations, but it can be prohibitively long running.

Algorithm	Description
`'small'`	Use an algorithm similar to the k-means algorithm to find `k` medoids. This option employs a variant of the Lloyd's iterations based on [2]. The algorithm proceeds as follows. **1** For each point in each cluster, calculate the sum of distances from the point to every other point in the cluster. Choose the point that minimizes the sum as the new medoid. **2** Update the cluster membership for each data point to reflect the new medoid. The algorithm repeats these steps until no further updates occur or other termination criteria are met. The algorithm has an optional PAM-like online update phase (specified by the `'OnlinePhase'` name-value pair argument) that improves cluster quality. It tends to return higher quality solutions than the `clara` or `large` algorithms, but it may not be the best choice for very large data.
`'clara'`	Clustering LARge Applications (CLARA) [1] repeatedly performs the PAM algorithm on random subsets of the data. It aims to overcome scaling challenges posed by the PAM algorithm through sampling. The algorithm proceeds as follows. **1** Select a subset of the data and apply the PAM algorithm to the subset. **2** Assign points of the full data set to clusters by picking the closest medoid. The algorithm repeats these steps until the medoids do not change, or other termination criteria are met. For the best performance, it is recommended that you perform multiple replicates. By default, the program performs five replicates. Each replicate samples `s` rows from X (specified by `'NumSamples'` name-value pair argument) to perform clustering on. By default, `40+2*k` samples are selected.
`'large'`	This is similar to the `small` scale algorithm and repeatedly performs searches using a k-means like update. However, the algorithm examines only a random sample of cluster members during each iteration. The user-adjustable parameter, `'PercentNeighbors'`, controls the number of neighbors to examine. If there is no improvement after the neighbors are examined, the algorithm terminates the local search. The algorithm performs a total of *r* replicates (specified by `'Replicates'` name-value pair argument) and returns the best clustering result. The algorithm has an optional PAM-like online phase (specified by the `'OnlinePhase'` name-value pair argument) that improves cluster quality.

Example: `'Algorithm','pam'`

`OnlinePhase` — Flag to perform PAM-like online update phase
`'on'` (default) | `'off'`

A flag to perform PAM-like online update phase, specified as a comma-separated pair consisting of `'OnlinePhase'` and `'on'` or `'off'`.

If it is `on`, then `kmedoids` performs a PAM-like update to the medoids after the Lloyd iterations in the `small` and `large` algorithms. During this online update phase, the algorithm chooses a small subset of data points in each cluster that are the furthest from and nearest to medoid. For each chosen point, it reassigns the clustering of the entire data set and check if this creates a smaller sum of distances than the best known.

In other words, the swap considerations are limited to the points near the medoids and far from the medoids. The near points are considered in order to refine the clustering. The far points are considered in order to escape local minima. Turning on this feature tends to improve the quality of solutions generated by both algorithms. Total run time tends to increase as well, but the increase typically is less than one iteration of PAM.

Example: `OnlinePhase,'off'`

`Distance` — Distance metric

`'sqEuclidean'` (default) | `'euclidean'` | character vector | string scalar | function handle | ...

Distance metric, specified as the name of a distance metric described in the following table, or a function handle. `kmedoids` minimizes the sum of medoid to cluster member distances.

Value	Description
`'sqEuclidean'`	Squared Euclidean distance (default)
`'euclidean'`	Euclidean distance
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, `S = std(X,'omitnan')`.
`'cityblock'`	City block distance
`'minkowski'`	Minkowski distance. The exponent is 2.
`'chebychev'`	Chebychev distance (maximum coordinate difference)
`'mahalanobis'`	Mahalanobis distance using the sample covariance of `X`, `C = cov(X,'omitrows')`
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors)
`'correlation'`	One minus the sample correlation between points (treated as sequences of values)
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)
`'hamming'`	Hamming distance, which is the percentage of coordinates that differ
`'jaccard'`	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ

Value	Description

`@distfun`	Custom distance function handle. A distance function has the form
	`function D2 = distfun(ZI,ZJ)`
	`% calculation of distance`
	`...`
	where
	• `ZI` is a `1`-by-`n` vector containing a single observation.
	• `ZJ` is an `m2`-by-`n` matrix containing multiple observations. `distfun` must accept a matrix `ZJ` with an arbitrary number of observations.
	• `D2` is an `m2`-by-`1` vector of distances, and `D2(k)` is the distance between observations `ZI` and `ZJ(k,:)`.
	If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.

For the definition of each distance metric, see “Distance Metrics” on page 33-4495.

Example: `'Distance','hamming'`

`Options` — Options to control iterative algorithm to minimize fitting criteria
`[]` (default) | structure array returned by `statset`

Options to control the iterative algorithm to minimize fitting criteria, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. Supported fields of the structure array specify options for controlling the iterative algorithm. This table summarizes the supported fields.

Field	Description
`Display`	Level of display output. Choices are `'off'` (default) and `'iter'`.
`MaxIter`	Maximum number of iterations allowed. The default is `100`.
`UseParallel`	If `true`, compute in parallel. If Parallel Computing Toolbox is not available, then computation occurs in serial mode. The default is `false`, meaning serial computation.
`UseSubstreams`	Set to `true` to compute in parallel in a reproducible fashion. The default is `false`. To compute reproducibly, you must also set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
`Streams`	A `RandStream` object or cell array of such objects. For details about these options and parallel computing in Statistics and Machine Learning Toolbox, see “Speed Up Statistical Computations” or enter `help parallelstats` at the command line.

Example: `'Options',statset('Display','off')`

`Replicates` — Number of times to repeat clustering using new initial cluster medoid positions
positive integer

Number of times to repeat clustering using new initial cluster medoid positions, specified as a positive integer. The default value depends on the choice of algorithm. For `pam` and `small`, the default is 1. For `clara`, the default is 5. For `large`, the default is 3.

Example: `'Replicates',4`

`NumSamples` — Number of samples to take from data when executing `clara` algorithm
`40+2*k` (default) | positive integer

Number of samples to take from the data when executing the `clara` algorithm, specified as a positive integer. The default number of samples is calculated as `40+2*k`.

Example: `'NumSamples',160`

`PercentNeighbors` — Percent of data set to examine using large algorithm
0.001 (default) | scalar value between 0 and 1

Percent of the data set to examine using the `large` algorithm, specified as a positive number.

The program examines `percentneighbors*size(X,1)` number of neighbors for the medoids. If there is no improvement in the within-cluster sum of distances, then the algorithm terminates.

The value of this parameter between 0 and 1, where a value closer to 1 tends to give higher quality solutions, but the algorithm takes longer to run, and a value closer to 0 tends to give lower quality solutions, but finishes faster.

Example: `'PercentNeighbors',0.01`

`Start` — Method for choosing initial cluster medoid positions
`'plus'` (default) | `'sample'` | `'cluster'` | matrix

Method for choosing initial cluster medoid positions, specified as the comma-separated pair consisting of `'Start'` and `'plus'`, `'sample'`, `'cluster'`, or a matrix. This table summarizes the available methods.

Method	Description
`'plus'` (default)	Select `k` observations from `X` according to the *k*-means++ algorithm on page 33-3329 for cluster center initialization.
`'sample'`	Select `k` observations from `X` at random.
`'cluster'`	Perform preliminary clustering phase on a random subsample (10%) of `X`. This preliminary phase is itself initialized using `sample`, that is, the observations are selected at random.
matrix	A custom `k`-by-*p* matrix of starting locations. In this case, you can pass in `[]` for the `k` input argument, and `kmedoids` infers `k` from the first dimension of the matrix. You can also supply a 3-D array, implying a value for `'Replicates'` from the array's third dimension.

Example: `'Start','sample'`

Data Types: `char` | `string` | `single` | `double`

Output Arguments

`idx` — Medoid indices

numeric column vector

Medoid indices, returned as a numeric column vector. `idx` has as many rows as `X`, and each row indicates the medoid assignment of the corresponding observation.

`C` — Cluster medoid locations

numeric matrix

Cluster medoid locations, returned as a numeric matrix. `C` is a *k*-by-*p* matrix, where row *j* is the medoid of cluster *j*

`sumd` — Within-cluster sums of point-to-medoid distances

numeric column vector

Within-cluster sums of point-to-medoid distances, returned as a numeric column vector. `sumd` is a `k`-by1 vector, where element *j* is the sum of point-to-medoid distances within cluster *j*.

`D` — Distances from each point to every medoid

numeric matrix

Distances from each point to every medoid, returned as a numeric matrix. `D` is an *n*-by-`k` matrix, where element (*j*,*m*) is the distance from observation *j* to medoid *m*.

`midx` — Index to `X`

column vector

Index to `X`, returned as a column vector of indices. `midx` is a `k`-by-1 vector and the indices satisfy `C = X(midx,:)`.

`info` — Algorithm information

struct

Algorithm information, returned as a struct. `info` contains options used by the function when executed such as *k*-medoid clustering algorithm (`algorithm`), method used to choose initial cluster medoid positions (`start`), distance metric (`distance`), number of iterations taken in the best replicate (`iterations`) and the replicate number of the returned results (`bestReplicate`).

More About

k-medoids Clustering

k-medoids clustering is a partitioning method commonly used in domains that require robustness to outlier data, arbitrary distance metrics, or ones for which the mean or median does not have a clear definition.

It is similar to *k*-means, and the goal of both methods is to divide a set of measurements or observations into *k* subsets or clusters so that the subsets minimize the sum of distances between a measurement and a center of the measurement's cluster. In the *k*-means algorithm, the center of the subset is the mean of measurements in the subset, often called a centroid. In the *k*-medoids algorithm, the center of the subset is a member of the subset, called a medoid.

The *k*-medoids algorithm returns medoids which are the actual data points in the data set. This allows you to use the algorithm in situations where the mean of the data does not exist within the data set. This is the main difference between *k*-medoids and *k*-means where the centroids returned by *k*-means may not be within the data set. Hence *k*-medoids is useful for clustering categorical data where a mean is impossible to define or interpret.

The function `kmedoids` provides several iterative algorithms that minimize the sum of distances from each object to its cluster medoid, over all clusters. One of the algorithms is called partitioning around medoids (PAM) [1] which proceeds in two steps.

1. Build-step: Each of *k* clusters is associated with a potential medoid. This assignment is performed using a technique specified by the `'Start'` name-value pair argument.
2. Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.

You can control the details of the minimization using several optional input parameters to `kmedoids`, including ones for the initial values of the cluster medoids, and for the maximum number of iterations. By default, `kmedoids` uses the *k*-means++ algorithm on page 33-3329 for cluster medoid initialization and the squared Euclidean metric to determine distances.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

knnsearch

Find *k*-nearest neighbors using searcher object

Syntax

```
Idx = knnsearch(Mdl,Y)
Idx = knnsearch(Mdl,Y,Name,Value)
[Idx,D] = knnsearch( ___ )
```

Description

`Idx = knnsearch(Mdl,Y)` searches for the nearest neighbor (i.e., the closest point, row, or observation) in `Mdl.X` to each point (i.e., row or observation) in the query data `Y` using an exhaustive search or a *K*d-tree. `knnsearch` returns `Idx`, which is a column vector of the indices in `Mdl.X` representing the nearest neighbors.

`Idx = knnsearch(Mdl,Y,Name,Value)` returns the indices of the closest points in `Mdl.X` to `Y` with additional options specified by one or more `Name,Value` pair arguments. For example, specify the number of nearest neighbors to search for, distance metric different from the one stored in `Mdl.Distance`. You can also specify which action to take if the closest distances are tied.

`[Idx,D] = knnsearch( ___ )` additionally returns the matrix `D` using any of the input arguments in the previous syntaxes. `D` contains the distances between each observation in `Y` that correspond to the closest observations in `Mdl.X`. By default, the function arranges the columns of `D` in ascending order by closeness, with respect to the distance metric.

Examples

Search for Nearest Neighbors Using *K*d-tree and Exhaustive Search

`knnsearch` accepts `ExhaustiveSearcher` or `KDTreeSearcher` model objects to search the training data for the nearest neighbors to the query data. An `ExhaustiveSearcher` model invokes the exhaustive searcher algorithm, and a `KDTreeSearcher` model defines a *K*d-tree, which `knnsearch` uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data.

```
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),:); % Training data
Y = meas(idx,:);                % Query data
```

The variable `meas` contains 4 predictors.

Grow a default four-dimensional *K*d-tree.

```
MdlKDT = KDTreeSearcher(X)
```

```
MdlKDT =
  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'euclidean'
    DistParameter: []
                X: [145x4 double]
```

`MdlKDT` is a `KDTreeSearcher` model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbor searcher.

```
MdlES = ExhaustiveSearcher(X)
```

```
MdlES =
  ExhaustiveSearcher with properties:

        Distance: 'euclidean'
    DistParameter: []
                X: [145x4 double]
```

`MdlKDT` is an `ExhaustiveSearcher` model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a *K*d-tree or prepare an exhaustive nearest neighbor searcher using `createns`.

Search the training data for the nearest neighbors indices that correspond to each query observation. Conduct both types of searches using the default settings. By default, the number of neighbors to search for per query observation is `1`.

```
IdxKDT = knnsearch(MdlKDT,Y);
IdxES = knnsearch(MdlES,Y);
[IdxKDT IdxES]
```

```
ans = 5×2

    17    17
     6     6
     1     1
    89    89
   124   124
```

In this case, the results of the search are the same.

Search for Nearest Neighbors of Query Data Using Minkowski Distance

Grow a *K*d-tree nearest neighbor searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find *k*-nearest neighbors.

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional *K*d-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```
Mdl = createns(X,'Distance','minkowski')
```

```
Mdl =
  KDTreeSearcher with properties:

       BucketSize: 50
         Distance: 'minkowski'
    DistParameter: 2
                X: [145x4 double]
```

Because `X` has four columns and the distance metric is Minkowski, `createns` creates a `KDTreeSearcher` model object by default. The Minkowski distance exponent is `2` by default.

Find the indices of the training data (`Mdl.X`) that are the two nearest neighbors of each point in the query data (`Q`).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

```
IdxNN = 5×2

    17     4
     6     2
     1    12
    89    66
   124   100
```

Each row of `IdxNN` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, based on the Minkowski distance, the second nearest neighbor of `Q(3,:)` is `X(12,:)`.

Include Ties in Nearest Neighbor Search

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
```

```
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional *K*d-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```
Mdl = KDTreeSearcher(X);
```

`Mdl` is a `KDTreeSearcher` model object. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (`X`) that are the seven nearest neighbors of each point in the query data (`Y`).

```
[Idx,D] = knnsearch(Mdl,Y,'K',7,'IncludeTies',true);
```

`Idx` and `D` are five-element cell arrays of vectors, with each vector having at least seven elements.

Display the lengths of the vectors in `Idx`.

```
cellfun('length',Idx)
```

```
ans = 5×1

     8
     7
     7
     7
     7
```

Because cell `1` contains a vector with length greater than $k = 7$, query observation 1 (`Y(1,:)`) is equally close to at least two observations in `X`.

Display the indices of the nearest neighbors to `Y(1,:)` and their distances.

```
nn5 = Idx{1}
```

```
nn5 = 1×8

    91    98    67    69    71    93    88    95
```

```
nn5d = D{1}
```

```
nn5d = 1×8

    0.1414    0.2646    0.2828    0.3000    0.3464    0.3742    0.3873    0.3873
```

Training observations `88` and `95` are 0.3873 cm away from query observation `1`.

Compare *k*-Nearest Neighbors Using Different Distance Metrics

Train two `KDTreeSearcher` models using different distance metrics, and compare *k*-nearest neighbors of query data for the two models.

Load Fisher's iris data set. Consider the petal measurements as predictors.

```
load fisheriris
X = meas(:,3:4); % Predictors
Y = species;     % Response
```

Train a `KDTreeSearcher` model object by using the predictors. Specify the Minkowski distance with exponent 5.

```
KDTreeMdl = KDTreeSearcher(X,'Distance','minkowski','P',5)
```

```
KDTreeMdl =
  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'minkowski'
    DistParameter: 5
                X: [150x2 double]
```

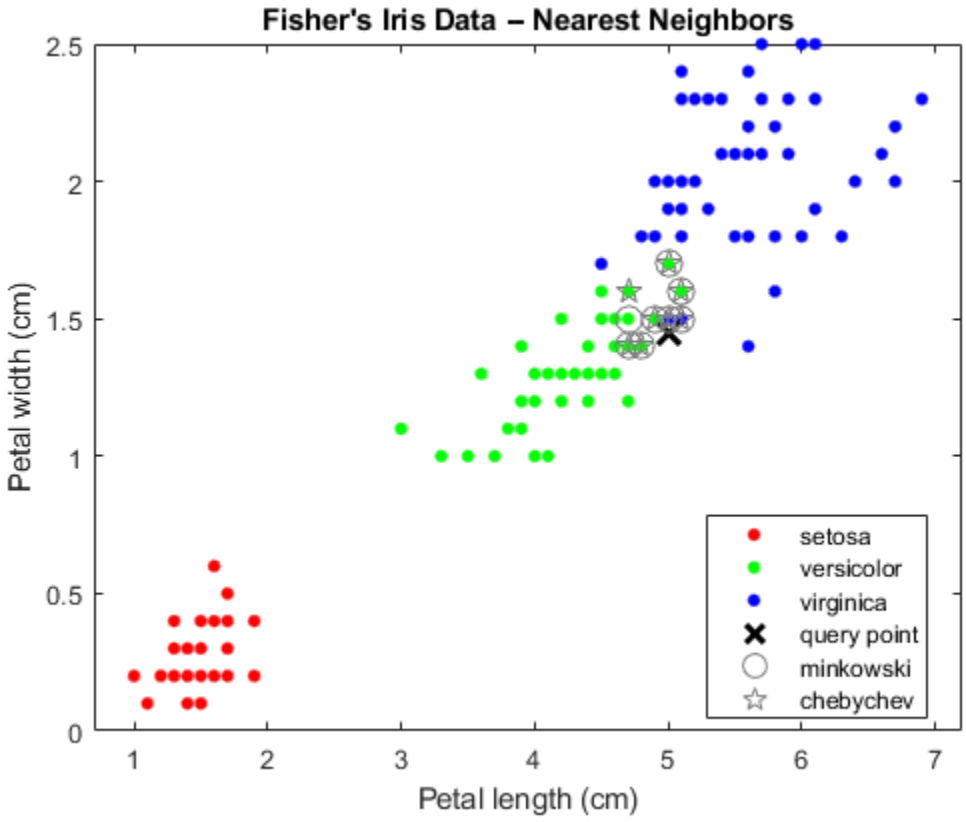
Find the 10 nearest neighbors from `X` to a query point (`newpoint`), first using Minkowski then Chebychev distance metrics. The query point must have the same column dimension as the data used to train the model.

```
newpoint = [5 1.45];
[IdxMk,DMk] = knnsearch(KDTreeMdl,newpoint,'k',10);
[IdxCb,DCb] = knnsearch(KDTreeMdl,newpoint,'k',10,'Distance','chebychev');
```

`IdxMk` and `IdxCb` are 1-by-10 matrices containing the row indices of `X` corresponding to the nearest neighbors to `newpoint` using Minkowski and Chebychev distances, respectively. Element (1,1) is the nearest, element (1,2) is the next nearest, and so on.

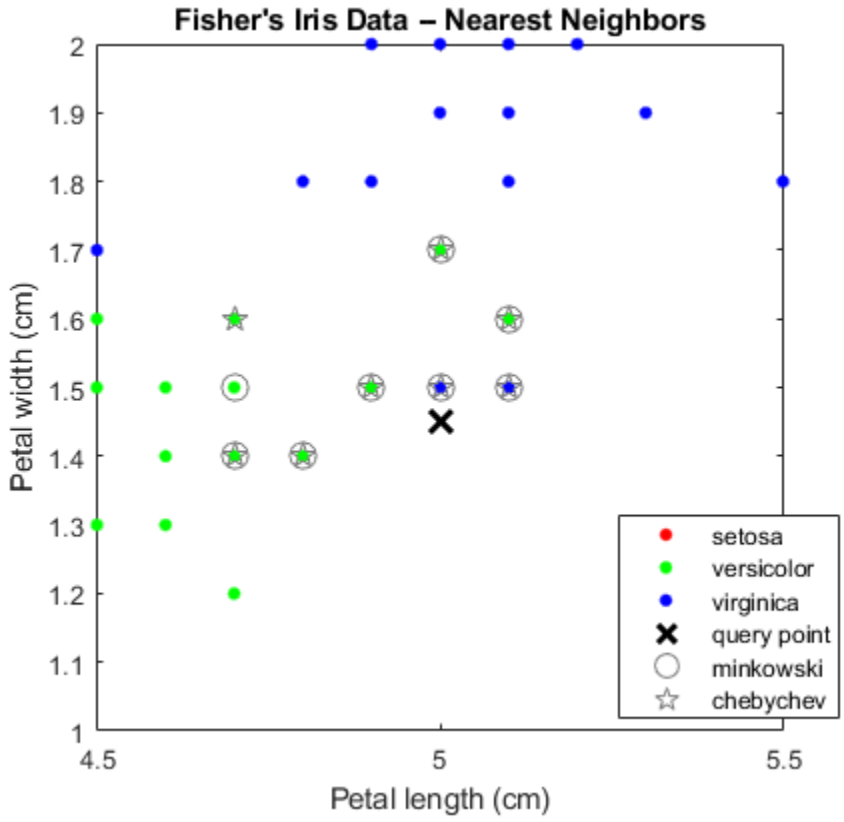
Plot the training data, query point, and nearest neighbors.

```
figure;
gscatter(X(:,1),X(:,2),Y);
title('Fisher''s Iris Data -- Nearest Neighbors');
xlabel('Petal length (cm)');
ylabel('Petal width (cm)');
hold on
plot(newpoint(1),newpoint(2),'kx','MarkerSize',10,'LineWidth',2);   % Query point
plot(X(IdxMk,1),X(IdxMk,2),'o','Color',[.5 .5 .5],'MarkerSize',10); % Minkowski nearest neighbors
plot(X(IdxCb,1),X(IdxCb,2),'p','Color',[.5 .5 .5],'MarkerSize',10); % Chebychev nearest neighbors
legend('setosa','versicolor','virginica','query point',...
   'minkowski','chebychev','Location','Best');
```



Zoom in on the points of interest.

```
h = gca; % Get current axis handle.
h.XLim = [4.5 5.5];
h.YLim = [1 2];
axis square;
```



Several observations are equal, which is why only eight nearest neighbors are identified in the plot.

Input Arguments

`Mdl` — Nearest neighbor searcher

`ExhaustiveSearcher` model object | `KDTreeSearcher` model object

Nearest neighbor searcher, specified as an `ExhaustiveSearcher` or `KDTreeSearcher` model object, respectively.

If `Mdl` is an `ExhaustiveSearcher` model, then `knnsearch` searches for nearest neighbors using an exhaustive search. Otherwise, `knnsearch` uses the grown *K*d-tree to search for nearest neighbors.

`Y` — Query data

numeric matrix

Query data, specified as a numeric matrix.

`Y` is an *m*-by-*K* matrix. Rows of `Y` correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). `Y` must have the same number of columns as the training data stored in `Mdl.X`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'K',2,'Distance','minkowski'` specifies to find the two nearest neighbors of `Mdl.X` to each point in `Y` and to use the Minkowski distance metric.

For Both Nearest Neighbor Searchers

`Distance` — Distance metric
`Mdl.Distance` (default) | `'cityblock'` | `'euclidean'` | `'mahalanobis'` | `'minkowski'` | `'seuclidean'` | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of `'Distance'` and a character vector, string scalar, or function handle.

For both types of nearest neighbor searchers, `knnsearch` supports these distance metrics.

Value	Description
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'cityblock'`	City block distance.
`'euclidean'`	Euclidean distance.
`'minkowski'`	Minkowski distance. The default exponent is 2. To specify a different exponent, use the `'P'` name-value pair argument.

If `Mdl` is an `ExhaustiveSearcher` model object, then `knnsearch` also supports these distance metrics.

Value	Description
`'correlation'`	One minus the sample linear correlation between observations (treated as sequences of values).
`'cosine'`	One minus the cosine of the included angle between observations (treated as row vectors).
`'hamming'`	Hamming distance, which is the percentage of coordinates that differ.
`'jaccard'`	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
`'mahalanobis'`	Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the `'Cov'` name-value pair argument.

Value	Description
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in Mdl.X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from Mdl.X. To specify another scaling, use the 'Scale' name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

If Mdl is an ExhaustiveSearcher model object, then you can also specify a function handle for a custom distance metric by using @ (for example, @distfun). The custom distance function must:

- Have the form function D2 = distfun(ZI,ZJ).
- Take as arguments:
  - A 1-by-*K* vector ZI containing a single row from Mdl.X or Y, where *K* is the number of columns of Mdl.X.
  - An *m*-by-*K* matrix ZJ containing multiple rows of Mdl.X or Y, where *m* is a positive integer.
- Return an *m*-by-1 vector of distances D2, where D2(*j*) is the distance between the observations ZI and ZJ(*j*,:).

For more details, see “Distance Metrics” on page 18-12.

Example: 'Distance','minkowski'

IncludeTies — Flag to include all nearest neighbors
false (0) (default) | true (1)

Flag to include nearest neighbors that have the same distance from query observations, specified as the comma-separated pair consisting of 'IncludeTies' and false (0) or true (1).

If IncludeTies is true, then:

- knnsearch includes all nearest neighbors whose distances are equal to the *k*th smallest distance in the output arguments, where *k* is the number of searched nearest neighbors specified by the 'K' name-value pair argument.
- Idx and D are *m*-by-1 cell arrays such that each cell contains a vector of at least *k* indices and distances, respectively. Each vector in D contains arranged distances in ascending order. Each row in Idx contains the indices of the nearest neighbors corresponding to the distances in D.

If IncludeTies is false, then knnsearch chooses the observation with the smallest index among the observations that have the same distance from a query point.

Example: 'IncludeTies',true

K — Number of nearest neighbors
1 (default) | positive integer

Number of nearest neighbors to search for in the training data per query observation, specified as the comma-separated pair consisting of 'K' and a positive integer.

Example: `'K',2`

Data Types: `single` | `double`

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. This argument is valid only if `'Distance'` is `'minkowski'`.

Example: `'P',3`

Data Types: `single` | `double`

For Kd-Tree Nearest Neighbor Searchers

SortIndices — Flag to sort returned indices according to distance

`true` (`1`) (default) | `false` (`0`)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of `'SortIndices'` and either `true` (`1`) or `false` (`0`).

For faster performance, you can set `SortIndices` to `false` when the following are true:

- `Y` contains many observations that have many nearest neighbors in `X`.
- `Mdl` is a `KDTreeSearcher` model object.
- `IncludeTies` is `false`.

In this case, `knnsearch` returns the indices of the nearest neighbors in no particular order. When `SortIndices` is `true`, the function arranges the nearest-neighbor indices in ascending order by distance.

`SortIndices` is `true` by default. When `Mdl` is an `ExhaustiveSearcher` model object or `IncludeTies` is `true`, the function always sorts the indices.

Example: `'SortIndices',false`

Data Types: `logical`

For Exhaustive Nearest Neighbor Searchers

Cov — Covariance matrix for Mahalanobis distance metric

`cov(Mdl.X,'omitrows')` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix. `Cov` is a K-by-K matrix, where K is the number of columns of `Mdl.X`. If you specify `Cov` and do not specify `'Distance','mahalanobis'`, then `knnsearch` returns an error message.

Example: `'Cov',eye(3)`

Data Types: `single` | `double`

Scale — Scale parameter value for standardized Euclidean distance metric

`std(Mdl.X,'omitnan')` (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of `'Scale'` and a nonnegative numeric vector. `Scale` has length *K*, where *K* is the number of columns of `Mdl.X`.

The software scales each difference between the training and query data using the corresponding element of `Scale`. If you specify `Scale` and do not specify `'Distance','seuclidean'`, then `knnsearch` returns an error message.

Example: `'Scale',quantile(Mdl.X,0.75) - quantile(Mdl.X,0.25)`

Data Types: `single` | `double`

Note If you specify `'Distance'`, `'Cov'`, `'P'`, or `'Scale'`, then `Mdl.Distance` and `Mdl.DistParameter` do not change value.

Output Arguments

`Idx` — Training data indices of nearest neighbors

numeric matrix | cell array of numeric vectors

Training data indices of nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (`false` by default), then `Idx` is an *m*-by-*k* numeric matrix, where *m* is the number of rows in `Y` and *k* is the number of searched nearest neighbors specified by the `'K'` name-value pair argument. `Idx(j,i)` indicates that `Mdl.X(Idx(j,i),:)` is one of the *k* closest observations in `Mdl.X` to the query observation `Y(j,:)`.
- If you specify `'IncludeTies',true`, then `Idx` is an *m*-by-`1` cell array such that cell `j` (`Idx{j}`) contains a vector of at least *k* indices of the closest observations in `Mdl.X` to the query observation `Y(j,:)`.

If `SortIndices` is `true`, then `knnsearch` arranges the indices in ascending order by distance.

`D` — Distances of nearest neighbors

numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (`false` by default), then `D` is an *m*-by-*k* numeric matrix, where *m* is the number of rows in `Y` and *k* is the number of searched nearest neighbors specified by the `'K'` name-value pair argument. `D(j,i)` is the distance between `Mdl.X(Idx(j,i),:)` and the query observation `Y(j,:)` with respect to the distance metric.
- If you specify `'IncludeTies',true`, then `D` is an *m*-by-`1` cell array such that cell `j` (`D{j}`) contains a vector of at least *k* distances of the closest observations in `Mdl.X` to the query observation `Y(j,:)`.

If `SortIndices` is `true`, then `knnsearch` arranges the distances in ascending order.

Tips

`knnsearch` finds the *k* (positive integer) points in `Mdl.X` that are *k*-nearest for each `Y` point. In contrast, `rangesearch` finds all the points in `Mdl.X` that are within distance `r` (positive scalar) of each `Y` point.

Alternative Functionality

- `knnsearch` is an object function that requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object and query data. Under equivalent conditions, the `knnsearch` object function returns the same results as the `knnsearch` function when you specify the name-value pair argument `'NSMethod','exhaustive'` or `'NSMethod','kdtree'`, respectively.
- For *k*-nearest neighbors classification, see `fitcknn` and `ClassificationKNN`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This table contains notes about the arguments of `knnsearch`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
`Mdl`	There are two ways to use `Mdl` in code generation. For an example, see “Code Generation for Nearest Neighbor Searcher” on page 32-19. • Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `knnsearch` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `knnsearch` function. Then use `codegen` to generate code for the entry-point function. • Include `coder.Constant(Mdl)` in the `-args` value of `codegen`. If `Mdl` is a `KDTreeSearcher` object, and the code generation build type is a MEX function, then `codegen` generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, `codegen` generates code using `parfor`. • MEX function for the *k*d-tree search algorithm — `codegen` generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb. If you generate the MEX function to test the generated code of the `parfor` version, you can disable the usage of Intel TBB. Set the `ExtrinsicCalls` property of the MEX configuration object to `false`. For details, see `coder.MexCodeConfig`. • MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of `knnsearch` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see `https://www.mathworks.com/support/compilers/current_release/`. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.
`'Distance'`	• Cannot be a custom distance function. • Must be a compile-time constant; its value cannot change in the generated code.
`'IncludeTies'`	Must be a compile-time constant; its value cannot change in the generated code.
`'SortIndices'`	Not supported. The output arguments are always sorted.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include `{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0}` in the `-args` value of `codegen`.

Argument	Notes and Limitations
`Idx`	• When you specify `'IncludeTies'` as `true`, the sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision. • Starting in R2020a, `knnsearch` returns integer-type (`int32`) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information, see “Introduction to Code Generation” on page 32-2 and “Code Generation for Nearest Neighbor Searcher” on page 32-19.

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-14
“Distance Metrics” on page 18-12

Introduced in R2010a

knnsearch

Find *k*-nearest neighbors using input data

Syntax

```
Idx = knnsearch(X,Y)
Idx = knnsearch(X,Y,Name,Value)
[Idx,D] = knnsearch( ___ )
```

Description

`Idx = knnsearch(X,Y)` finds the nearest neighbor in `X` for each query point in `Y` and returns the indices of the nearest neighbors in `Idx`, a column vector. `Idx` has the same number of rows as `Y`.

`Idx = knnsearch(X,Y,Name,Value)` returns `Idx` with additional options specified using one or more name-value pair arguments. For example, you can specify the number of nearest neighbors to search for and the distance metric used in the search.

`[Idx,D] = knnsearch( ___ )` additionally returns the matrix `D`, using any of the input arguments in the previous syntaxes. `D` contains the distances between each observation in `Y` and the corresponding closest observations in `X`.

Examples

Find Nearest Neighbors

Find the patients in the `hospital` data set that most closely resemble the patients in `Y`, according to age and weight.

Load the `hospital` data set.

```
load hospital;
X = [hospital.Age hospital.Weight];
Y = [20 162; 30 169; 40 168; 50 170; 60 171];   % New patients
```

Perform a `knnsearch` between `X` and `Y` to find indices of nearest neighbors.

```
Idx = knnsearch(X,Y);
```

Find the patients in `X` closest in age and weight to those in `Y`.

```
X(Idx,:)
```

```
ans = 5×2

    25   171
    25   171
    39   164
    49   170
    50   172
```

Find *k*-Nearest Neighbors Using Different Distance Metrics

Find the 10 nearest neighbors in X to each point in Y, first using the Minkowski distance metric and then using the Chebychev distance metric.

Load Fisher's iris data set.

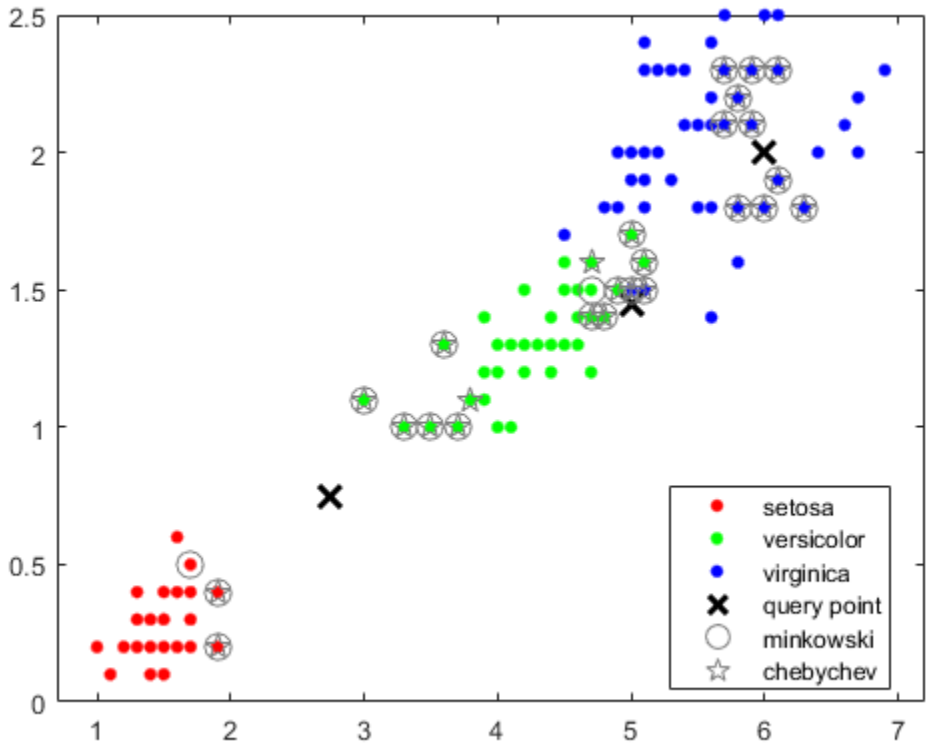
```
load fisheriris
X = meas(:,3:4);    % Measurements of original flowers
Y = [5 1.45;6 2;2.75 .75];  % New flower data
```

Perform a `knnsearch` between X and the query points Y using Minkowski and Chebychev distance metrics.

```
[mIdx,mD] = knnsearch(X,Y,'K',10,'Distance','minkowski','P',5);
[cIdx,cD] = knnsearch(X,Y,'K',10,'Distance','chebychev');
```

Visualize the results of the two nearest neighbor searches. Plot the training data. Plot the query points with the marker X. Use circles to denote the Minkowski nearest neighbors. Use pentagrams to denote the Chebychev nearest neighbors.

```
gscatter(X(:,1),X(:,2),species)
line(Y(:,1),Y(:,2),'Marker','x','Color','k',...
   'Markersize',10,'Linewidth',2,'Linestyle','none')
line(X(mIdx,1),X(mIdx,2),'Color',[.5 .5 .5],'Marker','o',...
   'Linestyle','none','Markersize',10)
line(X(cIdx,1),X(cIdx,2),'Color',[.5 .5 .5],'Marker','p',...
   'Linestyle','none','Markersize',10)
legend('setosa','versicolor','virginica','query point',...
'minkowski','chebychev','Location','best')
```



Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix. Rows of X correspond to observations, and columns correspond to variables.

Data Types: `single` | `double`

Y — Query points

numeric matrix

Query points, specified as a numeric matrix. Rows of Y correspond to observations, and columns correspond to variables. Y must have the same number of columns as X.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `knnsearch(X,Y,'K',10,'IncludeTies',true,'Distance','cityblock')` searches for 10 nearest neighbors, including ties and using the city block distance.

K — Number of nearest neighbors

1 (default) | positive integer

Number of nearest neighbors to find in X for each point in Y, specified as the comma-separated pair consisting of 'K' and a positive integer.

Example: 'K',10

Data Types: single | double

IncludeTies — Flag to include all nearest neighbors

false (0) (default) | true (1)

Flag to include all nearest neighbors that have the same distance from query points, specified as the comma-separated pair consisting of 'IncludeTies' and false (0) or true (1).

If 'IncludeTies' is false, then knnsearch chooses the observation with the smallest index among the observations that have the same distance from a query point.

If 'IncludeTies' is true, then:

- knnsearch includes all nearest neighbors whose distances are equal to the *k*th smallest distance in the output arguments. To specify *k*, use the 'K' name-value pair argument.
- Idx and D are *m*-by-1 cell arrays such that each cell contains a vector of at least *k* indices and distances, respectively. Each vector in D contains distances arranged in ascending order. Each row in Idx contains the indices of the nearest neighbors corresponding to the distances in D.

Example: 'IncludeTies',true

NSMethod — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and one of these values.

- 'kdtree' — Creates and uses a *K*d-tree to find nearest neighbors. 'kdtree' is the default value when the number of columns in X is less than or equal to 10, X is not sparse, and the distance metric is 'euclidean', 'cityblock', 'chebychev', or 'minkowski'. Otherwise, the default value is 'exhaustive'.

  The value 'kdtree' is valid only when the distance metric is one of the four metrics noted above.
- 'exhaustive' — Uses the exhaustive search algorithm by computing the distance values from all the points in X to each point in Y.

Example: 'NSMethod','exhaustive'

Distance — Distance metric

'euclidean' (default) | 'seuclidean' | 'cityblock' | 'chebychev' | 'minkowski' | 'mahalanobis' | function handle | ...

Distance metric knnsearch uses, specified as the comma-separated pair consisting of 'Distance' and one of the values in this table or a function handle.

Value	Description
'euclidean'	Euclidean distance.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows and the query matrix Y is scaled by dividing by the corresponding element standard deviation computed from X. To specify another scaling, use the 'S name-value pair argument.
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different expon use the 'P' name-value pair argument.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matri change the value of the covariance matrix, use the 'Cov' name-value pair argument.
'cosine'	One minus the cosine of the included angle between observations (treated vectors).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coor that differ.

You can also specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form `function D2 = distfun(ZI,ZJ)`.
- Take as arguments:
  - A 1-by-*n* vector ZI containing a single row from X or from the query points Y.
  - An m_2-by-*n* matrix ZJ containing multiple rows of X or Y.
- Return an m_2-by-1 vector of distances D2, whose jth element is the distance between the observations ZI and ZJ(j,:).

For more information, see “Distance Metrics” on page 18-12.

Example: 'Distance','chebychev'

P — Exponent for Minkowski distance metric
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar.

This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

`Cov` — Covariance matrix for Mahalanobis distance metric
`cov(X,'omitrows')` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix.

This argument is valid only if `'Distance'` is `'mahalanobis'`.

Example: `'Cov',eye(4)`

Data Types: `single` | `double`

`Scale` — Scale parameter value for standardized Euclidean distance metric
`std(X,'omitnan')` (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of `'Scale'` and a nonnegative numeric vector. `'Scale'` has length equal to the number of columns in `X`. When `knnsearch` computes the standardized Euclidean distance, each coordinate of `X` is scaled by the corresponding element of `'Scale'`, as is each query point. This argument is valid only when `'Distance'` is `'seuclidean'`.

Example: `'Scale',quantile(X,0.75) - quantile(X,0.25)`

Data Types: `single` | `double`

`BucketSize` — Maximum number of data points in leaf node of *K*d-tree
`50` (default) | positive integer

Maximum number of data points in the leaf node of the *K*d-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer. This argument is valid only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',20`

Data Types: `single` | `double`

`SortIndices` — Flag to sort returned indices according to distance
`true` (`1`) (default) | `false` (`0`)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of `'SortIndices'` and either `true` (`1`) or `false` (`0`).

For faster performance, you can set `SortIndices` to `false` when the following are true:

- `Y` contains many observations that have many nearest neighbors in `X`.
- `NSMethod` is `'kdtree'`.
- `IncludeTies` is `false`.

In this case, `knnsearch` returns the indices of the nearest neighbors in no particular order. When `SortIndices` is `true`, the function arranges the nearest-neighbor indices in ascending order by distance.

`SortIndices` is `true` by default. When `NSMethod` is `'exhaustive'` or `IncludeTies` is `true`, the function always sorts the indices.

Example: `'SortIndices',false`

Data Types: `logical`

Output Arguments

`Idx` — Input data indices of nearest neighbors

numeric matrix | cell array of numeric vectors

Input data indices of the nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (`false` by default), then `Idx` is an *m*-by-*k* numeric matrix, where *m* is the number of rows in `Y` and *k* is the number of searched nearest neighbors. `Idx(j,i)` indicates that `X(Idx(j,i),:)` is one of the *k* closest observations in `X` to the query point `Y(j,:)`.
- If you specify `'IncludeTies',true`, then `Idx` is an *m*-by-`1` cell array such that cell `j` (`Idx{j}`) contains a vector of at least *k* indices of the closest observations in `X` to the query point `Y(j,:)`.

If `SortIndices` is `true`, then `knnsearch` arranges the indices in ascending order by distance.

`D` — Distances of nearest neighbors

numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query points, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (`false` by default), then `D` is an *m*-by-*k* numeric matrix, where *m* is the number of rows in `Y` and *k* is the number of searched nearest neighbors. `D(j,i)` is the distance between `X(Idx(j,i),:)` and `Y(j,:)` with respect to the distance metric.
- If you specify `'IncludeTies',true`, then `D` is an *m*-by-`1` cell array such that cell `j` (`D{j}`) contains a vector of at least *k* distances of the closest observations in `X` to the query point `Y(j,:)`.

If `SortIndices` is `true`, then `knnsearch` arranges the distances in ascending order.

Tips

- For a fixed positive integer *k*, `knnsearch` finds the *k* points in `X` that are the nearest to each point in `Y`. To find all points in `X` within a fixed distance of each point in `Y`, use `rangesearch`.
- `knnsearch` does not save a search object. To create a search object, use `createns`.

Algorithms

For information on a specific search algorithm, see “k-Nearest Neighbor Search and Radius Search” on page 18-14.

Alternative Functionality

If you set the `knnsearch` function's `'NSMethod'` name-value pair argument to the appropriate value (`'exhaustive'` for an exhaustive search algorithm or `'kdtree'` for a *K*d-tree algorithm), then the search results are equivalent to the results obtained by conducting a distance search using the `knnsearch` object function. Unlike the `knnsearch` function, the `knnsearch` object function requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object.

[1] Friedman, J. H., J. Bentely, and R. A. Finkel. “An Algorithm for Finding Best Matches in Logarithmic Expected Time.” *ACM Transactions on Mathematical Software* 3, no. 3 (1977): 209–226.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- If `X` is a tall array, then `Y` cannot be a tall array. Similarly, if `Y` is a tall array, then `X` cannot be a tall array.

For more information, see “Tall Arrays”.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, the default value of the `'NSMethod'` name-value pair argument is `'exhaustive'` when the number of columns in `X` is greater than 7.
- The value of the `'Distance'` name-value pair argument must be a compile-time constant and cannot be a custom distance function.
- The value of the `'IncludeTies'` name-value pair argument must be a compile-time constant.
- The `'SortIndices'` name-value pair argument is not supported. The output arguments are always sorted.
- Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include `{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0}` in the `-args` value of `codegen`.
- When you specify `'IncludeTies'` as `true`, the sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
- When `knnsearch` uses the *k*d-tree search algorithm, and the code generation build type is a MEX function, `codegen` generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, `codegen` generates code using `parfor`.
  - MEX function for the *k*d-tree search algorithm — `codegen` generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

    If you generate the MEX function to test the generated code of the `parfor` version, you can disable the usage of Intel TBB. Set the `ExtrinsicCalls` property of the MEX configuration object to `false`. For details, see `coder.MexCodeConfig`.
  - MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of `knnsearch` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your

compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see `https://www.mathworks.com/support/compilers/current_release/`. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.

- Starting in R2020a, `knnsearch` returns integer-type (`int32`) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'IncludeTies'`, `'NSMethod'`, and `'SortIndices'` name-value pair arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2010a

kruskalwallis

Kruskal-Wallis test

Syntax

```
p = kruskalwallis(x)
p = kruskalwallis(x,group)
p = kruskalwallis(x,group,displayopt)
[p,tbl,stats] = kruskalwallis( ___ )
```

Description

`p = kruskalwallis(x)` returns the *p*-value for the null hypothesis that the data in each column of the matrix `x` comes from the same distribution, using a Kruskal-Wallis test on page 33-3376. The alternative hypothesis is that not all samples come from the same distribution. `kruskalwallis` also returns an ANOVA table and a box plot.

`p = kruskalwallis(x,group)` returns the *p*-value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable `group` comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

`p = kruskalwallis(x,group,displayopt)` returns the *p*-value of the test and lets you display or suppress the ANOVA table and box plot.

`[p,tbl,stats] = kruskalwallis( ___ )` also returns the ANOVA table as the cell array `tbl` and the structure `stats` containing information about the test statistics.

Examples

Test Data Samples for the Same Distribution

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`, and the second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];
```

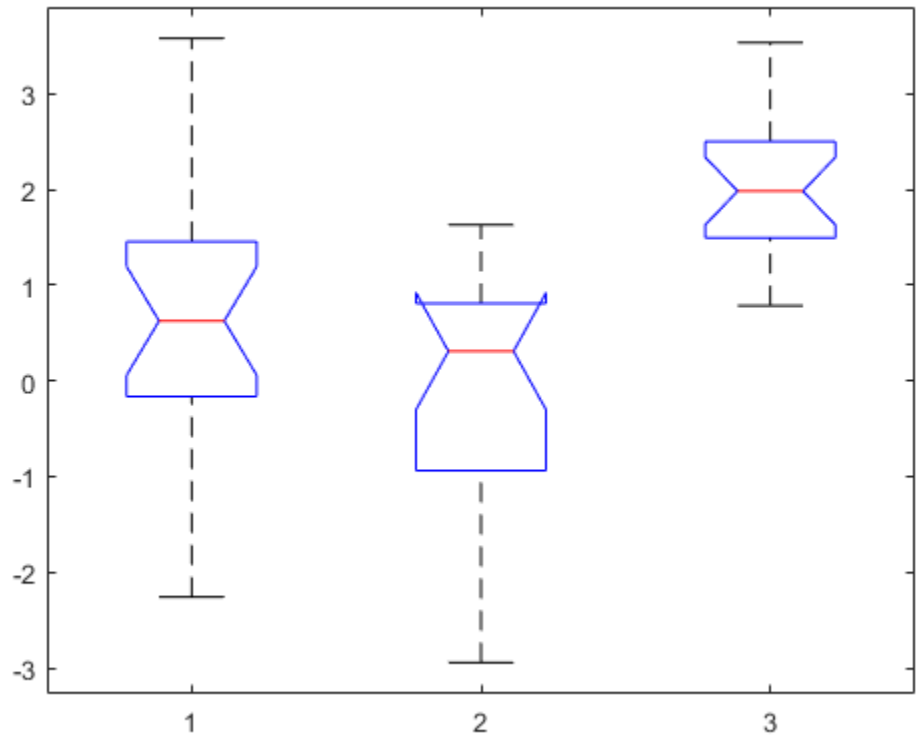
The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution.

```
p = kruskalwallis(x)
```

Kruskal-Wallis ANOVA Table

Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	7631.1	2	3815.55	25.02	3.68957e-06
Error	10363.9	57	181.82		
Total	17995	59			



```
p = 3.6896e-06
```

The returned value of `p` indicates that `kruskalwallis` rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in `x`.

Conduct Followup Tests for Unequal Medians

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`. The second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution. Suppress the output displays, and generate the structure `stats` to use in further testing.

```
[p,tbl,stats] = kruskalwallis(x,[],'off')
```

```
p = 3.6896e-06

tbl=4×6 cell array
  Columns 1 through 5

    {'Source' }    {'SS'        }    {'df'}    {'MS'        }    {'Chi-sq'  }
    {'Columns'}    {[7.6311e+03]}    {[ 2]}    {[3.8155e+03]}    {[ 25.0200]}
    {'Error'  }    {[1.0364e+04]}    {[57]}    {[  181.8228]}    {0x0 double}
    {'Total'  }    {[     17995]}    {[59]}    {0x0 double  }    {0x0 double}

  Column 6

    {'Prob>Chi-sq'}
    {[ 3.6896e-06]}
    {0x0 double   }
    {0x0 double   }

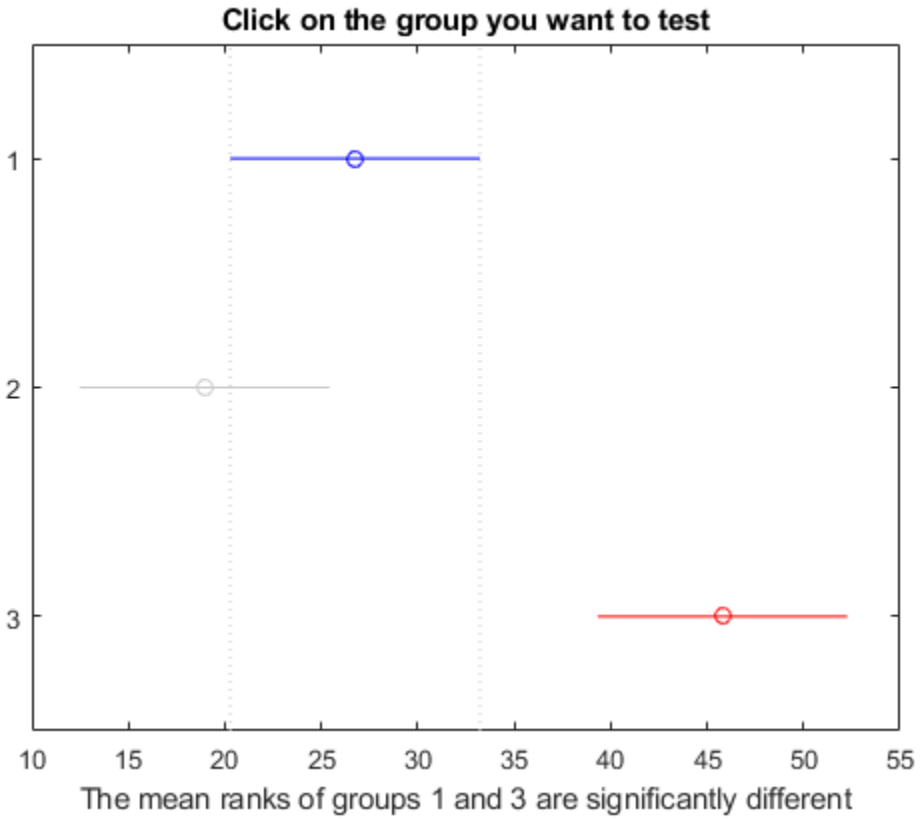
stats = struct with fields:
       gnames: [3x1 char]
            n: [20 20 20]
       source: 'kruskalwallis'
    meanranks: [26.7500 18.9500 45.8000]
         sumt: 0
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure `stats` to perform additional followup testing. The cell array `tbl` contains the same data as the graphical ANOVA table, including column and row labels.

Conduct a followup test to identify which data sample comes from a different distribution.

```
c = multcompare(stats)
```

```
Note: Intervals can be used for testing but are not simultaneous confidence intervals.
```



```
c = 3×6

    1.0000    2.0000   -5.1435    7.8000   20.7435    0.3345
    1.0000    3.0000  -31.9935  -19.0500   -6.1065    0.0016
    2.0000    3.0000  -39.7935  -26.8500  -13.9065    0.0000
```

The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

Test for the Same Distribution Across Groups

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, indicating the type of metal alloy from which the corresponding beam is made.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];

alloy = {'st','st','st','st','st','st','st','st',...
         'al1','al1','al1','al1','al1','al1',...
         'al2','al2','al2','al2','al2','al2'};
```

Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

```
p = kruskalwallis(strength,alloy,'off')
```

```
p = 0.0018
```

The returned value of p indicates that the test rejects the null hypothesis at the 1% significance level.

Input Arguments

x — Sample data

vector | matrix

Sample data for the hypothesis test, specified as a vector or an *m*-by-*n* matrix. If x is an *m*-by-*n* matrix, each of the *n* columns represents an independent sample containing *m* mutually independent observations.

Data Types: `single` | `double`

group — Grouping variable

numeric vector | logical vector | character array | string array | cell array of character vectors

Grouping variable, specified as a numeric or logical vector, a character or string array, or a cell array of character vectors.

- If x is a vector, then each element in `group` identifies the group to which the corresponding element in x belongs, and `group` must be a vector of the same length as x. If a row of `group` contains an empty value, that row and the corresponding observation in x are disregarded. `NaN` values in either x or `group` are similarly ignored.
- If x is a matrix, then each column in x represents a different group, and you can use `group` to specify labels for these columns. The number of elements in `group` and the number of columns in x must be equal.

The labels contained in `group` also annotate the box plot.

Example: `{'red','blue','green','blue','red','blue','green','green','red'}`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

displayopt — Display option

`'on'` (default) | `'off'`

Display option, specified as `'on'` or `'off'`. If `displayopt` is `'on'`, `kruskalwallis` displays the following figures:

- An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in x.
- A box plot of the data in each column of the data matrix x. The box plots are based on the actual data values, rather than on the ranks.

If `displayopt` is `'off'`, `kruskalwallis` does not display these figures.

If you specify a value for `displayopt`, you must also specify a value for `group`. If you do not have a grouping variable, specify `group` as `[]`.

Example: `'off'`

Output Arguments

p — *p*-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

`tbl` — ANOVA table
cell array

ANOVA table of test results, returned as a cell array. `tbl` includes the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`, as well as column and row labels.

`stats` — Test data
structure

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of sample medians by using `multcompare`, with `stats` as the input value.

More About

Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups. The Kruskal-Wallis test is valid for data that has two or more groups. It compares the medians of the groups of data in `x` to determine if the samples come from the same population (or, equivalently, from different populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. The *F*-statistic used in classical one-way ANOVA is replaced by a chi-square statistic, and the *p*-value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects, and that all observations are mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the stronger assumption that the populations have normal distributions.

Introduced before R2006a

ksdensity

Kernel smoothing function estimate for univariate and bivariate data

Syntax

```
[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity( ___ ,Name,Value)
[f,xi,bw] = ksdensity( ___ )

ksdensity( ___ )
ksdensity(ax, ___ )
```

Description

`[f,xi] = ksdensity(x)` returns a probability density estimate, `f`, for the sample data in the vector or two-column matrix `x`. The estimate is based on a normal kernel function, and is evaluated at equally-spaced points, `xi`, that cover the range of the data in `x`. `ksdensity` estimates the density at 100 points for univariate data, or 900 points for bivariate data.

`ksdensity` works best with continuously distributed samples.

`[f,xi] = ksdensity(x,pts)` specifies points (`pts`) to evaluate `f`. Here, `xi` and `pts` contain identical values.

`[f,xi] = ksdensity( ___ ,Name,Value)` uses additional options specified by one or more name-value pair arguments in addition to any of the input arguments in the previous syntaxes. For example, you can define the function type `ksdensity` evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

`[f,xi,bw] = ksdensity( ___ )` also returns the bandwidth of the kernel smoothing window, `bw`. The default bandwidth is the optimal for normal densities.

`ksdensity( ___ )` plots the kernel smoothing function estimate.

`ksdensity(ax, ___ )` plots the results using axes with the handle, `ax`, instead of the current axes returned by `gca`.

Examples

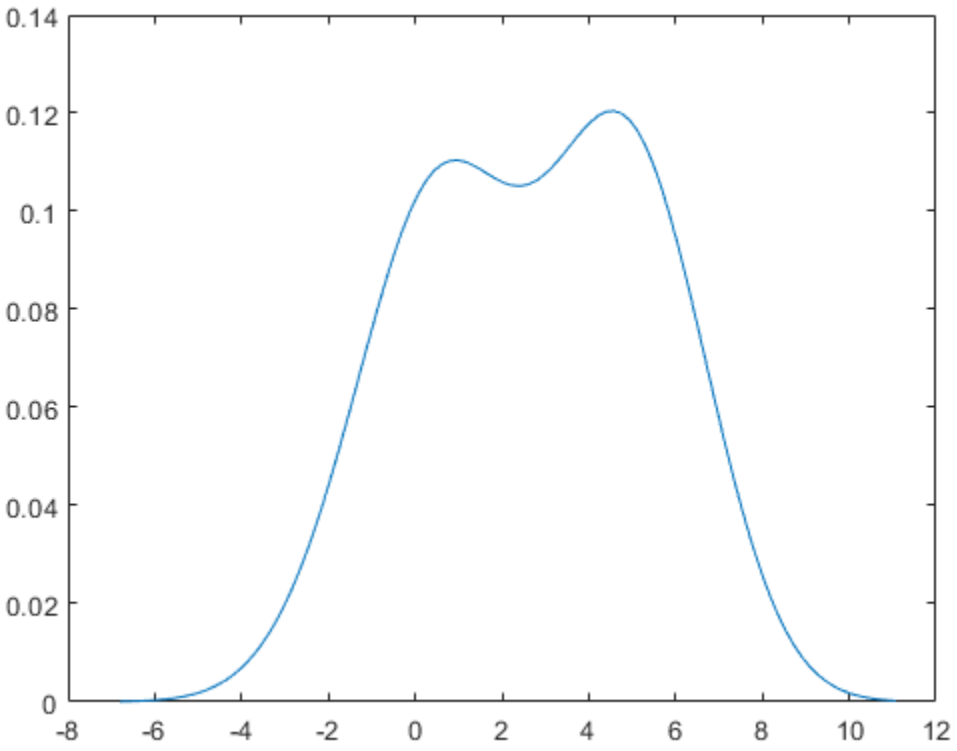
Estimate Density

Generate a sample data set from a mixture of two normal distributions.

```
rng('default')  % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Plot the estimated density.

```
[f,xi] = ksdensity(x);
figure
plot(xi,f);
```



The density estimate shows the bimodality of the sample.

Estimate Density with Boundary Correction

Generate a nonnegative sample data set from the half-normal distribution.

```
rng('default') % For reproducibility
pd = makedist('HalfNormal','mu',0,'sigma',1);
x = random(pd,100,1);
```

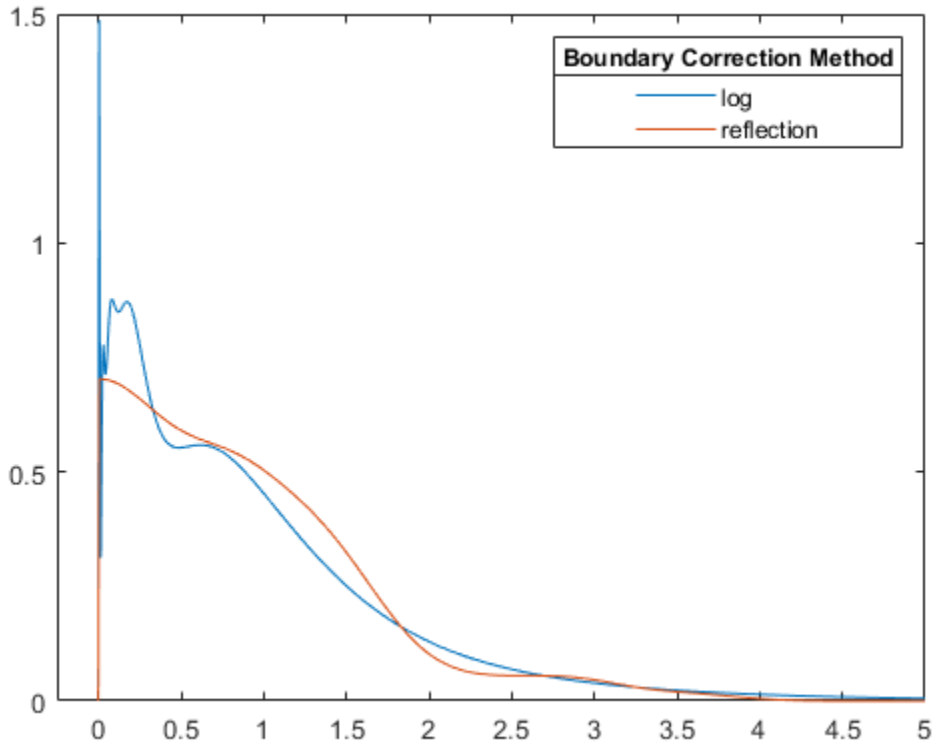
Estimate pdfs with two different boundary correction methods, log transformation and reflection, by using the `'BoundaryCorrection'` name-value pair argument.

```
pts = linspace(0,5,1000); % points to evaluate the estimator
[f1,xi1] = ksdensity(x,pts,'Support','positive');
[f2,xi2] = ksdensity(x,pts,'Support','positive','BoundaryCorrection','reflection');
```

Plot the two estimated pdfs.

```
plot(xi1,f1,xi2,f2)
lgd = legend('log','reflection');
title(lgd, 'Boundary Correction Method')
```

```
xl = xlim;
xlim([xl(1)-0.25 xl(2)])
```



`ksdensity` uses a boundary correction method when you specify either positive or bounded support. The default boundary correction method is log transformation. When `ksdensity` transforms the support back, it introduces the `1/x` term in the kernel density estimator. Therefore, the estimate has a peak near `x = 0`. On the other hand, the reflection method does not cause undesirable peaks near the boundary.

Estimate Cumulative Distribution Function at Specified Values

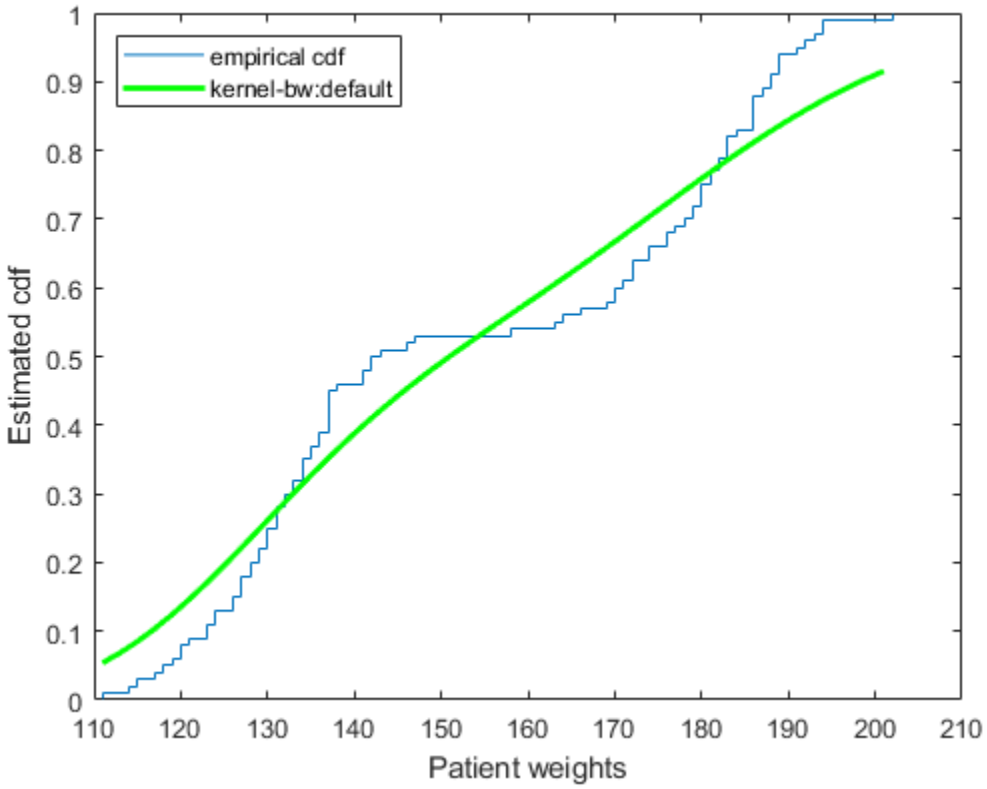
Load the sample data.

```
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```
pts = (min(hospital.Weight):2:max(hospital.Weight));
figure()
ecdf(hospital.Weight)
hold on
[f,xi,bw] = ksdensity(hospital.Weight,pts,'Support','positive',...
    'Function','cdf');
plot(xi,f,'-g','LineWidth',2)
legend('empirical cdf','kernel-bw:default','Location','northwest')
```

```
xlabel('Patient weights')
ylabel('Estimated cdf')
```



`ksdensity` seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

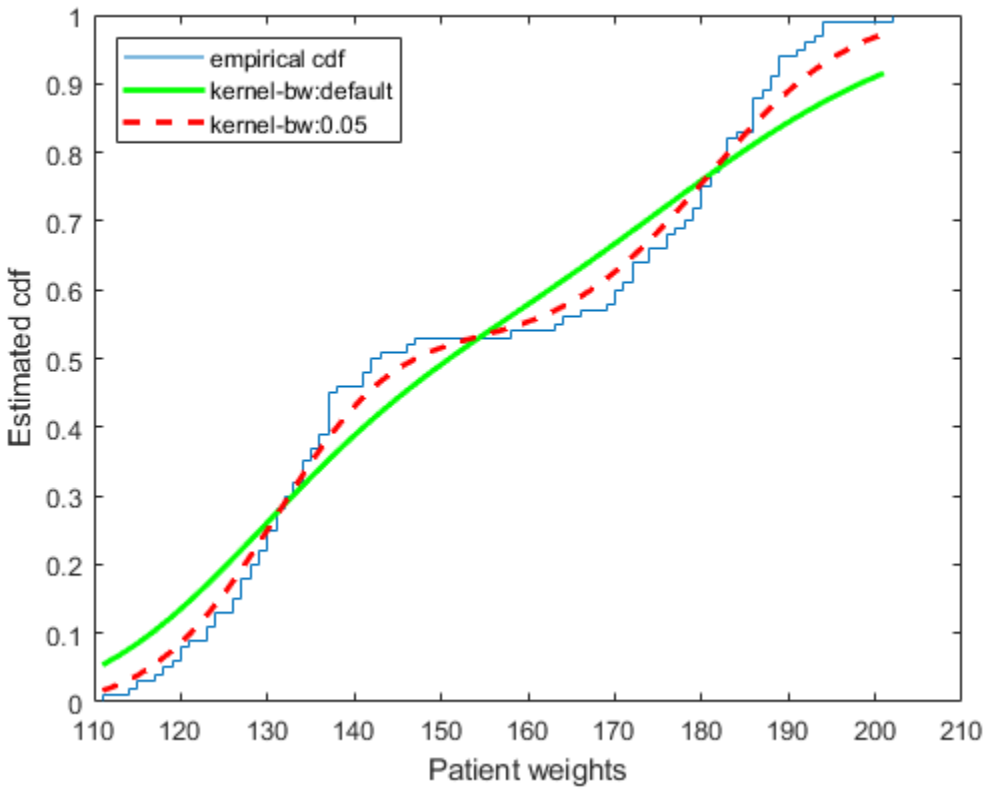
Return the bandwidth of the smoothing window.

```
bw
```

```
bw = 0.1070
```

Plot the cumulative distribution function estimate using a smaller bandwidth.

```
[f,xi] = ksdensity(hospital.Weight,pts,'Support','positive',...
    'Function','cdf','Bandwidth',0.05);
plot(xi,f,'--r','LineWidth',2)
legend('empirical cdf','kernel-bw:default','kernel-bw:0.05',...
    'Location','northwest')
hold off
```



The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

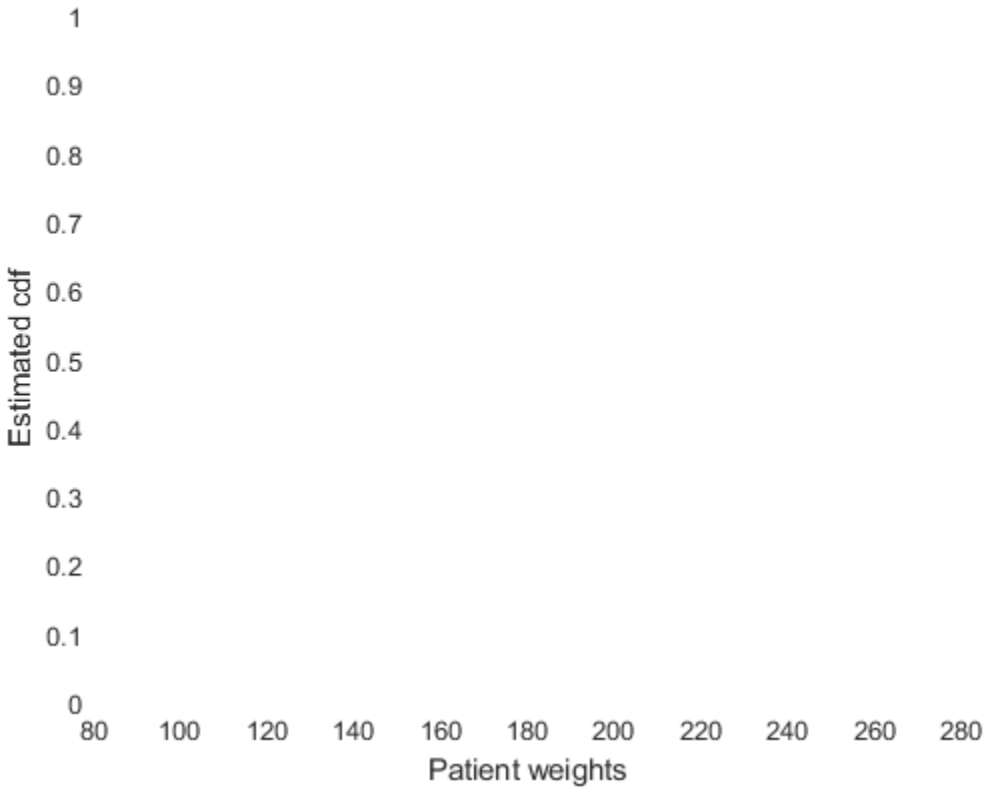
Plot Estimated Cumulative Density Function for Given Number of Points

Load the sample data.

```
load hospital
```

Plot the estimated cdf evaluated at 50 equally spaced points.

```
figure()
ksdensity(hospital.Weight,'Support','positive','Function','cdf',...
'NumPoints',50)
xlabel('Patient weights')
ylabel('Estimated cdf')
```



Estimate Survivor and Cumulative Hazard for Censored Failure Data

Generate sample data from an exponential distribution with mean 3.

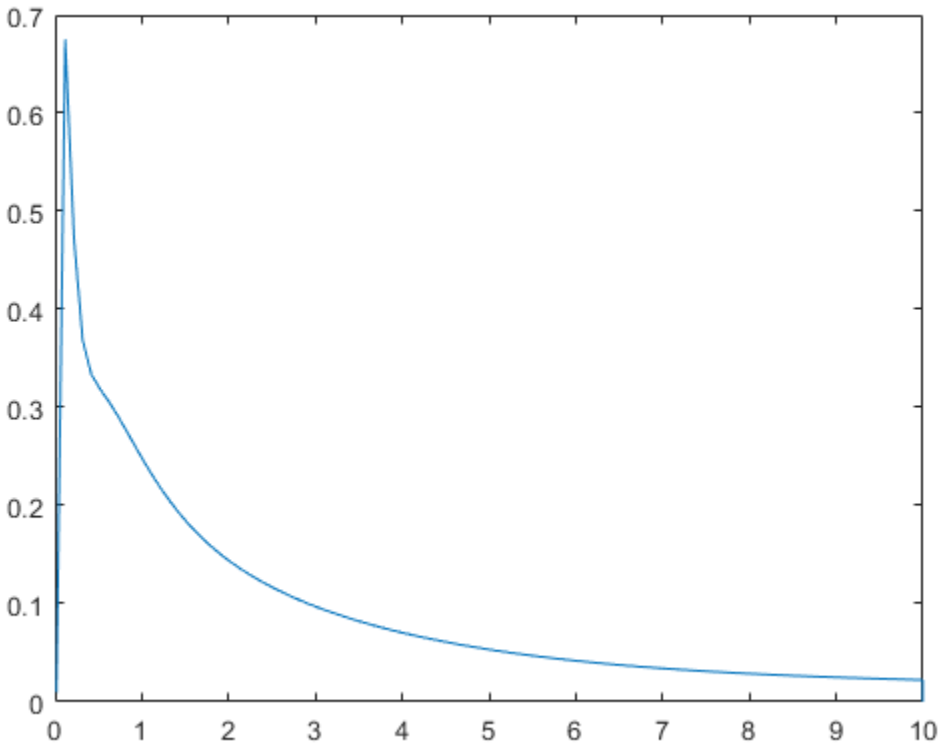
```
rng('default')  % For reproducibility
x = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```
T = 10;
cens = (x>T);
```

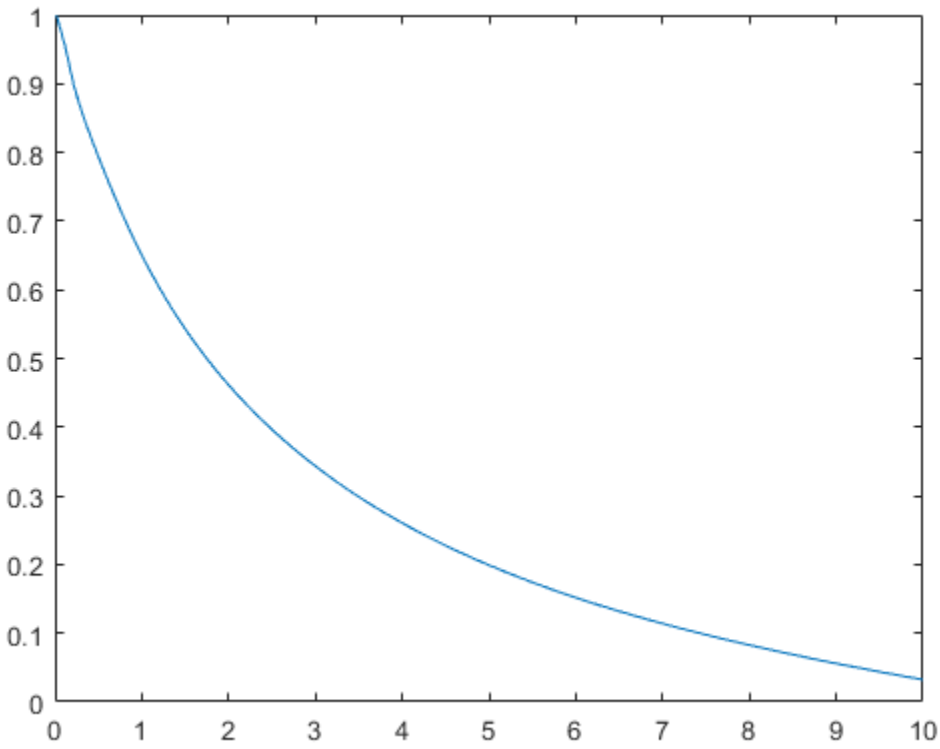
Compute and plot the estimated density function.

```
figure
ksdensity(x,'Support','positive','Censoring',cens);
```



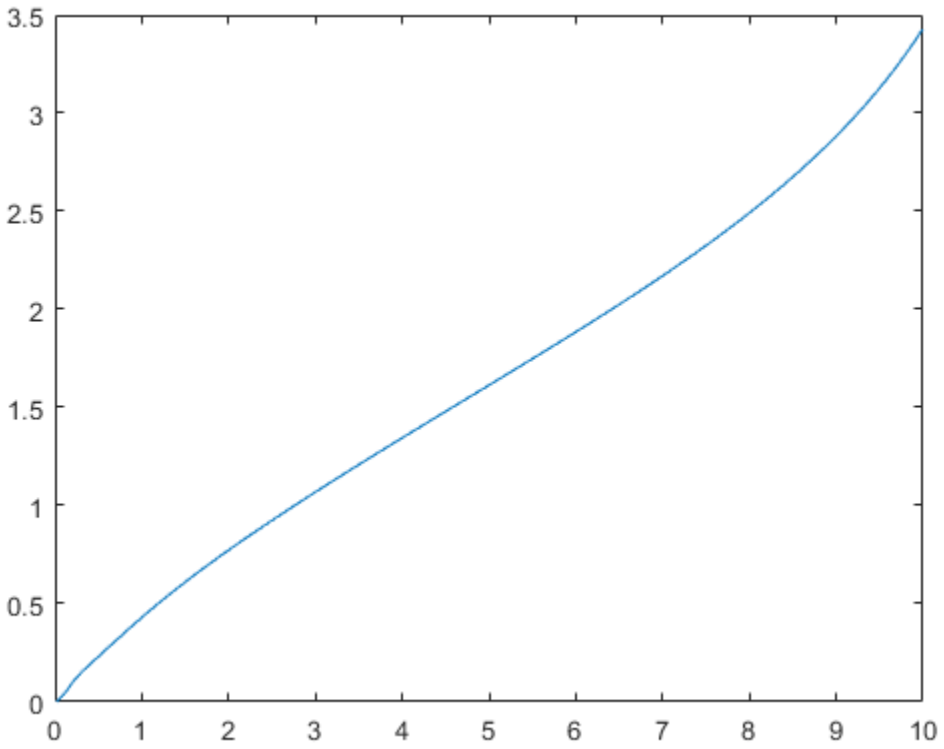
Compute and plot the survivor function.

```
figure
ksdensity(x,'Support','positive','Censoring',cens,...
'Function','survivor');
```



Compute and plot the cumulative hazard function.

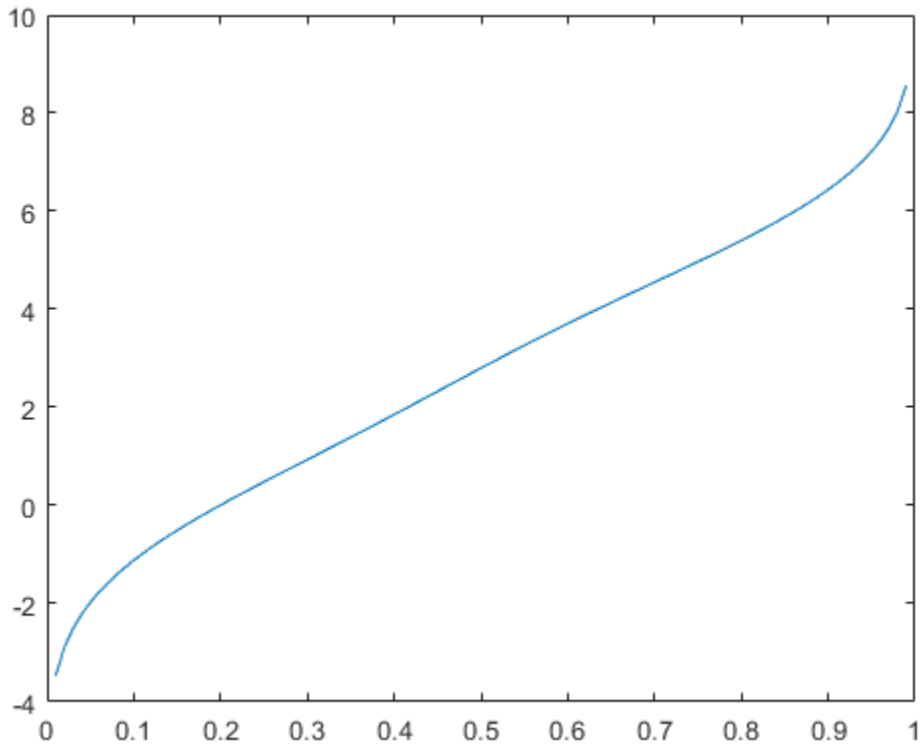
```
figure
ksdensity(x,'Support','positive','Censoring',cens,...
'Function','cumhazard');
```



Estimate Inverse Cumulative Distribution Function for Specified Probability Values

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```
rng('default')  % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
figure
ksdensity(x,pi,'Function','icdf');
```



Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

```
rng('default')  % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Return the bandwidth of the smoothing window for the probability density estimate.

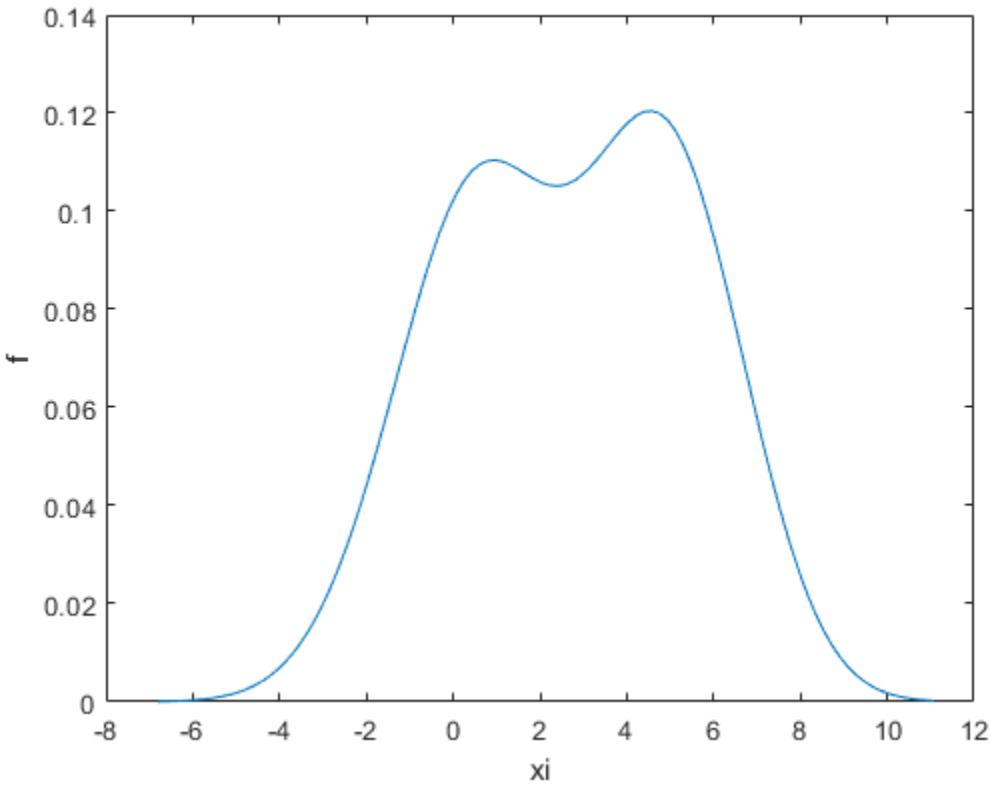
```
[f,xi,bw] = ksdensity(x);
bw
```

```
bw = 1.5141
```

The default bandwidth is optimal for normal densities.

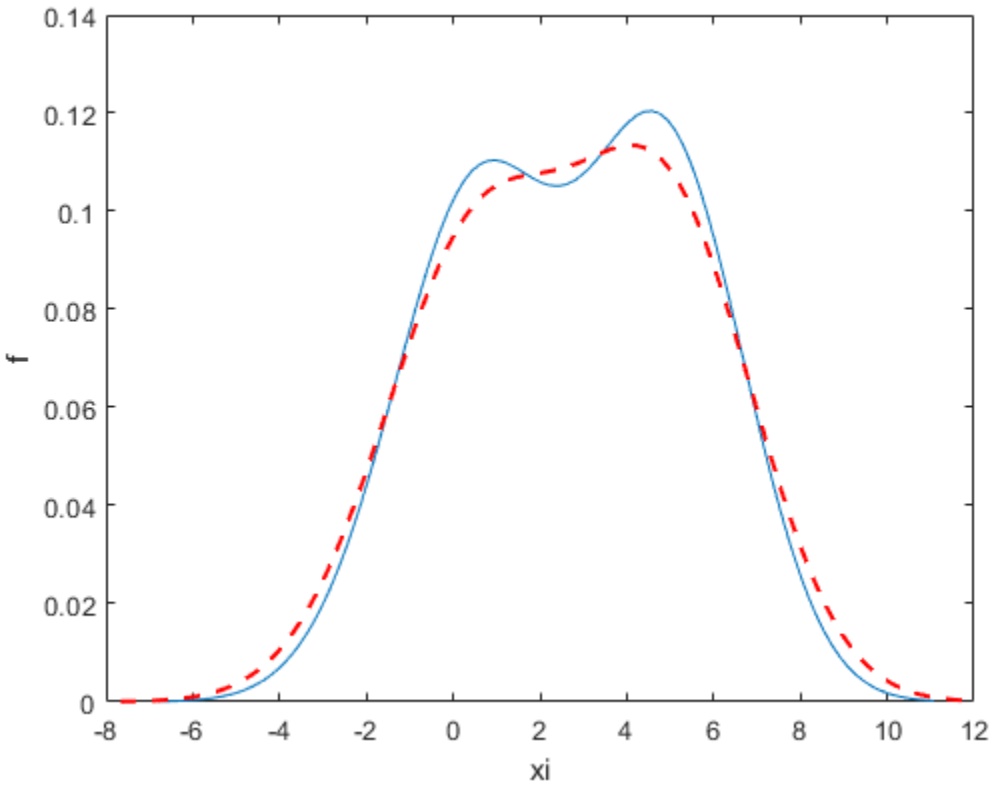
Plot the estimated density.

```
figure
plot(xi,f);
xlabel('xi')
ylabel('f')
hold on
```



Plot the density using an increased bandwidth value.

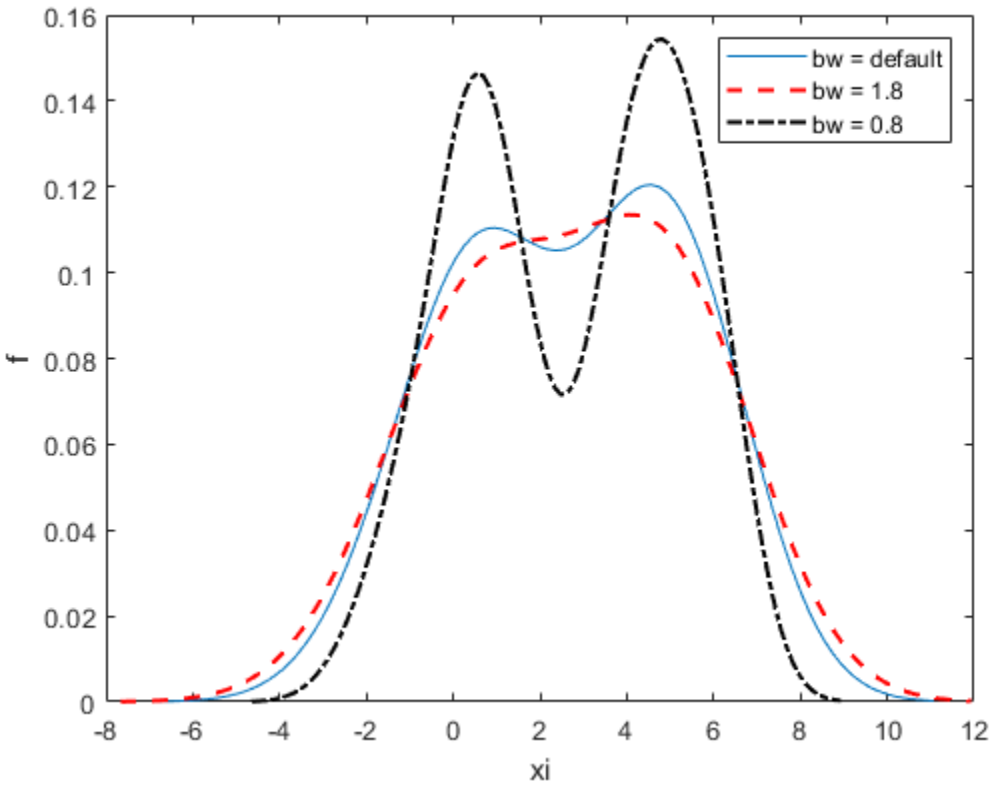
```
[f,xi] = ksdensity(x,'Bandwidth',1.8);
plot(xi,f,'--r','LineWidth',1.5)
```



A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

```
[f,xi] = ksdensity(x,'Bandwidth',0.8);
plot(xi,f,'-.k','LineWidth',1.5)
legend('bw = default','bw = 1.8','bw = 0.8')
hold off
```



A smaller bandwidth smooths the density estimate less, which exaggerates some characteristics of the sample.

Plot Kernel Density Estimate of Bivariate Data

Create a two-column vector of points at which to evaluate the density.

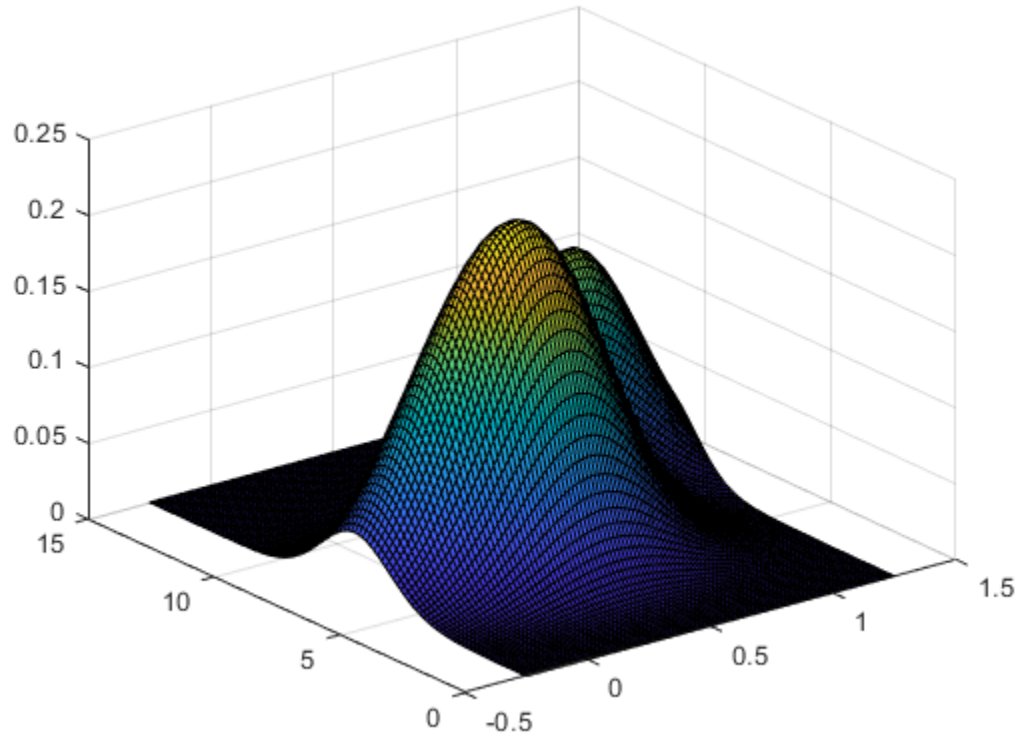
```
gridx1 = -0.25:.05:1.25;
gridx2 = 0:.1:15;
[x1,x2] = meshgrid(gridx1, gridx2);
x1 = x1(:);
x2 = x2(:);
xi = [x1 x2];
```

Generate a 30-by-2 matrix containing random numbers from a mixture of bivariate normal distributions.

```
rng('default')  % For reproducibility
x = [0+.5*rand(20,1) 5+2.5*rand(20,1);
            .75+.25*rand(10,1) 8.75+1.25*rand(10,1)];
```

Plot the estimated density of the sample data.

```
figure
ksdensity(x,xi);
```



Input Arguments

x — Sample data

column vector | two-column matrix

Sample data for which `ksdensity` returns `f` values, specified as a column vector or two-column matrix. Use a column vector for univariate data, and a two-column matrix for bivariate data.

Example: `[f,xi] = ksdensity(x)`

Data Types: `single` | `double`

pts — Points at which to evaluate f

vector | two-column matrix

Points at which to evaluate `f`, specified as a vector or two-column matrix. For univariate data, `pts` can be a row or column vector. The length of the returned output `f` is equal to the number of points in `pts`.

Example: `pts = (0:1:25); ksdensity(x,pts);`

Data Types: `single` | `double`

ax — Axes handle

handle

Axes handle for the figure `ksdensity` plots to, specified as a handle.

For example, if h is a handle for a figure, then ksdensity can plot to that figure as follows.

Example: ksdensity(h,x)

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Censoring',cens,'Kernel','triangle','NumPoints',20,'Function','cdf' specifies that ksdensity estimates the cdf by evaluating at 20 equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector cens.

Bandwidth — Bandwidth of the kernel smoothing window

optimal value for normal densities (default) | scalar value | two-element vector

The bandwidth of the kernel-smoothing window, which is a function of the number of points in x, specified as the comma-separated pair consisting of 'Bandwidth' and a scalar value. If the sample data is bivariate, Bandwidth can also be a two-element vector. The default is optimal for estimating normal densities [1], but you might want to choose a larger or smaller value to smooth more or less.

If you specify 'BoundaryCorrection' as 'log'(default) and 'Support' as either 'positive' or a vector [L U], ksdensity converts bounded data to be unbounded by using log transformation. The value of 'Bandwidth' is on the scale of the transformed values.

Example: 'Bandwidth',0.8

Data Types: single | double

BoundaryCorrection — Boundary correction method

'log' (default) | 'reflection'

Boundary correction method, specified as the comma-separated pair consisting of 'BoundaryCorrection' and 'log' or 'reflection'.

Value	Description
'log'	ksdensity converts bounded data x to be unbounded by one of the following transformations. Then, it transforms back to the original bounded scale after density estimation. • For univariate data, if you specify 'Support','positive', then ksdensity applies log(x). • For univariate data, if you specify 'Support',[L U], where L and U are numeric scalars and L < U, then ksdensity applies log((x-L)/(U–x)). • For bivariate data, ksdensity transforms each column of x in the same way with the univariate data. The value of 'Bandwidth' and the bw output are on the scale of the transformed values.
'reflection'	ksdensity augments bounded data by adding reflected data near the boundaries, then it returns estimates corresponding to the original support. For details, see “Reflection Method” on page 33-3396.

`ksdensity` applies boundary correction only when you specify `'Support'` as a value other than `'unbounded'`.

Example: `'BoundaryCorrection','reflection'`

`Censoring` — Logical vector
vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as the comma-separated pair consisting of `'Censoring'` and a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring. This name-value pair is only valid for univariate data.

Example: `'Censoring',censdata`

Data Types: `logical`

`Function` — Function to estimate
`'pdf'` (default) | `'cdf'` | `'icdf'` | `'survivor'` | `'cumhazard'`

Function to estimate, specified as the comma-separated pair consisting of `'Function'` and one of the following.

Value	Description
`'pdf'`	Probability density function.
`'cdf'`	Cumulative distribution function.
`'icdf'`	Inverse cumulative distribution function. `ksdensity` computes the estimated inverse cdf of the values in `x`, and evaluates it at the probability values specified in `pi`. This value is valid only for univariate data.
`'survivor'`	Survivor function.
`'cumhazard'`	Cumulative hazard function. This value is valid only for univariate data.

Example: `'Function','icdf'`

`Kernel` — Type of kernel smoother
`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'` | function handle | character vector | string scalar

Type of kernel smoother, specified as the comma-separated pair consisting of `'Kernel'` and one of the following.

- `'normal'` (default)
- `'box'`
- `'triangle'`
- `'epanechnikov'`
- A kernel function that is a custom or built-in function. Specify the function as a function handle (for example, `@myfunction` or `@normpdf`) or as a character vector or string scalar (for example, `'myfunction'` or `'normpdf'`). The software calls the specified function with one argument that

is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

When `'Function'` is `'pdf'`, the kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when `'Function'` is `'icdf'` returns an error.

For bivariate data, `ksdensity` applies the same kernel to each dimension.

Example: `'Kernel','box'`

`NumPoints` — Number of equally spaced points
100 (default) | scalar value

Number of equally spaced points in `xi`, specified as the comma-separated pair consisting of `'NumPoints'` and a scalar value. This name-value pair is only valid for univariate data.

For example, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

Example: `'NumPoints',80`

Data Types: `single` | `double`

`Support` — Support for the density
`'unbounded'` (default) | `'positive'` | two-element vector, `[L U]` | two-by-two matrix, `[L1 L2; U1 U2]`

Support for the density, specified as the comma-separated pair consisting of `'support'` and one of the following.

Value	Description
`'unbounded'`	Default. Allow the density to extend over the whole real line.
`'positive'`	Restrict the density to positive values.
Two-element vector, `[L U]`	Give the finite lower and upper bounds for the support of the density. This option is only valid for univariate sample data.
Two-by-two matrix, `[L1 L2; U1 U2]`	Give the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. This option is only valid for bivariate sample data.

For bivariate data, `'Support'` can be a combination of positive, unbounded, or bounded variables specified as `[0 -Inf; Inf Inf]` or `[0 L; Inf U]`.

Example: `'Support','positive'`

Example: `'Support',[0 10]`

Data Types: `single` | `double` | `char` | `string`

`PlotFcn` — Function used to create kernel density plot
`'surf'` (default) | `'contour'` | `'plot3'` | `'surfc'`

Function used to create kernel density plot, specified as the comma-separated pair consisting of `'PlotFcn'` and one of the following.

Value	Description
`'surf'`	3-D shaded surface plot, created using `surf`
`'contour'`	Contour plot, created using `contour`
`'plot3'`	3-D line plot, created using `plot3`
`'surfc'`	Contour plot under a 3-D shaded surface plot, created using `surfc`

This name-value pair is only valid for bivariate sample data.

Example: `'PlotFcn','contour'`

`Weights` — Weights for sample data
vector

Weights for sample data, specified as the comma-separated pair consisting of `'Weights'` and a vector of length `size(x,1)`, where `x` is the sample data.

Example: `'Weights',xw`

Data Types: `single` | `double`

Output Arguments

`f` — Estimated function values
vector

Estimated function values, returned as a vector whose length is equal to the number of points in `xi` or `pts`.

`xi` — Evaluation points
100 equally spaced points | 900 equally spaced points | vector | two-column matrix

Evaluation points at which `ksdensity` calculates `f`, returned as a vector or a two-column matrix. For univariate data, the default is 100 equally-spaced points that cover the range of data in `x`. For bivariate data, the default is 900 equally-spaced points created using `meshgrid` from 30 equally-spaced points in each dimension.

`bw` — Bandwidth of smoothing window
scalar value

Bandwidth of smoothing window, returned as a scalar value.

If you specify `'BoundaryCorrection'` as `'log'`(default) and `'Support'` as either `'positive'` or a vector `[L U]`, `ksdensity` converts bounded data to be unbounded by using log transformation. The value of `bw` is on the scale of the transformed values.

More About

Kernel Distribution

A kernel distribution is a nonparametric representation of the probability density function (pdf) of a random variable. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data.

A kernel distribution is defined by a smoothing function and a bandwidth value, which control the smoothness of the resulting density curve.

The kernel density estimator is the estimated pdf of a random variable. For any real values of x, the kernel density estimator's formula is given by

$$\widehat{f}_h(x) = \frac{1}{nh}\sum_{i=1}^{n} K\left(\frac{x - x_i}{h}\right),$$

where x_1, x_2, ..., x_n are random samples from an unknown distribution, n is the sample size, $K(\cdot)$ is the kernel smoothing function, and h is the bandwidth.

The kernel estimator for the cumulative distribution function (cdf), for any real values of x, is given by

$$\widehat{F}_h(x) = \int_{-\infty}^{x} \widehat{f}_h(t)dt = \frac{1}{n}\sum_{i=1}^{n} G\left(\frac{x - x_i}{h}\right),$$

where $G(x) = \int_{-\infty}^{x} K(t)dt$.

For more details, see “Kernel Distribution” on page B-78.

Reflection Method

The reflection method is a boundary correction method that accurately finds kernel density estimators when a random variable has bounded support. If you specify `'BoundaryCorrection','reflection'`, `ksdensity` uses the reflection method. This method augments bounded data by adding reflected data near the boundaries, and estimates the pdf. Then, `ksdensity` returns the estimated pdf corresponding to the original support with proper normalization, so that the estimated pdf's integral over the original support is equal to one.

If you additionally specify `'Support',[L U]`, then `ksdensity` finds the kernel estimator as follows.

- If `'Function'` is `'pdf'`, then the kernel density estimator is

  $$\widehat{f}_h(x) = \frac{1}{nh}\sum_{i=1}^{n}\left[K\left(\frac{x - x_i^-}{h}\right) + K\left(\frac{x - x_i}{h}\right) + K\left(\frac{x - x_i^+}{h}\right)\right] \text{ for } L \le x \le U,$$

  where $x_i^- = 2L - x_i$, $x_i^+ = 2U - x_i$, and x_i is the `i`th sample data.
- If `'Function'` is `'cdf'`, then the kernel estimator for cdf is

  $$\widehat{F}_h(x) = \frac{1}{n}\sum_{i=1}^{n}\left[G\left(\frac{x - x_i^-}{h}\right) + G\left(\frac{x - x_i}{h}\right) + G\left(\frac{x - x_i^+}{h}\right)\right] - \frac{1}{n}\sum_{i=1}^{n}\left[G\left(\frac{L - x_i^-}{h}\right) + G\left(\frac{L - x_i}{h}\right) + G\left(\frac{L - x_i^+}{h}\right)\right]$$

  for $L \le x \le U$.
- To obtain a kernel estimator for an inverse cdf, a survivor function, or a cumulative hazard function (when `'Function'` is `'icdf'`, `'survivor'`, or `'cumhazrd'`), `ksdensity` uses both $\widehat{f}_h(x)$ and $\widehat{F}_h(x)$.

If you additionally specify `'Support'` as `'positive'` or `[0 inf]`, then `ksdensity` finds the kernel estimator by replacing `[L U]` with `[0 inf]` in the above equations.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- Some options that require extra passes or sorting of the input data are not supported:
  - `'BoundaryCorrection'`
  - `'Censoring'`
  - `'Support'` (support is always unbounded).
- Uses standard deviation (instead of median absolute deviation) to compute the bandwidth.

For more information, see “Tall Arrays for Out-of-Memory Data”.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Plotting is not supported.
- Names in name-value pair arguments must be compile-time constants.
- Values in the following name-value pair arguments must also be compile-time constants: `'BoundaryCorrection'`, `'Function'`, and `'Kernel'`. For example, to use the `'Function','cdf'` name-value pair argument in the generated code, include `{coder.Constant('Function'),coder.Constant('cdf')}` in the `-args` value of `codegen`.
- The value of the `'Kernel'` name-value pair argument cannot be a custom function handle. To specify a custom kernel function, use a character vector or string scalar.
- For the value of the `'Support'` name-value pair argument, the compile-time data type must match the runtime data type.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

Introduced before R2006a

kstest

One-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest(x)
h = kstest(x,Name,Value)
[h,p] = kstest( ___ )
[h,p,ksstat,cv] = kstest( ___ )
```

Description

`h = kstest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test on page 33-3405. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`h = kstest(x,Name,Value)` returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.

`[h,p] = kstest( ___ )` also returns the *p*-value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,ksstat,cv] = kstest( ___ )` also returns the value of the test statistic `ksstat` and the approximate critical value `cv` of the test.

Examples

Test for Standard Normal Distribution

Perform the one-sample Kolmogorov-Smirnov test by using `kstest`. Confirm the test decision by visually comparing the empirical cumulative distribution function (cdf) to the standard normal cdf.

Load the `examgrades` data set. Create a vector containing the first column of the exam grade data.

```
load examgrades
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector, because `kstest` tests for a standard normal distribution by default.

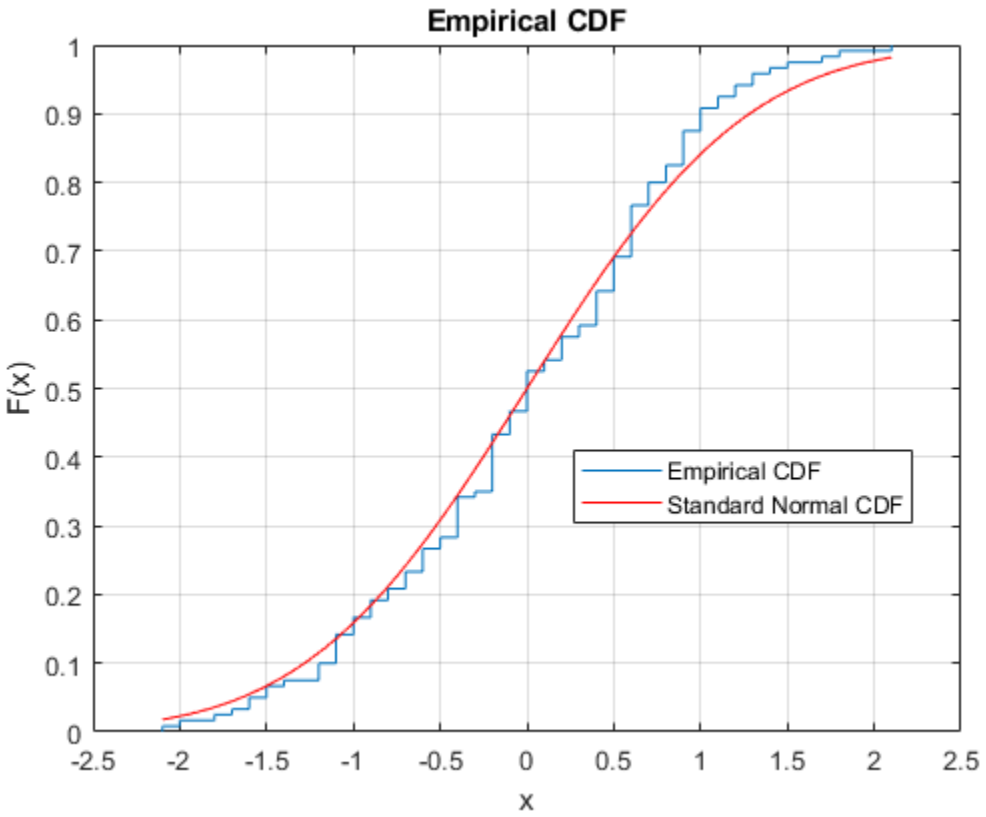
```
x = (test1-75)/10;
h = kstest(x)
```

```
h = logical
   0
```

The returned value of `h = 0` indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
cdfplot(x)
hold on
x_values = linspace(min(x),max(x));
plot(x_values,normcdf(x_values,0,1),'r-')
legend('Empirical CDF','Standard Normal CDF','Location','best')
```



The figure shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

Specify the Hypothesized Distribution Using a Two-Column Matrix

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector `x`. Column 2 contains cdf values evaluated at each value in `x` for a hypothesized Student's *t* distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = [x,cdf('tlocationscale',x,75,10,1)];
```

Test if the data are from the hypothesized distribution.

```
h = kstest(x,'CDF',test_cdf)
```

```
h = logical
   1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Specify the Hypothesized Distribution Using a Probability Distribution Object

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's *t* distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that the data comes from the hypothesized distribution.

```
h = kstest(x,'CDF',test_cdf)
```

```
h = logical
   1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades.

```
load examgrades;
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's *t* distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```
[h,p] = kstest(x,'CDF',test_cdf,'Alpha',0.01)
```

```
h = logical
   1

p = 0.0021
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the 1% significance level.

Conduct a One-Sided Hypothesis Test

Load the sample data. Create a vector containing the third column of the stock return data matrix.

```
load stockreturns;
x = stocks(:,3);
```

Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the population cdf of the data is larger than the standard normal cdf.

```
[h,p,k,c] = kstest(x,'Tail','larger')
```

```
h = logical
   1

p = 5.0854e-05

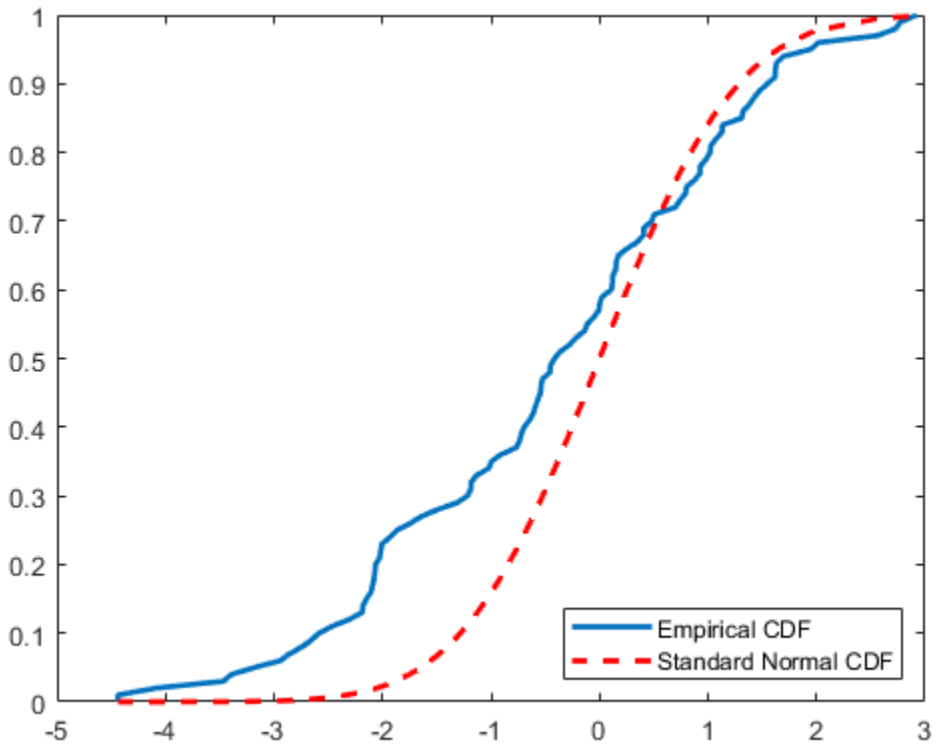
k = 0.2197

c = 0.1207
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis in favor of the alternative hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);
J = plot(x_values,f);
hold on;
K = plot(x_values,normcdf(x_values),'r--');
set(J,'LineWidth',2);
set(K,'LineWidth',2);
legend([J K],'Empirical CDF','Standard Normal CDF','Location','SE');
```



The plot shows the difference between the empirical cdf of the data vector `x` and the cdf of the standard normal distribution.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','larger','Alpha',0.01` specifies a test using the alternative hypothesis that the cdf of the population from which the sample data is drawn is greater than the cdf of the hypothesized distribution, conducted at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`CDF` — cdf of hypothesized continuous distribution
matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of `'CDF'` and either a two-column matrix or a continuous probability distribution object. When `CDF` is a matrix, column 1 contains a set of possible *x* values, and column 2 contains the corresponding hypothesized cumulative distribution function values $G(x)$. The calculation is most efficient if `CDF` is specified such that column 1 contains the values in the data vector `x`. If there are values in `x` not found in column 1 of `CDF`, `kstest` approximates $G(x)$ by interpolation. All values in `x` must lie in the interval between the smallest and largest values in the first column of `CDF`. By default, `kstest` tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test on page 33-3405 is only valid for continuous cumulative distribution functions, and requires `CDF` to be predetermined. The result is not accurate if `CDF` is estimated from the data. To test `x` against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use `lillietest` instead.

Data Types: `single` | `double`

`Tail` — Type of alternative hypothesis
`'unequal'` (default) | `'larger'` | `'smaller'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'unequal'`	Test the alternative hypothesis that the cdf of the population from which `x` is drawn is not equal to the cdf of the hypothesized distribution.
`'larger'`	Test the alternative hypothesis that the cdf of the population from which `x` is drawn is greater than the cdf of the hypothesized distribution.
`'smaller'`	Test the alternative hypothesis that the cdf of the population from which `x` is drawn is less than the cdf of the hypothesized distribution.

If the values in the data vector `x` tend to be larger than expected from the hypothesized distribution, the empirical distribution function of `x` tends to be smaller, and vice versa.

Example: `'Tail','larger'`

Output Arguments

`h` — Hypothesis test result
`1` | `0`

Hypothesis test result, returned as a logical value.

- If `h = 1`, this indicates the rejection of the null hypothesis at the `Alpha` significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the `Alpha` significance level.

p — *p*-value
scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

ksstat — Test statistic
nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

cv — Critical value
nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

More About

One-Sample Kolmogorov-Smirnov Test

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for "unequal" cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from x and the hypothesized cdf:

$$D^* = \max_x\left(\left|\widehat{F}(x) - G(x)\right|\right),$$

where $\widehat{F}(x)$ is the empirical cdf and $G(x)$ is the cdf of the hypothesized distribution.

The one-sided test for a "larger" cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf. The test statistic is the maximum amount by which the empirical cdf calculated from x exceeds the hypothesized cdf:

$$D^* = \max_x\left(\widehat{F}(x) - G(x)\right).$$

The one-sided test for a "smaller" cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from x:

$$D^* = \max_x\left(G(x) - \widehat{F}(x)\right).$$

`kstest` computes the critical value `cv` using an approximate formula or by interpolation in a table. The formula and table cover the range `0.01 ≤ alpha ≤ 0.2` for two-sided tests and `0.005 ≤ alpha ≤ 0.1` for one-sided tests. `cv` is returned as `NaN` if `alpha` is outside this range.

Algorithms

`kstest` decides to reject the null hypothesis by comparing the *p*-value `p` with the significance level `Alpha`, not by comparing the test statistic `ksstat` with the critical value `cv`. Since `cv` is

approximate, comparing `ksstat` with `cv` occasionally leads to a different conclusion than comparing `p` with `Alpha`.

Introduced before R2006a

kstest2

Two-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2(___)
[h,p,ks2stat] = kstest2(___)
```

Description

`h = kstest2(x1,x2)` returns a test decision for the null hypothesis that the data in vectors `x1` and `x2` are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test on page 33-3410. The alternative hypothesis is that `x1` and `x2` are from different continuous distributions. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, and `0` otherwise.

`h = kstest2(x1,x2,Name,Value)` returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = kstest2(___)` also returns the asymptotic *p*-value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,ks2stat] = kstest2(___)` also returns the test statistic `ks2stat`.

Examples

Test Two Samples for the Same Distribution

Generate sample data from two different Weibull distributions.

```
rng(1);     % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution.

```
h = kstest2(x1,x2)
```

```
h = logical
   1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Generate sample data from two different Weibull distributions.

```
rng(1);     % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data vectors `x1` and `x2` are from populations with the same distribution at the 1% significance level.

```
[h,p] = kstest2(x1,x2,'Alpha',0.01)
```

```
h = logical
   0

p = 0.0317
```

The returned value of `h = 0` indicates that `kstest` does not reject the null hypothesis at the 1% significance level.

One-Sided Hypothesis Test

Generate sample data from two different Weibull distributions.

```
rng(1);     % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`.

```
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

```
h = logical
   1

p = 0.0158

k = 0.2800
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`, at the default 5% significance level. The returned value of `k` is the test statistic for the two-sample Kolmogorov-Smirnov test.

Input Arguments

x1 — Sample data

vector

Sample data from the first sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

x2 — Sample data

vector

Sample data from the second sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','larger','Alpha',0.01` specifies a test using the alternative hypothesis that the empirical cdf of `x1` is larger than the empirical cdf of `x2`, conducted at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'unequal'` (default) | `'larger'` | `'smaller'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'unequal'`	Test the alternative hypothesis that the empirical cdf of `x1` is unequal to the empirical cdf of `x2`.
`'larger'`	Test the alternative hypothesis that the empirical cdf of `x1` is larger than the empirical cdf of `x2`.
`'smaller'`	Test the alternative hypothesis that the empirical cdf of `x1` is smaller than the empirical cdf of `x2`.

If the data values in `x1` tend to be larger than those in `x2`, the empirical distribution function of `x1` tends to be smaller than that of `x2`, and vice versa.

Example: `'Tail','larger'`

Output Arguments

h — Hypothesis test result

`1` | `0`

Hypothesis test result, returned as a logical value.

- If `h = 1`, this indicates the rejection of the null hypothesis at the `Alpha` significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the `Alpha` significance level.

`p` — Asymptotic *p*-value
scalar value in the range (0,1)

Asymptotic *p*-value of the test, returned as a scalar value in the range (0,1). `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic *p*-value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes `n1` and `n2`, such that `(n1*n2)/(n1 + n2)` ≥ 4.

`ks2stat` — Test statistic
nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

More About

Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of *x* in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

$$D^* = \max_x\left(\left|\widehat{F}_1(x) - \widehat{F}_2(x)\right|\right),$$

where $\widehat{F}_1(x)$ is the proportion of `x1` values less than or equal to *x* and $\widehat{F}_2(x)$ is the proportion of `x2` values less than or equal to *x*.

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

$$D^* = \max_x\left(\widehat{F}_1(x) - \widehat{F}_2(x)\right).$$

Algorithms

In `kstest2`, the decision to reject the null hypothesis is based on comparing the *p*-value `p` with the significance level `Alpha`, not by comparing the test statistic `ks2stat` with a critical value.

kurtosis

Kurtosis

Syntax

```
k = kurtosis(X)
k = kurtosis(X,flag)
k = kurtosis(X,flag,'all')
k = kurtosis(X,flag,dim)
k = kurtosis(X,flag,vecdim)
```

Description

`k = kurtosis(X)` returns the sample kurtosis of `X`.

- If `X` is a vector, then `kurtosis(X)` returns a scalar value that is the kurtosis of the elements in `X`.
- If `X` is a matrix, then `kurtosis(X)` returns a row vector that contains the sample kurtosis of each column in `X`.
- If `X` is a multidimensional array, then `kurtosis(X)` operates along the first nonsingleton dimension of `X`.

`k = kurtosis(X,flag)` specifies whether to correct for bias (`flag` is `0`) or not (`flag` is `1`, the default). When `X` represents a sample from a population, the kurtosis of `X` is biased, meaning it tends to differ from the population kurtosis by a systematic amount based on the sample size. You can set `flag` to `0` to correct for this systematic bias.

`k = kurtosis(X,flag,'all')` returns the kurtosis of all elements of `X`.

`k = kurtosis(X,flag,dim)` returns the kurtosis along the operating dimension `dim` of `X`.

`k = kurtosis(X,flag,vecdim)` returns the kurtosis over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `kurtosis(X,1,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the biased kurtosis of the elements on the corresponding page of `X`.

Examples

Find Kurtosis of Matrix

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a matrix with 5 rows and 4 columns.

```
X = randn(5,4)
```

```
X = 5×4
```

```
    0.5377   -1.3077   -1.3499   -0.2050
    1.8339   -0.4336    3.0349   -0.1241
   -2.2588    0.3426    0.7254    1.4897
    0.8622    3.5784   -0.0631    1.4090
    0.3188    2.7694    0.7147    1.4172
```

Find the sample kurtosis of `X`.

```
k = kurtosis(X)
```

```
k = 1×4

    2.7067    1.4069    2.3783    1.1759
```

`k` is a row vector containing the sample kurtosis of each column in `X`.

Correct for Bias in Sample Kurtosis

For an input vector, correct for bias in the calculation of kurtosis by specifying the `flag` input argument.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a vector of length 10.

```
x = randn(10,1)
```

```
x = 10×1

    0.5377
    1.8339
   -2.2588
    0.8622
    0.3188
   -1.3077
   -0.4336
    0.3426
    3.5784
    2.7694
```

Find the biased kurtosis of `x`. By default, `kurtosis` sets the value of `flag` to `1` for computing the biased kurtosis.

```
k1 = kurtosis(x) % flag is 1 by default
```

```
k1 = 2.3121
```

Find the bias-corrected kurtosis of `x` by setting the value of `flag` to `0`.

```
k2 = kurtosis(x,0)
```

```
k2 = 2.7483
```

Find Kurtosis Along Given Dimension

Find the kurtosis along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4,3,2])
```

```
X =
X(:,:,1) =

    0.5377    0.3188    3.5784
    1.8339   -1.3077    2.7694
   -2.2588   -0.4336   -1.3499
    0.8622    0.3426    3.0349

X(:,:,2) =

    0.7254   -0.1241    0.6715
   -0.0631    1.4897   -1.2075
    0.7147    1.4090    0.7172
   -0.2050    1.4172    1.6302
```

Find the kurtosis of `X` along the default dimension.

```
k1 = kurtosis(X)
```

```
k1 =
k1(:,:,1) =

    2.1350    1.7060    2.2789

k1(:,:,2) =

    1.0542    2.3278    2.0996
```

By default, `kurtosis` operates along the first dimension of `X` whose size does not equal 1. In this case, this dimension is the first dimension of `X`. Therefore, `k1` is a 1-by-3-by-2 array.

Find the biased kurtosis of `X` along the second dimension.

```
k2 = kurtosis(X,1,2)
```

```
k2 =
k2(:,:,1) =

    1.5000
    1.5000
```

```
    1.5000
    1.5000

k2(:,:,2) =

    1.5000
    1.5000
    1.5000
    1.5000
```

`k2` is a 4-by-1-by-2 array.

Find the biased kurtosis of `X` along the third dimension.

```
k3 = kurtosis(X,1,3)
```

```
k3 = 4×3

    1.0000    1.0000    1.0000
    1.0000    1.0000    1.0000
    1.0000    1.0000    1.0000
    1.0000    1.0000    1.0000
```

`k3` is a 4-by-3 matrix.

Find Kurtosis Along Vector of Dimensions

Find the kurtosis over multiple dimensions by using the `'all'` and `vecdim` input arguments.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4 3 2])
```

```
X =
X(:,:,1) =

    0.5377    0.3188    3.5784
    1.8339   -1.3077    2.7694
   -2.2588   -0.4336   -1.3499
    0.8622    0.3426    3.0349

X(:,:,2) =

    0.7254   -0.1241    0.6715
   -0.0631    1.4897   -1.2075
    0.7147    1.4090    0.7172
   -0.2050    1.4172    1.6302
```

Find the biased kurtosis of X.

```
kall = kurtosis(X,1,'all')
```

```
kall = 2.8029
```

`kall` is the biased kurtosis of the entire input data set X.

Find the biased kurtosis of each page of X by specifying the first and second dimensions.

```
kpage = kurtosis(X,1,[1 2])
```

```
kpage =
kpage(:,:,1) =

    1.9345

kpage(:,:,2) =

    2.5877
```

For example, `kpage(1,1,2)` is the biased kurtosis of the elements in `X(:,:,2)`.

Find the biased kurtosis of the elements in each `X(i,:,:)` slice by specifying the second and third dimensions.

```
krow = kurtosis(X,1,[2 3])
```

```
krow = 4×1

    3.8457
    1.4306
    1.7094
    2.3378
```

For example, `krow(3)` is the biased kurtosis of the elements in `X(3,:,:)`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If X is a vector, then `kurtosis(X)` returns a scalar value that is the kurtosis of the elements in X.
- If X is a matrix, then `kurtosis(X)` returns a row vector that contains the sample kurtosis of each column in X.
- If X is a multidimensional array, then `kurtosis(X)` operates along the first nonsingleton dimension of X.

To specify the operating dimension when X is a matrix or an array, use the `dim` input argument.

`kurtosis` treats `NaN` values in `X` as missing values and removes them.

Data Types: `single` | `double`

`flag` — Indicator for bias

1 (default) | 0

Indicator for the bias, specified as `0` or `1`.

- If `flag` is `1` (default), then the kurtosis of `X` is biased, meaning it tends to differ from the population kurtosis by a systematic amount based on the sample size.
- If `flag` is `0`, then `kurtosis` corrects for the systematic bias.

Data Types: `single` | `double` | `logical`

`dim` — Dimension

positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for `dim`, then the default is the first dimension of `X` whose size does not equal 1.

Consider the kurtosis of a matrix `X`:

- If `dim` is equal to 1, then `kurtosis` returns a row vector that contains the sample kurtosis of each column in `X`.
- If `dim` is equal to 2, then `kurtosis` returns a column vector that contains the sample kurtosis of each row in `X`.

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `kurtosis` returns an array of `NaN`s the same size as `X`.

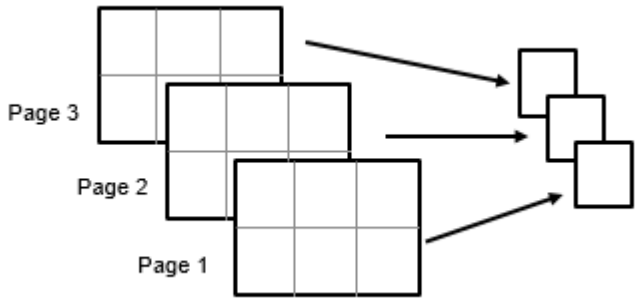
Data Types: `single` | `double`

`vecdim` — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `k` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `k`.

For example, if `X` is a 2-by-3-by-3 array, then `kurtosis(X,1,[1 2])` returns a 1-by-1-by-3 array. Each element of the output is the biased kurtosis of the elements on the corresponding page of `X`.



Data Types: `single` | `double`

Output Arguments

k — Kurtosis

scalar | vector | matrix | multidimensional array

Kurtosis, returned as a scalar, vector, matrix, or multidimensional array.

Algorithms

Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution on page B-119 is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3. Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The `kurtosis` function does not use this convention.

The kurtosis of a distribution is defined as

$$k = \frac{E(x-\mu)^4}{\sigma^4},$$

where μ is the mean of x, σ is the standard deviation of x, and $E(t)$ represents the expected value of the quantity t. The `kurtosis` function computes a sample version of this population value.

When you set `flag` to `1`, the kurtosis is biased, and the following equation applies:

$$k_1 = \frac{\frac{1}{n}\sum_{i=1}^{n}(x_i-\bar{x})^4}{\left(\frac{1}{n}\sum_{i=1}^{n}(x_i-\bar{x})^2\right)^2}.$$

When you set `flag` to `0`, `kurtosis` corrects for the systematic bias, and the following equation applies:

$$k_0 = \frac{n-1}{(n-2)(n-3)}((n+1)k_1 - 3(n-1)) + 3.$$

This bias-corrected equation requires that `X` contain at least four elements.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see "Automatic dimension restriction" (MATLAB Coder).

For more information on code generation, see "Introduction to Code Generation" on page 32-2 and "General Code Generation Workflow" on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

Topics

"Normal Distribution" on page B-119

Introduced before R2006a

lasso

Lasso or elastic net regularization for linear models

Syntax

```
B = lasso(X,y)
B = lasso(X,y,Name,Value)
[B,FitInfo] = lasso(___)
```

Description

`B = lasso(X,y)` returns fitted least-squares regression coefficients for linear models of the predictor data `X` and the response `y`. Each column of `B` corresponds to a particular regularization coefficient in `Lambda`. By default, `lasso` performs lasso regularization using a geometric sequence of `Lambda` values.

`B = lasso(X,y,Name,Value)` fits regularized regressions with additional options specified by one or more name-value pair arguments. For example, `'Alpha',0.5` sets elastic net as the regularization method, with the parameter `Alpha` equal to 0.5.

`[B,FitInfo] = lasso(___)` also returns the structure `FitInfo`, which contains information about the fit of the models, using any of the input arguments in the previous syntaxes.

Examples

Remove Redundant Predictors Using Lasso Regularization

Construct a data set with redundant predictors and identify those predictors by using `lasso`.

Create a matrix `X` of 100 five-dimensional normal variables. Create a response vector `y` from just two components of `X`, and add a small amount of noise.

```
rng default % For reproducibility
X = randn(100,5);
weights = [0;2;0;-3;0]; % Only two nonzero coefficients
y = X*weights + randn(100,1)*0.1; % Small added noise
```

Construct the default lasso fit.

```
B = lasso(X,y);
```

Find the coefficient vector for the 25th `Lambda` value in `B`.

```
B(:,25)
```

```
ans = 5×1

         0
    1.6093
         0
```

```
   -2.5865
         0
```

`lasso` identifies and removes the redundant predictors.

Create Linear Model Without Intercept Term Using Lasso Regularization

Create sample data with predictor variable X and response variable $y = 0 + 2X + \varepsilon$.

```
rng('default') % For reproducibility
X = rand(100,1);
y = 2*X + randn(100,1)/10;
```

Specify a regularization value, and find the coefficient of the regression model without an intercept term.

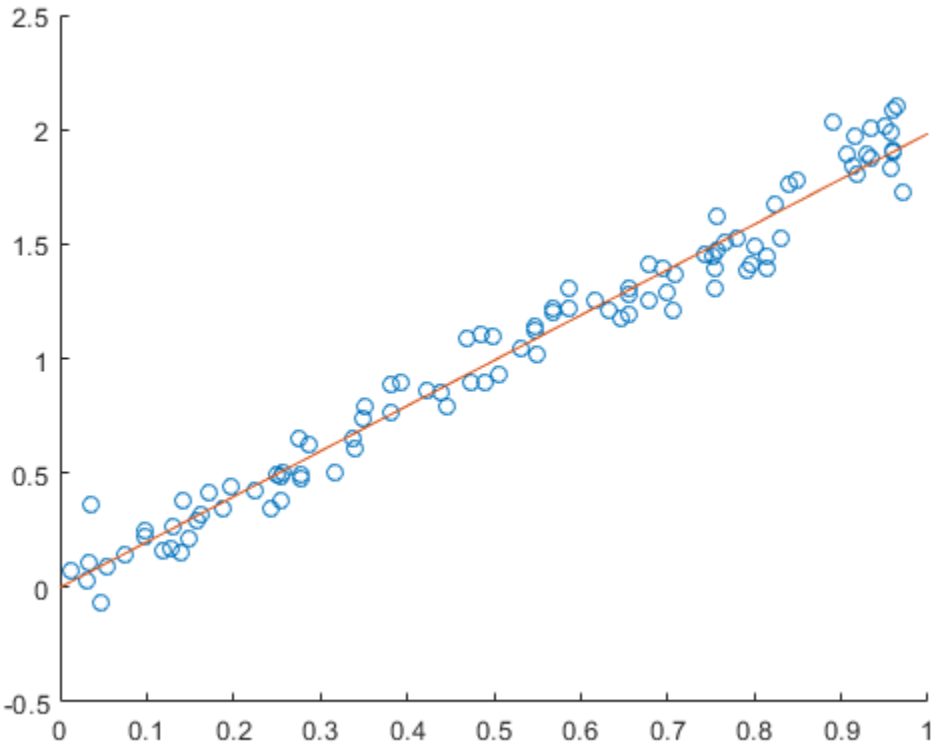
```
lambda = 1e-03;
B = lasso(X,y,'Lambda',lambda,'Intercept',false)
```

```
Warning: When the 'Intercept' value is false, the 'Standardize' value is set to false.
```

```
B = 1.9825
```

Plot the real values (points) against the predicted values (line).

```
scatter(X,y)
hold on
x = 0:0.1:1;
plot(x,x*B)
hold off
```



Remove Redundant Predictors by Using Cross-Validated Fits

Construct a data set with redundant predictors and identify those predictors by using cross-validated `lasso`.

Create a matrix `X` of 100 five-dimensional normal variables. Create a response vector `y` from two components of `X`, and add a small amount of noise.

```
rng default % For reproducibility
X = randn(100,5);
weights = [0;2;0;-3;0]; % Only two nonzero coefficients
y = X*weights + randn(100,1)*0.1; % Small added noise
```

Construct the lasso fit by using 10-fold cross-validation with labeled predictor variables.

```
[B,FitInfo] = lasso(X,y,'CV',10,'PredictorNames',{'x1','x2','x3','x4','x5'});
```

Display the variables in the model that corresponds to the minimum cross-validated mean squared error (MSE).

```
idxLambdaMinMSE = FitInfo.IndexMinMSE;
minMSEModelPredictors = FitInfo.PredictorNames(B(:,idxLambdaMinMSE)~=0)
```

```
minMSEModelPredictors = 1x2 cell
    {'x2'}    {'x4'}
```

Display the variables in the sparsest model within one standard error of the minimum MSE.

```
idxLambda1SE = FitInfo.Index1SE;
sparseModelPredictors = FitInfo.PredictorNames(B(:,idxLambda1SE)~=0)
```

```
sparseModelPredictors = 1x2 cell
    {'x2'}    {'x4'}
```

In this example, `lasso` identifies the same predictors for the two models and removes the redundant predictors.

Lasso Plot with Cross-Validated Fits

Visually examine the cross-validated error of various levels of regularization.

Load the sample data.

```
load acetylene
```

Create a design matrix with interactions and no constant term.

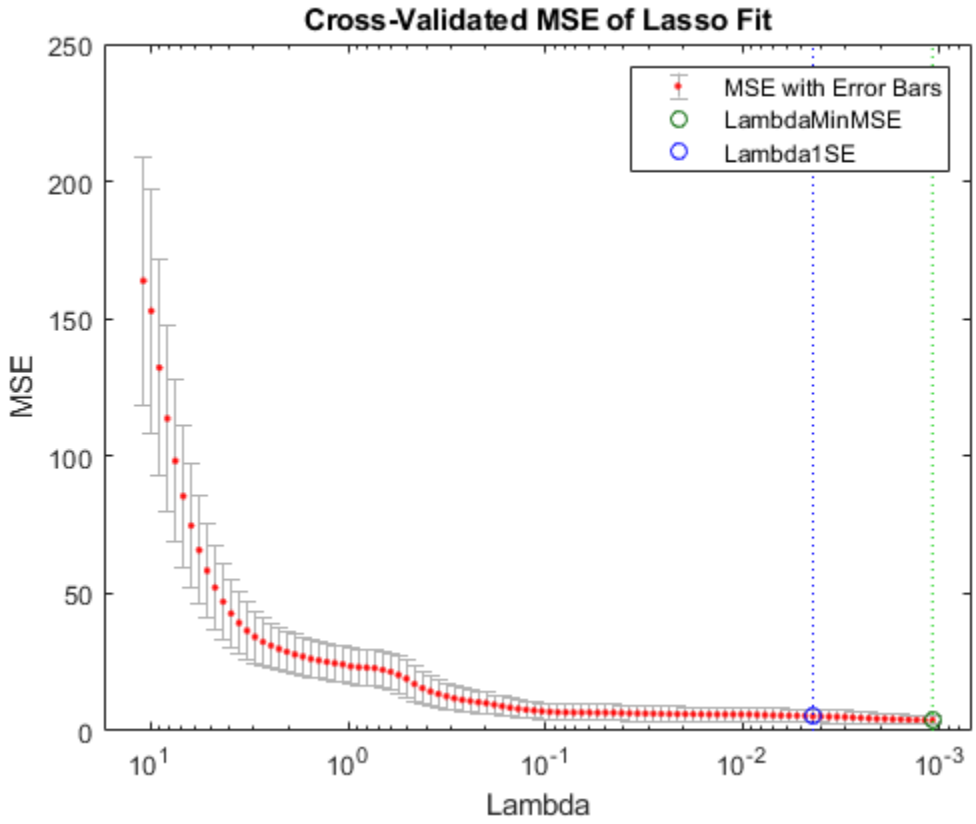
```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
```

Construct the lasso fit using 10-fold cross-validation. Include the `FitInfo` output so you can plot the result.

```
rng default % For reproducibility
[B,FitInfo] = lasso(D,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');
legend('show') % Show legend
```



The green circle and dotted line locate the `Lambda` with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Predict Values Using Elastic Net Regularization

Predict students' exam scores using `lasso` and the elastic net method.

Load the `examgrades` data set.

```
load examgrades
X = grades(:,1:4);
y = grades(:,5);
```

Split the data into training and test sets.

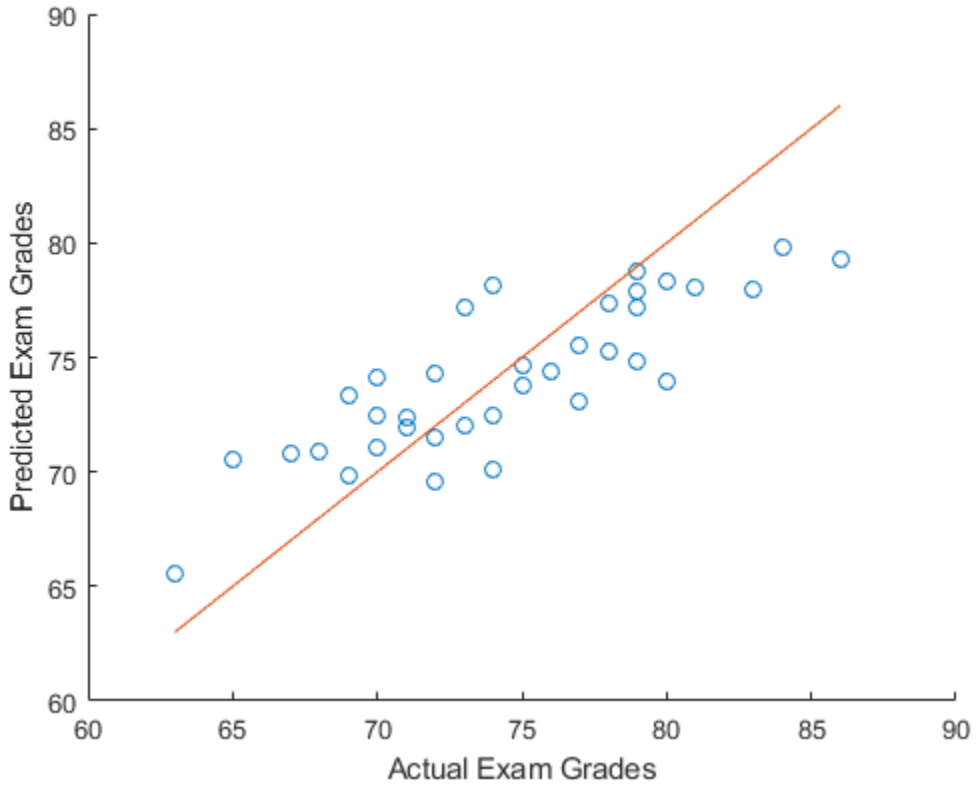
```
n = length(y);
c = cvpartition(n,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
XTrain = X(idxTrain,:);
yTrain = y(idxTrain);
XTest = X(idxTest,:);
yTest = y(idxTest);
```

Find the coefficients of a regularized linear regression model using 10-fold cross-validation and the elastic net method with `Alpha` = 0.75. Use the largest `Lambda` value such that the mean squared error (MSE) is within one standard error of the minimum MSE.

```
[B,FitInfo] = lasso(XTrain,yTrain,'Alpha',0.75,'CV',10);
idxLambda1SE = FitInfo.Index1SE;
coef = B(:,idxLambda1SE);
coef0 = FitInfo.Intercept(idxLambda1SE);
```

Predict exam scores for the test data. Compare the predicted values to the actual exam grades using a reference line.

```
yhat = XTest*coef + coef0;
hold on
scatter(yTest,yhat)
plot(yTest,yTest)
xlabel('Actual Exam Grades')
ylabel('Predicted Exam Grades')
hold off
```



Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row represents one observation, and each column represents one predictor variable.

Data Types: `single` | `double`

y — Response data
numeric vector

Response data, specified as a numeric vector. `y` has length *n*, where *n* is the number of rows of `X`. The response `y(i)` corresponds to the *i*th row of `X`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `lasso(X,y,'Alpha',0.75,'CV',10)` performs elastic net regularization with 10-fold cross-validation. The `'Alpha',0.75` name-value pair argument sets the parameter used in the elastic net optimization.

`AbsTol` — Absolute error tolerance
`1e−4` (default) | positive scalar

Absolute error tolerance used to determine the convergence of the "ADMM Algorithm" on page 33-3432, specified as the comma-separated pair consisting of `'AbsTol'` and a positive scalar. The algorithm converges when successive estimates of the coefficient vector differ by an amount less than `AbsTol`.

Note This option applies only when you use `lasso` on tall arrays. See "Extended Capabilities" on page 33-0 for more information.

Example: `'AbsTol',1e−3`

Data Types: `single` | `double`

`Alpha` — Weight of lasso versus ridge optimization
`1` (default) | positive scalar

Weight of lasso (L^1) versus ridge (L^2) optimization, specified as the comma-separated pair consisting of `'Alpha'` and a positive scalar value in the interval `(0,1]`. The value `Alpha = 1` represents lasso regression, `Alpha` close to `0` approaches ridge regression on page 11-109, and other values represent elastic net optimization. See "Elastic Net" on page 33-3431.

Example: `'Alpha',0.5`

Data Types: `single` | `double`

`B0` — Initial values for *x*-coefficients in ADMM Algorithm
vector of zeros (default) | numeric vector

Initial values for *x*-coefficients in "ADMM Algorithm" on page 33-3432, specified as the comma-separated pair consisting of `'B0'` and a numeric vector.

Note This option applies only when you use `lasso` on tall arrays. See "Extended Capabilities" on page 33-0 for more information.

Data Types: `single` | `double`

`CV` — Cross-validation specification for estimating mean squared error

`'resubstitution'` (default) | positive integer scalar | `cvpartition` object

Cross-validation specification for estimating the mean squared error (MSE), specified as the comma-separated pair consisting of `'CV'` and one of the following:

- `'resubstitution'` — `lasso` uses `X` and `y` to fit the model and to estimate the MSE without cross-validation.
- Positive scalar integer `K` — `lasso` uses `K`-fold cross-validation.
- `cvpartition` object `cvp` — `lasso` uses the cross-validation method expressed in `cvp`. You cannot use a `'leaveout'` partition with `lasso`.

Example: `'CV',3`

`DFmax` — Maximum number of nonzero coefficients

`Inf` (default) | positive integer scalar

Maximum number of nonzero coefficients in the model, specified as the comma-separated pair consisting of `'DFmax'` and a positive integer scalar. `lasso` returns results only for `Lambda` values that satisfy this criterion.

Example: `'DFmax',5`

Data Types: `single` | `double`

`Intercept` — Flag for fitting the model with intercept term

`true` (default) | `false`

Flag for fitting the model with the intercept term, specified as the comma-separated pair consisting of `'Intercept'` and either `true` or `false`. The default value is `true`, which indicates to include the intercept term in the model. If `Intercept` is `false`, then the returned intercept value is 0.

Example: `'Intercept',false`

Data Types: `logical`

`Lambda` — Regularization coefficients

nonnegative vector

Regularization coefficients, specified as the comma-separated pair consisting of `'Lambda'` and a vector of nonnegative values. See "Lasso" on page 33-3431.

- If you do not supply `Lambda`, then `lasso` calculates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, then `lasso` ignores `LambdaRatio` and `NumLambda`.
- If `Standardize` is `true`, then `Lambda` is the set of values used to fit the models with the `X` data standardized to have zero mean and a variance of one.

The default is a geometric sequence of `NumLambda` values, with only the largest value able to produce `B = 0`.

Example: `'Lambda',linspace(0,1)`

Data Types: `single` | `double`

`LambdaRatio` — Ratio of smallest to largest `Lambda` values
`1e–4` (default) | positive scalar

Ratio of the smallest to the largest `Lambda` values when you do not supply `Lambda`, specified as the comma-separated pair consisting of `'LambdaRatio'` and a positive scalar.

If you set `LambdaRatio = 0`, then `lasso` generates a default sequence of `Lambda` values and replaces the smallest one with `0`.

Example: `'LambdaRatio',1e–2`

Data Types: `single` | `double`

`MaxIter` — Maximum number of iterations allowed
positive integer scalar

Maximum number of iterations allowed, specified as the comma-separated pair consisting of `'MaxIter'` and a positive integer scalar.

If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance `RelTol`, then the function stops iterating and returns a warning message.

The function can return more than one warning when `NumLambda` is greater than `1`.

Default values are `1e5` for standard data and `1e4` for tall arrays.

Example: `'MaxIter',1e3`

Data Types: `single` | `double`

`MCReps` — Number of Monte Carlo repetitions for cross-validation
`1` (default) | positive integer scalar

Number of Monte Carlo repetitions for cross-validation, specified as the comma-separated pair consisting of `'MCReps'` and a positive integer scalar.

- If `CV` is `'resubstitution'` or a `cvpartition` of type `'resubstitution'`, then `MCReps` must be `1`.
- If `CV` is a `cvpartition` of type `'holdout'`, then `MCReps` must be greater than `1`.

Example: `'MCReps',5`

Data Types: `single` | `double`

`NumLambda` — Number of `Lambda` values
`100` (default) | positive integer scalar

Number of `Lambda` values `lasso` uses when you do not supply `Lambda`, specified as the comma-separated pair consisting of `'NumLambda'` and a positive integer scalar. `lasso` can return fewer than `NumLambda` fits if the residual error of the fits drops below a threshold fraction of the variance of `y`.

Example: `'NumLambda',50`

Data Types: `single` | `double`

`Options` — Option to cross-validate in parallel and specify random streams
structure

Option to cross-validate in parallel and specify the random streams, specified as the comma-separated pair consisting of `'Options'` and a structure. This option requires Parallel Computing Toolbox.

Create the `Options` structure with `statset`. The option fields are:

- `UseParallel` — Set to `true` to compute in parallel. The default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. For reproducibility, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. The default is `false`.
- `Streams` — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, then `lasso` uses the default stream.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

`PredictorNames` — Names of predictor variables
`{}` (default) | string array | cell array of character vectors

Names of the predictor variables, in the order in which they appear in `X`, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array or cell array of character vectors.

Example: `'PredictorNames',{'x1','x2','x3','x4'}`

Data Types: `string` | `cell`

`RelTol` — Convergence threshold for coordinate descent algorithm
`1e–4` (default) | positive scalar

Convergence threshold for the coordinate descent algorithm [3], specified as the comma-separated pair consisting of `'RelTol'` and a positive scalar. The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Example: `'RelTol',5e–3`

Data Types: `single` | `double`

`Rho` — Augmented Lagrangian parameter
positive scalar

Augmented Lagrangian parameter ρ for the "ADMM Algorithm" on page 33-3432, specified as the comma-separated pair consisting of `'Rho'` and a positive scalar. The default is automatic selection.

Note This option applies only when you use `lasso` on tall arrays. See "Extended Capabilities" on page 33-0 for more information.

Example: `'Rho',2`

Data Types: `single` | `double`

`Standardize` — Flag for standardizing predictor data before fitting models
`true` (default) | `false`

Flag for standardizing the predictor data `X` before fitting the models, specified as the comma-separated pair consisting of `'Standardize'` and either `true` or `false`. If `Standardize` is `true`, then the `X` data is scaled to have zero mean and a variance of one. `Standardize` affects whether the regularization is applied to the coefficients on the standardized scale or the original scale. The results are always presented on the original data scale.

If `Intercept` is `false`, then the software sets `Standardize` to `false`, regardless of the `Standardize` value you specify.

`X` and `y` are always centered when `Intercept` is `true`.

Example: `'Standardize',false`

Data Types: `logical`

`U0` — Initial value of scaled dual variable
vector of zeros (default) | numeric vector

Initial value of the scaled dual variable *u* in the "ADMM Algorithm" on page 33-3432, specified as the comma-separated pair consisting of `'U0'` and a numeric vector.

Note This option applies only when you use `lasso` on tall arrays. See "Extended Capabilities" on page 33-0 for more information.

Data Types: `single` | `double`

`Weights` — Observation weights
`1/n*ones(n,1)` (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a nonnegative vector. `Weights` has length *n*, where *n* is the number of rows of `X`. The `lasso` function scales `Weights` to sum to `1`.

Data Types: `single` | `double`

Output Arguments

`B` — Fitted coefficients
numeric matrix

Fitted coefficients, returned as a numeric matrix. `B` is a *p*-by-*L* matrix, where *p* is the number of predictors (columns) in `X`, and *L* is the number of `Lambda` values. You can specify the number of `Lambda` values using the `NumLambda` name-value pair argument.

The coefficient corresponding to the intercept term is a field in `FitInfo`.

Data Types: `single` | `double`

`FitInfo` — Fit information of models
structure

Fit information of the linear models, returned as a structure with the fields described in this table.

Field in `FitInfo`	Description
`Intercept`	Intercept term β_0 for each linear model, a 1-by-L vector
`Lambda`	Lambda parameters in ascending order, a 1-by-L vector
`Alpha`	Value of the `Alpha` parameter, a scalar
`DF`	Number of nonzero coefficients in `B` for each value of `Lambda`, a 1-by-L vector
`MSE`	Mean squared error (MSE), a 1-by-L vector
`PredictorNames`	Value of the `PredictorNames` parameter, stored as a cell array of character vectors

If you set the `CV` name-value pair argument to cross-validate, the `FitInfo` structure contains these additional fields.

Field in `FitInfo`	Description
`SE`	Standard error of MSE for each `Lambda`, as calculated during cross-validation, a 1-by-L vector
`LambdaMinMSE`	`Lambda` value with the minimum MSE, a scalar
`Lambda1SE`	Largest `Lambda` value such that MSE is within one standard error of the minimum MSE, a scalar
`IndexMinMSE`	Index of `Lambda` with the value `LambdaMinMSE`, a scalar
`Index1SE`	Index of `Lambda` with the value `Lambda1SE`, a scalar

More About

Lasso

For a given value of λ, a nonnegative parameter, `lasso` solves the problem

$$\min_{\beta_0,\beta}\left(\frac{1}{2N}\sum_{i=1}^{N}\left(y_i-\beta_0-x_i^T\beta\right)^2+\lambda\sum_{j=1}^{p}\left|\beta_j\right|\right).$$

- N is the number of observations.
- y_i is the response at observation i.
- x_i is data, a vector of length p at observation i.
- λ is a nonnegative regularization parameter corresponding to one value of `Lambda`.
- The parameters β_0 and β are a scalar and a vector of length p, respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β, as contrasted with the elastic net algorithm.

Elastic Net

For α strictly between 0 and 1, and nonnegative λ, elastic net solves the problem

$$\min_{\beta_0,\beta}\left(\frac{1}{2N}\sum_{i=1}^{N}\left(y_i-\beta_0-x_i^T\beta\right)^2+\lambda P_\alpha(\beta)\right),$$

where

$$P_\alpha(\beta)=\frac{(1-\alpha)}{2}\|\beta\|_2^2+\alpha\|\beta\|_1=\sum_{j=1}^{p}\left(\frac{(1-\alpha)}{2}\beta_j^2+\alpha\left|\beta_j\right|\right).$$

Elastic net is the same as lasso when $\alpha = 1$. For other values of α, the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β. As α shrinks toward 0, elastic net approaches `ridge` regression.

Algorithms

ADMM Algorithm

When operating on tall arrays, `lasso` uses an algorithm based on the Alternating Direction Method of Multipliers (ADMM) [5]. The notation used here is the same as in the reference paper. This method solves problems of the form

Minimize $l(x) + g(z)$

Subject to $Ax + Bz = c$

Using this notation, the lasso regression problem is

Minimize $l(x)+g(z)=\frac{1}{2}\|Ax-b\|_2^2+\lambda\|z\|_1$

Subject to $x - z = 0$

Because the loss function $l(x)=\frac{1}{2}\|Ax-b\|_2^2$ is quadratic, the iterative updates performed by the algorithm amount to solving a linear system of equations with a single coefficient matrix but several right-hand sides. The updates performed by the algorithm during each iteration are

$$x^{k+1}=\left(A^TA+\rho I\right)^{-1}\left(A^Tb+\rho\left(z^k-u^k\right)\right)$$
$$z^{k+1}=S_{\lambda/\rho}\left(x^{k+1}+u^k\right)$$
$$u^{k+1}=u^k+x^{k+1}-z^{k+1}$$

A is the dataset (a tall array), x contains the coefficients, ρ is the penalty parameter (augmented Lagrangian parameter), b is the response (a tall array), and S is the soft thresholding operator.

$$S_\kappa(a)=\begin{cases}a-\kappa, & a>\kappa\\ 0, & |a|\le\kappa\\ a+\kappa, & a<\kappa\end{cases}.$$

`lasso` solves the linear system using Cholesky factorization because the coefficient matrix $A^TA+\rho I$ is symmetric and positive definite. Because ρ does not change between iterations, the Cholesky factorization is cached between iterations.

Even though A and b are tall arrays, they appear only in the terms A^TA and A^Tb. The results of these two matrix multiplications are small enough to fit in memory, so they are precomputed and the iterative updates between iterations are performed entirely within memory.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- With tall arrays, `lasso` uses an algorithm based on ADMM (Alternating Direction Method of Multipliers).
- No elastic net support. The `'Alpha'` parameter is always 1.
- No cross-validation (`'CV'` parameter) support, which includes the related parameter `'MCReps'`.
- The output `FitInfo` does not contain the additional fields `'SE'`, `'LambdaMinMSE'`, `'Lambda1SE'`, `'IndexMinMSE'`, and `'Index1SE'`.
- The `'Options'` parameter is not supported because it does not contain options that apply to the ADMM algorithm. You can tune the ADMM algorithm using name-value pair arguments.
- Supported name-value pair arguments are:
  - `'Lambda'`
  - `'LambdaRatio'`
  - `'NumLambda'`
  - `'Standardize'`
  - `'PredictorNames'`
  - `'RelTol'`
  - `'Weights'`
- Additional name-value pair arguments to control the ADMM algorithm are:

- `'Rho'` — Augmented Lagrangian parameter, ρ. The default value is automatic selection.
- `'AbsTol'` — Absolute tolerance used to determine convergence. The default value is `1e–4`.
- `'MaxIter'` — Maximum number of iterations. The default value is `1e4`.
- `'B0'` — Initial values for the coefficients x. The default value is a vector of zeros.
- `'U0'` — Initial values of the scaled dual variable u. The default value is a vector of zeros.

For more information, see “Tall Arrays”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2011b

lassoglm

Lasso or elastic net regularization for generalized linear models

Syntax

```
B = lassoglm(X,y)
B = lassoglm(X,y,distr)
B = lassoglm(X,y,distr,Name,Value)
[B,FitInfo] = lassoglm( ___ )
```

Description

`B = lassoglm(X,y)` returns penalized, maximum-likelihood fitted coefficients for generalized linear models of the predictor data `X` and the response `y`, where the values in `y` are assumed to have a normal probability distribution. Each column of `B` corresponds to a particular regularization coefficient in `Lambda`. By default, `lassoglm` performs lasso regularization using a geometric sequence of `Lambda` values.

`B = lassoglm(X,y,distr)` performs lasso regularization to fit the models using the probability distribution `distr` for `y`.

`B = lassoglm(X,y,distr,Name,Value)` fits regularized generalized linear regressions with additional options specified by one or more name-value pair arguments. For example, `'Alpha',0.5` sets elastic net as the regularization method, with the parameter `Alpha` equal to 0.5.

`[B,FitInfo] = lassoglm( ___ )` also returns the structure `FitInfo`, which contains information about the fit of the models, using any of the input arguments in the previous syntaxes.

Examples

Remove Redundant Predictors Using Lasso Regularization

Construct a data set with redundant predictors and identify those predictors by using `lassoglm`.

Create a random matrix `X` with 100 observations and 10 predictors. Create the normally distributed response `y` using only four of the predictors and a small amount of noise.

```
rng default
X = randn(100,10);
weights = [0.6;0.5;0.7;0.4];
y = X(:,[2 4 5 7])*weights + randn(100,1)*0.1; % Small added noise
```

Perform lasso regularization.

```
B = lassoglm(X,y);
```

Find the coefficient vector for the 75th `Lambda` value in `B`.

```
B(:,75)
```

```
ans = 10×1

         0
    0.5431
         0
    0.3944
    0.6173
         0
    0.3473
         0
         0
         0
```

`lassoglm` identifies and removes the redundant predictors.

Cross-Validated Lasso Regularization of Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors by using `lassoglm`.

Create data with 20 predictors. Create a Poisson response variable using only three of the predictors plus a constant.

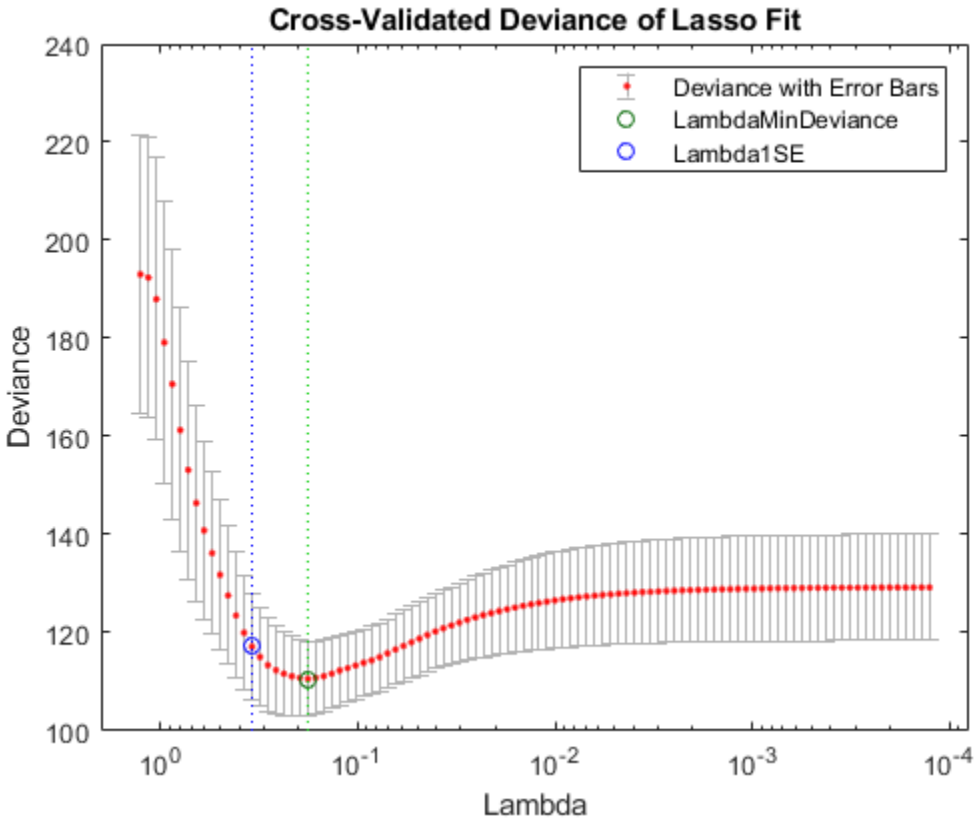
```
rng default % For reproducibility
X = randn(100,20);
weights = [.4;.2;.3];
mu = exp(X(:,[5 10 15])*weights + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```
[B,FitInfo] = lassoglm(X,y,'poisson','CV',10);
```

Examine the cross-validation plot to see the effect of the `Lambda` regularization parameter.

```
lassoPlot(B,FitInfo,'plottype','CV');
legend('show') % Show legend
```



The green circle and dotted line locate the `Lambda` with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```
idxLambdaMinDeviance = FitInfo.IndexMinDeviance;
mincoefs = find(B(:,idxLambdaMinDeviance))
```

```
mincoefs = 7×1

     3
     5
     6
    10
    11
    15
    16
```

```
idxLambda1SE = FitInfo.Index1SE;
min1coefs = find(B(:,idxLambda1SE))
```

```
min1coefs = 3×1

     5
    10
```

```
    15
```

The coefficients from the minimum-plus-one standard error point are exactly those coefficients used to create the data.

Predict Values Using Lasso Regularization

Predict whether students got a B or above on their last exam by using `lassoglm`.

Load the `examgrades` data set. Convert the last exam grades to a logical vector, where `1` represents a grade of 80 or above and `0` represents a grade below 80.

```
load examgrades
X = grades(:,1:4);
y = grades(:,5);
yBinom = (y>=80);
```

Partition the data into training and test sets.

```
rng default    % Set the seed for reproducibility
c = cvpartition(yBinom,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
XTrain = X(idxTrain,:);
yTrain = yBinom(idxTrain);
XTest = X(idxTest,:);
yTest = yBinom(idxTest);
```

Perform lasso regularization for generalized linear model regression with 3-fold cross-validation on the training data. Assume the values in `y` are binomially distributed. Choose model coefficients corresponding to the `Lambda` with minimum expected deviance.

```
[B,FitInfo] = lassoglm(XTrain,yTrain,'binomial','CV',3);
idxLambdaMinDeviance = FitInfo.IndexMinDeviance;
B0 = FitInfo.Intercept(idxLambdaMinDeviance);
coef = [B0; B(:,idxLambdaMinDeviance)]
```

```
coef = 5×1

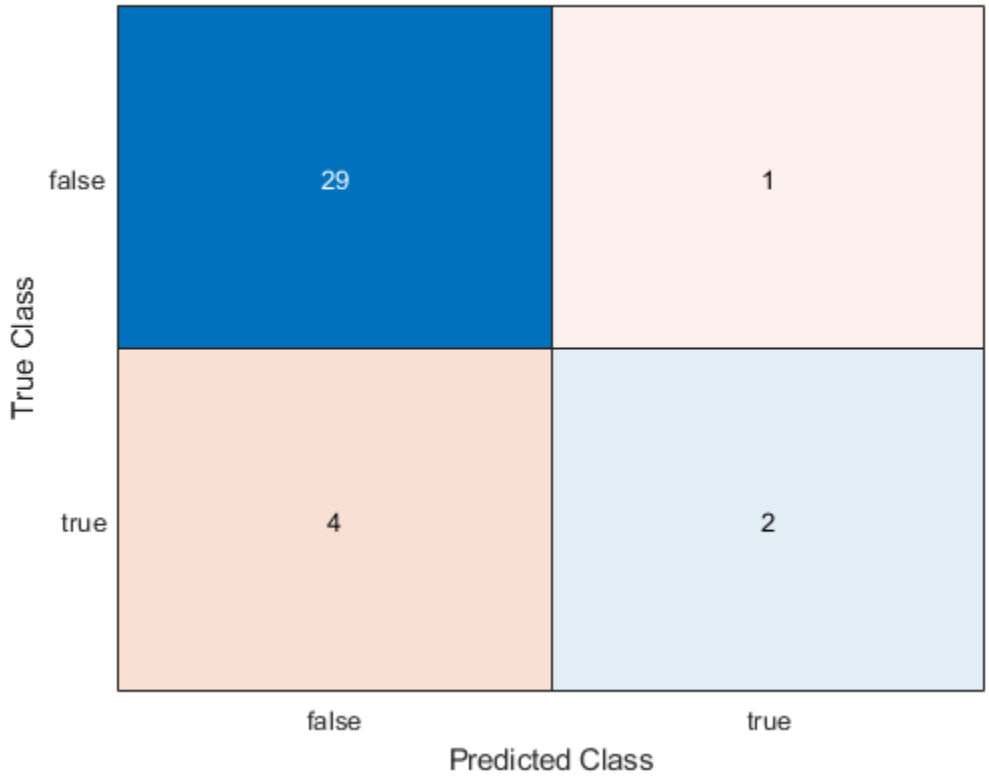
  -21.1911
    0.0235
    0.0670
    0.0693
    0.0949
```

Predict exam grades for the test data using the model coefficients found in the previous step. Specify the link function for a binomial response using `'logit'`. Convert the prediction values to a logical vector.

```
yhat = glmval(coef,XTest,'logit');
yhatBinom = (yhat>=0.5);
```

Determine the accuracy of the predictions using a confusion matrix.

```
c = confusionchart(yTest,yhatBinom);
```



The function correctly predicts 31 exam grades. However, the function incorrectly predicts that 1 student receives a B or above and 4 students receive a grade below a B.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row represents one observation, and each column represents one predictor variable.

Data Types: `single` | `double`

y — Response data

numeric vector | logical vector | categorical array | numeric matrix

Response data, specified as a numeric vector, logical vector, categorical array, or two-column numeric matrix.

- When `distr` is not `'binomial'`, `y` is a numeric vector or categorical array of length *n*, where *n* is the number of rows in `X`. The response `y(i)` corresponds to row *i* in `X`.
- When `distr` is `'binomial'`, `y` is one of the following:

- Numeric vector of length *n*, where each entry represents success (`1`) or failure (`0`)
- Logical vector of length *n*, where each entry represents success or failure
- Categorical array of length *n*, where each entry represents success or failure
- Two-column numeric matrix, where the first column contains the number of successes for each observation and the second column contains the total number of trials

Data Types: `single` | `double` | `logical` | `categorical`

`distr` — Distribution of response data
`'normal'` | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of response data, specified as one of the following:

- `'normal'`
- `'binomial'`
- `'poisson'`
- `'gamma'`
- `'inverse gaussian'`

`lassoglm` uses the default link function on page 33-3445 corresponding to `distr`. Specify another link function using the `Link` name-value pair argument.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `lassoglm(X,y,'poisson','Alpha',0.5)` performs elastic net regularization assuming that the response values are Poisson distributed. The `'Alpha',0.5` name-value pair argument sets the parameter used in the elastic net optimization.

`Alpha` — Weight of lasso versus ridge optimization
`1` (default) | positive scalar

Weight of lasso (L^1) versus ridge (L^2) optimization, specified as the comma-separated pair consisting of `'Alpha'` and a positive scalar value in the interval `(0,1]`. The value `Alpha = 1` represents lasso regression, `Alpha` close to `0` approaches ridge regression, and other values represent elastic net optimization. See “Elastic Net” on page 33-3446.

Example: `'Alpha',0.75`

Data Types: `single` | `double`

`CV` — Cross-validation specification for estimating deviance
`'resubstitution'` (default) | positive integer scalar | `cvpartition` object

Cross-validation specification for estimating the deviance, specified as the comma-separated pair consisting of `'CV'` and one of the following:

- `'resubstitution'` — `lassoglm` uses `X` and `y` to fit the model and to estimate the deviance without cross-validation.
- Positive scalar integer `K` — `lassoglm` uses `K`-fold cross-validation.

- `cvpartition` object `cvp` — `lassoglm` uses the cross-validation method expressed in `cvp`. You cannot use a `'leaveout'` partition with `lassoglm`.

Example: `'CV',10`

`DFmax` — Maximum number of nonzero coefficients
`Inf` (default) | positive integer scalar

Maximum number of nonzero coefficients in the model, specified as the comma-separated pair consisting of `'DFmax'` and a positive integer scalar. `lassoglm` returns results only for `Lambda` values that satisfy this criterion.

Example: `'DFmax',25`

Data Types: `single` | `double`

`Lambda` — Regularization coefficients
nonnegative vector

Regularization coefficients, specified as the comma-separated pair consisting of `'Lambda'` and a vector of nonnegative values. See “Lasso” on page 33-3446.

- If you do not supply `Lambda`, then `lassoglm` estimates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, then `lassoglm` ignores `LambdaRatio` and `NumLambda`.
- If `Standardize` is `true`, then `Lambda` is the set of values used to fit the models with the `X` data standardized to have zero mean and a variance of one.

The default is a geometric sequence of `NumLambda` values, with only the largest value able to produce `B = 0`.

Data Types: `single` | `double`

`LambdaRatio` — Ratio of smallest to largest `Lambda` values
`1e–4` (default) | positive scalar

Ratio of the smallest to the largest `Lambda` values when you do not supply `Lambda`, specified as the comma-separated pair consisting of `'LambdaRatio'` and a positive scalar.

If you set `LambdaRatio = 0`, then `lassoglm` generates a default sequence of `Lambda` values and replaces the smallest one with `0`.

Example: `'LambdaRatio',1e–2`

Data Types: `single` | `double`

`Link` — Mapping between mean of response and linear predictor
`'comploglog'` | `'identity'` | `'log'` | `'logit'` | `'loglog'` | ...

Mapping between the mean μ of the response and the linear predictor Xb, specified as the comma-separated pair consisting of `'Link'` and one of the values in this table.

Value	Description
`'comploglog'`	$\log(-\log((1 - \mu))) = Xb$

Value	Description
`'identity'`, default for the distribution `'normal'`	$\mu = Xb$
`'log'`, default for the distribution `'poisson'`	$\log(\mu) = Xb$
`'logit'`, default for the distribution `'binomial'`	$\log(\mu/(1 - \mu)) = Xb$
`'loglog'`	$\log(-\log(\mu)) = Xb$
`'probit'`	$\Phi^{-1}(\mu) = Xb$, where Φ is the normal (Gaussian) cumulative distribution function
`'reciprocal'`, default for the distribution `'gamma'`	$\mu^{-1} = Xb$
`p` (a number), default for the distribution `'inverse gaussian'` (with $p = -2$)	$\mu^p = Xb$
A cell array of the form `{FL FD FI}`, containing three function handles created using `@`, which define the link (`FL`), the derivative of the link (`FD`), and the inverse link (`FI`). Or, a structure of function handles with the field `Link` containing `FL`, the field `Derivative` containing `FD`, and the field `Inverse` containing `FI`.	User-specified link function (see "Custom Link Function" on page 12-12)

Example: `'Link','probit'`

Data Types: `char` | `string` | `single` | `double` | `cell`

`MaxIter` — Maximum number of iterations allowed
`1e4` (default) | positive integer scalar

Maximum number of iterations allowed, specified as the comma-separated pair consisting of `'MaxIter'` and a positive integer scalar.

If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance `RelTol`, then the function stops iterating and returns a warning message.

The function can return more than one warning when `NumLambda` is greater than `1`.

Example: `'MaxIter',1e3`

Data Types: `single` | `double`

`MCReps` — Number of Monte Carlo repetitions for cross-validation
`1` (default) | positive integer scalar

Number of Monte Carlo repetitions for cross-validation, specified as the comma-separated pair consisting of `'MCReps'` and a positive integer scalar.

- If `CV` is `'resubstitution'` or a `cvpartition` of type `'resubstitution'`, then `MCReps` must be `1`.
- If `CV` is a `cvpartition` of type `'holdout'`, then `MCReps` must be greater than `1`.

Example: `'MCReps',2`

Data Types: `single` | `double`

`NumLambda` — Number of Lambda values
`100` (default) | positive integer scalar

Number of `Lambda` values `lassoglm` uses when you do not supply `Lambda`, specified as the comma-separated pair consisting of `'NumLambda'` and a positive integer scalar. `lassoglm` can return fewer than `NumLambda` fits if the deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors `X`).

Example: `'NumLambda',150`

Data Types: `single` | `double`

`Offset` — Additional predictor variable
numeric vector

Additional predictor variable, specified as the comma-separated pair consisting of `'Offset'` and a numeric vector with the same number of rows as `X`. The `lassoglm` function keeps the coefficient value of `Offset` fixed at `1.0`.

Data Types: `single` | `double`

`Options` — Option to cross-validate in parallel and specify random streams
structure

Option to cross-validate in parallel and specify the random streams, specified as the comma-separated pair consisting of `'Options'` and a structure. This option requires Parallel Computing Toolbox.

Create the `Options` structure with `statset`. The option fields are:

- `UseParallel` — Set to `true` to compute in parallel. The default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. For reproducibility, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. The default is `false`.
- `Streams` — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, then `lassoglm` uses the default stream.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

`PredictorNames` — Names of predictor variables
`{}` (default) | string array | cell array of character vectors

Names of the predictor variables, in the order in which they appear in `X`, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array or cell array of character vectors.

Example: `'PredictorNames',{'Height','Weight','Age'}`

Data Types: `string` | `cell`

`RelTol` — Convergence threshold for coordinate descent algorithm
`1e–4` (default) | positive scalar

Convergence threshold for the coordinate descent algorithm [3], specified as the comma-separated pair consisting of `'RelTol'` and a positive scalar. The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Example: `'RelTol',2e–3`

Data Types: `single` | `double`

`Standardize` — Flag for standardizing predictor data before fitting models
`true` (default) | `false`

Flag for standardizing the predictor data `X` before fitting the models, specified as the comma-separated pair consisting of `'Standardize'` and either `true` or `false`. If `Standardize` is `true`, then the `X` data is scaled to have zero mean and a variance of one. `Standardize` affects whether the regularization is applied to the coefficients on the standardized scale or the original scale. The results are always presented on the original data scale.

Example: `'Standardize',false`

Data Types: `logical`

`Weights` — Observation weights
`1/n*ones(n,1)` (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a nonnegative vector. `Weights` has length *n*, where *n* is the number of rows of `X`. At least two values must be positive.

Data Types: `single` | `double`

Output Arguments

`B` — Fitted coefficients
numeric matrix

Fitted coefficients, returned as a numeric matrix. `B` is a *p*-by-*L* matrix, where *p* is the number of predictors (columns) in `X`, and *L* is the number of `Lambda` values. You can specify the number of `Lambda` values using the `NumLambda` name-value pair argument.

The coefficient corresponding to the intercept term is a field in `FitInfo`.

Data Types: `single` | `double`

`FitInfo` — Fit information of models
structure

Fit information of the generalized linear models, returned as a structure with the fields described in this table.

Field in `FitInfo`	Description
`Intercept`	Intercept term β_0 for each linear model, a `1`-by-*L* vector
`Lambda`	Lambda parameters in ascending order, a `1`-by-*L* vector
`Alpha`	Value of the `Alpha` parameter, a scalar

Field in FitInfo	Description
DF	Number of nonzero coefficients in B for each value of Lambda, a 1-by-*L* vector
Deviance	Deviance of the fitted model for each value of Lambda, a 1-by-*L* vector If the model is cross-validated, then the values for Deviance represent the estimated expected deviance of the model applied to new data, as calculated by cross-validation. Otherwise, Deviance is the deviance of the fitted model applied to the data used to perform the fit.
PredictorNames	Value of the PredictorNames parameter, stored as a cell array of character vectors

If you set the CV name-value pair argument to cross-validate, the FitInfo structure contains these additional fields.

Field in FitInfo	Description
SE	Standard error of Deviance for each Lambda, as calculated during cross-validation, a 1-by-*L* vector
LambdaMinDeviance	Lambda value with minimum expected deviance, as calculated by cross-validation, a scalar
Lambda1SE	Largest Lambda value such that Deviance is within one standard error of the minimum, a scalar
IndexMinDeviance	Index of Lambda with the value LambdaMinDeviance, a scalar
Index1SE	Index of Lambda with the value Lambda1SE, a scalar

More About

Link Function

A link function $f(\mu)$ maps a distribution with mean μ to a linear model with data X and coefficient vector b using the formula

$f(\mu) = Xb$.

You can find the formulas for the link functions in the Link name-value pair argument description. This table lists the link functions that are typically used for each distribution.

Distribution Family	Default Link Function	Other Typical Link Functions
'normal'	'identity'	
'binomial'	'logit'	'comploglog', 'loglog', 'probit'
'poisson'	'log'	
'gamma'	'reciprocal'	
'inverse gaussian'	–2	

Lasso

For a nonnegative value of λ, `lassoglm` solves the problem

$$\min_{\beta_0,\beta}\left(\frac{1}{N}\text{Deviance}(\beta_0,\beta)+\lambda\sum_{j=1}^{p}\left|\beta_j\right|\right).$$

- The function Deviance in this equation is the deviance of the model fit to the responses using the intercept β_0 and the predictor coefficients β. The formula for Deviance depends on the `distr` parameter you supply to `lassoglm`. Minimizing the λ-penalized deviance is equivalent to maximizing the λ-penalized loglikelihood.
- N is the number of observations.
- λ is a nonnegative regularization parameter corresponding to one value of `Lambda`.
- The parameters β_0 and β are a scalar and a vector of length p, respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β, as contrasted with the elastic net algorithm.

Elastic Net

For α strictly between 0 and 1, and nonnegative λ, elastic net solves the problem

$$\min_{\beta_0,\beta}\left(\frac{1}{N}\text{Deviance}(\beta_0,\beta)+\lambda P_\alpha(\beta)\right),$$

where

$$P_\alpha(\beta)=\frac{(1-\alpha)}{2}\|\beta\|_2^2+\alpha\|\beta\|_1=\sum_{j=1}^{p}\left(\frac{(1-\alpha)}{2}\beta_j^2+\alpha\left|\beta_j\right|\right).$$

Elastic net is the same as lasso when $\alpha = 1$. For other values of α, the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β. As α shrinks toward 0, elastic net approaches `ridge` regression.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

lassoPlot

Trace plot of lasso fit

Syntax

```
lassoPlot(B)
lassoPlot(B,FitInfo)
lassoPlot(B,FitInfo,Name,Value)
[ax,figh] = lassoPlot( ___ )
```

Description

`lassoPlot(B)` creates a trace plot of the values in `B` against the L^1 norm of `B`.

`lassoPlot(B,FitInfo)` creates a plot with type depending on the data type of `FitInfo` and the value, if any, of the `PlotType` name-value pair.

`lassoPlot(B,FitInfo,Name,Value)` creates a plot with additional options specified by one or more `Name,Value` pair arguments.

`[ax,figh] = lassoPlot( ___ )`, for any previous input syntax, returns a handle `ax` to the plot axis, and a handle `figh` to the figure window.

Input Arguments

`B`

Coefficients of a sequence of regression fits, as returned from the `lasso` or `lassoglm` functions. `B` is a `p`-by-`NLambda` matrix, where `p` is the number of predictors, and each column of `B` is a set of coefficients `lasso` calculates using one `Lambda` penalty value.

`FitInfo`

Information controlling the plot:

- `FitInfo` is a structure, especially as returned from `lasso` or `lassoglm` — `lassoPlot` creates a plot based on the `PlotType` name-value pair.
- `FitInfo` is a vector — `lassoPlot` forms the *x*-axis of the plot from the values in `FitInfo`. The length of `FitInfo` must equal the number of columns of `B`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Parent`

Axis in which to draw the plot.

Default: New plot

`PlotType`

Plot type when you specify a `FitInfo` vector or structure:

`PlotType`	Plot
`'L1'`	`lassoPlot` creates the *x*-axis from the L^1 norm of the coefficients in `B`. The *x*-axis at the top of the plot contains the degrees of freedom (`df`), meaning the number of nonzero coefficients of `B`.
`'Lambda'` When you choose this value, `FitInfo` must be a structure.	`lassoPlot` creates the *x*-axis from the `Lambda` field of `FitInfo`. The *x*-axis at the top of the plot contains the degrees of freedom (`df`), meaning the number of nonzero coefficients of `B`.
`'CV'` When you choose this value, `FitInfo` must be a cross-validated structure.	• For each `Lambda`, `lassoPlot` plots an estimate of the mean squared prediction error on new data for the model fitted by `lasso` with that value of `Lambda`. • `lassoPlot` plots error bars for the estimates.

If you include a cross-validated `FitInfo` structure, `lassoPlot` also indicates two specific `Lambda` values with green and blue dashed lines.

- A green, dashed line indicates the value of `Lambda` with a minimum cross-validated mean squared error (MSE).
- A blue, dashed line indicates the greatest `Lambda` that is within one standard error of the minimum MSE. This Lambda value makes the sparsest model with relatively low MSE.

To display the label for each plot in the legend of the figure, type `legend('show')` in the Command Window.

Default: `'L1'`

`PredictorNames`

String array or cell array of character vectors to label each coefficient of `B`. If the length of `PredictorNames` is less than the number of rows of `B`, the remaining labels are padded with default values.

`lassoPlot` uses `PredictorNames` in `FitInfo` only if:

- You created `FitInfo` with a call to `lasso` that included a `PredictorNames` name-value pair.
- You call `lassoPlot` *without* a `PredictorNames` name-value pair.
- You include `FitInfo` in your `lassoPlot` call.

For an example, see “Lasso Plot with Default Plot Type” on page 33-3450.

Default: `{'B1','B2',...}`

`XScale`

- `'linear'` for linear x-axis
- `'log'` for logarithmic scaled x-axis

Default: `'linear'`, except `'log'` for the `'CV'` plot type

Output Arguments

`ax`

Handle to the axis of the plot (see “Axes Appearance”).

`figh`

Handle to the figure window (see “Special Object Identifiers”).

Examples

Lasso Plot with Default Plot Type

Load the sample data

```
load acetylene
```

Prepare the design matrix for lasso fit with interactions.

```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
```

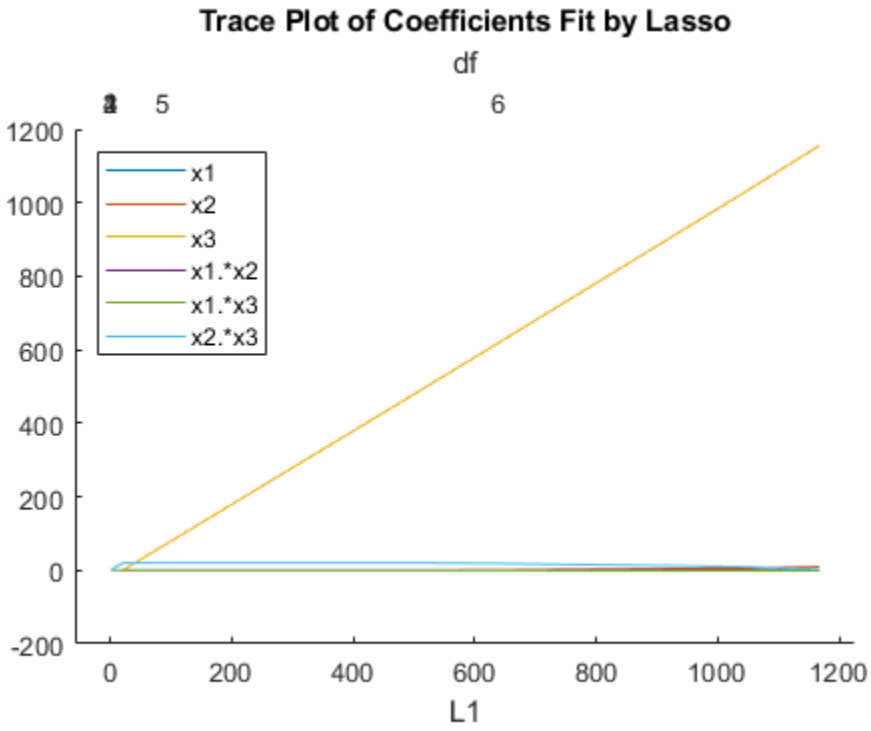
The `x2fx` function returns the quadratic model in the order of a constant term, linear terms and interaction terms: constant term, `x1`, `x2`, `x3`, `x1.*x2`, `x1.*x3`, and `x2.*x3`

Fit a regularized model of the data using `lasso`.

```
B = lasso(D,y);
```

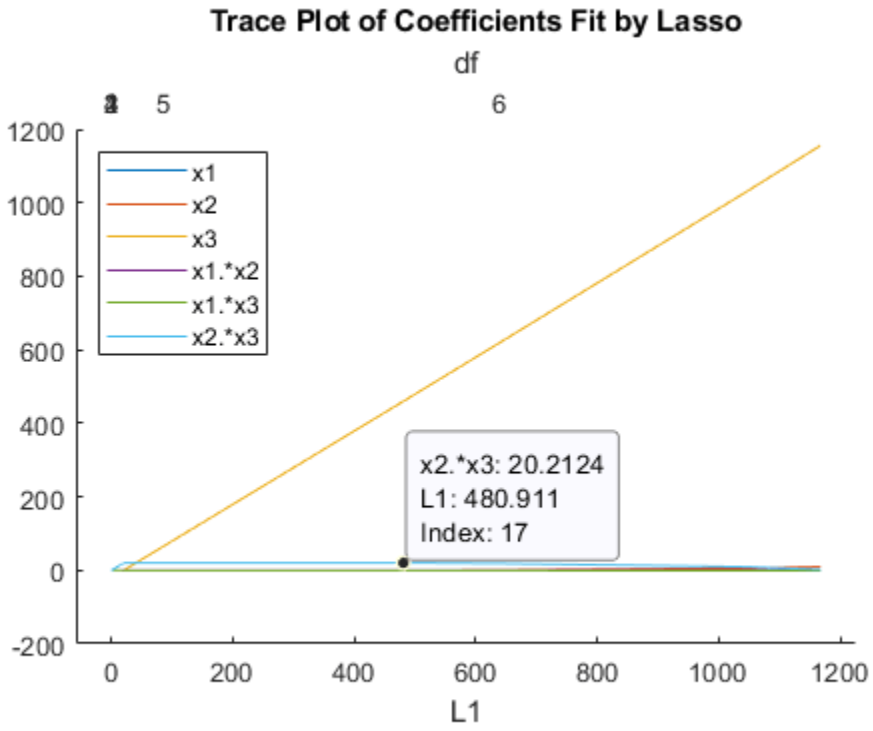
Plot the lasso fits with labeled coefficients by using the `PredictorNames` name-value pair.

```
lassoPlot(B,'PredictorNames',{'x1','x2','x3','x1.*x2','x1.*x3','x2.*x3'});
legend('show','Location','NorthWest') % Show legend
```



Each line represents a trace of the values in B for a single predictor variable: `x1`, `x2`, `x3`, `x1.*x2`, `x1.*x3`, and `x2.*x3`.

Display a data tip for the trace plot. A data tip appears when you hover over a data tip.



A data tip displays these lines of information: the name of the selected coefficient with a fitted value, the L1 norm of a set of coefficients including the selected coefficient, and the index of the corresponding Lambda.

Lasso Plot with Lambda Plot Type

Load the sample data.

```
load acetylene
```

Prepare the data for lasso fit with interactions.

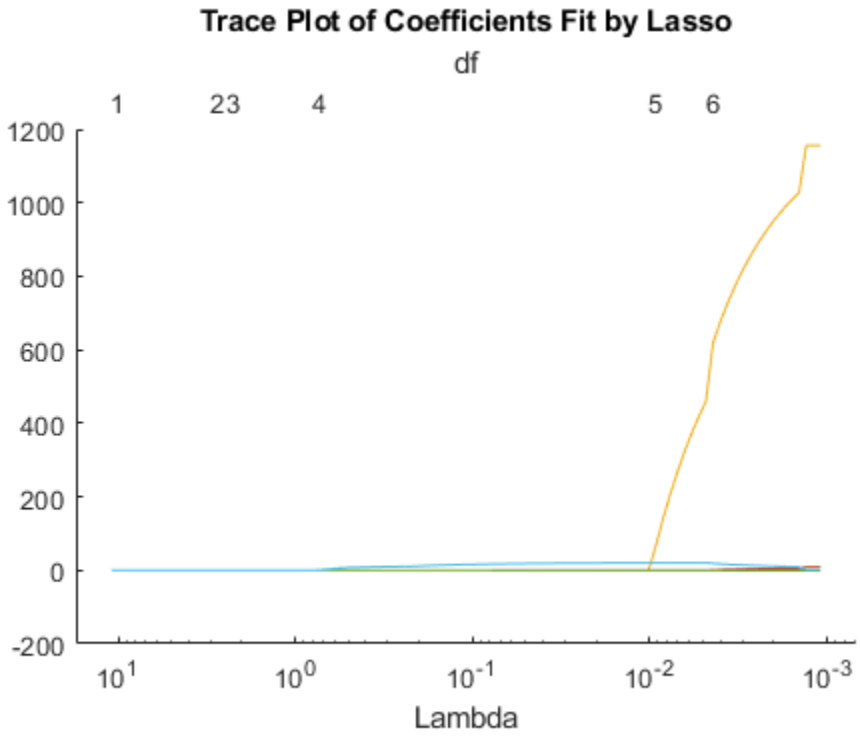
```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with `lasso`.

```
[B,FitInfo] = lasso(D,y);
```

Plot the fits with the `Lambda` plot type and logarithmic scaling.

```
lassoPlot(B,FitInfo,'PlotType','Lambda','XScale','log');
```



Lasso Plot with Cross-Validated Fits

Visually examine the cross-validated error of various levels of regularization.

Load the sample data.

```
load acetylene
```

Create a design matrix with interactions and no constant term.

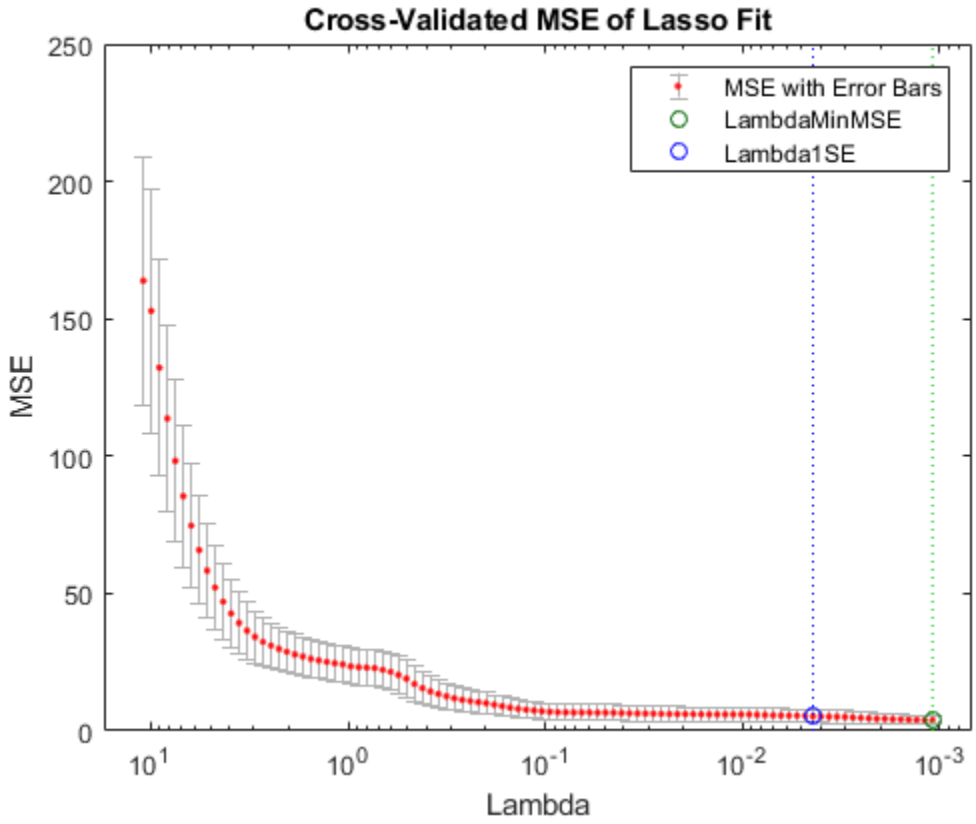
```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
```

Construct the lasso fit using 10-fold cross-validation. Include the `FitInfo` output so you can plot the result.

```
rng default % For reproducibility
[B,FitInfo] = lasso(D,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');
legend('show') % Show legend
```



The green circle and dotted line locate the `Lambda` with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Introduced in R2011b

le

Class: `qrandstream`

Less than or equal relation for handles

Syntax

```
h1 <= h2
```

Description

Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.

`h1 <= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = le(h1, h2)` stores the result in a logical array of the same dimensions.

learnerCoderConfigurer

Create coder configurer of machine learning model

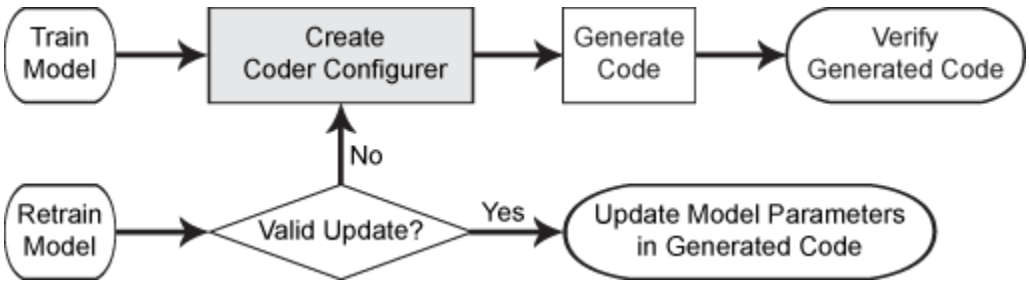
Syntax

```
configurer = learnerCoderConfigurer(Mdl,X)
configurer = learnerCoderConfigurer(Mdl,X,Name,Value)
```

Description

After training a machine learning model, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the object functions and properties of the configurer to specify code generation options and to generate C/C++ code for the `predict` and `update` functions of the machine learning model. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow using a coder configurer. Use `learnerCoderConfigurer` for the highlighted step.



`configurer = learnerCoderConfigurer(Mdl,X)` returns the coder configurer `configurer` for the machine learning model `Mdl`. Specify the predictor data `X` for the `predict` function of `Mdl`.

`configurer = learnerCoderConfigurer(Mdl,X,Name,Value)` returns a coder configurer with additional options specified by one or more name-value pair arguments. For example, you can specify the number of output arguments in the `predict` function, the file name of generated C/C++ code, and the verbosity level of the coder configurer.

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carsmall` data set and train a support vector machine (SVM) regression model.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

`Mdl` is a `RegressionSVM` object.

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)
```

```
configurer =
  RegressionSVMCoderConfigurer with properties:

   Update Inputs:
             Alpha: [1x1 LearnerCoderInput]
    SupportVectors: [1x1 LearnerCoderInput]
             Scale: [1x1 LearnerCoderInput]
              Bias: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]

   Code Generation Parameters:
        NumOutputs: 1
    OutputFileName: 'RegressionSVMModel'

  Properties, Methods
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
initialize('update',varargin{:});
end
```

```
type initialize.m
```

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                       SupportVectors
        %                       Scale
        %                       Bias
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end
```

Update Parameters of SVM Classification Model in Generated Code

Train a SVM model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`). Train a binary SVM classification model using the first 50 observations.

```
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `ClassificationSVM` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:),'NumOutputs',2);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 34 predictors, so the value of the `SizeVector` attribute must be 34 and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 34];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration constrai
```

```
configurer.SupportVectors.VariableDimensions = [true false];
```

```
VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.
VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration c
```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the

modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM classification model (`Mdl`) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'
Code generation successful.
```

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
   1
```

`isequal` returns logical 1 (`true`) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =

  0x1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance `1e–8`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score] = predict(retrainedMdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
isequal(label,label_mex)
```

```
ans = logical
   1
```

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =

  0x1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

Input Arguments

`Mdl` — Machine learning model

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in this table of supported models.

Model	Full/Compact Model Object	Training Function
Binary decision tree for multiclass classification	`ClassificationTree`, `CompactClassificationTree`	`fitctree`
SVM for one-class and binary classification	`ClassificationSVM`, `CompactClassificationSVM`	`fitcsvm`
Linear model for binary classification	`ClassificationLinear`	`fitclinear`

Model	Full/Compact Model Object	Training Function
Multiclass model for SVMs and linear models	`ClassificationECOC`, `CompactClassificationECOC`	`fitcecoc`
Binary decision tree for regression	`RegressionTree`, `CompactRegressionTree`	`fitrtree`
Support vector machine (SVM) regression	`RegressionSVM`, `CompactRegressionSVM`	`fitrsvm`
Linear regression	`RegressionLinear`	`fitrlinear`

For the code generation usage notes and limitations of a machine learning model, see the Code Generation section of the model object page.

`X` — Predictor data

numeric matrix

Predictor data for the `predict` function of `Mdl`, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictor variables. To instead specify `X` as a *p*-by-*n* matrix, where the observations correspond to columns, you must set the `'ObservationsIn'` name-value pair argument to `'columns'`. This option is available only for linear models and ECOC models with linear binary learners.

The `predict` function of a machine learning model predicts labels for classification and responses for regression for given predictor data. After creating the coder configurer `configurer`, you can use the `generateCode` function to generate C/C++ code for the `predict` function of `Mdl`. The generated code accepts predictor data that has the same size and data type of `X`. You can specify whether each dimension has a variable size or fixed size after creating `configurer`.

For example, if you want to generate C/C++ code that predicts labels using 100 observations with three predictor variables, then specify `X` as `zeros(100,3)`. The `learnerCoderConfigurer` function uses only the size and data type of `X`, not its values. Therefore, `X` can be predictor data or a MATLAB expression that represents the set of values with a certain data type. The output `configurer` stores the size and data type of `X` in the `X` property of `configurer`. You can modify the size and data type of `X` after creating `configurer`. For example, change the number of observations to 200 and the data type to `single`.

```
configurer.X.SizeVector = [200 3];
configurer.X.DataType = 'single';
```

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify `X` as `zeros(100,3)` and change the `VariableDimensions` property.

```
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

```
configurer.X.SizeVector = [Inf 3];
```

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2,'OutputFileName','myModel')` sets the number of outputs in `predict` to 2 and specifies the file name `'myModel'` for the generated C/C++ code.

`NumOutputs` — Number of outputs in `predict`

1 (default) | positive integer

Number of output arguments in the `predict` function of the machine learning model `Mdl`, specified as the comma-separated pair consisting of `'NumOutputs'` and a positive integer `n`.

This table lists the outputs for the `predict` function of different models. `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function in the order given in the Outputs column.

Model	`predict` Function of Model	Outputs
Binary decision tree for multiclass classification	`predict`	`label` (predicted class labels), `score` (posterior probabilities), `node` (node numbers for predicted classes), `cnum` (class numbers of predicted labels)
SVM for one-class and binary classification	`predict`	`label` (predicted class labels), `score` (scores or posterior probabilities)
Linear model for binary classification	`predict`	`Label` (predicted class labels), `Score` (classification scores)
Multiclass model for SVMs and linear models	`predict`	`label` (predicted class labels), `NegLoss` (negated average binary losses), `PBScore` (positive-class scores)
Binary decision tree for regression	`predict`	`Yfit` (predicted responses), `node` (node numbers for predictions)
SVM regression	`predict`	`yfit` (predicted responses)
Linear regression	`predict`	`YHat` (predicted responses)

For example, if you specify `'NumOutputs',1` for an SVM classification model, then `predict` returns predicted class labels in the generated C/C++ code.

After creating the coder configurer `configurer`, you can modify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The `'NumOutputs'` name-value pair argument is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` of a coder configurer generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively—and generates C/C++ code for the two entry-point functions. The specified value for `'NumOutputs'` corresponds to the number of output arguments in `predict.m`.

Example: `'NumOutputs',2`

Data Types: `single` | `double`

`OutputFileName` — File name of generated C/C++ code
`Mdl` object name plus `'Model'` (default) | character vector | string scalar

File name of the generated C/C++ code, specified as the comma-separated pair consisting of `'OutputFileName'` and a character vector or string scalar.

The object function `generateCode` of a coder configurer generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

The default file name is the object name of `Mdl` followed by `'Model'`. For example, if `Mdl` is a `CompactClassificationSVM` or `ClassificationSVM` object, then the default name is `'ClassificationSVMModel'`.

After creating the coder configurer `configurer`, you can modify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Example: `'OutputFileName','myModel'`

Data Types: `char` | `string`

`Verbose` — Verbosity level
`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line for the coder configurer `configurer`.

Value	Description
`true` (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
`false` (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Example: `'Verbose',false`

Data Types: `logical`

`ObservationsIn` — Predictor data observation dimension
`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and either `'rows'` or `'columns'`. If you set `'ObservationsIn'` to `'columns'`, then the predictor data `X` must be oriented so that the observations correspond to columns.

Note The `'columns'` option is available only for linear models and ECOC models with linear binary learners.

Example: `'ObservationsIn','columns'`

Output Arguments

`configurer` — Coder configurer
coder configurer object

Coder configurer of a machine learning model, returned as one of the coder configurer objects in this table.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	`ClassificationTreeCoderConfigurer`
SVM for one-class and binary classification	`ClassificationSVMCoderConfigurer`
Linear model for binary classification	`ClassificationLinearCoderConfigurer`
Multiclass model for SVMs and linear models	`ClassificationECOCCoderConfigurer`
Binary decision tree for regression	`RegressionTreeCoderConfigurer`
Support vector machine (SVM) regression	`RegressionSVMCoderConfigurer`
Linear regression	`RegressionLinearCoderConfigurer`

Use the object functions and properties of a coder configurer object to configure code generation options and to generate C/C++ code for the `predict` and `update` functions of the machine learning model.

Introduced in R2018b

length

Class: `dataset`

(Not Recommended) Length of dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
n = length(A)
```

Description

`n = length(A)` returns the number of observations in the dataset `A`. `length` is equivalent to `size(A,1)`.

See Also

`size`

levelcounts

(Not Recommended) Element counts by level of a nominal or ordinal array

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the "Categorical Arrays" data type instead.

Syntax

```
C = levelcounts(A)
C = levelcounts(A,dim)
```

Description

`C = levelcounts(A)` returns counts of the number of elements in the nominal or ordinal array `A` equal to each possible level in `A`.

- If `A` is a vector, then `C` is a vector containing as many elements as the number of levels in `A`.
- If `A` is a matrix, then `C` is a matrix of column counts.
- If `A` is an *N*-dimensional array, then `levelcounts` operates along the first nonsingleton dimension.

`C = levelcounts(A,dim)` operates along the dimension `dim`.

Examples

Count Observations in Each Level

Create a nominal array from data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
                 {'blue','green','red'})
```

```
colors = 3x3 nominal
     red        blue      green
     green      red       blue
     blue       red       green
```

Count the number of observations of each level in each column.

```
levelcounts(colors)
```

```
ans = 3×3

     1     1     1
     1     0     2
     1     2     0
```

Count the number of observations of each level in each row.

```
levelcounts(colors,2)
```

```
ans = 3×3

     1     1     1
     1     1     1
     1     1     1
```

Alternatively, you can use `summary` to display the counts with their labels. The default is to count elements in each column.

```
summary(colors)
```

```
     blue       1      1      1
     green      1      0      2
     red        1      2      0
```

You can also count elements in each row.

```
summary(colors,2)
```

```
     blue      green      red
     1         1          1
     1         1          1
     1         1          1
```

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

dim — Dimension along which to count

positive integer value

Dimension along which to count the number of elements in each level, specified as a positive integer value. For example, if the dimension is 1, then `levelcounts` counts along each column, while if the dimension is 2, then `levelcounts` counts along each row.

Data Types: `double` | `single`

`nominal` | `ordinal` | `summary`

Introduced in R2007a

leverage

Leverage

Syntax

```
h = leverage(data)
h = leverage(data,model)
```

Description

`h = leverage(data)` finds the leverage of each row (point) in the matrix `data` for a linear additive regression model.

`h = leverage(data,model)` finds the leverage on a regression, using a specified model type, where `model` can be one of the following:

- `'linear'` - includes constant and linear terms
- `'interaction'` - includes constant, linear, and cross product terms
- `'quadratic'` - includes interactions and squared terms
- `'purequadratic'` - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.

Examples

One rule of thumb is to compare the leverage to *2p/n* where *n* is the number of observations and *p* is the number of parameters in the model. For the Hald data set this value is 0.7692.

```
load hald
h = max(leverage(ingredients,'linear'))
h =
  0.7004
```

Since 0.7004 < 0.7692, there are no high leverage points using this rule.

Algorithms

```
[Q,R] = qr(x2fx(data,'model'),0);

leverage = (sum(Q'.*Q'))'
```

lhsdesign

Latin hypercube sample

Syntax

```
X = lhsdesign(n,p)
X = lhsdesign(n,p,Name,Value)
```

Description

`X = lhsdesign(n,p)` returns a Latin hypercube sample matrix of size `n`-by-`p`. For each column of `X`, the `n` values are randomly distributed with one from each interval `(0,1/n)`, `(1/n,2/n)`, ..., `(1 - 1/n,1)`, and randomly permuted.

`X = lhsdesign(n,p,Name,Value)` modifies the resulting design using one or more name-value pair arguments. For example, you can obtain a discrete design by specifying `'Smooth','off'`.

Examples

Create Latin Hypercube Sample

Create a Latin hypercube sample of 10 rows and 4 columns.

```
rng default % For reproducibility
X = lhsdesign(10,4)
```

```
X = 10×4

    0.1893    0.2569    0.0147    0.5583
    0.8038    0.1089    0.9378    0.1950
    0.5995    0.6818    0.3649    0.3097
    0.3225    0.8736    0.4487    0.8055
    0.9183    0.9854    0.1598    0.2509
    0.0131    0.3864    0.5924    0.7511
    0.7916    0.7131    0.2760    0.6662
    0.6600    0.5420    0.6877    0.9100
    0.2740    0.0450    0.7816    0.0631
    0.4200    0.4855    0.8760    0.4889
```

Each column of `X` contains one random number in each interval `[0,0.1]`, `[0.1,0.2]`, `[0.2,0.3]`, `[0.3,0.4]`, `[0.4,0.5]`, `[0.5,0.6]`, `[0.6,0.7]`, `[0.7,0.8]`, `[0.8,0.9]`, and `[0.9,1]`.

Latin Hypercube Design with Nondefault Options

Determine the effects of various name-value pair arguments in `lhsdesign`. Start with a default design for 10 rows and four columns.

```
rng default % For reproducibility
X = lhsdesign(10,4)
```

```
X = 10×4

    0.1893    0.2569    0.0147    0.5583
    0.8038    0.1089    0.9378    0.1950
    0.5995    0.6818    0.3649    0.3097
    0.3225    0.8736    0.4487    0.8055
    0.9183    0.9854    0.1598    0.2509
    0.0131    0.3864    0.5924    0.7511
    0.7916    0.7131    0.2760    0.6662
    0.6600    0.5420    0.6877    0.9100
    0.2740    0.0450    0.7816    0.0631
    0.4200    0.4855    0.8760    0.4889
```

To obtain a discrete design. as opposed to a continuous design, set the `'Smooth'` name-value pair argument to `'off'`.

```
rng default % For reproducibility
X = lhsdesign(10,4,'Smooth','off')
```

```
X = 10×4

    0.2500    0.3500    0.7500    0.8500
    0.1500    0.8500    0.2500    0.3500
    0.8500    0.7500    0.4500    0.7500
    0.9500    0.1500    0.6500    0.1500
    0.0500    0.0500    0.8500    0.9500
    0.4500    0.5500    0.9500    0.4500
    0.3500    0.9500    0.5500    0.0500
    0.5500    0.4500    0.0500    0.2500
    0.6500    0.6500    0.1500    0.6500
    0.7500    0.2500    0.3500    0.5500
```

The resulting design is discrete.

Calculate the sum of squares of the between-column correlations of the returned design.

```
y = corr(X);
(sum(y(:).^2) - 4)/2 % Subtract 4 to remove the diagonal terms of corr(X)
```

```
ans = 0.4874
```

Observe the effect of changing the `'Criterion'` name-value pair argument to `'correlation'`, which minimizes the sum of between-column squared correlations. The `'correlation'` criterion always gives a discrete design, as if `'Smooth'` is set to `'off'`.

```
rng default % For reproducibility
X = lhsdesign(10,4,'Criterion','correlation')
```

```
X = 10×4

    0.6500    0.0500    0.4500    0.7500
    0.2500    0.3500    0.0500    0.1500
    0.1500    0.9500    0.8500    0.4500
    0.8500    0.5500    0.9500    0.0500
```

```
    0.5500    0.2500    0.5500    0.3500
    0.3500    0.4500    0.7500    0.8500
    0.4500    0.1500    0.6500    0.6500
    0.0500    0.6500    0.2500    0.5500
    0.9500    0.8500    0.3500    0.9500
    0.7500    0.7500    0.1500    0.2500
```

```
y = corr(X);
(sum(y(:).^2) - 4)/2
```

```
ans = 0.0102
```

Minimizing the correlations results in a design with much lower sum of squared correlations.

Specify fewer iterations to improve the criterion.

```
rng default % For reproducibility
X = lhsdesign(10,4,'Criterion','correlation','Iterations',2)
```

```
X = 10×4
```

```
    0.6500    0.0500    0.4500    0.7500
    0.3500    0.3500    0.0500    0.1500
    0.1500    0.9500    0.8500    0.4500
    0.9500    0.5500    0.9500    0.0500
    0.5500    0.2500    0.5500    0.3500
    0.2500    0.4500    0.7500    0.8500
    0.4500    0.1500    0.6500    0.6500
    0.0500    0.6500    0.2500    0.5500
    0.8500    0.8500    0.3500    0.9500
    0.7500    0.7500    0.1500    0.2500
```

```
y = corr(X);
(sum(y(:).^2) - 4)/2
```

```
ans = 0.0328
```

Lowering the number of iterations results in a worse design (higher sum of squared correlations).

Input Arguments

n — Number of returned samples

positive integer

Number of returned samples, specified as a positive integer.

Example: 24

Data Types: `single` | `double`

p — Number of returned variables

positive integer

Number of returned variables, specified as a positive integer.

Example: 4

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `X = lhsdesign(n,p,'Smooth','off')` returns a discrete Latin hypercube design

`Smooth` — Indication for continuous samples

`'on'` (default) | `'off'`

Indication for continuous samples, specified as the comma-separated pair consisting of `'Smooth'` and `'on'` (continuous samples) or `'off'` (discrete samples). When this option is `'off'`, the returned values in each column of `X` are a random permutation of the values `0.5/n`, `1.5/n`, ..., `1 − 0.5/n`.

Example: `'Smooth','off'`

Data Types: `char` | `string`

`Criterion` — Criterion for iterative sample generation

`'maximin'` (default) | `'none'` | `'correlation'`

Criterion for iterative sample generation, specified as the comma-separated pair consisting of `'Criterion'` and `'maximin'`, `'none'`, or `'correlation'`. The algorithm uses up to `Iterations` tries to improve the criterion.

Note The `'correlation'` criterion gives discrete samples, as if `Smooth` is set to `'off'`.

Criterion	Description
`'maximin'`	Maximize the minimum distance between points.
`'correlation'`	Minimize the sum of between-column squared correlations.
`'none'`	No iteration

Example: `'Criterion','correlation'`

Data Types: `char` | `string`

`Iterations` — Maximum number of iterations to improve criterion

5 (default) | positive integer

Maximum number of iterations to improve `Criterion`, specified as the comma-separated pair consisting of `'Iterations'` and a positive integer. The algorithm uses up to `Iterations` tries to improve the criterion.

Example: `'Iterations',10`

Data Types: `single` | `double`

`haltonset` | `lhsnorm` | `sobolset` | `unifrnd`

Introduced before R2006a

lhsnorm

Latin hypercube sample from normal distribution

Syntax

```
X = lhsnorm(mu,sigma,n)
X = lhsnorm(mu,sigma,n,flag)
[X,Z] = lhsnorm(...)
```

Description

`X = lhsnorm(mu,sigma,n)` returns an *n*-by-*p* matrix, `X`, containing a Latin hypercube sample of size `n` from a *p*-dimensional multivariate normal distribution with mean vector, `mu`, and covariance matrix, `sigma`.

`X` is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.

`X = lhsnorm(mu,sigma,n,flag)` controls the amount of smoothing in the sample. If *`flag`* is `'off'`, each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values `G(0.5/n), G(1.5/n), ..., G(1-0.5/n)`, where `G` is the inverse normal cumulative distribution for that column's marginal distribution. If *`flag`* is `'on'` (the default), each column has points uniformly distributed on the probability scale. For example, in place of `0.5/n` you use a value having a uniform distribution on the interval `(0/n,1/n)`.

`[X,Z] = lhsnorm(...)` also returns `Z`, the original multivariate normal sample before the marginals are adjusted to obtain `X`.

References

[1] Stein, M. “Large sample properties of simulations using latin hypercube sampling.” *Technometrics*. Vol. 29, No. 2, 1987, pp. 143–151. Correction, Vol. 32, p. 367.

`lhsdesign` | `mvnrnd`

Introduced before R2006a

lillietest

Lilliefors test

Syntax

```
h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest( ___ )
[h,p,kstat,critval] = lillietest( ___ )
```

Description

`h = lillietest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, and `0` otherwise.

`h = lillietest(x,Name,Value)` returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the *p*-value using a Monte Carlo approximation.

`[h,p] = lillietest( ___ )` also returns the *p*-value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,kstat,critval] = lillietest( ___ )` also returns the test statistic `kstat` and the critical value `critval` for the test.

Examples

Test for Normal Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (`MPG`), follows a normal distribution across different makes of cars.

```
load carbig
[h,p,k,c] = lillietest(MPG)
```

```
Warning: P is less than the smallest tabulated value, returning 0.001.
```

```
h = 1
```

```
p = 1.0000e-03
```

```
k = 0.0789
```

```
c = 0.0451
```

The test statistic `k` is greater than the critical value `c`, so `lillietest` returns a result of `h = 1` to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates

that the returned *p*-value is less than the smallest value in the table of precomputed values. To find a more accurate *p*-value, use `MCTol` to run a Monte Carlo approximation. See “Determine the p-value Using Monte Carlo Approximation” on page 33-3480.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students’ exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

```
[h,p] = lillietest(x,'Alpha',0.01)
```

```
h = 0
```

```
p = 0.0348
```

The returned value of `h = 0` indicates that `lillietest` does not reject the null hypothesis at the 1% significance level.

Test for Exponential Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (`MPG`), follows an exponential distribution across different makes of cars.

```
load carbig
h = lillietest(MPG,'Distribution','exponential')
```

```
h = 1
```

The returned value of `h = 1` indicates that `lillietest` rejects the null hypothesis at the default 5% significance level.

Test for Weibull Distribution

Generate two sample data sets, one from a Weibull distribution and another from a lognormal distribution. Perform the Lilliefors test to assess whether each data set is from a Weibull distribution. Confirm the test decision by performing a visual comparison using a Weibull probability plot (`wblplot`).

Generate samples from a Weibull distribution.

```
rng('default')
data1 = wblrnd(0.5,2,[500,1]);
```

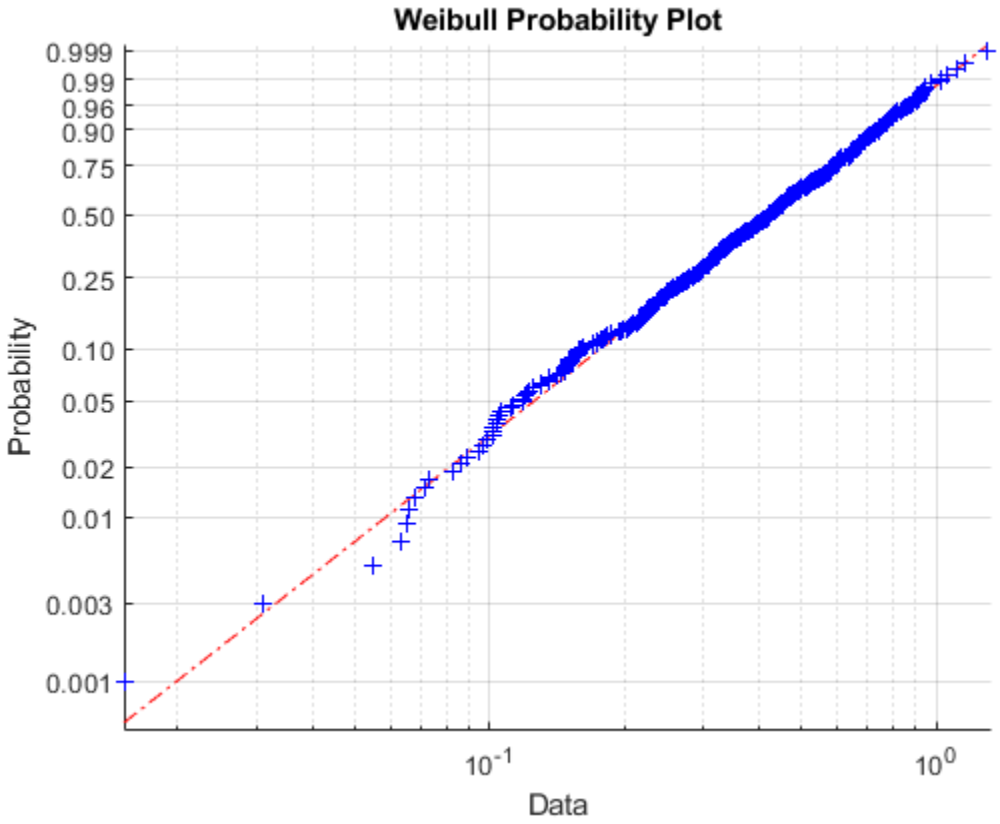
Perform the Lilliefors test by using the `lillietest`. To test data for a Weibull distribution, test if the logarithm of the data has an extreme value distribution.

```
h1 = lillietest(log(data1),'Distribution','extreme value')
```

```
h1 = 0
```

The returned value of `h1 = 0` indicates that `lillietest` fails to reject the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data1)
```



The plot indicates that the data follows a Weibull distribution.

Generate samples from a lognormal distribution.

```
data2 =lognrnd(5,2,[500,1]);
```

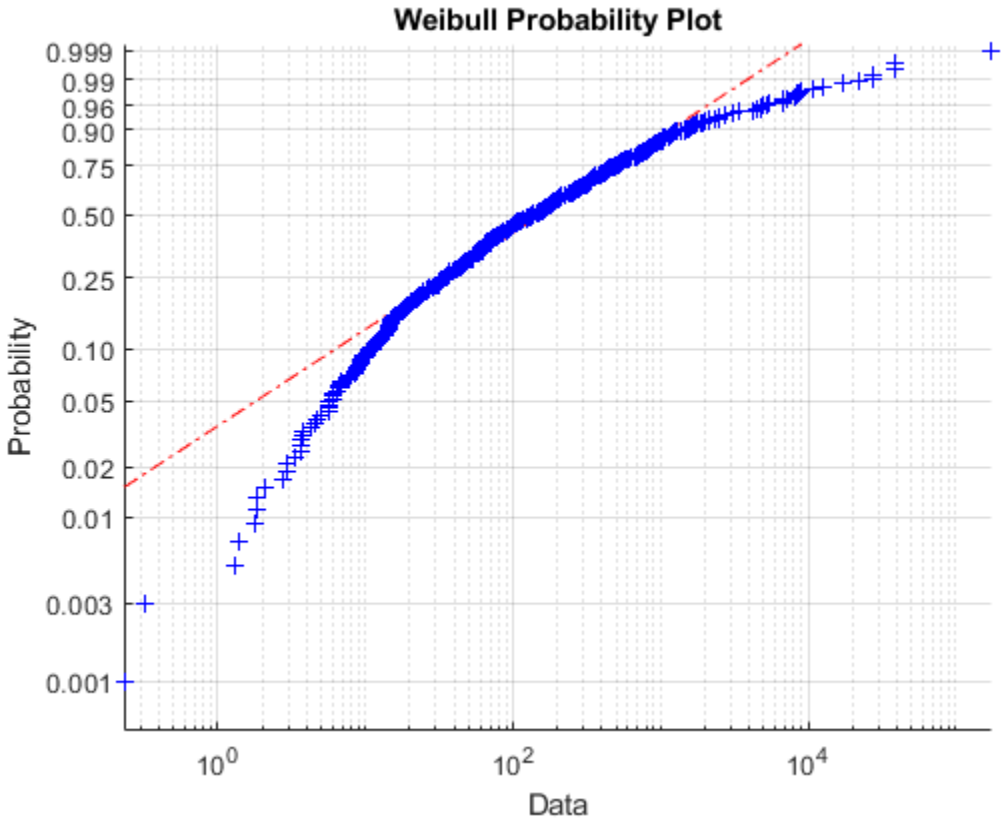
Perform the Lilliefors test.

```
h2 = lillietest(log(data2),'Distribution','extreme value')
```

```
h2 = 1
```

The returned value of `h2 = 1` indicates that `lillietest` rejects the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data2)
```



The plot indicates that the data does not follow a Weibull distribution.

Determine the p-value Using Monte Carlo Approximation

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (`MPG`), follows a normal distribution across different makes of cars. Determine the *p*-value using a Monte Carlo approximation with a maximum Monte Carlo standard error of `1e-4`.

```
load carbig
[h,p] = lillietest(MPG,'MCTol',1e-4)
```

```
h = 1
```

```
p = 8.3333e-06
```

The returned value of `h = 1` indicates that `lillietest` rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distribution','exponential','Alpha',0.01` tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

`Alpha` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

- If `MCTol` is not used, `Alpha` must be in the range [0.001,0.50].
- If `MCTol` is used, `Alpha` must be in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`Distribution` — Distribution family

`'normal'` (default) | `'exponential'` | `'extreme value'`

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of `'Distr'` and one of the following.

`'normal'`	Normal distribution
`'exponential'`	Exponential distribution
`'extreme value'`	Extreme value distribution

- To test `x` for a lognormal distribution, test if `log(x)` has a normal distribution.
- To test `x` for a Weibull distribution, test if `log(x)` has an extreme value distribution.

Example: `'Distribution','exponential'`

`MCTol` — Maximum Monte Carlo standard error

scalar value in the range (0,1)

Maximum Monte Carlo standard error on page 33-3483 for `p`, the *p*-value of the test, specified as the comma-separated pair consisting of `'MCTol'` and a scalar value in the range (0,1).

Example: `'MCTol',0.001`

Data Types: `single` | `double`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as `1` or `0`.

- If `h = 1`, this indicates the rejection of the null hypothesis at the `Alpha` significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the `Alpha` significance level.

p — *p*-value

scalar value in the range (0,1)

p-value of the test, returned as a scalar value in the range (0,1). `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

- If `MCTol` is not used, `p` is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. `lillietest` warns when `p` is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If `MCTol` is used, `lillietest` conducts a Monte Carlo simulation to compute a more accurate *p*-value, and `p` is returned as a scalar value in the range (0,1).

kstat — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

critval — Critical value

nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

More About

Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

$$D^* = \max_x \left| \widehat{F}(x) - G(x) \right|,$$

where $\widehat{F}(x)$ is the empirical cdf of the sample data and $G(x)$ is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

`lillietest` can be used to test whether the data vector `x` has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test `x` for a lognormal distribution, test if `log(x)` has a normal distribution.

- To test `x` for a Weibull distribution, test if `log(x)` has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the *p*-value.

The Monte Carlo standard error is calculated as:

$$SE = \sqrt{\frac{(\widehat{p})(1-\widehat{p})}{\text{mcreps}}},$$

where $\widehat{p}$ is the estimated *p*-value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, `mcreps`, is determined such that the Monte Carlo standard error for $\widehat{p}$ less than the value specified for `MCTol`.

Algorithms

To compute the critical value for the hypothesis test, `lillietest` interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by `lillietest` is larger and more accurate than the table originally introduced by Lilliefors. If a more accurate *p*-value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the `MCTol` input argument can be used to run a Monte Carlo simulation to calculate the *p*-value more exactly.

When the computed value of the test statistic is greater than the critical value, `lillietest` rejects the null hypothesis at significance level `Alpha`.

`lillietest` treats `NaN` values in `x` as missing values and ignores them.

lime

Local interpretable model-agnostic explanations (LIME)

Description

"LIME" on page 33-3505 explains a prediction of a machine learning model (classification or regression) for a query point by finding important predictors and fitting a simple interpretable model.

You can create a `lime` object for a machine learning model with a specified query point (`queryPoint`) and a specified number of important predictors (`numImportantPredictors`). The software generates a synthetic data set, and fits a simple interpretable model of important predictors that effectively explains the predictions for the synthetic data around the query point. The simple model can be a linear model (default) or decision tree model.

Use the fitted simple model to explain a prediction of the machine learning model locally, at the specified query point. Use the `plot` function to visualize the LIME results. Based on the local explanations, you can decide whether or not to trust the machine learning model.

Fit a new simple model for another query point by using the `fit` function.

Creation

Syntax

```
results = lime(blackbox)
results = lime(blackbox,X)
results = lime(blackbox,'CustomSyntheticData',customSyntheticData)

results = lime( ___ ,'QueryPoint',queryPoint,'NumImportantPredictors',
numImportantPredictors)

results = lime( ___ ,Name,Value)
```

Description

`results = lime(blackbox)` creates a `lime` object using a machine learning model object `blackbox` that contains predictor data. The `lime` function generates samples of a synthetic predictor data set and computes the predictions for the samples. To fit a simple model, use the `fit` function with `results`.

`results = lime(blackbox,X)` creates a `lime` object using the predictor data in `X`.

`results = lime(blackbox,'CustomSyntheticData',customSyntheticData)` creates a `lime` object using the pregenerated, custom synthetic predictor data set `customSyntheticData`. The `lime` function computes the predictions for the samples in `customSyntheticData`.

`results = lime( ___ ,'QueryPoint',queryPoint,'NumImportantPredictors', numImportantPredictors)` also finds the specified number of important predictors and fits a

linear simple model for the query point `queryPoint`. You can specify `queryPoint` and `numImportantPredictors` in addition to any of the input argument combinations in the previous syntaxes.

`results = lime( ___ ,Name,Value)` specifies additional options using one or more name-value arguments. For example, `'SimpleModelType','tree'` specifies the type of simple model as a decision tree model.

Input Arguments

`blackbox` — Machine learning model to be interpreted

regression model object | classification model object | function handle

Machine learning model to be interpreted, specified as a full or compact regression or classification model object or a function handle.

- Full or compact model object — You can specify a full or compact regression or classification model object, which has a `predict` object function. The software uses the `predict` function to compute the predictions for the query point and the synthetic predictor data set.
  - If you specify a model object that does not contain predictor data (for example, a compact model), then you must provide predictor data using `X` or `customSyntheticData`.
  - `lime` does not support a model object trained with a sparse matrix. When you train a model, use a full numeric matrix or table for the predictor data where rows correspond to individual observations.

  Regression Model Object

Supported Model	Full or Compact Regression Model Object
Ensemble of regression models	`RegressionEnsemble`, `RegressionBaggedEnsemble`, `CompactRegressionEnsemble`
Gaussian kernel regression model using random feature expansion	`RegressionKernel`
Gaussian process regression	`RegressionGP`, `CompactRegressionGP`
Generalized additive model	`RegressionGAM`, `CompactRegressionGAM`
Linear regression for high-dimensional data	`RegressionLinear`
Neural network regression model	`RegressionNeuralNetwork`, `CompactRegressionNeuralNetwork`
Regression tree	`RegressionTree`, `CompactRegressionTree`
Support vector machine regression	`RegressionSVM`, `CompactRegressionSVM`

Classification Model Object

Supported Model	Full or Compact Classification Model Object
Binary decision tree for multiclass classification	`ClassificationTree`, `CompactClassificationTree`
Discriminant analysis classifier	`ClassificationDiscriminant`, `CompactClassificationDiscriminant`
Ensemble of learners for classification	`ClassificationEnsemble`, `CompactClassificationEnsemble`, `ClassificationBaggedEnsemble`
Gaussian kernel classification model using random feature expansion	`ClassificationKernel`
Generalized additive model	`ClassificationGAM`, `CompactClassificationGAM`
k-nearest neighbor model	`ClassificationKNN`
Linear classification model	`ClassificationLinear`
Multiclass model for support vector machines or other classifiers	`ClassificationECOC`, `CompactClassificationECOC`
Naive Bayes model	`ClassificationNaiveBayes`, `CompactClassificationNaiveBayes`
Neural network classifier	`ClassificationNeuralNetwork`, `CompactClassificationNeuralNetwork`
Support vector machine for binary classification	`ClassificationSVM`, `CompactClassificationSVM`

- Function handle — You can specify a function handle that accepts predictor data and returns a column vector containing a prediction for each observation in the predictor data. The prediction is a predicted response for regression or a classified label for classification. You must provide the predictor data using `X` or `customSyntheticData` and specify the `'Type'` name-value argument.

`X` — Predictor data
numeric matrix | table

Predictor data, specified as a numeric matrix or table. Each row of `X` corresponds to one observation, and each column corresponds to one variable.

`X` must be consistent with the predictor data that trained `blackbox`, stored in `blackbox.X`. The specified value must not contain a response variable.

- `X` must have the same data types as the predictor variables (for example, `trainX`) that trained `blackbox`. The variables that make up the columns of `X` must have the same number and order as in `trainX`.
  - If you train `blackbox` using a numeric matrix, then `X` must be a numeric matrix.
  - If you train `blackbox` using a table, then `X` must be a table. All predictor variables in `X` must have the same variable names and data types as in `trainX`.
- `lime` does not support a sparse matrix.

If `blackbox` is a model object that does not contain predictor data or a function handle, you must provide `X` or `customSyntheticData`. If `blackbox` is a full machine learning model object and you specify this argument, then `lime` does not use the predictor data in `blackbox`. It uses the specified predictor data only.

Data Types: `single` | `double` | `table`

`customSyntheticData` — Pregenerated, custom synthetic predictor data set
`[]` (default) | numeric matrix | table

Pregenerated, custom synthetic predictor data set, specified as a numeric matrix or table.

If you provide a pregenerated data set, then `lime` uses the provided data set instead of generating a new synthetic predictor data set.

`customSyntheticData` must be consistent with the predictor data that trained `blackbox`, stored in `blackbox.X`. The specified value must not contain a response variable.

- `customSyntheticData` must have the same data types as the predictor variables (for example, `trainX`) that trained `blackbox`. The variables that make up the columns of `customSyntheticData` must have the same number and order as in `trainX`
  - If you train `blackbox` using a numeric matrix, then `customSyntheticData` must be a numeric matrix.
  - If you train `blackbox` using a table, then `customSyntheticData` must be a table. All predictor variables in `customSyntheticData` must have the same variable names and data types as in `trainX`.
- `lime` does not support a sparse matrix.

If `blackbox` is a model object that does not contain predictor data or a function handle, you must provide `X` or `customSyntheticData`. If `blackbox` is a full machine learning model object and you specify this argument, then `lime` does not use the predictor data in `blackbox`; it uses the specified predictor data only.

Data Types: `single` | `double` | `table`

`queryPoint` — Query point
row vector of numeric values | single-row table

Query point at which `lime` explains a prediction, specified as a row vector of numeric values or a single-row table. `queryPoint` must have the same data type and number of columns as `X`, `customSyntheticData`, or the predictor data in `blackbox`.

If you specify `numImportantPredictors` and `queryPoint`, then the `lime` function fits a simple model when creating a `lime` object.

`queryPoint` must not contain missing values.

Example: `blackbox.X(1,:)` specifies the query point as the first observation of the predictor data in the full machine learning model `blackbox`.

Data Types: `single` | `double` | `table`

`numImportantPredictors` — Number of important predictors to use in simple model
positive integer scalar value

Number of important predictors to use in the simple model, specified as a positive integer scalar value.

- If `'SimpleModelType'` is `'linear'`, then the software selects the specified number of important predictors and fits a linear model of the selected predictors.
- If `'SimpleModelType'` is `'tree'`, then the software specifies the maximum number of decision splits (or branch nodes) as the number of important predictors so that the fitted decision tree uses at most the specified number of predictors.

If you specify `numImportantPredictors` and `queryPoint`, then the `lime` function fits a simple model when creating a `lime` object.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `lime(blackbox,'QueryPoint',q,'NumImportantPredictors',n,'SimpleModelType','tree')` specifies the query point as `q`, the number of important predictors to use for the simple model as `n`, and the type of simple model as a decision tree model. `lime` generates samples of a synthetic predictor data set, computes the predictions for the samples, and fits a decision tree model for the query point using at most the specified number of predictors.

Options for Synthetic Predictor Data

`DataLocality` — Locality of synthetic data for data generation
`'global'` (default) | `'local'`

Locality of the synthetic data for data generation, specified as the comma-separated pair consisting of `'DataLocality'` and `'global'` or `'local'`.

- `'global'` — The software estimates distribution parameters using the whole predictor data set (`X` or the predictor data in `blackbox`). The software generates a synthetic predictor data set with the estimated parameters and uses the data set for simple model fitting of any query point.
- `'local'` — The software estimates the distribution parameters using the *k*-nearest neighbors of a query point, where *k* is the `'NumNeighbors'` value. The software generates a new synthetic predictor data set each time it fits a simple model for the specified query point.

For more details, see “LIME” on page 33-3505.

Example: `'DataLocality','local'`

Data Types: `char` | `string`

`NumNeighbors` — Number of neighbors of query point
1500 (default) | positive integer scalar value

Number of neighbors of the query point, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer scalar value. This argument is valid only when `'DataLocality'` is `'local'`.

If you specify a value larger than the number of observations in the predictor data set (`X` or the predictor data in `blackbox`), then `lime` uses all observations.

Example: `'NumNeighbors',2000`

Data Types: `single` | `double`

`NumSyntheticData` — Number of samples to generate for synthetic data set

5000 (default) | positive integer scalar value

Number of samples to generate for the synthetic data set, specified as the comma-separated pair consisting of `'NumSyntheticData'` and a positive integer scalar value. This argument is valid only when `'DataLocality'` is `'local'`.

Example: `'NumSyntheticData',2500`

Data Types: `single` | `double`

Options for Simple Model

`KernelWidth` — Kernel width

0.75 (default) | numeric scalar value

Kernel width of the squared exponential (or Gaussian) kernel function, specified as the comma-separated pair consisting of `'KernelWidth'` and a numeric scalar value.

The `lime` function computes distances between the query point and the samples in the synthetic predictor data set, and then converts the distances to weights by using the squared exponential kernel function. If you lower the `'KernelWidth'` value, then `lime` uses weights that are more focused on the samples near the query point. For details, see “LIME” on page 33-3505.

Example: `'KernelWidth',0.5`

Data Types: `single` | `double`

`SimpleModelType` — Type of simple model

`'linear'` (default) | `'tree'`

Type of the simple model, specified as the comma-separated pair consisting of `'SimpleModelType'` and `'linear'` or `'tree'`.

- `'linear'` — The software fits a linear model by using `fitrlinear` for regression or `fitclinear` for classification.
- `'tree'` — The software fits a decision tree model by using `fitrtree` for regression or `fitctree` for classification.

Example: `'SimpleModelType','tree'`

Data Types: `char` | `string`

Options for Machine Learning Model

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `blackbox` uses a subset of input variables as predictors, then the software indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the variable names of the predictor data in the form of a table. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the variable names of the predictor data in the form of a table.
`'all'`	All predictors are categorical.

- If you specify `blackbox` as a function handle, then `lime` identifies categorical predictors from the predictor data `X` or `customSyntheticData`. If the predictor data is in a table, `lime` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix, `lime` assumes that all predictors are continuous.
- If you specify `blackbox` as a regression or classification model object, then `lime` identifies categorical predictors by using the `CategoricalPredictors` property of the model object.

`lime` does not support an ordered categorical predictor.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

Type — Type of machine learning model
`'regression'` | `'classification'`

Type of the machine learning model, specified as the comma-separated pair consisting of `'Type'` and `'regression` or `'classification'`.

You must specify this argument when you specify `blackbox` as a function handle. If you specify `blackbox` as a regression or classification model object, then `lime` determines the `'Type'` value depending on the model type.

Example: `'Type','classification'`

Data Types: `char` | `string`

Options for Computing Distances

`Distance` — Distance metric
character vector | string scalar | function handle

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a character vector, string scalar, or function handle.

- If the predictor data includes only continuous variables, then `lime` supports these distance metrics.

Value	Description
`'euclidean'`	Euclidean distance.
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, `S = std(PD,'omitnan')`, where `PD` is the predictor data or synthetic predictor data. To specify different scaling, use the `'Scale'` name-value argument.
`'mahalanobis'`	Mahalanobis distance using the sample covariance of `PD`, `C = cov(PD,'omitrows')`. To change the value of the covariance matrix, use the `'Cov'` name-value argument.
`'cityblock'`	City block distance.
`'minkowski'`	Minkowski distance. The default exponent is 2. To specify a different exponent, use the `'P'` name-value argument.
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors).
`'correlation'`	One minus the sample correlation between points (treated as sequences of values).
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

`@`*`distfun`*	Custom distance function handle. A distance function has the form
	`function D2 = distfun(ZI,ZJ)`
	`% calculation of distance`
	`...`
	where
	• `ZI` is a `1`-by-`t` vector containing a single observation.
	• `ZJ` is an `s`-by-`t` matrix containing multiple observations. `distfun` must accept a matrix `ZJ` with an arbitrary number of observations.
	• `D2` is an `s`-by-`1` vector of distances, and `D2(k)` is the distance between observations `ZI` and `ZJ(k,:)`.
	If your data is not sparse, you can generally compute distance more quickly by using a built-in distance metric instead of a function handle.

- If the predictor data includes both continuous and categorical variables, then `lime` supports these distance metrics.

Value	Description
`'goodall3'`	Modified Goodall distance

Value	Description
'ofd'	Occurrence frequency distance

For definitions, see “Distance Metrics” on page 33-3503.

The default value is 'euclidean' if the predictor data includes only continuous variables, or 'goodall3' if the predictor data includes both continuous and categorical variables.

Example: 'Distance','ofd'

Data Types: char | string | function_handle

Cov — Covariance matrix for Mahalanobis distance metric
positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a *K*-by-*K* positive definite matrix, where *K* is the number of predictors.

This argument is valid only if 'Distance' is 'mahalanobis'.

The default 'Cov' value is cov(PD,'omitrows'), where PD is the predictor data or synthetic predictor data. If you do not specify the 'Cov' value, then the software uses different covariance matrices when computing the distances for both the predictor data and the synthetic predictor data.

Example: 'Cov',eye(3)

Data Types: single | double

P — Exponent for Minkowski distance metric
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar.

This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

Scale — Scale parameter value for standardized Euclidean distance metric
nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector of length *K*, where *K* is the number of predictors.

This argument is valid only if 'Distance' is 'seuclidean'.

The default 'Scale' value is std(PD,'omitnan'), where PD is the predictor data or synthetic predictor data. If you do not specify the 'Scale' value, then the software uses different scale parameters when computing the distances for both the predictor data and the synthetic predictor data.

Example: 'Scale',quantile(X,0.75) - quantile(X,0.25)

Data Types: single | double

Properties

Specified Properties

You can specify the following properties when creating a `lime` object.

`BlackboxModel` — Machine learning model to be interpreted
regression model object | classification model object | function handle

This property is read-only.

Machine learning model to be interpreted, specified as a regression or classification model object or a function handle.

The `blackbox` argument sets this property.

`CategoricalPredictors` — Categorical predictor indices
vector of positive integers | `[]`

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

- If you specify `blackbox` using a function handle, then `lime` identifies categorical predictors from the predictor data `X` or `customSyntheticData`. If you specify the `'CategoricalPredictors'` name-value argument, then the argument sets this property.
- If you specify `blackbox` as a regression or classification model object, then `lime` determines this property by using the `CategoricalPredictors` property of the model object.

`lime` does not support an ordered categorical predictor.

If `'SimpleModelType'` is `'linear'`(default), then `lime` creates dummy variables for each identified categorical predictor. `lime` treats the category of the specified query point as a reference group and creates one less dummy variable than the number of categories. For more details, see “Dummy Variables with Reference Group” on page 2-48.

Data Types: `single` | `double`

`DataLocality` — Locality of synthetic data for data generation
`'global'` | `'local'`

This property is read-only.

Locality of the synthetic data for data generation, specified as `'global'` or `'local'`.

The `'DataLocality'` name-value argument sets this property.

`NumImportantPredictors` — Number of important predictors to use in simple model
positive integer scalar value

This property is read-only.

Number of important predictors to use in the simple model (`SimpleModel`), specified as a positive integer scalar value.

The `numImportantPredictors` argument of `lime` or the `numImportantPredictors` argument of `fit` sets this property.

Data Types: `single` | `double`

`NumSyntheticData` — Number of samples in synthetic data set
positive integer scalar value

This property is read-only.

Number of samples in the synthetic data set, specified as a positive integer scalar value.

- If you specify `customSyntheticData`, then the number of samples in the custom synthetic data set sets this property.
- Otherwise, the `'NumSyntheticData'` name-value argument of `lime` or the `'NumSyntheticData'` name-value argument of `fit` sets this property.

Data Types: `single` | `double`

`QueryPoint` — Query point
row vector of numeric values | single-row table

This property is read-only.

Query point at which `lime` explains a prediction using the simple model (`SimpleModel`), specified as a row vector of numeric values or single-row table.

The `queryPoint` argument of `lime` or the `queryPoint` argument of `fit` sets this property.

Data Types: `single` | `double` | `table`

`Type` — Type of machine learning model
`'regression'` | `'classification'`

This property is read-only.

Type of the machine learning model (`BlackboxModel`), specified as `'regression` or `'classification'`.

- If you specify `blackbox` as a regression or classification model object, then `lime` determines this property depending on the model type.
- If you specify `blackbox` using a function handle, then the `'Type'` name-value argument sets this property.

`X` — Predictor data
numeric matrix | table

This property is read-only.

Predictor data, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- If you specify the `X` argument, then the argument sets this property.
- If you specify the `customSyntheticData` argument, then this property is empty.

- If you specify `blackbox` as a full machine learning model object and do not specify `X` or `customSyntheticData`, then this property value is the predictor data used to train `blackbox`.

`lime` does not use rows that contain missing values and does not store the rows in `X`.

Data Types: `single` | `double` | `table`

Computed Properties

The software computes the following properties.

`BlackboxFitted` — Prediction for query point computed by machine learning model
scalar

This property is read-only.

Prediction for the query point computed by the machine learning model (`BlackboxModel`), specified as a scalar. The prediction is a predicted response for regression or a classified label for classification.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`Fitted` — Predictions for synthetic predictor data computed by machine learning model
vector

This property is read-only.

Predictions for synthetic predictor data computed by the machine learning model (`BlackboxModel`), specified as a vector.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`ImportantPredictors` — Important predictor indices
vector of positive integers

This property is read-only.

Important predictor indices, specified as a vector of positive integers. `ImportantPredictors` contains the index values corresponding to the columns of the predictors used in the simple model (`SimpleModel`).

Data Types: `single` | `double`

`SimpleModel` — Simple model
`RegressionLinear` model object | `RegressionTree` model object | `ClassificationLinear` model object | `ClassificationTree` model object

This property is read-only.

Simple model, specified as a `RegressionLinear`, `RegressionTree`, `ClassificationLinear`, or `ClassificationTree` model object. `lime` determines the type of simple model object depending on the type of the machine learning model (`Type`) and the type of the simple model (`'SimpleModelType'`).

`SimpleModelFitted` — Prediction for query point computed by simple model
scalar

This property is read-only.

Prediction for the query point computed by the simple model (`SimpleModel`), specified as a scalar.

If `SimpleModel` is `ClassificationLinear`, then the `SimpleModelFitted` value is 1 or –1.

- The `SimpleModelFitted` value is 1 if the prediction from the simple model is the same as `BlackboxFitted` (prediction from the machine learning model).
- The `SimpleModelFitted` value is –1 if the prediction from the simple model is different from `BlackboxFitted`. If the `BlackboxFitted` value is `A`, then the `plot` function displays the `SimpleModelFitted` value as `Not A`.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`SyntheticData` — Synthetic predictor data
numeric matrix | table

This property is read-only.

Synthetic predictor data, specified as a numeric matrix or a table.

- If you specify the `customSyntheticData` input argument, then the argument sets this property.
- Otherwise, `lime` estimates distribution parameters from the predictor data `X` and generates a synthetic predictor data set.

Data Types: `single` | `double` | `table`

Object Functions

fit Fit simple model of local interpretable model-agnostic explanations (LIME)
plot Plot results of local interpretable model-agnostic explanations (LIME)

Examples

Explain Prediction with Decision Tree Simple Model

Train a classification model and create a `lime` object that uses a decision tree simple model. When you create a `lime` object, specify a query point and the number of important predictors so that the software generates samples of a synthetic data set and fits a simple model for the query point with important predictors. Then display the estimated predictor importance in the simple model by using the object function `plot`.

Load the `CreditRating_Historical` data set. The data set contains customer IDs and their financial ratios, industry labels, and credit ratings.

```
tbl = readtable('CreditRating_Historical.dat');
```

Display the first three rows of the table.

```
head(tbl,3)
```

```
ans=3×8 table
     ID      WC_TA    RE_TA    EBIT_TA    MVE_BVTD    S_TA     Industry    Rating
    _____    _____    _____    _______    ________    _____    _________    ______
```

```
    62394    0.013    0.104     0.036      0.447      0.142       3        {'BB'}
    48608    0.232    0.335     0.062      1.969      0.281       8        {'A' }
    42444    0.311    0.367     0.074      1.935      0.366       1        {'A' }
```

Create a table of predictor variables by removing the columns of customer IDs and ratings from `tbl`.

```
tblX = removevars(tbl,["ID","Rating"]);
```

Train a blackbox model of credit ratings by using the `fitcecoc` function.

```
blackbox = fitcecoc(tblX,tbl.Rating,'CategoricalPredictors','Industry');
```

Create a `lime` object that explains the prediction for the last observation using a decision tree simple model. Specify `'NumImportantPredictors'` as six to find at most 6 important predictors. If you specify the `'QueryPoint'` and `'NumImportantPredictors'` values when you create a `lime` object, then the software generates samples of a synthetic data set and fits a simple interpretable model to the synthetic data set.

```
queryPoint = tblX(end,:)
```

```
queryPoint=1×6 table
    WC_TA    RE_TA    EBIT_TA    MVE_BVTD    S_TA    Industry
    _____    _____    _______    ________    ____    ________

    0.239    0.463     0.065      2.924      0.34       2
```

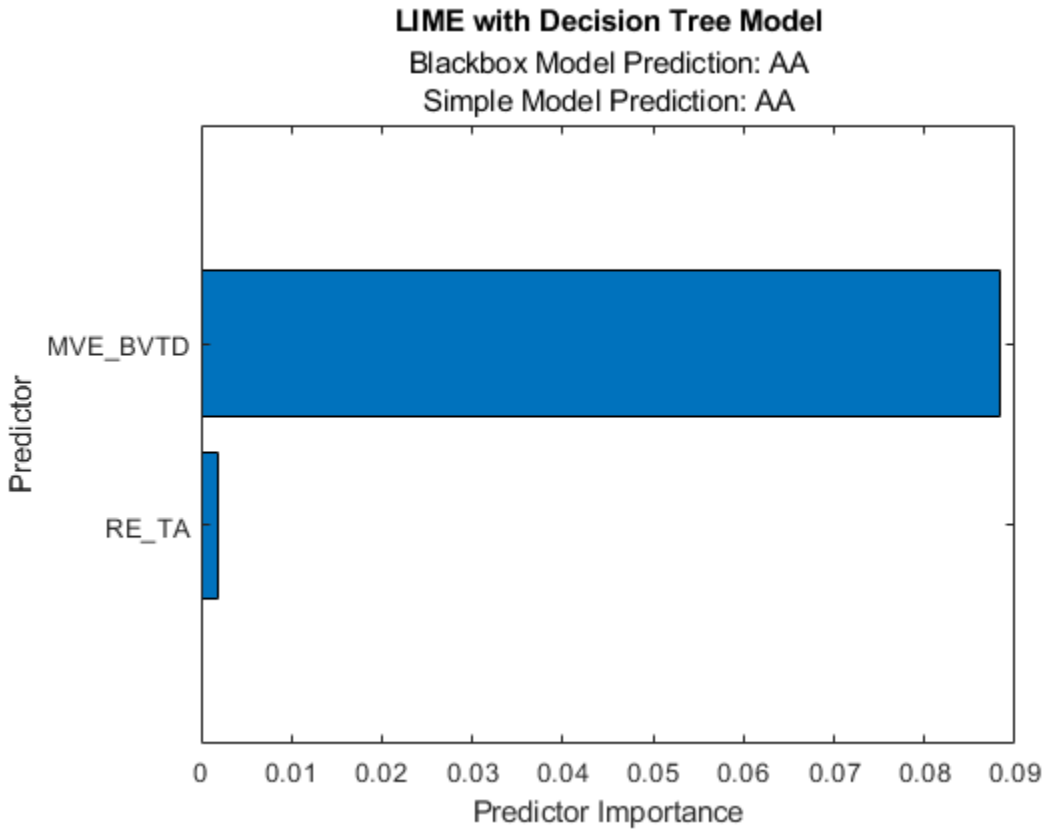
```
rng('default') % For reproducibility
results = lime(blackbox,'QueryPoint',queryPoint,'NumImportantPredictors',6, ...
    'SimpleModelType','tree')
```

```
results =
  lime with properties:

             BlackboxModel: [1x1 ClassificationECOC]
              DataLocality: 'global'
     CategoricalPredictors: 6
                      Type: 'classification'
                         X: [3932x6 table]
                QueryPoint: [1x6 table]
    NumImportantPredictors: 6
          NumSyntheticData: 5000
             SyntheticData: [5000x6 table]
                    Fitted: {5000x1 cell}
               SimpleModel: [1x1 ClassificationTree]
       ImportantPredictors: [2x1 double]
            BlackboxFitted: {'AA'}
         SimpleModelFitted: {'AA'}
```

Plot the `lime` object `results` by using the object function `plot`. To display an existing underscore in any predictor name, change the `TickLabelInterpreter` value of the axes to `'none'`.

```
f = plot(results);
f.CurrentAxes.TickLabelInterpreter = 'none';
```

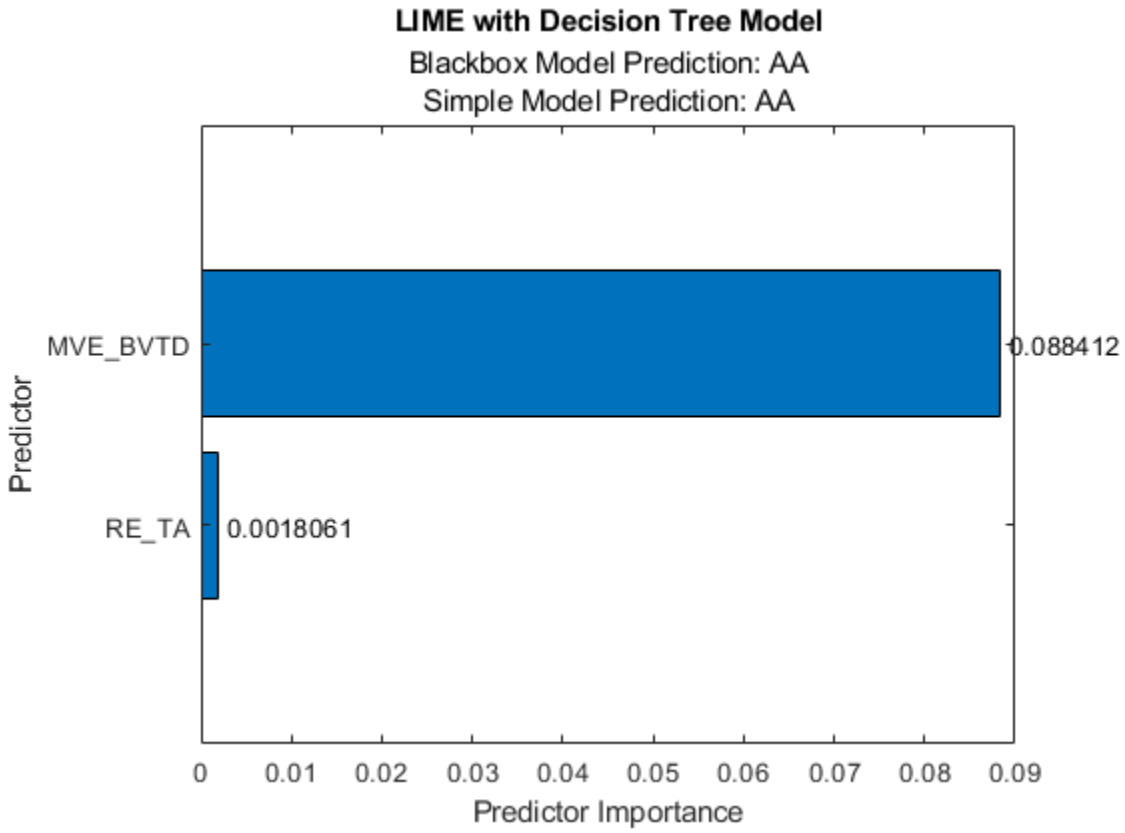


The plot displays two predictions for the query point, which correspond to the “BlackboxFitted” on page 33-0 property and the “SimpleModelFitted” on page 33-0 property of `results`.

The horizontal bar graph shows the sorted predictor importance values. `lime` finds the financial ratio variables `EBIT_TA` and `WC_TA` as important predictors for the query point.

You can read the bar lengths by using data tips or Bar Properties. For example, you can find `Bar` objects by using the `findobj` function and add labels to the ends of the bars by using the `text` function.

```
b = findobj(f,'Type','bar');
text(b.YEndPoints+0.001,b.XEndPoints,string(b.YData))
```



Alternatively, you can display the coefficient values in a table with the predictor variable names.

```
imp = b.YData;
flipud(array2table(imp', ...
    'RowNames',f.CurrentAxes.YTickLabel,'VariableNames',{'Predictor Importance'}))
```

```
ans=2×1 table
               Predictor Importance
               ____________________

    MVE_BVTD          0.088412
    RE_TA            0.0018061
```

Explain Prediction with Linear Simple Model

Train a regression model and create a `lime` object that uses a linear simple model. When you create a `lime` object, if you do not specify a query point and the number of important predictors, then the software generates samples of a synthetic data set but does not fit a simple model. Use the object function `fit` to fit a simple model for a query point. Then display the coefficients of the fitted linear simple model by using the object function `plot`.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table containing the predictor variables `Acceleration`, `Cylinders`, and so on, as well as the response variable `MPG`.

```
tbl = table(Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight,MPG);
```

Removing missing values in a training set can help reduce memory consumption and speed up training for the `fitrkernel` function. Remove missing values in `tbl`.

```
tbl = rmmissing(tbl);
```

Create a table of predictor variables by removing the response variable from `tbl`.

```
tblX = removevars(tbl,'MPG');
```

Train a blackbox model of `MPG` by using the `fitrkernel` function.

```
rng('default') % For reproducibility
mdl = fitrkernel(tblX,tbl.MPG,'CategoricalPredictors',[2 5]);
```

Create a `lime` object. Specify a predictor data set because `mdl` does not contain predictor data.

```
results = lime(mdl,tblX)
```

```
results =
  lime with properties:

             BlackboxModel: [1x1 RegressionKernel]
              DataLocality: 'global'
     CategoricalPredictors: [2 5]
                      Type: 'regression'
                         X: [392x6 table]
                QueryPoint: []
    NumImportantPredictors: []
          NumSyntheticData: 5000
             SyntheticData: [5000x6 table]
                    Fitted: [5000x1 double]
               SimpleModel: []
       ImportantPredictors: []
            BlackboxFitted: []
          SimpleModelFitted: []
```

`results` contains the generated synthetic data set. The `SimpleModel` property is empty (`[]`).

Fit a linear simple model for the first observation in `tblX`. Specify the number of important predictors to find as 3.

```
queryPoint = tblX(1,:)
```

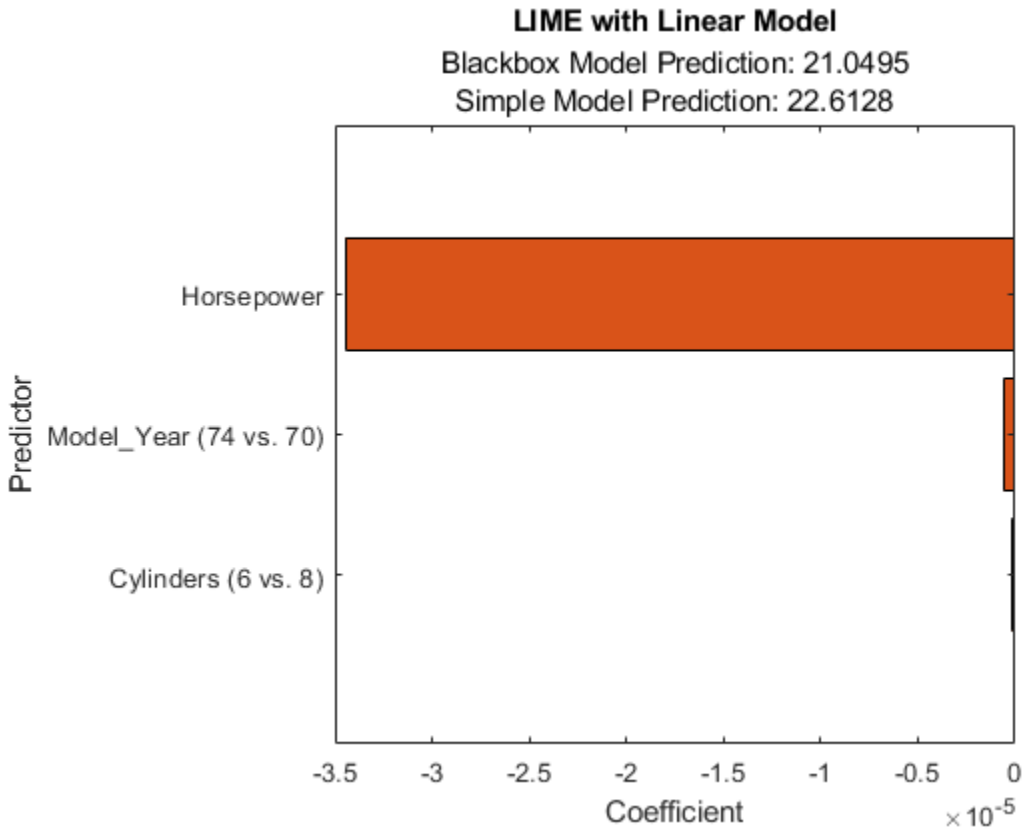
```
queryPoint=1×6 table
    Acceleration    Cylinders    Displacement    Horsepower    Model_Year    Weight
    ____________    _________    ____________    __________    __________    ______

         12             8            307            130            70         3504
```

```
results = fit(results,queryPoint,3);
```

Plot the `lime` object `results` by using the object function `plot`. To display an existing underscore in any predictor name, change the `TickLabelInterpreter` value of the axes to `'none'`.

```
f = plot(results);
f.CurrentAxes.TickLabelInterpreter = 'none';
```



The plot displays two predictions for the query point, which correspond to the “BlackboxFitted” on page 33-0 property and the “SimpleModelFitted” on page 33-0 property of `results`.

The horizontal bar graph shows the coefficient values of the simple model, sorted by their absolute values. LIME finds `Horsepower`, `Model_Year`, and `Cylinders` as important predictors for the query point.

`Model_Year` and `Cylinders` are categorical predictors that have multiple categories. For a linear simple model, the software creates one less dummy variable than the number of categories for each categorical predictor. The bar graph displays only the most important dummy variable. You can check the coefficients of the other dummy variables using the `SimpleModel` property of `results`. Display the sorted coefficient values, including all categorical dummy variables.

```
[~,I] = sort(abs(results.SimpleModel.Beta),'descend');
table(results.SimpleModel.ExpandedPredictorNames(I)',results.SimpleModel.Beta(I), ...
    'VariableNames',{'Exteded Predictor Name','Coefficient'})
```

```
ans=17×2 table
      Exteded Predictor Name      Coefficient
    ___________________________    ___________
```

```
    {'Horsepower'            }    -3.4485e-05
    {'Model_Year (74 vs. 70)'}    -6.1279e-07
    {'Model_Year (80 vs. 70)'}     -4.015e-07
    {'Model_Year (81 vs. 70)'}     3.4176e-07
    {'Model_Year (82 vs. 70)'}    -2.2483e-07
    {'Cylinders (6 vs. 8)'   }    -1.9024e-07
    {'Model_Year (76 vs. 70)'}     1.8136e-07
    {'Cylinders (5 vs. 8)'   }     1.7461e-07
    {'Model_Year (71 vs. 70)'}      1.558e-07
    {'Model_Year (75 vs. 70)'}     1.5456e-07
    {'Model_Year (77 vs. 70)'}      1.521e-07
    {'Model_Year (78 vs. 70)'}     1.4272e-07
    {'Model_Year (72 vs. 70)'}     6.7001e-08
    {'Model_Year (73 vs. 70)'}     4.7214e-08
    {'Cylinders (4 vs. 8)'   }     4.5118e-08
    {'Model_Year (79 vs. 70)'}    -2.2598e-08
      ⋮
```

Specify Blackbox Model as Function Handle

Train a regression model and create a `lime` object using a function handle to the `predict` function of the model. Use the object function `fit` to fit a simple model for the specified query point. Then display the coefficients of the fitted linear simple model by using the object function `plot`.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table containing the predictor variables `Acceleration`, `Cylinders`, and so on.

```
tbl = table(Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight);
```

Train a blackbox model of `MPG` by using the `TreeBagger` function.

```
rng('default') % For reproducibility
Mdl = TreeBagger(100,tbl,MPG,'Method','regression','CategoricalPredictors',[2 5]);
```

`lime` does not support a `TreeBagger` object directly, so you cannot specify the first input argument (blackbox model) of `lime` as a `TreeBagger` object. Instead, you can use a function handle to the `predict` function. You can also specify options of the `predict` function using name-value arguments of the function.

Create the function handle to the `predict` function of the `TreeBagger` object `Mdl`. Specify the array of tree indices to use as `1:50`.

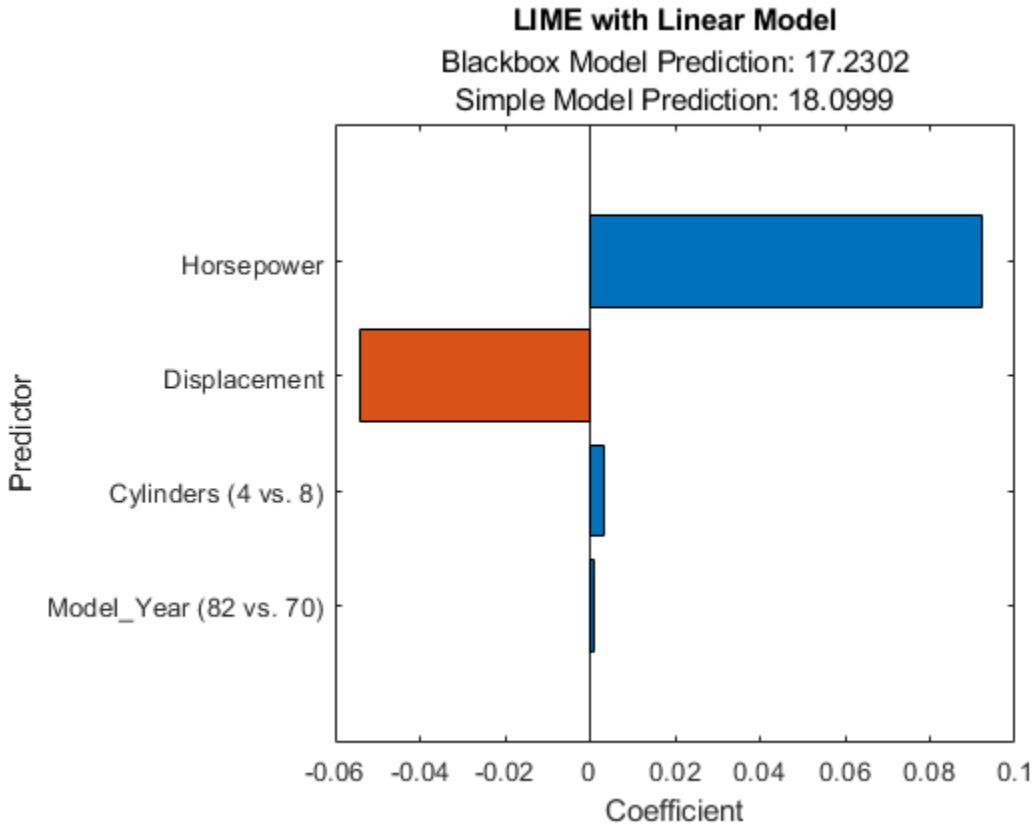
```
myPredict = @(tbl) predict(Mdl,tbl,'Trees',1:50);
```

Create a `lime` object using the function handle `myPredict`. When you specify a blackbox model as a function handle, you must provide the predictor data and specify the `'Type'` name-value argument. `tbl` includes categorical predictors (`Cylinder` and `Model_Year`) with the `double` data type. By default, `lime` does not treat variables with the `double` data type as categorical predictors. Specify the second (`Cylinder`) and fifth (`Model_Year`) variables as categorical predictors.

```
results = lime(myPredict,tbl,'Type','regression','CategoricalPredictors',[2 5]);
```

Fit a linear simple model for the first observation in `tbl`. To display an existing underscore in any predictor name, change the `TickLabelInterpreter` value of the axes to `'none'`.

```
results = fit(results,tbl(1,:),4);
f = plot(results);
f.CurrentAxes.TickLabelInterpreter = 'none';
```



`lime` finds `Horsepower`, `Displacement`, `Cylinders`, and `Model_Year` as important predictors.

More About

Distance Metrics

A distance metric is a function that defines a distance between two observations. `lime` supports various distance metrics for continuous variables and a mix of continuous and categorical variables.

- Distance metrics for continuous variables

  Given an mx-by-n data matrix X, which is treated as mx (1-by-n) row vectors x_1, x_2, ..., x_{mx}, and an my-by-n data matrix Y, which is treated as my (1-by-n) row vectors y_1, y_2, ...,y_{my}, the various distances between the vector x_s and y_t are defined as follows:

  - Euclidean distance

    $d_{st}^2 = (x_s - y_t)(x_s - y_t)'$.

The Euclidean distance is a special case of the Minkowski distance, where $p = 2$.

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)',$$

where V is the n-by-n diagonal matrix whose jth diagonal element is $(S(j))^2$, where S is a vector of scaling factors for each dimension.

- Mahalanobis distance

$$d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)',$$

where C is the covariance matrix.

- City block distance

$$d_{st} = \sum_{j=1}^{n} \left| x_{sj} - y_{tj} \right|.$$

The city block distance is a special case of the Minkowski distance, where $p = 1$.

- Minkowski distance

$$d_{st} = \sqrt[p]{\sum_{j=1}^{n} \left| x_{sj} - y_{tj} \right|^p}.$$

For the special case of $p = 1$, the Minkowski distance gives the city block distance. For the special case of $p = 2$, the Minkowski distance gives the Euclidean distance. For the special case of $p = \infty$, the Minkowski distance gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{ \left| x_{sj} - y_{tj} \right| \}.$$

The Chebychev distance is a special case of the Minkowski distance, where $p = \infty$.

- Cosine distance

$$d_{st} = \left(1 - \frac{x_s y'_t}{\sqrt{(x_s x'_s)(y_t y'_t)}} \right).$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'}\sqrt{(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}},$$

where

$$\bar{x}_s = \frac{1}{n}\sum_j x_{sj}$$

and

$$\bar{y}_t = \frac{1}{n}\sum_j y_{tj}.$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'}\sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}},$$

  where

  - r_{sj} is the rank of x_{sj} taken over x_{1j}, x_{2j}, ...$x_{mx,j}$, as computed by `tiedrank`.
  - r_{tj} is the rank of y_{tj} taken over y_{1j}, y_{2j}, ...$y_{my,j}$, as computed by `tiedrank`.
  - r_s and r_t are the coordinate-wise rank vectors of x_s and y_t, that is, $r_s = (r_{s1}, r_{s2}, \ldots r_{sn})$ and $r_t = (r_{t1}, r_{t2}, \ldots r_{tn})$.
  - $\bar{r}_s = \frac{1}{n}\sum_j r_{sj} = \frac{(n+1)}{2}$.
  - $\bar{r}_t = \frac{1}{n}\sum_j r_{tj} = \frac{(n+1)}{2}$.

- Distance metrics for a mix of continuous and categorical variables

  - Modified Goodall distance

    This distance is a variant of the Goodall distance, which assigns a small distance if the matching values are infrequent regardless of the frequencies of the other values. For mismatches, the distance contribution of the predictor is 1/(number of variables).

  - Occurrence frequency distance

    For a match, the occurrence frequency distance assigns zero distance. For a mismatch, the occurrence frequency distance assigns a higher distance on a less frequent value and a lower distance on a more frequent value.

Algorithms

LIME

To explain a prediction of a machine learning model using LIME [1], the software generates a synthetic data set and fits a simple interpretable model to the synthetic data set by using `lime` and `fit`, as described in steps 1–5.

- If you specify the `queryPoint` and `numImportantPredictors` values of `lime`, then the `lime` function performs all steps.
- If you do not specify `queryPoint` and `numImportantPredictors` and specify `'DataLocality'` as `'global'` (default), then the `lime` function generates a synthetic data set (steps 1–2), and the `fit` function fits a simple model (steps 3–5).
- If you do not specify `queryPoint` and `numImportantPredictors` and specify `'DataLocality'` as `'local'`, then the `fit` function performs all steps.

The `lime` and `fit` functions perform these steps:

1 Generate a synthetic predictor data set X_s using a multivariate normal distribution for continuous variables and a multinomial distribution for each categorical variable. You can specify the number of samples to generate by using the `'NumSyntheticData'` name-value argument.

- If `'DataLocality'` is `'global'` (default), then the software estimates the distribution parameters from the whole predictor data set (`X` or predictor data in `blackbox`).
- If `'DataLocality'` is `'local'`, then the software estimates the distribution parameters using the k-nearest neighbors of the query point, where k is the `'NumNeighbors'` value. You can specify a distance metric to find the nearest neighbors by using the `'Distance'` name-value argument.

The software ignores missing values in the predictor data set when estimating the distribution parameters.

Alternatively, you can provide a pregenerated, custom synthetic predictor data set by using the `customSyntheticData` input argument of `lime`.

2. Compute the predictions Y_s for the synthetic data set X_s. The predictions are predicted responses for regression or classified labels for classification. The software uses the `predict` function of the `blackbox` model to compute the predictions. If you specify `blackbox` as a function handle, then the software computes the predictions by using the function handle.
3. Compute the distances d between the query point and the samples in the synthetic predictor data set using the distance metric specified by `'Distance'`.
4. Compute the weight values w_q of the samples in the synthetic predictor data set with respect to the query point q using the squared exponential (or Gaussian) kernel function

$$w_q(x_s) = \exp\left(-\frac{1}{2}\left(\frac{d(x_s, q)}{\sqrt{p}\sigma}\right)^2\right).$$

- x_s is a sample in the synthetic predictor data set X_s.
- $d(x_s,q)$ is the distance between the sample x_s and the query point q.
- p is the number of predictors in X_s.
- σ is the kernel width, which you can specify by using the `'KernelWidth'` name-value argument. The default `'KernelWidth'` value is 0.75.

The weight value at the query point is 1, and then it converges to zero as the distance value increases. The `'KernelWidth'` value controls how fast the weight value converges to zero. The lower the `'KernelWidth'` value, the faster the weight value converges to zero. Therefore, the algorithm gives more weight to samples near the query point. Because this algorithm uses such weight values, the selected important predictors and fitted simple model effectively explain the predictions for the synthetic data locally, around the query point.

5. Fit a simple model.

- If `'SimpleModelType'` is `'linear'` (default), then the software selects important predictors and fits a linear model of the selected important predictors.
  - Select n important predictors ($\tilde{X}_s$) by using the group orthogonal matching pursuit (OMP) algorithm [2][3], where n is the `numImportantPredictors` value. This algorithm uses the synthetic predictor data set (X_s), predictions (Y_s), and weight values (w_q).
  - Fit a linear model of the selected important predictors ($\tilde{X}_s$) to the predictions (Y_s) using the weight values (w_q). The software uses `fitrlinear` for regression or `fitclinear` for classification. For a multiclass model, the software uses the one-versus-all scheme to construct a binary classification problem. The positive class is the predicted class for the query point from the `blackbox` model, and the negative class refers to the other classes.

- If `'SimpleModelType'` is `'tree'`, then the software fits a decision tree model by using `fitrtree` for regression or `fitctree` for classification. The software specifies the maximum number of decision splits (or branch nodes) as the number of important predictors so that the fitted decision tree uses at most the specified number of predictors.

LinearModel

Linear regression model

Description

`LinearModel` is a fitted linear regression model object. A regression model describes the relationship between a response and predictors. The linearity in a linear regression model refers to the linearity of the predictor coefficients.

Use the properties of a `LinearModel` object to investigate a fitted linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data. Use the object functions to predict responses and to modify, evaluate, and visualize the linear regression model.

Creation

Create a `LinearModel` object by using `fitlm` or `stepwiselm`.

`fitlm` fits a linear regression model to data using a fixed model specification. Use `addTerms`, `removeTerms`, or `step` to add or remove terms from the model. Alternatively, use `stepwiselm` to fit a model using stepwise linear regression.

Properties

Coefficient Estimates

`CoefficientCovariance` — Covariance matrix of coefficient estimates
numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a *p*-by-*p* matrix of numeric values. *p* is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-58.

Data Types: `single` | `double`

`CoefficientNames` — Coefficient names
cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: `cell`

`Coefficients` — Coefficient values
table

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — *t*-statistic for a test that the coefficient is zero
- `pValue` — *p*-value for the *t*-statistic

Use `anova` (only for a linear regression model) or `coefTest` to perform other tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```
beta = mdl.Coefficients.Estimate
```

Data Types: `table`

`NumCoefficients` — Number of model coefficients
positive integer

This property is read-only.

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

Data Types: `double`

`NumEstimatedCoefficients` — Number of estimated coefficients
positive integer

This property is read-only.

Number of estimated coefficients in the model, specified as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

Data Types: `double`

Summary Statistics

`DFE` — Degrees of freedom for error
positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: `double`

`Diagnostics` — Observation diagnostics
table

This property is read-only.

Observation diagnostics, specified as a table that contains one row for each observation and the columns described in this table.

Column	Meaning	Description
`Leverage`	Diagonal elements of `HatMatrix`	`Leverage` for each observation indicates to what extent the fit is determined by the observed predictor values. A value close to `1` indicates that the fit is largely determined by that observation, with little contribution from the other observations. A value close to `0` indicates that the fit is largely determined by the other observations. For a model with `P` coefficients and `N` observations, the average value of `Leverage` is `P/N`. A `Leverage` value greater than `2*P/N` indicates high leverage.
`CooksDistance`	Cook's distance	`CooksDistance` is a measure of scaled change in fitted values. An observation with `CooksDistance` greater than three times the mean Cook's distance can be an outlier.
`Dffits`	Delete-1 scaled differences in fitted values	`Dffits` is the scaled change in the fitted values for each observation that results from excluding that observation from the fit. Values greater than `2*sqrt(P/N)` in absolute value can be considered influential.
`S2_i`	Delete-1 variance	`S2_i` is a set of residual variance estimates obtained by deleting each observation in turn. These estimates can be compared with the mean squared error (MSE) value, stored in the `MSE` property.
`CovRatio`	Delete-1 ratio of determinant of covariance	`CovRatio` is the ratio of the determinant of the coefficient covariance matrix, with each observation deleted in turn, to the determinant of the covariance matrix for the full model. Values greater than `1 + 3*P/N` or less than `1 – 3*P/N` indicate influential points.
`Dfbetas`	Delete-1 scaled differences in coefficient estimates	`Dfbetas` is an `N`-by-`P` matrix of the scaled change in the coefficient estimates that results from excluding each observation in turn. Values greater than `3/sqrt(N)` in absolute value indicate that the observation has a significant influence on the corresponding coefficient.
`HatMatrix`	Projection matrix to compute `fitted` from observed responses	`HatMatrix` is an `N`-by-`N` matrix such that `Fitted = HatMatrix*Y`, where `Y` is the response vector and `Fitted` is the vector of fitted response values.

`Diagnostics` contains information that is helpful in finding outliers and influential observations. Delete-1 diagnostics capture the changes that result from excluding each observation in turn from the fit. For more details, see “Hat Matrix and Leverage” on page 11-77, “Cook’s Distance” on page 11-55, and “Delete-1 Statistics” on page 11-63.

Use `plotDiagnostics` to plot observation diagnostics.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain `NaN` values in the `CooksDistance`, `Dffits`, `S2_i`, and `CovRatio` columns and zeros in the `Leverage`, `Dfbetas`, and `HatMatrix` columns.

To obtain any of these columns as an array, index into the property using dot notation. For example, obtain the delete-1 variance vector in the model `mdl`:

```
S2i = mdl.Diagnostics.S2_i;
```

Data Types: `table`

`Fitted` — Fitted response values based on input data

numeric vector

This property is read-only.

Fitted (predicted) response values based on input data, specified as an *n*-by-1 numeric vector. *n* is the number of observations in the input data. Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Data Types: `single` | `double`

`LogLikelihood` — Loglikelihood

numeric value

This property is read-only.

Loglikelihood of response values, specified as a numeric value, based on the assumption that each response value follows a normal distribution. The mean of the normal distribution is the fitted (predicted) response value, and the variance is the `MSE`.

Data Types: `single` | `double`

`ModelCriterion` — Criterion for model comparison

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- `AIC` — Akaike information criterion. `AIC = –2*logL + 2*m`, where `logL` is the loglikelihood and `m` is the number of estimated parameters.
- `AICc` — Akaike information criterion corrected for the sample size. `AICc = AIC + (2*m*(m + 1))/(n – m – 1)`, where `n` is the number of observations.
- `BIC` — Bayesian information criterion. `BIC = –2*logL + m*log(n)`.
- `CAIC` — Consistent Akaike information criterion. `CAIC = –2*logL + m*(log(n) + 1)`.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

`MSE` — Mean squared error
numeric value

This property is read-only.

Mean squared error (residuals), specified as a numeric value.

$$MSE = SSE / DFE,$$

where *MSE* is the mean squared error, *SSE* is the sum of squared errors, and *DFE* is the degrees of freedom.

Data Types: `single` | `double`

`Residuals` — Residuals for fitted model
table

This property is read-only.

Residuals for the fitted model, specified as a table that contains one row for each observation and the columns described in this table.

Column	Description
`Raw`	Observed minus fitted values
`Pearson`	Raw residuals divided by the root mean squared error (RMSE)
`Standardized`	Raw residuals divided by their estimated standard deviation
`Studentized`	Raw residual divided by an independent estimate of the residual standard deviation. The residual for observation *i* is divided by an estimate of the error standard deviation based on all observations except observation *i*.

Use `plotResiduals` to create a plot of the residuals. For details, see “Residuals” on page 11-80.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain `NaN` values.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the raw residual vector `r` in the model `mdl`:

```
r = mdl.Residuals.Raw
```

Data Types: `table`

`RMSE` — Root mean squared error
numeric value

This property is read-only.

Root mean squared error (residuals), specified as a numeric value.

$$RMSE = \text{sqrt}(MSE),$$

where *RMSE* is the root mean squared error and *MSE* is the mean squared error.

Data Types: `single` | `double`

Rsquared — R-squared value for model

structure

This property is read-only.

R-squared value for the model, specified as a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

The R-squared value is the proportion of the total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$Rsquared = SSR/SST,$$

where SST is the total sum of squares, and SSR is the regression sum of squares.

For details, see “Coefficient of Determination (R-Squared)” on page 11-61.

To obtain either of these values as a scalar, index into the property using dot notation. For example, obtain the adjusted R-squared value in the model `mdl`:

```
r2 = mdl.Rsquared.Adjusted
```

Data Types: `struct`

SSE — Sum of squared errors

numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

SSR — Regression sum of squares

numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

SST — Total sum of squares
numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector `y` from the `mean(y)`.

The Pythagorean theorem implies
`SST = SSE + SSR`,
where `SST` is the total sum of squares, `SSE` is the sum of squared errors, and `SSR` is the regression sum of squares.

Data Types: `single` | `double`

Fitting Method

`Robust` — Robust fit information
structure

This property is read-only.

Robust fit information, specified as a structure with the fields described in this table.

Field	Description
`WgtFun`	Robust weighting function, such as `'bisquare'` (see `'RobustOpts'`)
`Tune`	Tuning constant. This field is empty (`[]`) if `WgtFun` is `'ols'` or if `WgtFun` is a function handle for a custom weight function with the default tuning constant 1.
`Weights`	Vector of weights used in the final iteration of robust fit. This field is empty for a `CompactLinearModel` object.

This structure is empty unless you fit the model using robust regression.

Data Types: `struct`

`Steps` — Stepwise fitting information
structure

This property is read-only.

Stepwise fitting information, specified as a structure with the fields described in this table.

Field	Description
`Start`	Formula representing the starting model
`Lower`	Formula representing the lower bound model. The terms in `Lower` must remain in the model.
`Upper`	Formula representing the upper bound model. The model cannot contain more terms than `Upper`.
`Criterion`	Criterion used for the stepwise algorithm, such as `'sse'`

Field	Description
`PEnter`	Threshold for `Criterion` to add a term
`PRemove`	Threshold for `Criterion` to remove a term
`History`	Table representing the steps taken in the fit

The `History` table contains one row for each step, including the initial fit, and the columns described in this table.

Column	Description
`Action`	Action taken during the step: • `'Start'` — First step • `'Add'` — A term is added • `'Remove'` — A term is removed
`TermName`	• If `Action` is `'Start'`, `TermName` specifies the starting model specification. • If `Action` is `'Add'` or `'Remove'`, `TermName` specifies the term added or removed in the step.
`Terms`	Model specification in a “Terms Matrix” on page 33-3525
`DF`	Regression degrees of freedom after the step
`delDF`	Change in regression degrees of freedom from the previous step (negative for steps that remove a term)
`Deviance`	Deviance (residual sum of squares) at the step (only for a generalized linear regression model)
`FStat`	*F*-statistic that leads to the step
`PValue`	*p*-value of the *F*-statistic

The structure is empty unless you fit the model using stepwise regression.

Data Types: `struct`

Input Data

`Formula` — Model information

`LinearFormula` object

This property is read-only.

Model information, specified as a `LinearFormula` object.

Display the formula of the fitted model `mdl` using dot notation:

```
mdl.Formula
```

`NumObservations` — Number of observations

positive integer

This property is read-only.

Number of observations the fitting function used in fitting, specified as a positive integer. `NumObservations` is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `'Exclude'` name-value pair argument) or rows with missing values.

Data Types: `double`

`NumPredictors` — Number of predictor variables
positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: `double`

`NumVariables` — Number of variables
positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

`NumVariables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `double`

`ObservationInfo` — Observation information
table

This property is read-only.

Observation information, specified as an *n*-by-4 table, where *n* is equal to the number of rows of input data. `ObservationInfo` contains the columns described in this table.

Column	Description
`Weights`	Observation weights, specified as a numeric value. The default value is `1`.
`Excluded`	Indicator of excluded observations, specified as a logical value. The value is `true` if you exclude the observation from the fit by using the `'Exclude'` name-value pair argument.
`Missing`	Indicator of missing observations, specified as a logical value. The value is `true` if the observation is missing.
`Subset`	Indicator of whether or not the fitting function uses the observation, specified as a logical value. The value is `true` if the observation is not excluded or missing, meaning the fitting function uses the observation.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the weight vector `w` of the model `mdl`:

```
w = mdl.ObservationInfo.Weights
```

Data Types: `table`

`ObservationNames` — Observation names

cell array of character vectors

This property is read-only.

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array.

Data Types: `cell`

`PredictorNames` — Names of predictors used to fit model

cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: `cell`

`ResponseName` — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

`VariableInfo` — Information about variables

table

This property is read-only.

Information about variables contained in `Variables`, specified as a table with one row for each variable and the columns described in this table.

Column	Description
`Class`	Variable class, specified as a cell array of character vectors, such as `'double'` and `'categorical'`
`Range`	Variable range, specified as a cell array of vectors • Continuous variable — Two-element vector `[`*`min`*`,`*`max`*`]`, the minimum and maximum values • Categorical variable — Vector of distinct variable values
`InModel`	Indicator of which variables are in the fitted model, specified as a logical vector. The value is `true` if the model includes the variable.
`IsCategorical`	Indicator of categorical variables, specified as a logical vector. The value is `true` if the variable is categorical.

`VariableInfo` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

`VariableNames` — Names of variables
cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` contains the values specified by the `'VarNames'` name-value pair argument of the fitting method. The default value of `'VarNames'` is `{'x1','x2',...,'xn','y'}`.

`VariableNames` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `cell`

`Variables` — Input data
table

This property is read-only.

Input data, specified as a table. `Variables` contains both predictor and response values. If the fit is based on a table or dataset array, `Variables` contains all the data from the table or dataset array. Otherwise, `Variables` is a table created from the input data matrix `X` and the response vector `y`.

`Variables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

Object Functions

Create `CompactLinearModel`

compact	Compact linear regression model

Add or Remove Terms from Linear Model

addTerms	Add terms to linear regression model
removeTerms	Remove terms from linear regression model
step	Improve linear regression model by adding or removing terms

Predict Responses

feval	Predict responses of linear regression model using one input for each predictor
predict	Predict responses of linear regression model
random	Simulate responses with random noise for linear regression model

Evaluate Linear Model

anova	Analysis of variance for linear regression model
coefCI	Confidence intervals of coefficient estimates of linear regression model
coefTest	Linear hypothesis test on linear regression model coefficients
dwtest	Durbin-Watson test with linear regression model object
partialDependence	Compute partial dependence

Visualize Linear Model and Summary Statistics

plot	Scatter plot or added variable plot of linear regression model
plotAdded	Added variable plot of linear regression model
plotAdjustedResponse	Adjusted response plot of linear regression model
plotDiagnostics	Plot observation diagnostics of linear regression model
plotEffects	Plot main effects of predictors in linear regression model
plotInteraction	Plot interaction effects of two predictors in linear regression model
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
plotResiduals	Plot residuals of linear regression model
plotSlice	Plot of slices through fitted linear regression surface

Gather Properties of Linear Model

gather	Gather properties of machine learning model from GPU

Examples

Fit Linear Regression Using Data in Matrix

Fit a linear regression model using a matrix input data set.

Load the `carsmall` data set, a matrix input data set.

```
load carsmall
X = [Weight,Horsepower,Acceleration];
```

Fit a linear regression model by using `fitlm`.

```
mdl = fitlm(X,MPG)
```

```
mdl =
Linear regression model:
    y ~ 1 + x1 + x2 + x3

Estimated Coefficients:
                   Estimate        SE          tStat        pValue
                  __________    _________    _________    __________

    (Intercept)        47.977       3.8785        12.37    4.8957e-21
    x1             -0.0065416    0.0011274      -5.8023    9.8742e-08
    x2              -0.042943     0.024313      -1.7663       0.08078
    x3              -0.011583      0.19333    -0.059913       0.95236

Number of observations: 93, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 4.09
R-squared: 0.752,  Adjusted R-Squared: 0.744
F-statistic vs. constant model: 90, p-value = 7.38e-27
```

The model display includes the model formula, estimated coefficients, and model summary statistics.

The model formula in the display, `y ~ 1 + x1 + x2 + x3`, corresponds to $y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \epsilon$.

The model display also shows the estimated coefficient information, which is stored in the `Coefficients` property. Display the `Coefficients` property.

```
mdl.Coefficients
```

```
ans=4×4 table
                    Estimate        SE          tStat        pValue
                   __________    _________    _________    __________

    (Intercept)       47.977       3.8785        12.37    4.8957e-21
    x1             -0.0065416    0.0011274      -5.8023    9.8742e-08
    x2              -0.042943     0.024313      -1.7663       0.08078
    x3              -0.011583      0.19333    -0.059913       0.95236
```

The `Coefficient` property includes these columns:

- `Estimate` — Coefficient estimates for each corresponding term in the model. For example, the estimate for the constant term (`intercept`) is 47.977.
- `SE` — Standard error of the coefficients.
- `tStat` — *t*-statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that `tStat = Estimate/SE`. For example, the *t*-statistic for the intercept is 47.977/3.8785 = 12.37.
- `pValue` — *p*-value for the *t*-statistic of the hypothesis test that the corresponding coefficient is equal to zero or not. For example, the *p*-value of the *t*-statistic for `x2` is greater than 0.05, so this term is not significant at the 5% significance level given the other terms in the model.

The summary statistics of the model are:

- `Number of observations` — Number of rows without any `NaN` values. For example, `Number of observations` is 93 because the `MPG` data vector has six `NaN` values and the `Horsepower` data vector has one `NaN` value for a different observation, where the number of rows in `X` and `MPG` is 100.
- `Error degrees of freedom` — $n - p$, where n is the number of observations, and p is the number of coefficients in the model, including the intercept. For example, the model has four predictors, so the `Error degrees of freedom` is 93 – 4 = 89.
- `Root mean squared error` — Square root of the mean squared error, which estimates the standard deviation of the error distribution.
- `R-squared` and `Adjusted R-squared` — Coefficient of determination and adjusted coefficient of determination, respectively. For example, the `R-squared` value suggests that the model explains approximately 75% of the variability in the response variable `MPG`.

- `F-statistic vs. constant model` — Test statistic for the *F*-test on the regression model, which tests whether the model fits significantly better than a degenerate model consisting of only a constant term.
- `p-value` — *p*-value for the *F*-test on the model. For example, the model is significant with a *p*-value of 7.3816e-27.

You can find these statistics in the model properties (`NumObservations`, `DFE`, `RMSE`, and `Rsquared`) and by using the `anova` function.

```
anova(mdl,'summary')
```

Linear Regression with Categorical Predictor

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use `anova` to test the significance of the categorical variable.

Model with Categorical Predictor

Load the `carsmall` data set and create a linear regression model of `MPG` as a function of `Model_Year`. To treat the numeric vector `Model_Year` as a categorical variable, identify the predictor using the `'CategoricalVars'` name-value pair argument.

```
load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Model_Year

Estimated Coefficients:
                    Estimate      SE      tStat       pValue
                    ________    ______    ______    __________

    (Intercept)        17.69    1.0328    17.127    3.2371e-30
    Model_Year_76     3.8839    1.4059    2.7625     0.0069402
    Model_Year_82      14.02    1.4369    9.7571    8.2164e-16

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531,  Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

The model formula in the display, `MPG ~ 1 + Model_Year`, corresponds to

$$\text{MPG} = \beta_0 + \beta_1 I_{\text{Year} = 76} + \beta_2 I_{\text{Year} = 82} + \epsilon,$$

where $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$ are indicator variables whose value is one if the value of `Model_Year` is 76 and 82, respectively. The `Model_Year` variable includes three distinct values, which you can check by using the `unique` function.

```
unique(Model_Year)
```

```
ans = 3×1

    70
    76
    82
```

`fitlm` chooses the smallest value in `Model_Year` as a reference level (`'70'`) and creates two indicator variables $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

Model with Full Indicator Variables

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1 = 70} + (\beta_0 + \beta_1) I_{x_1 = 76} + (\beta_0 + \beta_2) I_{x_2 = 82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

```
mdl =
Linear regression model:
    MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82

Estimated Coefficients:
                     Estimate      SE       tStat       pValue
                     ________    _______    ______    __________

    Model_Year_70      17.69      1.0328    17.127    3.2371e-30
    Model_Year_76     21.574     0.95387    22.617    4.0156e-39
    Model_Year_82      31.71     0.99896    31.743    5.2234e-51

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
```

Choose Reference Level in Model

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```
categories(Year)
```

```
ans = 3x1 cell
    {'70'}
    {'76'}
    {'82'}
```

If you use `Year` as a predictor variable, then `fitlm` chooses the first category `'70'` as a reference level. Reorder `Year` by using the `reordercats` function.

```
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
```

```
ans = 3x1 cell
    {'76'}
    {'70'}
    {'82'}
```

The first category of `Year_reordered` is `'76'`. Create a linear regression model of `MPG` as a function of `Year_reordered`.

```
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

```
mdl2 =
Linear regression model:
    MPG ~ 1 + Model_Year

Estimated Coefficients:
                    Estimate      SE        tStat       pValue
                    ________    _______    _______    __________

    (Intercept)       21.574     0.95387     22.617    4.0156e-39
    Model_Year_70    -3.8839      1.4059    -2.7625     0.0069402
    Model_Year_82     10.136      1.3812     7.3385    8.7634e-11

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531,  Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

`mdl2` uses `'76'` as a reference level and includes two indicator variables $I_{\text{Year = 70}}$ and $I_{\text{Year = 82}}$.

Evaluate Categorical Predictor

The model display of `mdl2` includes a *p*-value of each term to test whether or not the corresponding coefficient is equal to zero. Each *p*-value examines each indicator variable. To examine the categorical variable `Model_Year` as a group of indicator variables, use `anova`. Use the `'components'`(default) option to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```
anova(mdl2,'components')
```

```
ans=2×5 table
                  SumSq     DF    MeanSq      F         pValue
                  ______    __    ______    _____    __________

    Model_Year    3190.1     2    1595.1    51.56    1.0694e-15
    Error         2815.2    91    30.936
```

The component ANOVA table includes the *p*-value of the `Model_Year` variable, which is smaller than the *p*-values of the indicator variables.

Fit Robust Linear Regression Model

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a robust linear regression model to the data.

```
mdl = fitlm(ingredients,heat,'RobustOpts','on')
```

```
mdl =
Linear regression model (robust fit):
    y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
                   Estimate      SE        tStat       pValue
                   ________    _______    ________    ________

    (Intercept)       60.09     75.818     0.79256      0.4509
    x1               1.5753    0.80585      1.9548    0.086346
    x2               0.5322    0.78315     0.67957     0.51596
    x3              0.13346     0.8166     0.16343     0.87424
    x4             -0.12052     0.7672    -0.15709     0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979,  Adjusted R-Squared: 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

For more details, see the topic “Reduce Outlier Effects Using Robust Regression” on page 11-104, which compares the results of a robust fit to a standard least-squares fit.

Fit Linear Model Using Stepwise Regression

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a stepwise linear regression model to the data. Specify 0.06 as the threshold for the criterion to add a term to the model.

```
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)
```

```
1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

mdl =
Linear regression model:
    y ~ 1 + x1 + x2

Estimated Coefficients:
                   Estimate       SE       tStat       pValue
                   ________    ________    ______    __________

    (Intercept)     52.577       2.2862    22.998    5.4566e-10
    x1              1.4683       0.1213    12.105    2.6922e-07
    x2             0.66225     0.045855    14.442     5.029e-08

Number of observations: 13, Error degrees of freedom: 10
Root Mean Squared Error: 2.41
R-squared: 0.979,  Adjusted R-Squared: 0.974
F-statistic vs. constant model: 230, p-value = 4.41e-09
```

By default, the starting model is a constant model. `stepwiselm` performs forward selection and adds the `x4`, `x1`, and `x2` terms (in that order), because the corresponding *p*-values are less than the `PEnter` value of 0.06. `stepwiselm` then uses backward elimination and removes `x4` from the model because, once `x2` is in the model, the *p*-value of `x4` is greater than the default value of `PRemove`, 0.1.

More About

Terms Matrix

A terms matrix `T` is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `x1`, `x2`, and `x3` and the response variable `y` in the order `x1`, `x2`, `x3`, and `y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `x2`; equivalently, `x1^0 * x2^1 * x3^0`
- `[1 0 1 0]` — `x1*x3`
- `[2 0 0 0]` — `x1^2`
- `[0 1 2 0]` — `x2*(x3^2)`

The `0` at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include `0` for the response variable in the last column of each row.

Alternative Functionality

- For reduced computation time on high-dimensional data sets, fit a linear regression model using the `fitrlinear` function.
- To regularize a regression, use `fitrlinear`, `lasso`, `ridge`, or `plsregress`.
  - `fitrlinear` regularizes a regression for high-dimensional data sets using lasso or ridge regression.
  - `lasso` removes redundant predictors in linear regression using lasso or elastic net.
  - `ridge` regularizes a regression with correlated terms using ridge regression.
  - `plsregress` regularizes a regression with correlated terms using partial least squares.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `random` functions support code generation.

For more information, see “Introduction to Code Generation” on page 32-2.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The following object functions fully support GPU arrays:
  - `feval`
  - `predict`
  - `random`
  - `partialDependence`
  - `plotPartialDependence`
- The following object functions support model objects fitted with GPU array input arguments:
  - `compact`
  - `addTerms`
  - `removeTerms`
  - `step`
  - `anova`
  - `coefCI`

- `coefTest`
- `dwtest`
- `plot`
- `plotAdded`
- `plotAdjustedResponse`
- `plotDiagnostics`
- `plotEffects`
- `plotInteraction`
- `plotResiduals`
- `plotSlice`
- `gather`

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Linear Regression” on page 11-9
“What Is a Linear Regression Model?” on page 11-6

Introduced in R2012a

LinearMixedModel class

Linear mixed-effects model class

Description

A `LinearMixedModel` object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a linear mixed-effects model using `fitlme(tbl,formula)` if your data is in a table or dataset array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

Input Arguments

`tbl` — Input data

table | `dataset` array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or `dataset` array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-45). You must specify the model for the variables using `formula`.

Data Types: `table`

`formula` — Formula for model specification

character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see “Formula” on page 33-3540.

Example: `'y ~ treatment +(1|block)'`

`X` — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of `X` corresponds to one observation, and each column of `X` corresponds to one variable.

Data Types: `single` | `double`

`y` — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then `Z` must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then `Z` must be a cell array of length *R*. Each cell of `Z` contains an *n*-by-*q*(*r*) design matrix `Z{r}`, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, `Z{r}`.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables on page 2-45, specified as either of the following.

- If there is one random-effects term, then `G` must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.

  `G` can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.
- If there are multiple random-effects terms, then `G` must be a cell array of length *R*. Each cell of `G` contains a grouping variable `G{r}`, *r* = 1, 2, ..., *R*, with *M*(*r*) levels.

  `G{r}` can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

Properties

Coefficients — Fixed-effects coefficient estimates

dataset array

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

`Name`	Name of the term.
`Estimate`	Estimated value of the coefficient.
`SE`	Standard error of the coefficient.
`tStat`	*t*-statistics for testing the null hypothesis that the coefficient is equal to zero.

`DF`	Degrees of freedom for the *t*-test. Method to compute `DF` is specified by the `'DFMethod'` name-value pair argument. `Coefficients` always uses the `'Residual'` method for `'DFMethod'`.
`pValue`	*p*-value for the *t*-test.
`Lower`	Lower limit of the confidence interval for coefficient. `Coefficients` always uses the 95% confidence level, i.e.`'alpha'` is 0.05.
`Upper`	Upper limit of confidence interval for coefficient. `Coefficients` always uses the 95% confidence level, i.e.`'alpha'` is 0.05.

You can change `'DFMethod'` and `'alpha'` while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the `coefCI` and `coefTest` methods.

`CoefficientCovariance` — Covariance of the estimated fixed-effects coefficients
p-by-*p* matrix

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a *p*-by-*p* matrix, where *p* is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the `covarianceParameters` method.

Data Types: `double`

`CoefficientNames` — Names of the fixed-effects coefficients
1-by-*p* cell array of character vectors

Names of the fixed-effects coefficients of a linear mixed-effects model, stored as a 1-by-*p* cell array of character vectors.

Data Types: `cell`

`DFE` — Residual degrees of freedom
positive integer value

Residual degrees of freedom, stored as a positive integer value. $DFE = n - p$, where n is the number of observations, and p is the number of fixed-effects coefficients.

This corresponds to the `'Residual'` method of calculating degrees of freedom in the `fixedEffects` and `randomEffects` methods.

Data Types: `double`

`FitMethod` — Method used to fit the linear mixed-effects model
`ML` | `REML`

Method used to fit the linear mixed-effects model, stored as either of the following.

- `ML`, if the fitting method is maximum likelihood
- `REML`, if the fitting method is restricted maximum likelihood

Data Types: `char`

`Formula` — Specification of the fixed- and random-effects terms, and grouping variables

object

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see “Formula” on page 33-3540.

`LogLikelihood` — Maximized log or restricted log likelihood

scalar value

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

Data Types: `double`

`ModelCriterion` — Model criterion

dataset array

Model criterion to compare fitted linear mixed-effects models, stored as a dataset array with the following columns.

`AIC`	Akaike Information Criterion
`BIC`	Bayesian Information Criterion
`Loglikelihood`	Log likelihood value of the model
`Deviance`	–2 times the log likelihood of the model

If n is the number of observations used in fitting the model, and p is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
  - n, when the fitting method is maximum likelihood (ML)
  - $n – p$, when the fitting method is restricted maximum likelihood (REML)

`MSE` — ML or REML estimate

positive scalar value

ML or REML estimate, based on the fitting method used for estimating σ^2, stored as a positive scalar value. σ^2 is the residual variance or variance of the observation error term of the linear mixed-effects model.

Data Types: `double`

`NumCoefficients` — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: `double`

`NumEstimatedCoefficients` — Number of estimated fixed-effects coefficients
positive integer value

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: `double`

`NumObservations` — Number of observations
positive integer value

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the table or dataset array, or the design matrices minus the excluded rows or rows with `NaN` values.

Data Types: `double`

`NumPredictors` — Number of predictors
positive integer value

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

Data Types: `double`

`NumVariables` — Total number of variables
positive integer value

Total number of variables including the response and predictors, stored as a positive integer value.

- If the sample data is in a table or dataset array `tbl`, `NumVariables` is the total number of variables in `tbl` including the response variable.
- If the fit is based on matrix input, `NumVariables` is the total number of columns in the predictor matrix or matrices, and response vector.

`NumVariables` includes variables, if there are any, that are not used as predictors or as the response.

Data Types: `double`

`ObservationInfo` — Information about the observations
table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following four columns.

`Weights`	The value of the weighted variable for that observation. Default value is 1.
`Excluded`	`true`, if the observation was excluded from the fit using the `'Exclude'` name-value pair argument, `false`, otherwise. 1 stands for `true` and 0 stands for `false`.

`Missing`	`true`, if the observation was excluded from the fit because any response or predictor value is missing, `false`, otherwise. Missing values include `NaN` for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the `<undefined>` value for categorical arrays.
`Subset`	`true`, if the observation was used in the fit, `false`, if it was not used because it is missing or excluded.

Data Types: `table`

`ObservationNames` — Names of observations
cell array of character vectors

Names of observations used in the fit, stored as a cell array of character vectors.

- If the data is in a table or dataset array, `tbl`, containing observation names, `ObservationNames` has those names.
- If the data is provided in matrices, or a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: `cell`

`PredictorNames` — Names of predictors
cell array of character vectors

Names of the variables that you use as predictors in the fit, stored as a cell array of character vectors that has the same length as `NumPredictors`.

Data Types: `cell`

`ResponseName` — Names of response variable
character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

Data Types: `char`

`Rsquared` — Proportion of variability in the response explained by the fitted model
structure

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. `Rsquared` has two fields.

`Ordinary`	R-squared value, stored as a scalar value in a structure. `Rsquared.Ordinary = 1 – SSE./SST`

`Adjusted`	R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure. `Rsquared.Adjusted = 1 – (SSE./SST)*(DFT./DFE)`, where `DFE = n – p`, `DFT = n – 1`, and `n` is the total number of observations, `p` is the number of fixed-effects coefficients.

Data Types: `struct`

SSE — Error sum of squares
positive scalar value

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

`SSE = sum((y – F).^2)`, where `y` is the response vector, and `F` is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: `double`

SSR — Regression sum of squares
positive scalar value

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar value. It is the sum of squared deviations of the conditional fitted values from their mean.

`SSR = sum((F – mean(F)).^2)`, where `F` is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: `double`

SST — Total sum of squares
positive scalar value

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

`SST = sum((y – mean(y)).^2) = SSR + SSE`, where `y` is the response vector.

Data Types: `double`

`Variables` — Variables
table

Variables, stored as a table.

- If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.
- If the fit is based on matrix input, then `Variables` is a table containing all the variables in the predictor matrix or matrices, and response variable.

Data Types: `table`

`VariableInfo` — Information about the variables

table

Information about the variables used in the fit, stored as a table.

`VariableInfo` has one row for each variable and contains the following four columns.

`Class`	Class of the variable (`'double'`, `'cell'`, `'nominal'`, and so on).
`Range`	Value range of the variable. • For a numerical variable, it is a two-element vector of the form `[min,max]`. • For a cell or categorical variable, it is a cell or categorical array containing all unique values of the variable.
`InModel`	`true`, if the variable is a predictor in the fitted model. `false`, if the variable is not in the fitted model.
`IsCategorical`	`true`, if the variable has a type that is treated as a categorical predictor, such as cell, logical, or categorical, or if it is specified as categorical by the `'Categorical'` name-value pair argument of the `fit` method. `false`, if it is a continuous predictor.

Data Types: `table`

`VariableNames` — Names of the variables

cell array of character vectors

Names of the variables used in the fit, stored as a cell array of character vectors.

- If sample data is in a table or dataset array `tbl`, `VariableNames` contains the names of the variables in `tbl`.
- If sample data is in matrix format, then `VariableInfo` includes variable names you supply while fitting the model. If you do not supply the variable names, then `VariableInfo` contains the default names.

Data Types: `cell`

Object Functions

anova	Analysis of variance for linear mixed-effects model
coefCI	Confidence intervals for coefficients of linear mixed-effects model
coefTest	Hypothesis test on fixed and random effects of linear mixed-effects model
compare	Compare linear mixed-effects models
covarianceParameters	Extract covariance parameters of linear mixed-effects model
designMatrix	Fixed- and random-effects design matrices

fitted	Fitted responses from a linear mixed-effects model
fixedEffects	Estimates of fixed effects and related statistics
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
plotResiduals	Plot residuals of linear mixed-effects model
predict	Predict response of linear mixed-effects model
random	Generate random responses from fitted linear mixed-effects model
randomEffects	Estimates of random effects and related statistics
residuals	Residuals of fitted linear mixed-effects model
response	Response vector of the linear mixed-effects model

Copy Semantics

Examples

Random Intercept Model with Categorical Predictor

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

Because region is a nominal variable, `fitlme` takes the first region, `NE`, as the reference and creates eight dummy variables representing the other eight regions. For example, I[MidAtl] is the dummy variable representing the region `MidAtl`. For details, see “Dummy Variables” on page 2-48.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SAtl}]_i + \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \ldots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j, $j = 0, 1, \ldots, 8$, are the fixed-effects coefficients, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the

observation error for observation i. The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')
```

```
lme =

       0.18705    -0.033621      0.17162
       0.37191    -0.055948      0.14929
     0.0022936     -0.26276    -0.057514

Random effects covariance parameters (95% CIs):
Group: Date (52 Levels)
    Name1                  Name2                  Type           Estimate
    {'(Intercept)'}        {'(Intercept)'}        {'std'}        0.6443

    Lower     Upper
    0.5297    0.78368

Group: Error
    Name               Estimate    Lower      Upper
```

```
    {'Res Std'}        0.26627     0.24878    0.285
```

The *p*-values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b, do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{\text{WNCentral, 10/9/2005}} &= \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
```

```
y_hat = 1.2884
```

You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans = 1.2884
```

Compute the fitted marginal response for region `WNCentral` in week 10/9/2005.

```
F = fitted(lme,'Conditional',false);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans = 1.4602
```

Linear Mixed-Effects Model with a Random Slope

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m}\text{Acc}_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix}\right),$$

where m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Use the `'fminunc'` optimization algorithm.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'},...
'FitMethod','REML')
```

```
lme =
Linear mixed-effects model fit by REML

    3.5289e-75    -0.18398    -0.15518

Random effects covariance parameters (95% CIs):
Group: Model_Year (13 Levels)
    Name1                   Name2                   Type            Estimate
    {'Intercept'   }        {'Intercept'   }        {'std' }           3.72
    {'Acceleration'}        {'Intercept'   }        {'corr'}        -0.8769
    {'Acceleration'}        {'Acceleration'}        {'std' }         0.3593
```

```
    Lower       Upper
      1.5215      9.0954
    -0.98275    -0.33845
     0.19418     0.66483

Group: Error
    Name               Estimate    Lower     Upper
    {'Res Std'}        3.6913      3.4331    3.9688
```

The fixed effects coefficients display includes the estimate, standard errors (`SE`), and the 95% confidence interval limits (`Lower` and `Upper`). The *p*-values for (`pValue`) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the `compare` method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

```
lme.CoefficientCovariance
```

```
ans = 3×3

    5.3711   -0.2809   -0.0126
   -0.2809    0.0192    0.0005
   -0.0126    0.0005    0.0001
```

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is `sqrt(5.3711)`.

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is –0.2809 and the correlation between acceleration and horsepower is 0.0005.

Display the coefficient of determination for the model.

```
lme.Rsquared
```

```
ans = struct with fields:
    Ordinary: 0.7866
    Adjusted: 0.7855
```

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

More About

Formula

In general, a formula for model specification is a character vector or string scalar of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|`

`grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, X_j, which can be continuous or grouping variables
- Grouping variables, g_1, g_2, ..., g_R,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random`$_1$`|g`$_1$`) + ... + (random`$_R$`|g`$_R$`)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random`$_1$ is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1, and similarly `random`$_R$ is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
`1`	Constant (intercept) term
`X^k`, where `k` is a positive integer	`X`, X^2, ..., X^k
`X1 + X2`	`X1`, `X2`
`X1*X2`	`X1`, `X2`, `X1.*X2 (elementwise multiplication of X1 and X2)`
`X1:X2`	`X1.*X2` only
`- X2`	Do not include `X2`
`X1*X2 + X3`	`X1`, `X2`, `X3`, `X1*X2`
`X1 + X2 + X3 + X1:X2`	`X1`, `X2`, `X3`, `X1*X2`
`X1*X2*X3 - X1:X2:X3`	`X1`, `X2`, `X3`, `X1*X2`, `X1*X3`, `X2*X3`
`X1*(X2 + X3)`	`X1`, `X2`, `X3`, `X1*X2`, `X1*X3`

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
`'y ~ X1 + X2'`	Fixed effects for the intercept, `X1` and `X2`. This is equivalent to `'y ~ 1 + X1 + X2'`.
`'y ~ -1 + X1 + X2'`	No intercept and fixed effects for `X1` and `X2`. The implicit intercept term is suppressed by including `-1`.

Formula	Description
`'y ~ 1 + (1 | g1)'`	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable `g1`.
`'y ~ X1 + (1 | g1)'`	Random intercept model with a fixed slope.
`'y ~ X1 + (X1 | g1)'`	Random intercept and slope, with possible correlation between them. This is equivalent to `'y ~ 1 + X1 + (1 + X1|g1)'`.
`'y ~ X1 + (1 | g1) + (-1 + X1 | g1)'`	Independent random effects terms for intercept and slope.
`'y ~ 1 + (1 | g1) + (1 | g2) + (1 | g1:g2)'`	Random intercept model with independent main effects for `g1` and `g2`, plus an independent interaction effect.

linhyptest

Linear hypothesis test

Syntax

```
p = linhyptest(beta,COVB,c,H,dfe)
[p,t,r] = linhyptest(...)
```

Description

`p = linhyptest(beta,COVB,c,H,dfe)` returns the *p* value `p` of a hypothesis test on a vector of parameters. `beta` is a vector of *k* parameter estimates. `COVB` is the *k*-by-*k* estimated covariance matrix of the parameter estimates. `c` and `H` specify the null hypothesis in the form `H*b = c`, where `b` is the vector of unknown parameters estimated by `beta`. `dfe` is the degrees of freedom for the `COVB` estimate, or `Inf` if `COVB` is known rather than estimated.

`beta` is required. The remaining arguments have default values:

- `COVB = eye(k)`
- `c = zeros(k,1)`
- `H = eye(K)`
- `dfe = Inf`

If `H` is omitted, `c` must have *k* elements and it specifies the null hypothesis values for the entire parameter vector.

Note The following functions return outputs suitable for use as the `COVB` input argument to `linhyptest`: `nlinfit`, `coxphfit`, `glmfit`, `mnrfit`, `regstats`, `robustfit`. `nlinfit` returns `COVB` directly; the other functions return `COVB` in `stats.covb`.

`[p,t,r] = linhyptest(...)` also returns the test statistic `t` and the rank `r` of the hypothesis matrix `H`. If `dfe` is `Inf` or is not given, `t*r` is a chi-square statistic with `r` degrees of freedom . If `dfe` is specified as a finite value, `t` is an *F* statistic with `r` and `dfe` degrees of freedom.

`linhyptest` performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation procedure for which the parameter covariances are available, such as `regstats` or `glmfit`. For linear regression, the *p*-values are exact. For other procedures, the *p*-values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

Examples

Fit a multiple linear model to the data in `hald.mat`:

```
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
```

```
beta =
   62.4054
    1.5511
    0.5102
    0.1019
   -0.1441
```

Perform an *F*-test that the last two coefficients are both 0:

```
SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhyptest(beta,SIGMA,c,H,dfe)
p =
    0.4668
F =
    0.8391
```

Introduced in R2007a

linhyptest

Linear hypothesis tests on Cox model coefficients

Syntax

```
testTable = linhyptest(coxMdl)
```

Description

`testTable = linhyptest(coxMdl)` returns an ANOVA-style table with *p*-values for tests that determine if sequential combinations of Cox model coefficient estimates are zero. `linhyptest` tests successive null hypotheses, starting with the hypothesis that all the coefficients are 0. The function then tests to determine if all but the first coefficient are 0, all but the first two coefficients are zero, and so on, up to the number of coefficients minus one. A significant *p*-value indicates that you can reject the null hypothesis, meaning the assumption that all coefficients in a particular combination of coefficients are 0.

Examples

Perform Linear Hypothesis Test

Examine the result of `linhyptest` on the `readmissiontimes` data set.

```
load readmissiontimes
coxMdl = fitcox([Age,Sex,Weight],ReadmissionTime,...
    'Censoring',Censored);
testTable = linhyptest(coxMdl)
```

```
testTable=3×2 table
       Predictor          pValue
    ________________    __________

    {'Empty Model'}    2.5612e-07
    {'X1'         }    7.9753e-08
    {'X1, X2'     }      0.095973
```

- The first row of the returned table indicates that you can reject the hypothesis that all model coefficients are 0 at the `.05` or `.01` significance levels.
- The second row indicates that you can reject the hypothesis that only the `Sex` and `Weight` coefficients are 0 at the `.05` or `.01` significance levels.
- The third row indicates that you cannot reject the hypothesis that only the `Weight` coefficient is 0 at the `.05` or `.01` significance levels.

Input Arguments

`coxMdl` — Fitted Cox proportional hazards model

`CoxModel` object

Fitted Cox proportional hazards model, specified as a `CoxModel` object. Create `coxMdl` using `fitcox`.

Output Arguments

`testTable` — Significance levels of cumulative hypothesis tests

table

Significance levels of cumulative hypothesis tests, returned as a table. The tested coefficients are in the `Coefficients` property of the model. The table returns tests of successive null hypotheses, starting with the hypothesis that all the coefficients are 0. The second row tests whether all but the first coefficient is 0. The third row tests whether all but the first two coefficients are zero, and so on. The last row tests whether all coefficients but the last are zero. A significant *p*-value indicates that you can reject the null hypothesis, meaning the assumption that all coefficients in a particular combination of coefficients are 0. A significant *p*-value is one that is smaller than a specified significance level.

Introduced in R2021a

linkage

Agglomerative hierarchical cluster tree

Syntax

```
Z = linkage(X)
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X,method,metric,'savememory',value)

Z = linkage(X,method,pdist_inputs)

Z = linkage(y)
Z = linkage(y,method)
```

Description

`Z = linkage(X)` returns a matrix `Z` that encodes a tree containing hierarchical clusters of the rows of the input data matrix `X`.

`Z = linkage(X,method)` creates the tree using the specified `method`, which describes how to measure the distance between clusters. For more information, see “Linkages” on page 33-3554.

`Z = linkage(X,method,metric)` performs clustering by passing `metric` to the `pdist` function, which computes the distance between the rows of `X`.

`Z = linkage(X,method,metric,'savememory',value)` uses a memory-saving algorithm when `value` is `'on'`, and uses the standard algorithm when `value` is `'off'`.

`Z = linkage(X,method,pdist_inputs)` passes `pdist_inputs` to the `pdist` function, which computes the distance between the rows of `X`. The `pdist_inputs` argument consists of the `'seuclidean'`, `'minkowski'`, or `'mahalanobis'` metric and an additional distance metric option.

`Z = linkage(y)` uses a vector representation `y` of a distance matrix. `y` is either computed by `pdist` or is a more general dissimilarity matrix conforming to the output format of `pdist`.

`Z = linkage(y,method)` creates the tree using the specified `method`, which describes how to measure the distance between clusters.

Examples

Cluster Data and Plot Result

Randomly generate sample data with 20,000 observations.

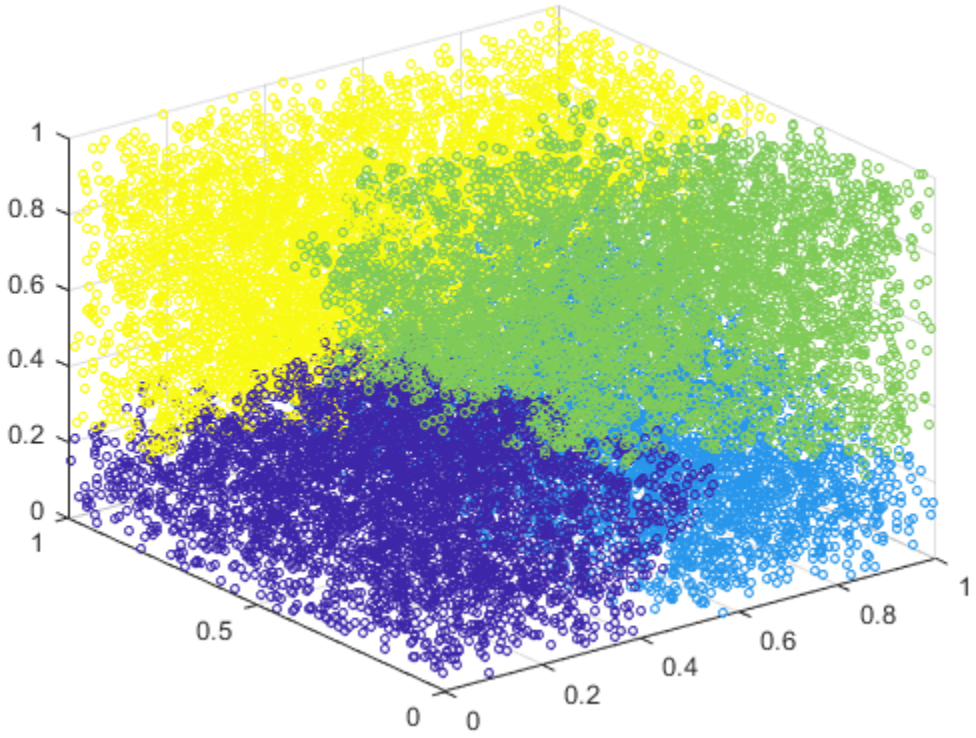
```
rng('default') % For reproducibility
X = rand(20000,3);
```

Create a hierarchical cluster tree using the `ward` linkage method. In this case, the `'SaveMemory'` option of the `clusterdata` function is set to `'on'` by default. In general, specify the best value for `'SaveMemory'` based on the dimensions of `X` and the available memory.

```
Z = linkage(X,'ward');
```

Cluster the data into a maximum of four groups and plot the result.

```
c = cluster(Z,'Maxclust',4);
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```



`cluster` identifies four groups in the data.

Compare Cluster Assignments to Classes

Find a maximum of three clusters in the `fisheriris` data set and compare cluster assignments of the flowers to their known classification.

Load the sample data.

```
load fisheriris
```

Create a hierarchical cluster tree using the `'average'` method and the `'chebychev'` metric.

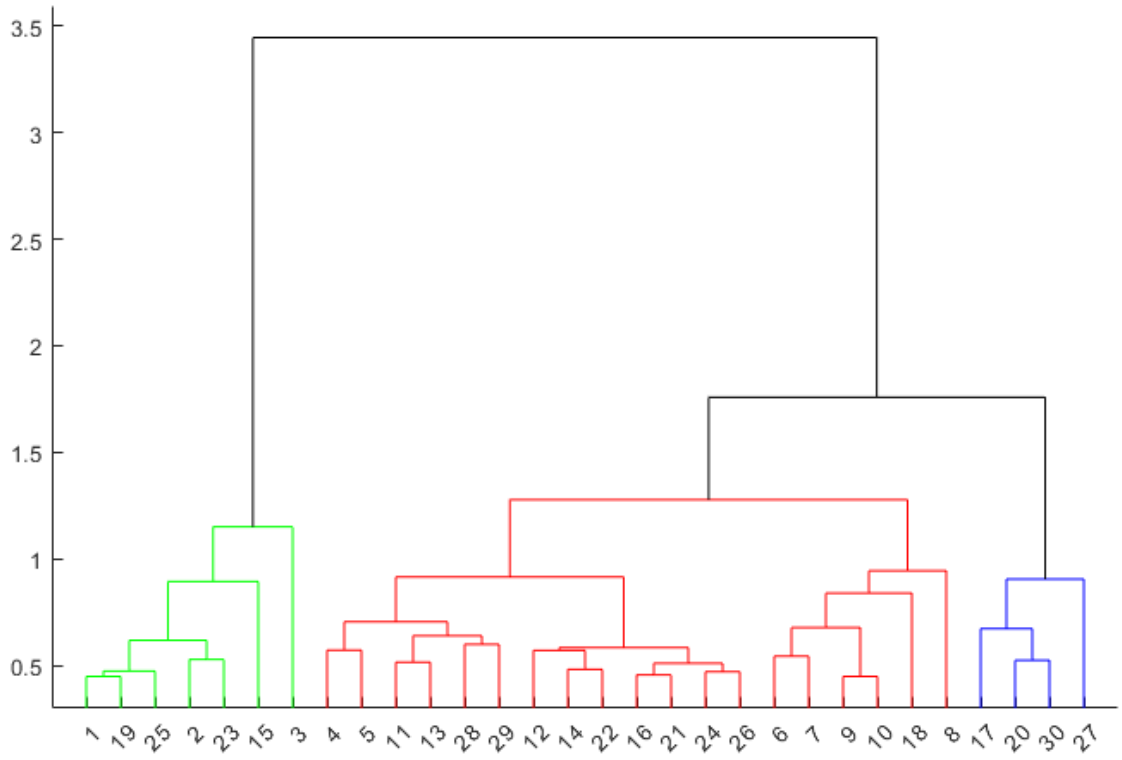
```
Z = linkage(meas,'average','chebychev');
```

Find a maximum of three clusters in the data.

```
T = cluster(Z,'maxclust',3);
```

Create a dendrogram plot of `Z`. To see the three clusters, use `'ColorThreshold'` with a cutoff halfway between the third-from-last and second-from-last linkages.

```
cutoff = median([Z(end-2,3) Z(end-1,3)]);
dendrogram(Z,'ColorThreshold',cutoff)
```



Display the last two rows of `Z` to see how the three clusters are combined into one. `linkage` combines the 293rd (blue) cluster with the 297th (red) cluster to form the 298th cluster with a linkage of `1.7583`. `linkage` then combines the 296th (green) cluster with the 298th cluster.

```
lastTwo = Z(end-1:end,:)
```

```
lastTwo = 2×3

  293.0000  297.0000    1.7583
  296.0000  298.0000    3.4445
```

See how the cluster assignments correspond to the three species. For example, one of the clusters contains `50` flowers of the second species and `40` flowers of the third species.

```
crosstab(T,species)
```

```
ans = 3×3

     0     0    10
     0    50    40
    50     0     0
```

Observe Clustering Step in Hierarchical Tree

Load the `examgrades` data set.

```
load examgrades
```

Create a hierarchical tree using `linkage`. Use the `'single'` method and the Minkowski metric with an exponent of 3.

```
Z = linkage(grades,'single',{'minkowski',3});
```

Observe the 25th clustering step.

```
Z(25,:)
```

```
ans = 1×3

   86.0000  137.0000    4.5307
```

`linkage` combines the 86th observation and the 137th cluster to form a cluster of index 120 + 25 = 145, where 120 is the total number of observations in `grades` and 25 is the row number in `Z`. The shortest distance between the 86th observation and any of the points in the 137th cluster is `4.5307`.

Cluster Data Using Dissimilarity Matrix

Create an agglomerative hierarchical cluster tree using a dissimilarity matrix.

Take a dissimilarity matrix `X` and convert it to a vector form that `linkage` accepts by using `squareform`.

```
X = [0 1 2 3; 1 0 4 5; 2 4 0 6; 3 5 6 0];
y = squareform(X);
```

Create a cluster tree using `linkage` with the `'complete'` method of calculating the distance between clusters. The first two columns of `Z` show how `linkage` combines clusters. The third column of `Z` gives the distance between clusters.

```
Z = linkage(y,'complete')
```

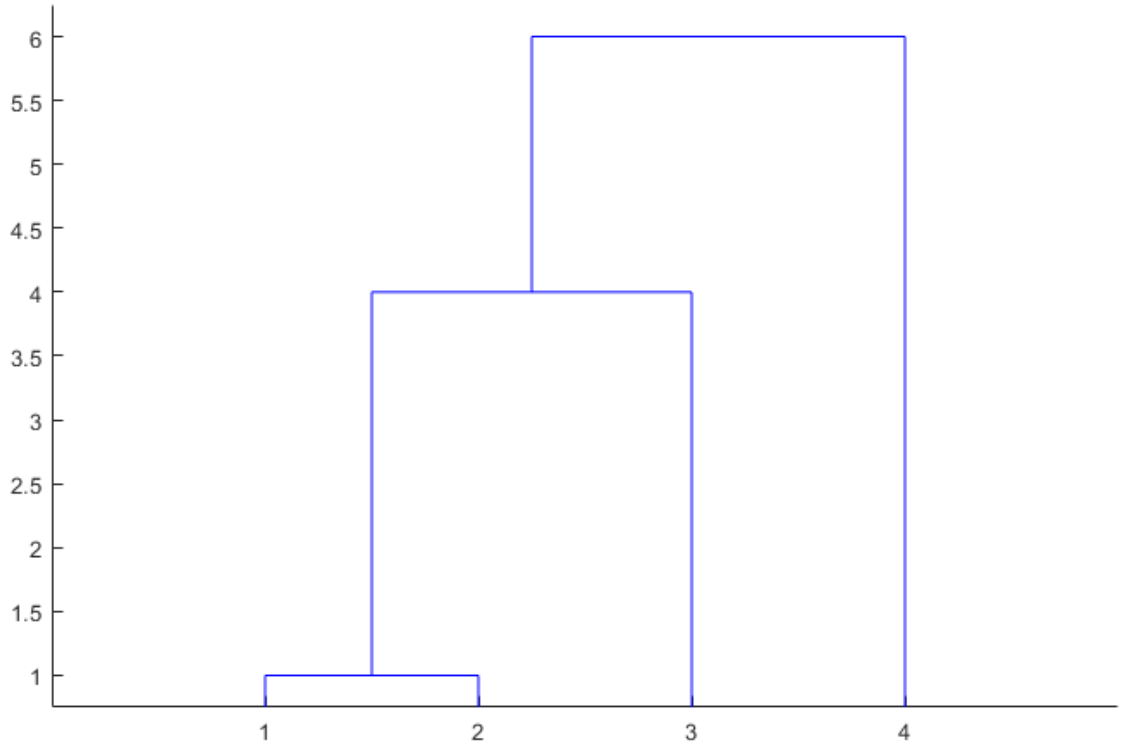
```
Z = 3×3

     1     2     1
     3     5     4
```

```
    4     6     6
```

Create a dendrogram plot of Z. The x-axis corresponds to the leaf nodes of the tree, and the y-axis corresponds to the linkage distances between clusters.

```
dendrogram(Z)
```



Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix with two or more rows. The rows represent observations, and the columns represent categories or dimensions.

Data Types: `single` | `double`

`method` — Algorithm for computing distance between clusters

`'single'` (default) | `'average'` | `'centroid'` | `'complete'` | ...

Algorithm for computing the distance between clusters, specified as one of the values in this table.

Method	Description
'average'	Unweighted average distance (UPGMA)
'centroid'	Centroid distance (UPGMC), appropriate for Euclidean distances only
'complete'	Farthest distance
'median'	Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only
'single'	Shortest distance
'ward'	Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only
'weighted'	Weighted average distance (WPGMA)

For more information on these methods, see “Linkages” on page 33-3554.

`metric` — Distance metric

`'euclidean'` (default) | `'squaredeuclidean'` | `'seuclidean'` | `'mahalanobis'` | function handle | ...

Distance metric, specified as any metric accepted by the `pdist` function. These metrics are described in the following table.

Value	Description
'euclidean'	Euclidean distance (default).
'squaredeuclidean'	Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, `S = std(X,'omitnan')`. Use `DistParameter` to specify another value for `S`.
'mahalanobis'	Mahalanobis distance using the sample covariance of `X`, `C = cov(X,'omitrows')`. Use `DistParameter` to specify another value for `C`, where the matrix `C` is symmetric and positive definite.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. Use `DistParameter` to specify a different exponent `P`, where `P` is a positive scalar value of the exponent.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

Value	Description

`@distfun`	Custom distance function handle. A distance function has the form
	`function D2 = distfun(ZI,ZJ)`
	`% calculation of distance`
	`...`
	where
	• `ZI` is a 1-by-n vector containing a single observation.
	• `ZJ` is an m2-by-n matrix containing multiple observations. `distfun` must accept a matrix `ZJ` with an arbitrary number of observations.
	• `D2` is an m2-by-1 vector of distances, and `D2(k)` is the distance between observations `ZI` and `ZJ(k,:)`.
	If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.

For more information, see “Distance Metrics” on page 33-4495.

Use `pdist_inputs` instead of `metric` to specify the additional input argument `DistParameter` of `pdist` for `'seuclidean'`, `'minkowski'`, or `'mahalanobis'`.

Data Types: `char` | `string` | `function_handle`

`pdist_inputs` — Distance metric and distance metric option
cell array

Distance metric and distance metric option, specified as a cell array of the comma-separated pair consisting of the two input arguments `Distance` and `DistParameter` of the function `pdist`. This argument is valid only for specifying `'seuclidean'`, `'minkowski'`, or `'mahalanobis'`.

Example: `{'minkowski',5}`

Data Types: `cell`

`value` — Flag for `'savememory'` option
`'on'` | `'off'`

Flag for the `'savememory'` option, specified as either `'on'` or `'off'`. The `'on'` setting causes `linkage` to construct clusters without computing the distance matrix. The `'on'` setting is available only when `method` is `'centroid'`, `'median'`, or `'ward'` and `metric` is `'euclidean'`.

When `value` is `'on'`, the `linkage` run time is proportional to the number of dimensions (number of columns of `X`). When `value` is `'off'`, the `linkage` memory requirement is proportional to N^2, where N is the number of observations. The best (least-time) setting to use for `value` depends on the problem dimensions, number of observations, and available memory. The default `value` setting is a rough approximation of an optimal setting.

The default is `'on'` when `X` has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix. Otherwise, the default is `'off'`.

Example: `'savememory','on'`

`y` — Distances
numeric vector

Distances, specified as a numeric vector with the same format as the output of the `pdist` function:

- A row vector of length $m(m – 1)/2$, corresponding to pairs of observations in a matrix with m rows
- Distances arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m – 1))

`y` can be a more general dissimilarity matrix conforming to the output format of `pdist`.

Data Types: `single` | `double`

Output Arguments

Z — Agglomerative hierarchical cluster tree

numeric matrix

Agglomerative hierarchical cluster tree, returned as a numeric matrix. `Z` is an (m – 1)-by-3 matrix, where m is the number of observations in the original data. Columns 1 and 2 of `Z` contain cluster indices linked in pairs to form a binary tree. The leaf nodes are numbered from 1 to m. Leaf nodes are the singleton clusters from which all higher clusters are built. Each newly formed cluster, corresponding to row `Z(I,:)`, is assigned the index m + `I`. The entries `Z(I,1)` and `Z(I,2)` contain the indices of the two component clusters that form cluster m + `I`. The m – 1 higher clusters correspond to the interior nodes of the clustering tree. `Z(I,3)` contains the linkage distance between the two clusters merged in row `Z(I,:)`.

For example, consider building a tree with 30 initial nodes. Suppose that cluster 5 and cluster 7 are combined at step 12, and that the distance between them at that step is 1.5. Then `Z(12,:)` is `[5 7 1.5]`. The newly formed cluster has index 12 + 30 = 42. If cluster 42 appears in a later row, then the function is combining the cluster created at step 12 into a larger cluster.

Data Types: `single` | `double`

More About

Linkages

A *linkage* is the distance between two clusters.

The following notation describes the linkages used by the various methods:

- Cluster r is formed from clusters p and q.
- n_r is the number of objects in cluster r.
- x_{ri} is the ith object in cluster r.
- *Single linkage*, also called *nearest neighbor*, uses the smallest distance between objects in the two clusters.

  $$d(r,s) = \min(dist(x_{ri}, x_{sj})), i \in (i, ..., n_r), j \in (1, ..., n_s)$$

- *Complete linkage*, also called *farthest neighbor*, uses the largest distance between objects in the two clusters.

  $$d(r,s) = \max(dist(x_{ri}, x_{sj})), i \in (1, ..., n_r), j \in (1, ..., n_s)$$

- *Average linkage* uses the average distance between all pairs of objects in any two clusters.

$$d(r,s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} dist(x_{ri}, x_{sj})$$

- *Centroid linkage* uses the Euclidean distance between the centroids of the two clusters.

  $$d(r,s) = \|\bar{x}_r - \bar{x}_s\|_2,$$

  where

  $$\bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri}$$

- *Median linkage* uses the Euclidean distance between weighted centroids of the two clusters.

  $$d(r,s) = \|\tilde{x}_r - \tilde{x}_s\|_2,$$

  where $\tilde{x}_r$ and $\tilde{x}_s$ are weighted centroids for the clusters r and s. If cluster r was created by combining clusters p and q, $\tilde{x}_r$ is defined recursively as

  $$\tilde{x}_r = \frac{1}{2}(\tilde{x}_p + \tilde{x}_q)$$

- *Ward's linkage* uses the incremental sum of squares, that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares metric is equivalent to the following distance metric $d(r,s)$, which is the formula `linkage` uses.

  $$d(r,s) = \sqrt{\frac{2n_r n_s}{(n_r + n_s)}} \|\bar{x}_r - \bar{x}_s\|_2,$$

  where

  - $\|\|_2$ is the Euclidean distance.
  - $\bar{x}_r$ and $\bar{x}_s$ are the centroids of clusters r and s.
  - n_r and n_s are the number of elements in clusters r and s.

  In some references, Ward's linkage does not use the factor of 2 multiplying $n_r n_s$. The `linkage` function uses this factor so that the distance between two singleton clusters is the same as the Euclidean distance.

- *Weighted average linkage* uses a recursive definition for the distance between two clusters. If cluster r was created by combining clusters p and q, the distance between r and another cluster s is defined as the average of the distance between p and s and the distance between q and s.

  $$d(r,s) = \frac{(d(p,s) + d(q,s))}{2}$$

Tips

- Computing `linkage(y)` can be slow when `y` is a vector representation of the distance matrix. For the `'centroid'`, `'median'`, and `'ward'` methods, `linkage` checks whether `y` is a Euclidean distance. Avoid this time-consuming check by passing in `X` instead of `y`.

- The `'centroid'` and `'median'` methods can produce a cluster tree that is not monotonic. This result occurs when the distance from the union of two clusters, *r* and *s*, to a third cluster is less than the distance between *r* and *s*. In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this result, use another method. This figure shows a nonmonotonic cluster tree.

  In this case, cluster 1 and cluster 3 are joined into a new cluster, and the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. The result is a nonmonotonic tree.

- You can provide the output `Z` to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

Topics

“Hierarchical Clustering” on page 16-6

Introduced before R2006a

loadCompactModel

(To be removed) Reconstruct model object from saved model for code generation

Note `loadCompactModel` will be removed in a future release. Use `loadLearnerForCoder` instead. To update your code, simply replace instances of `loadCompactModel` with `loadLearnerForCoder`.

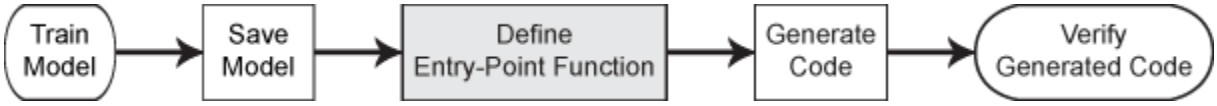
Syntax

```
Mdl = loadCompactModel(filename)
```

Description

To generate C/C++ code for the object functions (`predict`, `random`, `knnsearch`, or `rangesearch`) of machine learning models, use `saveCompactModel`, `loadCompactModel`, and `codegen`. After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls an object function. Then use `codegen` or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use `loadCompactModel` for the highlighted step.



`Mdl = loadCompactModel(filename)` reconstructs a classification model, regression model, or nearest neighbor searcher (`Mdl`) from the model stored in the MATLAB formatted binary file (MAT-file) named `filename`. You must create the `filename` file by using `saveCompactModel`.

Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls the `predict` function of the trained model. Then use `codegen` (MATLAB Coder) to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 32-19.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that `X` and `Y` contain data for two classes only.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `SVMIris.mat` by using `saveCompactModel`.

```
saveCompactModel(Mdl,'SVMIris');
```

```
Warning: saveCompactModel will be removed in a future release. Use <a href="matlab:doc saveLearne
```

Define Entry-Point Function

Define an entry-point function named `classifyIrises` that does the following:

- Accept iris flower measurements with columns corresponding to `meas`, and return predicted labels.
- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

```
type classifyIrises.m % Display contents of classifyIrises.m file
```

```
function label = classifyIrises(X) %#codegen
%CLASSIFYIRISES Classify iris species using SVM Model
%   CLASSIFYIRISES classifies the iris flower measurements in X using the
%   compact SVM model in the file SVMIris.mat, and then returns class
%   labels in label.
CompactMdl = loadCompactModel('SVMIris');
label = predict(CompactMdl,X);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen` (MATLAB Coder). Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point

function at compile time. Pass `X` as the value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof` (MATLAB Coder). For details, see "Specify Variable-Size Arguments for Code Generation" on page 32-45 and "Specify Properties of Entry-Point Function Inputs" (MATLAB Coder).

```
codegen classifyIrises -args {X}
```

```
Code generation successful.
```

`codegen` generates the MEX function `classifyIrises_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIrises`, and `classifyIrises_mex`.

```
label1 = predict(Mdl,X);
label2 = classifyIrises(X);
```

```
Warning: loadCompactModel will be removed in a future release. Use <a href="matlab:doc loadLearne
```

```
label3 = classifyIrises_mex(X);
```

```
Warning: loadCompactModel will be removed in a future release. Use <a href="matlab:doc loadLearne
```

```
verify_label = isequal(label1,label2,label3)
```

```
verify_label = logical
   1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

Input Arguments

`filename` — Name of MAT-file that contains structure array representing a model object
character vector | string scalar

Name of the MAT-file that contains the structure array representing a model object, specified as a character vector or string scalar. You must create the `filename` file using `saveCompactModel`.

`loadCompactModel` reconstructs the model stored in the `filename` file at compile time. For supported models, see the `Mdl` input argument of `saveCompactModel`.

The extension of the `filename` file must be `.mat`. If `filename` has no extension, then `loadCompactModel` appends `.mat`.

If `filename` does not include a full path, then `loadCompactModel` loads the file from the current folder.

Example: `'Mdl'`

Data Types: `char` | `string`

Output Arguments

`Mdl` — Machine learning model
model object

Machine learning model, returned as one of these model objects:

- Classification model object
  - `ClassificationKNN`
  - `ClassificationLinear`
  - `CompactClassificationDiscriminant`
  - `CompactClassificationECOC`
  - `CompactClassificationEnsemble`
  - `CompactClassificationNaiveBayes`
  - `CompactClassificationSVM` — If you use `saveCompactModel` to save an SVM model that is equipped to predict posterior probabilities, and use `loadCompactModel` to load the model, then `loadCompactModel` cannot restore the ScoreTransform property into the MATLAB Workspace. However, `loadCompactModel` can load the model, including the ScoreTransform property, at compile time for code generation, within an entry-point function.
  - `CompactClassificationTree`
- Regression model object
  - `CompactGeneralizedLinearModel`
  - `CompactLinearModel` — Suppose you train a linear model by using `fitlm` and specifying `'RobustOpts'` as a structure with an anonymous function handle for the `RobustWgtFun` field, use `saveCompactModel` to save the model, and then use `loadCompactModel` to load the model. In this case, `loadCompactModel` cannot restore the Robust property into the MATLAB Workspace. However, `loadCompactModel` can load the model at compile time within an entry-point function for code generation.
  - `CompactRegressionEnsemble`
  - `CompactRegressionGP`
  - `CompactRegressionSVM`
  - `CompactRegressionTree`
  - `RegressionLinear`
- Nearest neighbor searcher object
  - `ExhaustiveSearcher`
  - `KDTreeSearcher`

Algorithms

`saveCompactModel` prepares a machine learning model (`Mdl`) for code generation. The function removes some properties that are not required for prediction.

- For a model that has a corresponding compact model, the `saveCompactModel` function applies the appropriate `compact` function to the model before saving it.

- For a model that does not have a corresponding compact model, such as `ClassificationKNN`, `ClassificationLinear`, `RegressionLinear`, `ExhaustiveSearcher`, and `KDTreeSearcher`, the `saveCompactModel` function removes properties such as hyperparameter optimization properties, training solver information, and others.

`loadCompactModel` loads the model saved by `saveCompactModel`.

Alternative Functionality

- Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	`ClassificationTreeCoderConfigurer`
SVM for one-class and binary classification	`ClassificationSVMCoderConfigurer`
Linear model for binary classification	`ClassificationLinearCoderConfigurer`
Multiclass model for SVMs and linear models	`ClassificationECOCCoderConfigurer`
Binary decision tree for regression	`RegressionTreeCoderConfigurer`
Support vector machine (SVM) regression	`RegressionSVMCoderConfigurer`
Linear regression	`RegressionLinearCoderConfigurer`

  After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 32-80.

Compatibility Considerations

`loadCompactModel` will be removed

Warns starting in R2020b

`loadCompactModel` will be removed in a future release. Use `loadLearnerForCoder` instead.

`saveLearnerForCoder` and `loadLearnerForCoder` provide broader functionality, including fixed-point code generation for supported models.

This table shows how to update your code to use `loadLearnerForCoder`.

Not Recommended	Recommended
`Mdl = loadCompactModel('MyModel');`	`Mdl = loadLearnerForCoder('MyModel');`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Introduced in R2016b

loadLearnerForCoder

Reconstruct model object from saved model for code generation

Syntax

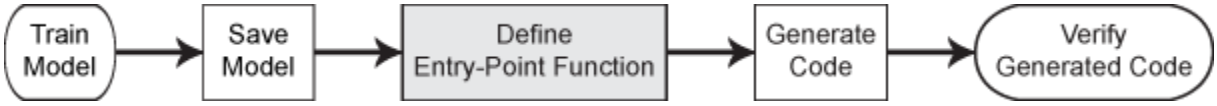
```
Mdl = loadLearnerForCoder(filename)
Mdl = loadLearnerForCoder(filename,'DataType','single')
Mdl = loadLearnerForCoder(filename,'DataType',T)
```

Description

To generate C/C++ code for the object functions of machine learning models (including `predict`, `random`, `knnsearch`, `rangesearch`, and incremental learning functions) , use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`. After training a machine learning model, save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls an object function. Then use `codegen` or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

For functions that support single-precision C/C++ code generation, use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`; specify the name-value argument `'DataType','single'` when you call the `loadLearnerForCoder` function.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use `loadLearnerForCoder` for the highlighted step.



Fixed-point C/C++ code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

This flow chart shows the fixed-point code generation workflow for the `predict` function of a machine learning model. Use `loadLearnerForCoder` for the highlighted step.

`Mdl = loadLearnerForCoder(filename)` reconstructs a classification model, regression model, or nearest neighbor searcher (`Mdl`) from the model stored in the MATLAB formatted binary file (MAT-file) named `filename`. You must create the `filename` file by using `saveLearnerForCoder`.

`Mdl = loadLearnerForCoder(filename,'DataType','single')` reconstructs a single-precision classification or regression model (`Mdl`) from the model stored in the MATLAB formatted binary file (MAT-file) named `filename`.

`Mdl = loadLearnerForCoder(filename,'DataType',T)` returns a fixed-point version of the model stored in `filename`. The structure `T` contains the fields that specify the fixed-point data types

for the variables required to use the `predict` function of the model. Create `T` using the function generated by `generateLearnerDataTypeFcn`.

Use this syntax in an entry-point function, and use `codegen` to generate fixed-point code for the entry-point function. You can use this syntax only when generating code.

Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the trained model. Then use `codegen` (MATLAB Coder) to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 32-19.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that `X` and `Y` contain data for two classes only.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `SVMIris.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'SVMIris');
```

Define Entry-Point Function

Define an entry-point function named `classifyIris` that does the following:

- Accept iris flower measurements with columns corresponding to `meas`, and return predicted labels.
- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

```
type classifyIris.m % Display contents of classifyIris.m file
```

```
function label = classifyIris(X) %#codegen
%CLASSIFYIRIS Classify iris species using SVM Model
%   CLASSIFYIRIS classifies the iris flower measurements in X using the SVM
%   model in the file SVMIris.mat, and then returns class labels in label.
Mdl = loadLearnerForCoder('SVMIris');
label = predict(Mdl,X);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen` (MATLAB Coder). Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass `X` as the value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof` (MATLAB Coder). For details, see “Specify Variable-Size Arguments for Code Generation” on page 32-45 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen classifyIris -args {X}
```

```
Code generation successful.
```

`codegen` generates the MEX function `classifyIris_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIris`, and `classifyIris_mex`.

```
label1 = predict(Mdl,X);
label2 = classifyIris(X);
label3 = classifyIris_mex(X);
verify_label = isequal(label1,label2,label3)
```

```
verify_label = logical
   1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

Generate Single-Precision C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the trained model. Then use `codegen` (MATLAB Coder) to generate C/C++ code.

This example briefly explains the single-precision code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22 for details.

Train Model

Load the `fisheriris` data set. Create `X` as a numeric matrix that contains four petal measurements for 150 irises. Create `Y` as a cell array of character vectors that contains the corresponding iris species.

```
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using predictors `X` and class labels `Y`.

```
Mdl = fitcnb(X,Y);
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

Save Model

Save the naive Bayes classification model to the file `naiveBayesIris.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'naiveBayesIris');
```

Define Entry-Point Function

Define an entry-point function named `classifyIrisSingle` that does the following:

- Accept iris flower measurements with columns corresponding to petal measurements, and return predicted labels.
- Load a trained naive Bayes classification model.
- Predict labels using the single-precision loaded classification model for the iris flower measurements.

```
type classifyIrisSingle.m
```

```
function label = classifyIrisSingle(X) %#codegen
% CLASSIFYIRISSINGLE Classify iris species using single-precision naive
% Bayes model
% CLASSIFYIRISSINGLE classifies the iris flower measurements in X using the
% single-precision naive Bayes model in the file naiveBayesIris.mat, and
% then returns the predicted labels in label.
Mdl = loadLearnerForCoder('naiveBayesIris','DataType','single');
label = predict(Mdl,X);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB, then MATLAB opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen` (MATLAB Coder). Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass `X` as the value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof` (MATLAB Coder). For details, see “Specify Variable-Size Arguments for Code Generation” on page 32-45 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
Xpred = single(X);
codegen classifyIrisSingle -args Xpred
```

```
Code generation successful.
```

`codegen` generates the MEX function `classifyIrisSingle_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIrisSingle`, and `classifyIrisSingle_mex`.

```
label1 = predict(Mdl,X);
label2 = classifyIrisSingle(X);
label3 = classifyIrisSingle_mex(Xpred);
verify_label = isequal(label1,label2,label3)
```

```
verify_label = logical
   1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same. If the generated MEX function `classifyIrisSingle_mex` and the function `predict` do not produce the same classification results, you can compute the percentage of incorrectly classified labels.

```
sum(strcmp(label3,label1)==0)/numel(label1)*100
```

```
ans = 0
```

Generate Fixed-Point C/C++ Code for Prediction

After training a machine learning model, save the model using `saveLearnerForCoder`. For fixed-point code generation, specify the fixed-point data types of the variables required for prediction by using the data type function generated by `generateLearnerDataTypeFcn`. Then, define an entry-point function that loads the model by using both `loadLearnerForCoder` and the specified fixed-point data types, and calls the `predict` function of the model. Use `codegen` (MATLAB Coder) to generate fixed-point C/C++ code for the entry-point function, and then verify the generated code.

Before generating code using `codegen`, you can use `buildInstrumentedMex` (Fixed-Point Designer) and `showInstrumentationResults` (Fixed-Point Designer) to optimize the fixed-point

data types to improve the performance of the fixed-point code. Record minimum and maximum values of named and internal variables for prediction by using `buildInstrumentedMex`. View the instrumentation results using `showInstrumentationResults`; then, based on the results, tune the fixed-point data type properties of the variables. For details regarding this optional step, see “Fixed-Point Code Generation for Prediction of SVM” on page 32-87.

Train Model

Load the `ionosphere` data set and train a binary SVM classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y,'KernelFunction','gaussian');
```

`Mdl` is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'myMdl');
```

Define Fixed-Point Data Types

Use `generateLearnerDataTypeFcn` to generate a function that defines the fixed-point data types of the variables required for prediction of the SVM model.

```
generateLearnerDataTypeFcn('myMdl',X)
```

`generateLearnerDataTypeFcn` generates the `myMdl_datatype` function.

Create a structure `T` that defines the fixed-point data types by using `myMdl_datatype`.

```
T = myMdl_datatype('Fixed')
```

```
T = struct with fields:
               XDataType: [0x0 embedded.fi]
           ScoreDataType: [0x0 embedded.fi]
    InnerProductDataType: [0x0 embedded.fi]
```

The structure `T` includes the fields for the named and internal variables required to run the `predict` function. Each field contains a fixed-point object, returned by `fi` (Fixed-Point Designer). The fixed-point object specifies fixed-point data type properties, such as word length and fraction length. For example, display the fixed-point data type properties of the predictor data.

```
T.XDataType
```

```
ans =

[]

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 14

        RoundingMethod: Floor
        OverflowAction: Wrap
```

```
          ProductMode: FullPrecision
  MaxProductWordLength: 128
              SumMode: FullPrecision
      MaxSumWordLength: 128
```

Define Entry-Point Function

Define an entry-point function named `myFixedPointPredict` that does the following:

- Accept the predictor data `X` and the fixed-point data type structure `T`.
- Load a fixed-point version of a trained SVM classification model by using both `loadLearnerForCoder` and the structure `T`.
- Predict labels and scores using the loaded model.

```
type myFixedPointPredict.m % Display contents of myFixedPointPredict.m file
```

```
function [label,score] = myFixedPointPredict(X,T) %#codegen
Mdl = loadLearnerForCoder('myMdl','DataType',T);
[label,score] = predict(Mdl,X);
end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

Generate Code

The `XDataType` field of the structure `T` specifies the fixed-point data type of the predictor data. Convert `X` to the type specified in `T.XDataType` by using the `cast` (Fixed-Point Designer) function.

```
X_fx = cast(X,'like',T.XDataType);
```

Generate code for the entry-point function using `codegen`. Specify `X_fx` and constant folded `T` as input arguments of the entry-point function.

```
codegen myFixedPointPredict -args {X_fx,coder.Constant(T)}
```

```
Code generation successful.
```

`codegen` generates the MEX function `myFixedPointPredict_mex` with a platform-dependent extension.

Verify Generated Code

Pass predictor data to `predict` and `myFixedPointPredict_mex` to compare the outputs.

```
[labels,scores] = predict(Mdl,X);
[labels_fx,scores_fx] = myFixedPointPredict_mex(X_fx,T);
```

Compare the outputs from `predict` and `myFixedPointPredict_mex`.

```
verify_labels = isequal(labels,labels_fx)
```

```
verify_labels = logical
   1
```

`isequal` returns logical 1 (true), which means `labels` and `labels_fx` are equal. If the labels are not equal, you can compute the percentage of incorrectly classified labels as follows.

```
sum(strcmp(labels_fx,labels)==0)/numel(labels_fx)*100
```

```
ans = 0
```

Find the maximum of the relative differences between the score outputs.

```
relDiff_scores = max(abs((scores_fx.double(:,1)-scores(:,1))./scores(:,1)))
```

```
relDiff_scores = 0.0055
```

If you are not satisfied with the comparison results and want to improve the precision of the generated code, you can tune the fixed-point data types and regenerate the code. For details, see “Tips” on page 33-2632 in `generateLearnerDataTypeFcn`, “Data Type Function” on page 33-2631, and “Fixed-Point Code Generation for Prediction of SVM” on page 32-87.

Input Arguments

`filename` — Name of MAT-file that contains structure array representing a model object

character vector | string scalar

Name of the MAT-file that contains the structure array representing a model object, specified as a character vector or string scalar. You must create the `filename` file using `saveLearnerForCoder`. `loadLearnerForCoder` reconstructs the model stored in the `filename` file at compile time.

The extension of the `filename` file must be `.mat`. If `filename` has no extension, then `loadLearnerForCoder` appends `.mat`.

If `filename` does not include a full path, then `loadLearnerForCoder` loads the file from the current folder.

These tables show the models you can save using `saveLearnerForCoder` and whether each model supports fixed-point and single-precision code generation.

- **Classification Model Object**

Model	Full/Compact Model Objects	Fixed-Point Code Generation Support	Single-Precision Code Generation Support
Binary decision tree for classification	`ClassificationTree`, `CompactClassificationTree`	Yes	Yes
Discriminant analysis classification	`ClassificationDiscriminant`, `CompactClassificationDiscriminant`	No	Yes
Ensemble classifier	`ClassificationEnsemble`, `CompactClassificationEnsemble`, `ClassificationBaggedEnsemble`	Yes (Only for ensembles of decision trees)	Yes
Binary classification linear model for incremental learning	`incrementalClassificationLinear`	No	Yes
k-nearest neighbor classification	`ClassificationKNN`	No	Yes
Linear model for binary classification of high-dimensional data	`ClassificationLinear`	No	Yes
Multiclass model for support vector machines (SVMs) or other classifiers	`ClassificationECOC`, `CompactClassificationECOC`	No	Yes
Naive Bayes classifier	`ClassificationNaiveBayes`, `CompactClassificationNaiveBayes`	No	Yes
SVM for one-class and binary classification	`ClassificationSVM`, `CompactClassificationSVM`	Yes	Yes

- **Regression Model Object**

Model	Full/Compact Model Object	Fixed-Point Code Generation Support	Single-Precision Code Generation Support
Ensemble regression	`RegressionEnsemble`, `CompactRegressionEnsemble`, `RegressionBaggedEnsemble`	Yes	Yes
Gaussian process regression	`RegressionGP`, `CompactRegressionGP`	No	Yes (see "Tips" on page 33-3574)
Generalized linear model	`GeneralizedLinearModel`, `CompactGeneralizedLinearModel`	No	No
Linear regression model for incremental learning	`incrementalRegressionLinear`	No	Yes
Linear regression model	`LinearModel`, `CompactLinearModel`	No	Yes
Linear regression for high-dimensional data	`RegressionLinear`	No	No
Regression tree	`RegressionTree`, `CompactRegressionTree`	Yes	Yes
SVM regression	`RegressionSVM`, `CompactRegressionSVM`	Yes	Yes

- **Nearest Neighbor Searcher Object**

Model	Model Object	Fixed-Point Code Generation Support	Single-Precision Code Generation Support
Exhaustive nearest neighbor searcher	`ExhaustiveSearcher`	No	No
Nearest neighbor searcher using *K*d-tree	`KDTreeSearcher`	No	No

Example: `'Mdl'`

Data Types: `char` | `string`

T — Fixed-point data types
structure

Fixed-point data types, specified as a structure. This argument is for fixed-point C/C++ code generation.

Create `T` using a function generated by `generateLearnerDataTypeFcn`. For details about the generated function and the structure `T`, see `generateLearnerDataTypeFcn` and "Data Type Function" on page 33-2631.

You can use this argument when the model in the `filename` file is an SVM model, a decision tree model, and an ensemble of decision trees.

Data Types: `struct`

Output Arguments

`Mdl` — Machine learning model

model object

Machine learning model, returned as one of these model objects:

- Classification model object
  - `ClassificationKNN`
  - `ClassificationLinear`
  - `CompactClassificationDiscriminant`
  - `CompactClassificationECOC`
  - `CompactClassificationEnsemble`
  - `CompactClassificationNaiveBayes`
  - `CompactClassificationSVM` — If you use `saveLearnerForCoder` to save an SVM model that is equipped to predict posterior probabilities, and use `loadLearnerForCoder` to load the model, then `loadLearnerForCoder` cannot restore the ScoreTransform property into the MATLAB Workspace. However, `loadLearnerForCoder` can load the model, including the ScoreTransform property, at compile time for code generation, within an entry-point function.
  - `CompactClassificationTree`
  - `incrementalClassificationLinear`
- Regression model object
  - `CompactGeneralizedLinearModel`
  - `CompactLinearModel` — Suppose you train a linear model by using `fitlm` and specifying `'RobustOpts'` as a structure with an anonymous function handle for the `RobustWgtFun` field, use `saveLearnerForCoder` to save the model, and then use `loadLearnerForCoder` to load the model. In this case, `loadLearnerForCoder` cannot restore the Robust property into the MATLAB Workspace. However, `loadLearnerForCoder` can load the model at compile time within an entry-point function for code generation.
  - `CompactRegressionEnsemble`
  - `CompactRegressionGP`
  - `CompactRegressionSVM`
  - `CompactRegressionTree`
  - `incrementalRegressionLinear`

  - `RegressionLinear`
- Nearest neighbor searcher object
  - `ExhaustiveSearcher`
  - `KDTreeSearcher`

Tips

- For single-precision code generation for a Gaussian process regression (GPR) model, create the model by using `fitrgp(X,Y,'Standardize',1)`.

Algorithms

`saveLearnerForCoder` prepares a machine learning model (`Mdl`) for code generation. The function removes some unnecessary properties.

- For a model that has a corresponding compact model, the `saveLearnerForCoder` function applies the appropriate `compact` function to the model before saving it.
- For a model that does not have a corresponding compact model, such as `ClassificationKNN`, `ClassificationLinear`, `RegressionLinear`, `ExhaustiveSearcher`, and `KDTreeSearcher`, the `saveLearnerForCoder` function removes properties such as hyperparameter optimization properties, training solver information, and others.

`loadLearnerForCoder` loads the model saved by `saveLearnerForCoder`.

Alternative Functionality

- Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	`ClassificationTreeCoderConfigurer`
SVM for one-class and binary classification	`ClassificationSVMCoderConfigurer`
Linear model for binary classification	`ClassificationLinearCoderConfigurer`
Multiclass model for SVMs and linear models	`ClassificationECOCCoderConfigurer`
Binary decision tree for regression	`RegressionTreeCoderConfigurer`
Support vector machine (SVM) regression	`RegressionSVMCoderConfigurer`
Linear regression	`RegressionLinearCoderConfigurer`

  After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 32-80.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For fixed-point C/C++ code generation, the input argument T must be a compile-time constant. For an example, see “Generate Fixed-Point C/C++ Code for Prediction” on page 33-3567.

For more information, see “Introduction to Code Generation” on page 32-2.

Introduced in R2019b

logncdf

Lognormal cumulative distribution function

Syntax

```
p = logncdf(x)
p = logncdf(x,mu)
p = logncdf(x,mu,sigma)

[p,pLo,pUp] = logncdf(x,mu,sigma,pCov)
[p,pLo,pUp] = logncdf(x,mu,sigma,pCov,alpha)

___ = logncdf( ___ ,'upper')
```

Description

`p = logncdf(x)` returns the cumulative distribution function (cdf) of the standard lognormal distribution, evaluated at the values in `x`. In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

`p = logncdf(x,mu)` returns the cdf of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the values in `x`.

`p = logncdf(x,mu,sigma)` returns the cdf of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values), evaluated at the values in `x`.

`[p,pLo,pUp] = logncdf(x,mu,sigma,pCov)` also returns the 95% confidence bounds `[pLo,pUp]` of `p` using the estimated parameters (`mu` and `sigma`) and their covariance matrix `pCov`.

`[p,pLo,pUp] = logncdf(x,mu,sigma,pCov,alpha)` specifies the confidence level for the confidence interval `[pLo,pUp]` to be `100(1–alpha)`%.

`___ = logncdf( ___ ,'upper')` returns the complement of the cdf, evaluated at the values in `x`, using an algorithm that more accurately computes the extreme upper-tail probabilities. `'upper'` can follow any of the input argument combinations in the previous syntaxes.

Examples

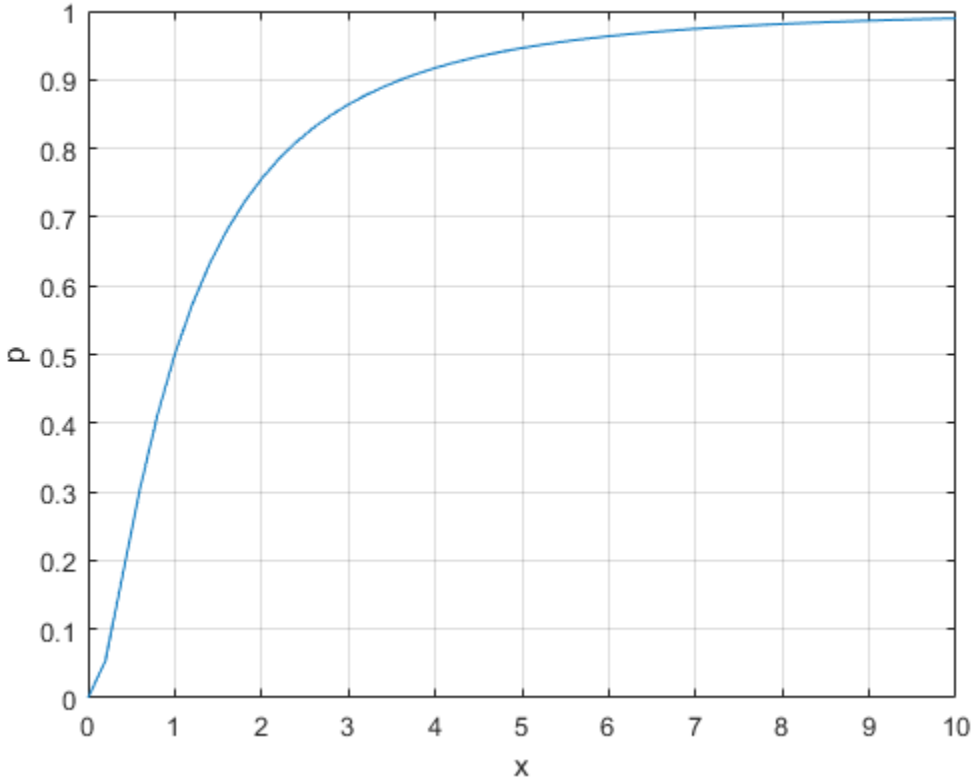
Compute Lognormal Distribution cdf

Compute the cdf values evaluated at the values in `x` for the lognormal distribution with mean `mu` and standard deviation `sigma`.

```
x = 0:0.2:10;
mu = 0;
sigma = 1;
p = logncdf(x,mu,sigma);
```

Plot the cdf.

```
plot(x,p)
grid on
xlabel('x')
ylabel('p')
```



Confidence Interval of Lognormal cdf Value

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```
phat = mle(x,'distribution','LogNormal')
```

```
phat = 1×2
```

```
    4.9347    1.9969
```

```
muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `lognlike`. The function `lognlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = lognlike(phat,x)
```

```
pCov = 2×2

    0.0040   -0.0000
   -0.0000    0.0020
```

Find the cdf value at 0.5 and its 95% confidence interval.

```
[p,pLo,pUp] = logncdf(0.5,muHat,sigmaHat,pCov)
```

```
p = 0.0024
```

```
pLo = 0.0016
```

```
pUp = 0.0037
```

`p` is the cdf value of the lognormal distribution with the parameters `muHat` and `sigmaHat`. The interval `[pLo,pUp]` is the 95% confidence interval of the cdf evaluated at 0.5, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 95% confidence interval means the probability that `[pLo,pUp]` contains the true cdf value is 0.95.

Complementary cdf (Tail Distribution)

Determine the probability that an observation from a standard lognormal distribution will fall on the interval `[exp(10),Inf]`.

```
p1 = 1 - logncdf(exp(10))
```

```
p1 = 0
```

`logncdf(exp(10))` is nearly 1, so `p1` becomes 0. Specify `'upper'` so that `logncdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = logncdf(exp(10),'upper')
```

```
p2 = 7.6199e-24
```

You can also use `'upper'` to compute a right-tailed *p*-value.

Input Arguments

x — Values at which to evaluate cdf

positive scalar value | array of positive scalar values

Values at which to evaluate the cdf, specified as a positive scalar value or an array of positive scalar values.

If you specify `pCov` to compute the confidence interval `[pLo,pUp]`, then `x` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logncdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[-1,0,3,4]`

Data Types: `single` | `double`

`mu` — Mean of logarithmic values
`0` (default) | scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval `[pLo,pUp]`, then `mu` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logncdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

`sigma` — Standard deviation of logarithmic values
`1` (default) | positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify `pCov` to compute the confidence interval `[pLo,pUp]`, then `sigma` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logncdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

`pCov` — Covariance of estimates
2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval `[pLo,pUp]`, then `x`, `mu`, and `sigma` must be scalar values.

You can estimate the maximum likelihood estimates of `mu` and `sigma` by using `mle`, and estimate the covariance of `mu` and `sigma` by using `lognlike`. For an example, see “Confidence Interval of Lognormal cdf Value” on page 33-3577.

Data Types: `single` | `double`

`alpha` — Significance level
0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is `100(1–alpha)`%, where `alpha` is the probability that the confidence interval does not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

Output Arguments

`p` — cdf values
scalar value | array of scalar values

cdf values, evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

`pLo` — Lower confidence bound for `p`
scalar value | array of scalar values

Lower confidence bound for `p`, returned as a scalar value or an array of scalar values. `pLo` has the same size as `p`.

`pUp` — Upper confidence bound for `p`
scalar value | array of scalar values

Upper confidence bound for `p`, returned as a scalar value or an array of scalar values. `pUp` has the same size as `p`.

More About

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The cumulative distribution function (cdf) of the lognormal distribution is

$$p = F(x \mid \mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}}\int_0^x \frac{1}{t}\exp\left\{\frac{-(\log t-\mu)^2}{2\sigma^2}\right\}dt, \quad \text{for } x > 0.$$

Algorithms

- The `logncdf` function uses the complementary error function `erfc`. The relationship between `logncdf` and `erfc` is

  $$\text{logncdf}(x, 0, 1) = \frac{1}{2}\text{erfc}\left(-\frac{\log x}{\sqrt{2}}\right).$$

  The complementary error function `erfc(x)` is defined as

  $$\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}}\int_x^\infty e^{-t^2}dt.$$

- The `logncdf` function computes confidence bounds for `p` by using the delta method. The normal distribution cdf value of `log(x)` with the parameters `mu` and `sigma` is equivalent to the cdf value of `(log(x)–mu)/sigma` with the parameters 0 and 1. Therefore, the `logncdf` function estimates the variance of `(log(x)–mu)/sigma` using the covariance matrix of `mu` and `sigma` by the delta method, and finds the confidence bounds of `(log(x)–mu)/sigma` using the estimates of this variance. Then, the function transforms the bounds to the scale of `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pCov` from large samples.

Alternative Functionality

- `logncdf` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, create a `LognormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `logncdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Introduced before R2006a

lognfit

Lognormal parameter estimates

Syntax

```
pHat = lognfit(x)

[pHat,pCI] = lognfit(x)
[pHat,pCI] = lognfit(x,alpha)

[ ___ ] = lognfit(x,alpha,censoring)
[ ___ ] = lognfit(x,alpha,censoring,freq)
[ ___ ] = lognfit(x,alpha,censoring,freq,options)
```

Description

`pHat = lognfit(x)` returns unbiased estimates of lognormal distribution parameters, given the sample data in `x`. `pHat(1)` and `pHat(2)` are the mean and standard deviation of logarithmic values, respectively.

`[pHat,pCI] = lognfit(x)` also returns 95% confidence intervals for the parameter estimates.

`[pHat,pCI] = lognfit(x,alpha)` specifies the confidence level for the confidence intervals to be `100(1–alpha)`%.

`[ ___ ] = lognfit(x,alpha,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed. With censoring, the `phat` values are the maximum likelihood estimates (MLEs).

`[ ___ ] = lognfit(x,alpha,censoring,freq)` specifies the frequency or weights of observations.

`[ ___ ] = lognfit(x,alpha,censoring,freq,options)` specifies optimization options for the iterative algorithm `lognfit` to use to compute MLEs with censoring. Create `options` by using the function `statset`.

You can pass in `[]` for `alpha`, `censoring`, and `freq` to use their default values.

Examples

Estimate Parameters and Confidence Intervals

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Find the parameter estimates and the 99% confidence intervals.

```
[pHat,pCI] = lognfit(x,0.01)
```

```
pHat = 1×2

    4.9347    1.9979

pCI = 2×2

    4.7717    1.8887
    5.0978    2.1196
```

`pHat(1)` and `pHat(2)` are the mean and standard deviation of logarithmic values, respectively. `pCI` contains the 99% confidence intervals of the mean and standard deviation parameters. The values in the first row are the lower bounds, and the values in the second row are the upper bounds.

Change Algorithm Options

Find the MLEs of a data set with censoring by using `lognfit`. Use `statset` to specify the iterative algorithm options that `lognfit` uses to compute MLEs for censored data, and then find the MLEs again.

Generate the true times `x` that follow the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Generate the censoring times. Note that the censoring times must be independent of the true times `x`.

```
censtime = normrnd(150,20,size(x));
```

Specify the indicator for the censoring times and the observed times.

```
censoring = x>censtime;
y = min(x,censtime);
```

Find the MLEs of the lognormal distribution parameters. The second input argument of `lognfit` specifies the confidence level. Pass in `[]` to use its default value 0.05. The third input argument specifies the censorship information.

```
pHat = lognfit(y,[],censoring)
```

```
pHat = 1×2

    4.9535    1.9996
```

Display the default algorithm parameters that `lognfit` uses to estimate the lognormal distribution parameters.

```
statset('lognfit')
```

```
ans = struct with fields:
          Display: 'off'
```

```
      MaxFunEvals: 200
          MaxIter: 100
           TolBnd: 1.0000e-06
           TolFun: 1.0000e-08
        TolTypeFun: []
              TolX: 1.0000e-08
         TolTypeX: []
          GradObj: []
         Jacobian: []
        DerivStep: []
      FunValCheck: []
           Robust: []
     RobustWgtFun: []
           WgtFun: []
             Tune: []
      UseParallel: []
    UseSubstreams: []
          Streams: {}
        OutputFcn: []
```

Save the options using a different name. Change how the results are displayed (`Display`) and the termination tolerance for the objective function (`TolFun`).

```
options = statset('lognfit');
options.Display = 'final';
options.TolFun = 1e-10;
```

Alternatively, you can specify algorithm parameters by using the name-value pair arguments of the function `statset`.

```
options = statset('Display','final','TolFun',1e-10);
```

Find the MLEs with the new algorithm parameters.

```
pHat = lognfit(y,[],censoring,[],options)
```

```
Successful convergence: Norm of gradient less than OPTIONS.TolFun

pHat = 1×2

    4.9535    1.9996
```

`lognfit` displays a report on the final iteration.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence intervals, specified as a scalar in the range (0,1). The confidence level is `100(1–alpha)`%, where `alpha` is the probability that the confidence intervals do not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

`censoring` — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in `x`, specified as a logical vector of the same size as `x`. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

`freq` — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted MLEs for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

`options` — Optimization options

`statset('lognfit')` (default) | structure

Optimization options, specified as a structure. `options` determines the control parameters for the iterative algorithm that `lognfit` uses to compute MLEs for censored data.

Create `options` by using the function `statset` or by creating a structure array containing the fields and values described in this table.

Field Name	Value	Default Value
`Display`	Amount of information displayed by the algorithm. • `'off'` — Displays no information. • `'final'` — Displays the final output.	`'off'`
`MaxFunEvals`	Maximum number of objective function evaluations allowed, specified as a positive integer.	`200`
`MaxIter`	Maximum number of iterations allowed, specified as a positive integer.	`100`

Field Name	Value	Default Value
`TolBnd`	Lower bound of the standard deviation parameter estimate, specified as a positive scalar. The bounds for the mean and standard deviation parameter estimates are `[–Inf,Inf]` and `[TolBnd,Inf]`, respectively.	`1e-6`
`TolFun`	Termination tolerance for the objective function value, specified as a positive scalar.	`1e-8`
`TolX`	Termination tolerance for the parameters, specified as a positive scalar.	`1e-8`

You can also enter `statset('lognfit')` in the Command Window to see the names and default values of the fields that `lognfit` accepts in the `options` structure.

Example: `statset('Display','final','MaxIter',1000)` specifies to display the final information of the iterative algorithm results, and change the maximum number of iterations allowed to 1000.

Data Types: `struct`

Output Arguments

`pHat` — Estimates of lognormal distribution parameters

1-by-2 vector

Estimates of lognormal distribution parameters, returned as a 1-by-2 vector. `pHat(1)` and `pHat(2)` are the mean and standard deviation of logarithmic values, respectively.

- With no censoring, the `pHat` values are unbiased estimates. To compute the MLEs with no censoring, use the `mle` function.
- With censoring, the `pHat` values are the MLEs. To compute the weighted MLEs, specify the weights of observations by using `freq`.

`pCI` — Confidence intervals for parameter estimates

2-by-2 matrix

Confidence intervals for parameter estimates of the lognormal distribution, returned as a 2-by-2 matrix containing the lower and upper bounds of the `100(1–alpha)`% confidence intervals.

The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

Algorithms

To compute the confidence intervals, `lognfit` uses the exact method for uncensored data and the Wald method for censored data. The exact method provides exact coverage for uncensored samples based on *t* and chi-square distributions.

Alternative Functionality

`lognfit` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mle`, `fitdist`, and `paramci` and the **Distribution Fitter** app, which support various probability distributions.

- `mle` returns MLEs and the confidence intervals of MLEs for the parameters of various probability distributions. You can specify the probability distribution name or a custom probability density function.
- Create a `LognormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object properties `mu` and `sigma` store the parameter estimates. To obtain the confidence intervals for the parameter estimates, pass the object to `paramci`.

Topics

“Lognormal Distribution” on page B-88

Introduced before R2006a

logninv

Lognormal inverse cumulative distribution function

Syntax

```
x = logninv(p)
x = logninv(p,mu)
x = logninv(p,mu,sigma)

[x,xLo,xUp] = logninv(p,mu,sigma,pCov)
[x,xLo,xUp] = logninv(p,mu,sigma,pCov,alpha)
```

Description

`x = logninv(p)` returns the inverse of the standard lognormal cumulative distribution function (cdf), evaluated at the probability values in `p`. In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

`x = logninv(p,mu)` returns the inverse of the lognormal cdf with the distribution parameters `mu` (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the probability values in `p`.

`x = logninv(p,mu,sigma)` returns the inverse of the lognormal cdf with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values), evaluated at the probability values in `p`.

`[x,xLo,xUp] = logninv(p,mu,sigma,pCov)` also returns the 95% confidence bounds [`xLo`,`xUp`] of `x` using the estimated parameters (`mu` and `sigma`) and their covariance matrix `pCov`.

`[x,xLo,xUp] = logninv(p,mu,sigma,pCov,alpha)` specifies the confidence level for the confidence interval [`xLo`,`xUp`] to be `100(1–alpha)`%.

Examples

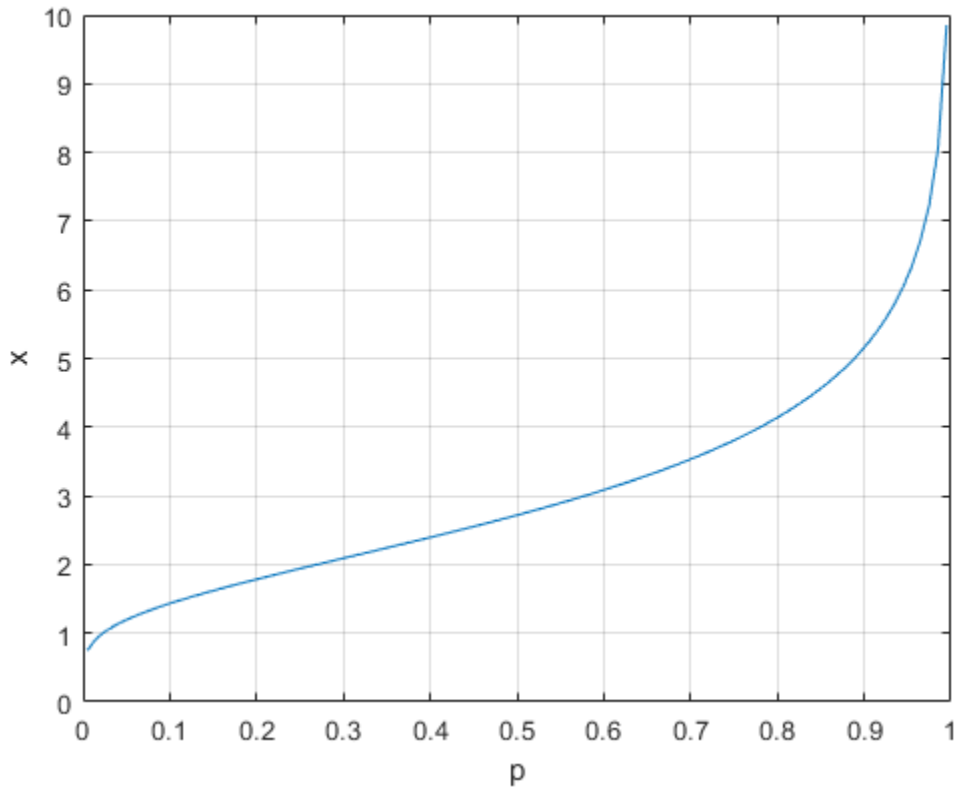
Inverse of Lognormal Distribution cdf

Compute the inverse of cdf values evaluated at the probability values in `p` for the lognormal distribution with mean `mu` and standard deviation `sigma`.

```
p = 0.005:0.01:0.995;
mu = 1;
sigma = 0.5;
x = logninv(p,mu,sigma);
```

Plot the inverse cdf.

```
plot(p,x)
grid on
xlabel('p');
ylabel('x');
```



Confidence Interval of Inverse Lognormal cdf Value

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```
phat = mle(x,'distribution','LogNormal')
```

```
phat = 1×2

    4.9347    1.9969
```

```
muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `lognlike`. The function `lognlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = lognlike(phat,x)
```

```
pCov = 2×2

    0.0040   -0.0000
   -0.0000    0.0020
```

Find the inverse cdf value at 0.5 and its 99% confidence interval.

```
[x,xLo,xUp] = logninv(0.5,muHat,sigmaHat,pCov,0.01)
```

```
x = 139.0364

xLo = 118.1643

xUp = 163.5953
```

`x` is the inverse cdf value using the lognormal distribution with the parameters `muHat` and `sigmaHat`. The interval `[xLo,xUp]` is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 99% confidence interval means the probability that `[xLo,xUp]` contains the true inverse cdf value is 0.99.

Input Arguments

`p` — Probability values at which to evaluate inverse of cdf

scalar value in `[0,1]` | array of scalar values

Probability values at which to evaluate the inverse of the cdf (icdf), specified as a scalar value or an array of scalar values, where each element is in the range `[0,1]`.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `p` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logninv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[0.1,0.5,0.9]`

Data Types: `single` | `double`

`mu` — Mean of logarithmic values

`0` (default) | scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `mu` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logninv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

`sigma` — Standard deviation of logarithmic values

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `sigma` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logninv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

`pCov` — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `p`, `mu`, and `sigma` must be scalar values.

You can estimate the maximum likelihood estimates of `mu` and `sigma` by using `mle`, and estimate the covariance of `mu` and `sigma` by using `lognlike`. For an example, see “Confidence Interval of Inverse Lognormal cdf Value” on page 33-3590.

Data Types: `single` | `double`

`alpha` — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is `100(1–alpha)`%, where `alpha` is the probability that the confidence interval does not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

Output Arguments

x — icdf values

scalar value | array of scalar values

icdf values, evaluated at the probability values in `p`, returned as a scalar value or an array of scalar values. `x` is the same size as `p`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

xLo — Lower confidence bound for x

scalar value | array of scalar values

Lower confidence bound for `x`, returned as a scalar value or an array of scalar values. `xLo` has the same size as `x`.

xUp — Upper confidence bound for x

scalar value | array of scalar values

Upper confidence bound for `x`, returned as a scalar value or an array of scalar values. `xUp` has the same size as `x`.

More About

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The lognormal inverse function is defined in terms of the lognormal cdf as

$$x = F^{-1}(p\left|\mu,\sigma\right.) = \left\{x : F(x\left|\mu,\sigma\right.) = p\right\}$$

where

$$p = F(x\left|\mu,\sigma\right.) = \frac{1}{\sigma\sqrt{2\pi}}\int_0^x \frac{1}{t}\exp\left\{\frac{-(\log t-\mu)^2}{2\sigma^2}\right\}dt, \quad \text{for } x > 0.$$

Algorithms

- The function `logninv` uses the inverse complementary error function `erfcinv`. The relationship between `logninv` and `erfcinv` is

  $$\text{logninv}(p,0,1) = \exp(-\sqrt{2}\,\text{erfcinv}(2p)).$$

  The inverse complementary error function `erfcinv(x)` is defined as `erfcinv(erfc(x))=x`, and the complementary error function `erfc(x)` is defined as

  $$\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}}\int_x^\infty e^{-t^2}dt.$$

- The `logninv` function computes confidence bounds for `x` by using the delta method. `log(logninv(p,mu,sigma))` is equivalent to `mu + sigma*log(logninv(p,0,1))`. Therefore, the `logninv` function estimates the variance of `mu + sigma*log(logninv(p,0,1))`

using the covariance matrix of `mu` and `sigma` by the delta method, and finds the confidence bounds using the estimates of this variance. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pCov` from large samples.

Alternative Functionality

- `logninv` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, create a `LognormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `logninv` is faster than the generic function `icdf`.

Topics

“Lognormal Distribution” on page B-88

Introduced before R2006a

lognlike

Lognormal negative loglikelihood

Syntax

```
nlogL = lognlike(params,x)
nlogL = lognlike(params,x,censoring)
nlogL = lognlike(params,x,censoring,freq)

[nlogL,aVar] = lognlike( ___ )
```

Description

`nlogL = lognlike(params,x)` returns the lognormal negative loglikelihood of the distribution parameters (`params`) given the sample data (`x`). `params(1)` and `params(2)` are the mean and standard deviation of logarithmic values, respectively.

`nlogL = lognlike(params,x,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed.

`nlogL = lognlike(params,x,censoring,freq)` specifies the frequency or weights of observations. To specify `freq` without specifying `censoring`, you can pass `[]` for `censoring`.

`[nlogL,aVar] = lognlike( ___ )` also returns the inverse of the Fisher information matrix `aVar`, using any of the input argument combinations in the previous syntaxes. If values in `params` are the maximum likelihood estimates (MLEs) of the parameters, `aVar` is an approximation to the asymptotic covariance matrix.

Examples

Negative Loglikelihood of MLEs

Find the MLEs of a data set with censoring by using `mle`, and then find the negative loglikelihood of the MLEs by using `lognlike`.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```
phat = mle(x,'distribution','LogNormal')
```

```
phat = 1×2
```

```
    4.9347    1.9969
```

Find the negative loglikelihood of the MLEs.

```
nlogL = lognlike(phat,x)
```

```
nlogL = 7.0453e+03
```

Confidence Interval of Lognormal cdf Value

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```
phat = mle(x,'distribution','LogNormal')
```

```
phat = 1×2

    4.9347    1.9969
```

```
muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `lognlike`. The function `lognlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = lognlike(phat,x)
```

```
pCov = 2×2

    0.0040   -0.0000
   -0.0000    0.0020
```

Find the cdf value at 0.5 and its 95% confidence interval.

```
[p,pLo,pUp] = logncdf(0.5,muHat,sigmaHat,pCov)
```

```
p = 0.0024
```

```
pLo = 0.0016
```

```
pUp = 0.0037
```

`p` is the cdf value of the lognormal distribution with the parameters `muHat` and `sigmaHat`. The interval `[pLo,pUp]` is the 95% confidence interval of the cdf evaluated at 0.5, considering the

uncertainty of `muHat` and `sigmaHat` using `pCov`. The 95% confidence interval means the probability that `[pLo,pUp]` contains the true cdf value is 0.95.

Input Arguments

`params` — Lognormal distribution parameters

vector of two numeric values

Lognormal distribution parameters, specified as a vector of two numeric values. `params(1)` and `params(2)` are the mean and standard deviation of logarithmic values, respectively. `params(2)` must be positive.

Example: `[0,1]`

Data Types: `single` | `double`

`x` — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

`censoring` — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in `x`, specified as a logical vector of the same size as `x`. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

`freq` — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted negative loglikelihood for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

Output Arguments

`nlogL` — Negative loglikelihood

numeric scalar

Negative loglikelihood value of the distribution parameters (`params`) given the sample data (`x`), returned as a numeric scalar.

aVar — Inverse of Fisher information matrix
numeric matrix

Inverse of the Fisher information matrix, returned as a 2-by-2 numeric matrix. `aVar` is based on the observed Fisher information given the observed data (`x`), not the expected information.

If values in `params` are the MLEs of the parameters, `aVar` is an approximation to the asymptotic variance-covariance matrix (also known as the asymptotic covariance matrix). To find the MLEs, use `mle`.

Alternative Functionality

`lognlike` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mlecov`, `fitdist`, `negloglik`, and `proflik` and the **Distribution Fitter** app, which support various probability distributions.

- `mlecov` returns the asymptotic covariance matrix of the MLEs of the parameters for a distribution specified by a custom probability density function. For example, `mlecov(params,x,'pdf',@lognpdf)` returns the asymptotic covariance matrix of the MLEs for the lognormal distribution.
- Create a `LognormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object property `ParameterCovariance` stores the covariance matrix of the parameter estimates. To obtain the negative loglikelihood of the parameter estimates and the profile of the likelihood function, pass the object to `negloglik` and `proflik`, respectively.

lognpdf

Lognormal probability density function

Syntax

```
y = lognpdf(x)
y = lognpdf(x,mu)
y = lognpdf(x,mu,sigma)
```

Description

`y = lognpdf(x)` returns the probability density function (pdf) of the standard lognormal distribution, evaluated at the values in `x`. In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

`y = lognpdf(x,mu)` returns the pdf of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the values in `x`.

`y = lognpdf(x,mu,sigma)` returns the pdf of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values), evaluated at the values in `x`.

Examples

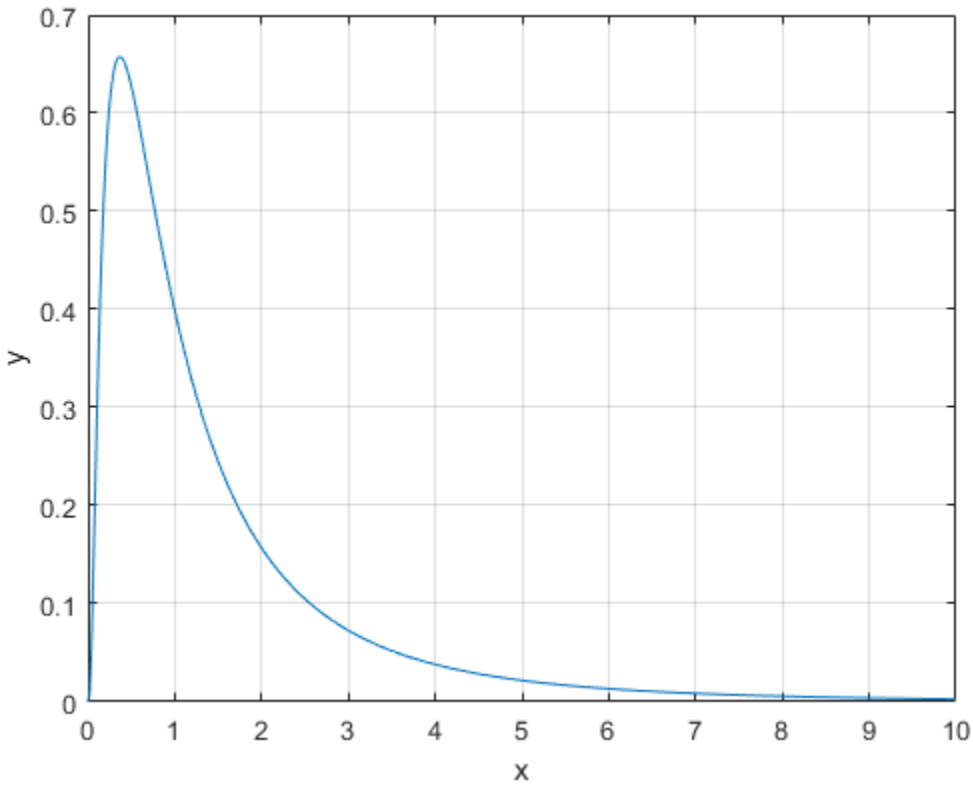
Compute Lognormal Distribution pdf

Compute the pdf values evaluated at the values in `x` for the lognormal distribution with mean `mu` and standard deviation `sigma`.

```
x = 0:0.02:10;
mu = 0;
sigma = 1;
y = lognpdf(x,mu,sigma);
```

Plot the pdf.

```
plot(x,y)
grid on
xlabel('x')
ylabel('y')
```



Input Arguments

x — Values at which to evaluate pdf

positive scalar value | array of positive scalar values

Values at which to evaluate the pdf, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify `x` using an array. To evaluate the pdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `lognpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[-1,0,3,4]`

Data Types: `single` | `double`

mu — Mean of logarithmic values

`0` (default) | scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

To evaluate the pdf at multiple values, specify `x` using an array. To evaluate the pdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `lognpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

`sigma` — Standard deviation of logarithmic values
`1` (default) | positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify `x` using an array. To evaluate the pdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `lognpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

Output Arguments

`y` — pdf values
scalar value | array of scalar values

pdf values, evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `y` is the same size as `x`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

More About

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The probability density function (pdf) of the lognormal distribution is

$$y = f(x\left|\mu,\sigma\right.) = \frac{1}{x\sigma\sqrt{2\pi}}\exp\left\{\frac{-(\log x-\mu)^2}{2\sigma^2}\right\},\quad \text{for } x > 0.$$

Alternative Functionality

- `lognpdf` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create a `LognormalDistribution` probability distribution object and pass the object as an input

argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `lognpdf` is faster than the generic function `pdf`.

- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Introduced before R2006a

lognrnd

Lognormal random numbers

Syntax

```
r = lognrnd(mu,sigma)
r = lognrnd(mu,sigma,sz1,...,szN)
r = lognrnd(mu,sigma,sz)
```

Description

`r = lognrnd(mu,sigma)` generates a random number from the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values).

`r = lognrnd(mu,sigma,sz1,...,szN)` generates an array of lognormal random numbers, where `sz1,...,szN` indicates the size of each dimension.

`r = lognrnd(mu,sigma,sz)` generates an array of lognormal random numbers, where vector `sz` specifies `size(r)`.

Examples

Generate Lognormal Random Number

Find the distribution parameters from the mean and variance of a lognormal distribution and generate a lognormal random value from the distribution.

Find the distribution parameters `mu` and `sigma` from the mean and variance.

```
m = 1; % mean
v = 2; % variance
mu = log((m^2)/sqrt(v+m^2))
```

```
mu = -0.5493
```

```
sigma = sqrt(log(v/(m^2)+1))
```

```
sigma = 1.0481
```

Generate a lognormal random value.

```
rng('default') % For reproducibility
r = lognrnd(mu,sigma)
```

```
r = 1.0144
```

Reset Random Number Generator

Save the current state of the random number generator. Then create a 1-by-5 vector of lognormal random numbers from the lognormal distribution with the parameters 3 and 10.

```
s = rng;
r = lognrnd(3,10,[1,5])
```

```
r = 1×5
10^9 ×

    0.0000    1.8507    0.0000    0.0001    0.0000
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```
rng(s);
r1 = lognrnd(3,10,[1,5])
```

```
r1 = 1×5
10^9 ×

    0.0000    1.8507    0.0000    0.0001    0.0000
```

Clone Size from Existing Array

Create a matrix of lognormally distributed random numbers with the same size as an existing array.

```
A = [3 2; -2 1];
sz = size(A);
R = lognrnd(0,1,sz)
```

```
R = 2×2

    1.7120    0.1045
    6.2582    2.3683
```

You can combine the previous two lines of code into a single line.

```
R = lognrnd(1,0,size(A));
```

Input Arguments

`mu` — Mean of logarithmic values

scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple distributions, specify `mu` and `sigma` using arrays. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar,

then `lognrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

`sigma` — Standard deviation of logarithmic values
nonnegative scalar value | array of nonnegative scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If `sigma` is zero, then the output `r` is always equal to `exp(mu)`.

To generate random numbers from multiple distributions, specify `mu` and `sigma` using arrays. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `lognrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

`sz1,...,szN` — Size of each dimension (as separate arguments)
integers

Size of each dimension, specified as separate arguments of integers. For example, specifying `5,3,2` generates a 5-by-3-by-2 array of random numbers from the lognormal probability distribution.

If either `mu` or `sigma` is an array, then the specified dimensions `sz1,...,szN` must match the common dimensions of `mu` and `sigma` after any necessary scalar expansion. The default values of `sz1,...,szN` are the common dimensions.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `lognrnd` ignores trailing dimensions with a size of 1. For example, `lognrnd(mu,sigma,3,1,1,1)` produces a 3-by-1 vector of random numbers.

Example: `5,3,2`

Data Types: `single` | `double`

`sz` — Size of each dimension (as a row vector)
row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying `[5 3 2]` generates a 5-by-3-by-2 array of random numbers from the lognormal probability distribution.

If either `mu` or `sigma` is an array, then the specified dimensions `sz` must match the common dimensions of `mu` and `sigma` after any necessary scalar expansion. The default values of `sz` are the common dimensions.

- If you specify a single value `[sz1]`, then `r` is a square matrix of size `sz1`-by-`sz1`.

- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `lognrnd` ignores trailing dimensions with a size of 1. For example, `lognrnd(mu,sigma,[3,1,1,1])` produces a 3-by-1 vector of random numbers.

Example: `[5 3 2]`

Data Types: `single` | `double`

Output Arguments

`r` — Lognormal random numbers

scalar value | array of scalar values

Lognormal random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1,...,szN` or `sz`. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

More About

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The mean m and variance v of a lognormal random variable are functions of the lognormal distribution parameters μ and σ:

$$m = \exp\left(\mu + \sigma^2/2\right)$$

$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

Also, you can compute the lognormal distribution parameters μ and σ from the mean m and variance v:

$$\mu = \log\left(m^2/\sqrt{v + m^2}\right)$$

$$\sigma = \sqrt{\log\left(v/m^2 + 1\right)}$$

Alternative Functionality

- `lognrnd` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, create a `LognormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `lognrnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

lognstat

Lognormal mean and variance

Syntax

```
[m,v] = lognstat(mu,sigma)
```

Description

`[m,v] = lognstat(mu,sigma)` returns the mean and variance of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values).

Examples

Compute Mean and Variance

Compute the mean and variance of the lognormal distribution with parameters `mu` and `sigma`.

```
mu = 0;
sigma = 1;
[m,v] = lognstat(mu,sigma)
```

```
m = 1.6487
```

```
v = 4.6708
```

Input Arguments

`mu` — Mean of logarithmic values

scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `lognstat` expands the scalar argument into a constant array of the same size as the other argument. Each element in `m` and `v` is the mean and variance of the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

`sigma` — Standard deviation of logarithmic values

positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `lognstat` expands the scalar argument into a constant array of the same size as the other argument. Each element in `m` and `v` is the mean and variance of the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

Output Arguments

`m` — Mean

scalar value | array of scalar values

Mean of the lognormal distribution, returned as a scalar value or an array of scalar values. `m` is the same size as `mu` and `sigma` after any necessary scalar expansion. Each element in `m` is the mean of the lognormal distribution specified by the corresponding elements in `mu` and `sigma`.

`v` — Variance

scalar value | array of scalar values

Variance of the lognormal distribution, returned as a scalar value or an array of scalar values. `v` is the same size as `mu` and `sigma` after any necessary scalar expansion. Each element in `v` is the variance of the lognormal distribution specified by the corresponding elements in `mu` and `sigma`.

More About

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The mean m and variance v of a lognormal random variable are functions of the lognormal distribution parameters μ and σ:

$$m = \exp\left(\mu + \sigma^2/2\right)$$

$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

Also, you can compute the lognormal distribution parameters μ and σ from the mean m and variance v:

$$\mu = \log\left(m^2/\sqrt{v + m^2}\right)$$

$$\sigma = \sqrt{\log\left(v/m^2 + 1\right)}$$

Alternative Functionality

- `lognstat` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers generic functions to compute summary statistics, including mean (`mean`), median (`median`), interquartile range (`iqr`), variance (`var`), and standard deviation (`std`). These generic functions support various probability distributions. To use these functions, create a `LognormalDistribution` probability distribution object and pass the object as an input argument.

logp

Log unconditional probability density for discriminant analysis classifier

Syntax

```
lp = logp(obj,Xnew)
```

Description

`lp = logp(obj,Xnew)` returns the log of the unconditional probability density of each row of `Xnew`, computed using the discriminant analysis model `obj`.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Xnew

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `Xnew` must equal the number of predictors in `obj`.

Output Arguments

lp

Column vector with the same number of rows as `Xnew`. Each entry is the logarithm of the unconditional probability density of the corresponding row of `Xnew`.

Examples

Compute Log Unconditional Probability Density of an Observation

Construct a discriminant analysis classifier for Fisher's iris data, and examine its prediction for an average measurement.

Load Fisher's iris data and construct a default discriminant analysis classifier.

```
load fisheriris
Mdl = fitcdiscr(meas,species);
```

Find the log probability of the discriminant model applied to an average iris.

```
logpAverage = logp(Mdl,mean(meas))
```

```
logpAverage = -1.7254
```

More About

Unconditional Probability Density

The unconditional probability density of a point x of a discriminant analysis model is

$$P(x) = \sum_{k=1}^{K} P(x,k),$$

where $P(x,k)$ is the conditional density of the model at x for class k, when the total number of classes is K.

The conditional density $P(x,k)$ is

$P(x,k) = P(k)P(x|k)$,

where $P(k)$ is the prior probability of class k, and $P(x|k)$ is the conditional density of x given class k. The conditional density function of the multivariate normal with 1-by-d mean μ_k and d-by-d covariance Σ_k at a 1-by-d point x is

$$P(x|k) = \frac{1}{\left((2\pi)^d|\Sigma_k|\right)^{1/2}}\exp\left(-\frac{1}{2}(x-\mu_k)\Sigma_k^{-1}(x-\mu_k)^T\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k, and Σ_k^{-1} is the inverse matrix.

logp

Log unconditional probability density for naive Bayes classifier

Syntax

```
lp = logp(Mdl,tbl)
lp = logp(Mdl,X)
```

Description

`lp = logp(Mdl,tbl)` returns the log "Unconditional Probability Density" on page 33-3617 (`lp`) of the observations (rows) in `tbl` using the naive Bayes model `Mdl`. You can use `lp` to identify outliers in the training data.

`lp = logp(Mdl,X)` returns the log unconditional probability density of the observations (rows) in `X` using the naive Bayes model `Mdl`.

Examples

Compute Unconditional Probability Densities of Observations

Compute the unconditional probability densities of the in-sample observations of a naive Bayes classifier model.

Load the `fisheriris` data set. Create `X` as a numeric matrix that contains four petal measurements for 150 irises. Create `Y` as a cell array of character vectors that contains the corresponding iris species.

```
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using the predictors `X` and class labels `Y`. A recommended practice is to specify the class names. `fitcnb` assumes that each predictor is conditionally and normally distributed.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'})
```

```
Mdl =
  ClassificationNaiveBayes
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
        DistributionNames: {'normal'  'normal'  'normal'  'normal'}
   DistributionParameters: {3x4 cell}

  Properties, Methods
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

Compute the unconditional probability densities of the in-sample observations.

```
lp = logp(Mdl,X);
```

Identify indices of observations that have very small or very large log unconditional probabilities (`ind`). Display lower (`L`) and upper (`U`) thresholds used by the outlier detection method.

```
[TF,L,U] = isoutlier(lp);
L
```

```
L = -6.9222
```

```
U
```

```
U = 3.0323
```

```
ind = find(TF)
```

```
ind = 4×1

    61
   118
   119
   132
```

Display the values of the outlier unconditional probability densities.

```
lp(ind)
```

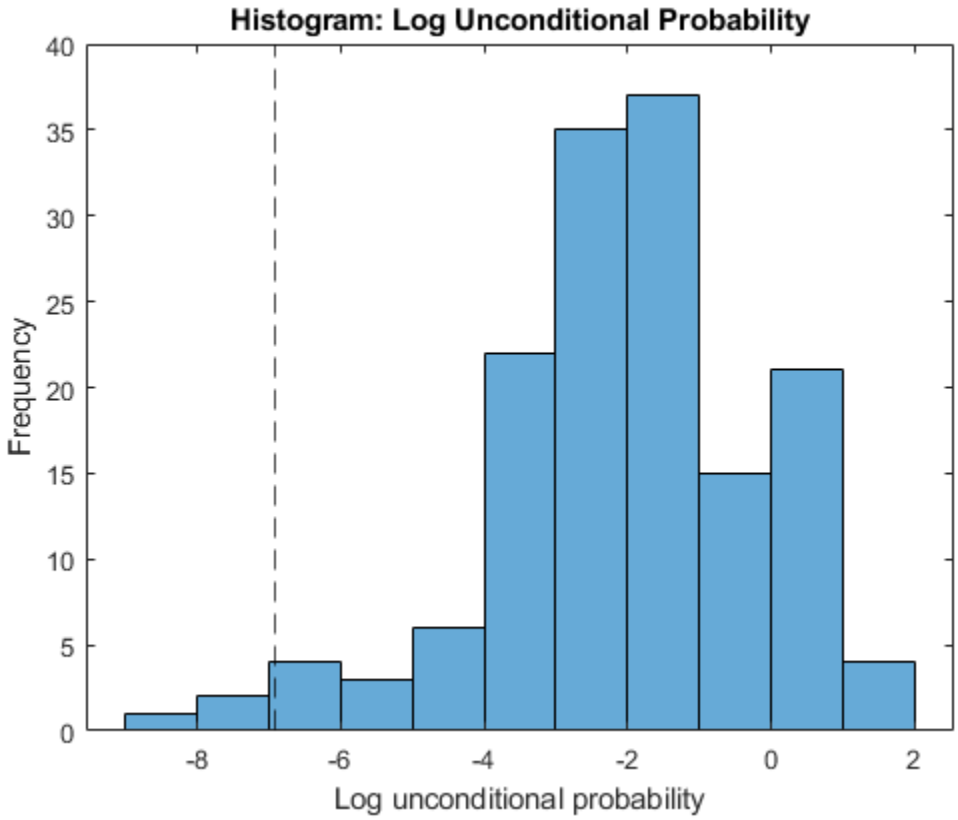
```
ans = 4×1

   -7.8995
   -8.4765
   -6.9854
   -7.8969
```

All the outliers are smaller than the lower outlier detection threshold.

Plot the unconditional probability densities.

```
histogram(lp)
hold on
xline(L,'k--')
hold off
xlabel('Log unconditional probability')
ylabel('Frequency')
title('Histogram: Log Unconditional Probability')
```



Input Arguments

`Mdl` — Naive Bayes classification model

`ClassificationNaiveBayes` model object | `CompactClassificationNaiveBayes` model object

Naive Bayes classification model, specified as a `ClassificationNaiveBayes` model object or `CompactClassificationNaiveBayes` model object returned by `fitcnb` or `compact`, respectively.

`tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed. Optionally, `tbl` can contain additional columns for the response variable and observation weights.

If you train `Mdl` using sample data contained in a table, then the input data for `logp` must also be in a table.

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an *instance* or *example*), and each column corresponds to one variable (also known as a *feature*). The variables in the columns of `X` must be the same as the variables that trained the `Mdl` classifier.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

More About

Unconditional Probability Density

The unconditional probability density of the predictors is the density's distribution marginalized over the classes.

In other words, the unconditional probability density is

$$P(X_1,..,X_P) = \sum_{k=1}^{K} P(X_1,..,X_P, Y = k) = \sum_{k=1}^{K} P(X_1,..,X_P \Big| y = k)\pi(Y = k),$$

where $\pi(Y = k)$ is the class prior probability. The conditional distribution of the data given the class ($P(X_1,..,X_P|y = k)$) and the class prior probability distributions are training options (that is, you specify them when training the classifier).

Prior Probability

The prior probability of a class is the assumed relative frequency with which observations from that class occur in a population.

logp

Log unconditional probability density of naive Bayes classification model for incremental learning

Syntax

```
lp = logp(Mdl,X)
```

Description

`lp = logp(Mdl,X)` returns the log unconditional probability densities on page 33-3621 `lp` of the observations in the predictor data `X` using the naive Bayes classification model for incremental learning `Mdl`. You can use `lp` to identify outliers in the training data.

Examples

Detect Outliers In Streaming Data

Train a naive Bayes classification model by using `fitcnb`, convert it to an incremental learner, and then use the incremental model to detect outliers in streaming data.

Load and Preprocess Data

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
rng(1); % For reproducibility
n = numel(actid);
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Train Naive Bayes Classification Model

Fit a naive Bayes classification model to a random sample of about 25% of the data.

```
idxtt = randsample([true false false false],n,true);
TTMdl = fitcnb(X(idxtt,:),Y(idxtt))
```

```
TTMdl =
  ClassificationNaiveBayes
              ResponseName: 'Y'
     CategoricalPredictors: []
                ClassNames: [1 2 3 4 5]
           ScoreTransform: 'none'
          NumObservations: 6167
         DistributionNames: {1×60 cell}
    DistributionParameters: {5×60 cell}
```

```
  Properties, Methods
```

`TTMdl` is a `ClassificationNaiveBayes` model object representing a traditionally trained model.

Convert Trained Model

Convert the traditionally trained model to a naive Bayes classification model for incremental learning.

```
IncrementalMdl = incrementalLearner(TTMdl)
```

```
IncrementalMdl =
  incrementalClassificationNaiveBayes

                   IsWarm: 1
                  Metrics: [1×2 table]
               ClassNames: [1 2 3 4 5]
           ScoreTransform: 'none'
        DistributionNames: {1×60 cell}
    DistributionParameters: {5×60 cell}

  Properties, Methods
```

`IncrementalMdl` is an `incrementalClassificationNaiveBayes` object. `IncrementalMdl` represents a naive Bayes classification model for incremental learning; the parameter values are the same as the parameters in `TTMdl`.

Detect Outliers

Determine unconditional density thresholds for outliers by using the traditionally trained model and training data. Observations in the streaming data yielding densities beyond the thresholds are considered outliers.

```
ttlp = logp(TTMdl,X(idxtt,:));
[~,lower,upper] = isoutlier(ttlp)
```

```
lower = -336.0424

upper = 399.9853
```

Detect outliers in the rest of the data, relative to what was learned to create `TTMdl`. Simulate a data stream by processing 1 observation at a time. At each iteration, call `logp` to compute the log unconditional probability density of the observation and store each value.

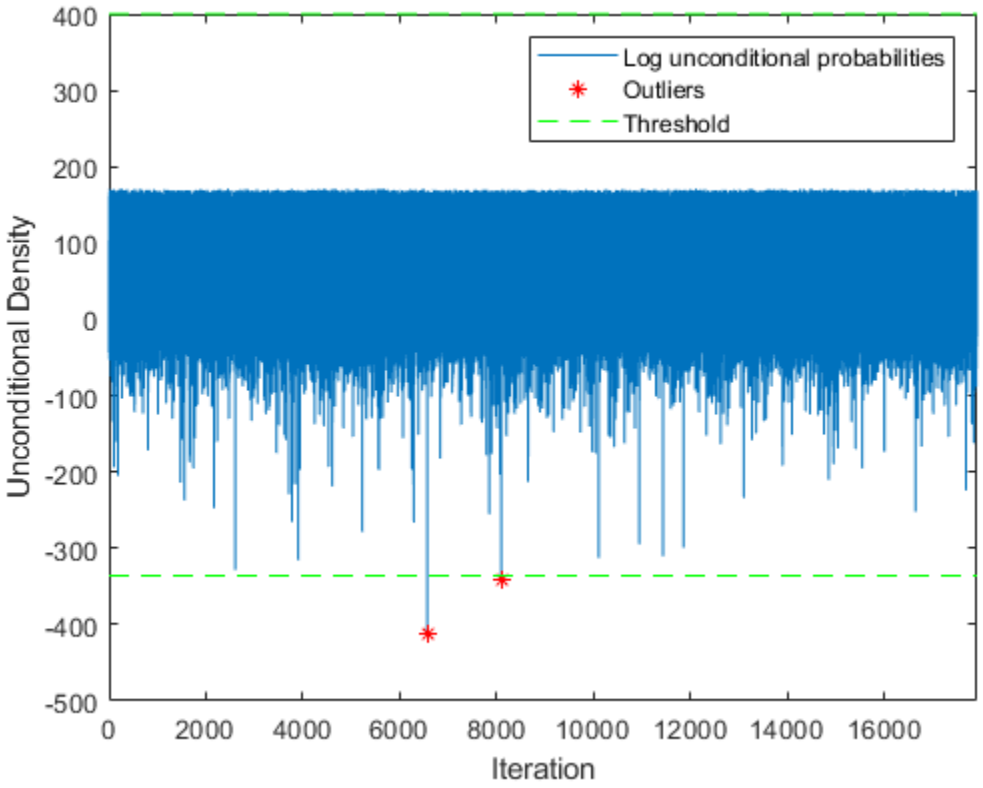
```
% Preallocation
idxil = ~idxtt;
nil = sum(idxil);
numObsPerChunk = 1;
nchunk = floor(nil/numObsPerChunk);
lp = zeros(nchunk,1);
iso = false(nchunk,1);
Xil = X(idxil,:);
Yil = Y(idxil);

% Incremental fitting
for j = 1:nchunk
```

```
    ibegin = min(nil,numObsPerChunk*(j-1) + 1);
    iend   = min(nil,numObsPerChunk*j);
    idx = ibegin:iend;
    lp(j) = logp(IncrementalMdl,Xil(idx,:));
    iso(j) = ((lp(j) < lower) + (lp(j) > upper)) >= 1;
end
```

Plot the log unconditional probability densities of the streaming data. Identify the outliers.

```
figure;
h1 = plot(lp);
hold on
x = 1:nchunk;
h2 = plot(x(iso),lp(iso),'r*');
h3 = line(xlim,[lower lower],'Color','g','LineStyle','--');
line(xlim,[upper upper],'Color','g','LineStyle','--')
xlim([0 nchunk]);
ylabel('Unconditional Density')
xlabel('Iteration')
legend([h1 h2 h3],["Log unconditional probabilities" "Outliers" "Threshold"])
hold off
```



Input Arguments

`Mdl` — Naive Bayes classification model for incremental learning
`incrementalClassificationNaiveBayes` model object

Naive Bayes classification model for incremental learning, specified as an `incrementalClassificationNaiveBayes` model object. You can create `Mdl` directly or by converting a supported, traditionally trained machine learning model using the `incrementalLearner` function. For more details, see the corresponding reference page.

You must configure `Mdl` to compute the log conditional probability densities on a batch of observations.

- If `Mdl` is a converted, traditionally trained model, you can compute the log conditional probabilities without any modifications.
- Otherwise, `Mdl.DistributionParameters` must be a cell matrix with `Mdl.NumPredictors` > 0 columns and at least one row, where each row corresponds to each class name in `Mdl.ClassNames`.

`X` — Batch of predictor data
floating-point matrix

Batch of predictor data with which to compute the log conditional probability densities, specified as an *n*-by-`Mdl.NumPredictors` floating-point matrix.

Note

- `logp` supports only floating-point input predictor data. If the input model `Mdl` represents a converted, traditionally trained model fit to categorical data, use `dummyvar` to convert each categorical variable to a numeric matrix of dummy variables, and concatenate all dummy variable matrices and any other numeric predictors. For more details, see “Dummy Variables” on page 2-48.
- For each $j = 1$ through n, if `X(j,:)` contains at least one `NaN`, `lp(j)` is `NaN`.

Data Types: `single` | `double`

Output Arguments

`lp` — Log conditional probability densities
floating-point vector

Log unconditional probability densities on page 33-3621, returned as an *n*-by-1 floating-point vector. `lp(j)` is the log unconditional probability density of the predictors evaluated at `X(j,:)`.

Data Types: `single` | `double`

More About

Unconditional Probability Density

The unconditional probability density of the predictors is the density's distribution marginalized over the classes.

In other words, the unconditional probability density is

$$P(X_1,..,X_P) = \sum_{k=1}^{K} P(X_1,..,X_P, Y = k) = \sum_{k=1}^{K} P(X_1,..,X_P \Big| y = k)\pi(Y = k),$$

where $\pi(Y = k)$ is the class prior probability. The conditional distribution of the data given the class ($P(X_1,..,X_P|y = k)$) and the class prior probability distributions are training options (that is, you specify them when training the classifier).

Prior Probability

The prior probability of a class is the assumed relative frequency with which observations from that class occur in a population.

Introduced in R2021a

loss

Package:

Classification loss for generalized additive model (GAM)

Syntax

```
L = loss(Mdl,Tbl,ResponseVarName)
L = loss(Mdl,Tbl,Y)
L = loss(Mdl,X,Y)
L = loss(___,Name,Value)
```

Description

`L = loss(Mdl,Tbl,ResponseVarName)` returns the "Classification Loss" on page 33-3628 (`L`), a scalar representing how well the generalized additive model `Mdl` classifies the predictor data in `Tbl` compared to the true class labels in `Tbl.ResponseVarName`.

The interpretation of `L` depends on the loss function (`'LossFun'`) and weighting scheme (`'Weights'`). In general, better classifiers yield smaller classification loss values. The default `'LossFun'` value is `'classiferror'` (misclassification rate in decimal).

`L = loss(Mdl,Tbl,Y)` uses the predictor data in table `Tbl` and the true class labels in `Y`.

`L = loss(Mdl,X,Y)` uses the predictor data in matrix `X` and the true class labels in `Y`.

`L = loss(___,Name,Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, `'LossFun','mincost'` sets the loss function to the minimal expected misclassification cost function.

Examples

Determine Test Sample Classification Loss

Determine the test sample classification error (loss) of a generalized additive model. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Randomly partition observations into a training set and a test set with stratification, using the class information in `Y`. Specify a 30% holdout sample for testing.

```
rng('default') % For reproducibility
cv = cvpartition(Y,'HoldOut',0.30);
```

Extract the training and test indices.

```
trainInds = training(cv);
testInds = test(cv);
```

Specify the training and test data sets.

```
XTrain = X(trainInds,:);
YTrain = Y(trainInds);
XTest = X(testInds,:);
YTest = Y(testInds);
```

Train a GAM using the predictors `XTrain` and class labels `YTrain`. A recommended practice is to specify the class names.

```
Mdl = fitcgam(XTrain,YTrain,'ClassNames',{'b','g'});
```

`Mdl` is a `ClassificationGAM` model object.

Determine how well the algorithm generalizes by estimating the test sample classification error. By default, the `loss` function of `ClassificationGAM` estimates classification error by using the `'classiferror'` loss (misclassification rate in decimal).

```
L = loss(Mdl,XTest,YTest)
```

```
L = 0.1052
```

The trained classifier misclassifies approximately 11% of the test sample.

Compare GAMs by Examining Classification Loss

Train a generalized additive model (GAM) that contains both linear and interaction terms for predictors, and estimate the classification loss with and without interaction terms. Specify whether to include interaction terms when estimating the classification loss for training and test data.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Partition the data set into two sets: one containing training data, and the other containing new, unobserved test data. Reserve 50 observations for the new test data set.

```
rng('default') % For reproducibility
n = size(X,1);
newInds = randsample(n,50);
inds = ~ismember(1:n,newInds);
XNew = X(newInds,:);
YNew = Y(newInds);
```

Train a GAM using the predictors `X` and class labels `Y`. A recommended practice is to specify the class names. Specify to include the 10 most important interaction terms.

```
Mdl = fitcgam(X(inds,:),Y(inds),'ClassNames',{'b','g'},'Interactions',10)
```

```
Mdl =
  ClassificationGAM
```

```
          ResponseName: 'Y'
CategoricalPredictors: []
           ClassNames: {'b'  'g'}
       ScoreTransform: 'logit'
            Intercept: 2.0026
         Interactions: [10x2 double]
      NumObservations: 301

  Properties, Methods
```

`Mdl` is a `ClassificationGAM` model object.

Compute the resubstitution classification loss both with and without interaction terms in `Mdl`. To exclude interaction terms, specify `'IncludeInteractions',false`.

```
resubl = resubLoss(Mdl)
```

```
resubl = 0
```

```
resubl_nointeraction = resubLoss(Mdl,'IncludeInteractions',false)
```

```
resubl_nointeraction = 0
```

Estimate the classification loss both with and without interaction terms in `Mdl`.

```
l = loss(Mdl,XNew,YNew)
```

```
l = 0.0615
```

```
l_nointeraction = loss(Mdl,XNew,YNew,'IncludeInteractions',false)
```

```
l_nointeraction = 0.0615
```

Including interaction terms does not change the classification loss for `Mdl`. The trained model classifies all training samples correctly and misclassifies approximately 6% of the test samples.

Input Arguments

`Mdl` — Generalized additive model

`ClassificationGAM` model object | `CompactClassificationGAM` model object

Generalized additive model, specified as a `ClassificationGAM` or `CompactClassificationGAM` model object.

- If you trained `Mdl` using sample data contained in a table, then the input data for `loss` must also be in a table (`Tbl`).
- If you trained `Mdl` using sample data contained in a matrix, then the input data for `loss` must also be in a matrix (`X`).

`Tbl` — Sample data

table

Sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

`Tbl` must contain all the predictors used to train `Mdl`. Optionally, `Tbl` can contain a column for the response variable and a column for the observation weights.

- The response variable must have the same data type as `Mdl.Y`. (The software treats string arrays as cell arrays of character vectors.) If the response variable in `Tbl` has the same name as the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName`.
- The weight values must be a numeric vector. You must specify the observation weights in `Tbl` by using `'Weights'`.

If you trained `Mdl` using sample data contained in a table, then the input data for `loss` must also be in a table.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as a character vector or string scalar containing the name of the response variable in `Tbl`. For example, if the response variable `Y` is stored in `Tbl.Y`, then specify it as `'Y'`.

Data Types: `char` | `string`

`Y` — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X` or `Tbl`.

`Y` must have the same data type as `Mdl.Y`. (The software treats string arrays as cell arrays of character vectors.)

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`X` — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

If you trained `Mdl` using sample data contained in a matrix, then the input data for `loss` must also be in a matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'IncludeInteractions',false,'Weights',w` specifies to exclude interaction terms from the model and to use the observation weights `w`.

`IncludeInteractions` — Flag to include interaction terms
`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`.

The default `'IncludeInteractions'` value is `true` if `Mdl` contains interaction terms. The value must be `false` if the model does not contain interaction terms.

Example: `'IncludeInteractions',false`

Data Types: `logical`

`LossFun` — Loss function
`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  For more details on loss functions, see “Classification Loss” on page 33-3628.

- To specify a custom loss function, use function handle notation. The function must have this form:

  `lossvalue = lossfun(C,S,W,Cost)`

  - The output argument `lossvalue` is a scalar.
  - You specify the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating the class to which the corresponding observation belongs. `n` is the number of observations in `Tbl` or `X`, and `K` is the number of distinct classes (`numel(Mdl.ClassNames)`. The column order corresponds to the class order in `Mdl.ClassNames`. Create `C` by setting `C(p,q) = 1`, if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights.
  - `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) – eye(K)` specifies a cost of `0` for correct classification and `1` for misclassification.

Example: `'LossFun','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as a vector of scalar values or the name of a variable in `Tbl`. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored in `Tbl.W`, then specify it as `'W'`.

`loss` normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Data Types: `single` | `double` | `char` | `string`

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Suppose the following:

- L is the weighted average classification loss.
- n is the sample size.
- y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
- $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so that they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

This table describes the supported loss functions that you can specify by using the `'LossFun'` name-value argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\{1 + \exp[-2m_j]\}$.

Loss Function	Value of LossFun	Equation
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$. $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).

Introduced in R2021a

loss

Loss of *k*-nearest neighbor classifier

Syntax

```
L = loss(mdl,tbl,ResponseVarName)
L = loss(mdl,tbl,Y)
L = loss(mdl,X,Y)
L = loss(___,Name,Value)
```

Description

`L = loss(mdl,tbl,ResponseVarName)` returns a scalar representing how well `mdl` classifies the data in `tbl` when `tbl.ResponseVarName` contains the true classifications. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

When computing the loss, the `loss` function normalizes the class probabilities in `tbl.ResponseVarName` to the class probabilities used for training, which are stored in the `Prior` property of `mdl`.

The meaning of the classification loss (`L`) depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values. For more details, see “Classification Loss” on page 33-3635.

`L = loss(mdl,tbl,Y)` returns a scalar representing how well `mdl` classifies the data in `tbl` when `Y` contains the true classifications.

When computing the loss, the `loss` function normalizes the class probabilities in `Y` to the class probabilities used for training, which are stored in the `Prior` property of `mdl`.

`L = loss(mdl,X,Y)` returns a scalar representing how well `mdl` classifies the data in `X` when `Y` contains the true classifications.

When computing the loss, the `loss` function normalizes the class probabilities in `Y` to the class probabilities used for training, which are stored in the `Prior` property of `mdl`.

`L = loss(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the loss function and the classification weights.

Examples

Loss Calculation

Create a *k*-nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the loss of the classifier for a mean observation classified as `'versicolor'`.

```
X = mean(meas);
Y = {'versicolor'};
L = loss(mdl,X,Y)
```

```
L = 0
```

All five nearest neighbors classify as `'versicolor'`.

Input Arguments

`mdl` — *k*-nearest neighbor classifier model

`ClassificationKNN` object

k-nearest neighbor classifier model, specified as a `ClassificationKNN` object.

`tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `mdl` using sample data contained in a `table`, then the input data for `loss` must also be in a table.

Data Types: `table`

`ResponseVarName` — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable is stored as `tbl.response`, then specify it as `'response'`. Otherwise, the software treats all columns of `tbl`, including `tbl.response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of X represents one observation, and each column represents one variable.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `loss(mdl,tbl,'response','LossFun','exponential','Weights','w')` returns the weighted exponential loss of `mdl` classifying the data in `tbl`. Here, `tbl.response` is the response variable, and `tbl.w` is the weight variable.

LossFun — Loss function

`'mincost'` (default) | `'binodeviance'` | `'classiferror'` | `'exponential'` | `'hinge'` | `'logit'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in loss function name or a function handle.

- The following table lists the available loss functions.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  `'mincost'` is appropriate for classification scores that are posterior probabilities. By default, *k*-nearest neighbor models return posterior probabilities as classification scores (see `predict`).

- You can specify a function handle for a custom loss function using `@` (for example, `@lossfun`). Let *n* be the number of observations in X and *K* be the number of distinct classes (`numel(mdl.ClassNames)`). Your custom loss function must have this form:

  ```
  function lossvalue = lossfun(C,S,W,Cost)
  ```

- `C` is an *n*-by-*K* logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `mdl.ClassNames`. Construct `C` by setting `C(p,q) = 1`, if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
- `S` is an *n*-by-*K* numeric matrix of classification scores. The column order corresponds to the class order in `mdl.ClassNames`. The argument `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an *n*-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to `1`.
- `Cost` is a *K*-by-*K* numeric matrix of misclassification costs. For example, `Cost = ones(K) – eye(K)` specifies a cost of `0` for correct classification and `1` for misclassification.
- The output argument `lossvalue` is a scalar.

For more details on loss functions, see “Classification Loss” on page 33-3635.

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | numeric vector | name of a variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector or the name of a variable in `tbl`.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, the name must be a character vector or string scalar. For example, if the weights are stored as `tbl.w`, then specify `Weights` as `'w'`. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

`loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `Weights`, `loss` computes the weighted classification loss.

Example: `'Weights','w'`

Data Types: `single` | `double` | `char` | `string`

Algorithms

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.

- $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.

- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of $K – 1$ zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

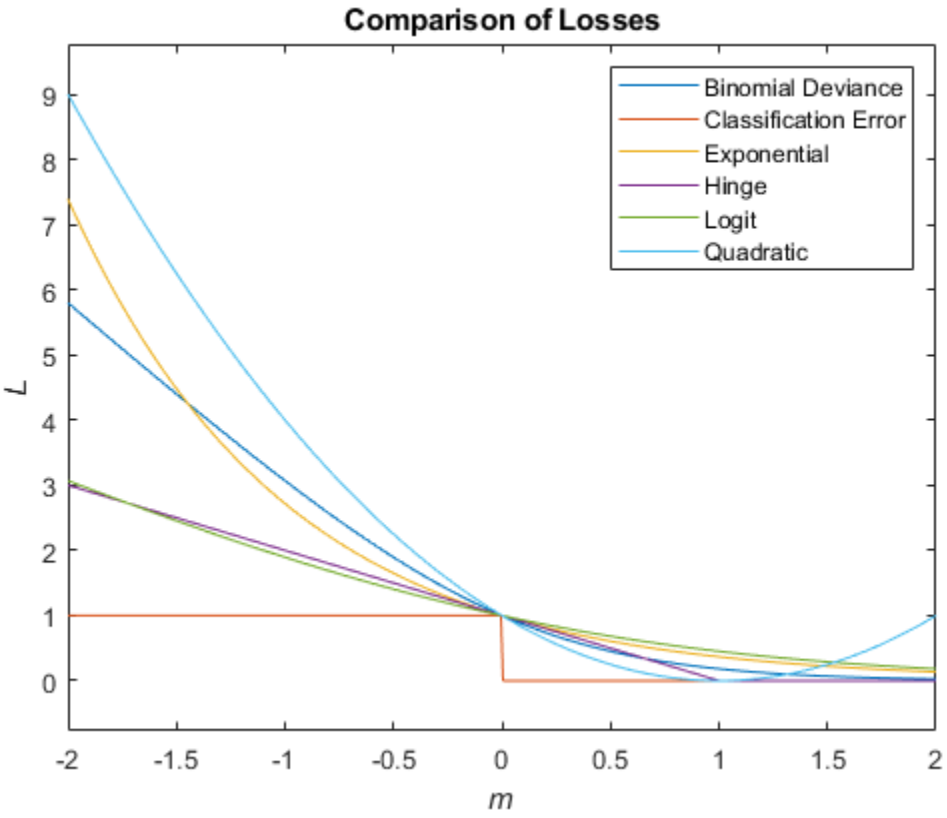
$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\{1 + \exp[-2m_j]\}$.
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$. $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn}$, where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.

Loss Function	Value of LossFun	Equation
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = (f(X_j)'C)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\hat{y}_j = \underset{k=1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j (1 - m_j)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the `'Cost'` name-value pair argument when you run `fitcknn`. The value `Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j) = 1` if `i ~= j`, and `Cost(i,j) = 0` if `i = j`. In other words, the cost is `0` for correct classification and `1` for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`, and you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns a matrix `cost` of size `Nobs`-by-`K`, among other outputs. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,j)` is

$$\sum_{i=1}^{K} \widehat{P}(i|Xnew(n))C(j|i),$$

where

- K is the number of classes.
- $\widehat{P}(i|X(n))$ is the posterior probability on page 33-4786 of class i for observation $Xnew(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as j when its true class is i.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

- This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).
- This function supports model objects fitted with GPU array input arguments.
- `loss` executes on a GPU in these cases only:
  - The input argument `X` is a `gpuArray`.
  - The input argument `tbl` contains `gpuArray` elements.
  - The input argument `mdl` was fitted with GPU array input arguments.

Introduced in R2012a

loss

Class: `ClassificationLinear`

Classification loss for linear classification models

Syntax

```
L = loss(Mdl,X,Y)

L = loss(Mdl,Tbl,ResponseVarName)
L = loss(Mdl,Tbl,Y)

L = loss( ___ ,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the classification losses on page 33-3647 for the binary, linear classification model `Mdl` using predictor data in `X` and corresponding class labels in `Y`. `L` contains classification error rates for each regularization strength in `Mdl`.

`L = loss(Mdl,Tbl,ResponseVarName)` returns the classification losses for the predictor data in `Tbl` and the true class labels in `Tbl.ResponseVarName`.

`L = loss(Mdl,Tbl,Y)` returns the classification losses for the predictor data in table `Tbl` and the true class labels in `Y`.

`L = loss( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify that columns in the predictor data correspond to observations or specify the classification loss function.

Input Arguments

`Mdl` — Binary, linear classification model

`ClassificationLinear` model object

Binary, linear classification model, specified as a `ClassificationLinear` model object. You can create a `ClassificationLinear` model object using `fitclinear`.

`X` — Predictor data

full matrix | sparse matrix

Predictor data, specified as an *n*-by-*p* full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time.

The length of `Y` and the number of observations in `X` must be equal.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array; logical or numeric vector; or cell array of character vectors.

- The data type of `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` must be equal to the number of observations in `X` or `Tbl`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain additional columns for the response variable and observation weights. `Tbl` must contain all the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `Mdl` using sample data contained in a table, then the input data for `loss` must also be in a table.

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. If `Tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must specify it as a character vector or string scalar. For example, if the response variable is stored as `Tbl.Y`, then specify `ResponseVarName` as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Tbl.Y`, as predictors.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

LossFun — Loss function
'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Misclassified rate in decimal
'exponential'	Exponential loss
'hinge'	Hinge loss
'logit'	Logistic loss
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic loss

  'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see predict).
- To specify a custom loss function, use function handle notation. The function must have this form:

  lossvalue = *lossfun*(C,S,W,Cost)

  - The output argument lossvalue is a scalar.
  - You specify the function name (*lossfun*).
  - C is an n-by-K logical matrix with rows indicating the class to which the corresponding observation belongs. n is the number of observations in Tbl or X, and K is the number of distinct classes (numel(Mdl.ClassNames). The column order corresponds to the class order in Mdl.ClassNames. Create C by setting C(p,q) = 1, if observation p is in class q, for each row. Set all other elements of row p to 0.
  - S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in Mdl.ClassNames. S is a matrix of classification scores, similar to the output of predict.
  - W is an n-by-1 numeric vector of observation weights.
  - Cost is a K-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) – eye(K) specifies a cost of 0 for correct classification and 1 for misclassification.

Example: 'LossFun',@*lossfun*

Data Types: char | string | function_handle

ObservationsIn — Predictor data observation dimension
'rows' (default) | 'columns'

Predictor data observation dimension, specified as 'rows' or 'columns'.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time. You cannot specify `'ObservationsIn','columns'` for predictor data in a table.

Data Types: `char` | `string`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | numeric vector | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector or the name of a variable in `Tbl`.

- If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of observations in `X` or `Tbl`.
- If you specify `Weights` as the name of a variable in `Tbl`, then the name must be a character vector or string scalar. For example, if the weights are stored as `Tbl.W`, then specify `Weights` as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `Tbl.W`, as predictors.

If you supply weights, then for each regularization strength, `loss` computes the weighted classification loss on page 33-3647 and normalizes weights to sum up to the value of the prior probability in the respective class.

Data Types: `double` | `single`

Output Arguments

`L` — Classification losses
numeric scalar | numeric row vector

Classification losses, returned as a numeric scalar or row vector. The interpretation of `L` depends on `Weights` and `LossFun`.

`L` is the same size as `Mdl.Lambda`. `L(`*j*`)` is the classification loss of the linear classification model trained using the regularization strength `Mdl.Lambda(`*j*`)`.

Examples

Estimate Test-Sample Classification Loss

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30);
CMdl = CVMdl.Trained{1};
```

`CVMdl` is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample classification error.

```
ceTrain = loss(CMdl,X(trainIdx,:),Ystats(trainIdx))
```

```
ceTrain = 1.3572e-04
```

```
ceTest = loss(CMdl,X(testIdx,:),Ystats(testIdx))
```

```
ceTest = 5.2804e-04
```

Because there is one regularization strength in `CMdl`, `ceTrain` and `ceTest` are numeric scalars.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Classification Loss” on page 33-3643, and transpose the predictor data.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Train a binary, linear classification model. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitclinear(X,Ystats,'Solver','sparsa','Holdout',0.30,...
    'ObservationsIn','columns');
CMdl = CVMdl.Trained{1};
```

`CVMdl` is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j - w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j, y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j. Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LossFun` name-value pair argument.

```
linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);
```

Estimate the training- and test-sample classification loss using the linear loss function.

```
ceTrain = loss(CMdl,X(:,trainIdx),Ystats(trainIdx),'LossFun',linearloss,...
    'ObservationsIn','columns')
```

```
ceTrain = -7.8330
```

```
ceTest = loss(CMdl,X(:,testIdx),Ystats(testIdx),'LossFun',linearloss,...
    'ObservationsIn','columns')
```

```
ceTest = -7.7383
```

Find Good Lasso Penalty Using Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 33-3644.

```
load nlpdata
Ystats = Y == 'stats';
X = X';

rng(10); % For reproducibility
Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6,-0.5,11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'CVPartition',Partition,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
  ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
```

```
        NumObservations: 31572
                  KFold: 1
              Partition: [1x1 cvpartition]
             ClassNames: [0 1]
         ScoreTransform: 'none'

  Properties, Methods
```

Extract the trained linear classification model.

```
Mdl = CVMdl.Trained{1}
```

```
Mdl =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'logit'
              Beta: [34023x11 double]
              Bias: [1x11 double]
            Lambda: [1x11 double]
           Learner: 'logistic'

  Properties, Methods
```

`Mdl` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample classification error.

```
ce = loss(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

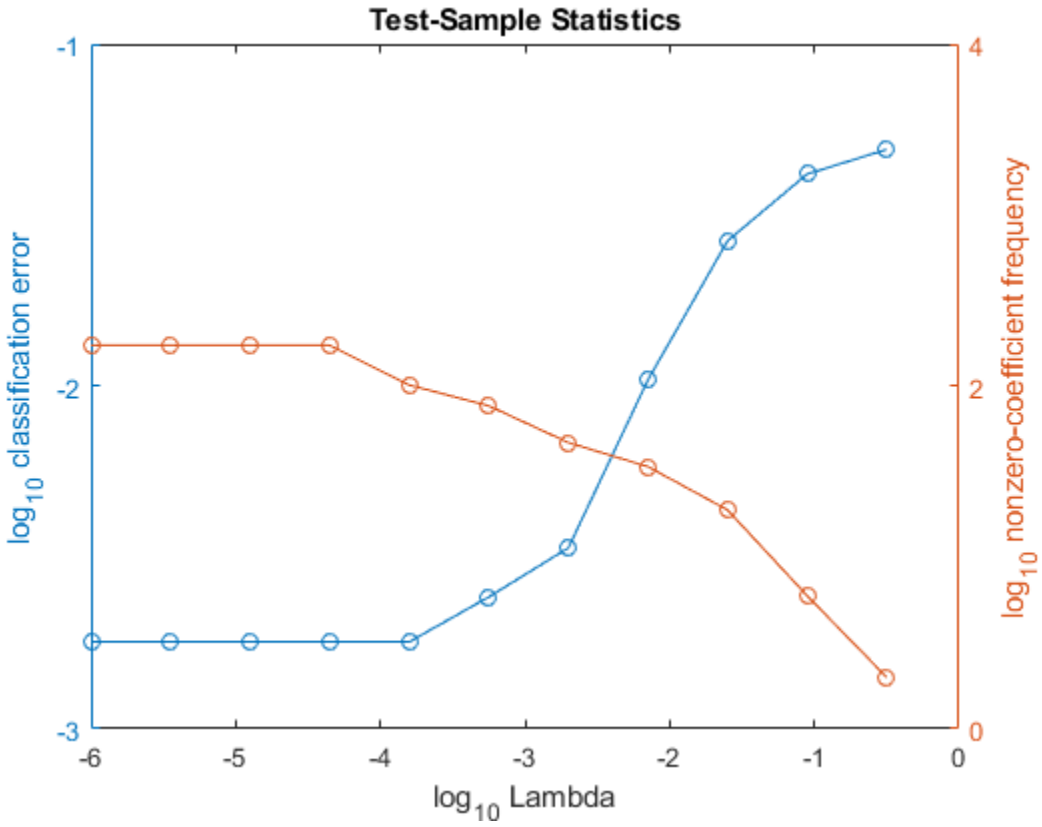
Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
```

```
title('Test-Sample Statistics')
hold off
```



Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.

- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of $K – 1$ zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

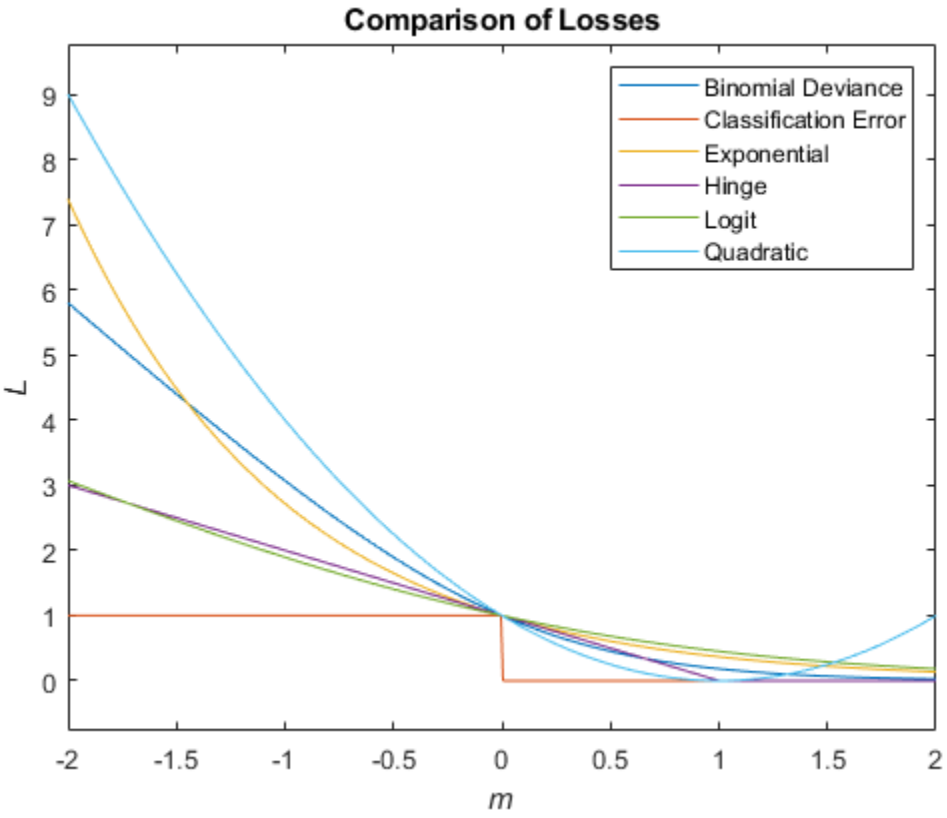
Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\hat{y}_j \neq y_j\right\}.$ $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.

Loss Function	Value of LossFun	Equation
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $$L = -\sum_{j=1}^{n}\frac{\tilde{w}_j \log(m_j)}{Kn},$$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



Algorithms

By default, observation weights are prior class probabilities. If you supply weights using `Weights`, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to estimate the weighted classification loss.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `loss` does not support tall `table` data.

For more information, see “Tall Arrays”.

`ClassificationLinear` | `fitclinear` | `predict`

Introduced in R2016a

loss

Classification error

Syntax

```
L = loss(obj,X,Y)
L = loss(obj,X,Y,Name,Value)
```

Description

`L = loss(obj,X,Y)` returns the classification loss on page 33-3654, which is a scalar representing how well `obj` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `obj`.

`L = loss(obj,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`obj`

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

`X`

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

`Y`

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`LossFun`

Built-in, loss-function name (character vector or string scalar in the table) or function handle.

- The following table lists the available loss functions. Specify one using the corresponding value.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

`'mincost'` is appropriate for classification scores that are posterior probabilities. Discriminant analysis models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

  Suppose that *n* be the number of observations in `X` and *K* be the number of distinct classes (`numel(Mdl.ClassNames)`). Your function must have this signature

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  where:

  - The output argument `lossvalue` is a scalar.
  - You choose the function name (*`lossfun`*).
  - `C` is an *n*-by-*K* logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an *n*-by-*K* numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an *n*-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to `1`.
  - `Cost` is a *K*-by-*K* numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification, and `1` for misclassification.

  Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see “Classification Loss” on page 33-3654.

Default: `'mincost'`

`Weights`

Numeric vector of length `N`, where `N` is the number of rows of `X`. `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

Default: `ones(N,1)`

Output Arguments

L

Classification loss on page 33-3654, a scalar. The interpretation of `L` depends on the values in `weights` and `lossfun`.

Examples

Estimate Classification Error

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using all observations in the data.

```
Mdl = fitcdiscr(meas,species);
```

Estimate the classification error of the model using the training observations.

```
L = loss(Mdl,meas,species)
```

```
L = 0.0200
```

Alternatively, if `Mdl` is not compact, then you can estimate the training-sample classification error by passing `Mdl` to `resubLoss`.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* =$

[0 0 1 0]′. The order of the classes corresponds to the order in the `ClassNames` property of the input model.

- $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
- $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

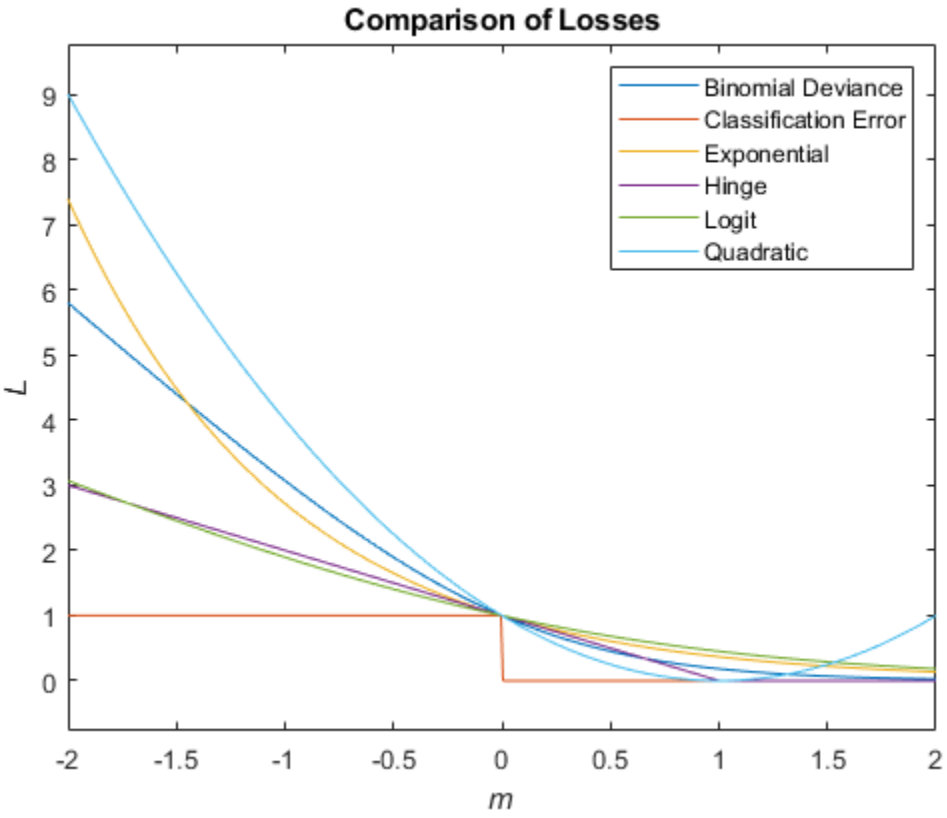
$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\hat{y}_j \neq y_j\right\}.$ $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn},$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp\left(-m_j\right).$
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\left\{0, 1 - m_j\right\}.$
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log\left(1 + \exp\left(-m_j\right)\right).$

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



Posterior Probability

The posterior probability that a point x belongs to class k is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with 1-by-d mean μ_k and d-by-d covariance Σ_k at a 1-by-d point x is

$$P(x|k) = \frac{1}{\left((2\pi)^d|\Sigma_k|\right)^{1/2}}\exp\left(-\frac{1}{2}(x-\mu_k)\Sigma_k^{-1}(x-\mu_k)^T\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k, and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k. Then the posterior probability that an observation x is of class k is

$$\widehat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- `'uniform'` — The prior probability of class `k` is one over the total number of classes.
- `'empirical'` — The prior probability of class `k` is the number of training samples of class `k` divided by the total number of training samples.

- Custom — The prior probability of class `k` is the `k`th element of the `prior` vector. See `fitcdiscr`.

After creating a classification model (`Mdl`) you can set the prior using dot notation:

```
Mdl.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 20-7.

Extended Capabilities

Tall Arrays
Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays”.

loss

Package:

Classification loss for multiclass error-correcting output codes (ECOC) model

Syntax

```
L = loss(Mdl,tbl,ResponseVarName)
L = loss(Mdl,tbl,Y)

L = loss(Mdl,X,Y)

L = loss(___,Name,Value)
```

Description

`L = loss(Mdl,tbl,ResponseVarName)` returns the classification loss (`L`), a scalar representing how well the trained multiclass error-correcting output codes (ECOC) model `Mdl` classifies the predictor data in `tbl` compared to the true class labels in `tbl.ResponseVarName`. By default, `loss` uses the classification error on page 33-3665 to compute `L`.

`L = loss(Mdl,tbl,Y)` returns the classification loss for the predictor data in table `tbl` and the true class labels in `Y`.

`L = loss(Mdl,X,Y)` returns the classification loss for the predictor data in matrix `X` and the true class labels in `Y`.

`L = loss(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify a decoding scheme, classification loss function, and verbosity level.

Examples

Determine Test-Sample Loss of ECOC Model

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Specify a 15% holdout sample, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1};           % Extract trained, compact classifier
```

`PMdl` is a `ClassificationPartitionedECOC` model. It has the property `Trained`, a 1-by-1 cell array containing the `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test-sample classification error, which is the default classification loss.

```
testInds = test(PMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
L = loss(Mdl,XTest,YTest)
```

```
L = 0
```

The ECOC model correctly classifies all irises in the test sample.

Determine ECOC Model Quality Using Custom Loss

Determine the quality of an ECOC model by using a custom loss function that considers the minimal binary loss for each observation.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);  % Class order
rng(1) % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Specify a 15% holdout sample, standardize the predictors using an SVM template, and define the class order.

```
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1};           % Extract trained, compact classifier
```

`PMdl` is a `ClassificationPartitionedECOC` model. It has the property `Trained`, a 1-by-1 cell array containing the `CompactClassificationECOC` model that the software trained using the training set.

Create a function that takes the minimal loss for each observation, then averages the minimal losses for all observations. `S` corresponds to the `NegLoss` output of `predict`.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the test-sample custom loss.

```
testInds = test(PMdl.Partition);  % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
loss(Mdl,XTest,YTest,'LossFun',lossfun)
```

```
ans = 0.0033
```

The average minimal binary loss for the test-sample observations is `0.0033`.

Input Arguments

`Mdl` — Full or compact multiclass ECOC model

`ClassificationECOC` model object | `CompactClassificationECOC` model object

Full or compact multiclass ECOC model, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object.

To create a full or compact ECOC model, see `ClassificationECOC` or `CompactClassificationECOC`.

`tbl` — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If you train `Mdl` using sample data contained in a `table`, then the input data for `loss` must also be in a table.

When training `Mdl`, assume that you set `'Standardize',true` for a template object specified in the `'Learners'` name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner `j`, the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `tbl.y`, then specify `ResponseVarName` as `'y'`. Otherwise, the software treats all columns of `tbl`, including `tbl.y`, as predictors.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

`X` — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation, and each column corresponds to one variable. The variables in the columns of `X` must be the same as the variables that trained the classifier `Mdl`.

The number of rows in `X` must equal the number of rows in `Y`.

When training `Mdl`, assume that you set `'Standardize',true` for a template object specified in the `'Learners'` name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner `j`, the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must have the same data type as `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The number of rows in `Y` must equal the number of rows in `tbl` or `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `loss(Mdl,X,Y,'BinaryLoss','hinge','LossFun',@lossfun)` specifies `'hinge'` as the binary learner loss function and the custom function handle `@lossfun` as the overall loss function.

BinaryLoss — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the *K*-by-*L* coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-*L* row vector of classification scores.
  - `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
  - *K* is the number of classes.
  - *L* is the number of binary learners.

  For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-3666.

Example: `'Decoding','lossbased'`

`LossFun` — Loss function

`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'classiferror'` or a function handle.

- Specify the built-in function `'classiferror'`. In this case, the loss function is the classification error on page 33-3665, which is the proportion of misclassified observations.
- Or, specify your own function using function handle notation.

  Assume that `n = size(X,1)` is the sample size and `K` is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

  - The output argument `lossvalue` is a scalar.
  - You specify the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `Mdl.ClassNames`. The input `S` resembles the output argument `NegLoss` of `predict`.
  - `W` is an `n`-by-`1` numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to `1`.
  - `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) – eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

  Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `string` | `function_handle`

`ObservationsIn` — Predictor data observation dimension
`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`. `Mdl.BinaryLearners` must contain `ClassificationLinear` models.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, you can experience a significant reduction in execution time. You cannot specify `'ObservationsIn','columns'` for predictor data in a table.

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

`Weights` — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector or the name of a variable in `tbl`. If you supply weights, then `loss` computes the weighted loss.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, you must do so as a character vector or string scalar. For example, if the weights are stored as `tbl.w`, then specify `Weights` as `'w'`. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

If you do not specify your own loss function (using `LossFun`), then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`L` — Classification loss

numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or row vector. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but in general, better classifiers yield smaller classification loss values.

If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `L` is a 1-by-ℓ vector, where ℓ is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`). The value `L(j)` is the loss for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

Otherwise, `L` is a scalar value.

More About

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_j s_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_j s_j)/2$

Value	Description	Score Domain	$g(y_j,s_j)$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_j s_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_j s_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_j s_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `loss` does not support tall `table` data when `Mdl` contains kernel or linear binary learners.

For more information, see “Tall Arrays”.

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

Introduced in R2014b

loss

Classification error

Syntax

```
L = loss(ens,tbl,ResponseVarName)
L = loss(ens,tbl,Y)
L = loss(ens,X,Y)
L = loss( ___ ,Name,Value)
```

Description

`L = loss(ens,tbl,ResponseVarName)` returns the classification error for ensemble `ens` computed using table of predictors `tbl` and true class labels `tbl.ResponseVarName`.

`L = loss(ens,tbl,Y)` returns the classification error for ensemble `ens` computed using table of predictors `tbl` and true class labels `Y`.

`L = loss(ens,X,Y)` returns the classification error for ensemble `ens` computed using matrix of predictors `X` and true class labels `Y`.

`L = loss( ___ ,Name,Value)` computes classification error with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

When computing the loss, `loss` normalizes the class probabilities in `ResponseVarName` or `Y` to the class probabilities used for training, stored in the `Prior` property of `ens`.

Input Arguments

`ens`

Classification ensemble created with `fitcensemble`, or a compact classification ensemble created with `compact`.

`tbl`

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all of the predictors used to train the model. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `ens` using sample data contained in a `table`, then the input data for this method must also be in a table.

`ResponseVarName`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

X

Matrix of data to classify. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train `ens`. X should have the same number of rows as the number of elements in Y.

If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Y

Class labels of observations in `tbl` or X. Y should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `tbl` or X.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from `1` to `ens.NumTrained`. `loss` uses only these learners for calculating loss.

Default: `1:NumTrained`

`Lossfun`

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  `'mincost'` is appropriate for classification scores that are posterior probabilities.

  - Bagged and subspace ensembles return posterior probabilities by default (`ens.Method` is `'Bag'` or `'Subspace'`).

- If the ensemble method is `'AdaBoostM1'`, `'AdaBoostM2'`, `GentleBoost`, or `'LogitBoost'`, then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

  ```
  ens.ScoreTransform = 'doublelogit';
  ```

- For all other ensemble methods, the software does not support posterior probabilities as classification scores.

- Specify your own function using function handle notation.

  Suppose that `n` be the number of observations in `X` and `K` be the number of distinct classes (`numel(ens.ClassNames)`, `ens` is the input model). Your function must have this signature

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  where:

  - The output argument `lossvalue` is a scalar.
  - You choose the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to `1`.
  - `Cost` is a *K*-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification, and `1` for misclassification.

  Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see “Classification Loss” on page 33-3672.

Default: `'classiferror'`

`mode`

Meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

`UseObsForLearner`

A logical matrix of size `N`-by-`T`, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When UseObsForLearner(i,j) is true, learner j is used in predicting the class of row i of X.

Default: true(N,T)

weights

Vector of observation weights, with nonnegative entries. The length of weights must equal the number of rows in X. When you specify weights, loss normalizes the weights so that observation weights in each class sum to the prior probability of that class.

Default: ones(size(X,1),1)

Output Arguments

L

Classification loss on page 33-3672, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Classification Error

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification ensemble of 100 decision trees using AdaBoostM2. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the classification error of the model using the training observations.

```
L = loss(ens,meas,species)
```

```
L = 0.0333
```

Alternatively, if ens is not compact, then you can estimate the training-sample classification error by passing ens to resubLoss.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

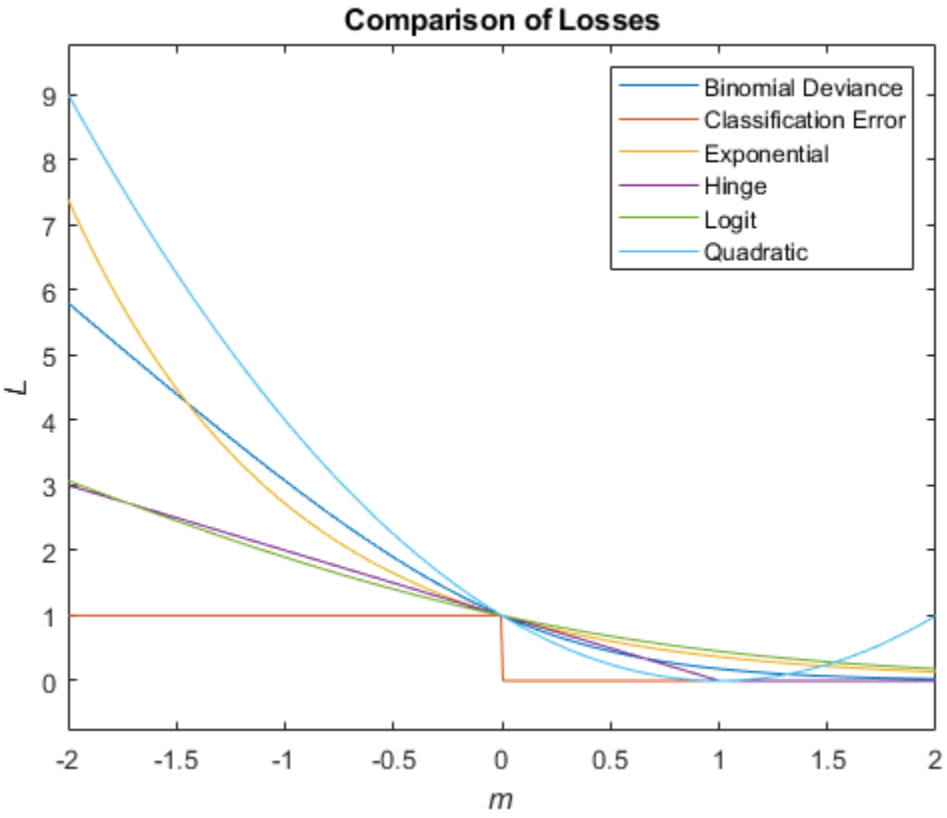
Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\{1 + \exp[-2m_j]\}$.
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$. $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.

Loss Function	Value of LossFun	Equation
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $$L = -\sum_{j=1}^{n}\frac{\tilde{w}_j \log(m_j)}{Kn},$$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

loss

Classification loss for naive Bayes classifier

Syntax

```
L = loss(Mdl,tbl,ResponseVarName)
L = loss(Mdl,tbl,Y)

L = loss(Mdl,X,Y)

L = loss(___,Name,Value)
```

Description

`L = loss(Mdl,tbl,ResponseVarName)` returns the "Classification Loss" on page 33-3682, a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data in table `tbl` compared to the true class labels in `tbl.ResponseVarName`.

`loss` normalizes the class probabilities in `tbl.ResponseVarName` to the prior class probabilities used by `fitcnb` for training, which are stored in the `Prior` property of `Mdl`.

`L = loss(Mdl,tbl,Y)` returns the classification loss for the predictor data in table `tbl` and the true class labels in `Y`.

`L = loss(Mdl,X,Y)` returns the classification loss based on the predictor data in matrix `X` compared to the true class labels in `Y`.

`L = loss(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify the loss function and the classification weights.

Examples

Determine Test Sample Classification Loss of Naive Bayes Classifier

Determine the test sample classification error (loss) of a naive Bayes classifier. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Load the `fisheriris` data set. Create `X` as a numeric matrix that contains four petal measurements for 150 irises. Create `Y` as a cell array of character vectors that contains the corresponding iris species.

```
load fisheriris
X = meas;
Y = species;
rng('default')  % for reproducibility
```

Randomly partition observations into a training set and a test set with stratification, using the class information in `Y`. Specify a 30% holdout sample for testing.

```
cv = cvpartition(Y,'HoldOut',0.30);
```

Extract the training and test indices.

```
trainInds = training(cv);
testInds = test(cv);
```

Specify the training and test data sets.

```
XTrain = X(trainInds,:);
YTrain = Y(trainInds);
XTest = X(testInds,:);
YTest = Y(testInds);
```

Train a naive Bayes classifier using the predictors `XTrain` and class labels `YTrain`. A recommended practice is to specify the class names. `fitcnb` assumes that each predictor is conditionally and normally distributed.

```
Mdl = fitcnb(XTrain,YTrain,'ClassNames',{'setosa','versicolor','virginica'})
```

```
Mdl =
  ClassificationNaiveBayes
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 105
        DistributionNames: {'normal'  'normal'  'normal'  'normal'}
   DistributionParameters: {3x4 cell}

  Properties, Methods
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(Mdl,XTest,YTest)
```

```
L = 0.0444
```

The naive Bayes classifier misclassifies approximately 4% of the test sample.

You might decrease the classification error by specifying better predictor distributions when you train the classifier with `fitcnb`.

Determine Test Sample Logit Loss of Naive Bayes Classifier

Load the `fisheriris` data set. Create `X` as a numeric matrix that contains four petal measurements for 150 irises. Create `Y` as a cell array of character vectors that contains the corresponding iris species.

```
load fisheriris
X = meas;
```

```
Y = species;
rng('default')  % for reproducibility
```

Randomly partition observations into a training set and a test set with stratification, using the class information in `Y`. Specify a 30% holdout sample for testing.

```
cv = cvpartition(Y,'HoldOut',0.30);
```

Extract the training and test indices.

```
trainInds = training(cv);
testInds = test(cv);
```

Specify the training and test data sets.

```
XTrain = X(trainInds,:);
YTrain = Y(trainInds);
XTest = X(testInds,:);
YTest = Y(testInds);
```

Train a naive Bayes classifier using the predictors `XTrain` and class labels `YTrain`. A recommended practice is to specify the class names. `fitcnb` assumes that each predictor is conditionally and normally distributed.

```
Mdl = fitcnb(XTrain,YTrain,'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

Determine how well the algorithm generalizes by estimating the test sample logit loss.

```
L = loss(Mdl,XTest,YTest,'LossFun','logit')
```

```
L = 0.3359
```

The logit loss is approximately 0.34.

Input Arguments

`Mdl` — Naive Bayes classification model

`ClassificationNaiveBayes` model object | `CompactClassificationNaiveBayes` model object

Naive Bayes classification model, specified as a `ClassificationNaiveBayes` model object or `CompactClassificationNaiveBayes` model object returned by `fitcnb` or `compact`, respectively.

`tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed. Optionally, `tbl` can contain additional columns for the response variable and observation weights.

If you train `Mdl` using sample data contained in a table, then the input data for `loss` must also be in a table.

ResponseVarName — Response variable name
name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors.

If `tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName`.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an *instance* or *example*), and each column corresponds to one variable (also known as a *feature*). The variables in the columns of `X` must be the same as the variables that trained the `Mdl` classifier.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must have the same data type as `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` must be equal to the number of rows of `tbl` or `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `loss(Mdl,tbl,Y,'Weights',W)` weighs the observations in each row of `tbl` using the corresponding weight in each row of the variable `W`.

LossFun — Loss function
`'mincost'` (default) | `'binodeviance'` | `'classiferror'` | `'exponential'` | `'hinge'` | `'logit'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in loss function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  `'mincost'` is appropriate for classification scores that are posterior probabilities. Naive Bayes models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

  Suppose that `n` is the number of observations in `X` and `K` is the number of distinct classes (`numel(Mdl.ClassNames)`, where `Mdl` is the input model). Your function must have this signature

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  where:

  - The output argument `lossvalue` is a scalar.
  - You specify the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

    Create `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to `1`.
  - `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification and `1` for misclassification.

  Specify your function using `'LossFun',@`*`lossfun`*.

For more details on loss functions, see “Classification Loss” on page 33-3682.

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of a variable in `tbl`

Observation weights, specified as a numeric vector or the name of a variable in `tbl`. The software weighs the observations in each row of `X` or `tbl` with the corresponding weights in `Weights`.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows of `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, then the name must be a character vector or string scalar. For example, if the weights are stored as `tbl.w`, then specify `Weights` as `'w'`. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

If you do not specify a loss function, then the software normalizes `Weights` to add up to `1`.

Data Types: `double` | `char` | `string`

Output Arguments

`L` — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme; in general, better classifiers yield smaller loss values.

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.

- $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
- $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

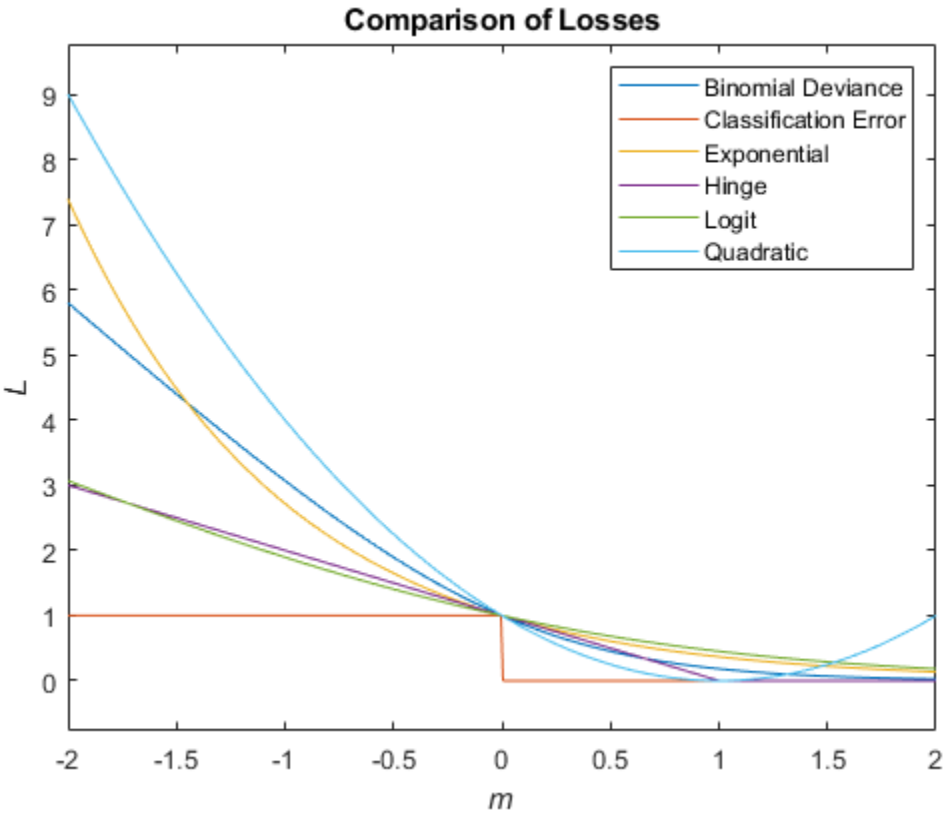
$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\widehat{y}_j \neq y_j\right\}.$ $\widehat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\widetilde{w}_j \log(m_j)}{Kn},$ where the weights $\widetilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp\left(-m_j\right).$
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\left\{0, 1 - m_j\right\}.$
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log\left(1 + \exp\left(-m_j\right)\right).$

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



Misclassification Cost

A misclassification cost is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- True misclassification cost — A K-by-K matrix, where element (i,j) indicates the misclassification cost of predicting an observation into class j if its true class is i. The software stores the misclassification cost in the property `Mdl.Cost`, and uses it in computations. By default, `Mdl.Cost(i,j) = 1` if `i ≠ j`, and `Mdl.Cost(i,j) = 0` if `i = j`. In other words, the cost is `0` for correct classification and `1` for any incorrect classification.
- Expected misclassification cost — A K-dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k, weighted by the class posterior probabilities.

  $$c_k = \sum_{j=1}^{K} \widehat{P}(Y = j | x_1, ..., x_P) Cost_{jk}.$$

  In other words, the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation $(x_1,...,x_P)$ is

$$\widehat{P}(Y = k \,|\, x_1, .., x_P) = \frac{P(X_1, ..., X_P \,|\, y = k)\pi(Y = k)}{P(X_1, ..., X_P)},$$

where:

- $P(X_1, ..., X_P \,|\, y = k)$ is the conditional joint density of the predictors given they are in class k. `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, .., X_P)$ is the joint density of the predictors. The classes are discrete, so $P(X_1, ..., X_P) = \sum_{k=1}^{K} P(X_1, ..., X_P \,|\, y = k)\pi(Y = k)$.

Prior Probability

The prior probability of a class is the assumed relative frequency with which observations from that class occur in a population.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays”.

Introduced in R2014b

loss

Package:

Classification loss for neural network classifier

Syntax

```
L = loss(Mdl,Tbl,ResponseVarName)
L = loss(Mdl,Tbl,Y)

L = loss(Mdl,X,Y)

L = loss( ___ ,Name,Value)
```

Description

`L = loss(Mdl,Tbl,ResponseVarName)` returns the classification loss on page 33-3694 for the trained neural network classifier `Mdl` using the predictor data in table `Tbl` and the class labels in the `ResponseVarName` table variable.

`L` is returned as a scalar value that represents the classification error by default.

`L = loss(Mdl,Tbl,Y)` returns the classification loss for the classifier `Mdl` using the predictor data in table `Tbl` and the class labels in vector `Y`.

`L = loss(Mdl,X,Y)` returns the classification loss for the trained neural network classifier `Mdl` using the predictor data `X` and the corresponding class labels in `Y`.

`L = loss( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify that columns in the predictor data correspond to observations, specify the loss function, or supply observation weights.

Examples

Test Set Classification Error of Neural Network

Calculate the test set classification error of a neural network classifier.

Load the `patients` data set. Create a table from the data set. Each row corresponds to one patient, and each column corresponds to a diagnostic variable. Use the `Smoker` variable as the response variable, and the rest of the variables as predictors.

```
load patients
tbl = table(Diastolic,Systolic,Gender,Height,Weight,Age,Smoker);
```

Separate the data into a training set `tblTrain` and a test set `tblTest` by using a stratified holdout partition. The software reserves approximately 30% of the observations for the test data set and uses the rest of the observations for the training data set.

```
rng("default") % For reproducibility of the partition
c = cvpartition(tbl.Smoker,"Holdout",0.30);
trainingIndices = training(c);
testIndices = test(c);
tblTrain = tbl(trainingIndices,:);
tblTest = tbl(testIndices,:);
```

Train a neural network classifier using the training set. Specify the `Smoker` column of `tblTrain` as the response variable. Specify to standardize the numeric predictors.

```
Mdl = fitcnet(tblTrain,"Smoker", ...
    "Standardize",true);
```

Calculate the test set classification error. Classification error is the default loss type for neural network classifiers.

```
testError = loss(Mdl,tblTest,"Smoker")
```

```
testError = 0.0671
```

```
testAccuracy = 1 - testError
```

```
testAccuracy = 0.9329
```

The neural network model correctly classifies approximately 93% of the test set observations.

Select Features to Include in Neural Network Classifier

Perform feature selection by comparing test set classification margins, edges, errors, and predictions. Compare the test set metrics for a model trained using all the predictors to the test set metrics for a model trained using only a subset of the predictors.

Load the sample file `fisheriris.csv`, which contains iris data including sepal length, sepal width, petal length, petal width, and species type. Read the file into a table.

```
fishertable = readtable('fisheriris.csv');
```

Separate the data into a training set `trainTbl` and a test set `testTbl` by using a stratified holdout partition. The software reserves approximately 30% of the observations for the test data set and uses the rest of the observations for the training data set.

```
rng("default")
c = cvpartition(fishertable.Species,"Holdout",0.3);
trainTbl = fishertable(training(c),:);
testTbl = fishertable(test(c),:);
```

Train one neural network classifier using all the predictors in the training set, and train another classifier using all the predictors except `PetalWidth`. For both models, specify `Species` as the response variable, and standardize the predictors.

```
allMdl = fitcnet(trainTbl,"Species","Standardize",true);
subsetMdl = fitcnet(trainTbl,"Species ~ SepalLength + SepalWidth + PetalLength", ...
    "Standardize",true);
```

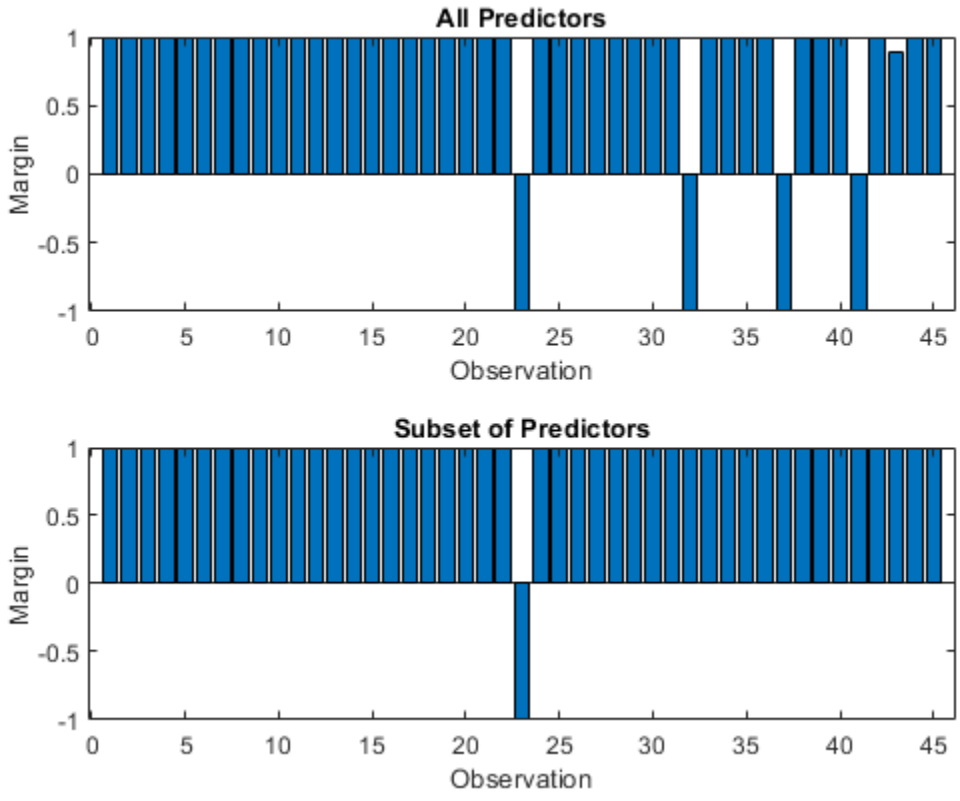
Calculate the test set classification margins for the two models. Because the test set includes only 45 observations, display the margins using bar graphs.

For each observation, the classification margin is the difference between the classification score for the true class and the maximal score for the false classes. Because neural network classifiers return classification scores that are posterior probabilities, margin values close to 1 indicate confident classifications and negative margin values indicate misclassifications.

```
tiledlayout(2,1)

% Top axes
ax1 = nexttile;
allMargins = margin(allMdl,testTbl);
bar(ax1,allMargins)
xlabel(ax1,"Observation")
ylabel(ax1,"Margin")
title(ax1,"All Predictors")

% Bottom axes
ax2 = nexttile;
subsetMargins = margin(subsetMdl,testTbl);
bar(ax2,subsetMargins)
xlabel(ax2,"Observation")
ylabel(ax2,"Margin")
title(ax2,"Subset of Predictors")
```



Compare the test set classification edge, or mean of the classification margins, of the two models.

```
allEdge = edge(allMdl,testTbl)
```

```
allEdge = 0.8198
```

```
subsetEdge = edge(subsetMdl,testTbl)
```

```
subsetEdge = 0.9556
```

Based on the test set classification margins and edges, the model trained on a subset of the predictors seems to outperform the model trained on all the predictors.

Compare the test set classification error of the two models.

```
allError = loss(allMdl,testTbl);
allAccuracy = 1-allError
```

```
allAccuracy = 0.9111
```

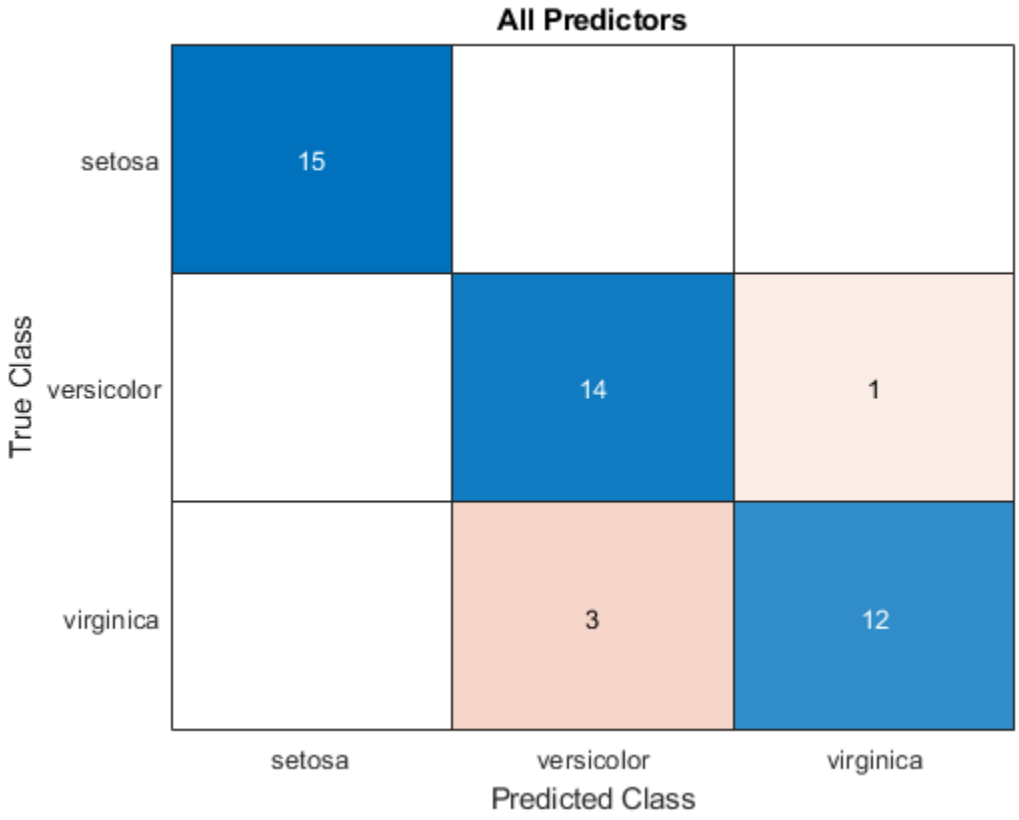
```
subsetError = loss(subsetMdl,testTbl);
subsetAccuracy = 1-subsetError
```

```
subsetAccuracy = 0.9778
```

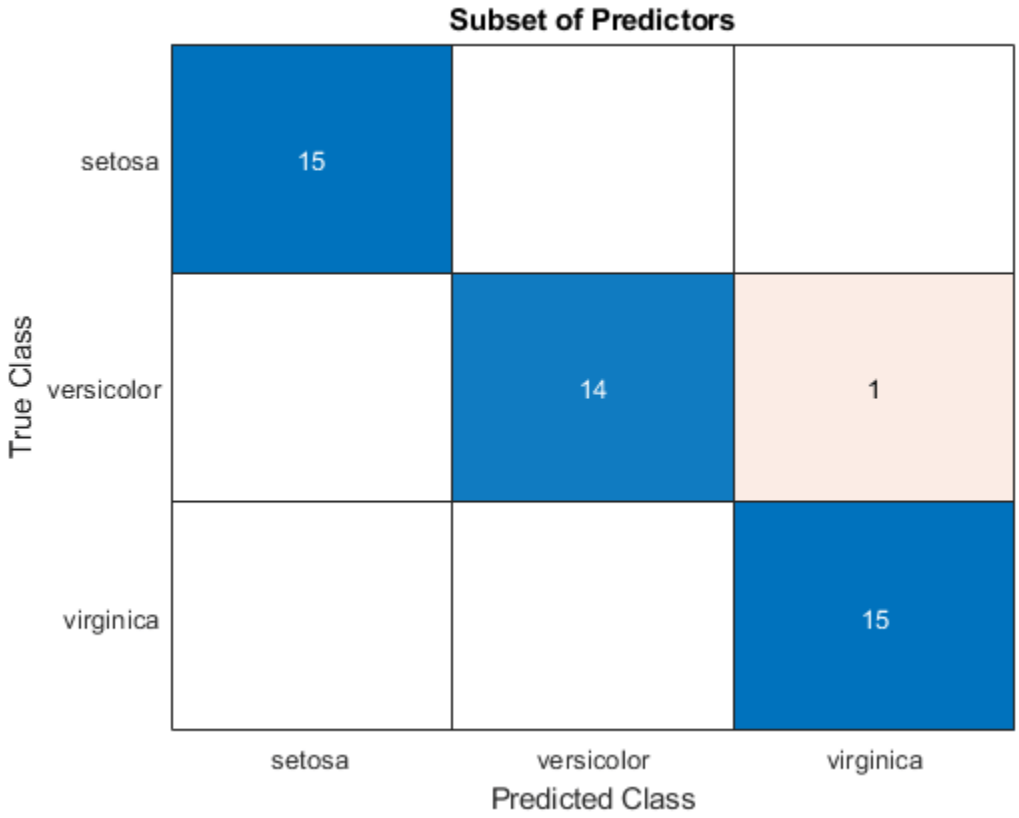
Again, the model trained using only a subset of the predictors seems to perform better than the model trained using all the predictors.

Visualize the test set classification results using confusion matrices.

```
allLabels = predict(allMdl,testTbl);
figure
confusionchart(testTbl.Species,allLabels)
title("All Predictors")
```



```
subsetLabels = predict(subsetMdl,testTbl);
figure
confusionchart(testTbl.Species,subsetLabels)
title("Subset of Predictors")
```



The model trained using all the predictors misclassifies four of the test set observations. The model trained using a subset of the predictors misclassifies only one of the test set observations.

Given the test set performance of the two models, consider using the model trained using all the predictors except `PetalWidth`.

Input Arguments

`Mdl` — Trained neural network classifier

`ClassificationNeuralNetwork` model object | `CompactClassificationNeuralNetwork` model object

Trained neural network classifier, specified as a `ClassificationNeuralNetwork` model object or `CompactClassificationNeuralNetwork` model object returned by `fitcnet` or `compact`, respectively.

`Tbl` — Sample data

table

Sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain an additional column for the

response variable. `Tbl` must contain all of the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName` or `Y`.
- If you trained `Mdl` using sample data contained in a table, then the input data for `loss` must also be in a table.
- If you set `'Standardize',true` in `fitcnet` when training `Mdl`, then the software standardizes the numeric columns of the predictor data using the corresponding means and standard deviations.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. If `Tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must specify it as a character vector or string scalar. For example, if the response variable is stored as `Tbl.Y`, then specify `ResponseVarName` as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Tbl.Y`, as predictors.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

`Y` — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array; logical or numeric vector; or cell array of character vectors.

- The data type of `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` must be equal to the number of observations in `X` or `Tbl`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`X` — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. By default, `loss` assumes that each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time.

The length of `Y` and the number of observations in `X` must be equal.

If you set `'Standardize',true` in `fitcnet` when training `Mdl`, then the software standardizes the numeric columns of the predictor data using the corresponding means and standard deviations.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `loss(Mdl,Tbl,"Response","LossFun","crossentropy")` specifies to compute the cross-entropy loss for the model `Mdl`.

LossFun — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'crossentropy'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'crossentropy'`	Cross-entropy loss (for neural networks only)
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  For more details on loss functions, see “Classification Loss” on page 33-3694.

- To specify a custom loss function, use function handle notation. The function must have this form:

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  - The output argument `lossvalue` is a scalar.
  - You specify the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating the class to which the corresponding observation belongs. `n` is the number of observations in `Tbl` or `X`, and `K` is the number of distinct classes (`numel(Mdl.ClassNames)`. The column order corresponds to the class order in `Mdl.ClassNames`. Create `C` by setting `C(p,q) = 1`, if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.

- `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an `n`-by-1 numeric vector of observation weights.
- `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) – eye(K)` specifies a cost of `0` for correct classification and `1` for misclassification.

Example: `'LossFun','crossentropy'`

Data Types: `char` | `string` | `function_handle`

`ObservationsIn` — Predictor data observation dimension
`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as `'rows'` or `'columns'`.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time. You cannot specify `'ObservationsIn','columns'` for predictor data in a table.

Data Types: `char` | `string`

`Weights` — Observation weights
nonnegative numeric vector | name of variable in `Tbl`

Observation weights, specified as a nonnegative numeric vector or the name of a variable in `Tbl`. The software weights each observation in `X` or `Tbl` with the corresponding value in `Weights`. The length of `Weights` must equal the number of observations in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

If you supply weights, then `loss` computes the weighted classification loss and normalizes weights to sum to the value of the prior probability in the respective class.

Data Types: `single` | `double` | `char` | `string`

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:

- y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
- $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.

- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\hat{y}_j \neq y_j\right\}.$ $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn},$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.

Loss Function	Value of LossFun	Equation
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = (f(X_j)'C)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\hat{y}_j = \underset{k=1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j (1 - m_j)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).

Topics

“Assess Neural Network Classifier Performance” on page 18-177

Introduced in R2021a

loss

Package: `classreg.learning.classif`

Find classification error for support vector machine (SVM) classifier

Syntax

```
L = loss(SVMModel,TBL,ResponseVarName)
L = loss(SVMModel,TBL,Y)

L = loss(SVMModel,X,Y)

L = loss( ___ ,Name,Value)
```

Description

`L = loss(SVMModel,TBL,ResponseVarName)` returns the classification error (see "Classification Loss" on page 33-3703), a scalar representing how well the trained support vector machine (SVM) classifier (`SVMModel`) classifies the predictor data in table `TBL` compared to the true class labels in `TBL.ResponseVarName`.

`loss` normalizes the class probabilities in `TBL.ResponseVarName` to the prior class probabilities that `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

The classification loss (`L`) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values.

`L = loss(SVMModel,TBL,Y)` returns the classification error for the predictor data in table `TBL` and the true class labels in `Y`.

`loss` normalizes the class probabilities in `Y` to the prior class probabilities that `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

`L = loss(SVMModel,X,Y)` returns the classification error based on the predictor data in matrix `X` compared to the true class labels in `Y`.

`L = loss( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the loss function and the classification weights.

Examples

Determine Test Sample Classification Error of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that `'g'` is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CompactSVMModel,XTest,YTest)
```

```
L = 0.0787
```

The SVM classifier misclassifies approximately 8% of the test sample.

Determine Test Sample Hinge Loss of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that `'g'` is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition);   % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample hinge loss.

```
L = loss(CompactSVMModel,XTest,YTest,'LossFun','hinge')
```

```
L = 0.2998
```

The hinge loss is approximately 0.3. Classifiers with hinge losses close to 0 are preferred.

Input Arguments

SVMModel — SVM classification model

ClassificationSVM model object | CompactClassificationSVM model object

SVM classification model, specified as a ClassificationSVM model object or CompactClassificationSVM model object returned by fitcsvm or compact, respectively.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMModel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName or Y.

If you trained SVMModel using sample data contained in a table, then the input data for loss must also be in a table.

If you set 'Standardize',true in fitcsvm when training SVMModel, then the software standardizes the columns of the predictor data using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: table

ResponseVarName — Response variable name

name of variable in TBL

Response variable name, specified as the name of a variable in TBL.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as TBL.Y, then specify ResponseVarName as 'Y'. Otherwise, the software treats all columns of TBL, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of X must be the same as the variables that trained the SVMModel classifier.

The length of Y and the number of rows in X must be equal.

If you set `'Standardize',true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and the standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must be the same as the data type of `SVMModel.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` must equal the number of rows in `TBL` or the number of rows in `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `loss(SVMModel,TBL,Y,'Weights',W)` weighs the observations in each row of `TBL` using the corresponding weight in each row of the variable `W` in `TBL`.

LossFun — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  `'mincost'` is appropriate for classification scores that are posterior probabilities. You can specify to use posterior probabilities as classification scores for SVM models by setting `'FitPosterior',true` when you cross-validate the model using `fitcsvm`.

- Specify your own function by using function handle notation.

Suppose that `n` is the number of observations in `X`, and `K` is the number of distinct classes (`numel(SVMModel.ClassNames)`) used to create the input model (`SVMModel`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*`lossfun`*).
- `C` is an `n`-by-`K` logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `SVMModel.ClassNames`.

  Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
- `S` is an `n`-by-`K` numeric matrix of classification scores, similar to the output of `predict`. The column order corresponds to the class order in `SVMModel.ClassNames`.
- `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to `1`.
- `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) – eye(K)` specifies a cost of `0` for correct classification and `1` for misclassification.

Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see “Classification Loss” on page 33-3703.

Example: `'LossFun','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of variable in `TBL`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector or the name of a variable in `TBL`. The software weighs the observations in each row of `X` or `TBL` with the corresponding weight in `Weights`.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or `TBL`.

If you specify `Weights` as the name of a variable in `TBL`, you must do so as a character vector or string scalar. For example, if the weights are stored as `TBL.W`, then specify `Weights` as `'W'`. Otherwise, the software treats all columns of `TBL`, including `TBL.W`, as predictors.

If you do not specify your own loss function, then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Example: `'Weights','W'`

Data Types: `single` | `double` | `char` | `string`

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of $K – 1$ zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

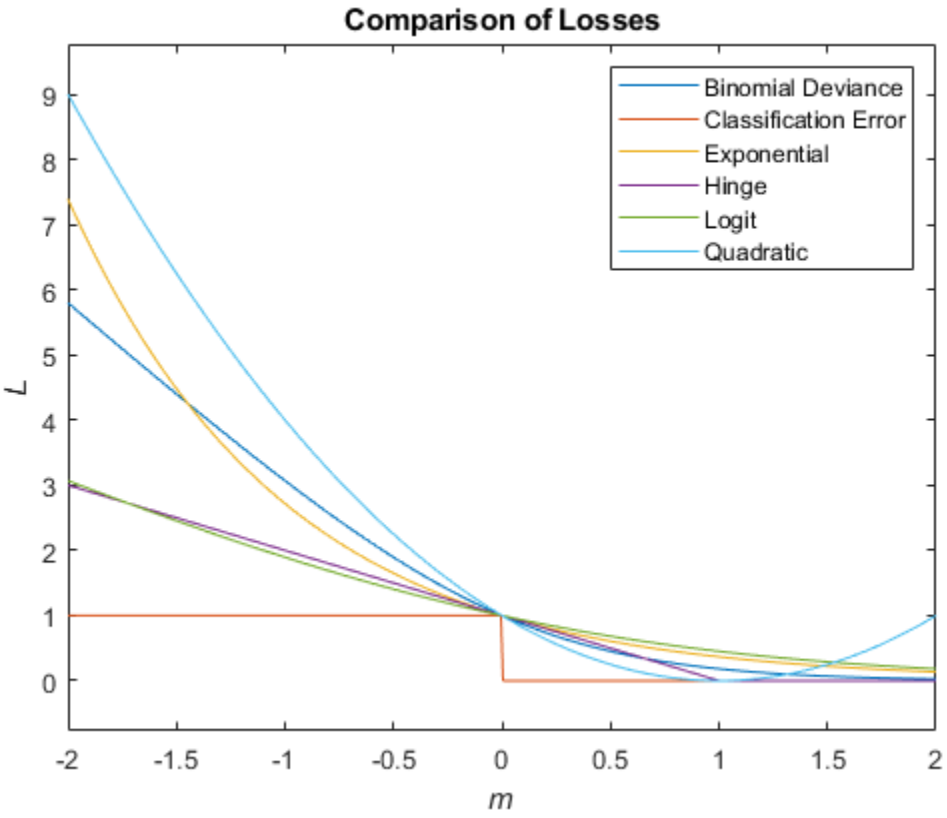
Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of `LossFun`	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$

Loss Function	Value of LossFun	Equation
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$. $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn}$, where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from -∞ to +∞. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical predicted response for x, or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^{n} \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, ..., \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x, or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j,x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b\,.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-150.

Introduced in R2014a

loss

Classification error

Syntax

```
L = loss(tree,TBL,ResponseVarName)
L = loss(tree,TBL,Y)
L = loss(tree,X,Y)

L = loss( ___ ,Name,Value)

[L,se,NLeaf,bestlevel] = loss( ___ )
```

Description

`L = loss(tree,TBL,ResponseVarName)` returns a scalar representing how well `tree` classifies the data in `TBL`, when `TBL.ResponseVarName` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `tree`.

`L = loss(tree,TBL,Y)` returns a scalar representing how well `tree` classifies the data in `TBL`, when `Y` contains the true classifications.

`L = loss(tree,X,Y)` returns a scalar representing how well `tree` classifies the data in `X`, when `Y` contains the true classifications.

`L = loss( ___ ,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

`[L,se,NLeaf,bestlevel] = loss( ___ )` also returns the vector of standard errors of the classification errors (`se`), the vector of numbers of leaf nodes in the trees of the pruning sequence (`NLeaf`), and the best pruning level as defined in the `TreeSize` name-value pair (`bestlevel`).

Input Arguments

`tree` — Trained classification tree

`ClassificationTree` model object | `CompactClassificationTree` model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, `tree` is a trained classification model returned by `fitctree` or `compact`.

`TBL` — Sample data

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional columns for the response variable and observation weights. `TBL` must contain all the predictors used to train `tree`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train tree, then you do not need to specify ResponseVarName or Y.

If you train tree using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

X — Data to classify
numeric matrix

Data to classify, specified as a numeric matrix. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train tree. X must have the same number of rows as the number of elements in Y.

Data Types: single | double

ResponseVarName — Response variable name
name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train tree, then you do not need to specify ResponseVarName.

If you specify ResponseVarName, then you must do so as a character vector or string scalar. For example, if the response variable is stored as TBL.Response, then specify it as 'Response'. Otherwise, the software treats all columns of TBL, including TBL.ResponseVarName, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: char | string

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Y must be of the same type as the classification used to train tree, and its number of elements must equal the number of rows of X.

Data Types: categorical | char | string | logical | single | double | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

LossFun — Loss function
'mincost' (default) | 'binodeviance' | 'classiferror' | 'exponential' | 'hinge' | 'logit' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  `'mincost'` is appropriate for classification scores that are posterior probabilities. Classification trees return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

  Suppose that `n` be the number of observations in `X` and `K` be the number of distinct classes (`numel(tree.ClassNames)`). Your function must have this signature

  `lossvalue = lossfun(C,S,W,Cost)`

  where:

  - The output argument `lossvalue` is a scalar.
  - You choose the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `tree.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `tree.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to `1`.
  - `Cost` is a *K*-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification, and `1` for misclassification.

  Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see “Classification Loss” on page 33-3715.

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | name of a variable in `TBL` | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or the name of a variable in `TBL`.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or `TBL`.

If you specify `Weights` as the name of a variable in `TBL`, you must do so as a character vector or string scalar. For example, if the weights are stored as `TBL.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `TBL`, including `TBL.W`, as predictors.

`loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `Weights`, `loss` computes weighted classification loss.

Data Types: `single` | `double` | `char` | `string`

`Name,Value` arguments associated with pruning subtrees:

`Subtrees` — Pruning level
0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `loss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`loss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single` | `double` | `char` | `string`

`TreeSize` — Tree size
`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following values:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

`L` — Classification loss
vector of scalar values

Classification loss on page 33-3715, returned as a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

se — Standard error of loss
vector of scalar values

Standard error of loss, returned as a vector the length of `Subtrees`.

NLeaf — Number of leaf nodes
vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of `Subtrees`.

bestlevel — Best pruning level
scalar value

Best pruning level as defined in the `TreeSize` name-value pair, returned as a scalar whose value depends on `TreeSize`:

- `TreeSize` = `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize` = `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

Examples

Compute the In-sample Classification Error

Compute the resubstituted classification error for the `ionosphere` data set.

```
load ionosphere
tree = fitctree(X,Y);
L = loss(tree,X,Y)
```

```
L = 0.0114
```

Examine the Classification Error for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

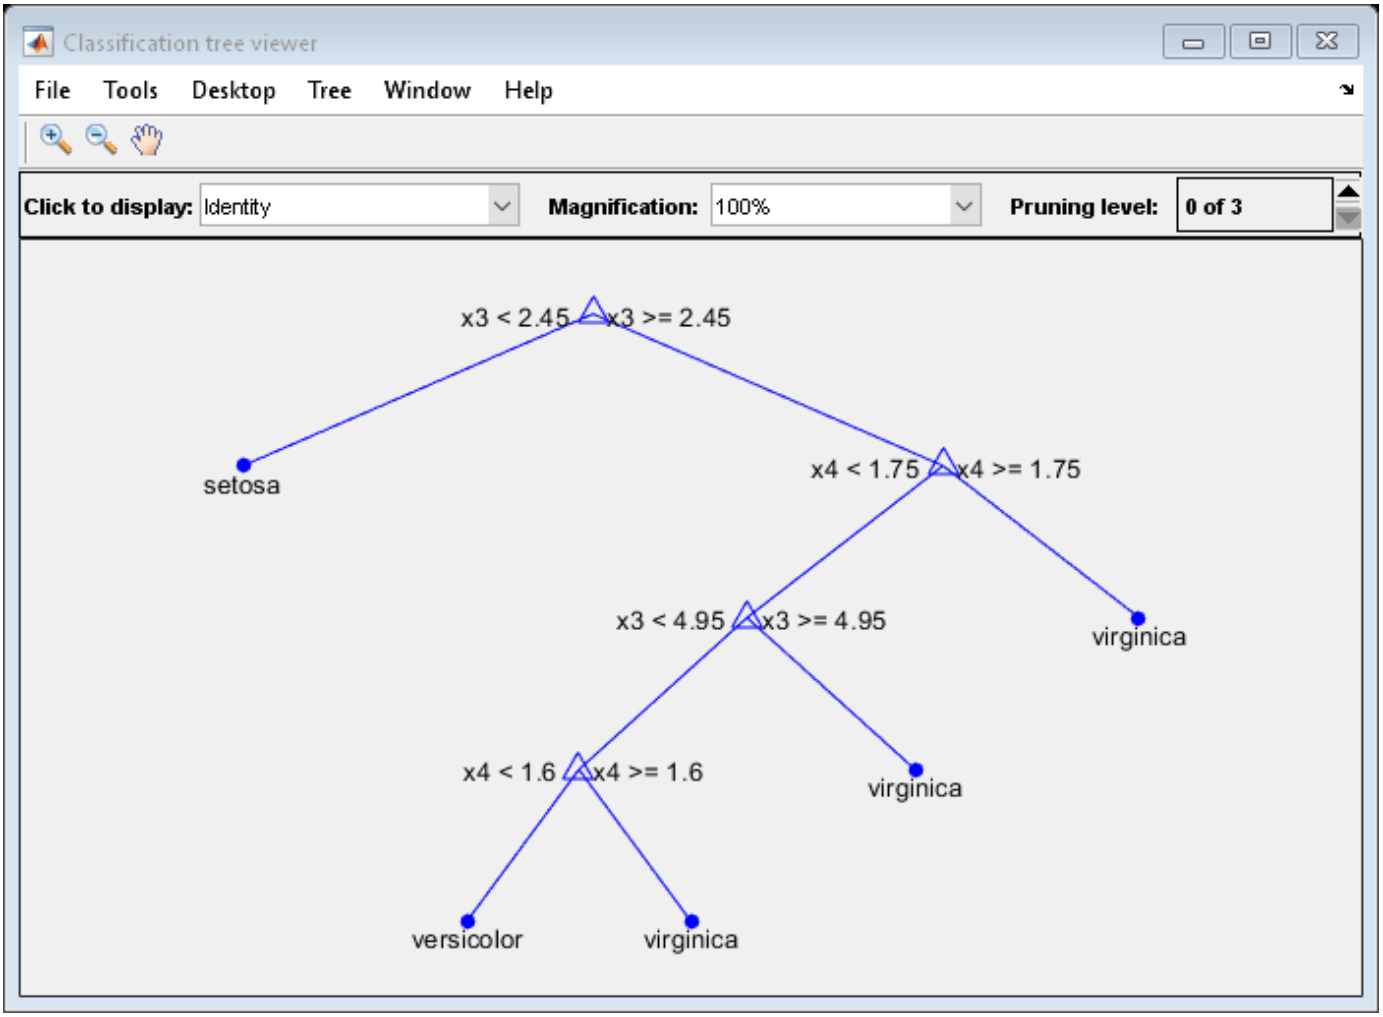
```
load fisheriris
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

View the classification tree.

```
view(Mdl,'Mode','graph');
```



The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
```

```
trnLoss = 3×1

    0.0267
    0.0533
```

```
    0.3067
```

- The full, unpruned tree misclassifies about 2.7% of the training observations.
- The tree pruned to level 1 misclassifies about 5.3% of the training observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

```
valLoss = loss(Mdl,meas(idxVal,:),species(idxVal),'SubTrees',0:m)
```

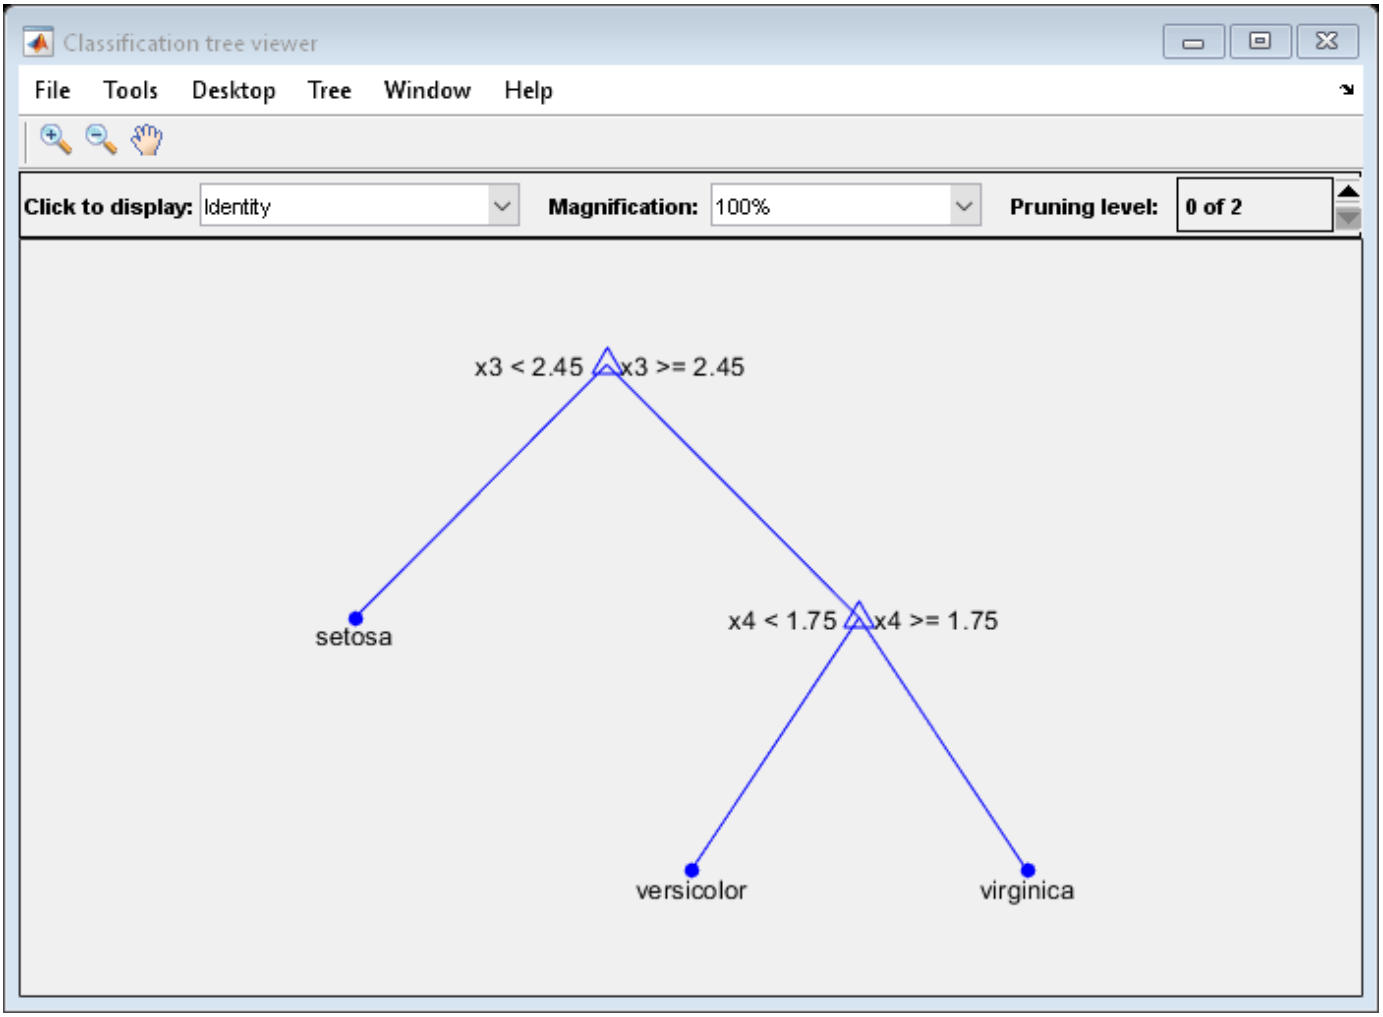
```
valLoss = 3×1

    0.0369
    0.0237
    0.3067
```

- The full, unpruned tree misclassifies about 3.7% of the validation observations.
- The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 1.

```
pruneMdl = prune(Mdl,'Level',1);
view(pruneMdl,'Mode','graph')
```



More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the

average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.

- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

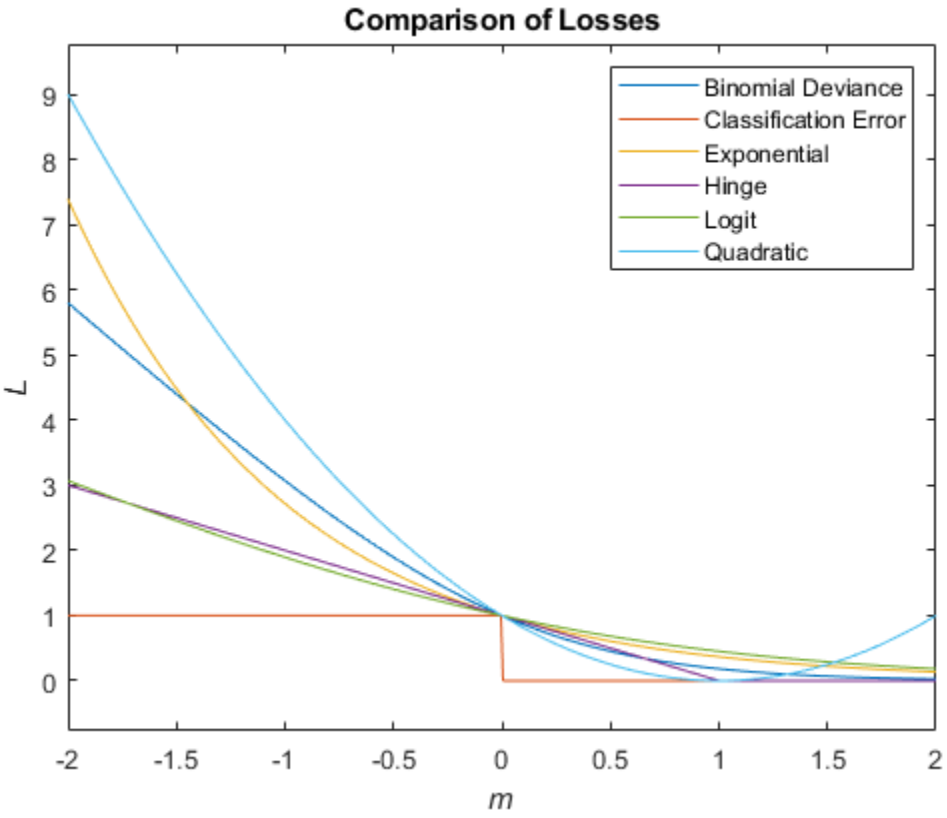
$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\hat{y}_j \neq y_j\right\}.$ $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn},$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp\left(-m_j\right).$

Loss Function	Value of LossFun	Equation
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = (f(X_j)'C)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\hat{y}_j = \underset{k=1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j (1 - m_j)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



True Misclassification Cost

The true misclassification cost is the cost of classifying an observation into an incorrect class.

You can set the true misclassification cost per class by using the `'Cost'` name-value argument when you create the classifier. `Cost(i,j)` is the cost of classifying an observation into class `j` when its true class is `i`. By default, `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is `0` for correct classification and `1` for incorrect classification.

Expected Misclassification Cost

The expected misclassification cost per observation is an averaged cost of classifying the observation into each class.

Suppose you have `Nobs` observations that you want to classify with a trained classifier, and you have `K` classes. You place the observations into a matrix `X` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n,k)` is

$$\sum_{i=1}^{K} \widehat{P}(i|X(n))C(k|i),$$

where:

- K is the number of classes.
- $\widehat{P}(i|X(n))$ is the posterior probability of class i for observation $X(n)$.
- $C(k|i)$ is the true misclassification cost of classifying an observation as k when its true class is i.

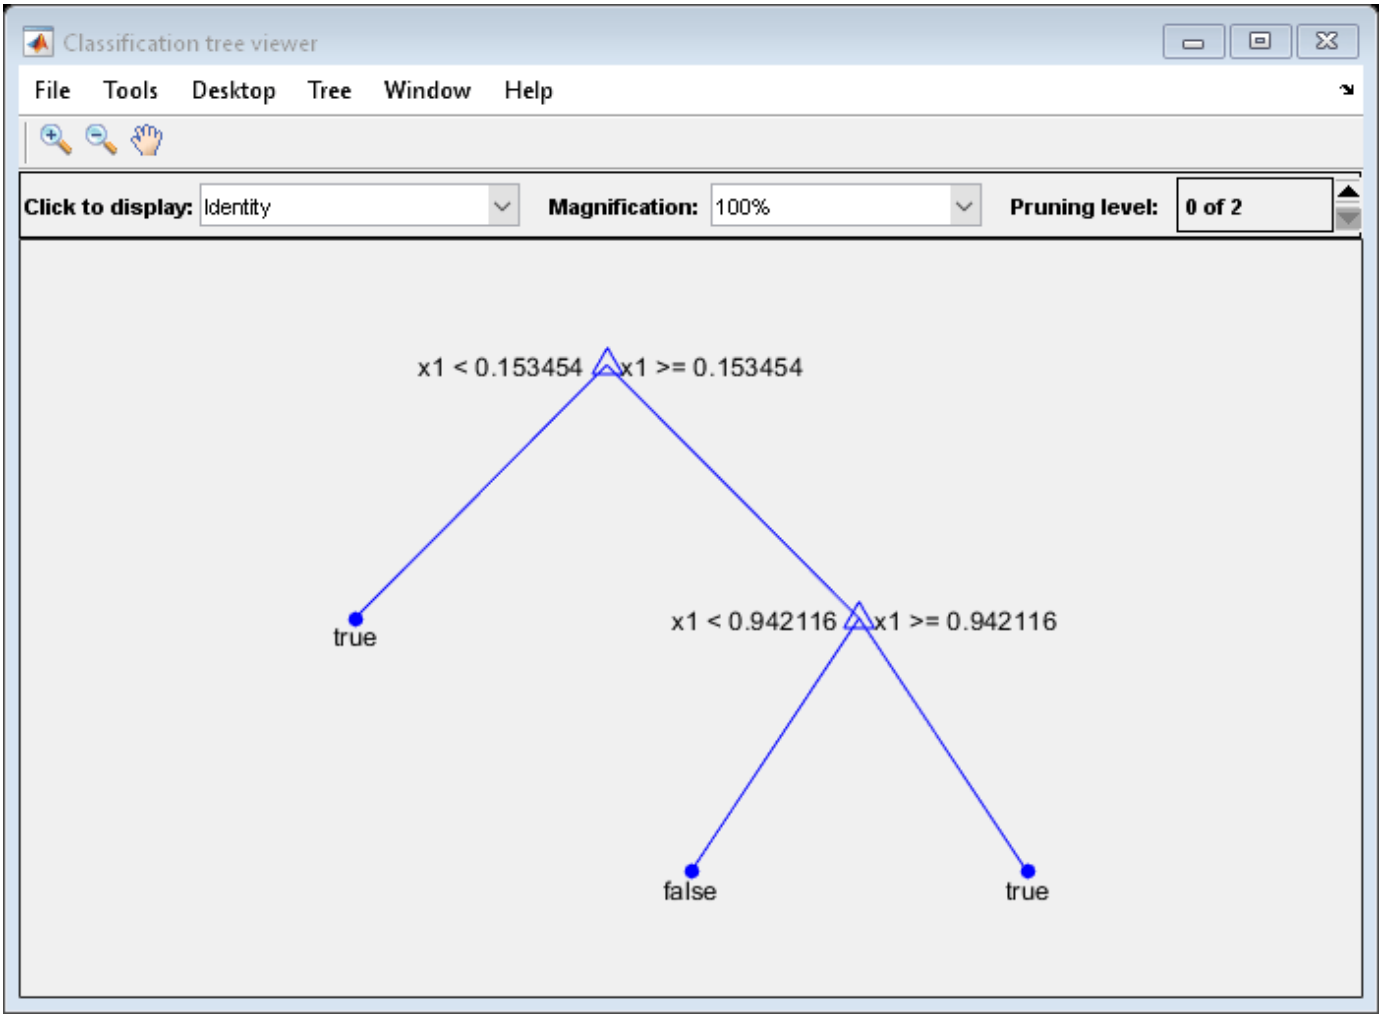
Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

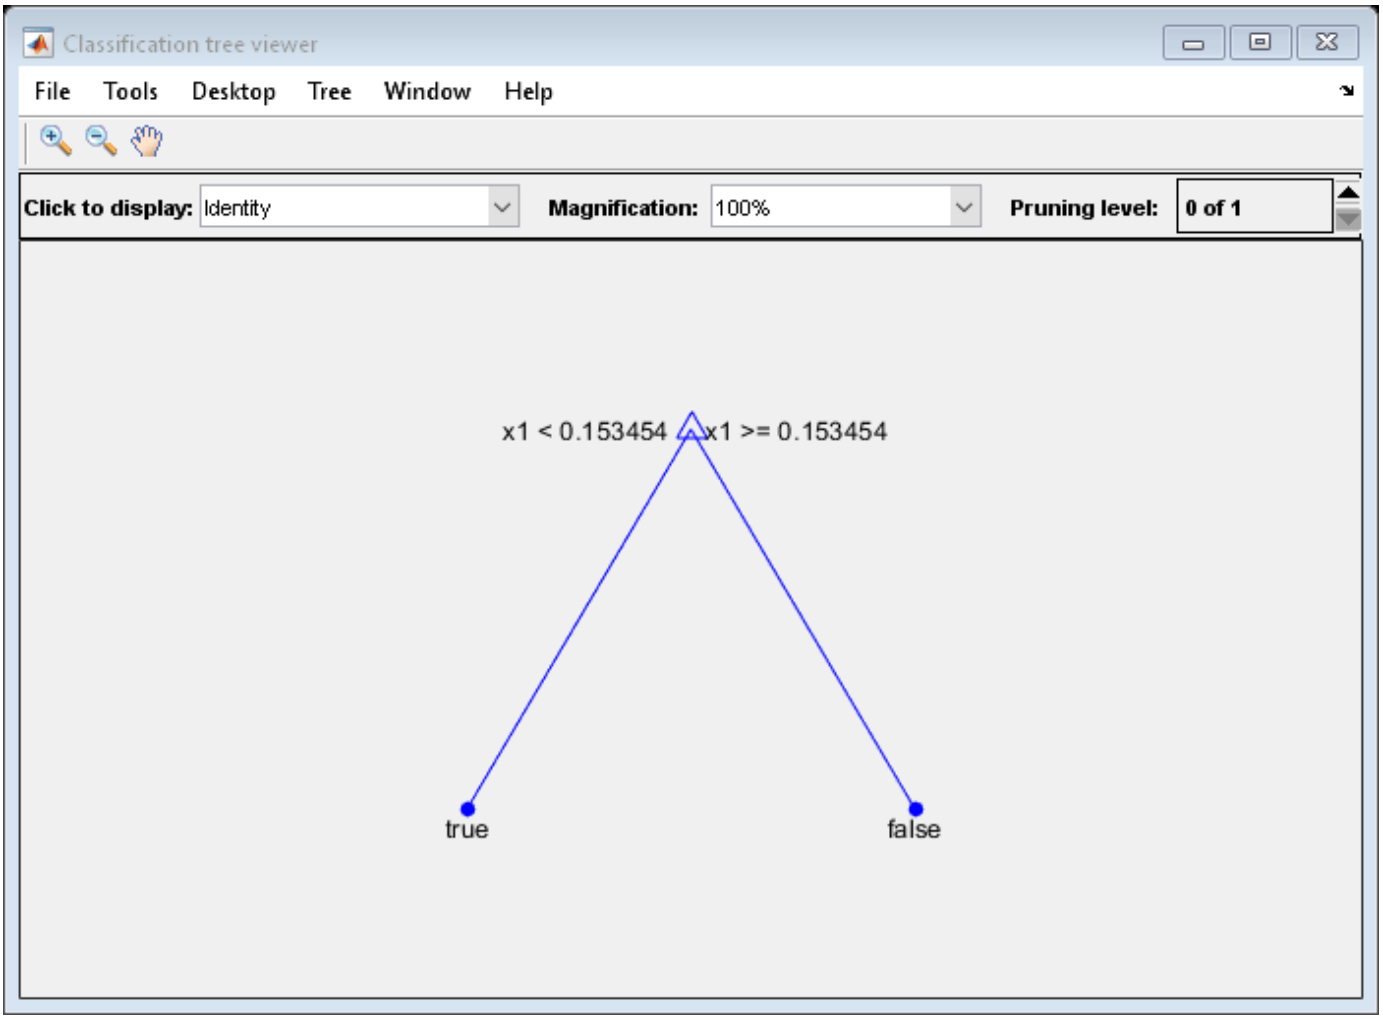
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10×3

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
```

```
     0    1.0000    0.0975
0.9059    0.0941    0.2785
0.9059    0.0941    0.5469
0.9059    0.0941    0.9575
0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Only one output is supported.
- You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays”.

loss

Regression error

Syntax

```
L = loss(ens,tbl,ResponseVarName)
L = loss(ens,tbl,Y)
L = loss(ens,X,Y)
L = loss( ___ ,Name,Value)
```

Description

`L = loss(ens,tbl,ResponseVarName)` returns the mean squared error between the predictions of `ens` to the data in `tbl`, compared to the true responses `tbl.ResponseVarName`.

`L = loss(ens,tbl,Y)` returns the mean squared error between the predictions of `ens` to the data in `tbl`, compared to the true responses `Y`.

`L = loss(ens,X,Y)` returns the mean squared error between the predictions of `ens` to the data in `X`, compared to the true responses `Y`.

`L = loss( ___ ,Name,Value)` computes the error in prediction with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`, or the `compact` method.

`tbl`

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all of the predictors used to train the model. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `ens` using sample data contained in a `table`, then the input data for this method must also be in a table.

`ResponseVarName`

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

`X`

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

`NaN` values in `X` are taken to be missing values. Observations with all missing values for `X` are not used in the calculation of loss.

If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Y`

A numeric column vector with the same number of rows as `tbl` or `X`. Each entry in `Y` is the response to the data in the corresponding row of `tbl` or `X`.

`NaN` values in `Y` are taken to be missing values. Observations with missing values for `Y` are not used in the calculation of loss.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from `1` to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

`lossfun`

Function handle for loss function, or `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: `'mse'`

`mode`

Meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.

- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

`UseObsForLearner`

A logical matrix of size `N`-by-`NumTrained`, where `N` is the number of observations in `ens.X`, and `NumTrained` is the number of weak learners. When `UseObsForLearner(I,J)` is `true`, `predict` uses learner `J` in predicting observation `I`.

Default: `true(N,NumTrained)`

`weights`

Numeric vector of observation weights with the same number of elements as `Y`. The formula for `loss` with `weights` is in “Weighted Mean Squared Error” on page 33-3724.

Default: `ones(size(Y))`

Output Arguments

`L`

Weighted mean squared error of predictions. The formula for `loss` is in “Weighted Mean Squared Error” on page 33-3724.

Examples

Find Mean-Squared Error of Ensemble Predictions

Find the loss of an ensemble predictor using the `carsmall` data set.

Load the `carsmall` data set and select engine displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of regression trees and find the regression error for predicting `MPG`.

```
ens = fitrensemble(X,MPG);
L = loss(ens,X,MPG)
```

```
L = 0.3463
```

More About

Weighted Mean Squared Error

Let n be the number of rows of data, x_j be the jth row of data, y_j be the true response to x_j, and let $f(x_j)$ be the response prediction of `ens` to x_j. Let w be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one: $w \to w/\Sigma w$. The mean squared error L is

$$L = \sum_{j=1}^{n} w_j \left(f\left(x_j\right) - y_j \right)^2 .$$

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

`fitrensemble` | `predict`

loss

Regression error for Gaussian process regression model

Syntax

```
L = loss(gprMdl,Xnew,Ynew)
L = loss(gprMdl,Xnew,Ynew,Name,Value)
```

Description

`L = loss(gprMdl,Xnew,Ynew)` returns the mean squared error for the Gaussian process regression (GPR) model `gpr`, using the predictors in `Xnew` and observed response in `Ynew`.

`L = loss(gprMdl,Xnew,Ynew,Name,Value)` returns the mean squared error for the GPR model, `gpr`, with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify a custom loss function or the observation weights.

Input Arguments

`gprMdl` — Gaussian process regression model

`RegressionGP` object | `CompactRegressionGP` object

Gaussian process regression model, specified as a `RegressionGP` (full) or `CompactRegressionGP` (compact) object.

`Xnew` — New observed data

`table` | *m*-by-*d* matrix

New data, specified as a `table` or an *n*-by-*d* matrix, where *m* is the number of observations, and *d* is the number of predictor variables in the training data.

If you trained `gprMdl` on a `table`, then `Xnew` must be a `table` that contains all the predictor variables used to train `gprMdl`.

If `Xnew` is a table, then it can also contain `Ynew`. And if it does, then you do not have to specify `Ynew`.

If you trained `gprMdl` on a matrix, then `Xnew` must be a numeric matrix with *d* columns, and can only contain values for the predictor variables.

Data Types: `single` | `double` | `table`

`Ynew` — New response values

n-by-1 vector

New observed response values, that correspond to the predictor values in `Xnew`, specified as an *n*-by-1 vector. *n* is the number of rows in `Xnew`. Each entry in `Ynew` is the observed response based on the predictor data in the corresponding row of `Xnew`.

If `Xnew` is a table containing new response values, you do not have to specify `Ynew`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`lossfun` — Loss function
`'mse'` (default) | function handle

Loss function, specified as `'mse'` (mean squared error) or a function handle.

If you pass a function handle, say `fun`, `loss` calls it as shown below: `fun(Y,Ypred,W)`, where `Y`, `Ypred` and `W` are numeric vectors of length *n*, and *n* is the number of rows in `Xnew`. `Y` is the observed response, `Ypred` is the predicted response, and `W` is the observation weights.

Example: `'lossfun',Fct` calls the loss function `Fct`.

Data Types: `char` | `string` | `function_handle`

`weights` — Observation weights
vector of 1s (default) | *n*-by-1 vector

Observation weights, specified as *n*-by-1 vector, where *n* is the number of rows in `Xnew`. By default, the weight of each observation is 1.

Example: `'weights',W` uses the observation weights in vector `W`.

Data Types: `double` | `single`

Output Arguments

`L` — Regression error
scalar value

Regression error for the trained Gaussian process regression model, `gprMdl`, returned as a scalar value.

Examples

Compute Regression Loss for Test Data

Load the sample data.

```
load('gprdata.mat')
```

The data has 8 predictor variables and contains 500 observations in training data and 100 observations in test data. This is simulated data.

Fit a GPR model using the squared exponential kernel function with separate length scales for each predictor. Standardize the predictor values in the training data. Use the exact method for fitting and prediction.

```
gprMdl = fitrgp(Xtrain,ytrain,'FitMethod','exact',...
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
'Standardize',1);
```

Compute the regression error for the test data.

```
L = loss(gprMdl,Xtest,ytest)
```

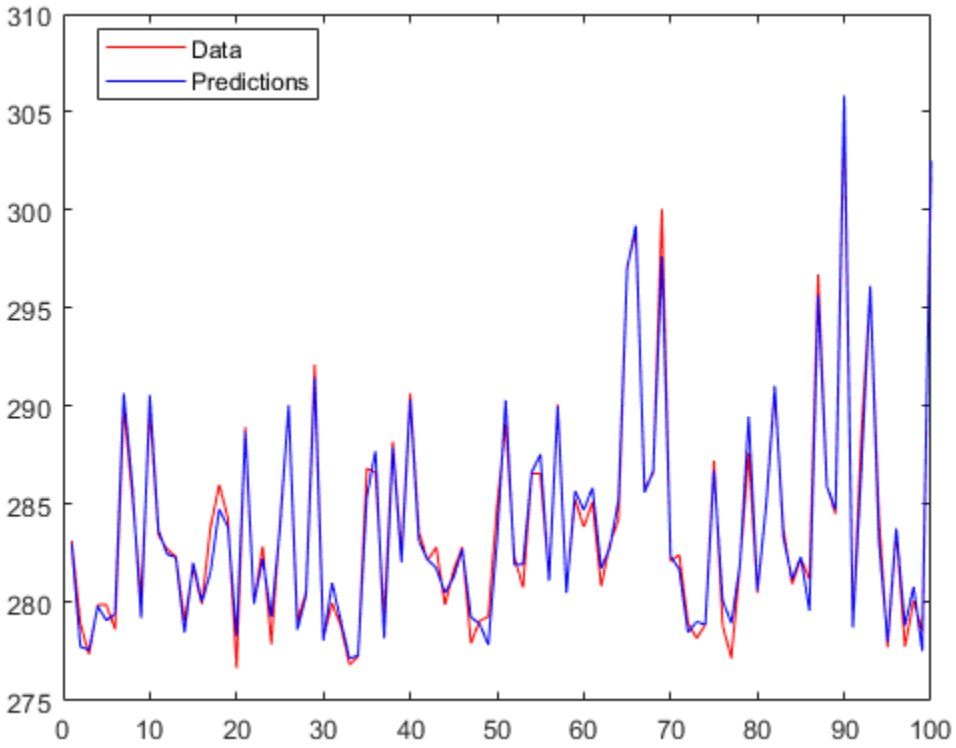
```
L = 0.6928
```

Predict the responses for test data.

```
ypredtest = predict(gprMdl,Xtest);
```

Plot the test response along with the predictions.

```
figure;
plot(ytest,'r');
hold on;
plot(ypredtest,'b');
legend('Data','Predictions','Location','Best');
```



Manually compute the regression loss.

```
L = (ytest - ypredtest)'*(ytest - ypredtest)/length(ytest)
```

```
L = 0.6928
```

Specify Custom Loss Function

Load the sample data and store in a `table`.

```
load fisheriris
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...
'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```
mdl = fitrgp(tbl,'meas1');
```

Predict the responses using the trained model.

```
ypred = predict(mdl,tbl);
```

Compute the mean absolute error.

```
n = height(tbl);
y = tbl.meas1;
fun = @(y,ypred,w) sum(abs(y-ypred))/n;
L = loss(mdl,tbl,'lossfun',fun)
```

```
L = 0.2345
```

Alternatives

You can use `resubLoss` to compute the regression error for the trained GPR model at the observations in the training data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

`CompactRegressionGP` | `RegressionGP` | `compact` | `fitrgp` | `predict` | `resubLoss`

Introduced in R2015b

loss

Package:

Loss for regression neural network

Syntax

```
L = loss(Mdl,Tbl,ResponseVarName)
L = loss(Mdl,Tbl,Y)

L = loss(Mdl,X,Y)

L = loss( ___ ,Name,Value)
```

Description

`L = loss(Mdl,Tbl,ResponseVarName)` returns the regression loss for the trained regression neural network `Mdl` using the predictor data in table `Tbl` and the response values in the `ResponseVarName` table variable.

`L` is returned as a scalar value that represents the mean squared error (MSE) by default.

`L = loss(Mdl,Tbl,Y)` returns the regression loss for the model `Mdl` using the predictor data in table `Tbl` and the response values in vector `Y`.

`L = loss(Mdl,X,Y)` returns the regression loss for the trained regression neural network `Mdl` using the predictor data `X` and the corresponding response values in `Y`.

`L = loss( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify that columns in the predictor data correspond to observations, specify the loss function, or supply observation weights.

Examples

Test Set Mean Squared Error of Neural Network

Calculate the test set mean squared error (MSE) of a regression neural network model.

Load the `patients` data set. Create a table from the data set. Each row corresponds to one patient, and each column corresponds to a diagnostic variable. Use the `Systolic` variable as the response variable, and the rest of the variables as predictors.

```
load patients
tbl = table(Age,Diastolic,Gender,Height,Smoker,Weight,Systolic);
```

Separate the data into a training set `tblTrain` and a test set `tblTest` by using a nonstratified holdout partition. The software reserves approximately 30% of the observations for the test data set and uses the rest of the observations for the training data set.

```
rng("default") % For reproducibility of the partition
c = cvpartition(size(tbl,1),"Holdout",0.30);
trainingIndices = training(c);
testIndices = test(c);
tblTrain = tbl(trainingIndices,:);
tblTest = tbl(testIndices,:);
```

Train a regression neural network model using the training set. Specify the `Systolic` column of `tblTrain` as the response variable. Specify to standardize the numeric predictors.

```
Mdl = fitrnet(tblTrain,"Systolic", ...
    "Standardize",true);
```

Calculate the test set MSE. Smaller MSE values indicate better performance.

```
testMSE = loss(Mdl,tblTest,"Systolic")
```

```
testMSE = 49.9595
```

Select Features to Include in Regression Neural Network

Perform feature selection by comparing test set losses and predictions. Compare the test set metrics for a regression neural network model trained using all the predictors to the test set metrics for a model trained using only a subset of the predictors.

Load the sample file `fisheriris.csv`, which contains iris data including sepal length, sepal width, petal length, petal width, and species type. Read the file into a table.

```
fishertable = readtable('fisheriris.csv');
```

Separate the data into a training set `trainTbl` and a test set `testTbl` by using a nonstratified holdout partition. The software reserves approximately 30% of the observations for the test data set and uses the rest of the observations for the training data set.

```
rng("default")
c = cvpartition(size(fishertable,1),"Holdout",0.3);
trainTbl = fishertable(training(c),:);
testTbl = fishertable(test(c),:);
```

Train one regression neural network model using all the predictors in the training set, and train another classifier using all the predictors except `PetalWidth`. For both models, specify `PetalLength` as the response variable, and standardize the predictors.

```
allMdl = fitrnet(trainTbl,"PetalLength","Standardize",true);
subsetMdl = fitrnet(trainTbl,"PetalLength ~ SepalLength + SepalWidth + Species", ...
    "Standardize",true);
```

Compare the test set mean squared error (MSE) of the two models. Smaller MSE values indicate better performance.

```
allMSE = loss(allMdl,testTbl)
```

```
allMSE = 0.0834
```

```
subsetMSE = loss(subsetMdl,testTbl)
```

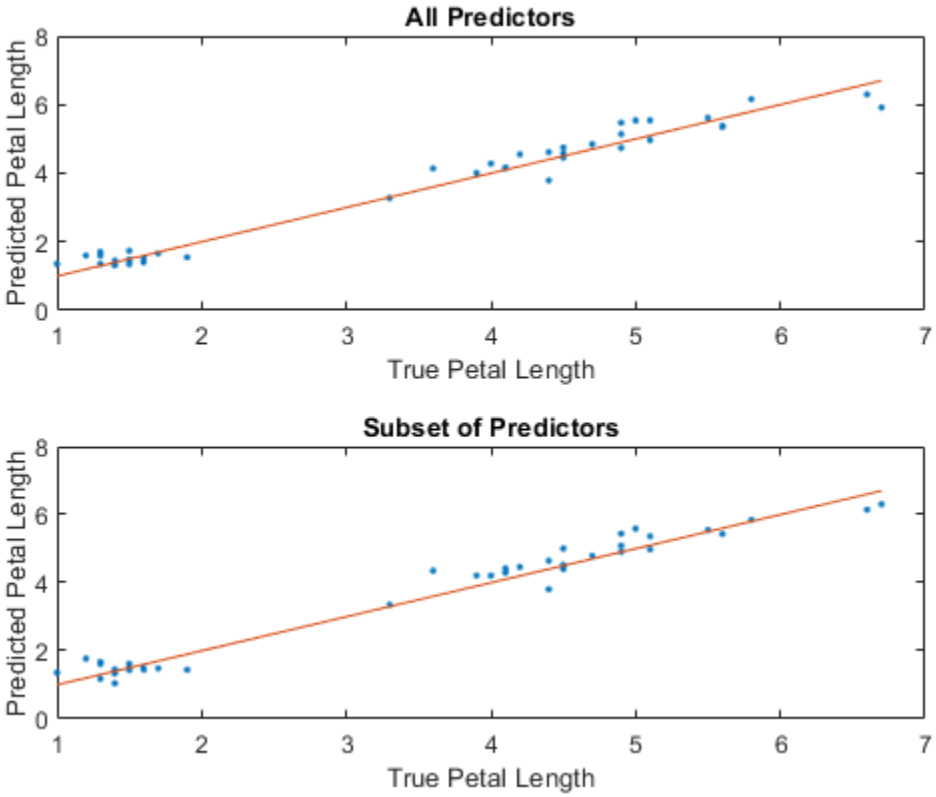
```
subsetMSE = 0.0887
```

For each model, compare the test set predicted petal lengths to the true petal lengths. Plot the predicted petal lengths along the vertical axis and the true petal lengths along the horizontal axis. Points on the reference line indicate correct predictions.

```
tiledlayout(2,1)

% Top axes
ax1 = nexttile;
allPredictedY = predict(allMdl,testTbl);
plot(ax1,testTbl.PetalLength,allPredictedY,".")
hold on
plot(ax1,testTbl.PetalLength,testTbl.PetalLength)
hold off
xlabel(ax1,"True Petal Length")
ylabel(ax1,"Predicted Petal Length")
title(ax1,"All Predictors")

% Bottom axes
ax2 = nexttile;
subsetPredictedY = predict(subsetMdl,testTbl);
plot(ax2,testTbl.PetalLength,subsetPredictedY,".")
hold on
plot(ax2,testTbl.PetalLength,testTbl.PetalLength)
hold off
xlabel(ax2,"True Petal Length")
ylabel(ax2,"Predicted Petal Length")
title(ax2,"Subset of Predictors")
```



Because both models seems to perform well, with predictions scattered near the reference line, consider using the model trained using all predictors except `PetalWidth`.

Input Arguments

`Mdl` — Trained regression neural network

`RegressionNeuralNetwork` model object | `CompactRegressionNeuralNetwork` model object

Trained regression neural network, specified as a `RegressionNeuralNetwork` model object or `CompactRegressionNeuralNetwork` model object returned by `fitrnet` or `compact`, respectively.

`Tbl` — Sample data

table

Sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain an additional column for the response variable. `Tbl` must contain all of the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName` or `Y`.
- If you trained `Mdl` using sample data contained in a table, then the input data for `loss` must also be in a table.

- If you set `'Standardize',true` in `fitrnet` when training `Mdl`, then the software standardizes the numeric columns of the predictor data using the corresponding means and standard deviations.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

If you specify `ResponseVarName`, then you must specify it as a character vector or string scalar. For example, if the response variable is stored as `Tbl.Y`, then specify `ResponseVarName` as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Tbl.Y`, as predictors.

Data Types: `char` | `string`

`Y` — Response data
numeric vector

Response data, specified as a numeric vector. The length of `Y` must be equal to the number of observations in `X` or `Tbl`.

Data Types: `single` | `double`

`X` — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. By default, `loss` assumes that each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time.

The length of `Y` and the number of observations in `X` must be equal.

If you set `'Standardize',true` in `fitrnet` when training `Mdl`, then the software standardizes the numeric columns of the predictor data using the corresponding means and standard deviations.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `loss(Mdl,Tbl,"Response","Weights","W")` specifies to use the `Response` and `W` variables in the table `Tbl` as the response values and observation weights, respectively.

`LossFun` — Loss function
`'mse'` (default) | function handle

Loss function, specified as `'mse'` or a function handle.

- `'mse'` — Weighted mean squared error.
- Function handle — To specify a custom loss function, use a function handle. The function must have this form:

  ```
  lossval = lossfun(Y,YFit,W)
  ```

  - The output argument `lossval` is a floating-point scalar.
  - You specify the function name (*`lossfun`*).
  - `Y` is a length *n* numeric vector of observed responses, where *n* is the number of observations in `Tbl` or `X`.
  - `YFit` is a length *n* numeric vector of corresponding predicted responses.
  - `W` is an *n*-by-1 numeric vector of observation weights.

Example: `'LossFun',@lossfun`

Data Types: `char` | `string` | `function_handle`

`ObservationsIn` — Predictor data observation dimension

`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as `'rows'` or `'columns'`.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time. You cannot specify `'ObservationsIn','columns'` for predictor data in a table.

Data Types: `char` | `string`

`Weights` — Observation weights

nonnegative numeric vector | name of variable in `Tbl`

Observation weights, specified as a nonnegative numeric vector or the name of a variable in `Tbl`. The software weights each observation in `X` or `Tbl` with the corresponding value in `Weights`. The length of `Weights` must equal the number of observations in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

If you supply weights, then `loss` computes the weighted regression loss and normalizes weights to sum to 1.

Data Types: `single` | `double` | `char` | `string`

“Assess Regression Neural Network Performance” on page 18-184

Introduced in R2021a

loss

Regression error for support vector machine regression model

Syntax

```
L = loss(mdl,tbl,ResponseVarName)
L = loss(mdl,tbl,Y)
L = loss(mdl,X,Y)
L = loss(___,Name,Value)
```

Description

`L = loss(mdl,tbl,ResponseVarName)` returns the loss for the predictions of the support vector machine (SVM) regression model, `mdl`, based on the predictor data in the table `tbl` and the true response values in `tbl.ResponseVarName`.

`L = loss(mdl,tbl,Y)` returns the loss for the predictions of the support vector machine (SVM) regression model, `mdl`, based on the predictor data in the table `X` and the true response values in the vector `Y`.

`L = loss(mdl,X,Y)` returns the loss for the predictions of the support vector machine (SVM) regression model, `mdl`, based on the predictor data in `X` and the true responses in `Y`.

`L = loss(___,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

Input Arguments

`mdl` — SVM regression model

`RegressionSVM` model | `CompactRegressionSVM` model

SVM regression model, specified as a `RegressionSVM` model or `CompactRegressionSVM` model returned by `fitrsvm` or `compact`, respectively.

`tbl` — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all of the predictors used to train `mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

`ResponseVarName` — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `tbl.Y`, then specify `ResponseVarName` as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix or table. Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

If you trained `mdl` using a matrix of predictor values, then `X` must be a numeric matrix with p columns. p is the number of predictors used to train `mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `single` | `double`

Y — Observed response values
vector of numeric values

Observed response values, specified as a vector of length n containing numeric values. Each entry in `Y` is the observed response based on the predictor data in the corresponding row of `X`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`LossFun` — Loss function
`'mse'` (default) | `'epsiloninsensitive'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'mse'`, `'epsiloninsensitive'`, or a function handle.

- The following table lists the available loss functions.

Value	Loss Function
`'mse'`	“Weighted Mean Squared Error” on page 33-3740
`'epsiloninsensitive'`	“Epsilon-Insensitive Loss Function” on page 33-3740

- Specify your own function using function handle notation.

  Your function must have the signature `lossvalue = lossfun(Y,Yfit,W)`, where:

- The output argument `lossvalue` is a scalar value.
- You choose the function name (*lossfun*).
- `Y` is an *n*-by-1 numeric vector of observed response values.
- `Yfit` is an *n*-by-1 numeric vector of predicted response values, calculated using the corresponding predictor values in `X` (similar to the output of `predict`).
- `W` is an *n*-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.

Specify your function using `'LossFun',@`*`lossfun`*.

Example: `'LossFun','epsiloninsensitive'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector. `Weights` must be the same length as the number of rows in `X`. The software weighs the observations in each row of `X` using the corresponding weight value in `Weights`.

Weights are normalized to sum to 1.

Data Types: `single` | `double`

Output Arguments

`L` — Regression loss
scalar value

Regression loss, returned as a scalar value.

Examples

Calculate Test Sample Loss for SVM Regression Model

This example shows how to train an SVM regression model, then calculate the resubstitution mean square error and epsilon-insensitive error.

Load the `carsmall` sample data.

```
load carsmall
rng default  % for reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (`X`), and `MPG` as the response variable (`Y`).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model. Standardize the data.

```
mdl = fitrsvm(X,Y,'Standardize',true);
```

`mdl` is a `RegressionSVM` model.

Determine how well the trained model generalizes to new predictor values by estimating the test sample mean square error and epsilon-insensitive error.

```
lossMSE = loss(mdl,X,Y)
lossEI = loss(mdl,X,Y,'LossFun','epsiloninsensitive')
```

```
lossMSE =

   17.0256

lossEI =

    2.2506
```

More About

Weighted Mean Squared Error

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^{n} w_j \left(f\left(x_j\right) - y_j\right)^2}{\sum_{j=1}^{n} w_j},$$

where:

- n is the number of rows of data
- x_j is the jth row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model `mdl` to x_j
- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the `'Weights'` name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Epsilon-Insensitive Loss Function

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (ε) of the function value. It is formally described as:

$$Loss_{\varepsilon} = \begin{cases} 0\,,\ if\ |y - f(x)| \le \varepsilon \\ |y - f(x)| - \varepsilon\,,\ otherwise\,. \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^{n} w_j \max\left(0, \left|y_j - f\left(x_j\right)\right| - \varepsilon\right)}{\sum_{j=1}^{n} w_j},$$

where:

- n is the number of rows of data
- x_j is the jth row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model `mdl` to x_j
- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the `'Weights'` name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Tips

- If `mdl` is a cross-validated `RegressionPartitionedSVM` model, use `kfoldLoss` instead of `loss` to calculate the regression error.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

Introduced in R2015b

loss

Regression error

Syntax

```
L = loss(tree,tbl,ResponseVarName)
L = loss(tree,x,y)
L = loss( ___ ,Name,Value)
[L,se,NLeaf,bestlevel] = loss( ___ )
```

Description

`L = loss(tree,tbl,ResponseVarName)` returns the mean squared error between the predictions of `tree` to the data in `tbl`, compared to the true responses `tbl.ResponseVarName`.

`L = loss(tree,x,y)` returns the mean squared error between the predictions of `tree` to the data in `x`, compared to the true responses `y`.

`L = loss( ___ ,Name,Value)` computes the error in prediction with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

`[L,se,NLeaf,bestlevel] = loss( ___ )` also returns the standard error of the loss (`se`), the number of leaves (terminal nodes) in the tree (`NLeaf`), and the optimal pruning level for `tree` (`bestlevel`).

Input Arguments

`tree` — Trained regression tree
`RegressionTree` object | `CompactRegressionTree` object

Trained regression tree, specified as a `RegressionTree` object constructed by `fitrtree` or a `CompactRegressionTree` object constructed by `compact`.

`x` — Predictor values
matrix of floating-point values

Predictor values, specified as matrix of floating-point values. Each column of `x` represents one variable, and each row represents one observation.

Data Types: `single` | `double`

`ResponseVarName` — Response variable name
name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify `ResponseVarName` as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

Data Types: `char` | `string`

y — Response data

numeric column vector

Response data, specified as a numeric column vector with the same number of rows as `x`. Each entry in `y` is the response to the data in the corresponding row of `x`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

LossFun — Loss function

`'mse'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle for loss, or `'mse'` representing mean-squared error. If you pass a function handle `fun`, `loss` calls `fun` as:

```
fun(Y,Yfit,W)
```

- `Y` is the vector of true responses.
- `Yfit` is the vector of predicted responses.
- `W` is the observation weights. If you pass `W`, the elements are normalized to sum to `1`.

All the vectors have the same number of rows as `Y`.

Example: `'LossFun','mse'`

Data Types: `function_handle` | `char` | `string`

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `loss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`loss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single` | `double` | `char` | `string`

`TreeSize` — Tree size
`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following:

- `'se'` — `loss` returns `bestlevel` that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.
- `'min'` — `loss` returns `bestlevel` that corresponds to the minimal MSE tree.

Example: `'TreeSize','min'`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | vector of scalar values | name of a variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The software weights the observations in each row of `X` or `tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `tbl`.

If you specify the input data as a table `tbl`, then `Weights` can be the name of a variable in `tbl` that contains a numeric vector. In this case, you must specify `Weights` as a variable name. For example, if weights vector `W` is stored as `tbl.W`, then specify `Weights` as `'W'`. Otherwise, the software treats all columns of `tbl`, including `W`, as predictors when training the model.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`L` — Classification error
vector of scalar values

Classification error, returned as a vector the length of `Subtrees`. The error for each tree is the mean squared error, weighted with `Weights`. If you include `LossFun`, `L` reflects the loss calculated with `LossFun`.

`se` — Standard error of loss
vector of scalar values

Standard error of loss, returned as a vector the length of `Subtrees`.

`NLeaf` — Number of leaf nodes
vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of `Subtrees`.

`bestlevel` — Best pruning level
scalar value

Best pruning level as defined in the `TreeSize` name-value pair, returned as a scalar whose value depends on `TreeSize`:

- `TreeSize` = `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize` = `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
tree = fitrtree(X,MPG);
```

Estimate the in-sample MSE.

```
L = loss(tree,X,MPG)
```

```
L = 4.8952
```

Find the Pruning Level Yielding the Optimal In-sample Loss

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

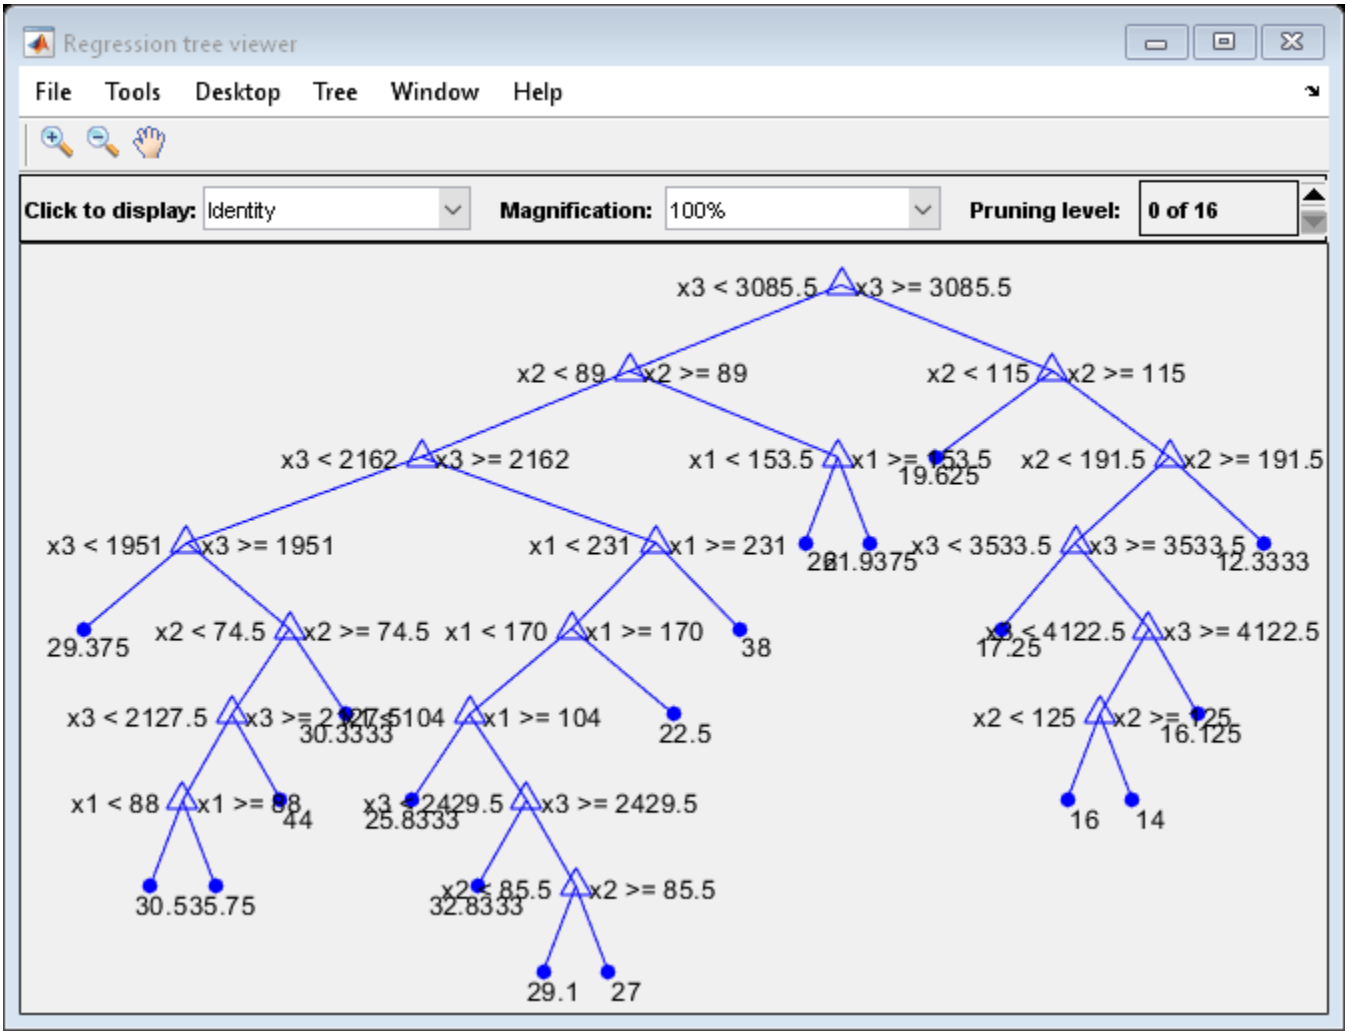
```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

View the regression tree.

```
view(Mdl,'Mode','graph');
```



Find the best pruning level that yields the optimal in-sample loss.

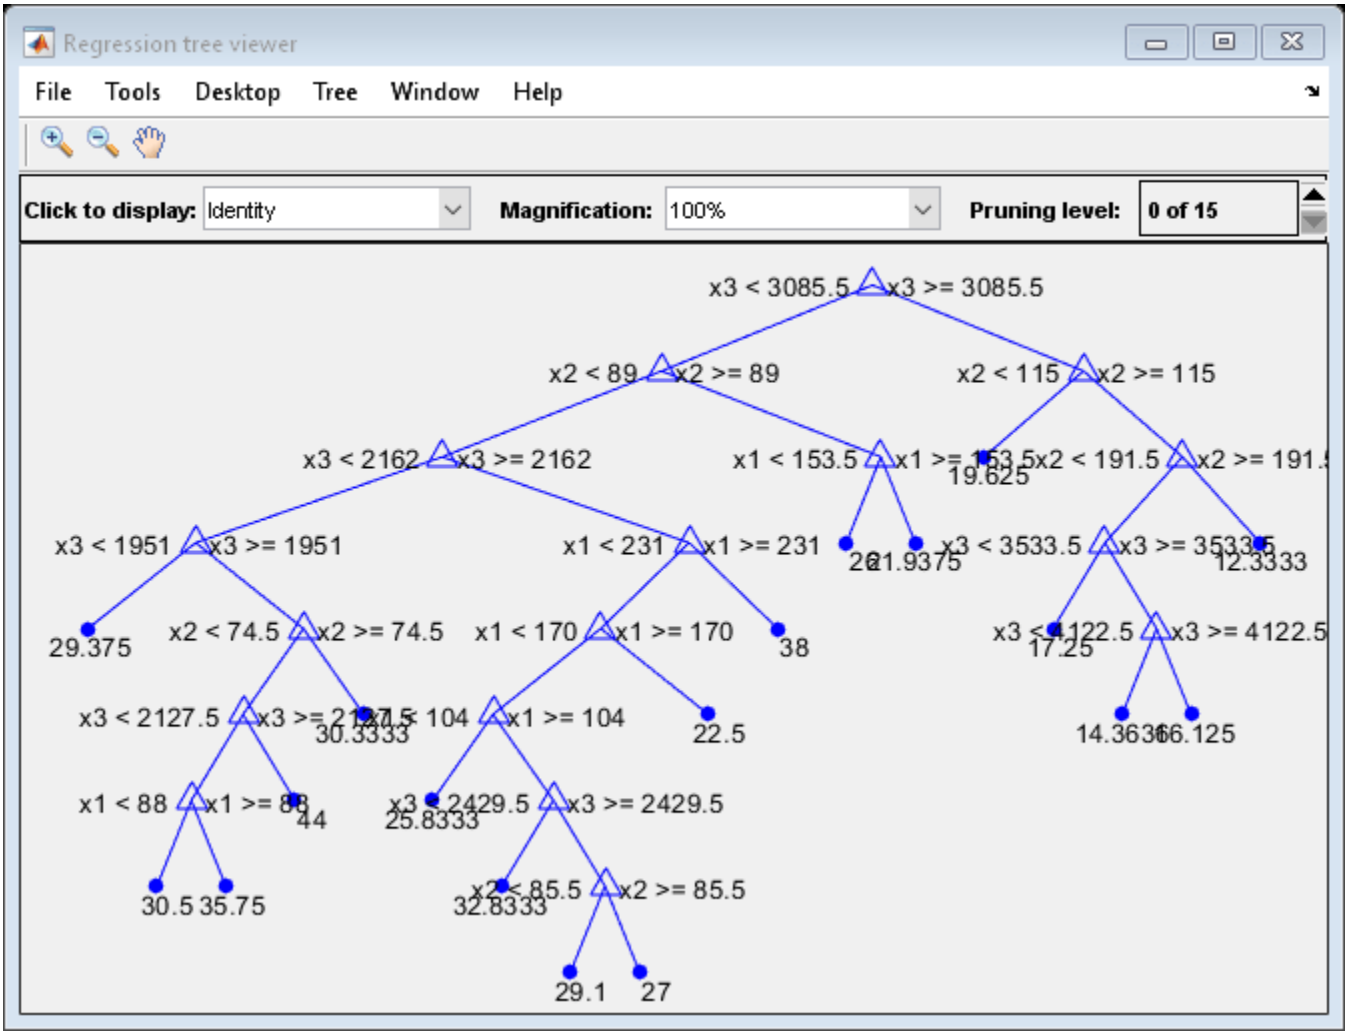
```
[L,se,NLeaf,bestLevel] = loss(Mdl,X,MPG,'Subtrees','all');
bestLevel
```

```
bestLevel = 1
```

The best pruning level is level 1.

Prune the tree to level 1.

```
pruneMdl = prune(Mdl,'Level',bestLevel);
view(pruneMdl,'Mode','graph');
```



Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
Y = MPG;
```

Partition the data into training (50%) and validation (50%) sets.

```
n = size(X,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
```

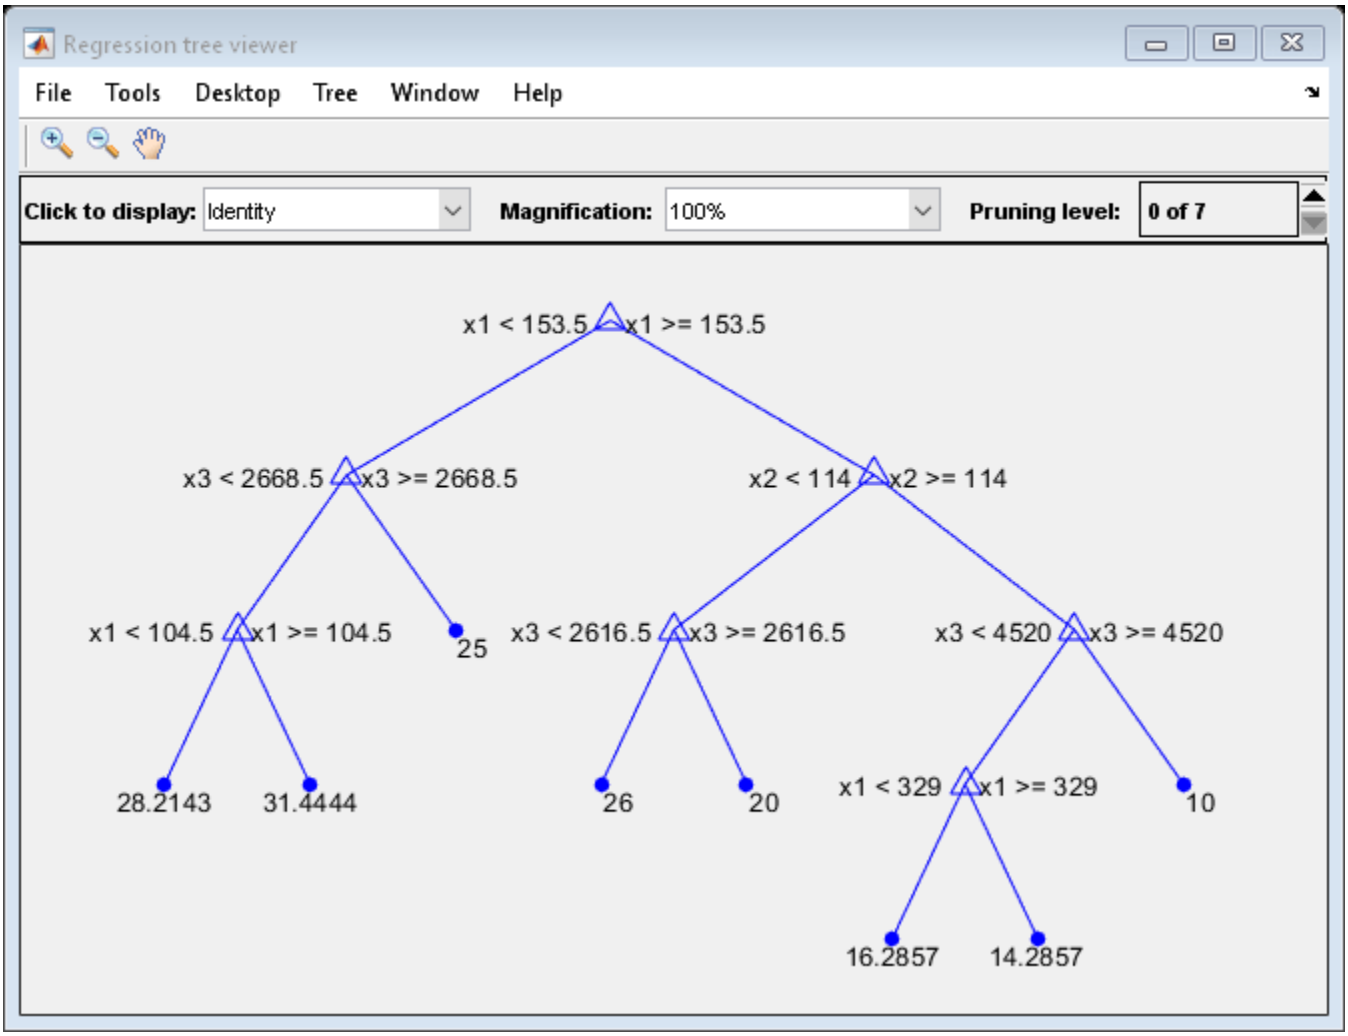
```
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a regression tree using the training set.

```
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));
```

View the regression tree.

```
view(Mdl,'Mode','graph');
```



The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
```

```
trnLoss = 7×1

    5.9789
```

```
    6.2768
    6.8316
    7.5209
    8.3951
   10.7452
   14.8445
```

- The MSE for the full, unpruned tree is about 6 units.
- The MSE for the tree pruned to level 1 is about 6.3 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

```
valLoss = loss(Mdl,X(idxVal,:),Y(idxVal),'SubTrees',0:m)
```

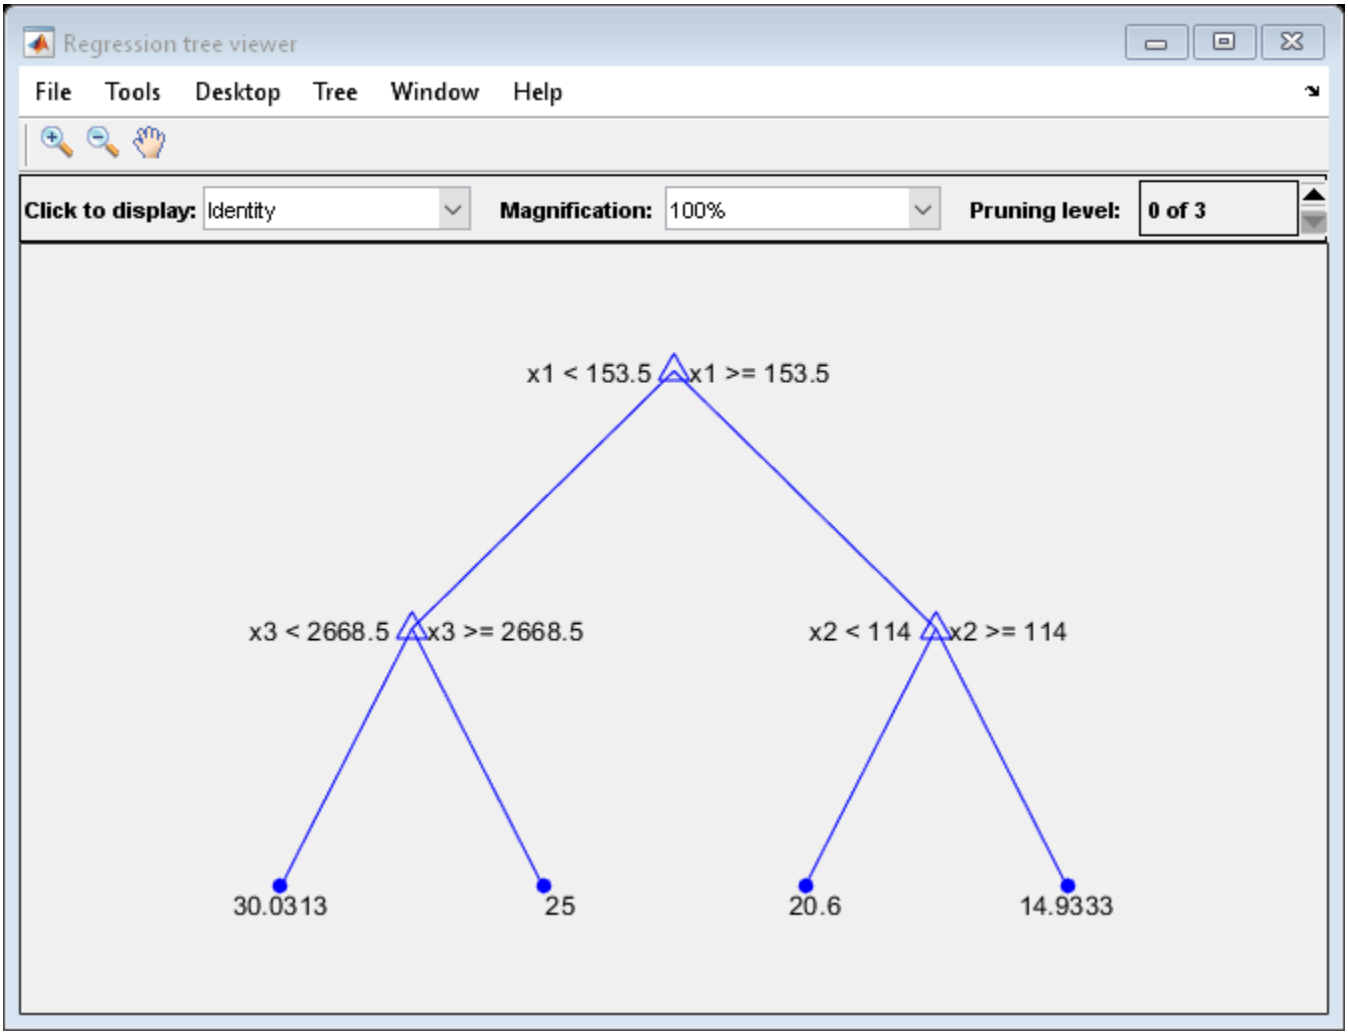
```
valLoss = 7×1

   32.1205
   31.5035
   32.0541
   30.8183
   26.3535
   30.0137
   38.4695
```

- The MSE for the full, unpruned tree (level 0) is about 32.1 units.
- The MSE for the tree pruned to level 4 is about 26.4 units.
- The MSE for the tree pruned to level 5 is about 30.0 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 4.

```
pruneMdl = prune(Mdl,'Level',4);
view(pruneMdl,'Mode','graph')
```



More About

Mean Squared Error

The mean squared error m of the predictions $f(X_n)$ with weight vector w is

$$m = \frac{\sum w_n (f(X_n) - Y_n)^2}{\sum w_n}.$$

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Only one output is supported.

- You can use models trained on either in-memory or tall data with this function.

For more information, see “Tall Arrays”.

`fitrtree` | `predict`

loss

Loss of linear model for incremental learning on batch of data

Syntax

```
L = loss(Mdl,X,Y)
L = loss(Mdl,X,Y,Name,Value)
```

Description

`loss` returns the regression or classification loss of a configured incremental learning model for linear regression (`incrementalRegressionLinear` object) or linear binary classification (`incrementalClassificationLinear` object).

To measure model performance on a data stream and store the results in the output model, call `updateMetrics` or `updateMetricsAndFit`.

`L = loss(Mdl,X,Y)` returns the loss for the incremental learning model `Mdl` using the batch of predictor data `X` and corresponding responses `Y`.

`L = loss(Mdl,X,Y,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify that the columns of the predictor data matrix correspond to observations, or specify the classification loss function .

Examples

Measure Model Performance During Incremental Learning

The performance of an incremental model on streaming data is measured in three ways:

1. Cumulative metrics measure the performance since the start of incremental learning.
2. Window metrics measure the performance on a specified window of observations. The metrics are updated every time the model processes the specified window.
3. The `loss` function measures the performance on a specified batch of data only.

Load the human activity data set. Randomly shuffle the data.

```
load humanactivity
n = numel(actid);
rng(1); % For reproducibility
idx = randsample(n,n);
X = feat(idx,:);
Y = actid(idx);
```

For details on the data set, enter `Description` at the command line.

Responses can be one of five classes: Sitting, Standing, Walking, Running, or Dancing. Dichotomize the response by identifying whether the subject is moving (`actid` > 2).

```
Y = Y > 2;
```

Create an incremental linear SVM model for binary classification. Configure it for `loss` by specifying the class names, prior class distribution (uniform), and arbitrary coefficient and bias values. Specify a metrics window size of 1000 observations.

```
p = size(X,2);
Beta = randn(p,1);
Bias = randn(1);
Mdl = incrementalClassificationLinear('Beta',Beta,'Bias',Bias,...
    'ClassNames',unique(Y),'Prior','uniform','MetricsWindowSize',1000);
```

`Mdl` is an `incrementalClassificationLinear` model. All its properties are read-only. Instead of specifying arbitrary values, you can take either of these actions to configure the model:

- Train an SVM model using `fitcsvm` or `fitclinear` on a subset of the data (if available), and then convert the model to an incremental learner by using `incrementalLearner`.
- Incrementally fit `Mdl` to data by using `fit`.

Simulate a data stream, and perform the following actions on each incoming chunk of 50 observations:

1. Call `updateMetrics` to measure the cumulative performance and the performance within a window of observations. Overwrite the previous incremental model with a new one to track performance metrics.
2. Call `loss` to measure the model performance on the incoming chunk.
3. Call `fit` to fit the model to the incoming chunk. Overwrite the previous incremental model with a new one fitted to the incoming observation.
4. Store all performance metrics to see how they evolve during incremental learning.

```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
ce = array2table(zeros(nchunk,3),'VariableNames',["Cumulative" "Window" "Loss"]);

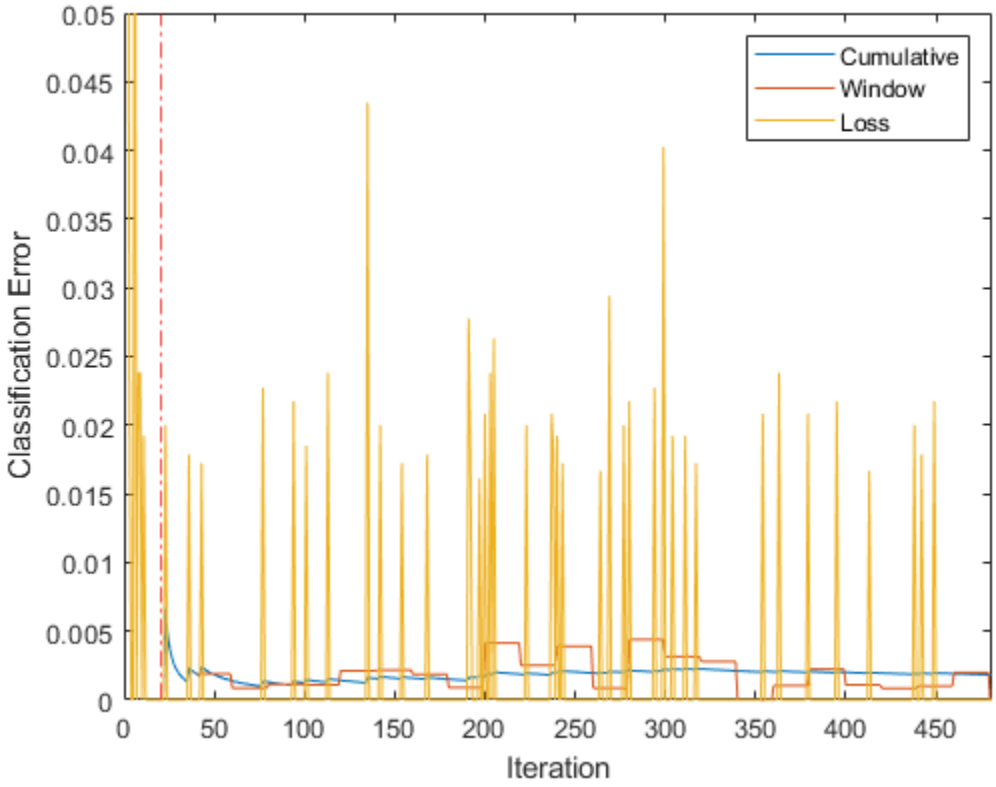
% Incremental learning
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetrics(Mdl,X(idx,:),Y(idx));
    ce{j,["Cumulative" "Window"]} = Mdl.Metrics{"ClassificationError",:};
    ce{j,"Loss"} = loss(Mdl,X(idx,:),Y(idx));
    Mdl = fit(Mdl,X(idx,:),Y(idx));
end
```

`Mdl` is an `incrementalClassificationLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetrics` checks the performance of the model on the incoming observation, then and the `fit` function fits the model to that observation. `loss` is agnostic of the metrics warm-up period, so it measures the classification error for all iterations.

To see how the performance metrics evolved during training, plot them.

```
figure;
plot(ce.Variables);
xlim([0 nchunk]);
```

```
ylim([0 0.05])
ylabel('Classification Error')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
legend(ce.Properties.VariableNames)
xlabel('Iteration')
```



During the metrics warm-up period (the area to the left of the red line), the yellow line represents the classification error on each incoming chunk of data. After the metrics warm-up period, `Mdl` tracks the cumulative and window metrics. The cumulative and batch losses converge as the `fit` function fits the incremental model to the incoming data.

Compute Custom Loss on Incoming Chunks of Data

Fit an incremental learning model for regression to streaming data, and compute the mean absolute deviation (MAD) on the incoming data batches.

Load the robot arm data set. Obtain the sample size `n` and the number of predictor variables `p`.

```
load robotarm
n = numel(ytrain);
p = size(Xtrain,2);
```

For details on the data set, enter `Description` at the command line.

Create an incremental linear model for regression. Configure the model as follows:

- Specify a metrics warm-up period of 1000 observations.
- Specify a metrics window size of 500 observations.
- Track the mean absolute deviation (MAD) to measure the performance of the model. Create an anonymous function that measures the absolute error of each new observation. Create a structure array containing the name `MeanAbsoluteError` and its corresponding function.
- Configure the model to predict responses by specifying that all regression coefficients and the bias are 0.

```
maefcn = @(z,zfit,w)(abs(z - zfit));
maemetric = struct("MeanAbsoluteError",maefcn);

Mdl = incrementalRegressionLinear('MetricsWarmupPeriod',1000,'MetricsWindowSize',500,...
    'Metrics',maemetric,'Beta',zeros(p,1),'Bias',0,'EstimationPeriod',0)
```

```
Mdl =
  incrementalRegressionLinear

               IsWarm: 0
              Metrics: [2x2 table]
    ResponseTransform: 'none'
                 Beta: [32x1 double]
                 Bias: 0
              Learner: 'svm'

  Properties, Methods
```

`Mdl` is an `incrementalRegressionLinear` model object configured for incremental learning.

Perform incremental learning. At each iteration:

- Simulate a data stream by processing a chunk of 50 observations.
- Call `updateMetrics` to compute cumulative and window metrics on the incoming chunk of data. Overwrite the previous incremental model with a new one fitted to overwrite the previous metrics.
- Call `loss` to compute the MAD on the incoming chunk of data. Whereas the cumulative and window metrics require that custom losses return the loss for each observation, `loss` requires the loss on the entire chunk. Compute the mean of the absolute deviation.
- Call `fit` to fit the incremental model to the incoming chunk of data.
- Store the cumulative, window, and chunk metrics to see how they evolve during incremental learning.

```
% Preallocation
numObsPerChunk = 50;
nchunk = floor(n/numObsPerChunk);
mae = array2table(zeros(nchunk,3),'VariableNames',["Cumulative" "Window" "Chunk"]);

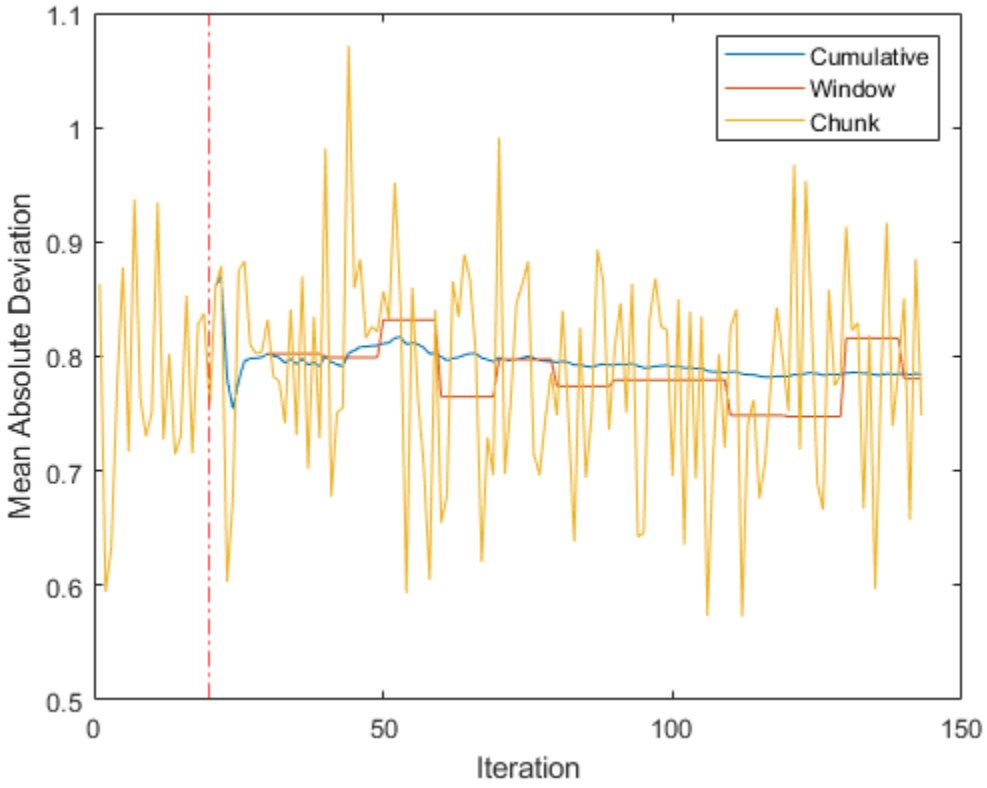
% Incremental fitting
for j = 1:nchunk
    ibegin = min(n,numObsPerChunk*(j-1) + 1);
    iend   = min(n,numObsPerChunk*j);
    idx = ibegin:iend;
    Mdl = updateMetrics(Mdl,Xtrain(idx,:),ytrain(idx));
    mae{j,1:2} = Mdl.Metrics{"MeanAbsoluteError",:};
```

```
    mae{j,3} = loss(Mdl,Xtrain(idx,:),ytrain(idx),'LossFun',@(x,y,w)mean(maefcn(x,y,w)));
    Mdl = fit(Mdl,Xtrain(idx,:),ytrain(idx));
end
```

`IncrementalMdl` is an `incrementalRegressionLinear` model object trained on all the data in the stream. During incremental learning and after the model is warmed up, `updateMetrics` checks the performance of the model on the incoming observation, and the `fit` function fits the model to that observation.

Plot the performance metrics to see how they evolved during incremental learning.

```
figure;
h = plot(mae.Variables);
ylabel('Mean Absolute Deviation')
xline(Mdl.MetricsWarmupPeriod/numObsPerChunk,'r-.');
xlabel('Iteration')
legend(h,mae.Properties.VariableNames)
```



The plot suggests the following:

- `updateMetrics` computes performance metrics after the metrics warm-up period only.
- `updateMetrics` computes the cumulative metrics during each iteration.
- `updateMetrics` computes the window metrics after processing 500 observations
- Because `Mdl` was configured to predict observations from the beginning of incremental learning, `loss` can compute the MAD on each incoming chunk of data.

Input Arguments

`Mdl` — Incremental learning model

`incrementalClassificationLinear` model object | `incrementalRegressionLinear` model object

Incremental learning model, specified as an `incrementalClassificationLinear` or `incrementalRegressionLinear` model object. You can create `Mdl` directly or by converting a supported, traditionally trained machine learning model using the `incrementalLearner` function. For more details, see the corresponding reference page.

You must configure `Mdl` to compute its loss on a batch of observations.

- If `Mdl` is a converted, traditionally trained model, you can compute its loss without any modifications.
- Otherwise, `Mdl` must satisfy the following criteria, which you can specify directly or by fitting `Mdl` to data using `fit` or `updateMetricsAndFit`.
  - If `Mdl` is an `incrementalRegressionLinear` model, its model coefficients `Mdl.Beta` and bias `Mdl.Bias` must be nonempty arrays.
  - If `Mdl` is an `incrementalClassificationLinear` model, its model coefficients `Mdl.Beta` and bias `Mdl.Bias` must be nonempty arrays, the class names `Mdl.ClassNames` must contain two classes, and the prior class distribution `Mdl.Prior` must contain known values.
  - Regardless of object type, if you configure the model so that functions standardize predictor data, the predictor means `Mdl.Mu` and standard deviations `Mdl.Sigma` must be nonempty arrays.

`X` — Batch of predictor data

floating-point matrix

Batch of predictor data with which to compute the loss, specified as a floating-point matrix of *n* observations and `Mdl.NumPredictors` predictor variables. The value of the `'ObservationsIn'` name-value pair argument determines the orientation of the variables and observations.

The length of the observation labels `Y` and the number of observations in `X` must be equal; `Y(`*j*`)` is the label of observation *j* (row or column) in `X`.

Note `loss` supports only floating-point input predictor data. If the input model `Mdl` represents a converted, traditionally trained model fit to categorical data, use `dummyvar` to convert each categorical variable to a numeric matrix of dummy variables, and concatenate all dummy variable matrices and any other numeric predictors. For more details, see “Dummy Variables” on page 2-48.

Data Types: `single` | `double`

`Y` — Batch of labels

categorical array | character array | string array | logical vector | floating-point vector | cell array of character vectors

Batch of labels with which to compute the loss, specified as a categorical, character, or string array, logical or floating-point vector, or cell array of character vectors for classification problems; or a floating-point vector for regression problems.

The length of the observation labels `Y` and the number of observations in `X` must be equal; `Y(j)` is the label of observation *j* (row or column) in `X`.

For classification problems:

- `loss` supports binary classification only.
- When the `ClassNames` property of the input model `Mdl` is nonempty, the following conditions apply:
