'linear'	Lambda, Learner, Coding (for three or more classes only)	Regularization	For more information, including hyperparameter search ranges, see OptimizeHyperparameters and OptimizeHyperparameters (for three or more classes only). Note that you cannot change hyperparameter search ranges when you use fitcauto.
'nb'	DistributionNames, Width	Kernel	For more information, including hyperparameter search ranges, see OptimizeHyperparameters. Note that you cannot change hyperparameter search ranges when you use fitcauto.

Learner Name	Hyperparameters for `'auto'`	Additional Hyperparameters for `'all'`	Notes
`'svm'`	`BoxConstraint`, `KernelScale`, `Coding` (for three or more classes only)	`KernelFunction`, `PolynomialOrder`, `Standardize`	• When the `Learners` value is `'all-linear'`, the `fitcauto` function does not optimize the `KernelFunction` or `PolynomialOrder` hyperparameters when the `OptimizeHyperparameters` value is `'all'`. • When the `Learners` value is `'all-nonlinear'`, the `fitcauto` function chooses among the `KernelFunction` values of `'gaussian'` and `'polynomial'`, regardless of the `OptimizeHyperparameters` value. • The `Standardize` value is `true` when the `OptimizeHyperparameters` value is `'auto'`. For more information, including hyperparameter search ranges, see `OptimizeHyperparameters` and `OptimizeHyperparameters` (for three or more classes only). Note that you cannot change hyperparameter search ranges when you use `fitcauto`.

Learner Name	Hyperparameters for 'auto'	Additional Hyperparameters for 'all'	Notes
'tree'	MinLeafSize	MaxNumSplits, SplitCriterion	For more information, including hyperparameter search ranges, see OptimizeHyperparameters. Note that you cannot change hyperparameter search ranges when you use fitcauto.

Note When 'Learners' is set to a value other than 'auto', the default values for the model hyperparameters not being optimized match the default fit function values, unless otherwise indicated in the table notes. When 'Learners' is set to 'auto', the optimized hyperparameter search ranges and nonoptimized hyperparameter values can vary, depending on the characteristics of the training data. For more information, see "Automatic Selection of Learners" on page 33-1570.

Example: 'OptimizeHyperparameters','all'

HyperparameterOptimizationOptions — Options for optimization
structure

Options for the optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. All fields in the structure are optional.

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of iterations (objective function evaluations)	30*L, where L is the number of learners (see Learners)
MaxTime	Time limit, specified as a positive real number. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best observed and estimated objective function values (so far) against the iteration number.	true
SaveIntermediateResults	Logical value indicating whether to save results. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
`Verbose`	Display at the command line: • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with additional information about the next point to be evaluated	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Specify only one of the following three options.		
`CVPartition`	`cvpartition` object, created by `cvpartition`	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	Scalar in the range `(0,1)` representing the holdout fraction	
`Kfold`	Integer greater than 1	

Example: `'HyperparameterOptimizationOptions',struct('UseParallel',true)`

Data Types: `struct`

Classification Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitcauto` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcauto` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. However, learners that use decision trees assume that mathematically ordered categorical vectors are continuous variables. If the predictor data is a matrix (`X`), `fitcauto` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value pair argument.

For more information on how fitting functions treat categorical predictors, see “Automatic Creation of Dummy Variables” on page 2-49.

Note

- `fitcauto` does not support categorical predictors for discriminant analysis classifiers. That is, if you want `Learners` to include `'discr'` models, you cannot specify the `'CategoricalPredictors'` name-value pair argument or use a table of sample data (`Tbl`) containing categorical predictors.
- `fitcauto` does not support a mix of numeric and categorical predictors for k-nearest neighbor models. That is, if you want `Learners` to include `'knn'` models, you must specify the `'CategoricalPredictors'` value as `'all'` or `[]`.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure array.

- If you specify a square matrix `Cost` and the true class of an observation is `i`, then `Cost(i,j)` is the cost of classifying a point into class `j`. That is, rows correspond to the true classes and columns correspond to the predicted classes. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- If you specify a structure `S`, then it must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
  - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default value for `Cost` is `ones(K) - eye(K)`, where `K` is the number of distinct classes.

Example: `'Cost',[0 1; 2 0]`

Data Types: `single` | `double` | `struct`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.

  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitcauto` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to `Mdl.ClassNames` or specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements to sum to `1`.
structure	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements to sum to `1`.

Example: `'Prior',struct('ClassNames',{{'b','g'}},'ClassProbs',1:2)`

Data Types: `single` | `double` | `char` | `string` | `struct`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ScoreTransform` — Score transformation
`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
positive numeric vector | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a positive numeric vector or the name of a variable in `Tbl`. The software weights each observation in `X` or `Tbl` with the corresponding value in `Weights`. The length of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response variable when training the model.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

The software normalizes `Weights` to sum to the value of the prior probability in the respective class.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`Mdl` — Trained classification model

classification model object

Trained classification model, returned as one of the classification model objects in this table.

Learner Name	Returned Model Object
`'discr'`	`CompactClassificationDiscriminant`
`'ensemble'`	`CompactClassificationEnsemble`
`'kernel'`	• `ClassificationKernel` for binary classification • `CompactClassificationECOC` for multiclass classification
`'knn'`	`ClassificationKNN`
`'linear'`	• `ClassificationLinear` for binary classification • `CompactClassificationECOC` for multiclass classification
`'nb'`	`CompactClassificationNaiveBayes`
`'svm'`	• `CompactClassificationSVM` for binary classification • `CompactClassificationECOC` for multiclass classification
`'tree'`	`CompactClassificationTree`

`OptimizationResults` — Optimization results

`BayesianOptimization` object

Optimization results, returned as a `BayesianOptimization` object. For more information on the Bayesian optimization process, see “Bayesian Optimization” on page 33-1571.

More About

Verbose Display

When you set the `Verbose` field of the `HyperparameterOptimizationOptions` name-value pair argument to `1` or `2`, the `fitcauto` function provides an iterative display of the optimization results.

The following table describes the columns in the display and their entries.

Column Name	Description
`Iter`	Iteration number — You can set a limit to the number of iterations by using the `MaxObjectiveEvaluations` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

Column Name	Description
`Active workers`	Number of active parallel workers — This column appears only when you run the optimization in parallel by setting the `UseParallel` field of the `'HyperparameterOptimizationOptions'` name-value pair argument to `true`.
`Eval result`	One of the following evaluation results: • `Best` — The learner and hyperparameter values at this iteration give the minimum observed validation loss computed so far. That is, the `Validation loss` value is the smallest computed so far. • `Accept` — The learner and hyperparameter values at this iteration give meaningful (for example, non-`NaN`) observed and estimated validation loss values. • `Error` — The learner and hyperparameter values at this iteration result in an error (for example, a `Validation loss` value of `NaN`).
`Validation loss`	Validation loss computed for the learner and hyperparameter values at this iteration — In particular, `fitcauto` computes the cross-validation classification error by default. You can change the validation scheme by using the `CVPartition`, `Holdout`, or `Kfold` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.
`Time for training & validation (sec)`	Time taken to train and compute the validation loss for the model with the learner and hyperparameter values at this iteration (in seconds) — In particular, this value excludes the time required to update the objective function model maintained by the Bayesian optimization process. For more details, see “Bayesian Optimization” on page 33-1571.
`Observed min validation loss`	Observed minimum validation loss computed so far — This value corresponds to the smallest `Validation loss` value computed so far in the optimization process. By default, `fitcauto` returns a plot of the optimization that displays dark blue points for the observed minimum validation loss values. This plot does not appear when the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument is set to `false`.

Column Name	Description
`Estimated min validation loss`	Estimated minimum validation loss — At each iteration, `fitcauto` updates an objective function model maintained by the Bayesian optimization process and uses this model to estimate the minimum validation loss. For more details, see “Bayesian Optimization” on page 33-2113. By default, `fitcauto` returns a plot of the optimization that displays light blue points for the estimated minimum validation loss values. This plot does not appear when the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument is set to `false`.
`Learner`	Model type evaluated at this iteration — Specify the learners used in the optimization by using the `'Learners'` name-value pair argument.
`Hyperparameter: Value`	Hyperparameter values at this iteration — Specify the hyperparameters used in the optimization by using the `'OptimizeHyperparameters'` name-value pair argument.

The display also includes a description of two models:

- `Best observed learner` — This model, with the listed learner type and hyperparameter values, yields the final observed minimum validation loss.
- `Best estimated learner` — This model, with the listed learner type and hyperparameter values, yields the final estimated minimum validation loss. `fitcauto` retrains the model on the entire training data set and returns it as the `Mdl` output.

Tips

- Depending on the size of your data and the number of learners you specify, `fitcauto` can take some time to run. If you have a Parallel Computing Toolbox license, you can speed up computations by running the optimization in parallel. To do so, specify `'HyperparameterOptimizationOptions',struct('UseParallel',true)`. You can include other fields in the structure to control other aspects of the optimization. See `HyperparameterOptimizationOptions`.

Algorithms

Automatic Selection of Learners

When you specify `'Learners','auto'`, the `fitcauto` function analyzes the predictor and response data in order to choose appropriate learners. The function considers whether the data set has any of these characteristics:

- Categorical predictors
- Missing values for more than 5% of the data
- Imbalanced data, where the ratio of the number of observations in the largest class to the number of observations in the smallest class is greater than 5
- More than 100 observations in the smallest class
- Wide data, where the number of predictors is greater than or equal to the number of observations
- High-dimensional data, where the number of predictors is greater than 100
- Large data, where the number of observations is greater than 50,000
- Binary response variable
- Ordinal response variable

The selected learners are always a subset of those listed in the `Learners` table. However, the associated models tried during the optimization process can have different default values for hyperparameters not being optimized, as well as different search ranges for hyperparameters being optimized.

Bayesian Optimization

The goal of Bayesian optimization, and optimization in general, is to find a point that minimizes an objective function. In the context of `fitcauto`, a point is a learner type together with a set of hyperparameter values for the learner (see `Learners` and `OptimizeHyperparameters`), and the objective function is the cross-validation classification error, by default. The Bayesian optimization implemented in `fitcauto` internally maintains a multi-`TreeBagger` model of the objective function. That is, the objective function model splits along the learner type and, for a given learner, the model is a `TreeBagger` ensemble for regression. (This underlying model differs from the Gaussian process model employed by other Statistics and Machine Learning Toolbox functions that use Bayesian optimization.) Bayesian optimization trains the underlying model by using objective function evaluations, and determines the next point to evaluate by using an acquisition function (`'expected-improvement'`). For more information, see “Expected Improvement” on page 10-4. The acquisition function balances between sampling at points with low modeled objective function values and exploring areas that are not well modeled yet. At the end of the optimization, `fitcauto` chooses the point with the minimum objective function model value, among the points evaluated during the optimization. For more information, see the `'Criterion','min-visited-mean'` name-value pair argument of `bestPoint`.

Alternative Functionality

- If you are unsure which models work best for your data set, you can alternatively use the **Classification Learner** app. Using the app, you can perform hyperparameter tuning for different models, and choose the optimized model that performs best. Although you must select a specific model before you can tune the model hyperparameters, **Classification Learner** provides greater flexibility for selecting optimizable hyperparameters and setting hyperparameter values. However, you cannot optimize in parallel, choose `'linear'` or `'kernel'` learners, specify observation weights, or specify prior probabilities in the app. For more information, see “Hyperparameter Optimization in Classification Learner App” on page 23-54.
- If you know which models might suit your data, you can alternatively use the corresponding model fit functions and specify the `'OptimizeHyperparameters'` name-value pair argument to tune hyperparameters. You can compare the results across the models to select the best classifier. For an example of this process, see “Moving Towards Automating Model Selection Using Bayesian Optimization” on page 18-197.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions',struct('UseParallel',true)` name-value pair argument in the call to this function.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Automated Classifier Selection with Bayesian Optimization” on page 18-205
“Hyperparameter Optimization in Classification Learner App” on page 23-54

Introduced in R2020a

fitcdiscr

Fit discriminant analysis classifier

Syntax

```
Mdl = fitcdiscr(Tbl,ResponseVarName)
Mdl = fitcdiscr(Tbl,formula)
Mdl = fitcdiscr(Tbl,Y)

Mdl = fitcdiscr(X,Y)

Mdl = fitcdiscr(___,Name,Value)
```

Description

`Mdl = fitcdiscr(Tbl,ResponseVarName)` returns a fitted discriminant analysis model based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `ResponseVarName`.

`Mdl = fitcdiscr(Tbl,formula)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcdiscr(Tbl,Y)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl` and response `Y`.

`Mdl = fitcdiscr(X,Y)` returns a discriminant analysis classifier based on the input variables `X` and response `Y`.

`Mdl = fitcdiscr(___,Name,Value)` fits a classifier with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can optimize hyperparameters to minimize the model's cross-validation loss, or specify the cost of misclassification, the prior probabilities for each class, or the observation weights.

Examples

Train Discriminant Analysis Model

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using the entire data set.

```
Mdl = fitcdiscr(meas,species)
```

```
Mdl =
  ClassificationDiscriminant
             ResponseName: 'Y'
    CategoricalPredictors: []
```

```
             ClassNames: {'setosa'  'versicolor'  'virginica'}
         ScoreTransform: 'none'
        NumObservations: 150
            DiscrimType: 'linear'
                     Mu: [3x4 double]
                 Coeffs: [3x3 struct]

  Properties, Methods
```

`Mdl` is a `ClassificationDiscriminant` model. To access its properties, use dot notation. For example, display the group means for each predictor.

```
Mdl.Mu
```

```
ans = 3×4

    5.0060    3.4280    1.4620    0.2460
    5.9360    2.7700    4.2600    1.3260
    6.5880    2.9740    5.5520    2.0260
```

To predict labels for new observations, pass `Mdl` and predictor data to `predict`.

Optimize Discriminant Analysis Model

This example shows how to optimize hyperparameters automatically using `fitcdiscr`. The example uses Fisher's iris data.

Load the data.

```
load fisheriris
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng(1)
Mdl = fitcdiscr(meas,species,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

```

```

The fit achieves about 2% loss for the default 5-fold cross validation.

Optimize Discriminant Analysis Model on Tall Array

This example shows how to optimize hyperparameters of a discriminant analysis model automatically using a tall array. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore that references the folder location with the data. Select a subset of the variables to work with, and treat `'NA'` values as missing data so that `datastore` replaces them with `NaN` values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek',...
                            'DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt  = tall(ds) % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

tt =

  M×7 tall table

    Month    DayofMonth    DayOfWeek    DepTime    ArrDelay    Distance    DepDelay

```

Remove rows in `X` and `Y` that contain missing data.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:end-1);
Y = R(:,end);
```

Standardize the predictor variables.

```
Z = zscore(X);
```

Optimize hyperparameters automatically using the `'OptimizeHyperparameters'` name-value pair argument. Find the optimal `'DiscrimType'` value that minimizes holdout cross-validation loss. (Specifying `'auto'` uses `'DiscrimType'`.) For reproducibility, use the `'expected-improvement-plus'` acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs”.

```
rng('default')
tallrng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(Z,Y,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('Holdout',0.3,...
    'AcquisitionFunctionName','expected-improvement-plus'))

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables

character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

The software considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Y` to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

X — Predictor data

numeric matrix

Predictor values, specified as a numeric matrix. Each column of `X` represents one variable, and each row represents one observation.

`fitcdiscr` considers `NaN` values in `X` as missing values. `fitcdiscr` does not use observations with missing values for `X` in the fit.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'DiscrimType','quadratic','SaveMemory','on'` specifies a quadratic discriminant classifier and does not store the covariance matrix in the output object.

Model Parameters

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.

- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Cost of misclassification
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

`Delta` — Linear coefficient threshold
`0` (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `Mdl` has magnitude smaller than `Delta`, `Mdl` sets this coefficient to `0`, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be `0` for quadratic discriminant models.

Data Types: `single` | `double`

`DiscrimType` — Discriminant type
`'linear'` (default) | `'quadratic'` | `'diaglinear'` | `'diagquadratic'` | `'pseudolinear'` | `'pseudoquadratic'`

Discriminant type, specified as the comma-separated pair consisting of `'DiscrimType'` and a character vector or string scalar in this table.

Value	Description	Predictor Covariance Treatment
`'linear'`	Regularized linear discriminant analysis (LDA)	• All classes have the same covariance matrix. • $\widehat{\Sigma}_\gamma = (1-\gamma)\widehat{\Sigma} + \gamma \mathrm{diag}\left(\widehat{\Sigma}\right)$. $\widehat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.
`'diaglinear'`	LDA	All classes have the same, diagonal covariance matrix.
`'pseudolinear'`	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
`'quadratic'`	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
`'diagquadratic'`	QDA	The covariance matrices are diagonal and can vary among classes.
`'pseudoquadratic'`	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note To use regularization, you must specify `'linear'`. To specify the amount of regularization, use the `Gamma` name-value pair argument.

Example: `'DiscrimType','quadratic'`

`FillCoeffs` — `Coeffs` property flag

`'on'` | `'off'`

`Coeffs` property flag, specified as the comma-separated pair consisting of `'FillCoeffs'` and `'on'` or `'off'`. Setting the flag to `'on'` populates the `Coeffs` property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is `'on'`, unless you specify a cross-validation name-value pair, in which case the flag is set to `'off'` by default.

Example: `'FillCoeffs','off'`

`Gamma` — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of `'Gamma'` and a scalar value in the interval [0,1]. `Gamma` provides finer control over the covariance matrix structure than `DiscrimType`.

- If you specify `0`, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.

  - For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
  - For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to `'linear'`.
- If you specify `1`, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: `'Gamma',1`

Data Types: `single` | `double`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitcdiscr` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',`
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to 1/*K*, where *K* is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to `Mdl.ClassNames` or specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements such that they sum to `1`.
structure	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to `1`.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`SaveMemory` — Flag to save covariance matrix
`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

Example: `'SaveMemory','on'`

`ScoreTransform` — Score transformation
`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights

numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(`*n*`,1)`, where *n* is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Cross-Validation Options

`CrossVal` — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'CrossVal','on'`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.
2. Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Hyperparameter Optimization Options

`OptimizeHyperparameters` — Parameters to optimize
`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Delta','Gamma'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitcdiscr` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcdiscr` are:

- `Delta` — `fitcdiscr` searches among positive values, by default log-scaled in the range `[1e-6,1e3]`.

- `DiscrimType` — `fitcdiscr` searches among `'linear'`, `'quadratic'`, `'diagLinear'`, `'diagQuadratic'`, `'pseudoLinear'`, and `'pseudoQuadratic'`.
- `Gamma` — `fitcdiscr` searches among real values in the range `[0,1]`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcdiscr',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Discriminant Analysis Model” on page 33-1574.

Example: `'auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`

Field Name	Values	Default
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`

Field Name	Values	Default
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see "Parallel Bayesian Optimization" on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained discriminant analysis classification model

`ClassificationDiscriminant` model object | `ClassificationPartitionedModel` cross-validated model object

Trained discriminant analysis classification model, returned as a `ClassificationDiscriminant` model object or a `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated model object. Otherwise, `Mdl` is a `ClassificationDiscriminant` model object.

To reference properties of `Mdl`, use dot notation. For example, to display the estimated component means at the Command Window, enter `Mdl.Mu`.

More About

Discriminant Classification

The model for discriminant analysis is:

- Each class (`Y`) generates data (`X`) using a multivariate normal distribution. That is, the model assumes `X` has a Gaussian mixture distribution (`gmdistribution`).
  - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
  - For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\widehat{y} = \underset{y = 1, \ldots, K}{\operatorname{argmin}} \sum_{k = 1}^{K} \widehat{P}(k|x) C(y|k),$$

where

- $\widehat{y}$ is the predicted classification.
- K is the number of classes.
- $\widehat{P}(k|x)$ is the posterior probability on page 20-6 of class k for observation x.
- $C(y|k)$ is the cost on page 20-7 of classifying an observation as y when its true class is k.

For details, see “Prediction Using Discriminant Analysis Models” on page 20-6.

Tips

After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Alternative Functionality

Functions

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use.

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross-validation or hyperparameter optimization.
- `classify` requires you to fit the classifier when changing prior probabilities.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
  - `Mdl = fitcdiscr(Tbl,Y)`
  - `Mdl = fitcdiscr(X,Y)`
  - `Mdl = fitcdiscr(___,Name,Value)`
  - `[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(___,Name,Value)` — `fitcdiscr` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the `'OptimizeHyperparameters'` name-value pair argument.
- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.
- The `HyperparameterOptimizationResults` output argument is a `BayesianOptimization` object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

  `'HyperparameterOptimizationResults'` is nonempty when the `'OptimizeHyperparameters'` name-value pair argument is nonempty at the time you create the model. The values in `'HyperparameterOptimizationResults'` depend on the value you specify for the `'HyperparameterOptimizationOptions'` name-value pair argument when you create the model.
  - If you specify `'bayesopt'` (default), then `HyperparameterOptimizationResults` is an object of class `BayesianOptimization`.
  - If you specify `'gridsearch'` or `'randomsearch'`, then `HyperparameterOptimizationResults` is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).
- Supported name-value pair arguments, and any differences, are:
  - `'ClassNames'`
  - `'Cost'`
  - `'DiscrimType'`
  - `'HyperparameterOptimizationOptions'` — For cross-validation, tall optimization supports only `'Holdout'` validation. By default, the software selects and reserves 20% of the data as holdout validation data, and trains the model using the rest of the data. You can specify a different value for the holdout fraction by using this argument. For example, specify `'HyperparameterOptimizationOptions',struct('Holdout',0.3)` to reserve 30% of the data as validation data.
  - `'OptimizeHyperparameters'` — The only eligible parameter to optimize is `'DiscrimType'`. Specifying `'auto'` uses `'DiscrimType'`.
  - `'PredictorNames'`
  - `'Prior'`

- 'ResponseName'
- 'ScoreTransform'
- 'Weights'

- For tall arrays and tall tables, fitcdiscr returns a CompactClassificationDiscriminant object, which contains most of the same properties as a ClassificationDiscriminant object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these ClassificationDiscriminant properties:

  - ModelParameters
  - NumObservations
  - HyperparameterOptimizationResults
  - RowsUsed
  - XCentered
  - W
  - X
  - Y

  Additionally, the compact object does not support these ClassificationDiscriminant methods:

  - compact
  - crossval
  - cvshrink
  - resubEdge
  - resubLoss
  - resubMargin
  - resubPredict

For more information, see “Tall Arrays”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptimizationOptions', struct('UseParallel',true) name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014a

fitcecoc

Fit multiclass models for support vector machines or other classifiers

Syntax

```
Mdl = fitcecoc(Tbl,ResponseVarName)
Mdl = fitcecoc(Tbl,formula)
Mdl = fitcecoc(Tbl,Y)

Mdl = fitcecoc(X,Y)

Mdl = fitcecoc(___,Name,Value)
[Mdl,HyperparameterOptimizationResults] = fitcecoc(___,Name,Value)
```

Description

`Mdl = fitcecoc(Tbl,ResponseVarName)` returns a full, trained, multiclass, error-correcting output codes (ECOC) model on page 33-1643 using the predictors in table `Tbl` and the class labels in `Tbl.ResponseVarName`. `fitcecoc` uses $K(K – 1)/2$ binary support vector machine (SVM) models using the one-versus-one coding design on page 33-1640, where K is the number of unique class labels (levels). `Mdl` is a `ClassificationECOC` model.

`Mdl = fitcecoc(Tbl,formula)` returns an ECOC model using the predictors in table `Tbl` and the class labels. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used for training.

`Mdl = fitcecoc(Tbl,Y)` returns an ECOC model using the predictors in table `Tbl` and the class labels in vector `Y`.

`Mdl = fitcecoc(X,Y)` returns a trained ECOC model using the predictors `X` and the class labels `Y`.

`Mdl = fitcecoc(___,Name,Value)` returns an ECOC model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

For example, specify different binary learners, a different coding design, or to cross-validate. It is good practice to cross-validate using the `Kfold` `Name,Value` pair argument. The cross-validation results determine how well the model generalizes.

`[Mdl,HyperparameterOptimizationResults] = fitcecoc(___,Name,Value)` also returns hyperparameter optimization details when you specify the `OptimizeHyperparameters` name-value pair argument and use linear or kernel binary learners. For other `Learners`, the `HyperparameterOptimizationResults` property of `Mdl` contains the results.

Examples

Train Multiclass Model Using SVM Learners

Train a multiclass error-correcting output codes (ECOC) model using support vector machine (SVM) binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train a multiclass ECOC model using the default options.

```
Mdl = fitcecoc(X,Y)
```

```
Mdl =
  ClassificationECOC
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
           BinaryLearners: {3x1 cell}
               CodingName: 'onevsone'

  Properties, Methods
```

`Mdl` is a `ClassificationECOC` model. By default, `fitcecoc` uses SVM binary learners and a one-versus-one coding design. You can access `Mdl` properties using dot notation.

Display the class names and the coding design matrix.

```
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
CodingMat = Mdl.CodingMatrix
```

```
CodingMat = 3×3

     1     1     0
    -1     0     1
     0    -1    -1
```

A one-versus-one coding design for three classes yields three binary learners. The columns of `CodingMat` correspond to the learners, and the rows correspond to the classes. The class order is the same as the order in `Mdl.ClassNames`. For example, `CodingMat(:,1)` is `[1; –1; 0]` and indicates that the software trains the first SVM binary learner using all observations classified as `'setosa'` and `'versicolor'`. Because `'setosa'` corresponds to `1`, it is the positive class; `'versicolor'` corresponds to `–1`, so it is the negative class.

You can access each binary learner using cell indexing and dot notation.

```
Mdl.BinaryLearners{1}   % The first binary learner
```

```
ans =
  CompactClassificationSVM
             ResponseName: 'Y'
```

```
    CategoricalPredictors: []
               ClassNames: [-1 1]
          ScoreTransform: 'none'
                    Beta: [4x1 double]
                    Bias: 1.4505
         KernelParameters: [1x1 struct]

  Properties, Methods
```

Compute the resubstitution classification error.

```
error = resubLoss(Mdl)
```

```
error = 0.0067
```

The classification error on the training data is small, but the classifier might be an overfitted model. You can cross-validate the classifier using `crossval` and compute the cross-validation classification error instead.

Train Multiclass Linear Classification Model

Train an ECOC model composed of multiple binary, linear classification models.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Create a default linear-classification-model template.

```
t = templateLinear();
```

To adjust the default values, see the “Name-Value Pair Arguments” on page 33-6131 on `templateLinear` page.

Train an ECOC model composed of multiple binary, linear classification models that can identify the product given the frequency distribution of words on a documentation web page. For faster training time, transpose the predictor data, and specify that observations correspond to columns.

```
X = X';
rng(1); % For reproducibility
Mdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns')
```

```
Mdl =
  CompactClassificationECOC
      ResponseName: 'Y'
        ClassNames: [1x13 categorical]
    ScoreTransform: 'none'
    BinaryLearners: {78x1 cell}
      CodingMatrix: [13x78 double]
```

```
  Properties, Methods
```

Alternatively, you can train an ECOC model composed of default linear classification models using `'Learners','Linear'`.

To conserve memory, `fitcecoc` returns trained ECOC models composed of linear classification learners in `CompactClassificationECOC` model objects.

Cross-Validate ECOC Classifier

Cross-validate an ECOC classifier with SVM binary learners, and estimate the generalized classification error.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```
t = templateSVM('Standardize',true)
```

```
t =
Fit template for classification SVM.

                     Alpha: [0x1 double]
             BoxConstraint: []
                 CacheSize: []
             CachingMethod: ''
                ClipAlphas: []
    DeltaGradientTolerance: []
                   Epsilon: []
              GapTolerance: []
              KKTTolerance: []
            IterationLimit: []
            KernelFunction: ''
               KernelScale: []
              KernelOffset: []
     KernelPolynomialOrder: []
                 NumPrint: []
                       Nu: []
          OutlierFraction: []
         RemoveDuplicates: []
          ShrinkagePeriod: []
                   Solver: ''
          StandardizeData: 1
       SaveSupportVectors: []
           VerbosityLevel: []
                  Version: 2
                   Method: 'SVM'
                     Type: 'classification'
```

`t` is an SVM template. Most of the template object properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```
CVMdl = crossval(Mdl);
```

`CVMdl` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalized classification error.

```
genError = kfoldLoss(CVMdl)
```

```
genError = 0.0400
```

The generalized classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the `'FitPosterior'` name-value pair argument. Specify the class order using the `'ClassNames'` name-value pair argument. Display diagnostic messages during training by using the `'Verbose'` name-value pair argument.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',true,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 2
Positive class indices: 1

Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 1

Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 2

Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the training-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities by using the `'Verbose'` name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...
```

```
Mdl.BinaryLoss
```

```
ans =
'quadratic'
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10×3 table
      TrueLabel         PredLabel                    Posterior
    ______________    ______________    ___________________________________

    {'virginica' }    {'virginica' }     0.0039319     0.0039866       0.99208
    {'virginica' }    {'virginica' }      0.017066      0.018262       0.96467
    {'virginica' }    {'virginica' }      0.014947      0.015855        0.9692
    {'versicolor'}    {'versicolor'}    2.2197e-14       0.87318       0.12682
```

```
    {'setosa'    }    {'setosa'    }         0.999    0.00025091    0.00074639
    {'versicolor'}    {'virginica' }    2.2195e-14      0.059427       0.94057
    {'versicolor'}    {'versicolor'}    2.2194e-14       0.97002      0.029984
    {'setosa'    }    {'setosa'    }         0.999     0.0002499    0.00074741
    {'versicolor'}    {'versicolor'}     0.0085638       0.98259     0.0088482
    {'setosa'    }    {'setosa'    }         0.999    0.00025013    0.00074718
```

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

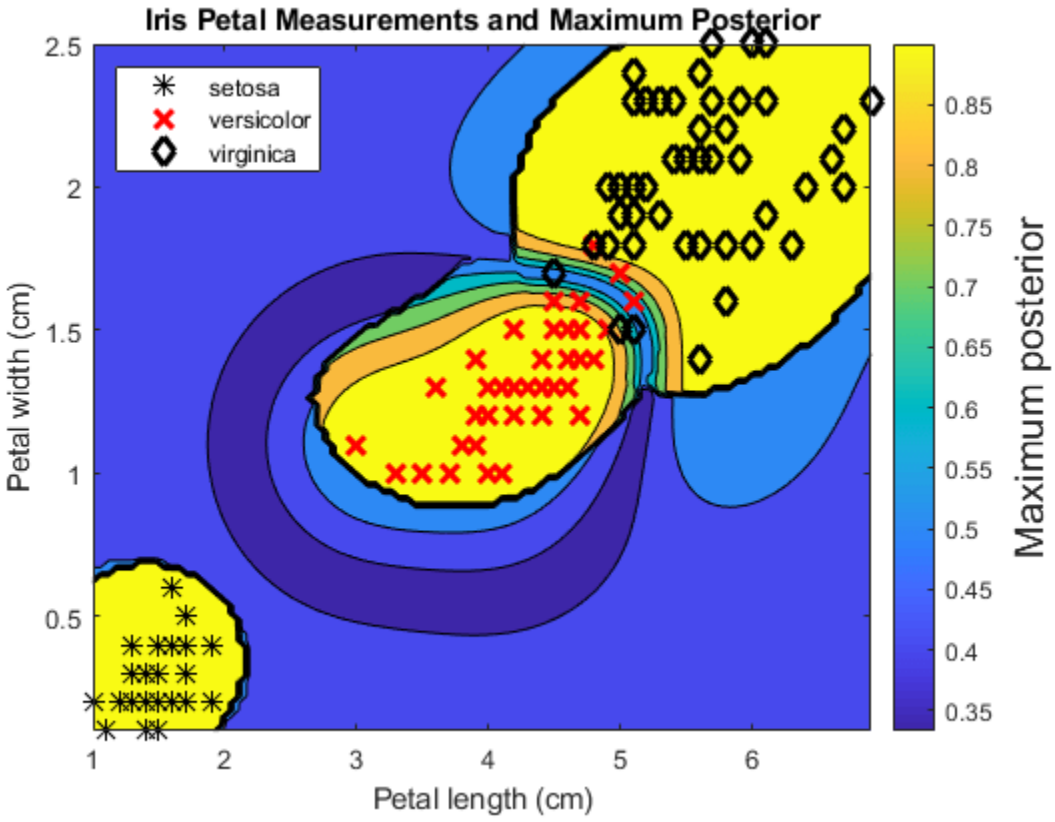
[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
contourf(x1Grid,x2Grid,...
        reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;

hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title('Iris Petal Measurements and Maximum Posterior')
xlabel('Petal length (cm)')
ylabel('Petal width (cm)')
axis tight
legend(gh,'Location','NorthWest')
hold off
```



Speed Up Training ECOC Classifiers Using Binning and Parallel Computing

Train a one-versus-all ECOC classifier using a `GentleBoost` ensemble of decision trees with surrogate splits. To speed up training, bin numeric predictors and use parallel computing. Binning is valid only when `fitcecoc` uses a tree learner. After training, estimate the classification error using 10-fold cross-validation. Note that parallel computing requires Parallel Computing Toolbox™.

Load Sample Data

Load and inspect the `arrhythmia` data set.

```
load arrhythmia
[n,p] = size(X)
```

```
n = 452
```

```
p = 279
```

```
isLabels = unique(Y);
nLabels = numel(isLabels)
```

```
nLabels = 13
```

```
tabulate(categorical(Y))
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
     15        5      1.11%
     16       22      4.87%
```

The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (Y). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

Train One-Versus-All ECOC Classifier

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify `'GentleBoost'` for the method, `100` for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```
tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

`tEnsemble` is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. To speed up training, use binning and parallel computing.

- Binning (`'NumBins',50`) — When you have a large training data set, you can speed up training (a potential decrease in accuracy) by using the `'NumBins'` name-value pair argument. This argument is valid only when `fitcecoc` uses a tree learner. If you specify the `'NumBins'` value, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. You can try `'NumBins',50` first, and then change the `'NumBins'` value depending on the accuracy and training speed.
- Parallel computing (`'Options',statset('UseParallel',true)`) — With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. The number of workers depends on your system configuration. When you use decision trees for binary learners, `fitcecoc` parallelizes training using Intel® Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the `'UseParallel'` option is not helpful on a single computer. Use this option on a cluster.

Additionally, specify that the prior probabilities are $1/K$, where $K = 13$ is the number of distinct classes.

```
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
                'Prior','uniform','NumBins',50,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

`Mdl` is a `ClassificationECOC` model.

Cross-Validation

Cross-validate the ECOC classifier using 10-fold cross-validation.

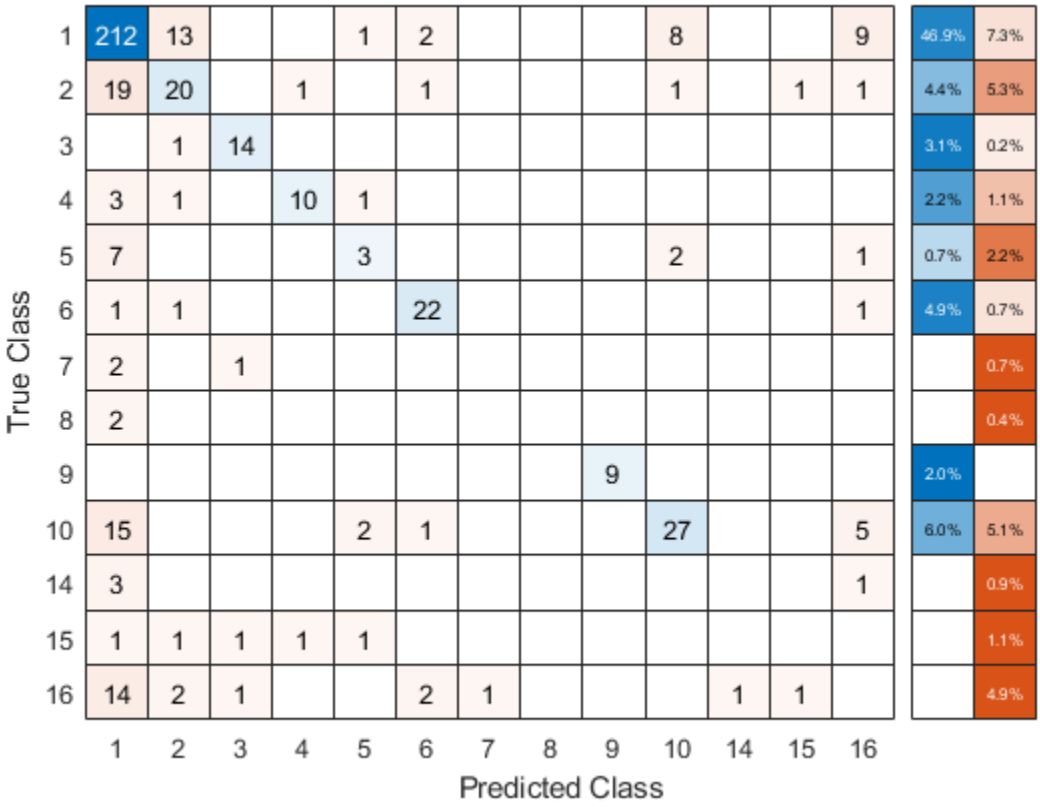
```
CVMdl = crossval(Mdl,'Options',options);
```

```
Warning: One or more folds do not contain points from all the groups.
```

`CVMdl` is a `ClassificationPartitionedECOC` model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering `CVMdl.Trained{1}`.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using `confusionchart`. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

```
oofLabel = kfoldPredict(CVMdl,'Options',options);
ConfMat = confusionchart(Y,oofLabel,'RowSummary','total-normalized');
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
```



Reproduce Binned Data

Reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

```
X = Mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are `0` for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

Optimize ECOC Classifier

Optimize hyperparameters automatically using `fitcecoc`.

Load the `fisheriris` data set.

```
load fisheriris
X = meas;
Y = species;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng default
Mdl = fitcecoc(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

```

Train Multiclass ECOC Model with SVMs and Tall Arrays

Create two multiclass ECOC models trained on tall data. Use linear binary learners for one of the models and kernel binary learners for the other. Compare the resubstitution classification error of the two models.

In general, you can perform multiclass classification of tall data by using `fitcecoc` with linear or kernel binary learners. When you use `fitcecoc` to train a model on tall arrays, you cannot use SVM binary learners directly. However, you can use either linear or kernel binary classification models that use SVMs.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore that references the folder containing Fisher's iris data set. Specify `'NA'` values as missing data so that `datastore` replaces them with `NaN` values. Create tall versions of the predictor and response data.

```
ds = datastore('fisheriris.csv','TreatAsMissing','NA');
t = tall(ds);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
X = [t.SepalLength t.SepalWidth t.PetalLength t.PetalWidth];
Y = t.Species;
```

Standardize the predictor data.

```
Z = zscore(X);
```

Train a multiclass ECOC model that uses tall data and linear binary learners. By default, when you pass tall arrays to `fitcecoc`, the software trains linear binary learners that use SVMs. Because the response data contains only three unique classes, change the coding scheme from one-versus-all (which is the default when you use tall data) to one-versus-one (which is the default when you use in-memory data).

For reproducibility, set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs”.

```
rng('default')
tallrng('default')
mdlLinear = fitcecoc(Z,Y,'Coding','onevsone')
```

```
Training binary learner 1 (Linear) out of 3.
Training binary learner 2 (Linear) out of 3.
Training binary learner 3 (Linear) out of 3.

mdlLinear =
  CompactClassificationECOC
      ResponseName: 'Y'
        ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    BinaryLearners: {3×1 cell}
      CodingMatrix: [3×3 double]

  Properties, Methods
```

`mdlLinear` is a `CompactClassificationECOC` model composed of three binary learners.

Train a multiclass ECOC model that uses tall data and kernel binary learners. First, create a `templateKernel` object to specify the properties of the kernel binary learners; in particular, increase the number of expansion dimensions to 2^{16}.

```
tKernel = templateKernel('NumExpansionDimensions',2^16)
```

```
tKernel =
Fit template for classification Kernel.

             BetaTolerance: []
                 BlockSize: []
             BoxConstraint: []
                   Epsilon: []
    NumExpansionDimensions: 65536
         GradientTolerance: []
        HessianHistorySize: []
            IterationLimit: []
               KernelScale: []
                    Lambda: []
                   Learner: 'svm'
              LossFunction: []
                    Stream: []
          VerbosityLevel: []
                   Version: 1
                    Method: 'Kernel'
                      Type: 'classification'
```

By default, the kernel binary learners use SVMs.

Pass the `templateKernel` object to `fitcecoc` and change the coding scheme to one-versus-one.

```
mdlKernel = fitcecoc(Z,Y,'Learners',tKernel,'Coding','onevsone')
```

```
Training binary learner 1 (Kernel) out of 3.
Training binary learner 2 (Kernel) out of 3.
Training binary learner 3 (Kernel) out of 3.
```

```
mdlKernel =
  CompactClassificationECOC
      ResponseName: 'Y'
        ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    BinaryLearners: {3×1 cell}
      CodingMatrix: [3×3 double]

  Properties, Methods
```

`mdlKernel` is also a `CompactClassificationECOC` model composed of three binary learners.

Compare the resubstitution classification error of the two models.

```
errorLinear = gather(loss(mdlLinear,Z,Y))
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1.4 sec
Evaluation completed in 1.6 sec

errorLinear = 0.0333
```

```
errorKernel = gather(loss(mdlKernel,Z,Y))
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 15 sec
Evaluation completed in 16 sec

errorKernel = 0.0067
```

`mdlKernel` misclassifies a smaller percentage of the training data than `mdlLinear`.

Input Arguments

`Tbl` — Sample data

table

Sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not accepted.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, specify a formula using `formula`.

If `Tbl` does not contain the response variable, specify a response variable using `Y`. The length of response variable and the number of `Tbl` rows must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the ECOC model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If `Y` is a character array, then each element must correspond to one row of the array.

The length of `Y` and the number of rows of `Tbl` or `X` must be equal.

It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`X` — Predictor data
full matrix | sparse matrix

Predictor data, specified as a full or sparse matrix.

The length of `Y` and the number of observations in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Note

- For linear classification learners, if you orient `X` so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you can experience a significant reduction in optimization-execution time.
- For all other learners, orient `X` so that observations correspond to rows.
- `fitcecoc` supports sparse matrices for training linear classification models only.

Data Types: `double` | `single`

Note The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing data. The software removes rows of `X` corresponding to missing values in `Y`. However, the treatment of missing values in `X` varies among binary learners. For details, see the training functions for your binary learners: `fitcdiscr`, `fitckernel`, `fitcknn`, `fitclinear`, `fitcnb`, `fitcsvm`, `fitctree`, or `fitcensemble`. Removing observations decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'Learners','tree','Coding','onevsone','CrossVal','on'` specifies to use decision trees for all binary learners, a one-versus-one coding design, and to implement 10-fold cross-validation.

ECOC Classifier Options

`Coding` — Coding design

`'onevsone'` (default) | `'allpairs'` | `'binarycomplete'` | `'denserandom'` | `'onevsall'` | `'ordinal'` | `'sparserandom'` | `'ternarycomplete'` | numeric matrix

Coding design name, specified as the comma-separated pair consisting of `'Coding'` and a numeric matrix or a value in this table.

Value	Number of Binary Learners	Description
`'allpairs'` and `'onevsone'`	$K(K-1)/2$	For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.
`'binarycomplete'`	$2^{(K-1)}-1$	This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are `-1` and `1` with at least one positive and negative class in the assignment.
`'denserandom'`	Random, but approximately $10\log_2 K$	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 33-1646.
`'onevsall'`	K	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.
`'ordinal'`	$K-1$	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.
`'sparserandom'`	Random, but approximately $15\log_2 K$	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 33-1646.

Value	Number of Binary Learners	Description
`'ternarycomplete'`	$\left(3^K - 2^{(K+1)} + 1\right)/2$	This design partitions the classes into all ternary combinations. All class assignments are `0`, `-1`, and `1` with at least one positive and one negative class in the assignment.

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a *K*-by-*L* matrix. Each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in `ClassNames`. Compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be `-1`, `0`, or `1`, and the value must correspond to a dichotomous class assignment. This table describes the meaning of `Coding(i,j)`, that is, the class that learner `j` assigns to observations in class `i`.

Value	Dichotomous Class Assignment
−1	Learner `j` assigns observations in class `i` to a negative class.
`0`	Before training, learner `j` removes observations in class `i` from the data set.
`1`	Learner `j` assigns observations in class `i` to a positive class.

- Every column must contain at least one `-1` or `1`.
- For all column indices `i`,`j` such that `i` ≠ `j`, `Coding(:,i)` cannot equal `Coding(:,j)` and `Coding(:,i)` cannot equal `-Coding(:,j)`.
- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 33-1644.

Example: `'Coding','ternarycomplete'`

Data Types: `char` | `string` | `double` | `single` | `int16` | `int32` | `int64` | `int8`

`FitPosterior` — Flag indicating whether to transform scores to posterior probabilities
`false` or `0` (default) | `true` or `1`

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of `'FitPosterior'` and a `true` (`1`) or `false` (`0`).

If `FitPosterior` is `true`, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using `kfoldPredict`, `predict`, or `resubPredict`.

`fitcecoc` does not support fitting posterior probabilities if:

- The ensemble method is `AdaBoostM2`, `LPBoost`, `RUSBoost`, `RobustBoost`, or `TotalBoost`.

- The binary learners (`Learners`) are linear or kernel classification models that implement SVM. To obtain posterior probabilities for linear or kernel classification models, implement logistic regression instead.

Example: `'FitPosterior',true`

Data Types: `logical`

`Learners` — Binary learner templates
`'svm'` (default) | `'discriminant'` | `'kernel'` | `'knn'` | `'linear'` | `'naivebayes'` | `'tree'` | template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of `'Learners'` and a character vector, string scalar, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM, and the ensembles that use `GentleBoost`, `LogitBoost`, and `RobustBoost`, to solve multiclass problems. However, `fitcecoc` also supports multiclass models as binary classifiers.

- If `Learners` is a character vector or string scalar, then the software trains each binary learner using the default values of the specified algorithm. This table summarizes the available algorithms.

Value	Description
`'discriminant'`	Discriminant analysis. For default options, see `templateDiscriminant`.
`'kernel'`	Kernel classification model. For default options, see `templateKernel`.
`'knn'`	*k*-nearest neighbors. For default options, see `templateKNN`.
`'linear'`	Linear classification model. For default options, see `templateLinear`.
`'naivebayes'`	Naive Bayes. For default options, see `templateNaiveBayes`.
`'svm'`	SVM. For default options, see `templateSVM`.
`'tree'`	Classification trees. For default options, see `templateTree`.

- If `Learners` is a template object, then each binary learner trains according to the stored options. You can create a template object using:
  - `templateDiscriminant`, for discriminant analysis.
  - `templateEnsemble`, for ensemble learning. You must at least specify the learning method (`Method`), the number of learners (`NLearn`), and the type of learner (`Learners`). You cannot use the `AdaBoostM2` ensemble method for binary learning.
  - `templateKernel`, for kernel classification.
  - `templateKNN`, for *k*-nearest neighbors.
  - `templateLinear`, for linear classification.
  - `templateNaiveBayes`, for naive Bayes.
  - `templateSVM`, for SVM.

  - `templateTree`, for classification trees.
- If `Learners` is a cell vector of template objects, then:
  - Cell *j* corresponds to binary learner *j* (in other words, column *j* of the coding design matrix), and the cell vector must have length *L*. *L* is the number of columns in the coding design matrix. For details, see `Coding`.
  - To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners. The former returns a score in the range (-∞,∞), and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as `predict` and `loss`.
  - You cannot specify linear classification model learner templates with any other template.
  - Similarly, you cannot specify kernel classification model learner templates with any other template.

By default, the software trains learners using default SVM templates.

Example: `'Learners','tree'`

`NumBins` — Number of bins for numeric predictors
`[]` (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar. This argument is valid only when `fitcecoc` uses a tree learner, that is, `'Learners'` is either `'tree'` or a template object created by using `templateTree`, or a template object created by using `templateEnsemble` with tree weak learners.

- If the `'NumBins'` value is empty (default), then `fitcecoc` does not bin any predictors.
- If you specify the `'NumBins'` value as a positive integer scalar (`numBins`), then `fitcecoc` bins every numeric predictor into at most `numBins` equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - The number of bins can be less than `numBins` if a predictor has fewer than `numBins` unique values.
  - `fitcecoc` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but might cause a potential decrease in accuracy. You can try `'NumBins',50` first, and then change the value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single` | `double`

`NumConcurrent` — Number of binary learners concurrently trained
`1` (default) | positive integer scalar

Number of binary learners concurrently trained, specified as the comma-separated pair consisting of `'NumConcurrent'` and a positive integer scalar. The default value is `1`, which means `fitcecoc` trains the binary learners sequentially.

Note This option applies only when you use `fitcecoc` on tall arrays. See “Tall Arrays” on page 33-1647 for more information.

Data Types: `single` | `double`

`ObservationsIn` — Predictor data observation dimension

`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`.

Note

- For linear classification learners, if you orient `X` so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you can experience a significant reduction in optimization-execution time.
- For all other learners, orient `X` so that observations correspond to rows.

Example: `'ObservationsIn','columns'`

`Verbose` — Verbosity level

`0` (default) | `1` | `2`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0`, `1`, or `2`. `Verbose` controls the amount of diagnostic information per binary learner that the software displays in the Command Window.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software does not display diagnostic information.
`1`	The software displays diagnostic messages every time it trains a new binary learner.
`2`	The software displays extra diagnostic messages every time it trains a new binary learner.

Each binary learner has its own verbosity level that is independent of this name-value pair argument. To change the verbosity level of a binary learner, create a template object and specify the `'Verbose'` name-value pair argument. Then, pass the template object to `fitcecoc` by using the `'Learners'` name-value pair argument.

Example: `'Verbose',1`

Data Types: `double` | `single`

Cross-Validation Options

`CrossVal` — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair arguments. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the *n* observations, where *n* is `size(Mdl.X,1)`, the software:

1. Reserves the observation as validation data, and trains the model using the other *n* – 1 observations
2. Stores the *n* compact, trained models in the cells of a *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Note Leave-one-out is not recommended for cross-validating ECOC models composed of linear or kernel classification model learners.

Example: `'Leaveout','on'`

Other Classification Options

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitcecoc` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.

Value	Description
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

Specification of `'CategoricalPredictors'` is appropriate if:

- At least one predictor is categorical and all binary learners are classification trees, naive Bayes learners, SVMs, linear learners, kernel learners, or ensembles of classification trees.
- All predictors are categorical and at least one binary learner is *k*NN.

If you specify `'CategoricalPredictors'` for any other learner, then the software warns that it cannot train that binary learner. For example, the software cannot train discriminant analysis classifiers using categorical predictors.

Each learner identifies and treats categorical predictors in the same way as the fitting function corresponding to the learner. See `'CategoricalPredictors'` of `fitckernel` for kernel learners, `'CategoricalPredictors'` of `fitcknn` for *k*-nearest learners, `'CategoricalPredictors'` of `fitclinear` for linear learners, `'CategoricalPredictors'` of `fitcnb` for naive Bayes learners, `'CategoricalPredictors'` of `fitcsvm` for SVM learners, and `'CategoricalPredictors'` of `fitctree` for tree learners.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
  - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(K) - eye(K)`, where K is the number of distinct classes.

Example: `'Cost',[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

`Options` — Parallel computing options
`[]` (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `fitcecoc` uses `'Streams'`, `'UseParallel'`, and `'UseSubtreams'` fields.

This table summarizes the available options.

Option	Description
`'Streams'`	A `RandStream` object or cell array of such objects. If you do not specify `Streams`, the software uses the default stream or streams. If you specify `Streams`, use a single object except when the following are true: • You have an open parallel pool. • `UseParallel` is `true`. • `UseSubstreams` is `false`. In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and `Streams` must supply a single random number stream.

Option	Description
'UseParallel'	If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting 'UseParallel',true. The fitcecoc function sends each binary learner to a worker in the pool. When you use decision trees for binary learners, fitcecoc parallelizes training using Intel Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the 'UseParallel' option is not helpful on a single computer. Use this option on a cluster. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.
'UseSubstreams'	Set to true to compute in parallel using the stream specified by 'Streams'. Default is false. For example, set Streams to a type allowing substreams, such as 'mlfg6331_64' or 'mrg32k3a'.

A best practice to ensure more predictable results is to use parpool and explicitly create a parallel pool before you invoke parallel computing using fitcecoc.

Example: 'Options',statset('UseParallel',true)

Data Types: struct

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of PredictorNames depends on the way you supply the training data.

- If you supply X and Y, then you can use PredictorNames to assign names to the predictor variables in X.
  - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
  - By default, PredictorNames is {'x1','x2',...}.
- If you supply Tbl, then you can use PredictorNames to choose which predictor variables to use in training. That is, fitcecoc uses only the predictor variables in PredictorNames and the response variable during training.
  - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
  - By default, PredictorNames contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either 'PredictorNames' or formula, but not both.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: `string` | `cell`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to 1/*K*, where *K* is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to `Mdl.ClassNames` or specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements such that they sum to `1`.
structure	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to `1`.

For more details on how the software incorporates class prior probabilities, see “Prior Probabilities and Cost” on page 33-1645.

Example: `struct('ClassNames',{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)`

Data Types: `single` | `double` | `char` | `string` | `struct`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ScoreTransform` — Score transformation
`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights

numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(`*n*`,1)`, where *n* is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Hyperparameter Optimization

`OptimizeHyperparameters` — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Coding'}` along with the default parameters for the specified `Learners`:
  - `Learners = 'svm'` (default) — `{'BoxConstraint','KernelScale'}`
  - `Learners = 'discriminant'` — `{'Delta','Gamma'}`
  - `Learners = 'kernel'` — `{'KernelScale','Lambda'}`
  - `Learners = 'knn'` — `{'Distance','NumNeighbors'}`
  - `Learners = 'linear'` — `{'Lambda','Learner'}`
  - `Learners = 'naivebayes'` — `{'DistributionNames','Width'}`
  - `Learners = 'tree'` — `{'MinLeafSize'}`
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcecoc` by varying the parameters. For information about cross-validation loss in a different context, see “Classification Loss” on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcecoc` are:

- `Coding` — `fitcecoc` searches among `'onevsall'` and `'onevsone'`.
- The eligible hyperparameters for the chosen `Learners`, as specified in this table.

Learners	Eligible Hyperparameters (Bold = Default)	Default Range
`'discriminant'`	**`Delta`**	Log-scaled in the range `[1e-6,1e3]`
	`DiscrimType`	`'linear'`, `'quadratic'`, `'diagLinear'`, `'diagQuadratic'`, `'pseudoLinear'`, and `'pseudoQuadratic'`
	`Gamma`	Real values in `[0,1]`
`'kernel'`	**`Lambda`**	Positive values log-scaled in the range `[1e-3/NumObservations,1e3/NumObservations]`
	`KernelScale`	Positive values log-scaled in the range `[1e-3,1e3]`
	`Learner`	`'svm'` and `'logistic'`
	`NumExpansionDimensions`	Integers log-scaled in the range `[100,10000]`

Learners	Eligible Hyperparameters (Bold = Default)	Default Range
'knn'	**Distance**	'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'
	DistanceWeight	'equal', 'inverse', and 'squaredinverse'
	Exponent	Positive values in [0.5,3]
	NumNeighbors	Positive integer values log-scaled in the range [1, max(2,round(NumObservations/2))]
	Standardize	'true' and 'false'
'linear'	**Lambda**	Positive values log-scaled in the range [1e-5/NumObservations,1e5/NumObservations]
	Learner	'svm' and 'logistic'
	Regularization	'ridge' and 'lasso'
'naivebayes'	**DistributionNames**	'normal' and 'kernel'
	Width	Positive values log-scaled in the range [MinPredictorDiff/4,max(MaxPredictorRange,MinPredictorDiff)]
	Kernel	'normal', 'box', 'epanechnikov', and 'triangle'
'svm'	**BoxConstraint**	Positive values log-scaled in the range [1e-3,1e3]
	KernelScale	Positive values log-scaled in the range [1e-3,1e3]
	KernelFunction	'gaussian', 'linear', and 'polynomial'
	PolynomialOrder	Integers in the range [2,4]
	Standardize	'true' and 'false'
'tree'	MaxNumSplits	Integers log-scaled in the range [1,max(2,NumObservations-1)]
	MinLeafSize	Integers log-scaled in the range [1,max(2,floor(NumObservations/2))]
	NumVariablesToSample	Integers in the range [1,max(2,NumPredictors)]
	SplitCriterion	'gdi', 'deviance', and 'twoing'

Alternatively, use `hyperparameters` with your chosen `Learners`, such as

```
load fisheriris % hyperparameters requires data and learner
params = hyperparameters('fitcecoc',meas,species,'svm');
```

To see the eligible and default hyperparameters, examine `params`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcecoc',meas,species,'svm');
params(2).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize ECOC Classifier” on page 33-1614.

Example: `'auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`

Field Name	Values	Default
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`

Field Name	Values	Default
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see "Parallel Bayesian Optimization" on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained ECOC model

`ClassificationECOC` model object | `CompactClassificationECOC` model object | `ClassificationPartitionedECOC` cross-validated model object | `ClassificationPartitionedLinearECOC` cross-validated model object | `ClassificationPartitionedKernelECOC` cross-validated model object

Trained ECOC classifier, returned as a `ClassificationECOC` or `CompactClassificationECOC` model object, or a `ClassificationPartitionedECOC`, `ClassificationPartitionedLinearECOC`, or `ClassificationPartitionedKernelECOC` cross-validated model object.

This table shows how the types of model objects returned by `fitcecoc` depend on the type of binary learners you specify and whether you perform cross-validation.

Linear Classification Model Learners	Kernel Classification Model Learners	Cross-Validation	Returned Model Object
No	No	No	`ClassificationECOC`
No	No	Yes	`ClassificationPartitionedECOC`
Yes	No	No	`CompactClassificationECOC`
Yes	No	Yes	`ClassificationPartitionedLinearECOC`
No	Yes	No	`CompactClassificationECOC`
No	Yes	Yes	`ClassificationPartitionedKernelECOC`

`HyperparameterOptimizationResults` — Description of cross-validation optimization of hyperparameters

`BayesianOptimization` object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. `HyperparameterOptimizationResults` is nonempty when the `OptimizeHyperparameters` name-value pair argument is nonempty and the `Learners` name-value pair argument designates linear or kernel binary learners. The value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair argument:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observation from smallest (best) to highest (worst)

Data Types: `table`

Limitations

- `fitcecoc` supports sparse matrices for training linear classification models only. For all other models, supply a full matrix of predictor data instead.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).

- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Coding Design

A coding design is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design, for a particular column (or binary learner):

- A row containing 1 directs the binary learner to group all observations in the corresponding class into a positive class.
- A row containing –1 directs the binary learner to group all observations in the corresponding class into a negative class.
- A row containing 0 directs the binary learner to ignore all observations in the corresponding class.

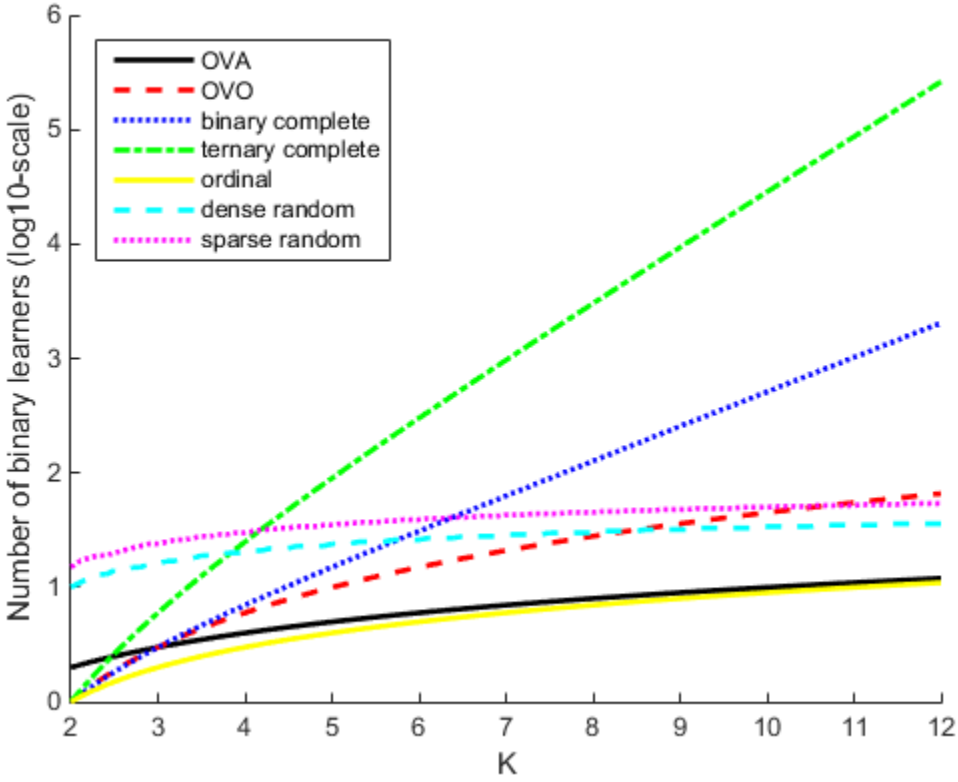
Coding design matrices with large, minimal, pairwise row distances based on the Hamming measure are optimal. For details on the pairwise row distance, see “Random Coding Design Matrices” on page 33-1646 and [4].

This table describes popular coding designs.

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
one-versus-all (OVA)	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.	K	2
one-versus-one (OVO)	For each binary learner, one class is positive, another is negative, and the rest are ignored. This design exhausts all combinations of class pair assignments.	$K(K – 1)/2$	1
binary complete	This design partitions the classes into all binary combinations, and does not ignore any classes. That is, all class assignments are `−1` and `1` with at least one positive class and one negative class in the assignment for each binary learner.	$2^{K-1} – 1$	2^{K-2}
ternary complete	This design partitions the classes into all ternary combinations. That is, all class assignments are `0`, `−1`, and `1` with at least one positive class and one negative class in the assignment for each binary learner.	$(3^K – 2^{K+1} + 1)/2$	3^{K-2}

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
ordinal	For the first binary learner, the first class is negative and the rest are positive. For the second binary learner, the first two classes are negative and the rest are positive, and so on.	K – 1	1
dense random	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 33-1646.	Random, but approximately 10 $\log_2 K$	Variable
sparse random	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 33-1646.	Random, but approximately 15 $\log_2 K$	Variable

This plot compares the number of binary learners for the coding designs with increasing K.



Error-Correcting Output Codes Model

An error-correcting output codes (ECOC) model reduces the problem of classification with three or more classes to a set of binary classification problems.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.

Assume the following:

- The classification problem has three classes.
- The coding design is one-versus-one. For three classes, this coding design is

	Learner 1	Learner 2	Learner 3
Class 1	1	1	0
Class 2	−1	0	1
Class 3	0	−1	−1

- The decoding scheme uses loss g.
- The learners are SVMs.

To build this classification model, the ECOC algorithm follows these steps.

1 Learner 1 trains on observations in Class 1 or Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly.

2 Let M be the coding design matrix with elements m_{kl}, and s_l be the predicted classification score for the positive class of learner l. The algorithm assigns a new observation to the class ($\widehat{k}$) that minimizes the aggregation of the losses for the L binary learners.

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{l=1}^{L} |m_{kl}| g(m_{kl}, s_l)}{\sum_{l=1}^{L} |m_{kl}|}.$$

ECOC models can improve classification accuracy, compared to other multiclass models [2].

Tips

- The number of binary learners grows with the number of classes. For a problem with many classes, the `binarycomplete` and `ternarycomplete` coding designs are not efficient. However:
  - If $K \leq 4$, then use `ternarycomplete` coding design rather than `sparserandom`.
  - If $K \leq 5$, then use `binarycomplete` coding design rather than `denserandom`.

  You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.
- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionchart`).
- Leave-one-out cross-validation (`Leaveout`) is inefficient for data sets with many observations. Instead, use k-fold cross-validation (`KFold`).
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

Custom Coding Design Matrices

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is -1, 0, or 1.
- Every column contains as least one -1 and one 1.
- For all distinct column vectors u and v, $u \neq v$ and $u \neq -v$.
- All rows vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
  - You can move vertically from 1 to -1 or -1 to 1.
  - You can move horizontally from a nonzero element to another nonzero element.

- You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row i to row j using these rules, then classes i and j cannot be separated by the design. For example, in the coding design

$$\begin{bmatrix} 1 & 0 \\ -1 & 0 \\ 0 & 1 \\ 0 & -1 \end{bmatrix}$$

classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

Parallel Computing

If you use parallel computing (see `Options`), then `fitcecoc` trains binary learners in parallel.

Prior Probabilities and Cost

- Prior probabilities — The software normalizes the specified class prior probabilities (`Prior`) for each binary learner. Let M be the coding design matrix and $I(A,c)$ be an indicator matrix. The indicator matrix has the same dimensions as A. If the corresponding element of A is c, then the indicator matrix has elements equaling one, and zero otherwise. Let M_{+1} and M_{-1} be K-by-L matrices such that:
  - $M_{+1} = M \bigcirc I(M,1)$, where $\bigcirc$ is element-wise multiplication (that is, `Mplus = M.*(M == 1)`). Also, let $m_l^{(+1)}$ be column vector l of M_{+1}.
  - $M_{-1} = -M \bigcirc I(M,-1)$ (that is, `Mminus = -M.*(M == -1)`). Also, let $m_l^{(-1)}$ be column vector l of M_{-1}.

  Let $\pi_l^{+1} = m_l^{(+1)} \circ \pi$ and $\pi_l^{-1} = m_l^{(-1)} \circ \pi$, where π is the vector of specified, class prior probabilities (`Prior`).

  Then, the positive and negative, scalar class prior probabilities for binary learner l are

  $$\widehat{\pi}_l^{(j)} = \frac{\left\| \pi_l^{(j)} \right\|_1}{\left\| \pi_l^{(+1)} \right\|_1 + \left\| \pi_l^{(-1)} \right\|_1},$$

  where $j = \{-1,1\}$ and $\|a\|_1$ is the one-norm of a.
- Cost — The software normalizes the K-by-K cost matrix C (`Cost`) for each binary learner. For binary learner l, the cost of classifying a negative-class observation into the positive class is

  $$c_l^{-+} = \left(\pi_l^{(-1)} \right)^{\top} C \pi_l^{(+1)}.$$

  Similarly, the cost of classifying a positive-class observation into the negative class is

  $$c_l^{+-} = \left(\pi_l^{(+1)} \right)^{\top} C \pi_l^{(-1)}.$$

  The cost matrix for binary learner l is

$$C_l = \begin{bmatrix} 0 & c_l^{-+} \\ c_l^{+-} & 0 \end{bmatrix}.$$

ECOC models accommodate misclassification costs by incorporating them with class prior probabilities. If you specify `Prior` and `Cost`, then the software adjusts the class prior probabilities as follows:

$$\tilde{\pi}_l^{-1} = \frac{c_l^{-+}\hat{\pi}_l^{-1}}{c_l^{-+}\hat{\pi}_l^{-1} + c^{+-}\hat{\pi}_l^{+1}}$$

$$\tilde{\pi}_l^{+1} = \frac{c_l^{+-}\hat{\pi}_l^{+1}}{c_l^{-+}\hat{\pi}_l^{-1} + c^{+-}\hat{\pi}_l^{+1}}.$$

Random Coding Design Matrices

For a given number of classes K, the software generates random coding design matrices as follows.

1. The software generates one of these matrices:
   a. Dense random — The software assigns 1 or –1 with equal probability to each element of the K-by-L_d coding design matrix, where $L_d \approx \lceil 10\log_2 K \rceil$.
   b. Sparse random — The software assigns 1 to each element of the K-by-L_s coding design matrix with probability 0.25, –1 with probability 0.25, and 0 with probability 0.5, where $L_s \approx \lceil 15\log_2 K \rceil$.
2. If a column does not contain at least one 1 and at least one –1, then the software removes that column.
3. For distinct columns u and v, if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal, pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5\sum_{l=1}^{L} \left|m_{k_1 l}\right|\left|m_{k_2 l}\right|\left|m_{k_1 l} - m_{k_2 l}\right|,$$

where $m_{k_j l}$ is an element of coding design matrix j.

Support Vector Storage

By default and for efficiency, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties for all linear SVM binary learners. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors',true)
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
  - `Mdl = fitcecoc(X,Y)`
  - `Mdl = fitcecoc(X,Y,Name,Value)`
  - `[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcecoc(X,Y,Name,Value)` — `fitcecoc` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the `'OptimizeHyperparameters'` name-value pair argument.
- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.
- Options related to cross-validation are not supported. The supported name-value pair arguments are:
  - `'ClassNames'`
  - `'Cost'`
  - `'Coding'` — Default value is `'onevsall'`.
  - `'HyperparameterOptimizationOptions'` — For cross-validation, tall optimization supports only `'Holdout'` validation. By default, the software selects and reserves 20% of the data as holdout validation data, and trains the model using the rest of the data. You can specify a different value for the holdout fraction by using this argument. For example, specify `'HyperparameterOptimizationOptions',struct('Holdout',0.3)` to reserve 30% of the data as validation data.
  - `'Learners'` — Default value is `'linear'`. You can specify `'linear'`,`'kernel'`, a `templateLinear` or `templateKernel` object, or a cell array of such objects.

- `'OptimizeHyperparameters'` — When you use linear binary learners, the value of the `'Regularization'` hyperparameter must be `'ridge'`.
- `'Prior'`
- `'Verbose'` — Default value is `1`.
- `'Weights'`

- This additional name-value pair argument is specific to tall arrays:
  - `'NumConcurrent'` — A positive integer scalar specifying the number of binary learners that are trained concurrently by combining file I/O operations. The default value for `'NumConcurrent'` is `1`, which means `fitcecoc` trains the binary learners sequentially. `'NumConcurrent'` is most beneficial when the input arrays cannot fit into the distributed cluster memory. Otherwise, the input arrays can be cached and speedup is negligible.

    If you run your code on Apache Spark™, `NumConcurrent` is upper bounded by the memory available for communications. Check the `'spark.executor.memory'` and `'spark.driver.memory'` properties in your Apache Spark configuration. See `parallel.cluster.Hadoop` (Parallel Computing Toolbox) for more details. For more information on Apache Spark and other execution environments that control where your code runs, see “Extend Tall Arrays with Other Products”.

For more information, see “Tall Arrays”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true` in one of these ways:

- Set the `'UseParallel'` field of the options structure to `true` using `statset` and specify the `'Options'` name-value pair argument in the call to `fitceoc`.

  For example: `'Options',statset('UseParallel',true)`

  For more information, see the `'Options'` name-value pair argument.
- Perform parallel hyperparameter optimization by using the `'HyperparameterOptions',struct('UseParallel',true)` name-value pair argument in the call to `fitceoc`.

  For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

Introduced in R2014b

fitcensemble

Fit ensemble of learners for classification

Syntax

```
Mdl = fitcensemble(Tbl,ResponseVarName)
Mdl = fitcensemble(Tbl,formula)
Mdl = fitcensemble(Tbl,Y)

Mdl = fitcensemble(X,Y)

Mdl = fitcensemble( ___ ,Name,Value)
```

Description

`Mdl = fitcensemble(Tbl,ResponseVarName)` returns the trained classification ensemble model object (`Mdl`) that contains the results of boosting 100 classification trees and the predictor and response data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`. By default, `fitcensemble` uses LogitBoost for binary classification and AdaBoostM2 for multiclass classification.

`Mdl = fitcensemble(Tbl,formula)` applies `formula` to fit the model to the predictor and response data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. For example, `'Y~X1+X2+X3'` fits the response variable `Tbl.Y` as a function of the predictor variables `Tbl.X1`, `Tbl.X2`, and `Tbl.X3`.

`Mdl = fitcensemble(Tbl,Y)` treats all variables in the table `Tbl` as predictor variables. `Y` is the array of class labels that is not in `Tbl`.

`Mdl = fitcensemble(X,Y)` uses the predictor data in the matrix `X` and the array of class labels in `Y`.

`Mdl = fitcensemble( ___ ,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments and any of the input arguments in the previous syntaxes. For example, you can specify the number of learning cycles, the ensemble aggregation method, or to implement 10-fold cross-validation.

Examples

Train Classification Ensemble

Create a predictive classification ensemble using all available predictor variables in the data. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the `census1994` data set.

```
load census1994
```

Train an ensemble of classification models using the entire data set and default options.

```
Mdl1 = fitcensemble(adultdata,'salary')
```

```
Mdl1 =
  ClassificationEnsemble
             PredictorNames: {1x14 cell}
               ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
                ClassNames: [<=50K    >50K]
            ScoreTransform: 'none'
           NumObservations: 32561
                NumTrained: 100
                    Method: 'LogitBoost'
              LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: [100x1 double]
       FitInfoDescription: {2x1 cell}

  Properties, Methods
```

`Mdl` is a `ClassificationEnsemble` model. Some notable characteristics of `Mdl` are:

- Because two classes are represented in the data, LogitBoost is the ensemble aggregation algorithm.
- Because the ensemble aggregation method is a boosting algorithm, classification trees that allow a maximum of 10 splits compose the ensemble.
- One hundred trees compose the ensemble.

Use the classification ensemble to predict the labels of a random set of five observations from the data. Compare the predicted labels with their true values.

```
rng(1) % For reproducibility
[pX,pIdx] = datasample(adultdata,5);
label = predict(Mdl1,pX);
table(label,adultdata.salary(pIdx),'VariableNames',{'Predicted','Truth'})
```

```
ans=5×2 table
    Predicted    Truth
    _________    _____

      <=50K      <=50K
      <=50K      <=50K
      <=50K      <=50K
      <=50K      <=50K
      <=50K      <=50K
```

Train a new ensemble using `age` and `education` only.

```
Mdl2 = fitcensemble(adultdata,'salary ~ age + education');
```

Compare the resubstitution losses between `Mdl1` and `Mdl2`.

```
rsLoss1 = resubLoss(Mdl1)
```

```
rsLoss1 = 0.1058
```

```
rsLoss2 = resubLoss(Mdl2)
```

```
rsLoss2 = 0.2037
```

The in-sample misclassification rate for the ensemble that uses all predictors is lower.

Speed Up Training by Binning Numeric Predictor Values

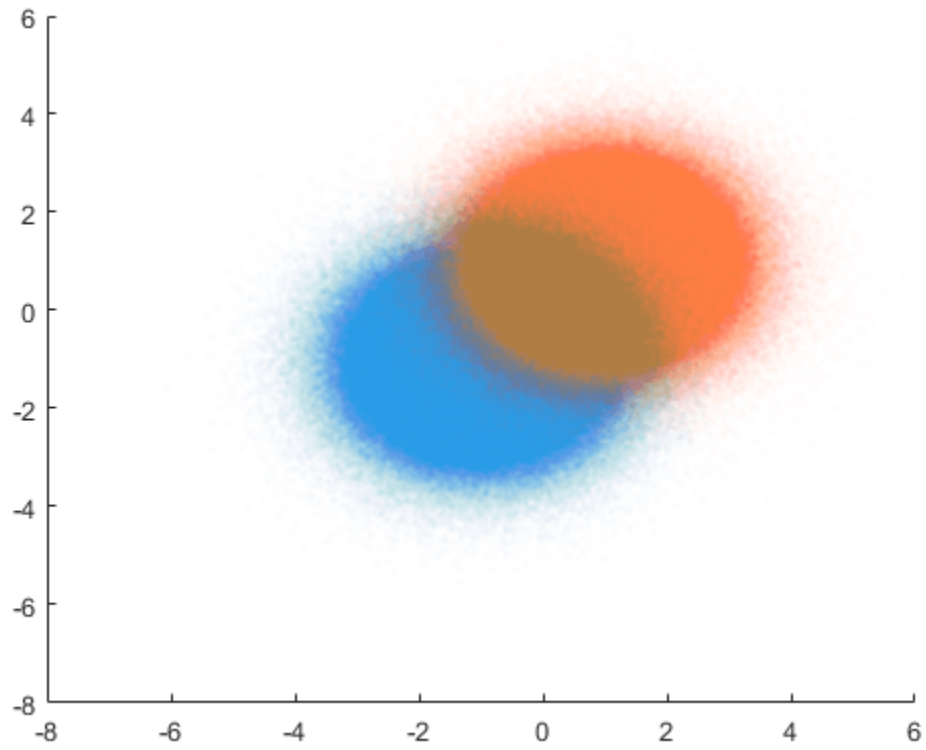
Train an ensemble of boosted classification trees by using `fitcensemble`. Reduce training time by specifying the `'NumBins'` name-value pair argument to bin numeric predictors. This argument is valid only when `fitcensemble` uses a tree learner. After training, you can reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

Generate a sample data set.

```
rng('default') % For reproducibility
N = 1e6;
X = [mvnrnd([-1 -1],eye(2),N); mvnrnd([1 1],eye(2),N)];
y = [zeros(N,1); ones(N,1)];
```

Visualize the data set.

```
figure
scatter(X(1:N,1),X(1:N,2),'Marker','.','MarkerEdgeAlpha',0.01)
hold on
scatter(X(N+1:2*N,1),X(N+1:2*N,2),'Marker','.','MarkerEdgeAlpha',0.01)
```



Train an ensemble of boosted classification trees using adaptive logistic regression (`LogitBoost`, the default for binary classification). Time the function for comparison purposes.

```
tic
Mdl1 = fitcensemble(X,y);
toc
```

```
Elapsed time is 478.988422 seconds.
```

Speed up training by using the `'NumBins'` name-value pair argument. If you specify the `'NumBins'` value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. The software does not bin categorical predictors.

```
tic
Mdl2 = fitcensemble(X,y,'NumBins',50);
toc
```

```
Elapsed time is 165.598434 seconds.
```

The process is about three times faster when you use binned data instead of the original data. Note that the elapsed time can vary depending on your operating system.

Compare the classification errors by resubstitution.

```
rsLoss1 = resubLoss(Mdl1)
```

```
rsLoss1 = 0.0788
```

```
rsLoss2 = resubLoss(Mdl2)
```

```
rsLoss2 = 0.0788
```

In this example, binning predictor values reduces training time without loss of accuracy. In general, when you have a large data set like the one in this example, using the binning option speeds up training but causes a potential decrease in accuracy. If you want to reduce training time further, specify a smaller number of bins.

Reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

```
X = Mdl2.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl2.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are `0` for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

Estimate Generalization Error of Boosting Ensemble

Estimate the generalization error of ensemble of boosted classification trees.

Load the `ionosphere` data set.

```
load ionosphere
```

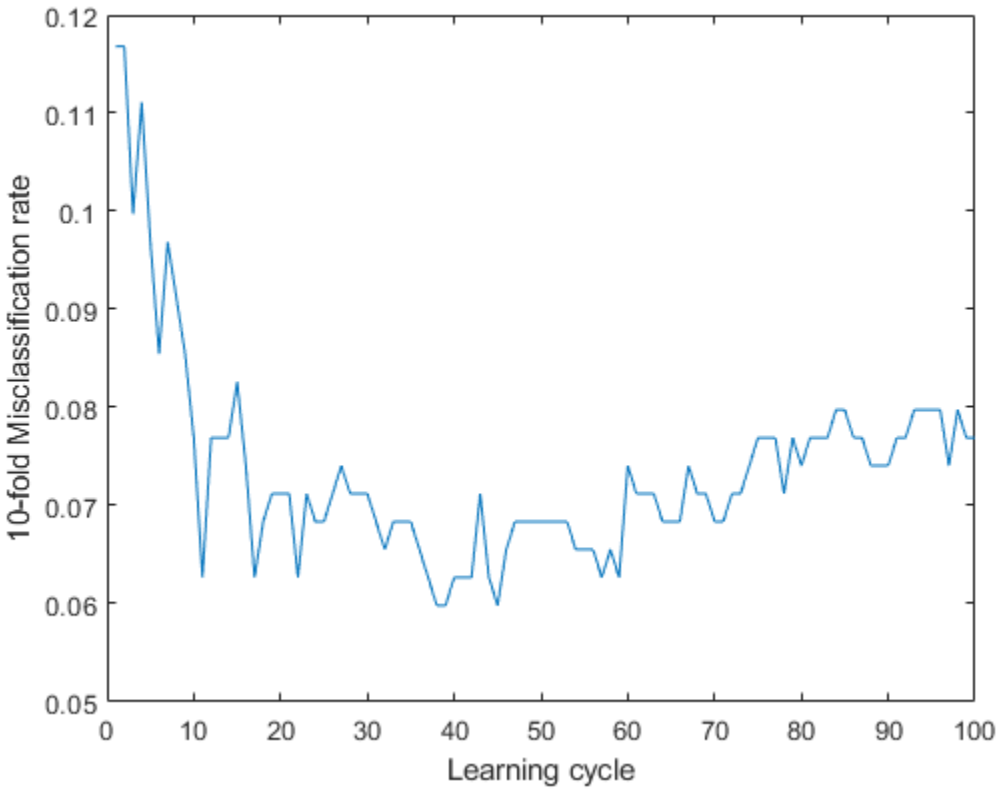
Cross-validate an ensemble of classification trees using AdaBoostM1 and 10-fold cross-validation. Specify that each tree should be split a maximum of five times using a decision tree template.

```
rng(5); % For reproducibility
t = templateTree('MaxNumSplits',5);
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t,'CrossVal','on');
```

`Mdl` is a `ClassificationPartitionedEnsemble` model.

Plot the cumulative, 10-fold cross-validated, misclassification rate. Display the estimated generalization error of the ensemble.

```
kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold Misclassification rate');
xlabel('Learning cycle');
```



```
estGenError = kflc(end)
```

```
estGenError = 0.0769
```

`kfoldLoss` returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves a misclassification rate of around 0.06 after accumulating about 50 weak learners. Then, the misclassification rate increase slightly as more weak learners enter the ensemble.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-validation. However, it is good practice to tune hyperparameters, such as the maximum number of decision splits per tree and the number of learning cycles.

Optimize Classification Ensemble

Optimize hyperparameters automatically using `fitcensemble`.

Load the `ionosphere` data set.

```
load ionosphere
```

You can find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

```
Mdl = fitcensemble(X,Y,'OptimizeHyperparameters','auto')
```

In this example, for reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function. Also, for reproducibility of random forest algorithm, specify the `'Reproducible'` name-value pair argument as `true` for tree learners.

```
rng('default')
t = templateTree('Reproducible',true);
Mdl = fitcensemble(X,Y,'OptimizeHyperparameters','auto','Learners',t, ...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-p
```

```

  Properties, Methods
```

The optimization searched over the ensemble aggregation methods for binary classification, over `NumLearningCycles`, over the `LearnRate` for applicable methods, and over the tree learner `MinLeafSize`. The output is the ensemble classifier with the minimum estimated cross-validation loss.

Optimize Classification Ensemble Using Cross-Validation

One way to create an ensemble of boosted classification trees that has satisfactory predictive performance is by tuning the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles.

This example manually finds optimal parameters by using the cross-validation option (the `'KFold'` name-value pair argument) and the `kfoldLoss` function. Alternatively, you can use the `'OptimizeHyperparameters'` name-value pair argument to optimize hyperparameters automatically. See “Optimize Classification Ensemble” on page 33-1654.

Load the `ionosphere` data set.

```
load ionosphere
```

To search for the optimal tree-complexity level:

1. Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most n - 1 splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.
2. Estimate the cross-validated misclassification rate of each ensemble.
3. For tree-complexity level j, $j = 1 \ldots J$, compare the cumulative, cross-validated misclassification rate of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
4. Choose the curve that achieves the minimal misclassification rate, and note the corresponding learning cycle and learning rate.

Cross-validate a deep classification tree and a stump. These classification trees serve as benchmarks.

```
rng(1) % For reproducibility
MdlDeep = fitctree(X,Y,'CrossVal','on','MergeLeaves','off', ...
    'MinParentSize',1);
MdlStump = fitctree(X,Y,'MaxNumSplits',1,'CrossVal','on');
```

Cross-validate an ensemble of 150 boosted classification trees using 5-fold cross-validation. Using a tree template, vary the maximum number of splits using the values in the sequence $\{3^0, 3^1, \ldots, 3^m\}$. m is such that 3^m is no greater than n - 1. For each variant, adjust the learning rate using each value in the set {0.1, 0.25, 0.5, 1};

```
n = size(X,1);
m = floor(log(n - 1)/log(3));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 3.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);

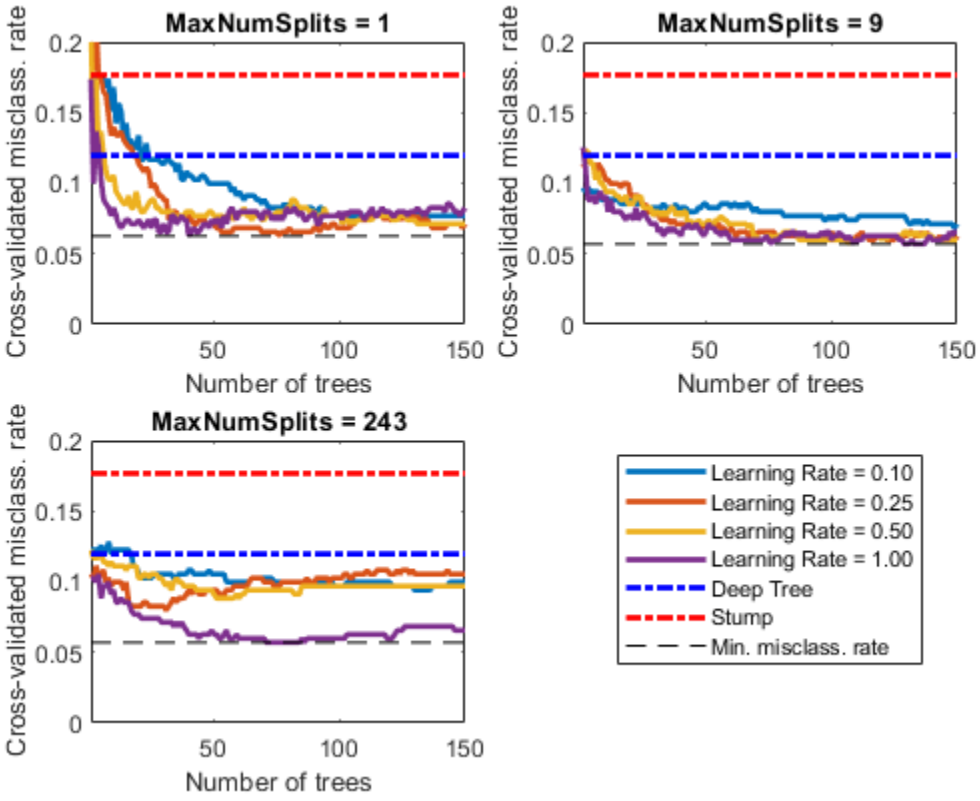
for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits',maxNumSplits(j));
        Mdl{j,k} = fitcensemble(X,Y,'NumLearningCycles',numTrees,...
            'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end
end
```

Estimate the cumulative, cross-validated misclassification rate for each ensemble and the classification trees serving as benchmarks.

```
kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);
```

Plot how the cross-validated misclassification rate behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```
mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure
for k = 1:3
    subplot(2,2,k)
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2)
    axis tight
    hold on
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'-.b','LineWidth',2)
    plot(h.XLim,[errorStump errorStump],'-.r','LineWidth',2)
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'--k')
    h.YLim = [0 0.2];
    xlabel('Number of trees')
    ylabel('Cross-validated misclass. rate')
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
    hold off
end
hL = legend([cellstr(num2str(learnRate','Learning Rate = %0.2f')); ...
        'Deep Tree';'Stump';'Min. misclass. rate']);
hL.Position(1) = 0.6;
```



Each curve contains a minimum cross-validated misclassification rate occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest misclassification rate overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);

fprintf('\nMin. misclass. rate = %0.5f',minErr)

Min. misclass. rate = 0.05413

fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);

Optimal Parameter Values:
Num. Trees = 47

fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
    maxNumSplits(idxMNS),learnRate(idxLR))

MaxNumSplits = 3
Learning Rate = 0.25
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```
tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS));
MdlFinal = fitcensemble(X,Y,'NumLearningCycles',idxNumTrees,...
    'Learners',tFinal,'LearnRate',learnRate(idxLR))

MdlFinal =
  ClassificationEnsemble
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}

               NumTrained: 47
                   Method: 'LogitBoost'
             LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: [47×1 double]
       FitInfoDescription: {2×1 cell}

  Properties, Methods
```

`MdlFinal` is a `ClassificationEnsemble`. To predict whether a radar return is good given predictor data, you can pass the predictor data and `MdlFinal` to `predict`.

Instead of searching optimal values manually by using the cross-validation option (`'KFold'`) and the `kfoldLoss` function, you can use the `'OptimizeHyperparameters'` name-value pair argument. When you specify `'OptimizeHyperparameters'`, the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using `'OptimizeHyperparameters'` can be different from those obtained using manual search.

```
mdl = fitcensemble(X,Y,'OptimizeHyperparameters',{'NumLearningCycles','LearnRate','MaxNumSplits'

  Properties, Methods
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using `formula`.
- If `Tbl` does not contain the response variable, then specify the response data using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Note To save memory and execution time, supply `X` and `Y` instead of `Tbl`.

Data Types: `table`

`ResponseVarName` — Response variable name

name of response variable in `Tbl`

Response variable name, specified as the name of the response variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitcensemble` treats all columns of `Tbl` as predictor variables.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitcensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`X` — Predictor data
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

`Y` — Response data
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each entry in `Y` is the response to or label for the observation in the corresponding row of `X` or `Tbl`. The length of `Y` and the number of rows of `X` or `Tbl` must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

You can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitcensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'CrossVal','on','LearnRate',0.05` specifies to implement 10-fold cross-validation and to use `0.05` as the learning rate.

General Ensemble Options

`Method` — Ensemble aggregation method
`'Bag'` | `'Subspace'` | `'AdaBoostM1'` | `'AdaBoostM2'` | `'GentleBoost'` | `'LogitBoost'` | `'LPBoost'` | `'RobustBoost'` | `'RUSBoost'` | `'TotalBoost'`

Ensemble aggregation method, specified as the comma-separated pair consisting of `'Method'` and one of the following values.

Value	Method	Classification Problem Support	Related Name-Value Pair Arguments
`'Bag'`	Bootstrap aggregation (bagging, for example, random forest[2]) — If `'Method'` is `'Bag'`, then `fitcensemble` uses bagging with random predictor selections at each split (random forest) by default. To use bagging without the random selections, use tree learners whose `'NumVariablesToSample'` value is `'all'` or use discriminant analysis learners.	Binary and multiclass	N/A
`'Subspace'`	Random subspace	Binary and multiclass	`NPredToSample`
`'AdaBoostM1'`	Adaptive boosting	Binary only	`LearnRate`
`'AdaBoostM2'`	Adaptive boosting	Multiclass only	`LearnRate`
`'GentleBoost'`	Gentle adaptive boosting	Binary only	`LearnRate`
`'LogitBoost'`	Adaptive logistic regression	Binary only	`LearnRate`
`'LPBoost'`	Linear programming boosting — Requires Optimization Toolbox	Binary and multiclass	`MarginPrecision`

Value	Method	Classification Problem Support	Related Name-Value Pair Arguments
`'RobustBoost'`	Robust boosting — Requires Optimization Toolbox	Binary only	`RobustErrorGoal`, `RobustMarginSigma`, `RobustMaxMargin`
`'RUSBoost'`	Random undersampling boosting	Binary and multiclass	`LearnRate`, `RatioToSmallest`
`'TotalBoost'`	Totally corrective boosting — Requires Optimization Toolbox	Binary and multiclass	`MarginPrecision`

You can specify sampling options (`FResample`, `Replace`, `Resample`) for training data when you use bagging (`'Bag'`) or boosting (`'TotalBoost'`, `'RUSBoost'`, `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, `'LogitBoost'`, `'RobustBoost'`, or `'LPBoost'`).

The defaults are:

- `'LogitBoost'` for binary problems and `'AdaBoostM2'` for multiclass problems if `'Learners'` includes only tree learners
- `'AdaBoostM1'` for binary problems and `'AdaBoostM2'` for multiclass problems if `'Learners'` includes both tree and discriminant analysis learners
- `'Subspace'` if `'Learners'` does not include tree learners

For details about ensemble aggregation algorithms and examples, see “Algorithms” on page 33-1684, “Tips” on page 33-1683, “Ensemble Algorithms” on page 18-39, and “Choose an Applicable Ensemble Aggregation Method” on page 18-32.

Example: `'Method','Bag'`

`NumLearningCycles` — Number of ensemble learning cycles
`100` (default) | positive integer | `'AllPredictorCombinations'`

Number of ensemble learning cycles, specified as the comma-separated pair consisting of `'NumLearningCycles'` and a positive integer or `'AllPredictorCombinations'`.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NumLearningCycles*numel(Learners)` learners.
- If you specify `'AllPredictorCombinations'`, then set `Method` to `'Subspace'` and specify one learner only for `Learners`. With these settings, the software trains learners for all possible combinations of predictors taken `NPredToSample` at a time. Consequently, the software trains `nchoosek(size(X,2),NPredToSample)` learners.

The software composes the ensemble using all trained learners and stores them in `Mdl.Trained`.

For more details, see “Tips” on page 33-1683.

Example: `'NumLearningCycles',500`

Data Types: `single` | `double` | `char` | `string`

`Learners` — Weak learners to use in ensemble
`'discriminant'` | `'knn'` | `'tree'` | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as the comma-separated pair consisting of `'Learners'` and a weak-learner name, weak-learner template object, or cell vector of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Setting
Discriminant analysis	`'discriminant'`	`templateDiscriminant`	Recommended for `'Subspace'`
k-nearest neighbors	`'knn'`	`templateKNN`	For `'Subspace'` only
Decision tree	`'tree'`	`templateTree`	All methods except `'Subspace'`

- Weak-learner name (`'discriminant'`, `'knn'`, or `'tree'`) — `fitcensemble` uses weak learners created by a template object creation function with default settings. For example, specifying `'Learners','discriminant'` is the same as specifying `'Learners',templateDiscriminant()`. See the template object creation function pages for the default settings of a weak learner.
- Weak-learner template object — `fitcensemble` uses the weak learners created by a template object creation function. Use the name-value pair arguments of the template object creation function to specify the settings of the weak learners.
- Cell vector of *m* weak-learner template objects — `fitcensemble` grows *m* learners per learning cycle (see `NumLearningCycles`). For example, for an ensemble composed of two types of classification trees, supply `{t1 t2}`, where `t1` and `t2` are classification tree template objects returned by `templateTree`.

The default `'Learners'` value is `'knn'` if `'Method'` is `'Subspace'`.

The default `'Learners'` value is `'tree'` if `'Method'` is `'Bag'` or any boosting method. The default values of `templateTree()` depend on the value of `'Method'`.

- For bagged decision trees, the maximum number of decision splits (`'MaxNumSplits'`) is `n–1`, where `n` is the number of observations. The number of predictors to select at random for each split (`'NumVariablesToSample'`) is the square root of the number of predictors. Therefore, `fitcensemble` grows deep decision trees. You can grow shallower trees to reduce model complexity or computation time.
- For boosted decision trees, `'MaxNumSplits'` is 10 and `'NumVariablesToSample'` is `'all'`. Therefore, `fitcensemble` grows shallow decision trees. You can grow deeper trees for better accuracy.

See `templateTree` for the default settings of a weak learner. To obtain reproducible results, you must specify the `'Reproducible'` name-value pair argument of `templateTree` as `true` if `'NumVariablesToSample'` is not `'all'`.

For details on the number of learners to train, see `NumLearningCycles` and “Tips” on page 33-1683.

Example: `'Learners',templateTree('MaxNumSplits',5)`

`NPrint` — Printout frequency
`'off'` (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of `'NPrint'` and a positive integer or `'off'`.

To track the number of *weak learners* or *folds* that `fitcensemble` trained so far, specify a positive integer. That is, if you specify the positive integer *m*:

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitcensemble` displays a message to the command line every time it completes training *m* weak learners.
- And a cross-validation option, then `fitcensemble` displays a message to the command line every time it finishes training *m* folds.

If you specify `'off'`, then `fitcensemble` does not display a message when it completes training weak learners.

Tip For fastest training of some boosted decision trees, set `NPrint` to the default value `'off'`. This tip holds when the classification `Method` is `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, or `'LogitBoost'`, or when the regression `Method` is `'LSBoost'`.

Example: `'NPrint',5`

Data Types: `single` | `double` | `char` | `string`

`NumBins` — Number of bins for numeric predictors

`[]` (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar. This argument is valid only when `fitcensemble` uses a tree learner, that is, `'Learners'` is either `'tree'` or a template object created by using `templateTree`.

- If the `'NumBins'` value is empty (default), then `fitcensemble` does not bin any predictors.
- If you specify the `'NumBins'` value as a positive integer scalar (`numBins`), then `fitcensemble` bins every numeric predictor into at most `numBins` equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - The number of bins can be less than `numBins` if a predictor has fewer than `numBins` unique values.
  - `fitcensemble` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but might cause a potential decrease in accuracy. You can try `'NumBins',50` first, and then change the value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single` | `double`

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitcensemble` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

Specification of `'CategoricalPredictors'` is appropriate if:

- `'Learners'` specifies tree learners.
- `'Learners'` specifies *k*-nearest learners where all predictors are categorical.

Each learner identifies and treats categorical predictors in the same way as the fitting function corresponding to the learner. See `'CategoricalPredictors'` of `fitcknn` for *k*-nearest learners and `'CategoricalPredictors'` of `fitctree` for tree learners.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`PredictorNames` — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitcensemble` uses only the predictor variables in `PredictorNames` and the response variable during training.

- `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
- By default, `PredictorNames` contains the names of all predictor variables.
- A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

Parallel Options

`Options` — Options for computing in parallel and setting random numbers
structure

Options for computing in parallel and setting random numbers, specified as a structure. Create the `Options` structure with `statset`.

Note You need Parallel Computing Toolbox to compute in parallel.

This table lists the option fields and their values.

Field Name	Value	Default
`UseParallel`	Set this value to `true` to compute in parallel. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.	`false`

Field Name	Value	Default
`UseSubstreams`	Set this value to `true` to run computations in parallel in a reproducible manner. To compute reproducibly, set `Streams` to a type that allows substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Also, use a tree template with the `'Reproducible'` name-value argument set to `true`. See “Reproducibility in Parallel Statistical Computations” on page 31-13.	`false`
`Streams`	Specify this value as a `RandStream` object or cell array of such objects. Use a single object except when the `UseParallel` value is `true` and the `UseSubstreams` value is `false`. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify `Streams`, then `fitcensemble` uses the default stream or streams.

For an example using reproducible parallel training, see “Train Classification Ensemble in Parallel” on page 18-109.

For dual-core systems and above, `fitcensemble` parallelizes training using Intel Threading Building Blocks (TBB). Therefore, specifying the `UseParallel` option as `true` might not provide a significant speedup on a single computer. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Cross-Validation Options

`CrossVal` — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other n – 1 observations.
2. Store the n compact, trained models in an n-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Other Classification Options

`ClassNames` — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
  - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(K) - eye(K)`, where K is the number of distinct classes.

Note `fitcensemble` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitcensemble` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost',[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

`Prior` — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to `Mdl.ClassNames` or specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements such that they sum to `1`.
structure array	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to `1`.

`fitcensemble` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `struct('ClassNames', {{'setosa','versicolor','virginica'}},'ClassProbs',1:3)`

Data Types: `char` | `string` | `double` | `single` | `struct`

`ScoreTransform` — Score transformation

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$

Value	Description
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights

numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(`*n*`,1)`, where *n* is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Sampling Options for Boosting Methods and Bagging

`FResample` — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in (0,1].

To use `'FResample'`, specify `'bag'` for `Method` or set `Resample` to `'on'`.

Example: 'FResample',0.75

Data Types: single | double

Replace — Flag indicating to sample with replacement
'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set Resample to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set Method to 'bag' or set Resample to 'on', Replace has no effect.

Example: 'Replace','off'

Resample — Flag indicating to resample
'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is a boosting method, then:
  - 'Resample','on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - 'Resample','off'(default) specifies to reweight observations at every learning iteration.
- If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

If you specify to resample using Resample, then it is good practice to resample to entire data set. That is, use the default setting of 1 for FResample.

AdaBoostM1, AdaBoostM2, LogitBoost, and GentleBoost Method Options

LearnRate — Learning rate for shrinkage
1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of 'LearnRate' and a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set LearnRate to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

RUSBoost Method Options

LearnRate — Learning rate for shrinkage
1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of `'LearnRate'` and a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than `1`, for example, `0.1` is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate',0.1`

Data Types: `single` | `double`

`RatioToSmallest` — Sampling proportion with respect to lowest-represented class

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of `'RatioToSmallest'` and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are K classes in the training data and the lowest-represented class has m observations in the training data.

- If you specify the positive numeric scalar s, then `fitcensemble` samples $s*m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 33-2275.
- If you specify the numeric vector $[s1,s2,...,sK]$, then `fitcensemble` samples $si*m$ observations from class i, $i = 1,...,K$. The elements of `RatioToSmallest` correspond to the order of the class names specified using `ClassNames` (see “Tips” on page 33-2274).

The default value is `ones(`K`,1)`, which specifies to sample m observations from each class.

Example: `'RatioToSmallest',[2,1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options

`MarginPrecision` — Margin precision to control convergence speed

`0.1` (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of `'MarginPrecision'` and a numeric scalar in the interval [0,1]. `MarginPrecision` affects the number of boosting iterations required for convergence.

Tip To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision',0.5`

Data Types: `single` | `double`

RobustBoost Method Options

`RobustErrorGoal` — Target classification error

`0.1` (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of `'RobustErrorGoal'` and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed `1`.

Tip For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal',0.05`

Data Types: `single` | `double`

`RobustMarginSigma` — Classification margin distribution spread

`0.1` (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of `'RobustMarginSigma'` and a positive numeric scalar. Before specifying `RobustMarginSigma`, consult the literature on `RobustBoost`, for example, [19].

Example: `'RobustMarginSigma',0.5`

Data Types: `single` | `double`

`RobustMaxMargin` — Maximal classification margin

`0` (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of `'RobustMaxMargin'` and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below `RobustMaxMargin`.

Example: `'RobustMaxMargin',1`

Data Types: `single` | `double`

Random Subspace Method Options

`NPredToSample` — Number of predictors to sample

`1` (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of `'NPredToSample'` and a positive integer in the interval 1,...,*p*, where *p* is the number of predictor variables (`size(X,2)` or `size(Tbl,2)`).

Data Types: `single` | `double`

Hyperparameter Optimization Options

`OptimizeHyperparameters` — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.

- `'auto'` — Use `{'Method','NumLearningCycles','LearnRate'}` along with the default parameters for the specified `Learners`:
  - `Learners = 'tree'` (default) — `{'MinLeafSize'}`
  - `Learners = 'discriminant'` — `{'Delta','Gamma'}`
  - `Learners = 'knn'` — `{'Distance','NumNeighbors'}`

  Note For hyperparameter optimization, `Learners` must be a single argument, not a string array or cell array.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcensemble` by varying the parameters. For information about cross-validation loss (albeit in a different context), see "Classification Loss" on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcensemble` are:

- `Method` — Depends on the number of classes.
  - Two classes — Eligible methods are `'Bag'`, `'GentleBoost'`, `'LogitBoost'`, `'AdaBoostM1'`, and `'RUSBoost'`.
  - Three or more classes — Eligible methods are `'Bag'`, `'AdaBoostM2'`, and `'RUSBoost'`.
- `NumLearningCycles` — `fitcensemble` searches among positive integers, by default log-scaled with range `[10,500]`.
- `LearnRate` — `fitcensemble` searches among positive reals, by default log-scaled with range `[1e-3,1]`.
- The eligible hyperparameters for the chosen `Learners`:

Learners	Eligible Hyperparameters Bold = Used By Default	Default Range
`'discriminant'`	**`Delta`**	Log-scaled in the range `[1e-6,1e3]`
	`DiscrimType`	`'linear'`, `'quadratic'`, `'diagLinear'`, `'diagQuadratic'`, `'pseudoLinear'`, and `'pseudoQuadratic'`
	`Gamma`	Real values in `[0,1]`

Learners	Eligible Hyperparameters Bold = Used By Default	Default Range
'knn'	**Distance**	'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'
	DistanceWeight	'equal', 'inverse', and 'squaredinverse'
	Exponent	Positive values in [0.5,3]
	NumNeighbors	Positive integer values log-scaled in the range [1, max(2,round(NumObservations/2))]
	Standardize	'true' and 'false'
'tree'	MaxNumSplits	Integers log-scaled in the range [1,max(2,NumObservations-1)]
	MinLeafSize	Integers log-scaled in the range [1,max(2,floor(NumObservations/2))]
	NumVariablesToSample	Integers in the range [1,max(2,NumPredictors)]
	SplitCriterion	'gdi', 'deviance', and 'twoing'

Alternatively, use `hyperparameters` with your chosen `Learners`. Note that you must specify the predictor data and response when creating an `optimizableVariable` object.

```
load fisheriris
params = hyperparameters('fitcensemble',meas,species,'Tree');
```

To see the eligible and default hyperparameters, examine `params`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcensemble',meas,species,'Tree');
params(4).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Classification Ensemble” on page 33-1654.

Example: `'OptimizeHyperparameters',{'Method','NumLearningCycles','LearnRate','MinLeafSize','MaxNumSplits'}`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`

Field Name	Values	Default
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	

Field Name	Values	Default
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained classification ensemble model

`ClassificationBaggedEnsemble` model object | `ClassificationEnsemble` model object | `ClassificationPartitionedEnsemble` cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Specify Any Cross-Validation Options?	`Method` Setting	`Resample` Setting
`ClassificationBaggedEnsemble`	No	`'Bag'`	`'on'`
`ClassificationEnsemble`	No	Any ensemble aggregation method for classification	`'off'`
`ClassificationPartitionedEnsemble`	Yes	Any ensemble aggregation method for classification	`'off'` or `'on'`

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NumLearningCycles` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of `1` for `FResample`.
- If the ensemble aggregation method (`Method`) is `'bag'` and:
  - The misclassification cost (`Cost`) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.

- The class prior probabilities (`Prior`) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using `Cost` or a less skewed prior probability vector using `Prior`.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the `ClassNames` name-value pair argument.

  - To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for `ClassNames`. For example, suppose the response variable (`Y`) is a cell array of labels. This code specifies the class order in the variable `classNames`.

    ```
    Ycat = categorical(Y);
    classNames = categories(Ycat)
    ```

    `categorical` assigns `<undefined>` to unclassified observations and `categories` excludes `<undefined>` from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.

  - To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to `ClassNames`. Following from the previous example, this code specifies the class order from lowest- to most-represented in `classNamesLH`.

    ```
    Ycat = categorical(Y);
    classNames = categories(Ycat);
    freq = countcats(Ycat);
    [~,idx] = sort(freq);
    classNamesLH = classNames(idx);
    ```

- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-39.
- If you set `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows shallow decision trees by default. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- For bagging (`'Method','Bag'`), `fitcensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag

error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.

- For the RUSBoost ensemble aggregation method (`'Method','RUSBoost'`), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: *A* and *B*. *A* has 100 observations and *B* has 10 observations. Suppose also that the lowest-represented class has *m* observations in the training data.
  - If you set `'RatioToSmallest',2`, then *s***m* = `2*10` = `20`. Consequently, `fitcensemble` trains every learner using 20 observations from class *A* and 20 observations from class *B*. If you set `'RatioToSmallest',[2 2]`, then you obtain the same result.
  - If you set `'RatioToSmallest',[2,1]`, then *s1***m* = `2*10` = `20` and *s2***m* = `1*10` = `10`. Consequently, `fitcensemble` trains every learner using 20 observations from class *A* and 10 observations from class *B*.
- For dual-core systems and above, `fitcensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

`fitcensemble` supports parallel training using the `'Options'` name-value argument. Create options using `statset`, such as `options = statset('UseParallel',true)`. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016b

fitcgam

Fit generalized additive model (GAM) for binary classification

Syntax

```
Mdl = fitcgam(Tbl,ResponseVarName)
Mdl = fitcgam(Tbl,formula)
Mdl = fitcgam(Tbl,Y)
Mdl = fitcgam(X,Y)
Mdl = fitcgam(___,Name,Value)
```

Description

`Mdl = fitcgam(Tbl,ResponseVarName)` returns a generalized additive model on page 33-1707 `Mdl` trained using the sample data contained in the table `Tbl`. The input argument `ResponseVarName` is the name of the variable in `Tbl` that contains the class labels for binary classification.

`Mdl = fitcgam(Tbl,formula)` uses the model specification argument `formula` to specify the class labels and predictor variables in `Tbl`. You can specify a subset of predictor variables and interaction terms for predictor variables by using `formula`.

`Mdl = fitcgam(Tbl,Y)` uses the predictor variables in the table `Tbl` and the class labels in the vector `Y`.

`Mdl = fitcgam(X,Y)` uses the predictors in the matrix `X` and the class labels in the vector `Y`.

`Mdl = fitcgam(___,Name,Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in the previous syntaxes. For example, `'Interactions',5` specifies to include five interaction terms in the model. You can also specify a list of interaction terms using the `'Interactions'` name-value argument.

Examples

Train Generalized Additive Model

Train a univariate generalized additive model, which contains linear terms for predictors. Then, interpret the prediction for a specified data instance by using the `plotLocalEffects` function.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a univariate GAM that identifies whether the radar return is bad (`'b'`) or good (`'g'`).

```
Mdl = fitcgam(X,Y)
```

```
Mdl =
  ClassificationGAM
```

```
           ResponseName: 'Y'
  CategoricalPredictors: []
             ClassNames: {'b'  'g'}
         ScoreTransform: 'logit'
              Intercept: 2.2715
        NumObservations: 351

  Properties, Methods
```

`Mdl` is a `ClassificationGAM` model object. The model display shows a partial list of the model properties. To view the full list of properties, double-click the variable name `Mdl` in the Workspace. The Variables editor opens for `Mdl`. Alternatively, you can display the properties in the Command Window by using dot notation. For example, display the class order of `Mdl`.

```
classOrder = Mdl.ClassNames
```

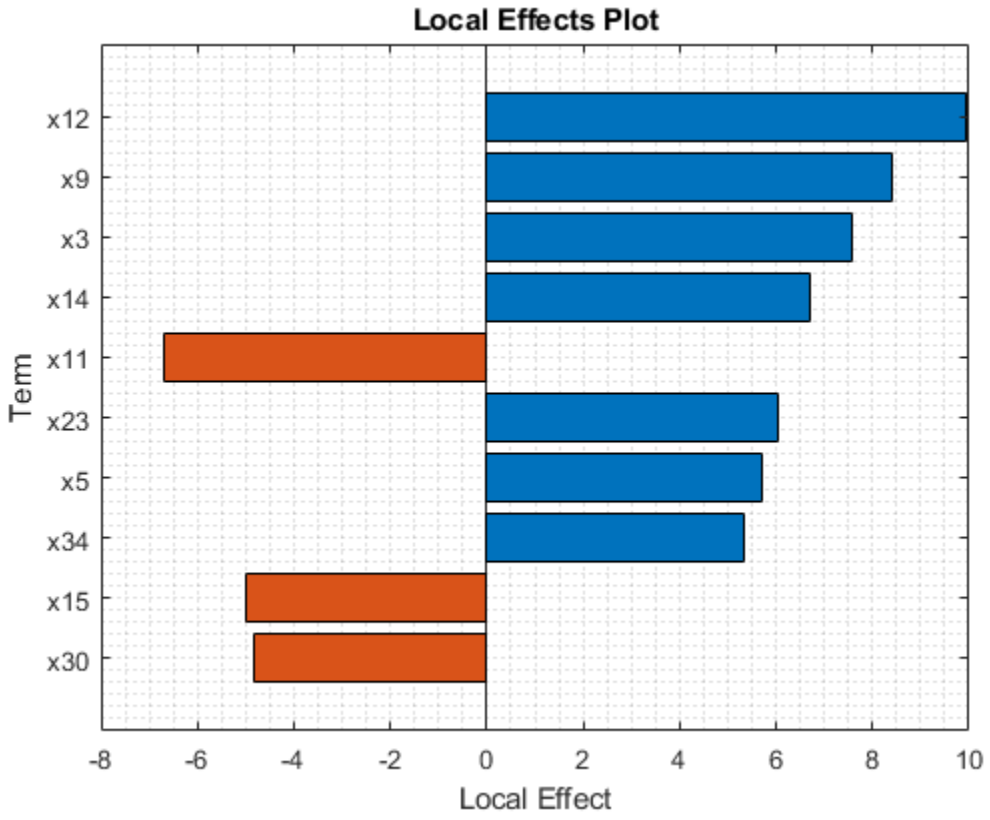
```
classOrder = 2x1 cell
    {'b'}
    {'g'}
```

Classify the first observation of the training data, and plot the local effects of the terms in `Mdl` on the prediction.

```
label = predict(Mdl,X(1,:))
```

```
label = 1x1 cell array
    {'g'}
```

```
plotLocalEffects(Mdl,X(1,:))
```



The `predict` function classifies the first observation `X(1,:)` as `'g'`. The `plotLocalEffects` function creates a horizontal bar graph that shows the local effects of the 10 most important terms on the prediction. Each local effect value shows the contribution of each term to the classification score for `'g'`, which is the logit of the posterior probability that the classification is `'g'` for the observation.

Train GAM with Interaction Terms

Train a generalized additive model that contains linear and interaction terms for predictors in three different ways:

- Specify the interaction terms using the `formula` input argument.
- Specify the `'Interactions'` name-value argument.
- Build a model with linear terms first and add interaction terms to the model by using the `addInteractions` function.

Load Fisher's iris data set. Create a table that contains observations for versicolor and virginica.

```
load fisheriris
inds = strcmp(species,'versicolor') | strcmp(species,'virginica');
tbl = array2table(meas(inds,:),'VariableNames',["x1","x2","x3","x4"]);
tbl.Y = species(inds,:);
```

Specify `formula`

Train a GAM that contains the four linear terms (`x1`, `x2`, `x3`, and `x4`) and two interaction terms (`x1*x2` and `x2*x3`). Specify the terms using a formula in the form `'Y ~ terms'`.

```
Mdl1 = fitcgam(tbl,'Y ~ x1 + x2 + x3 + x4 + x1:x2 + x2:x3');
```

The function adds interaction terms to the model in the order of importance. You can use the `Interactions` property to check the interaction terms in the model and the order in which `fitcgam` adds them to the model. Display the `Interactions` property.

```
Mdl1.Interactions
```

```
ans = 2×2

     2     3
     1     2
```

Each row of `Interactions` represents one interaction term and contains the column indexes of the predictor variables for the interaction term.

Specify `'Interactions'`

Pass the training data (`tbl`) and the name of the response variable in `tbl` to `fitcgam`, so that the function includes the linear terms for all the other variables as predictors. Specify the `'Interactions'` name-value argument using a logical matrix to include the two interaction terms, `x1*x2` and `x2*x3`.

```
Mdl2 = fitcgam(tbl,'Y','Interactions',logical([1 1 0 0; 0 1 1 0]));
Mdl2.Interactions
```

```
ans = 2×2

     2     3
     1     2
```

You can also specify `'Interactions'` as the number of interaction terms or as `'all'` to include all available interaction terms. Among the specified interaction terms, `fitcgam` identifies those whose *p*-values are not greater than the `'MaxPValue'` value and adds them to the model. The default `'MaxPValue'` is 1 so that the function adds all specified interaction terms to the model.

Specify `'Interactions','all'` and set the `'MaxPValue'` name-value argument to 0.01.

```
Mdl3 = fitcgam(tbl,'Y','Interactions','all','MaxPValue',0.01);
Mdl3.Interactions
```

```
ans = 5×2

     3     4
     2     4
     1     4
     2     3
     1     3
```

`Mdl3` includes five of the six available pairs of interaction terms.

Use `addInteractions` Function

Train a univariate GAM that contains linear terms for predictors, and then add interaction terms to the trained model by using the `addInteractions` function. Specify the second input argument of `addInteractions` in the same way you specify the `'Interactions'` name-value argument of `fitcgam`. You can specify the list of interaction terms using a logical matrix, the number of interaction terms, or `'all'`.

Specify the number of interaction terms as 5 to add the five most important interaction terms to the trained model.

```
Mdl4 = fitcgam(tbl,'Y');
UpdatedMdl4 = addInteractions(Mdl4,5);
UpdatedMdl4.Interactions
```

```
ans = 5×2

     3     4
     2     4
     1     4
     2     3
     1     3
```

`Mdl4` is a univariate GAM, and `UpdatedMdl4` is an updated GAM that contains all the terms in `Mdl4` and five additional interaction terms.

Create Cross-Validated GAM Using `fitcgam`

Train a cross-validated GAM with 10 folds, which is the default cross-validation option, by using `fitcgam`. Then, use `kfoldPredict` to predict class labels for validation-fold observations using a model trained on training-fold observations.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Create a cross-validated GAM by using the default cross-validation option. Specify the `'CrossVal'` name-value argument as `'on'`.

```
rng('default') % For reproducibility
CVMdl = fitcgam(X,Y,'CrossVal','on')
```

```
CVMdl =
  ClassificationPartitionedGAM
    CrossValidatedModel: 'GAM'
         PredictorNames: {1x34 cell}
           ResponseName: 'Y'
        NumObservations: 351
                  KFold: 10
              Partition: [1x1 cvpartition]
      NumTrainedPerFold: [1x1 struct]
             ClassNames: {'b'  'g'}
         ScoreTransform: 'logit'
```

```
  Properties, Methods
```

The `fitcgam` function creates a `ClassificationPartitionedGAM` model object `CVMdl` with 10 folds. During cross-validation, the software completes these steps:

1. Randomly partition the data into 10 sets.
2. For each set, reserve the set as validation data, and train the model using the other 9 sets.
3. Store the 10 compact, trained models in a 10-by-1 cell vector in the `Trained` property of the cross-validated model object `ClassificationPartitionedGAM`.

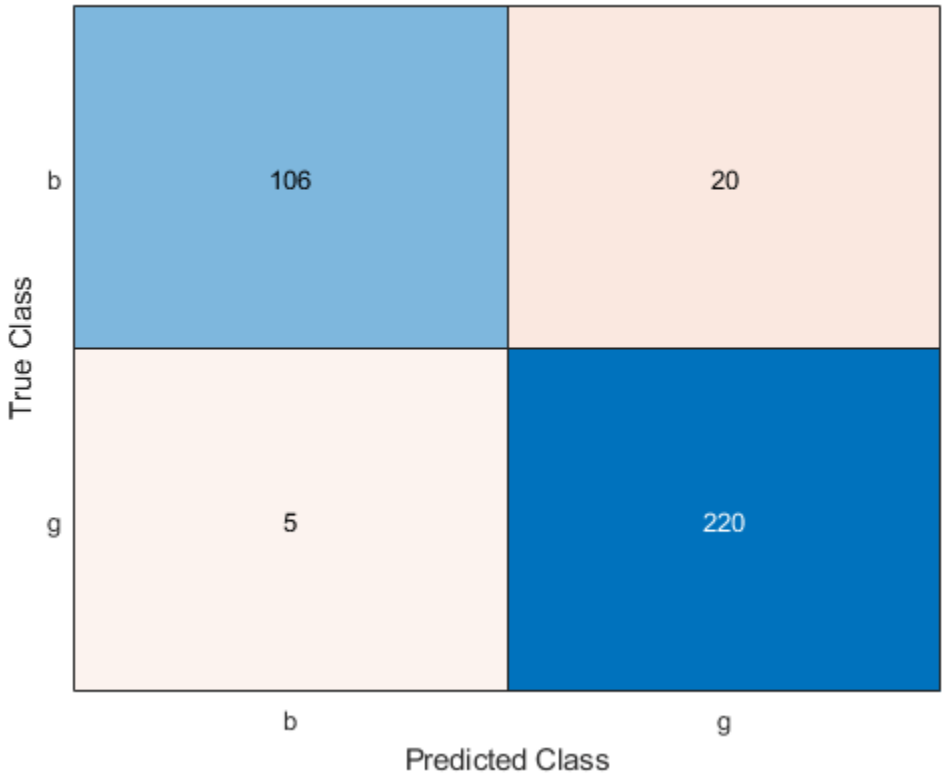
You can override the default cross-validation setting by using the `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'` name-value argument.

Classify the observations in `X` by using `kfoldPredict`. The function predicts class labels for every observation using the model trained without that observation.

```
label = kfoldPredict(CVMdl);
```

Create a confusion matrix to compare the true classes of the observations to their predicted labels.

```
C = confusionchart(Y,label);
```



Compute the classification error.

```
L = kfoldLoss(CVMdl)
```

```
L = 0.0712
```

The average misclassification rate over 10 folds is about 7%.

Optimize Cross-Validated GAM Using bayesopt

Optimize the parameters of a GAM with respect to cross-validation by using the `bayesopt` function.

Load the 1994 census data stored in `census1994.mat`. The data set consists of demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. The classification task is to fit a model that predicts the salary category of people given their age, working class, education level, marital status, race, and so on.

```
load census1994
```

`census1994` contains the training data set `adultdata` and the test data set `adulttest`. To reduce the running time for this example, subsample 500 training observations from `adultdata` by using the `datasample` function.

```
rng('default')
NumSamples = 5e2;
adultdata = datasample(adultdata,NumSamples,'Replace',false);
```

Prepare `optimizableVariable` objects for the name-value arguments that you want to optimize using Bayesian optimization. This example finds optimal values for the `MaxNumSplitsPerPredictor` and `NumTreesPerPredictor` arguments of `fitcgam`.

```
maxNumSplits = optimizableVariable('maxNumSplits',[1,10],'Type','integer');
numTrees = optimizableVariable('numTrees',[1,500],'Type','integer');
```

Create an objective function that takes an input `z = [maxNumSplits,numTrees]` and returns the cross-validated loss value of `z`.

```
minfun = @(z)kfoldLoss(fitcgam(adultdata,'salary','CrossVal','on', ...
    'MaxNumSplitsPerPredictor',z.maxNumSplits, ...
    'NumTreesPerPredictor',z.numTrees));
```

If you specify the cross-validation option (`'CrossVal','on'`), then the `fitcgam` function returns a cross-validated model object `ClassificationPartitionedGAM`. The `kfoldLoss` function returns the classification loss obtained by the cross-validated model. Therefore, the function handle `minfun` computes the cross-validation loss at the parameters in `z`.

Search for the best parameters `[maxNumSplits,numTrees]` using `bayesopt`. For reproducibility, choose the `'expected-improvement-plus'` acquisition function. The default acquisition function depends on run time and, therefore, can give varying results.

```
results = bayesopt(minfun,[maxNumSplits,numTrees],'Verbose',0, ...
    'IsObjectiveDeterministic',true, ...
    'AcquisitionFunctionName','expected-improvement-plus');
```

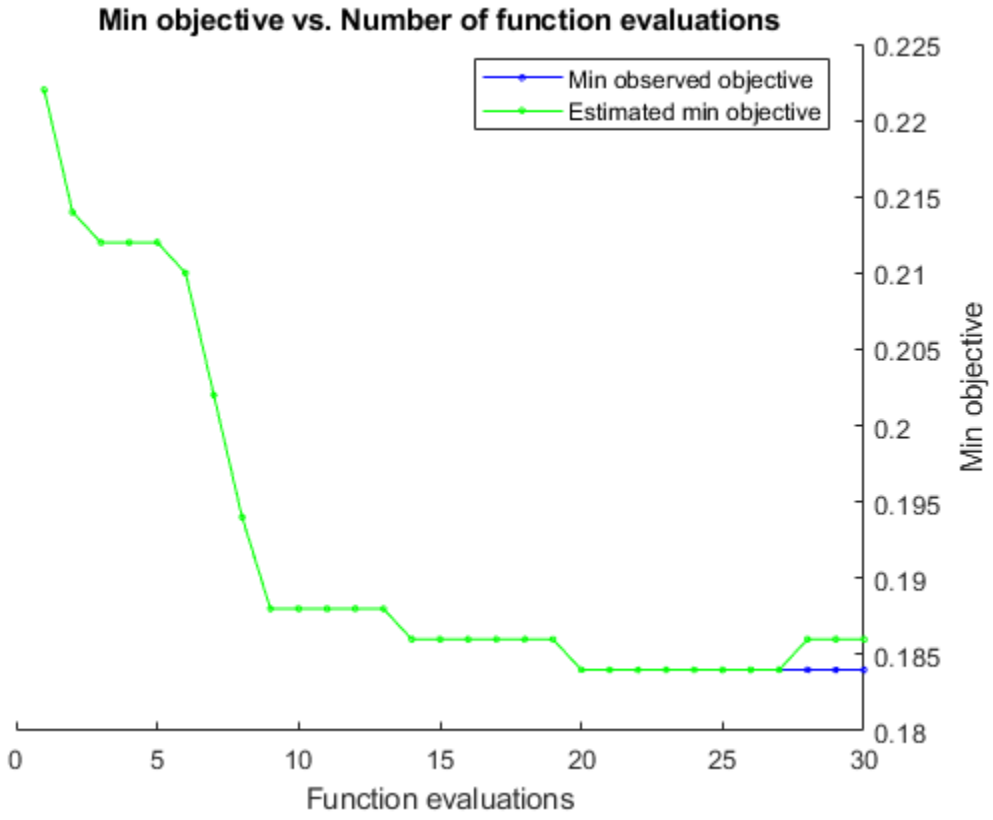
maxNumSplits
Observed points
Model mean
Next point
Model minimum feasible



Obtain the best point from `results`.

```
zbest = bestPoint(results)
```

```
zbest=1×2 table
    maxNumSplits    numTrees
    ____________    ________

          1             123
```

Train an optimized GAM using the `zbest` values.

```
Mdl = fitcgam(adultdata,'salary', ...
    'MaxNumSplitsPerPredictor',zbest.maxNumSplits, ...
    'NumTreesPerPredictor',zbest.numTrees);
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- Optionally, `Tbl` can contain a column for the response variable and a column for the observation weights.
  - The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. A good practice is to specify the order of the classes in the response variable by using the `'ClassNames'` name-value argument.
  - The column for the weights must be a numeric vector.

  You must specify the response variable in `Tbl` by using `ResponseVarName` or `formula` and specify the observation weights in `Tbl` by using `'Weights'`.
  - Specify the response variable by using `ResponseVarName` — `fitcgam` uses the remaining variables as predictors. To use a subset of the remaining variables in `Tbl` as predictors, specify predictor variables by using `'PredictorNames'`.
  - Define a model specification by using `formula` — `fitcgam` uses a subset of the variables in `Tbl` as predictor variables and the response variable, as specified in `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable `Y` and the number of rows in `Tbl` must be equal. To use a subset of the variables in `Tbl` as predictors, specify predictor variables by using `'PredictorNames'`.

`fitcgam` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Tbl` to be missing values.

- `fitcgam` does not use observations with all missing values in the fit.
- `fitcgam` does not use observations with missing response values in the fit.
- `fitcgam` uses observations with some missing values for predictors to find splits on variables for which these observations have valid values.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as a character vector or string scalar containing the name of the response variable in `Tbl`. For example, if the response variable `Y` is stored in `Tbl.Y`, then specify it as `'Y'`.

Data Types: `char` | `string`

`formula` — Model specification
character vector | string scalar

Model specification, specified as a character vector or string scalar in the form `'Y ~ terms'`. The `formula` argument specifies a response variable and linear and interaction terms for predictor variables. Use `formula` to specify a subset of variables in `Tbl` as predictors for training the model. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

For example, specify `'Y~x1+x2+x3+x1:x2'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the linear terms for the predictor variables. `x1:x2` represents the interaction term for `x1` and `x2`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable

names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Alternatively, you can specify a response variable and linear terms for predictors using `formula`, and specify interaction terms for predictors using `'Interactions'`.

`fitcgam` builds a set of interaction trees using only the terms whose *p*-values are not greater than the `'MaxPValue'` value.

Example: `'Y~x1+x2+x3+x1:x2'`

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X` or `Tbl`.

A good practice is to specify the order of the classes by using the `'ClassNames'` name-value argument.

`fitcgam` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Y` to be missing values. `fitcgam` does not use observations with missing response values in the fit.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

`fitcgam` considers `NaN` values in `X` as missing values. The function does not use observations with all missing values in the fit. `fitcgam` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Interactions','all','MaxPValue',0.05` specifies to include all available interaction terms whose *p*-values are not greater than 0.05.

GAM Options

InitialLearnRateForInteractions — Initial learning rate of gradient boosting for interaction terms

1 (default) | numeric scalar in (0,1]

Initial learning rate of gradient boosting for interaction terms, specified as a numeric scalar in the interval (0,1].

For each boosting iteration for interaction trees, `fitcgam` starts fitting with the initial learning rate. The function halves the learning rate until it finds a rate that improves the model fit.

Training a model using a small learning rate requires more learning iterations, but often achieves better accuracy.

For more details about gradient boosting, see “Gradient Boosting Algorithm” on page 33-1708.

Example: `'InitialLearnRateForInteractions',0.1`

Data Types: `single` | `double`

`InitialLearnRateForPredictors` — Initial learning rate of gradient boosting for linear terms

`1` (default) | numeric scalar in (0,1]

Initial learning rate of gradient boosting for linear terms, specified as a numeric scalar in the interval (0,1].

For each boosting iteration for predictor trees, `fitcgam` starts fitting with the initial learning rate. The function halves the learning rate until it finds a rate that improves the model fit.

Training a model using a small learning rate requires more learning iterations, but often achieves better accuracy.

For more details about gradient boosting, see “Gradient Boosting Algorithm” on page 33-1708.

Example: `'InitialLearnRateForPredictors',0.1`

Data Types: `single` | `double`

`Interactions` — Number or list of interaction terms

`0` (default) | nonnegative integer scalar | logical matrix | `'all'`

Number or list of interaction terms to include in the candidate set *S*, specified as a nonnegative integer scalar, a logical matrix, or `'all'`.

- Number of interaction terms, specified as a nonnegative integer — *S* includes the specified number of important interaction terms, selected based on the *p*-values of the terms.
- List of interaction terms, specified as a logical matrix — *S* includes the terms specified by a `t`-by-`p` logical matrix, where `t` is the number of interaction terms, and `p` is the number of predictors used to train the model. For example, `logical([1 1 0; 0 1 1])` represents two pairs of interaction terms: a pair of the first and second predictors, and a pair of the second and third predictors.

  If `fitcgam` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. That is, the column indexes of the logical matrix do not count the response and observation weight variables. The indexes also do not count any variables not used by the function.
- `'all'` — *S* includes all possible pairs of interaction terms, which is `p*(p – 1)/2` number of terms in total.

Among the interaction terms in *S*, the `fitcgam` function identifies those whose *p*-values are not greater than the `'MaxPValue'` value and uses them to build a set of interaction trees. Use the default value (`'MaxPValue',1`) to build interaction trees using all terms in *S*.

Example: `'Interactions','all'`

Data Types: `single` | `double` | `logical` | `char` | `string`

`MaxNumSplitsPerInteraction` — Maximum number of decision splits per interaction tree
4 (default) | positive integer scalar

Maximum number of decision splits (or branch nodes) for each interaction tree (boosted tree for an interaction term), specified as a positive integer scalar.

Example: `'MaxNumSplitsPerInteraction',5`

Data Types: `single` | `double`

`MaxNumSplitsPerPredictor` — Maximum number of decision splits per predictor tree
1 (default) | positive integer scalar

Maximum number of decision splits (or branch nodes) for each predictor tree (boosted tree for a linear term), specified as a positive integer scalar. By default, `fitcgam` uses a tree stump for a predictor tree.

Example: `'MaxNumSplitsPerPredictor',5`

Data Types: `single` | `double`

`MaxPValue` — Maximum *p*-value for detecting interaction terms
1 (default) | numeric scalar in [0,1]

Maximum *p*-value for detecting interaction terms, specified as a numeric scalar in the interval [0,1].

`fitcgam` first finds the candidate set *S* of interaction terms from `formula` or `'Interactions'`. Then the function identifies the interaction terms whose *p*-values are not greater than the `'MaxPValue'` value and uses them to build a set of interaction trees.

The default value (`'MaxPValue',1`) builds interaction trees for all interaction terms in the candidate set *S*.

For more details about detecting interaction terms, see “Interaction Term Detection” on page 33-1709.

Example: `'MaxPValue',0.05`

Data Types: `single` | `double`

`NumBins` — Number of bins for numeric predictors
`256` (default) | positive integer scalar | `[]` (empty)

Number of bins for numeric predictors, specified as a positive integer scalar or `[]` (empty).

- If you specify the `'NumBins'` value as a positive integer scalar (`numBins`), then `fitcgam` bins every numeric predictor into at most `numBins` equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - The number of bins can be less than `numBins` if a predictor has fewer than `numBins` unique values.

- `fitcgam` does not bin categorical predictors.

- If the `'NumBins'` value is empty (`[]`), then `fitcgam` does not bin any predictors.

When you use a large training data set, this binning option speeds up training but might cause a decrease in accuracy. You can first use the default value of `'NumBins'`, and then change the value depending on the accuracy and training speed.

The trained model `Mdl` stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single` | `double`

`NumTreesPerInteraction` — Number of trees per interaction term
100 (default) | positive integer scalar

Number of trees per interaction term, specified as a positive integer scalar.

The `'NumTreesPerInteraction'` value is equivalent to the number of gradient boosting iterations for the interaction terms for predictors. For each iteration, `fitcgam` adds a set of interaction trees to the model, one tree for each interaction term. To learn about the gradient boosting algorithm, see “Gradient Boosting Algorithm” on page 33-1708.

You can determine whether the fitted model has the specified number of trees by viewing the diagnostic message displayed when `'Verbose'` is 1 or 2, or by checking the `ReasonForTermination` property value of the model `Mdl`.

Example: `'NumTreesPerInteraction',500`

Data Types: `single` | `double`

`NumTreesPerPredictor` — Number of trees per linear term
300 (default) | positive integer scalar

Number of trees per linear term, specified as a positive integer scalar.

The `'NumTreesPerPredictor'` value is equivalent to the number of gradient boosting iterations for the linear terms for predictors. For each iteration, `fitcgam` adds a set of predictor trees to the model, one tree for each predictor. To learn about the gradient boosting algorithm, see “Gradient Boosting Algorithm” on page 33-1708.

You can determine whether the fitted model has the specified number of trees by viewing the diagnostic message displayed when `'Verbose'` is 1 or 2, or by checking the `ReasonForTermination` property value of the model `Mdl`.

Example: `'NumTreesPerPredictor',500`

Data Types: `single` | `double`

Other Classification Options

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitcgam` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcgam` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitcgam` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Misclassification cost
`[0 1; 1 0]` (default) | 2-by-2 numeric matrix | structure

Misclassification cost of a point, specified as one of the following:

- 2-by-2 numeric matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (that is, the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, set the `'ClassNames'` name-value argument.
- Structure `S` with two fields: `S.ClassNames`, which contains the group names as a variable of the same data type as the response variable in `Tbl` or `Y`; and `S.ClassificationCosts`, which contains the cost matrix.

Example: `'Cost',[0 2; 1 0]`

Data Types: `single` | `double` | `struct`

`NumPrint` — Number of iterations between diagnostic message printouts
`10` (default) | nonnegative integer scalar

Number of iterations between diagnostic message printouts, specified as a nonnegative integer scalar. This argument is valid only when you specify `'Verbose'` as 1.

If you specify `'Verbose',1` and `'NumPrint',numPrint`, then the software displays diagnostic messages every `numPrint` iterations in the Command Window.

Example: `'NumPrint',500`

Data Types: `single` | `double`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitcgam` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.

- By default, `PredictorNames` contains the names of all predictor variables.
- A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as one of the following:

- Character vector or string scalar.
  - `'empirical'` determines class probabilities from class frequencies in the response variable in `Y` or `Tbl`. If you pass observation weights, `fitcgam` uses the weights to compute the class probabilities.
  - `'uniform'` sets all class probabilities to be equal.
- Vector (one scalar value for each class). To specify the class order for the corresponding elements of `'Prior'`, set the `'ClassNames'` name-value argument.
- Structure `S` with two fields.
  - `S.ClassNames` contains the class names as a variable of the same type as the response variable in `Y` or `Tbl`.
  - `S.ClassProbs` contains a vector of corresponding probabilities.

`fitcgam` normalizes the weights in each class (`'Weights'`) to add up to the value of the prior probability of the respective class.

Example: `'Prior','uniform'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ScoreTransform` — Score transformation
`'logit'` (default) | `'none'` | function handle | ...

Score transformation, specified as a built-in transformation function name or function handle.

This table summarizes the available score transformations. Specify one using its corresponding character vector or string scalar.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

This argument determines the output score computation for object functions such as `predict`, `margin`, and `edge`. Use `'logit'` (default) to compute posterior probabilities, and use `'none'` to compute the logit of posterior probabilities.

Example: `'ScoreTransform','none'`

Data Types: `char` | `string` | `function_handle`

`Verbose` — Verbosity level
`0` (default) | `1` | `2`

Verbosity level, specified as `0`, `1`, or `2`. The `Verbose` value controls the amount of information that the software displays in the Command Window.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software displays no information.
`1`	The software displays diagnostic messages every `numPrint` iterations, where `numPrint` is the `'NumPrint'` value.
`2`	The software displays diagnostic messages at every iteration.

Each line of the diagnostic messages shows the information about each boosting iteration and includes the following columns:

- `Type` — Type of trained trees, `1D` (predictor trees, or boosted trees for linear terms for predictors) or `2D` (interaction trees, or boosted trees for interaction terms for predictors)
- `NumTrees` — Number of trees per linear term or interaction term that `fitcgam` added to the model so far

- `Deviance` — "Deviance" on page 33-1708 of the model
- `RelTol` — Relative change of model predictions: $(\widehat{y}_k - \widehat{y}_{k-1})'(\widehat{y}_k - \widehat{y}_{k-1})/\widehat{y}_k'\widehat{y}_k$, where $\widehat{y}_k$ is a column vector of model predictions at iteration k
- `LearnRate` — Learning rate used for the current iteration

Example: `'Verbose',1`

Data Types: `single` | `double`

`Weights` — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as a vector of scalar values or the name of a variable in `Tbl`. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored in `Tbl.W`, then specify it as `'W'`.

`fitcgam` normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation Options

`CrossVal` — Flag to train cross-validated model

`'off'` (default) | `'on'`

Flag to train a cross-validated model, specified as `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated model with 10 folds.

You can override this cross-validation setting using the `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'` name-value argument. You can use only one cross-validation name-value argument at a time to create a cross-validated model.

Alternatively, cross-validate after creating a model by passing `Mdl` to `crossval`.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.
2. Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Output Arguments

`Mdl` — Trained generalized additive model

`ClassificationGAM` model object | `ClassificationPartitionedGAM` cross-validated model object

Trained generalized additive model, returned as one of the model objects in this table.

Model Object	Cross-Validation Options to Train Model Object	Ways to Classify Observations Using Model Object
`ClassificationGAM`	None	Use `predict` to classify new observations, and use `resubPredict` to classify training observations.
`ClassificationPartitionedGAM`	Specify `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`	Use `kfoldPredict` to classify observations that `fitcgam` holds out during training. `kfoldPredict` predicts a class label for every observation by using the model trained without that observation.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Interactions` in the Command Window to display the interaction terms in `Mdl`.

More About

Generalized Additive Model (GAM) for Binary Classification

A generalized additive model (GAM) is an interpretable model that explains class scores (the logit of class probabilities) using a sum of univariate and bivariate shape functions of predictors.

`fitcgam` uses a boosted tree as a shape function for each predictor and, optionally, each pair of predictors; therefore, the function can capture a nonlinear relation between a predictor and the response variable. Because contributions of individual shape functions to the prediction (classification score) are well separated, the model is easy to interpret.

The standard GAM uses a univariate shape function for each predictor.

$$y \sim Binomial(n, \mu)$$

$$g(\mu) = \log\frac{\mu}{1-\mu} = c + f_1(x_1) + f_2(x_2) + \cdots + f_p(x_p),$$

where y is a response variable that follows the binomial distribution with the probability of success (probability of positive class) μ in n observations. $g(\mu)$ is a logit link function, and c is an intercept (constant) term. $f_i(x_i)$ is a univariate shape function for the ith predictor, which is a boosted tree for a linear term for the predictor (predictor tree).

You can include interactions between predictors in a model by adding bivariate shape functions of important interaction terms to the model.

$$g(\mu) = c + f_1(x_1) + f_2(x_2) + \cdots + f_p(x_p) + \sum_{i,\, j \in \{1, 2, \cdots, p\}} f_{ij}(x_i x_j),$$

where $f_{ij}(x_i x_j)$ is a bivariate shape function for the ith and jth predictors, which is a boosted tree for an interaction term for the predictors (interaction tree).

`fitcgam` finds important interaction terms based on the p-values of F-tests. For details, see "Interaction Term Detection" on page 33-1709.

Deviance

Deviance is a generalization of the residual sum of squares. It measures the goodness of fit compared to the saturated model.

The deviance of a fitted model is twice the difference between the loglikelihoods of the model and the saturated model:

$$-2(\log L - \log L_s),$$

where L and L_s are the likelihoods of the fitted model and the saturated model, respectively. The saturated model is the model with the maximum number of parameters that you can estimate.

`fitcgam` uses the deviance to measure the goodness of model fit and finds a learning rate that reduces the deviance at each iteration. Specify `'Verbose'` as 1 or 2 to display the deviance and learning rate in the Command Window.

Algorithms

Gradient Boosting Algorithm

`fitcgam` fits a generalized additive model using a gradient boosting algorithm ("Adaptive Logistic Regression" on page 18-48).

`fitcgam` first builds sets of predictor trees (boosted trees for linear terms for predictors) and then builds sets of interaction trees (boosted trees for interaction terms for predictors). The boosting algorithm iterates for at most `'NumTreesPerPredictor'` times for predictor trees, and then iterates for at most `'NumTreesPerInteraction'` times for interaction trees.

For each boosting iteration, `fitcgam` builds a set of predictor trees with the initial learning rate `'InitialLearnRateForPredictors'`, or builds a set of interaction trees with the initial learning rate `'InitialLearnRateForInteractions'`.

- When building a set of trees, the function trains one tree at a time. It fits a tree to the residual that is the difference between the response and the aggregated prediction from all trees grown previously. To control the boosting learning speed, the function shrinks the tree by the learning rate and then adds the tree to the model and updates the residual.
  - Updated model = current model + (learning rate)·(new tree)
  - Updated residual = current residual – (learning rate)·(response explained by new tree)
- If adding the set of trees improves the model fit (that is, reduces the deviance of the fit), then `fitcgam` moves to the next iteration.
- Otherwise, `fitcgam` halves the learning rate and uses it to update the model and residual. The function continues to halve the learning rate until it finds a rate that improves the model fit.
  - If the function cannot find such a learning rate for predictor trees, then it stops boosting iterations for linear terms and starts boosting iterations for interaction terms.

- If the function cannot find such a learning rate for interaction trees, then it terminates the model fitting.

You can determine why training stopped by checking the `ReasonForTermination` property of the trained model.

Interaction Term Detection

For each pairwise interaction term $x_i x_j$ (specified by `formula` or `'Interactions'`), the software performs an *F*-test to examine whether the term is statistically significant.

To speed up the process, `fitcgam` bins numeric predictors into at most 8 equiprobable bins. The number of bins can be less than 8 if a predictor has fewer than 8 unique values. The *F*-test examines the null hypothesis that the bins created by x_i and x_j have equal responses versus the alternative that at least one bin has a different response value from the others. A small *p*-value indicates that differences are significant, which implies that the corresponding interaction term is significant and, therefore, including the term can improve the model fit.

`fitcgam` builds a set of interaction trees using the terms whose *p*-values are not greater than the `'MaxPValue'` value. You can use the default `'MaxPValue'` value `1` to build interaction trees using all terms specified by `formula` or `'Interactions'`.

`fitcgam` adds interaction terms to the model in the order of importance based on the *p*-values. Use the `Interactions` property of the returned model to check the order of the interaction terms added to the model.

Topics

"Train Generalized Additive Model for Binary Classification" on page 12-77

Introduced in R2021a

fitcknn

Fit *k*-nearest neighbor classifier

Syntax

```
Mdl = fitcknn(Tbl,ResponseVarName)
Mdl = fitcknn(Tbl,formula)
Mdl = fitcknn(Tbl,Y)

Mdl = fitcknn(X,Y)

Mdl = fitcknn(___,Name,Value)
```

Description

`Mdl = fitcknn(Tbl,ResponseVarName)` returns a *k*-nearest neighbor classification model based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and output (response) `Tbl.ResponseVarName`.

`Mdl = fitcknn(Tbl,formula)` returns a *k*-nearest neighbor classification model based on the input variables in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl`.

`Mdl = fitcknn(Tbl,Y)` returns a *k*-nearest neighbor classification model based on the predictor variables in the table `Tbl` and response array `Y`.

`Mdl = fitcknn(X,Y)` returns a *k*-nearest neighbor classification model based on the predictor data `X` and response `Y`.

`Mdl = fitcknn(___,Name,Value)` fits a model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the tie-breaking algorithm, distance metric, or observation weights.

Examples

Train *k*-Nearest Neighbor Classifier

Train a *k*-nearest neighbor classifier for Fisher's iris data, where *k*, the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```
Mdl =
  ClassificationKNN
              ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
                 Distance: 'euclidean'
             NumNeighbors: 5

  Properties, Methods
```

`Mdl` is a trained `ClassificationKNN` classifier, and some of its properties appear in the Command Window.

To access the properties of `Mdl`, use dot notation.

```
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
Mdl.Prior
```

```
ans = 1×3

    0.3333    0.3333    0.3333
```

`Mdl.Prior` contains the class prior probabilities, which you can specify using the `'Prior'` name-value pair argument in `fitcknn`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3, respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to `predict` to label new measurements or `crossval` to cross-validate the classifier.

Train a *k*-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

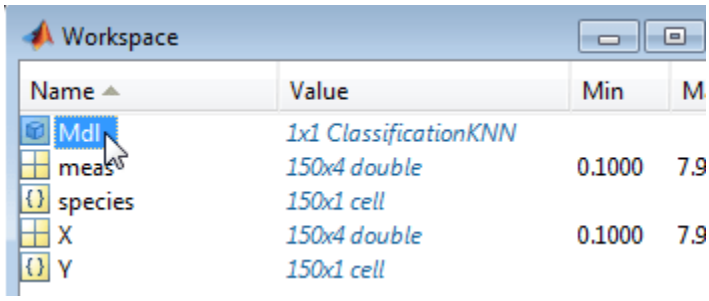
X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

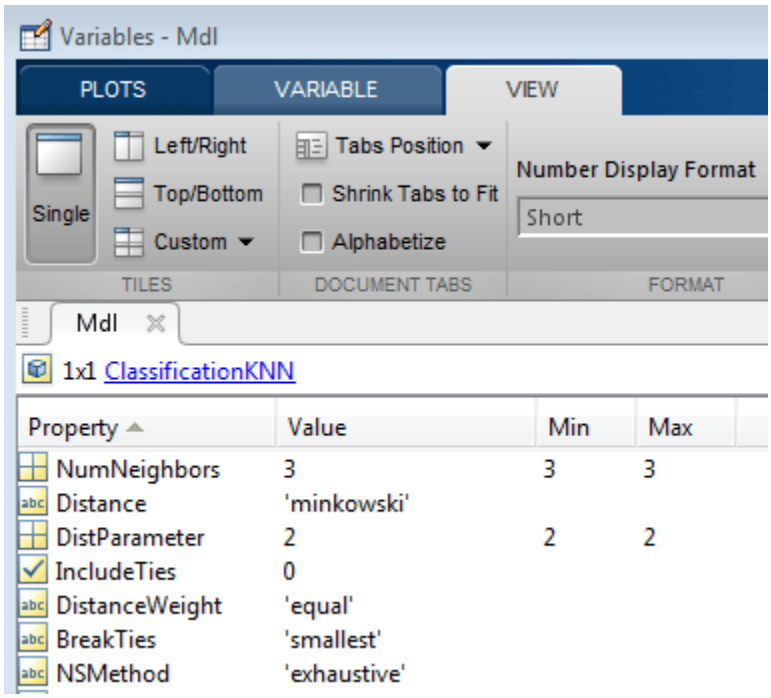
Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
    'NSMethod','exhaustive','Distance','minkowski',...
    'Standardize',1);
```

`Mdl` is a `ClassificationKNN` classifier.

You can examine the properties of `Mdl` by double-clicking `Mdl` in the Workspace window. This opens the Variable Editor.





Train a *k*-Nearest Neighbor Classifier Using a Custom Distance Metric

Train a *k*-nearest neighbor classifier using the chi-square distance.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

The chi-square distance between j-dimensional points x and z is

$$\chi(x,z) = \sqrt{\sum_{j=1}^{J} w_j (x_j - z_j)^2},$$

where w_j is a weight associated with dimension j.

Specify the chi-square distance function. The distance function must:

- Take one row of `X`, e.g., `x`, and the matrix `Z`.
- Compare `x` to each row of `Z`.
- Return a vector `D` of length n_z, where n_z is the number of rows of `Z`. Each element of `D` is the distance between the observation corresponding to `x` and the observations corresponding to each row of `Z`.

```
chiSqrDist = @(x,Z,wt)sqrt((bsxfun(@minus,x,Z).^2)*wt);
```

This example uses arbitrary weights for illustration.

Train a 3-nearest neighbor classifier. It is good practice to standardize noncategorical predictor data.

```
k = 3;
w = [0.3; 0.3; 0.2; 0.2];
KNNMdl = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w),...
    'NumNeighbors',k,'Standardize',1);
```

`KNNMdl` is a `ClassificationKNN` classifier.

Cross validate the KNN classifier using the default 10-fold cross validation. Examine the classification error.

```
rng(1); % For reproducibility
CVKNNMdl = crossval(KNNMdl);
classError = kfoldLoss(CVKNNMdl)
```

```
classError = 0.0600
```

`CVKNNMdl` is a `ClassificationPartitionedModel` classifier. The 10-fold classification error is 4%.

Compare the classifier with one that uses a different weighting scheme.

```
w2 = [0.2; 0.2; 0.3; 0.3];
CVKNNMdl2 = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w2),...
    'NumNeighbors',k,'KFold',10,'Standardize',1);
classError2 = kfoldLoss(CVKNNMdl2)
```

```
classError2 = 0.0400
```

The second weighting scheme yields a classifier that has better out-of-sample performance.

Optimize Fitted KNN Classifier

This example shows how to optimize hyperparameters automatically using `fitcknn`. The example uses the Fisher iris data.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng(1)
Mdl = fitcknn(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

```

  Properties, Methods
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

The software considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Y` to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`X` — Predictor data
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'NumNeighbors',3,'NSMethod','exhaustive','Distance','minkowski'` specifies a classifier for three-nearest neighbors using the nearest neighbor search method and the Minkowski metric.

Model Parameters

`BreakTies` — Tie-breaking algorithm

`'smallest'` (default) | `'nearest'` | `'random'`

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies','nearest'`

`BucketSize` — Maximum data points in node

`50` (default) | positive integer value

Maximum number of data points in the leaf node of the *k*d-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',40`

Data Types: `single` | `double`

`CategoricalPredictors` — Categorical predictor flag

`[]` | `'all'`

Categorical predictor flag, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- `'all'` — All predictors are categorical.
- `[]` — No predictors are categorical.

The predictor data for `fitcknn` must be either all continuous or all categorical.

- If the predictor data is in a table (`Tbl`), `fitcknn` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If `Tbl` includes both continuous and categorical values, then you must specify the value of `'CategoricalPredictors'` so that `fitcknn` can determine how to treat all predictors, as either continuous or categorical variables.
- If the predictor data is a matrix (`X`), `fitcknn` assumes that all predictors are continuous. To identify all predictors in `X` as categorical, specify `'CategoricalPredictors'` as `'all'`.

When you set `CategoricalPredictors` to `'all'`, the default `Distance` is `'hamming'`.

Example: `'CategoricalPredictors','all'`

`ClassNames` — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

`Cov` — Covariance matrix

`cov(X,'omitrows')` (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when `'Distance'` is `'mahalanobis'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

`Distance` — Distance metric
`'cityblock'` | `'chebychev'` | `'correlation'` | `'cosine'` | `'euclidean'` | `'hamming'` | function handle | ...

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see `NSMethod`).

NSMethod	Distance Metric Names
`exhaustive`	Any distance metric of `ExhaustiveSearcher`
`kdtree`	`'cityblock'`, `'chebychev'`, `'euclidean'`, or `'minkowski'`

This table includes valid distance metrics of `ExhaustiveSearcher`.

Distance Metric Names	Description
`'cityblock'`	City block distance.
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'correlation'`	One minus the sample linear correlation between observations (treated as sequences of values).
`'cosine'`	One minus the cosine of the included angle between observations (treated as vectors).
`'euclidean'`	Euclidean distance.
`'hamming'`	Hamming distance, percentage of coordinates that differ.
`'jaccard'`	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
`'mahalanobis'`	Mahalanobis distance, computed using a positive definite covariance matrix `C`. The default value of `C` is the sample covariance matrix of `X`, as computed by `cov(X,'omitrows')`. To specify a different value for `C`, use the `'Cov'` name-value pair argument.
`'minkowski'`	Minkowski distance. The default exponent is `2`. To specify a different exponent, use the `'Exponent'` name-value pair argument.
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between `X` and a query point is scaled, meaning divided by a scale value `S`. The default value of `S` is the standard deviation computed from `X`, `S = std(X,'omitnan')`. To specify another value for `S`, use the `Scale` name-value pair argument.
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

Distance Metric Names	Description

`@distfun`	Distance function handle. *`distfun`* has the form
	`function D2 = distfun(ZI,ZJ)`
	`% calculation of  distance`
	`...`
	where
	• `ZI` is a 1-by-`N` vector containing one row of `X` or `Y`.
	• `ZJ` is an `M2`-by-`N` matrix containing multiple rows of `X` or `Y`.
	• `D2` is an `M2`-by-1 vector of distances, and `D2(k)` is the distance between observations `ZI` and `ZJ(k,:)`.

If you specify `CategoricalPredictors` as `'all'`, then the default distance metric is `'hamming'`. Otherwise, the default distance metric is `'euclidean'`.

For definitions, see “Distance Metrics” on page 18-12.

Example: `'Distance','minkowski'`

Data Types: `char` | `string` | `function_handle`

`DistanceWeight` — Distance weighting function
`'equal'` (default) | `'inverse'` | `'squaredinverse'` | function handle

Distance weighting function, specified as the comma-separated pair consisting of `'DistanceWeight'` and either a function handle or one of the values in this table.

Value	Description
`'equal'`	No weighting
`'inverse'`	Weight is 1/distance
`'squaredinverse'`	Weight is $1/\text{distance}^2$
`@fcn`	*`fcn`* is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, `'squaredinverse'` is equivalent to `@(d)d.^(-2)`.

Example: `'DistanceWeight','inverse'`

Data Types: `char` | `string` | `function_handle`

`Exponent` — Minkowski distance exponent
2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of `'Exponent'` and a positive scalar value. This argument is only valid when `'Distance'` is `'minkowski'`.

Example: `'Exponent',3`

Data Types: `single` | `double`

`IncludeTies` — Tie inclusion flag
`false` (default) | `true`

Tie inclusion flag, specified as the comma-separated pair consisting of `'IncludeTies'` and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the `K`th smallest distance. If `IncludeTies` is `true`, `predict` includes all these neighbors. Otherwise, `predict` uses exactly `K` neighbors.

Example: `'IncludeTies',true`

Data Types: `logical`

`NSMethod` — Nearest neighbor search method
`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — Creates and uses a *k*d-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
  - `'euclidean'`
  - `'cityblock'`
  - `'minkowski'`
  - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm. When predicting the class of a new point `xnew`, the software computes the distance values from all points in `X` to `xnew` to find nearest neighbors.

The default is `'kdtree'` when `X` has `10` or fewer columns, `X` is not sparse or a `gpuArray`, and the distance metric is a `'kdtree'` type; otherwise, `'exhaustive'`.

Example: `'NSMethod','exhaustive'`

`NumNeighbors` — Number of nearest neighbors to find
`1` (default) | positive integer value

Number of nearest neighbors in `X` to find for classifying each point when predicting, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer value.

Example: `'NumNeighbors',3`

Data Types: `single` | `double`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.

- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitcknn` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to 1/*K*, where *K* is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to `Mdl.ClassNames` or specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements such that they sum to `1`.
structure	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to `1`.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`Scale` — Distance scale

`std(X,'omitnan')` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of `'Scale'` and a vector containing nonnegative scalar values with length equal to the number of columns in `X`. Each coordinate difference between `X` and a query point is scaled by the corresponding element of `Scale`. This argument is only valid when `'Distance'` is `'seuclidean'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

`ScoreTransform` — Score transformation

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Standardize` — Flag to standardize predictors

`false` (default) | `true`

Flag to standardize the predictors, specified as the comma-separated pair consisting of `'Standardize'` and `true` (`1`) or `false` (`0`).

If you set `'Standardize',true`, then the software centers and scales each column of the predictor data (`X`) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify `'Standardize',1` and either of `'Scale'` or `'Cov'`.

It is good practice to standardize the predictor data.

Example: `'Standardize',true`

Data Types: `logical`

`Weights` — Observation weights
numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(`*n*`,1)`, where *n* is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Cross Validation Options

`CrossVal` — Cross-validation flag
`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross validate `Mdl` later using the `crossval` method.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.

2 Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Hyperparameter Optimization Options

`OptimizeHyperparameters` — Parameters to optimize
`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Distance','NumNeighbors'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitcknn` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcknn` are:

- `Distance` — `fitcknn` searches among `'cityblock'`, `'chebychev'`, `'correlation'`, `'cosine'`, `'euclidean'`, `'hamming'`, `'jaccard'`, `'mahalanobis'`, `'minkowski'`, `'seuclidean'`, and `'spearman'`.
- `DistanceWeight` — `fitcknn` searches among `'equal'`, `'inverse'`, and `'squaredinverse'`.
- `Exponent` — `fitcknn` searches among positive real values, by default in the range `[0.5,3]`.
- `NumNeighbors` — `fitcknn` searches among positive integer values, by default log-scaled in the range `[1, max(2,round(NumObservations/2))]`.
- `Standardize` — `fitcknn` searches among the values `'true'` and `'false'`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcknn',meas,species);
params(1).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Fitted KNN Classifier” on page 33-1714.

Example: `'auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`

Field Name	Values	Default
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`

Field Name	Values	Default
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained *k*-nearest neighbor classification model

`ClassificationKNN` model object | `ClassificationPartitionedModel` cross-validated model object

Trained *k*-nearest neighbor classification model, returned as a `ClassificationKNN` model object or a `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated model object. Otherwise, `Mdl` is a `ClassificationKNN` model object.

To reference properties of `Mdl`, use dot notation. For example, to display the distance metric at the Command Window, enter `Mdl.Distance`.

More About

Prediction

`ClassificationKNN` predicts the classification of a point `xnew` using a procedure equivalent to this:

1. Find the `NumNeighbors` points in the training set `X` that are nearest to `xnew`.
2. Find the `NumNeighbors` response values `Y` to those nearest points.
3. Assign the classification label `ynew` that has the largest posterior probability among the values in `Y`.

For details, see “Posterior Probability” on page 33-4786 in the `predict` documentation.

Tips

After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- `NaN`s or `<undefined>`s indicate missing observations. The following describes the behavior of `fitcknn` when the data set or weights contain missing observations.
  - If any value of `Y` or any weight is missing, then `fitcknn` removes those values from `Y`, the weights, and the corresponding rows of `X` from the data. The software renormalizes the weights to sum to `1`.
  - If you specify to standardize predictors (`'Standardize',1`) or the standardized Euclidean distance (`'Distance','seuclidean'`) without a scale, then `fitcknn` removes missing observations from individual predictors before computing the mean and standard deviation. In other words, the software implements `mean` and `std` with the `'omitnan'` option on each predictor.
  - If you specify the Mahalanobis distance (`'Distance','mahalanbois'`) without its covariance matrix, then `fitcknn` removes rows of `X` that contain at least one missing value. In other words, the software implements `cov` with the `'omitrows'` option on the predictor matrix `X`.
- Suppose that you set `'Standardize',1`.
  - If you also specify `Prior` or `Weights`, then the software takes the observation weights into account. Specifically, the weighted mean of predictor j is

    $$\bar{x}_j = \sum_{B_j} w_k x_{jk}$$

    and the weighted standard deviation is

    $$s_j = \sum_{B_j} w_k (x_{jk} - \bar{x}_j),$$

    where B_j is the set of indices k for which x_{jk} and w_k are not missing.
  - If you also set `'Distance','mahalanobis'` or `'Distance','seuclidean'`, then you cannot specify `Scale` or `Cov`. Instead, the software:
    1. Computes the means and standard deviations of each predictor
    2. Standardizes the data using the results of step 1
    3. Computes the distance parameter values using their respective default.
- If you specify `Scale` and either of `Prior` or `Weights`, then the software scales observed distances by the weighted standard deviations.
- If you specify `Cov` and either of `Prior` or `Weights`, then the software applies the weighted covariance matrix to the distances. In other words,

$$Cov = \frac{\sum_B w_j}{\left(\sum_B w_j\right)^2 - \sum_B w_j^2} \sum_B w_j (x_j - \bar{x})'(x_j - \bar{x}),$$

where B is the set of indices j for which the observation x_j does not have any missing values and w_j is not missing.

Alternatives

Although `fitcknn` can train a multiclass KNN classifier, you can reduce a multiclass learning problem to a series of KNN binary learners using `fitcecoc`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- By default, `fitcknn` uses the exhaustive nearest neighbor search algorithm for `gpuArray` input arguments.
- You cannot specify the name-value argument `'NSMethod'` as `'kdtree'`.
- You cannot specify the name-value argument `'Distance'` as a function handle.
- `fitcknn` returns a classification model fitted with GPU array input arguments in these cases only:
  - The input argument `X` is a `gpuArray`.
  - The input argument `Tbl` contains `gpuArray` elements.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2014a

fitclinear

Fit linear classification model to high-dimensional data

Syntax

```
Mdl = fitclinear(X,Y)

Mdl = fitclinear(Tbl,ResponseVarName)
Mdl = fitclinear(Tbl,formula)
Mdl = fitclinear(Tbl,Y)

Mdl = fitclinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitclinear( ___ )
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear( ___ )
```

Description

`fitclinear` trains linear classification models for two-class (binary) learning with high-dimensional, full or sparse predictor data. Available linear classification models include regularized support vector machines (SVM) and logistic regression models. `fitclinear` minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

For reduced computation time on a high-dimensional data set that includes many predictor variables, train a linear classification model by using `fitclinear`. For low- through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 33-1767.

To train a linear classification model for multiclass learning by combining SVM or logistic regression binary classifiers using error-correcting output codes, see `fitcecoc`.

`Mdl = fitclinear(X,Y)` returns a trained linear classification model object `Mdl` that contains the results of fitting a binary support vector machine to the predictors `X` and class labels `Y`.

`Mdl = fitclinear(Tbl,ResponseVarName)` returns a linear classification model using the predictor variables in the table `Tbl` and the class labels in `Tbl.ResponseVarName`.

`Mdl = fitclinear(Tbl,formula)` returns a linear classification model using the sample data in the table `Tbl`. The input argument `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitclinear(Tbl,Y)` returns a linear classification model using the predictor variables in the table `Tbl` and the class labels in vector `Y`.

`Mdl = fitclinear(X,Y,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify that the columns of the predictor matrix correspond to observations, implement logistic regression, or specify to cross-validate. A good practice is to cross-validate using the `'Kfold'` name-value pair argument. The cross-validation results determine how well the model generalizes.

`[Mdl,FitInfo] = fitclinear( ___ )` also returns optimization details using any of the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

`[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear( ___ )` also returns hyperparameter optimization details when you pass an `OptimizeHyperparameters` name-value pair.

Examples

Train Linear Classification Model

Train a binary, linear classification model using support vector machines, dual SGD, and ridge regularization.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Train the model using the entire data set. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
rng(1); % For reproducibility
[Mdl,FitInfo] = fitclinear(X,Ystats)
```

```
Mdl =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [34023x1 double]
              Bias: -1.0059
            Lambda: 3.1674e-05
           Learner: 'svm'

  Properties, Methods

FitInfo = struct with fields:
                     Lambda: 3.1674e-05
                  Objective: 5.3783e-04
                  PassLimit: 10
                  NumPasses: 10
                 BatchLimit: []
             NumIterations: 238561
              GradientNorm: NaN
         GradientTolerance: 0
      RelativeChangeInBeta: 0.0562
             BetaTolerance: 1.0000e-04
```

```
          DeltaGradient: 1.4582
    DeltaGradientTolerance: 1
           TerminationCode: 0
         TerminationStatus: {'Iteration limit exceeded.'}
                     Alpha: [31572x1 double]
                   History: []
                   FitTime: 0.2014
                    Solver: {'dual'}
```

`Mdl` is a `ClassificationLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample classification error. Or, you can pass `Mdl` and new predictor data to `predict` to predict class labels for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. Because training time is small, you can try to retrain the model, but increase the number of passes through the data. This can improve measures like `DeltaGradient`.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6,-0.5,11);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Estimate the coefficients using SpaRSA. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
X = X';
rng(10); % For reproducibility
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
  ClassificationPartitionedLinear
```

```
    CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
        NumObservations: 31572
                  KFold: 5
              Partition: [1x1 cvpartition]
             ClassNames: [0 1]
         ScoreTransform: 'none'

  Properties, Methods
```

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

`CVMdl` is a `ClassificationPartitionedLinear` model. Because `fitclinear` implements 5-fold cross-validation, `CVMdl` contains 5 `ClassificationLinear` models that the software trains on each fold.

Display the first trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'logit'
              Beta: [34023x11 double]
              Bias: [1x11 double]
            Lambda: [1x11 double]
           Learner: 'logistic'

  Properties, Methods
```

`Mdl1` is a `ClassificationLinear` model object. `fitclinear` constructed `Mdl1` by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMdl);
```

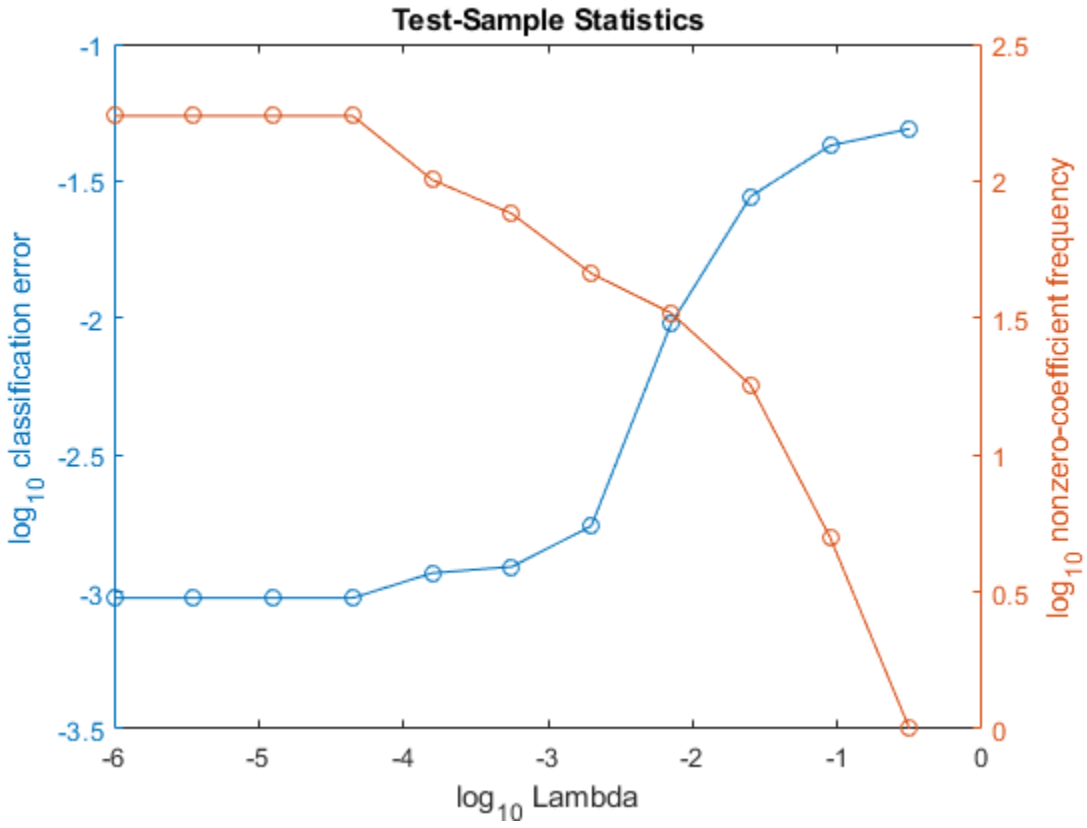
Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
```



Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Optimize Linear Classifier

This example shows how to minimize the cross-validation error in a linear classifier using `fitclinear`. The example uses the NLP data set.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. Identify the relevant labels.

```
X = X';
Ystats = Y == 'stats';
```

Optimize the classification using the `'auto'` parameters.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng default
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns','Solver','sparsa',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

```

Input Arguments

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an *n*-by-*p* full or sparse matrix.

The length of `Y` and the number of observations in `X` must be equal.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in optimization execution time.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the classification model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- `fitclinear` only supports binary classification. Either `Y` must contain exactly two distinct classes, or you must specify two classes for training using the `'ClassNames'` name-value pair argument. For multiclass learning, see `fitcecoc`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` must be equal to the number of observations in `X` or `Tbl`.
- A good practice is to specify the class order using the `ClassNames` name-value pair argument.

Data Types: `char` | `string` | `cell` | `categorical` | `logical` | `single` | `double`

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

Note The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing values, and removes observations with any of these characteristics:

- Missing value in the response variable (for example, `Y` or `ValidationData{2}`)

- At least one missing value in a predictor observation (for example, row in `X` or `ValidationData{1}`)
- `NaN` value or `0` weight (for example, value in `Weights` or `ValidationData{3}`)

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'ObservationsIn','columns','Learner','logistic','CrossVal','on'` specifies that the columns of the predictor matrix corresponds to observations, to implement logistic regression, to implement 10-fold cross-validation.

Linear Classification Options

`Lambda` — Regularization term strength
`'auto'` (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and `'auto'`, a nonnegative scalar, or a vector of nonnegative values.

- For `'auto'`, `Lambda` = 1/*n*.
  - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then *n* is the number of in-fold observations.
  - Otherwise, *n* is the training sample size.
- For a vector of nonnegative values, `fitclinear` sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.
  - If `Solver` is `'sgd'` or `'asgd'` and `Regularization` is `'lasso'`, `fitclinear` does not use the previous coefficient estimates as a warm start on page 33-1767 for the next optimization iteration. Otherwise, `fitclinear` uses warm starts.
  - If `Regularization` is `'lasso'`, then any coefficient estimate of 0 retains its value when `fitclinear` optimizes using subsequent values in `Lambda`.
  - `fitclinear` returns coefficient estimates for each specified regularization strength.

Example: `'Lambda',10.^(-(10:-2:2))`

Data Types: `char` | `string` | `double` | `single`

`Learner` — Linear classification model type
`'svm'` (default) | `'logistic'`

Linear classification model type, specified as the comma-separated pair consisting of `'Learner'` and `'svm'` or `'logistic'`.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
`'svm'`	Support vector machine	$y \in \{-1,1\}$; 1 for the positive class and –1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
`'logistic'`	Logistic regression	Same as `'svm'`	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: `'Learner','logistic'`

`ObservationsIn` — Predictor data observation dimension
`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as `'rows'` or `'columns'`.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time. You cannot specify `'ObservationsIn','columns'` for predictor data in a table.

Example: `'ObservationsIn','columns'`

Data Types: `char` | `string`

`Regularization` — Complexity penalty type
`'lasso'` | `'ridge'`

Complexity penalty type, specified as the comma-separated pair consisting of `'Regularization'` and `'lasso'` or `'ridge'`.

The software composes the objective function for minimization from the sum of the average loss function (see `Learner`) and the regularization term in this table.

Value	Description
`'lasso'`	Lasso (L1) penalty: $\lambda \sum_{j=1}^{p} \left|\beta_j\right|$
`'ridge'`	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^{p} \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use `Lambda`.

The software excludes the bias term (β_0) from the regularization penalty.

If `Solver` is `'sparsa'`, then the default value of `Regularization` is `'lasso'`. Otherwise, the default is `'ridge'`.

Tip

- For predictor variable selection, specify `'lasso'`. For more on variable selection, see “Introduction to Feature Selection” on page 15-49.
- For optimization accuracy, specify `'ridge'`.

Example: `'Regularization','lasso'`

`Solver` — Objective function minimization technique

`'sgd'` | `'asgd'` | `'dual'` | `'bfgs'` | `'lbfgs'` | `'sparsa'` | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description	Restrictions
`'sgd'`	Stochastic gradient descent (SGD) [4][2]	
`'asgd'`	Average stochastic gradient descent (ASGD) [7]	
`'dual'`	Dual SGD for SVM [1][6]	`Regularization` must be `'ridge'` and `Learner` must be `'svm'`.
`'bfgs'`	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [3]	Inefficient if `X` is very high-dimensional.
`'lbfgs'`	Limited-memory BFGS (LBFGS) [3]	`Regularization` must be `'ridge'`.
`'sparsa'`	Sparse Reconstruction by Separable Approximation (SpaRSA) [5]	`Regularization` must be `'lasso'`.

If you specify:

- A ridge penalty (see `Regularization`) and `X` contains 100 or fewer predictor variables, then the default solver is `'bfgs'`.
- An SVM model (see `Learner`), a ridge penalty, and `X` contains more than 100 predictor variables, then the default solver is `'dual'`.
- A lasso penalty and `X` contains 100 or fewer predictor variables, then the default solver is `'sparsa'`.

Otherwise, the default solver is `'sgd'`.

If you specify a string array or cell array of solver names, then the software uses all solvers in the specified order for each `Lambda`.

For more details on which solver to choose, see “Tips” on page 33-1768.

Example: `'Solver',{'sgd','lbfgs'}`

`Beta` — Initial linear coefficient estimates
`zeros(p,1)` (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of `'Beta'` and a p-dimensional numeric vector or a p-by-L numeric matrix. p is the number of predictor variables in `X` and L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a p-dimensional vector, then the software optimizes the objective function L times using this process.
  1. The software optimizes using `Beta` as the initial value and the minimum value of `Lambda` as the regularization strength.
  2. The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 33-1767, and the next smallest value in `Lambda` as the regularization strength.
  3. The software implements step 2 until it exhausts all values in `Lambda`.
- If you specify a p-by-L matrix, then the software optimizes the objective function L times. At iteration j, the software uses `Beta(:,j)` as the initial value and, after it sorts `Lambda` in ascending order, uses `Lambda(j)` as the regularization strength.

If you set `'Solver','dual'`, then the software ignores `Beta`.

Data Types: `single` | `double`

`Bias` — Initial intercept estimate
numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of `'Bias'` and a numeric scalar or an L-dimensional numeric vector. L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
  1. The software optimizes using `Bias` as the initial value and the minimum value of `Lambda` as the regularization strength.
  2. The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in `Lambda` as the regularization strength.
  3. The software implements step 2 until it exhausts all values in `Lambda`.
- If you specify an L-dimensional vector, then the software optimizes the objective function L times. At iteration j, the software uses `Bias(j)` as the initial value and, after it sorts `Lambda` in ascending order, uses `Lambda(j)` as the regularization strength.
- By default:
  - If `Learner` is `'logistic'`, then let g_j be 1 if `Y(j)` is the positive class, and -1 otherwise. `Bias` is the weighted average of the g for training or, for cross-validation, in-fold observations.

- If `Learner` is `'svm'`, then `Bias` is 0.

Data Types: `single` | `double`

`FitBias` — Linear model intercept inclusion flag

`true` (default) | `false`

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of `'FitBias'` and `true` or `false`.

Value	Description
`true`	The software includes the bias term b in the linear model, and then estimates it.
`false`	The software sets $b = 0$ during estimation.

Example: `'FitBias',false`

Data Types: `logical`

`PostFitBias` — Flag to fit linear model intercept after optimization

`false` (default) | `true`

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of `'PostFitBias'` and `true` or `false`.

Value	Description
`false`	The software estimates the bias term b and the coefficients β during optimization.
`true`	To estimate b, the software: **1** Estimates β and b using the model **2** Estimates classification scores **3** Refits b by placing the threshold on the classification scores that attains maximum accuracy

If you specify `true`, then `FitBias` must be true.

Example: `'PostFitBias',true`

Data Types: `logical`

`Verbose` — Verbosity level

`0` (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitclinear` displays at the command line.

Value	Description
`0`	`fitclinear` does not display diagnostic information.

Value	Description
1	`fitclinear` periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. `FitInfo.History` contains the diagnostic information.
Any other positive integer	`fitclinear` displays and stores diagnostic information at each optimization iteration. `FitInfo.History` contains the diagnostic information.

Example: `'Verbose',1`

Data Types: `double` | `single`

SGD and ASGD Solver Options

`BatchSize` — Mini-batch size
positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration, the software estimates the subgradient using `BatchSize` observations from the training data.

- If `X` is a numeric matrix, then the default value is `10`.
- If `X` is a sparse matrix, then the default value is `max([10,ceil(sqrt(ff))])`, where `ff = numel(X)/nnz(X)` (the fullness factor of `X`).

Example: `'BatchSize',100`

Data Types: `single` | `double`

`LearnRate` — Learning rate
positive scalar

Learning rate, specified as the comma-separated pair consisting of `'LearnRate'` and a positive scalar. `LearnRate` controls the optimization step size by scaling the subgradient.

- If `Regularization` is `'ridge'`, then `LearnRate` specifies the initial learning rate γ_0. `fitclinear` determines the learning rate for iteration t, γ_t, using

  $$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

  - λ is the value of `Lambda`.
  - If `Solver` is `'sgd'`, then $c = 1$.
  - If `Solver` is `'asgd'`, then c is 0.75 [7].
- If `Regularization` is `'lasso'`, then, for all iterations, `LearnRate` is constant.

By default, `LearnRate` is `1/sqrt(1+max((sum(X.^2,obsDim))))`, where `obsDim` is `1` if the observations compose the columns of the predictor data `X`, and `2` otherwise.

Example: `'LearnRate',0.01`

Data Types: `single` | `double`

`OptimizeLearnRate` — Flag to decrease learning rate

`true` (default) | `false`

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of `'OptimizeLearnRate'` and `true` or `false`.

If `OptimizeLearnRate` is `'true'`, then:

1. For the few optimization iterations, the software starts optimization using `LearnRate` as the learning rate.
2. If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
3. The software iterates step 2 until the objective function decreases.

Example: `'OptimizeLearnRate',true`

Data Types: `logical`

`TruncationPeriod` — Number of mini-batches between lasso truncation runs

`10` (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of `'TruncationPeriod'` and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing k = `TruncationPeriod` mini-batches, the software truncates the estimated coefficient j using

$$\widehat{\beta}_j^* = \begin{cases} \widehat{\beta}_j - u_t & \text{if } \widehat{\beta}_j > u_t, \\ 0 & \text{if } \left|\widehat{\beta}_j\right| \le u_t, \\ \widehat{\beta}_j + u_t & \text{if } \widehat{\beta}_j < -u_t. \end{cases}$$

- For SGD, $\widehat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t. λ is the value of `Lambda`.
- For ASGD, $\widehat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If `Regularization` is `'ridge'`, then the software ignores `TruncationPeriod`.

Example: `'TruncationPeriod',100`

Data Types: `single` | `double`

Other Classification Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table. The descriptions assume that the predictor data has observations in rows and predictors in columns.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitclinear` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitclinear` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitclinear` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitclinear` creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For an unordered categorical variable, `fitclinear` creates one dummy variable for each level of the categorical variable. For an ordered categorical variable, `fitclinear` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.

- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure.

- If you specify the square matrix `cost` (`'Cost',cost`), then `cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class, and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `cost`, use the `ClassNames` name-value pair argument.
- If you specify the structure `S` (`'Cost',S`), then it must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
  - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default value for `Cost` is `ones(`K`) − eye(`K`)`, where K is the number of distinct classes.

`fitclinear` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitclinear` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost',[0 2; 1 0]`

Data Types: `single` | `double` | `struct`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the predictor order in `X`. Assuming that `X` has the default orientation, with observations in rows and predictors in columns, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitclinear` uses only the predictor variables in `PredictorNames` and the response variable during training.

- `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
- By default, `PredictorNames` contains the names of all predictor variables.
- A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`Prior` — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and `'empirical'`, `'uniform'`, a numeric vector, or a structure array.

This table summarizes the available options for setting prior probabilities.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to 1/*K*, where *K* is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to their order in `Y`. If you specify the order using the `'ClassNames'` name-value pair argument, then order the elements accordingly.
structure array	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities.

`fitclinear` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `'Prior',struct('ClassNames',{{'setosa','versicolor'}},'ClassProbs',1:2)`

Data Types: `char` | `string` | `double` | `single` | `struct`

`ResponseName` — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ScoreTransform` — Score transformation

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights

nonnegative numeric vector | name of variable in `Tbl`

Observation weights, specified as a nonnegative numeric vector or the name of a variable in `Tbl`. The software weights each observation in `X` or `Tbl` with the corresponding value in `Weights`. The length of `Weights` must equal the number of observations in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response variable when training the model.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

The software normalizes `Weights` to sum to the value of the prior probability in the respective class.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation Options

`CrossVal` — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, or `KFold`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout',`*p*, then the software:

1. Randomly reserves *p*`*100`% of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold',`*k*, then the software:

1. Randomly partitions the data into *k* sets
2. For each set, reserves the set as validation data, and trains the model using the other *k* – 1 sets
3. Stores the *k* compact, trained models in the cells of a *k*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'KFold',8`

Data Types: `single` | `double`

SGD and ASGD Convergence Controls

`BatchLimit` — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of `'BatchLimit'` and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
  - The software passes through the data `PassLimit` times.
  - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is `ceil(1e6/BatchSize)`. `BatchSize` is the value of the `'BatchSize'` name-value pair argument.
- If you specify `'BatchLimit'` and `'PassLimit'`, then the software chooses the argument that results in processing the fewest observations.
- If you specify `'BatchLimit'` but not `'PassLimit'`, then the software processes enough batches to complete up to one entire pass through the data.

Example: `'BatchLimit',100`

Data Types: `single` | `double`

`BetaTolerance` — Relative tolerance on linear coefficients and bias term

`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`NumCheckConvergence` — Number of batches to process before next convergence check

positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: `'NumCheckConvergence',100`

Data Types: `single` | `double`

`PassLimit` — Maximal number of passes
1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

`fitclinear` processes all observations when it completes one pass through the data.

When `fitclinear` passes through the data `PassLimit` times, it terminates optimization.

If you specify `'BatchLimit'` and `'PassLimit'`, then `fitclinear` chooses the argument that results in processing the fewest observations.

Example: `'PassLimit',5`

Data Types: `single` | `double`

`ValidationData` — Validation data for optimization convergence detection
cell array | table

Validation data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array or table.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 33-1769. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

You can specify `ValidationData` as a table if you use a table `Tbl` of predictor data that contains the response variable. In this case, `ValidationData` must contain the same predictors and response contained in `Tbl`. The software does not apply weights to observations, even if `Tbl` contains a vector of weights. To specify weights, you must specify `ValidationData` as a cell array.

If you specify `ValidationData` as a cell array, then it must have the following format:

- `ValidationData{1}` must have the same data type and orientation as the predictor data. That is, if you use a predictor matrix `X`, then `ValidationData{1}` must be an *m*-by-*p* or *p*-by-*m* full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. Similarly, if you use a predictor table `Tbl` of predictor data, then `ValidationData{1}` must be a table containing the same predictor variables contained in `Tbl`. The number of observations in `ValidationData{1}` and the predictor data can vary.
- `ValidationData{2}` must match the data type and format of the response variable, either `Y` or `ResponseVarName`. If `ValidationData{2}` is an array of class labels, then it must have the same number of elements as the number of observations in `ValidationData{1}`. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`. If `ValidationData{1}` is a table, then `ValidationData{2}` can be the name of the response variable in the table. If you want to use the same `ResponseVarName` or `formula`, you can specify `ValidationData{2}` as `[]`.
- Optionally, you can specify `ValidationData{3}` as an *m*-dimensional numeric vector of observation weights or the name of a variable in the table `ValidationData{1}` that contains observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData` and want to display the validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Dual SGD Convergence Controls

`BetaTolerance` — Relative tolerance on linear coefficients and bias term
`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`DeltaGradientTolerance` — Gradient-difference tolerance
`1` (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 33-1862 violators, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then the software terminates optimization.
- If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'DeltaGapTolerance',1e-2`

Data Types: `double` | `single`

`NumCheckConvergence` — Number of passes through entire data set to process before next convergence check
`5` (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

Example: `'NumCheckConvergence',100`

Data Types: `single` | `double`

`PassLimit` — Maximal number of passes
`10` (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PassLimit` times, it terminates optimization.

Example: `'PassLimit',5`

Data Types: `single` | `double`

`ValidationData` — Validation data for optimization convergence detection
cell array | table

Validation data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array or table.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 33-1769. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

You can specify `ValidationData` as a table if you use a table `Tbl` of predictor data that contains the response variable. In this case, `ValidationData` must contain the same predictors and response contained in `Tbl`. The software does not apply weights to observations, even if `Tbl` contains a vector of weights. To specify weights, you must specify `ValidationData` as a cell array.

If you specify `ValidationData` as a cell array, then it must have the following format:

- `ValidationData{1}` must have the same data type and orientation as the predictor data. That is, if you use a predictor matrix `X`, then `ValidationData{1}` must be an *m*-by-*p* or *p*-by-*m* full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. Similarly, if you use a predictor table `Tbl` of predictor data, then `ValidationData{1}` must be a table containing the same predictor variables contained in `Tbl`. The number of observations in `ValidationData{1}` and the predictor data can vary.
- `ValidationData{2}` must match the data type and format of the response variable, either `Y` or `ResponseVarName`. If `ValidationData{2}` is an array of class labels, then it must have the same number of elements as the number of observations in `ValidationData{1}`. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`. If `ValidationData{1}` is a table, then `ValidationData{2}` can be the name of the response variable in the table. If you want to use the same `ResponseVarName` or `formula`, you can specify `ValidationData{2}` as `[]`.
- Optionally, you can specify `ValidationData{3}` as an *m*-dimensional numeric vector of observation weights or the name of a variable in the table `ValidationData{1}` that contains observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData` and want to display the validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

BFGS, LBFGS, and SpaRSA Convergence Controls

`BetaTolerance` — Relative tolerance on linear coefficients and bias term

`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`GradientTolerance` — Absolute gradient tolerance

`1e-6` (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let $\nabla \mathscr{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t. If $\|\nabla \mathscr{L}_t\|_\infty = \max|\nabla \mathscr{L}_t| <$ GradientTolerance, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'GradientTolerance',1e-5`

Data Types: `single` | `double`

`HessianHistorySize` — Size of history buffer for Hessian approximation

`15` (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest `HessianHistorySize` iterations.

The software does not support `'HessianHistorySize'` for SpaRSA.

Example: `'HessianHistorySize',10`

Data Types: `single` | `double`

`IterationLimit` — Maximal number of optimization iterations
`1000` (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. `IterationLimit` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Example: `'IterationLimit',500`

Data Types: `single` | `double`

`ValidationData` — Validation data for optimization convergence detection
cell array | table

Validation data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array or table.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 33-1769. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

You can specify `ValidationData` as a table if you use a table `Tbl` of predictor data that contains the response variable. In this case, `ValidationData` must contain the same predictors and response contained in `Tbl`. The software does not apply weights to observations, even if `Tbl` contains a vector of weights. To specify weights, you must specify `ValidationData` as a cell array.

If you specify `ValidationData` as a cell array, then it must have the following format:

- `ValidationData{1}` must have the same data type and orientation as the predictor data. That is, if you use a predictor matrix `X`, then `ValidationData{1}` must be an *m*-by-*p* or *p*-by-*m* full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. Similarly, if you use a predictor table `Tbl` of predictor data, then `ValidationData{1}` must be a table containing the same predictor variables contained in `Tbl`. The number of observations in `ValidationData{1}` and the predictor data can vary.
- `ValidationData{2}` must match the data type and format of the response variable, either `Y` or `ResponseVarName`. If `ValidationData{2}` is an array of class labels, then it must have the same number of elements as the number of observations in `ValidationData{1}`. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`. If `ValidationData{1}` is a table, then `ValidationData{2}` can be the name of the response variable in the table. If you want to use the same `ResponseVarName` or `formula`, you can specify `ValidationData{2}` as `[]`.
- Optionally, you can specify `ValidationData{3}` as an *m*-dimensional numeric vector of observation weights or the name of a variable in the table `ValidationData{1}` that contains observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData` and want to display the validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Hyperparameter Optimization

`OptimizeHyperparameters` — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Lambda','Learner'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitclinear` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitclinear` are:

- `Lambda` — `fitclinear` searches among positive values, by default log-scaled in the range `[1e-5/NumObservations,1e5/NumObservations]`.
- `Learner` — `fitclinear` searches among `'svm'` and `'logistic'`.
- `Regularization` — `fitclinear` searches among `'ridge'` and `'lasso'`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitclinear',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Linear Classifier” on page 33-1739.

Example: `'OptimizeHyperparameters','auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`

Field Name	Values	Default
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	

Field Name	Values	Default
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained linear classification model

`ClassificationLinear` model object | `ClassificationPartitionedLinear` cross-validated model object

Trained linear classification model, returned as a `ClassificationLinear` model object or `ClassificationPartitionedLinear` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedLinear` cross-validated model object. Otherwise, `Mdl` is a `ClassificationLinear` model object.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Beta` in the Command Window to display the vector or matrix of estimated coefficients.

Note Unlike other classification models, and for economical memory usage, `ClassificationLinear` and `ClassificationPartitionedLinear` model objects do not store the training data or training process details (for example, convergence history).

`FitInfo` — Optimization details

structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, `Objective` is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of `Lambda` and columns correspond to values of `Solver`.

This table describes some notable fields.

Field	Description
`TerminationStatus`	• Reason for optimization termination • Corresponds to a value in `TerminationCode`
`FitTime`	Elapsed, wall-clock time in seconds

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>History</td><td>A structure array of optimization information for each iteration. The field Solver stores solver types using integer coding.
<table>
<tr><th>Integer</th><th>Solver</th></tr>
<tr><td>1</td><td>SGD</td></tr>
<tr><td>2</td><td>ASGD</td></tr>
<tr><td>3</td><td>Dual SGD for SVM</td></tr>
<tr><td>4</td><td>LBFGS</td></tr>
<tr><td>5</td><td>BFGS</td></tr>
<tr><td>6</td><td>SpaRSA</td></tr>
</table></td></tr>
</table>

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

`HyperparameterOptimizationResults` — Cross-validation optimization of hyperparameters
`BayesianOptimization` object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. The output is nonempty when the value of `'OptimizeHyperparameters'` is not `'none'`. The output value depends on the `Optimizer` field value of the `'HyperparameterOptimizationOptions'` name-value pair argument:

Value of `Optimizer` Field	Value of `HyperparameterOptimizationResults`
`'bayesopt'` (default)	Object of class `BayesianOptimization`
`'gridsearch'` or `'randomsearch'`	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

More About

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Alternatives for Lower-Dimensional Data

High-dimensional linear classification and regression models minimize objective functions relatively quickly, but at the cost of some accuracy, the numeric-only predictor variables restriction, and the model must be linear with respect to the parameters. If your predictor data set is low- through medium-dimensional, or contains heterogeneous variables, then you should use the appropriate classification or regression fitting function. To help you decide which fitting function is appropriate for your low-dimensional data set, use this table.

Model to Fit	Function	Notable Algorithmic Differences
SVM	• Binary classification: `fitcsvm` • Multiclass classification: `fitcecoc` • Regression: `fitrsvm`	• Computes the Gram matrix of the predictor variables, which is convenient for nonlinear kernel transformations. • Solves dual problem using SMO, ISDA, or *L*1 minimization via quadratic programming using `quadprog`.
Linear regression	• Least-squares without regularization: `fitlm` • Regularized least-squares using a lasso penalty: `lasso` • Ridge regression: `ridge` or `lasso`	• `lasso` implements cyclic coordinate descent.
Logistic regression	• Logistic regression without regularization: `fitglm`. • Regularized logistic regression using a lasso penalty: `lassoglm`	• `fitglm` implements iteratively reweighted least squares. • `lassoglm` implements cyclic coordinate descent.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn','columns'`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy when you have high-dimensional predictor data and the `Regularization` value is `'ridge'`, set any of these options for `Solver`:
  - `'sgd'`
  - `'asgd'`
  - `'dual'` if `Learner` is `'svm'`
  - `{'sgd','lbfgs'}`
  - `{'asgd','lbfgs'}`
  - `{'dual','lbfgs'}` if `Learner` is `'svm'`

  Other options can result in poor optimization accuracy.
- For better optimization accuracy when you have moderate- to low-dimensional predictor data and the `Regularization` value is `'ridge'`, set `Solver` to `'bfgs'`.
- If `Regularization` is `'lasso'`, set any of these options for `Solver`:
  - `'sgd'`
  - `'asgd'`
  - `'sparsa'`
  - `{'sgd','sparsa'}`

  - `{'asgd','sparsa'}`
- When choosing between SGD and ASGD, consider that:
  - SGD takes less time per iteration, but requires more iterations to converge.
  - ASGD requires fewer iterations to converge, but takes more time per iteration.
- If your predictor data has few observations but many predictor variables, then:
  - Specify `'PostFitBias',true`.
  - For SGD or ASGD solvers, set `PassLimit` to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, `BatchSize` affects the rate of convergence.
  - If `BatchSize` is too small, then `fitclinear` achieves the minimum in many iterations, but computes the gradient per iteration quickly.
  - If `BatchSize` is too large, then `fitclinear` achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rates (see `LearnRate`) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- When using lasso penalties, experiment with various values of `TruncationPeriod`. For example, set `TruncationPeriod` to `1`, `10`, and then `100`.
- For efficiency, `fitclinear` does not standardize predictor data. To standardize `X`, enter

  ```
  X = bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2));
  ```

  The code requires that you orient the predictors and observations as the rows and columns of `X`, respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- If you specify `ValidationData`, then, during objective-function optimization:
  - `fitclinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.
  - When `fitclinear` estimates a validation loss, it compares the estimate to the minimal estimate.
  - When subsequent, validation loss estimates exceed the minimal estimate five times, `fitclinear` terminates optimization.
- If you specify `ValidationData` and to implement a cross-validation routine (`CrossVal`, `CVPartition`, `Holdout`, or `KFold`), then:

  1. `fitclinear` randomly partitions `X` and `Y` (or `Tbl`) according to the cross-validation routine that you choose.

2. `fitclinear` trains the model using the training-data partition. During objective-function optimization, `fitclinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
3. Once `fitclinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
   a. If you implement *k*-fold cross-validation, and `fitclinear` has not exhausted all training-set folds, then `fitclinear` returns to Step 2 to train using the next training-set fold.
   b. Otherwise, `fitclinear` terminates training, and then returns the cross-validated model.
4. You can determine the quality of the cross-validated model. For example:
   - To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
   - To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `fitclinear` does not support tall `table` data.
- Some name-value pair arguments have different defaults compared to the default values for the in-memory `fitclinear` function. Supported name-value pair arguments, and any differences, are:

- `'ObservationsIn'` — Supports only `'rows'`.
- `'Lambda'` — Can be `'auto'` (default) or a scalar.
- `'Learner'`
- `'Regularization'` — Supports only `'ridge'`.
- `'Solver'` — Supports only `'lbfgs'`.
- `'FitBias'` — Supports only `true`.
- `'Verbose'` — Default value is `1`.
- `'Beta'`
- `'Bias'`
- `'ClassNames'`
- `'Cost'`
- `'Prior'`
- `'Weights'` — Value must be a tall array.
- `'HessianHistorySize'`
- `'BetaTolerance'` — Default value is relaxed to `1e–3`.
- `'GradientTolerance'` — Default value is relaxed to `1e–3`.
- `'IterationLimit'` — Default value is relaxed to `20`.
- `'OptimizeHyperparameters'` — Value of `'Regularization'` parameter must be `'ridge'`.
- `'HyperparameterOptimizationOptions'` — For cross-validation, tall optimization supports only `'Holdout'` validation. By default, the software selects and reserves 20% of the data as holdout validation data, and trains the model using the rest of the data. You can specify a different value for the holdout fraction by using this argument. For example, specify `'HyperparameterOptimizationOptions',struct('Holdout',0.3)` to reserve 30% of the data as validation data.

- For tall arrays, `fitclinear` implements LBFGS by distributing the calculation of the loss and gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

  When initial values for `Beta` and `Bias` are not given, `fitclinear` refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016a

fitcnb

Train multiclass naive Bayes model

Syntax

```
Mdl = fitcnb(Tbl,ResponseVarName)
Mdl = fitcnb(Tbl,formula)
Mdl = fitcnb(Tbl,Y)

Mdl = fitcnb(X,Y)

Mdl = fitcnb( ___ ,Name,Value)
```

Description

`Mdl = fitcnb(Tbl,ResponseVarName)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in table `Tbl` and class labels in the variable `Tbl.ResponseVarName`.

`Mdl = fitcnb(Tbl,formula)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcnb(Tbl,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in the table `Tbl` and class labels in the array `Y`.

`Mdl = fitcnb(X,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by predictors `X` and class labels `Y`.

`Mdl = fitcnb( ___ ,Name,Value)` returns a naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Examples

Train a Naive Bayes Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas(:,3:4);
Y = species;
tabulate(Y)
```

```
       Value    Count   Percent
      setosa       50     33.33%
  versicolor       50     33.33%
   virginica       50     33.33%
```

The software can classify data with more than two classes using naive Bayes methods.

Train a naive Bayes classifier. It is good practice to specify the class order.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'})
```

```
Mdl =
  ClassificationNaiveBayes
              ResponseName: 'Y'
     CategoricalPredictors: []
                ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
         DistributionNames: {'normal'  'normal'}
    DistributionParameters: {3x2 cell}

  Properties, Methods
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within `setosa`.

```
setosaIndex = strcmp(Mdl.ClassNames,'setosa');
estimates = Mdl.DistributionParameters{setosaIndex,1}
```

```
estimates = 2×1

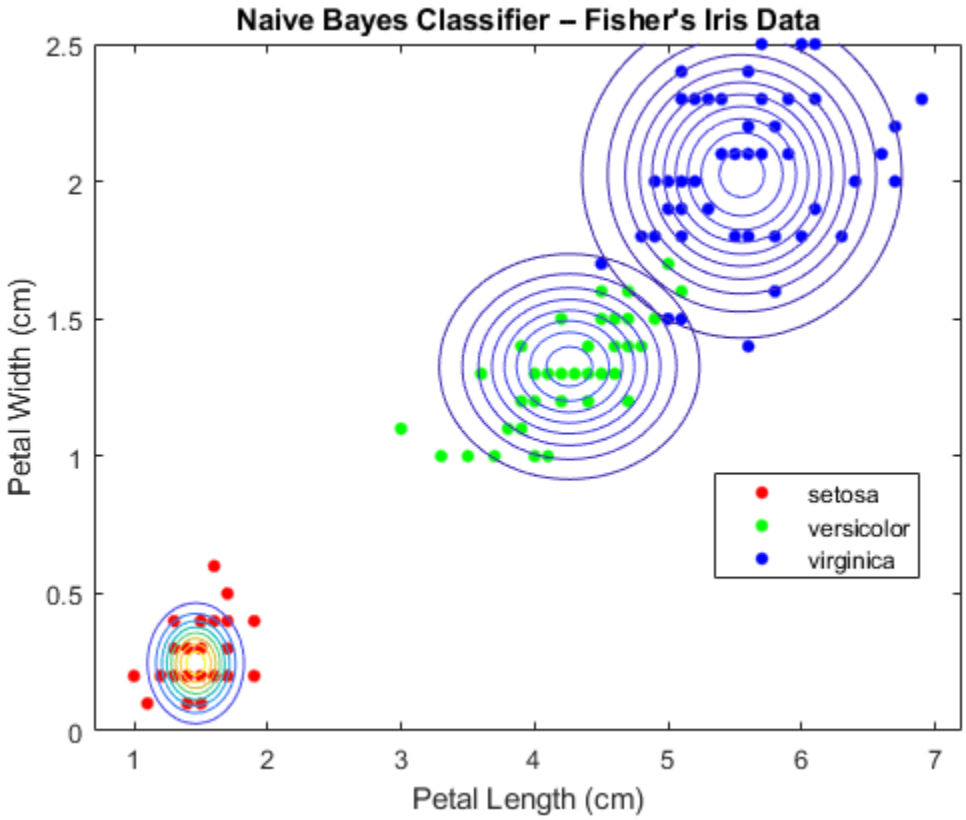
    1.4620
    0.1737
```

The mean is `1.4620` and the standard deviation is `0.1737`.

Plot the Gaussian contours.

```
figure
gscatter(X(:,1),X(:,2),Y);
h = gca;
cxlim = h.XLim;
cylim = h.YLim;
hold on
Params = cell2mat(Mdl.DistributionParameters);
Mu = Params(2*(1:3)-1,1:2); % Extract the means
Sigma = zeros(2,2,3);
for j = 1:3
    Sigma(:,:,j) = diag(Params(2*j,:)).^2; % Create diagonal covariance matrix
    xlim = Mu(j,1) + 4*[-1 1]*sqrt(Sigma(1,1,j));
    ylim = Mu(j,2) + 4*[-1 1]*sqrt(Sigma(2,2,j));
    f = @(x,y) arrayfun(@(x0,y0) mvnpdf([x0 y0],Mu(j,:),Sigma(:,:,j)),x,y);
    fcontour(f,[xlim ylim]) % Draw contours for the multivariate normal distributions
end
h.XLim = cxlim;
h.YLim = cylim;
title('Naive Bayes Classifier -- Fisher''s Iris Data')
xlabel('Petal Length (cm)')
ylabel('Petal Width (cm)')
```

```
legend('setosa','versicolor','virginica')
hold off
```



You can change the default distribution using the name-value pair argument `'DistributionNames'`. For example, if some predictors are categorical, then you can specify that they are multivariate, multinomial random variables using `'DistributionNames','mvmn'`.

Specify Prior Probabilities When Training Naive Bayes Classifiers

Construct a naive Bayes classifier for Fisher's iris data set. Also, specify prior probabilities during training.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
classNames = {'setosa','versicolor','virginica'}; % Class order
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

By default, the prior class probability distribution is the relative frequency distribution of the classes in the data set. In this case the prior probability is 33% for each species. However, suppose you know

that in the population 50% of the irises are setosa, 20% are versicolor, and 30% are virginica. You can incorporate this information by specifying this distribution as a prior probability during training.

Train a naive Bayes classifier. Specify the class order and prior class probability distribution.

```
prior = [0.5 0.2 0.3];
Mdl = fitcnb(X,Y,'ClassNames',classNames,'Prior',prior)
```

```
Mdl =
  ClassificationNaiveBayes
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
        DistributionNames: {'normal'  'normal'  'normal'  'normal'}
   DistributionParameters: {3x4 cell}

  Properties, Methods
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier, and some of its properties appear in the Command Window. The software treats the predictors as independent given a class, and, by default, fits them using normal distributions.

The naive Bayes algorithm does not use the prior class probabilities during training. Therefore, you can specify prior class probabilities after training using dot notation. For example, suppose that you want to see the difference in performance between a model that uses the default prior class probabilities and a model that uses different `prior`.

Create a new naive Bayes model based on `Mdl`, and specify that the prior class probability distribution is an empirical class distribution.

```
defaultPriorMdl = Mdl;
FreqDist = cell2table(tabulate(Y));
defaultPriorMdl.Prior = FreqDist{:,3};
```

The software normalizes the prior class probabilities to sum to `1`.

Estimate the cross-validation error for both models using 10-fold cross-validation.

```
rng(1); % For reproducibility
defaultCVMdl = crossval(defaultPriorMdl);
defaultLoss = kfoldLoss(defaultCVMdl)
```

```
defaultLoss = 0.0533
```

```
CVMdl = crossval(Mdl);
Loss = kfoldLoss(CVMdl)
```

```
Loss = 0.0340
```

`Mdl` performs better than `defaultPriorMdl`.

Specify Predictor Distributions for Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using every predictor. It is good practice to specify the class order.

```
Mdl1 = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'})
```

```
Mdl1 =
  ClassificationNaiveBayes
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
        DistributionNames: {'normal'  'normal'  'normal'  'normal'}
   DistributionParameters: {3x4 cell}

  Properties, Methods
```

```
Mdl1.DistributionParameters
```

```
ans=3×4 cell array
    {2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}
    {2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}
    {2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}
```

```
Mdl1.DistributionParameters{1,2}
```

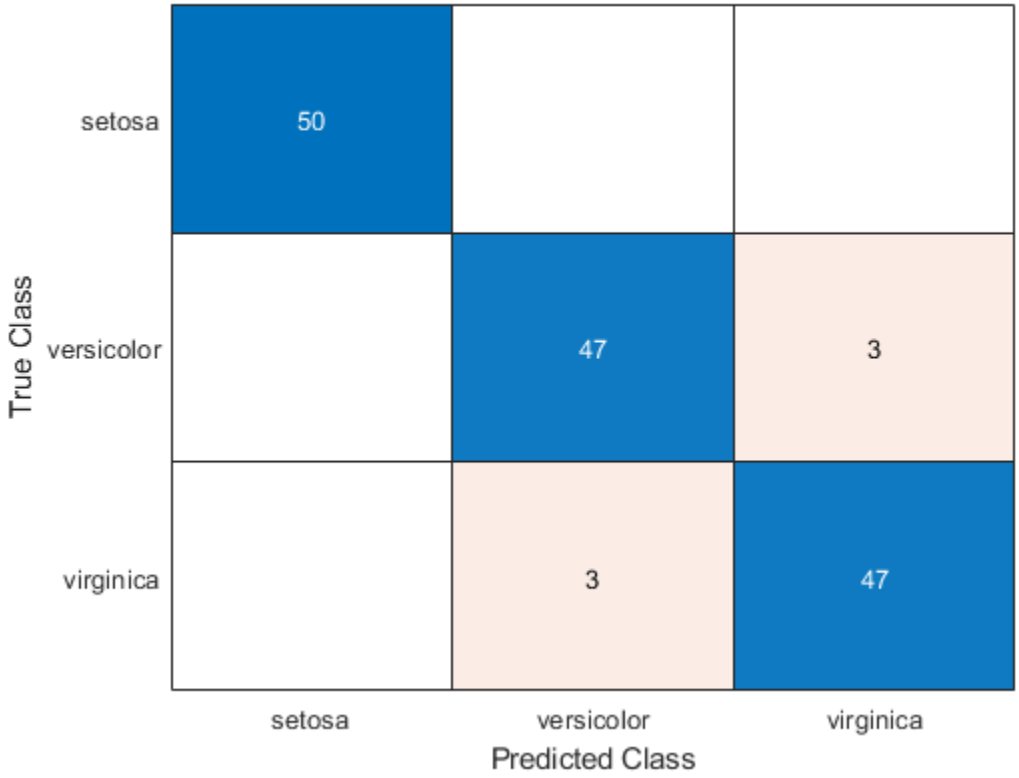
```
ans = 2×1

    3.4280
    0.3791
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in `Mdl1.DistributionParameters` corresponds to a numeric vector containing the mean and standard deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are `3.4280` and `0.3791`, respectively.

Estimate the confusion matrix for `Mdl1`.

```
isLabels1 = resubPredict(Mdl1);
ConfusionMat1 = confusionchart(Y,isLabels1);
```



Element (*j*, *k*) of the confusion matrix chart represents the number of observations that the software classifies as *k*, but are truly in class *j* according to the data.

Retrain the classifier using the Gaussian distribution for predictors 1 and 2 (the sepal lengths and widths), and the default normal kernel density for predictors 3 and 4 (the petal lengths and widths).

```
Mdl2 = fitcnb(X,Y,...
    'DistributionNames',{'normal','normal','kernel','kernel'},...
    'ClassNames',{'setosa','versicolor','virginica'});
Mdl2.DistributionParameters{1,2}
```

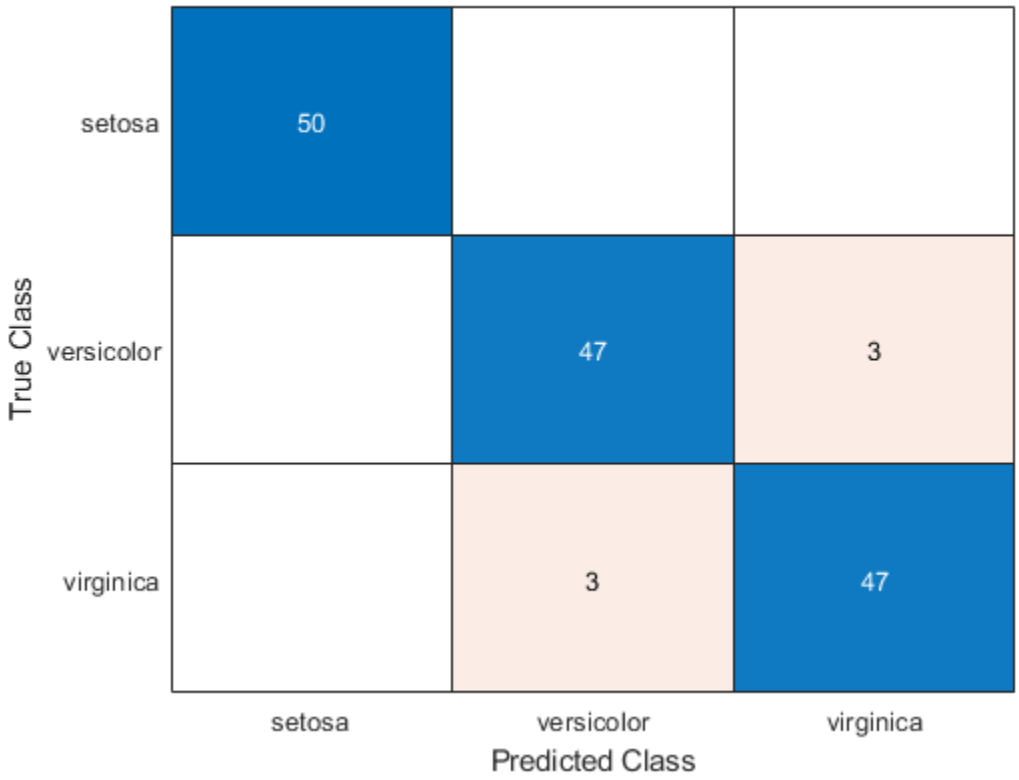
```
ans = 2×1

    3.4280
    0.3791
```

The software does not train parameters to the kernel density. Rather, the software chooses an optimal width. However, you can specify a width using the `'Width'` name-value pair argument.

Estimate the confusion matrix for `Mdl2`.

```
isLabels2 = resubPredict(Mdl2);
ConfusionMat2 = confusionchart(Y,isLabels2);
```



Based on the confusion matrices, the two classifiers perform similarly in the training sample.

Compare Classifiers Using Cross-Validation

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Train and cross-validate a naive Bayes classifier using the default options and *k*-fold cross-validation. It is good practice to specify the class order.

```
CVMdl1 = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'CrossVal','on');
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. `CVMdl1` is a `ClassificationPartitionedModel` model.

Create a default naive Bayes binary classifier template, and train an error-correcting, output codes multiclass model.

```
t = templateNaiveBayes();
CVMdl2 = fitcecoc(X,Y,'CrossVal','on','Learners',t);
```

`CVMdl2` is a `ClassificationPartitionedECOC` model. You can specify options for the naive Bayes binary learners using the same name-value pair arguments as for `fitcnb`.

Compare the out-of-sample *k*-fold classification error (proportion of misclassified observations).

```
classErr1 = kfoldLoss(CVMdl1,'LossFun','ClassifErr')
```

```
classErr1 = 0.0533
```

```
classErr2 = kfoldLoss(CVMdl2,'LossFun','ClassifErr')
```

```
classErr2 = 0.0467
```

`Mdl2` has a lower generalization error.

Train Naive Bayes Classifiers Using Multinomial Predictors

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, the predictors compose multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.

Create Training Data

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to `y` for each email.

```
n = 1000;                        % Sample size
rng(1);                          % For reproducibility
Y = randsample([-1 1],n,true);  % Random labels
```

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing random, multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```
tokenProbs = [0.2 0.3 0.1 0.15 0.25;...
    0.4 0.1 0.3 0.05 0.15];             % Token relative frequencies
tokensPerEmail = 20;                    % Fixed for convenience
X = zeros(n,5);
X(Y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(Y == 1));
X(Y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(Y == -1));
```

Train the Classifier

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```
Mdl = fitcnb(X,Y,'DistributionNames','mn');
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

Assess the in-sample performance of `Mdl` by estimating the misclassification error.

```
isGenRate = resubLoss(Mdl,'LossFun','ClassifErr')
```

```
isGenRate = 0.0200
```

The in-sample misclassification rate is 2%.

Create New Data

Randomly generate deviates that represent a new batch of emails.

```
newN = 500;
newY = randsample([-1 1],newN,true);
newX = zeros(newN,5);
newX(newY == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),...
    sum(newY == 1));
newX(newY == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),...
    sum(newY == -1));
```

Assess Classifier Performance

Classify the new emails using the trained naive Bayes classifier `Mdl`, and determine whether the algorithm generalizes.

```
oosGenRate = loss(Mdl,newX,newY)
```

```
oosGenRate = 0.0261
```

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

Optimize Naive Bayes Classifier

This example shows how to use the `OptimizeHyperparameters` name-value pair to minimize cross-validation loss in a naive Bayes classifier using `fitcnb`. The example uses Fisher's iris data.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
classNames = {'setosa','versicolor','virginica'};
```

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng default
Mdl = fitcnb(X,Y,'ClassNames',classNames,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

```
Warning: It is recommended that you first standardize all numeric predictors when optimizing the

  Properties, Methods
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the naive Bayes classifier is trained, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each element of `Y` defines the class membership of the corresponding row of `X`. `Y` supports K class levels.

If `Y` is a character array, then each row must correspond to one class label.

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`X` — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equivalent.

Data Types: `double`

Note: The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing data values.

- If `Y` contains missing values, then the software removes them and the corresponding rows of `X`.
- If `X` contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of `Y`.
- If `X` contains missing values and you set `'DistributionNames','mn'`, then the software removes those rows of `X` and the corresponding elements of `Y`.

- If a predictor is not represented in a class, that is, if all of its values are `NaN` within a class, then the software returns an error.

Removing rows of `X` and corresponding elements of `Y` decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'DistributionNames','mn','Prior','uniform','KSWidth',0.5` specifies that the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is `0.5` units.

Naive Bayes Options

`DistributionNames` — Data distributions
`'kernel'` | `'mn'` | `'mvmn'` | `'normal'` | string array | cell array of character vectors

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of `'DistributionNames'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description
`'kernel'`	Kernel smoothing density estimate.
`'mn'`	Multinomial distribution. If you specify `mn`, then all features are components of a multinomial distribution. Therefore, you cannot include `'mn'` as an element of a string array or a cell array of character vectors. For details, see “Algorithms” on page 33-1799.
`'mvmn'`	Multivariate multinomial distribution. For details, see “Algorithms” on page 33-1799.
`'normal'`	Normal (Gaussian) distribution.

If you specify a character vector or string scalar, then the software models all the features using that distribution. If you specify a 1-by-*P* string array or cell array of character vectors, then the software models feature *j* using the distribution in element *j* of the array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to `'mvmn'`. Otherwise, the default distribution is `'normal'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'DistributionNames','mn'`

Example: `'DistributionNames',{'kernel','normal','kernel'}`

`Kernel` — Kernel smoother type
`'normal'` (default) | `'box'` | `'epanechnikov'` | `'triangle'` | string array | cell array of character vectors

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and a character vector or string scalar, a string array, or a cell array of character vectors.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
`'box'`	Box (uniform)	$f(x) = 0.5I\{\|x\| \le 1\}$
`'epanechnikov'`	Epanechnikov	$f(x) = 0.75\left(1 - x^2\right)I\{\|x\| \le 1\}$
`'normal'`	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}}\exp\left(-0.5x^2\right)$
`'triangle'`	Triangular	$f(x) = (1 - \|x\|)I\{\|x\| \le 1\}$

If you specify a 1-by-*P* string array or cell array, with each element of the array containing any value in the table, then the software trains the classifier using the kernel smoother type in element *j* for feature *j* in `X`. The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is `'kernel'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Kernel',{'epanechnikov','normal'}`

`Support` — Kernel smoothing density support
`'unbounded'` (default) | `'positive'` | string array | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of `'Support'` and `'positive'`, `'unbounded'`, a string array, a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, `[L,U]`, where `L` and `U` are the finite lower and upper bounds, respectively, for the density support.
`'positive'`	The density support is all positive real values.
`'unbounded'`	The density support is all real values.

If you specify a 1-by-*P* string array or cell array, with each element in the string array containing any text value in the table and each element in the cell array containing any value in the table, then the

software trains the classifier using the kernel support in element *j* for feature *j* in `X`. The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is `'kernel'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'KSSupport',{[-10,20],'unbounded'}`

Data Types: `char` | `string` | `cell` | `double`

`Width` — Kernel smoothing window width

matrix of numeric values | numeric column vector | numeric row vector | scalar

Kernel smoothing window width, specified as the comma-separated pair consisting of `'Width'` and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are *K* class levels and *P* predictors. This table summarizes the available options for setting the kernel smoothing window width.

Value	Description
K-by-*P* matrix of numeric values	Element (*k*,*j*) specifies the width for predictor *j* in class *k*.
K-by-1 numeric column vector	Element *k* specifies the width for all predictors in class *k*.
1-by-*P* numeric row vector	Element *j* specifies the width in all class levels for predictor *j*.
scalar	Specifies the bandwidth for all features in all classes.

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify `Width` and it contains `NaN`s, then the software selects widths for the elements containing `NaN`s.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Width',[NaN NaN]`

Data Types: `double` | `struct`

Cross-Validation Options

`CrossVal` — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'CrossVal','on'`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other n – 1 observations.
2. Store the n compact, trained models in an n-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Other Classification Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitcnb` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcnb` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitcnb` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitcnb` uses multivariate multinomial distributions. For details, see `DistributionNames` and “Algorithms” on page 33-1799.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for training
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Cost of misclassification
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`.

Example: `'Cost',struct('ClassNames',{{'b','g'}},'ClassificationCosts',[0 0.5; 1 0])`

Data Types: `single` | `double` | `struct`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.

  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitcnb` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`Prior` — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to `Mdl.ClassNames` or specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements such that they sum to `1`.
structure	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to `1`.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ScoreTransform` — Score transformation
`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string

scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(`*n*`,1)`, where *n* is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Hyperparameter Optimization

`OptimizeHyperparameters` — Parameters to optimize
`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'DistributionNames','Width'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitcnb` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcnb` are:

- `DistributionNames` — `fitcnb` searches among `'normal'` and `'kernel'`.
- `Width` — `fitcnb` searches among real values, by default log-scaled in the range `[MinPredictorDiff/4,max(MaxPredictorRange,MinPredictorDiff)]`.
- `Kernel` — `fitcnb` searches among `'normal'`, `'box'`, `'epanechnikov'`, and `'triangle'`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcnb',meas,species);
params(2).Range = [1e-2,1e2];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is

log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Naive Bayes Classifier” on page 33-1781.

Example: `'auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`

Field Name	Values	Default
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		

Field Name	Values	Default
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained naive Bayes classification model

`ClassificationNaiveBayes` model object | `ClassificationPartitionedModel` cross-validated model object

Trained naive Bayes classification model, returned as a `ClassificationNaiveBayes` model object or a `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated model object. Otherwise, `Mdl` is a `ClassificationNaiveBayes` model object.

To reference properties of `Mdl`, use dot notation. For example, to access the estimated distribution parameters, enter `Mdl.DistributionParameters`.

More About

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in the observation. The number of categories (bins) in the multinomial model is the number of distinct tokens (number of predictors).

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Although the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm takes these steps:

1. Estimate the densities of the predictors within each class.
2. Model posterior probabilities according to Bayes rule. That is, for all $k = 1,...,K$,

$$\widehat{P}(Y = k \mid X_1, .., X_P) = \frac{\pi(Y = k) \prod_{j=1}^{P} P\left(X_j \middle| Y = k\right)}{\sum_{k=1}^{K} \pi(Y = k) \prod_{j=1}^{P} P\left(X_j \middle| Y = k\right)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
- $X_1,...,X_P$ are the random predictors of an observation.
- $\pi(Y = k)$ is the prior probability that a class index is k.

3 Classify an observation by estimating the posterior probability for each class, and then assign the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability $\widehat{P}(Y = k \mid X_1, .., X_P) \propto \pi(Y = k) P_{mn}(X_1, ..., X_P \mid Y = k)$, where $P_{mn}(X_1, ..., X_P \mid Y = k)$ is the probability mass function of a multinomial distribution.

Tips

- For classifying count-based data, such as the bag-of-tokens model on page 33-1798, use the multinomial distribution (e.g., set `'DistributionNames','mn'`).
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- If you specify `'DistributionNames','mn'` when training `Mdl` using `fitcnb`, then the software fits a multinomial distribution using the bag-of-tokens model on page 33-1798. The software stores the probability that token j appears in class k in the property `DistributionParameters{k,j}`. Using additive smoothing [2], the estimated probability is

  $$P(\text{token } j \,|\, \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

  where:

  - $c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$, which is the weighted number of occurrences of token j in class k.
  - n_k is the number of observations in class k.
  - w_i is the weight for observation i. The software normalizes weights within a class such that they sum to the prior probability for that class.
  - $c_k = \sum_{j=1}^{P} c_{j|k}$, which is the total weighted number of occurrences of all tokens in class k.
- If you specify `'DistributionNames','mvmn'` when training `Mdl` using `fitcnb`, then:

1. For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
2. For predictor j in class k, the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
3. The software stores the probability that predictor j, in class k, has level L in the property `DistributionParameters{k,j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L \,|\, \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

- $m_{j|k}(L) = n_k \dfrac{\sum_{i:\, y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i:\, y_i \in \text{class } k} w_i}$, which is the weighted number of observations for which predictor j equals L in class k.
- n_k is the number of observations in class k.
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
- w_i is the weight for observation i. The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j.
- m_k is the weighted number of observations in class k.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays with the limitations:

- Supported syntaxes are:
  - `Mdl = fitcnb(Tbl,Y)`
  - `Mdl = fitcnb(X,Y)`
  - `Mdl = fitcnb(___,Name,Value)`
- Options related to kernel densities, cross-validation, and hyperparameter optimization are not supported. The supported name-value pair arguments are:

- `'DistributionNames'` — `'kernel'` value is not supported.
- `'CategoricalPredictors'`
- `'Cost'`
- `'PredictorNames'`
- `'Prior'`
- `'ResponseName'`
- `'ScoreTransform'`
- `'Weights'` — Value must be a tall array.

For more information, see “Tall Arrays for Out-of-Memory Data”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

fitcnet

Train neural network classification model

Syntax

```
Mdl = fitcnet(Tbl,ResponseVarName)
Mdl = fitcnet(Tbl,formula)
Mdl = fitcnet(Tbl,Y)

Mdl = fitcnet(X,Y)

Mdl = fitcnet( ___ ,Name,Value)
```

Description

Use `fitcnet` to train a feedforward, fully connected neural network for classification. The first fully connected layer of the neural network has a connection from the network input (predictor data), and each subsequent layer has a connection from the previous layer. Each fully connected layer multiplies the input by a weight matrix and then adds a bias vector. An activation function follows each fully connected layer. The final fully connected layer and the subsequent softmax activation function produce the network's output, namely classification scores (posterior probabilities) and predicted labels. For more information, see “Neural Network Structure” on page 33-1823.

`Mdl = fitcnet(Tbl,ResponseVarName)` returns a neural network classification model `Mdl` trained using the predictors in the table `Tbl` and the class labels in the `ResponseVarName` table variable.

`Mdl = fitcnet(Tbl,formula)` returns a neural network classification model trained using the sample data in the table `Tbl`. The input argument `formula` is an explanatory model of the response and a subset of the predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcnet(Tbl,Y)` returns a neural network classification model using the predictor variables in the table `Tbl` and the class labels in vector `Y`.

`Mdl = fitcnet(X,Y)` returns a neural network classification model trained using the predictors in the matrix `X` and the class labels in vector `Y`.

`Mdl = fitcnet( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can adjust the number of outputs and the activation functions for the fully connected layers by specifying the `LayerSizes` and `Activations` name-value arguments.

Examples

Train Neural Network Classifier

Train a neural network classifier, and assess the performance of the classifier on a test set.

Read the sample file `CreditRating_Historical.dat` into a table. The predictor data consists of financial ratios and industry sector information for a list of corporate customers. The response

variable consists of credit ratings assigned by a rating agency. Preview the first few rows of the data set.

```
creditrating = readtable("CreditRating_Historical.dat");
head(creditrating)
```

```
ans=8×8 table
     ID      WC_TA     RE_TA     EBIT_TA    MVE_BVTD    S_TA     Industry    Rating
    _____    ______    ______    _______    ________    _____    ________    _______

    62394     0.013     0.104     0.036      0.447      0.142        3       {'BB' }
    48608     0.232     0.335     0.062      1.969      0.281        8       {'A'  }
    42444     0.311     0.367     0.074      1.935      0.366        1       {'A'  }
    48631     0.194     0.263     0.062      1.017      0.228        4       {'BBB'}
    43768     0.121     0.413     0.057      3.647      0.466       12       {'AAA'}
    39255    -0.117    -0.799      0.01      0.179      0.082        4       {'CCC'}
    62236     0.087     0.158     0.049      0.816      0.324        2       {'BBB'}
    39354     0.005     0.181     0.034      2.597      0.388        7       {'AA' }
```

Because each value in the `ID` variable is a unique customer ID, that is, `length(unique(creditrating.ID))` is equal to the number of observations in `creditrating`, the `ID` variable is a poor predictor. Remove the `ID` variable from the table, and convert the `Industry` variable to a `categorical` variable.

```
creditrating = removevars(creditrating,"ID");
creditrating.Industry = categorical(creditrating.Industry);
```

Convert the `Rating` response variable to an ordinal `categorical` variable.

```
creditrating.Rating = categorical(creditrating.Rating, ...
    ["AAA","AA","A","BBB","BB","B","CCC"],"Ordinal",true);
```

Partition the data into training and test sets. Use approximately 80% of the observations to train a neural network model, and 20% of the observations to test the performance of the trained model on new data. Use `cvpartition` to partition the data.

```
rng("default") % For reproducibility of the partition
c = cvpartition(creditrating.Rating,"Holdout",0.20);
trainingIndices = training(c); % Indices for the training set
testIndices = test(c); % Indices for the test set
creditTrain = creditrating(trainingIndices,:);
creditTest = creditrating(testIndices,:);
```

Train a neural network classifier by passing the training data `creditTrain` to the `fitcnet` function.

```
Mdl = fitcnet(creditTrain,"Rating")
```

```
Mdl =
  ClassificationNeuralNetwork
           PredictorNames: {'WC_TA'  'RE_TA'  'EBIT_TA'  'MVE_BVTD'  'S_TA'  'Industry'}
             ResponseName: 'Rating'
    CategoricalPredictors: 6
               ClassNames: [AAA    AA    A    BBB    BB    B    CCC]
           ScoreTransform: 'none'
          NumObservations: 3146
               LayerSizes: 10
              Activations: 'relu'
```

```
    OutputLayerActivation: 'softmax'
                   Solver: 'LBFGS'
         ConvergenceInfo: [1×1 struct]
         TrainingHistory: [1000×7 table]

  Properties, Methods
```

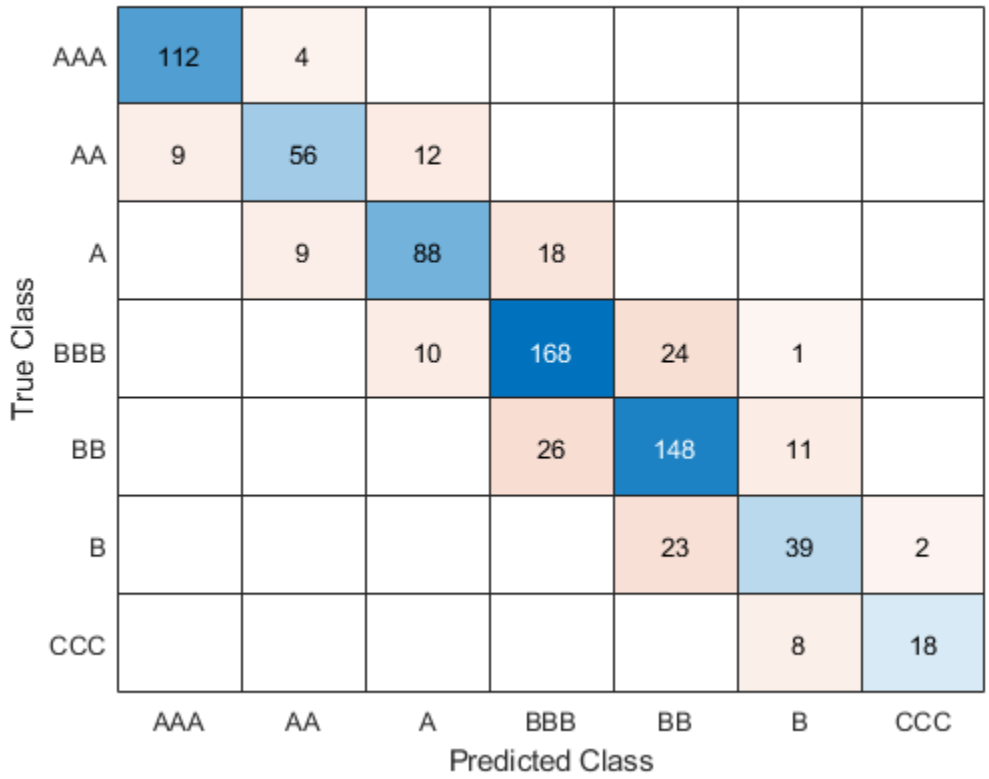
`Mdl` is a trained `ClassificationNeuralNetwork` classifier. You can use dot notation to access the properties of `Mdl`. For example, you can specify `Mdl.TrainingHistory` to get more information about the training history of the neural network model.

Evaluate the performance of the classifier on the test set by computing the test set classification error. Visualize the results by using a confusion matrix.

```
testAccuracy = 1 - loss(Mdl,creditTest,"Rating", ...
    "LossFun","classiferror")
```

```
testAccuracy = 0.8003
```

```
confusionchart(creditTest.Rating,predict(Mdl,creditTest))
```



Specify Neural Network Classifier Architecture

Specify the structure of a neural network classifier, including the size of the fully connected layers.

Load the `ionosphere` data set, which includes radar signal data. `X` contains the predictor data, and `Y` is the response variable, whose values represent either good ("g") or bad ("b") radar signals.

```
load ionosphere
```

Separate the data into training data (`XTrain` and `YTrain`) and test data (`XTest` and `YTest`) by using a stratified holdout partition. Reserve approximately 30% of the observations for testing, and use the rest of the observations for training.

```
rng("default") % For reproducibility of the partition
cvp = cvpartition(Y,"Holdout",0.3);
XTrain = X(training(cvp),:);
YTrain = Y(training(cvp));
XTest = X(test(cvp),:);
YTest = Y(test(cvp));
```

Train a neural network classifier. Specify to have 35 outputs in the first fully connected layer and 20 outputs in the second fully connected layer. By default, both layers use a rectified linear unit (ReLU) activation function. You can change the activation functions for the fully connected layers by using the `Activations` name-value argument.

```
Mdl = fitcnet(XTrain,YTrain, ...
    "LayerSizes",[35 20])
```

```
Mdl =
  ClassificationNeuralNetwork
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}
           ScoreTransform: 'none'
          NumObservations: 246
               LayerSizes: [35 20]
              Activations: 'relu'
    OutputLayerActivation: 'softmax'
                   Solver: 'LBFGS'
          ConvergenceInfo: [1×1 struct]
          TrainingHistory: [47×7 table]

  Properties, Methods
```

Access the weights and biases for the fully connected layers of the trained classifier by using the `LayerWeights` and `LayerBiases` properties of `Mdl`. The first two elements of each property correspond to the values for the first two fully connected layers, and the third element corresponds to the values for the final fully connected layer with a softmax activation function for classification. For example, display the weights and biases for the second fully connected layer.

```
Mdl.LayerWeights{2}
```

```
ans = 20×35

   -0.4839
   -0.3960
    0.9248
      ⋮
```

The final fully connected layer has two outputs, one for each class in the response variable. The number of layer outputs corresponds to the first dimension of the layer weights and layer biases.

```
size(Mdl.LayerWeights{end})
```

```
ans = 1×2

     2    20
```

```
size(Mdl.LayerBiases{end})
```

```
ans = 1×2

     2     1
```

To estimate the performance of the trained classifier, compute the test set classification error for `Mdl`.

```
testError = loss(Mdl,XTest,YTest, ...
    "LossFun","classiferror")
```

```
testError = 0.0774
```

```
accuracy = 1 - testError
```

```
accuracy = 0.9226
```

`Mdl` accurately classifies approximately 92% of the observations in the test set.

Stop Neural Network Training Early Using Validation Data

At each iteration of the training process, compute the validation loss of the neural network. Stop the training process early if the validation loss reaches a reasonable minimum.

Load the `patients` data set. Create a table from the data set. Each row corresponds to one patient, and each column corresponds to a diagnostic variable. Use the `Smoker` variable as the response variable, and the rest of the variables as predictors.

```
load patients
tbl = table(Diastolic,Systolic,Gender,Height,Weight,Age,Smoker);
```

Separate the data into a training set `tblTrain` and a validation set `tblValidation` by using a stratified holdout partition. The software reserves approximately 30% of the observations for the validation data set and uses the rest of the observations for the training data set.

```
rng("default") % For reproducibility of the partition
c = cvpartition(tbl.Smoker,"Holdout",0.30);
trainingIndices = training(c);
validationIndices = test(c);
tblTrain = tbl(trainingIndices,:);
tblValidation = tbl(validationIndices,:);
```

Train a neural network classifier by using the training set. Specify the `Smoker` column of `tblTrain` as the response variable. Evaluate the model at each iteration by using the validation set. Specify to display the training information at each iteration by using the `Verbose` name-value argument. By default, the training process ends early if the validation cross-entropy loss is greater than or equal to the minimum validation cross-entropy loss computed so far, six times in a row. To change the number of times the validation loss is allowed to be greater than or equal to the minimum, specify the `ValidationPatience` name-value argument.

```
Mdl = fitcnet(tblTrain,"Smoker", ...
    "ValidationData",tblValidation, ...
    "Verbose",1);
```

```

|=============|============|============|============|============|============|============|
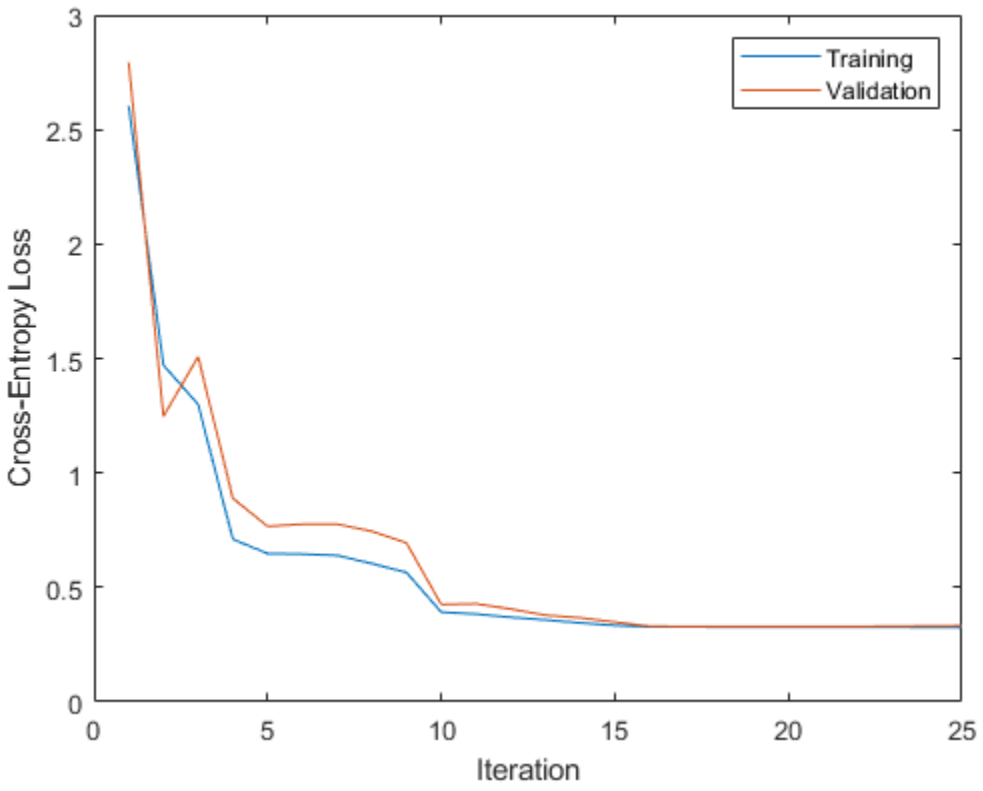
```

Create a plot that compares the training cross-entropy loss and the validation cross-entropy loss at each iteration. By default, `fitcnet` stores the loss information inside the `TrainingHistory` property of the object `Mdl`. You can access this information by using dot notation.

```
iteration = Mdl.TrainingHistory.Iteration;
trainLosses = Mdl.TrainingHistory.TrainingLoss;
valLosses = Mdl.TrainingHistory.ValidationLoss;

plot(iteration,trainLosses,iteration,valLosses)
legend(["Training","Validation"])
xlabel("Iteration")
ylabel("Cross-Entropy Loss")
```



Check the iteration that corresponds to the minimum validation loss. The final returned model `Mdl` is the model trained at this iteration.

```
[~,minIdx] = min(valLosses);
iteration(minIdx)
```

```
ans = 19
```

Find Good Regularization Strength for Neural Network Using Cross-Validation

Assess the cross-validation loss of neural network models with different regularization strengths, and choose the regularization strength corresponding to the best performing model.

Read the sample file `CreditRating_Historical.dat` into a table. The predictor data consists of financial ratios and industry sector information for a list of corporate customers. The response variable consists of credit ratings assigned by a rating agency. Preview the first few rows of the data set.

```
creditrating = readtable("CreditRating_Historical.dat");
head(creditrating)
```

```
ans=8×8 table
     ID      WC_TA     RE_TA     EBIT_TA    MVE_BVTD    S_TA     Industry    Rating
    _____    _____     _____     _______    ________    _____    ________    ______
```

```
    62394     0.013     0.104     0.036     0.447     0.142         3       {'BB' }
    48608     0.232     0.335     0.062     1.969     0.281         8       {'A'  }
    42444     0.311     0.367     0.074     1.935     0.366         1       {'A'  }
    48631     0.194     0.263     0.062     1.017     0.228         4       {'BBB'}
    43768     0.121     0.413     0.057     3.647     0.466        12       {'AAA'}
    39255    -0.117    -0.799      0.01     0.179     0.082         4       {'CCC'}
    62236     0.087     0.158     0.049     0.816     0.324         2       {'BBB'}
    39354     0.005     0.181     0.034     2.597     0.388         7       {'AA' }
```

Because each value in the `ID` variable is a unique customer ID, that is, `length(unique(creditrating.ID))` is equal to the number of observations in `creditrating`, the `ID` variable is a poor predictor. Remove the `ID` variable from the table, and convert the `Industry` variable to a `categorical` variable.

```
creditrating = removevars(creditrating,"ID");
creditrating.Industry = categorical(creditrating.Industry);
```

Convert the `Rating` response variable to an ordinal `categorical` variable.

```
creditrating.Rating = categorical(creditrating.Rating, ...
    ["AAA","AA","A","BBB","BB","B","CCC"],"Ordinal",true);
```

Create a `cvpartition` object for stratified 5-fold cross-validation. `cvp` partitions the data into five folds, where each fold has roughly the same proportions of different credit ratings. Set the random seed to the default value for reproducibility of the partition.

```
rng("default")
cvp = cvpartition(creditrating.Rating,"KFold",5);
```

Compute the cross-validation classification error for neural network classifiers with different regularization strengths. Try regularization strengths on the order of 1/*n*, where *n* is the number of observations. Specify to standardize the data before training the neural network models.

```
1/size(creditrating,1)
```

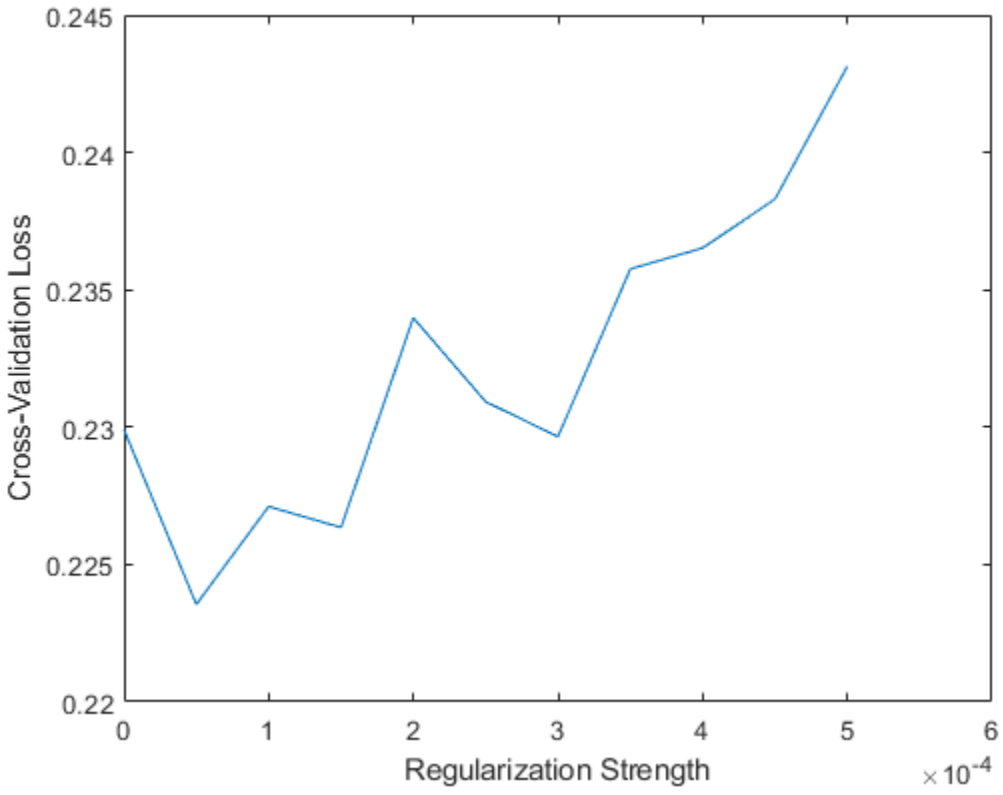
```
ans = 2.5432e-04
```

```
lambda = (0:0.5:5)*1e-4;
cvloss = zeros(length(lambda),1);

for i = 1:length(lambda)
    cvMdl = fitcnet(creditrating,"Rating","Lambda",lambda(i), ...
        "CVPartition",cvp,"Standardize",true);
    cvloss(i) = kfoldLoss(cvMdl,"LossFun","classiferror");
end
```

Plot the results. Find the regularization strength corresponding to the lowest cross-validation classification error.

```
plot(lambda,cvloss)
xlabel("Regularization Strength")
ylabel("Cross-Validation Loss")
```



```
[~,idx] = min(cvloss);
bestLambda = lambda(idx)
```

```
bestLambda = 5.0000e-05
```

Train a neural network classifier using the `bestLambda` regularization strength.

```
Mdl = fitcnet(creditrating,"Rating","Lambda",bestLambda, ...
    "Standardize",true)
```

```
Mdl =
  ClassificationNeuralNetwork
           PredictorNames: {'WC_TA'  'RE_TA'  'EBIT_TA'  'MVE_BVTD'  'S_TA'  'Industry'}

  Properties, Methods
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables

character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

Y — Class labels

numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class labels used to train the model, specified as a numeric, categorical, or logical vector; a character or string array; or a cell array of character vectors.

- If `Y` is a character array, then each element of the class labels must correspond to one row of the array.
- The length of `Y` must be equal to the number of rows in `Tbl` or `X`.
- A good practice is to specify the class order by using the `ClassNames` name-value argument.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

X — Predictor data

numeric matrix

Predictor data used to train the model, specified as a numeric matrix.

By default, the software treats each row of `X` as one observation, and each column as one predictor.

The length of `Y` and the number of observations in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value argument.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time.

Data Types: `single` | `double`

Note The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing values, and removes observations with any of these characteristics:

- Missing value in the response variable (for example, `Y` or `ValidationData{2}`)
- At least one missing value in a predictor observation (for example, row in `X` or `ValidationData{1}`)
- `NaN` value or `0` weight (for example, value in `Weights` or `ValidationData{3}`)

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitcnet(X,Y,'LayerSizes',[10 10],'Activations',["relu","tanh"])` specifies to create a neural network with two fully connected layers, each with 10 outputs. The first layer uses

a rectified linear unit (ReLU) activation function, and the second uses a hyperbolic tangent activation function.

Neural Network Options

`LayerSizes` — Sizes of fully connected layers

`10` (default) | positive integer vector

Sizes of the fully connected layers in the neural network model, specified as a positive integer vector. The *i*th element of `LayerSizes` is the number of outputs in the *i*th fully connected layer of the neural network model.

`LayerSizes` does not include the size of the final fully connected layer that uses a softmax activation function. For more information, see “Neural Network Structure” on page 33-1823.

Example: `'LayerSizes',[100 25 10]`

`Activations` — Activation functions for fully connected layers

`'relu'` (default) | `'tanh'` | `'sigmoid'` | `'none'` | string array | cell array of character vectors

Activation functions for the fully connected layers of the neural network model, specified as a character vector, string scalar, string array, or cell array of character vectors with values from this table.

Value	Description
`'relu'`	Rectified linear unit (ReLU) function — Performs a threshold operation on each element of the input, where any value less than zero is set to zero, that is, $$f(x) = \begin{cases} x, & x \geq 0 \\ 0, & x < 0 \end{cases}$$
`'tanh'`	Hyperbolic tangent (tanh) function — Applies the `tanh` function to each input element
`'sigmoid'`	Sigmoid function — Performs the following operation on each input element: $$f(x) = \frac{1}{1 + e^{-x}}$$
`'none'`	Identity function — Returns each input element without performing any transformation, that is, $f(x) = x$

- If you specify one activation function only, then `Activations` is the activation function for every fully connected layer of the neural network model, excluding the final fully connected layer. The activation function for the final fully connected layer is always softmax (see “Neural Network Structure” on page 33-1823).
- If you specify an array of activation functions, then the *i*th element of `Activations` is the activation function for the *i*th layer of the neural network model.

Example: `'Activations','sigmoid'`

`LayerWeightsInitializer` — Function to initialize fully connected layer weights
`'glorot'` (default) | `'he'`

Function to initialize the fully connected layer weights, specified as `'glorot'` or `'he'`.

Value	Description
`'glorot'`	Initialize the weights with the Glorot initializer [1] (also known as the Xavier initializer). For each layer, the Glorot initalizer independently samples from a uniform distribution with zero mean and variable `2/(I+O)`, where `I` is the input size and `O` is the output size for the layer.
`'he'`	Initialize the weights with the He initializer [2]. For each layer, the He initializer samples from a normal distribution with zero mean and variance `2/I`, where `I` is the input size for the layer.

Example: `'LayerWeightsFunction','he'`

`LayerBiasesInitializer` — Type of initial fully connected layer biases
`'zeros'` (default) | `'ones'`

Type of initial fully connected layer biases, specified as `'zeros'` or `'ones'`.

- If you specify the value `'zeros'`, then each fully connected layer has an initial bias of 0.
- If you specify the value `'ones'`, then each fully connected layer has an initial bias of 1.

Example: `'LayerBiasesInitializer','ones'`

Data Types: `char` | `string`

`ObservationsIn` — Predictor data observation dimension
`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as `'rows'` or `'columns'`.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time. You cannot specify `'ObservationsIn','columns'` for predictor data in a table.

Example: `'ObservationsIn','columns'`

Data Types: `char` | `string`

`Lambda` — Regularization term strength
`0` (default) | nonnegative scalar

Regularization term strength, specified as a nonnegative scalar. The software composes the objective function for minimization from the cross-entropy loss function and the ridge (L2) penalty term.

Example: `'Lambda',1e-4`

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictor data

`false` or `0` (default) | `true` or `1`

Flag to standardize the predictor data, specified as a numeric or logical `0` (`false`) or `1` (`true`). If you set `Standardize` to `true`, then the software centers and scales each numeric predictor variable by the corresponding column mean and standard deviation. The software does not standardize the categorical predictors.

Example: `'Standardize',true`

Data Types: `single` | `double` | `logical`

Convergence Control Options

`Verbose` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as `0` or `1`. The `'Verbose'` name-value argument controls the amount of diagnostic information that `fitcnet` displays at the command line.

Value	Description
`0`	`fitcnet` does not display diagnostic information.
`1`	`fitcnet` periodically displays diagnostic information.

By default, `StoreHistory` is set to `true` and `fitcnet` stores the diagnostic information inside of `Mdl`. Use `Mdl.TrainingHistory` to access the diagnostic information.

Example: `'Verbose',1`

Data Types: `single` | `double`

`VerboseFrequency` — Frequency of verbose printing

`1` (default) | positive integer scalar

Frequency of verbose printing, which is the number of iterations between printing to the command window, specified as a positive integer scalar. A value of 1 indicates to print diagnostic information at every iteration.

Note To use this name-value argument, set `Verbose` to `1`.

Example: `'VerboseFrequency',5`

Data Types: `single` | `double`

`StoreHistory` — Flag to store training history

`true` or `1` (default) | `false` or `0`

Flag to store the training history, specified as a numeric or logical `0` (`false`) or `1` (`true`). If `StoreHistory` is set to `true`, then the software stores diagnostic information inside of `Mdl`, which you can access by using `Mdl.TrainingHistory`.

Example: `'StoreHistory',false`

Data Types: `single` | `double` | `logical`

`IterationLimit` — Maximum number of training iterations
`1e3` (default) | positive integer scalar

Maximum number of training iterations, specified as a positive integer scalar.

The software returns a trained model regardless of whether the training routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: `'IterationLimit',1e8`

Data Types: `single` | `double`

`GradientTolerance` — Relative gradient tolerance
`1e-6` (default) | nonnegative scalar

Relative gradient tolerance, specified as a nonnegative scalar.

Let $\mathscr{L}_t$ be the loss function at training iteration t, $\nabla\mathscr{L}_t$ be the gradient of the loss function with respect to the weights and biases at iteration t, and $\nabla\mathscr{L}_0$ be the gradient of the loss function at an initial point. If $\max|\nabla\mathscr{L}_t| \le a \cdot \text{GradientTolerance}$, where $a = \max(1, \min|\mathscr{L}_t|, \max|\nabla\mathscr{L}_0|)$, then the training process terminates.

Example: `'GradientTolerance',1e-5`

Data Types: `single` | `double`

`LossTolerance` — Loss tolerance
`1e-6` (default) | nonnegative scalar

Loss tolerance, specified as a nonnegative scalar.

If the function loss at some iteration is smaller than `LossTolerance`, then the training process terminates.

Example: `'LossTolerance',1e-8`

Data Types: `single` | `double`

`StepTolerance` — Step size tolerance
`1e-6` (default) | nonnegative scalar

Step size tolerance, specified as a nonnegative scalar.

If the step size at some iteration is smaller than `StepTolerance`, then the training process terminates.

Example: `'StepTolerance',1e-4`

Data Types: `single` | `double`

`ValidationData` — Validation data for training convergence detection
cell array | table

Validation data for training convergence detection, specified as a cell array or table.

During the training process, the software periodically estimates the validation loss by using `ValidationData`. If the validation loss increases more than `ValidationPatience` times in a row, then the software terminates the training.

You can specify `ValidationData` as a table if you use a table `Tbl` of predictor data that contains the response variable. In this case, `ValidationData` must contain the same predictors and response contained in `Tbl`. The software does not apply weights to observations, even if `Tbl` contains a vector of weights. To specify weights, you must specify `ValidationData` as a cell array.

If you specify `ValidationData` as a cell array, then it must have the following format:

- `ValidationData{1}` must have the same data type and orientation as the predictor data. That is, if you use a predictor matrix `X`, then `ValidationData{1}` must be an *m*-by-*p* or *p*-by-*m* matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. Similarly, if you use a predictor table `Tbl` of predictor data, then `ValidationData{1}` must be a table containing the same predictor variables contained in `Tbl`. The number of observations in `ValidationData{1}` and the predictor data can vary.
- `ValidationData{2}` must match the data type and format of the response variable, either `Y` or `ResponseVarName`. If `ValidationData{2}` is an array of class labels, then it must have the same number of elements as the number of observations in `ValidationData{1}`. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`. If `ValidationData{1}` is a table, then `ValidationData{2}` can be the name of the response variable in the table. If you want to use the same `ResponseVarName` or `formula`, you can specify `ValidationData{2}` as `[]`.
- Optionally, you can specify `ValidationData{3}` as an *m*-dimensional numeric vector of observation weights or the name of a variable in the table `ValidationData{1}` that contains observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData` and want to display the validation loss at the command line, set `Verbose` to `1`.

`ValidationFrequency` — Number of iterations between validation evaluations
1 (default) | positive integer scalar

Number of iterations between validation evaluations, specified as a positive integer scalar. A value of 1 indicates to evaluate validation metrics at every iteration.

Note To use this name-value argument, you must specify `ValidationData`.

Example: `'ValidationFrequency',5`

Data Types: `single` | `double`

`ValidationPatience` — Stopping condition for validation evaluations
6 (default) | nonnegative integer scalar

Stopping condition for validation evaluations, specified as a nonnegative integer scalar. The training process stops if the validation loss is greater than or equal to the minimum validation loss computed so far, `ValidationPatience` times in a row. You can check the `Mdl.TrainingHistory` table to see the running total of times that the validation loss is greater than or equal to the minimum (`Validation Checks`).

Example: `'ValidationPatience',10`

Data Types: `single` | `double`

Other Classification Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table. The descriptions assume that the predictor data has observations in rows and predictors in columns.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitcnet` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcnet` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitcnet` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitcnet` creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For an unordered categorical variable, `fitcnet` creates one dummy variable for each level of the categorical variable. For an ordered categorical variable, `fitcnet` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the predictor order in `X`. Assuming that `X` has the default orientation, with observations in rows and predictors in columns, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcnet` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',`
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ScoreTransform` — Score transformation

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights

nonnegative numeric vector | name of variable in `Tbl`

Observation weights, specified as a nonnegative numeric vector or the name of a variable in `Tbl`. The software weights each observation in `X` or `Tbl` with the corresponding value in `Weights`. The length of `Weights` must equal the number of observations in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response variable when training the model.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

The software normalizes `Weights` to sum to the value of the prior probability in the respective class.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation Options

`CrossVal` — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value argument. You can use only one cross-validation name-value argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'Crossval','on'`

Data Types: `char` | `string`

`CVPartition` — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.
2. Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Output Arguments

`Mdl` — Trained neural network classifier
`ClassificationNeuralNetwork` object | `ClassificationPartitionedModel` object

Trained neural network classifier, returned as a `ClassificationNeuralNetwork` or `ClassificationPartitionedModel` object.

If you set any of the name-value arguments `CrossVal`, `CVPartition`, `Holdout`, `KFold`, or `Leaveout`, then `Mdl` is a `ClassificationPartitionedModel` object. Otherwise, `Mdl` is a `ClassificationNeuralNetwork` model.

To reference properties of `Mdl`, use dot notation.

More About

Neural Network Structure

The default neural network classifier has the following layer structure.

Structure	Description
	Input — This layer corresponds to the predictor data in `Tbl` or `X`.
	First fully connected layer — This layer has 10 outputs by default. • You can widen the layer or add more fully connected layers to the network by specifying the `LayerSizes` name-value argument. • You can find the weights and biases for this layer in the `Mdl.LayerWeights{1}` and `Mdl.LayerBiases{1}` properties of `Mdl`, respectively.
	ReLU activation function — `fitcnet` applies this activation function to the first fully connected layer. • You can change the activation function by specifying the `Activations` name-value argument.
	Final fully connected layer — This layer has K outputs, where K is the number of classes in the response variable. • You can find the weights and biases for this layer in the `Mdl.LayerWeights{end}` and `Mdl.LayerBiases{end}` properties of `Mdl`, respectively.
	Softmax function (for both binary and multiclass classification) — `fitcnet` applies this activation function to the final fully connected layer. The function takes each input x_i and returns the following, where K is the number of classes in the response variable: $$f(x_i) = \frac{\exp(x_i)}{\sum_{j=1}^{K} \exp(x_j)}.$$ The results correspond to the predicted classification scores (or posterior probabilities).
	Output — This layer corresponds to the predicted class labels.

For an example that shows how a neural network classifier with this layer structure returns predictions, see “Predict Using Layer Structure of Neural Network Classifier” on page 33-4850.

Tips

- Always try to standardize the numeric predictors (see `Standardize`). Standardization makes predictors insensitive to the scales on which they are measured.

Algorithms

Training Solver

`fitcnet` uses a limited-memory Broyden-Flecter-Goldfarb-Shanno quasi-Newton algorithm (LBFGS) [3] as its loss function minimization technique, where the software minimizes the cross-entropy loss.

Introduced in R2021a

fitcox

Create Cox proportional hazards model

Syntax

```
coxMdl = fitcox(X,T)
coxMdl = fitcox(X,T,Name,Value)
```

Description

The `fitcox` function creates a Cox proportional hazards model for lifetime data. The basic Cox model includes a hazard function $h_0(t)$ and model coefficients b such that, for predictor `X`, the hazard rate at time t is

$$h(X_i,t) = h_0(t)\exp\left[\sum_{j=1}^{p} x_{ij}b_j\right],$$

where the b coefficients do not depend on time. `fitcox` infers both the model coefficients b and the hazard rate $h_0(t)$, and stores them as properties in the resulting `CoxModel` object.

The full Cox model includes extensions to the basic model, such as hazards with respect to different baselines or the inclusion of stratification variables. See “Extension of Cox Proportional Hazards Model” on page 14-27.

`coxMdl = fitcox(X,T)` returns a Cox proportional hazards model object `coxMdl` using the predictor values `X` and event times `T`.

`coxMdl = fitcox(X,T,Name,Value)` modifies the fit using one or more `Name,Value` arguments. For example, when the data includes censoring (values that are not observed), the `Censoring` argument specifies the censored data.

Examples

Estimate Cox Proportional Hazard Regression

Weibull random variables with the same shape parameter have proportional hazard rates; see “Weibull Distribution” on page B-170. The hazard rate with scale parameter a and shape parameter b at time t is

$$\frac{b}{a^b}t^{b-1}.$$

Generate pseudorandom samples from the Weibull distribution with scale parameters 1, 5, and 1/3, and with the same shape parameter `B`.

```
rng default % For reproducibility
B = 2;
A = ones(100,1);
data1 = wblrnd(A,B);
```

```
A2 = 5*A;
data2 = wblrnd(A2,B);
A3 = A/3;
data3 = wblrnd(A3,B);
```

Create a table of data. The predictors are the three variable types, 1, 2, or 3.

```
predictors = categorical([A;2*A;3*A]);
data = table(predictors,[data1;data2;data3],'VariableNames',["Predictors" "Times"]);
```

Fit a Cox regression to the data.

```
mdl = fitcox(data,"Times")
```

```
mdl =
Cox Proportional Hazards regression model:

                     Beta        SE        zStat       pValue
                   _______    _______    _______    __________

    Predictors_2    -3.5834    0.33187    -10.798    3.5299e-27
    Predictors_3     2.1668    0.20802     10.416    2.0899e-25
```

```
rates = exp(mdl.Coefficients.Beta)
```

```
rates = 2×1

    0.0278
    8.7301
```

Fit Cox Proportional Hazards Model to Lifetime Data

Perform a Cox proportional hazards regression on the `lightbulb` data set, which contains simulated lifetimes of light bulbs. The first column of the light bulb data contains the lifetime (in hours) of two different types of bulbs. The second column contains a binary variable indicating whether the bulb is fluorescent or incandescent; 0 indicates the bulb is fluorescent, and 1 indicates it is incandescent. The third column contains the censoring information, where 0 indicates the bulb was observed until failure, and 1 indicates the observation was censored.

Load the `lightbulb` data set.

```
load lightbulb
```

Fit a Cox proportional hazards model for the lifetime of the light bulbs, accounting for censoring. The predictor variable is the type of bulb.

```
coxMdl = fitcox(lightbulb(:,2),lightbulb(:,1), ...
    'Censoring',lightbulb(:,3))
```

```
coxMdl =
Cox Proportional Hazards regression model:

           Beta       SE      zStat       pValue
         _______    ______    ______    __________
```

```
    X1    4.7262    1.0372    4.5568    5.1936e-06
```

Find the hazard rate of incandescent bulbs compared to fluorescent bulbs by evaluating exp(Beta).

```
hr = exp(coxMdl.Coefficients.Beta)
```

```
hr = 112.8646
```

The estimate of the hazard ratio is e^{Beta} = 112.8646, which means that the estimated hazard for the incandescent bulbs is 112.86 times the hazard for the fluorescent bulbs. The small value of `coxMdl.Coefficients.pValue` indicates there is a negligible chance that the two types of light bulbs have identical hazard rates, which would mean `Beta` = 0.

Input Arguments

X — Predictor values

matrix | table

Predictor values, specified as a matrix or table.

- A matrix contains one column for each predictor and one row for each observation.
- A table contains one row for each observation. A table can also contain the time data as well as the predictors.

By default, if the predictor data is in a table, `fitcox` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix, `fitcox` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `CategoricalPredictors` name-value argument.

If `X`, `T`, the value of `'Frequency'`, or the value of `'Stratification'` contains `NaN` values, then `fitcox` removes rows with `NaN` values from all data when fitting a Cox model.

Data Types: `double` | `table` | `categorical`

T — Event times

real column vector | real matrix with two columns | name of column in table `X` | formula in Wilkinson notation for table `X`

Event times, specified as one of the following:

- Real column vector.
- Real matrix with two columns representing the start and stop times.
- Name of a column in the table `X`.
- Formula in Wilkinson notation for the table `X`. For example, to specify that the table columns `'x'` and `'y'` are in the model, use

  ```
  'T ~ x + y'
  ```

  See “Wilkinson Notation” on page 11-91.

For vector or matrix entries, the number of rows of `T` must be the same as the number of rows of `X`.

Use the two-column form of `T` to fit a model with time-varying coefficients. See “Cox Proportional Hazards Model with Time-Dependent Covariates” on page 14-35.

Data Types: `single` | `double` | `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: To fit data with censored values `cens`, specify `'Censoring',cens`.

`Beta` — Coefficient initial values

`0.01/std(X)` (default) | numeric vector

Coefficient initial values, specified as a numeric vector of coefficient values. These values initiate the likelihood maximization iterations performed by `fitcox`.

Data Types: `double`

`Baseline` — `X` values at which to compute baseline hazard

`mean(X)`, the default for continuous predictors | `0`, the default for categorical predictors | real scalar | real row vector

`X` values at which to compute the baseline hazard, specified as a real scalar or row vector. If `Baseline` is a row vector, its length is the number of predictors, so there is one baseline for each predictor.

The default baseline for continuous predictors is `mean(X)`, so the default hazard rate at `X` for these predictors is `h(t)*exp((X – mean(X))*b)`. The default baseline for categorical predictors is `0`. Enter `0` to compute the baseline for all predictors relative to 0, so the hazard rate at `X` is `h(t)*exp(X*b)`. Changing the baseline changes the hazard ratio, but does not affect the coefficient estimates.

For the identified categorical predictors, `fitcox` creates dummy variables. `fitcox` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'Baseline',0`

Data Types: `double`

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data (`X`) that contains a categorical variable.
Logical vector	A `true` entry means that the corresponding column of predictor data (`X`) is a categorical variable.

Value	Description
Character matrix	Each row of the matrix is the name of a predictor variable in the table X. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable in the table X. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table, `fitcox` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix, `fitcox` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitcox` creates dummy variables. `fitcox` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`Censoring` — Indicator for censoring
array of 0s (default) | array of 0s and 1s | name of a column in table X

Indicator for censoring, specified as a Boolean vector with the same number of rows as X or the name of a column in the table X. Use 1 for observations that are right censored and 0 for observations that are fully observed. By default, all observations are fully observed. For an example, see “Cox Proportional Hazards Model for Censored Data” on page 14-31.

Example: `'Censoring',cens`

Data Types: `logical`

`Frequency` — Frequency or weights of observations
array of 1s (default) | vector of nonnegative scalar values

Frequency or weights of observations, specified as an array the same size as T containing nonnegative scalar values. The array can contain integer values corresponding to frequencies of observations or nonnegative values corresponding to observation weights.

The default is 1 per row of X and T.

If X, T, the value of `'Frequency'`, or the value of `'Stratification'` contains `NaN` values, then `fitcox` removes rows with `NaN` values from all data when fitting a Cox model.

Example: `'Frequency',w`

Data Types: `double`

`OptimizationOptions` — Algorithm control parameters
structure

Algorithm control parameters for the iterative algorithm `fitcox` uses to estimate the solution, specified as a structure. Create this structure using `statset`. For parameter names and default values, see the following table or enter `statset('fitcox')`.

In the table, "termination tolerance" means that if the internal iterations cause a change in the stated value less than the tolerance, the iterations stop.

Field in Structure	Description	Values
`Display`	Amount of information returned to the command line	• `'off'` — None (default) • `'final'` — Final output • `'iter'` — Output at each iteration
`MaxFunEvals`	Maximum number of function evaluations	Positive integer; default is `200`
`MaxIter`	Maximum number of iterations	Positive integer; default is `100`
`TolFun`	Termination tolerance on change in likelihood; see “Cox Proportional Hazards Model” on page 14-26	Positive scalar; default is `1e-8`
`TolX`	Termination tolerance for parameter (predictor estimate) change	Positive scalar; default is `1e-8`

Example: `'OptimizationOptions',statset('TolX',1e-6,'MaxIter',200)`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on how you supply the training data.

- If you supply `X` as a numeric array, then you can use `'PredictorNames'` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'X1','X2',...}`.
- If you supply `X` as a table, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcox` uses only the predictor variables in `PredictorNames` and the time variable during training.
  - `PredictorNames` must be a subset of `X.Properties.VariableNames` and cannot include the name of the time variable `T`.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - Specify the predictors for training using either `'PredictorNames'` or a formula in Wilkinson notation, but not both.

Example: `'PredictorNames',{'Sex','Age','Weight','Smoker'}`

Data Types: `string` | `cell`

`Stratification` — Stratification variables
`[]` (default) | matrix of real values | name of column in table `X` | array of categorical variables

Stratification variables, specified as a matrix of real values, the name of a column in table `X`, or an array of categorical variables. The matrix must have the same number of rows as `T`, with each row corresponding to an observation.

The default `[]` is no stratification variable.

If `X`, `T`, the value of `'Frequency'`, or the value of `'Stratification'` contains `NaN` values, then `fitcox` removes rows with `NaN` values from all data when fitting a Cox model.

Example: `'Stratification',Gender`

Data Types: `single` | `double` | `char` | `string` | `categorical`

`TieBreakMethod` — Method to handle tied failure times
`'breslow'` (default) | `'efron'`

Method to handle tied failure times, specified as `'breslow'` (Breslow's method) or `'efron'` (Efron's method). See “Partial Likelihood Function for Tied Events” on page 14-28.

Example: `'TieBreakMethod','efron'`

Data Types: `char` | `string`

Introduced in R2021a

fitcsvm

Train support vector machine (SVM) classifier for one-class and binary classification

Syntax

```
Mdl = fitcsvm(Tbl,ResponseVarName)
Mdl = fitcsvm(Tbl,formula)
Mdl = fitcsvm(Tbl,Y)

Mdl = fitcsvm(X,Y)

Mdl = fitcsvm( ___ ,Name,Value)
```

Description

`fitcsvm` trains or cross-validates a support vector machine (SVM) model for one-class and two-class (binary) classification on a low-dimensional or moderate-dimensional predictor data set. `fitcsvm` supports mapping the predictor data using kernel functions, and supports sequential minimal optimization (SMO), iterative single data algorithm (ISDA), or $L1$ soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM model for binary classification on a high-dimensional data set, that is, a data set that includes many predictor variables, use `fitclinear` instead.

For multiclass learning with combined binary SVM models, use error-correcting output codes (ECOC). For more details, see `fitcecoc`.

To train an SVM regression model, see `fitrsvm` for low-dimensional and moderate-dimensional predictor data sets, or `fitrlinear` for high-dimensional data sets.

`Mdl = fitcsvm(Tbl,ResponseVarName)` returns a support vector machine (SVM) classifier on page 33-1863 `Mdl` trained using the sample data contained in the table `Tbl`. `ResponseVarName` is the name of the variable in `Tbl` that contains the class labels for one-class or two-class classification.

`Mdl = fitcsvm(Tbl,formula)` returns an SVM classifier trained using the sample data contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of the predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcsvm(Tbl,Y)` returns an SVM classifier trained using the predictor variables in the table `Tbl` and the class labels in vector `Y`.

`Mdl = fitcsvm(X,Y)` returns an SVM classifier trained using the predictors in the matrix `X` and the class labels in vector `Y` for one-class or two-class classification.

`Mdl = fitcsvm( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the type of cross-validation, the cost for misclassification, and the type of score transformation function.

Examples

Train SVM Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths and all observed setosa irises.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```
SVMModel = fitcsvm(X,y)
```

```
SVMModel =
  ClassificationSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 100
                    Alpha: [24x1 double]
                     Bias: -14.4149
         KernelParameters: [1x1 struct]
           BoxConstraints: [100x1 double]
          ConvergenceInfo: [1x1 struct]
          IsSupportVector: [100x1 logical]
                   Solver: 'SMO'

  Properties, Methods
```

`SVMModel` is a trained `ClassificationSVM` classifier. Display the properties of `SVMModel`. For example, to determine the class order, use dot notation.

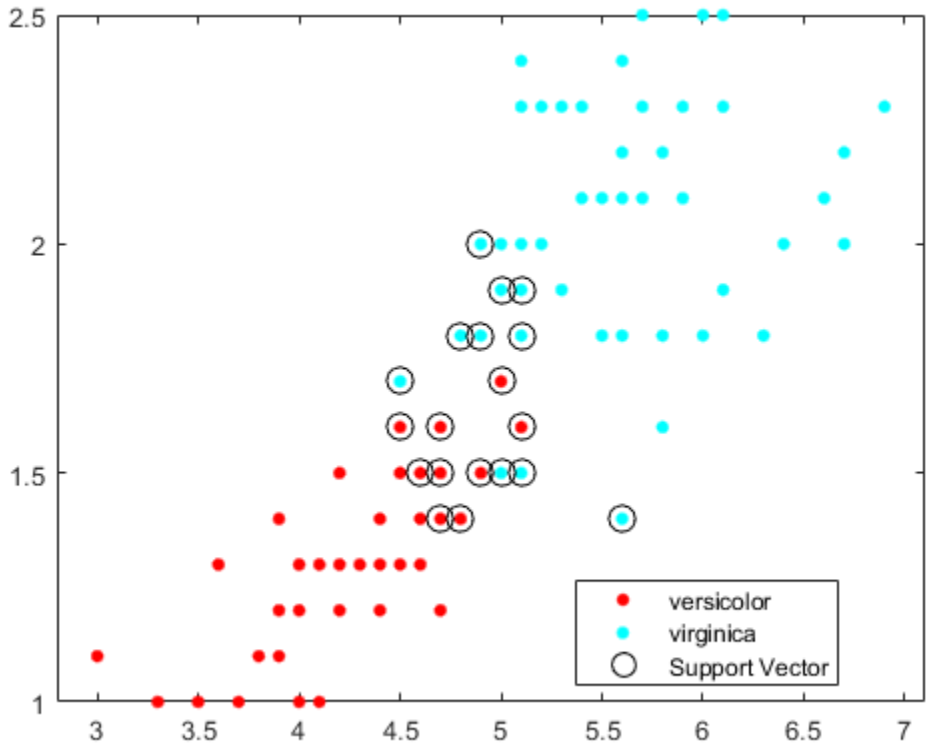
```
classOrder = SVMModel.ClassNames
```

```
classOrder = 2x1 cell
    {'versicolor'}
    {'virginica' }
```

The first class (`'versicolor'`) is the negative class, and the second (`'virginica'`) is the positive class. You can change the class order during training by using the `'ClassNames'` name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```
sv = SVMModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')
hold off
```



The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and, therefore, the number of support vectors) by setting a box constraint during training using the `'BoxConstraint'` name-value pair argument.

Train and Cross-Validate SVM Classifier

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier using the radial basis kernel. Let the software find a scale value for the kernel function. Standardize the predictors.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'KernelFunction','RBF',...
    'KernelScale','auto');
```

`SVMModel` is a trained `ClassificationSVM` classifier.

Cross-validate the SVM classifier. By default, the software uses 10-fold cross-validation.

```
CVSVMModel = crossval(SVMModel);
```

`CVSVMModel` is a `ClassificationPartitionedModel` cross-validated classifier.

Estimate the out-of-sample misclassification rate.

```
classLoss = kfoldLoss(CVSVMModel)
```

```
classLoss = 0.0484
```

The generalization rate is approximately 5%.

Detect Outliers Using SVM and One-Class Learning

Modify Fisher's iris data set by assigning all the irises to the same class. Detect outliers in the modified data set, and confirm the expected proportion of the observations that are outliers.

Load Fisher's iris data set. Remove the petal lengths and widths. Treat all irises as coming from the same class.

```
load fisheriris
X = meas(:,1:2);
y = ones(size(X,1),1);
```

Train an SVM classifier using the modified data set. Assume that 5% of the observations are outliers. Standardize the predictors.

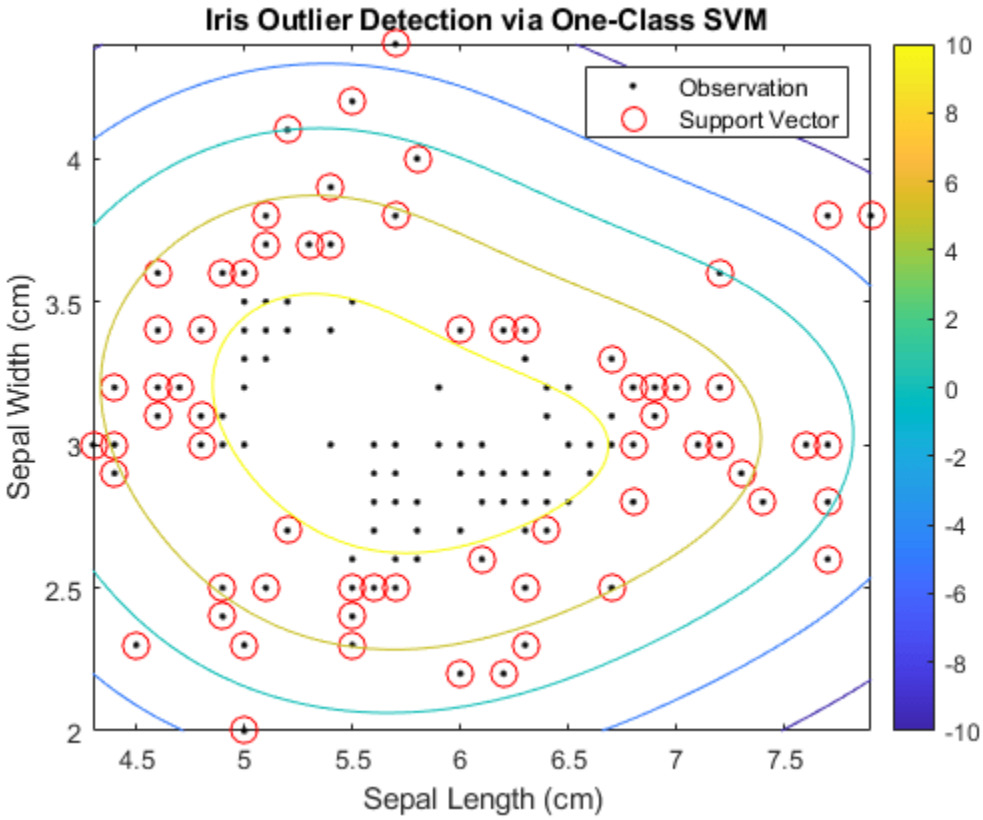
```
rng(1);
SVMModel = fitcsvm(X,y,'KernelScale','auto','Standardize',true,...
    'OutlierFraction',0.05);
```

`SVMModel` is a trained `ClassificationSVM` classifier. By default, the software uses the Gaussian kernel for one-class learning.

Plot the observations and the decision boundary. Flag the support vectors and potential outliers.

```
svInd = SVMModel.IsSupportVector;
h = 0.02; % Mesh grid step size
[X1,X2] = meshgrid(min(X(:,1)):h:max(X(:,1)),...
    min(X(:,2)):h:max(X(:,2)));
[~,score] = predict(SVMModel,[X1(:),X2(:)]);
scoreGrid = reshape(score,size(X1,1),size(X2,2));

figure
plot(X(:,1),X(:,2),'k.')
hold on
plot(X(svInd,1),X(svInd,2),'ro','MarkerSize',10)
contour(X1,X2,scoreGrid)
colorbar;
title('{\bf Iris Outlier Detection via One-Class SVM}')
xlabel('Sepal Length (cm)')
ylabel('Sepal Width (cm)')
legend('Observation','Support Vector')
hold off
```



The boundary separating the outliers from the rest of the data occurs where the contour value is `0`.

Verify that the fraction of observations with negative scores in the cross-validated data is close to 5%.

```
CVSVMModel = crossval(SVMModel);
[~,scorePred] = kfoldPredict(CVSVMModel);
outlierRate = mean(scorePred<0)
```

```
outlierRate = 0.0467
```

Find Multiple Class Boundaries Using Binary SVM

Create a scatter plot of the `fisheriris` data set. Treat coordinates of a grid within the plot as new observations from the distribution of the data set, and find class boundaries by assigning the coordinates to one of the three classes in the data set.

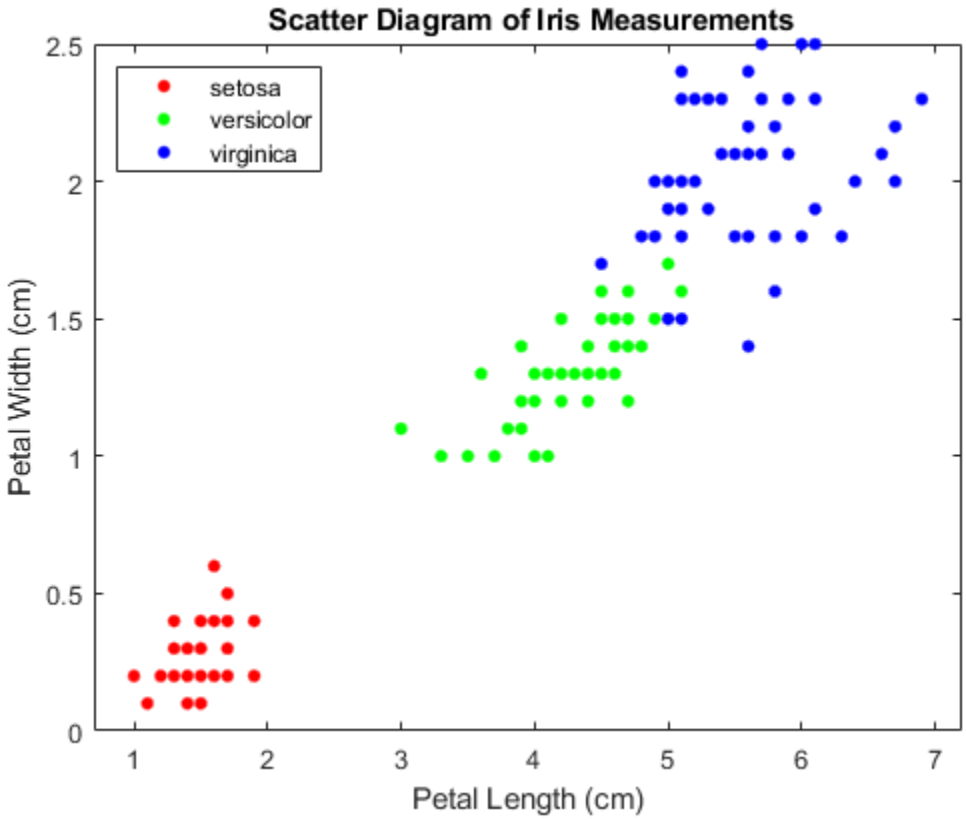
Load Fisher's iris data set. Use the petal lengths and widths as the predictors.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
```

```
h = gca;
lims = [h.XLim h.YLim]; % Extract the x and y axis limits
title('{\bf Scatter Diagram of Iris Measurements}');
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend('Location','Northwest');
```



The data contains three classes, one of which is linearly separable from the others.

For each class:

1. Create a logical vector (`indx`) indicating whether an observation is a member of the class.
2. Train an SVM classifier using the predictor data and `indx`.
3. Store the classifier in a cell of a cell array.

Define the class order.

```
SVMModels = cell(3,1);
classes = unique(Y);
rng(1); % For reproducibility

for j = 1:numel(classes)
    indx = strcmp(Y,classes(j)); % Create binary classes for each classifier
    SVMModels{j} = fitcsvm(X,indx,'ClassNames',[false true],'Standardize',true,...
        'KernelFunction','rbf','BoxConstraint',1);
end
```

`SVMModels` is a 3-by-1 cell array, with each cell containing a `ClassificationSVM` classifier. For each cell, the positive class is setosa, versicolor, and virginica, respectively.

Define a fine grid within the plot, and treat the coordinates as new observations from the distribution of the training data. Estimate the score of the new observations using each classifier.

```
d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
N = size(xGrid,1);
Scores = zeros(N,numel(classes));

for j = 1:numel(classes)
    [~,score] = predict(SVMModels{j},xGrid);
    Scores(:,j) = score(:,2); % Second column contains positive-class scores
end
```

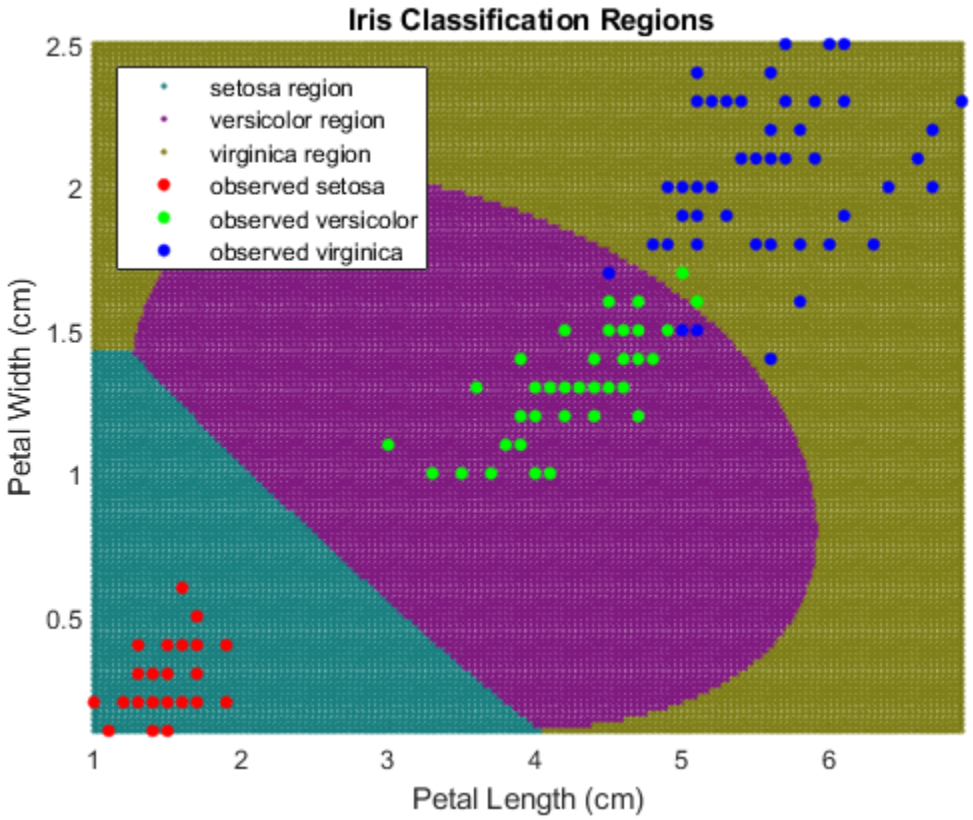
Each row of `Scores` contains three scores. The index of the element with the largest score is the index of the class to which the new class observation most likely belongs.

Associate each new observation with the classifier that gives it the maximum score.

```
[~,maxScore] = max(Scores,[],2);
```

Color in the regions of the plot based on the class to which the corresponding new observation belongs.

```
figure
h(1:3) = gscatter(xGrid(:,1),xGrid(:,2),maxScore,...
    [0.1 0.5 0.5; 0.5 0.1 0.5; 0.5 0.5 0.1]);
hold on
h(4:6) = gscatter(X(:,1),X(:,2),Y);
title('{\bf Iris Classification Regions}');
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend(h,{'setosa region','versicolor region','virginica region',...
    'observed setosa','observed versicolor','observed virginica'},...
    'Location','Northwest');
axis tight
hold off
```



Optimize SVM Classifier

Optimize hyperparameters automatically using `fitcsvm`.

Load the `ionosphere` data set.

```
load ionosphere
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng default
Mdl = fitcsvm(X,Y,'OptimizeHyperparameters','auto', ...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName', ...
    'expected-improvement-plus'))
```

```

  Properties, Methods
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the SVM model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- `Y` must contain at most two distinct classes. For multiclass learning, see `fitcecoc`.
- If `Y` is a character array, then each element of the class labels must correspond to one row of the array.
- The length of `Y` and the number of rows in `Tbl` or `X` must be equal.
- It is a good practice to specify the class order by using the `ClassNames` name-value pair argument.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`X` — Predictor data
matrix of numeric values

Predictor data to which the SVM classifier is trained, specified as a matrix of numeric values.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor (also known as a feature).

The length of `Y` and the number of rows in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `'PredictorNames'` name-value pair argument.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitcsvm(X,Y,'KFold',10,'Cost',[0 2;1 0],'ScoreTransform','sign')` performs 10-fold cross-validation, applies double the penalty to false positives compared to false negatives, and transforms scores using the sign function.

SVM Options

`BoxConstraint` — Box constraint
1 (default) | positive scalar

Box constraint on page 33-1862, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

For one-class learning, the software always sets the box constraint to `1`.

For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see "Algorithms" on page 33-1865.

Example: `'BoxConstraint',100`

Data Types: `double` | `single`

`KernelFunction` — Kernel function
`'linear'` | `'gaussian'` | `'rbf'` | `'polynomial'` | function name

Kernel function used to compute the elements of the Gram matrix on page 33-1862, specified as the comma-separated pair consisting of `'KernelFunction'` and a kernel function name. Suppose $G(x_j,x_k)$ is element (j,k) of the Gram matrix, where x_j and x_k are p-dimensional vectors representing observations j and k in `X`. This table describes supported kernel function names and their functional forms.

Kernel Function Name	Description	Formula
`'gaussian'` or `'rbf'`	Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning	$G(x_j, x_k) = \exp\left(-\|x_j - x_k\|^2\right)$
`'linear'`	Linear kernel, default for two-class learning	$G(x_j, x_k) = x_j' x_k$
`'polynomial'`	Polynomial kernel. Use `'PolynomialOrder',q` to specify a polynomial kernel of order q.	$G(x_j, x_k) = (1 + x_j' x_k)^q$

You can set your own kernel function, for example, `kernel`, by setting `'KernelFunction','kernel'`. The value `kernel` must have this form.

```
function G = kernel(U,V)
```

where:

- `U` is an *m*-by-*p* matrix. Columns correspond to predictor variables, and rows correspond to observations.
- `V` is an *n*-by-*p* matrix. Columns correspond to predictor variables, and rows correspond to observations.
- `G` is an *m*-by-*n* Gram matrix on page 33-1862 of the rows of `U` and `V`.

`kernel.m` must be on the MATLAB path.

It is a good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function `'mysigmoid'` rather than `'sigmoid'`.

Example: `'KernelFunction','gaussian'`

Data Types: `char` | `string`

`KernelScale` — Kernel scale parameter
1 (default) | `'auto'` | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar. The software divides all elements of the predictor matrix `X` by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify `'auto'`, then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using `rng` before training.
- If you specify `KernelScale` and your own kernel function, for example, `'KernelFunction','kernel'`, then the software throws an error. You must apply scaling within `kernel`.

Example: `'KernelScale','auto'`

Data Types: `double` | `single` | `char` | `string`

`PolynomialOrder` — Polynomial kernel function order
3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer.

If you set `'PolynomialOrder'` and `KernelFunction` is not `'polynomial'`, then the software throws an error.

Example: `'PolynomialOrder',2`

Data Types: `double` | `single`

`KernelOffset` — Kernel offset parameter
nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of `'KernelOffset'` and a nonnegative scalar.

The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- `0` if the solver is SMO (that is, you set `'Solver','SMO'`)
- `0.1` if the solver is ISDA (that is, you set `'Solver','ISDA'`)

Example: `'KernelOffset',0`

Data Types: `double` | `single`

`Standardize` — Flag to standardize predictor data
`false` (default) | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and `true` (`1`) or `false` (`0`).

If you set `'Standardize',true`:

- The software centers and scales each predictor variable (`X` or `Tbl`) by the corresponding weighted column mean and standard deviation. For details on weighted standardizing, see “Algorithms” on page 33-1865. MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the classifier using the standardized predictors, but stores the unstandardized predictors as a matrix or table in the classifier property `X`.

Example: `'Standardize',true`

Data Types: `logical`

`Solver` — Optimization routine
`'ISDA'` | `'L1QP'` | `'SMO'`

Optimization routine, specified as the comma-separated pair consisting of `'Solver'` and a value in this table.

Value	Description
`'ISDA'`	Iterative Single Data Algorithm (see [30])
`'L1QP'`	Uses `quadprog` to implement $L1$ soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
`'SMO'`	Sequential Minimal Optimization (see [17])

The default value is `'ISDA'` if you set `'OutlierFraction'` to a positive value for two-class learning, and `'SMO'` otherwise.

Example: `'Solver','ISDA'`

`Alpha` — Initial estimates of alpha coefficients
numeric vector of nonnegative values

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of `'Alpha'` and a numeric vector of nonnegative values. The length of `Alpha` must be equal to the number of rows in `X`.

- Each element of `'Alpha'` corresponds to an observation in `X`.

- `'Alpha'` cannot contain any `NaN`s.
- If you specify `'Alpha'` and any one of the cross-validation name-value pair arguments (`'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`), then the software returns an error.

If `Y` contains any missing values, then remove all rows of `Y`, `X`, and `'Alpha'` that correspond to the missing values. That is, enter:

```
idx = ~isundefined(categorical(Y));
Y = Y(idx,:);
X = X(idx,:);
alpha = alpha(idx);
```

Then pass `Y`, `X`, and `alpha` as the response, predictors, and initial alpha estimates, respectively.

The default values are:

- `0.5*ones(size(X,1),1)` for one-class learning
- `zeros(size(X,1),1)` for two-class learning

Example: `'Alpha',0.1*ones(size(X,1),1)`

Data Types: `double` | `single`

`CacheSize` — Cache size
`1000` (default) | `'maximal'` | positive scalar

Cache size, specified as the comma-separated pair consisting of `'CacheSize'` and `'maximal'` or a positive scalar.

If `CacheSize` is `'maximal'`, then the software reserves enough memory to hold the entire *n*-by-*n* Gram matrix on page 33-1862.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of memory for training the model.

Example: `'CacheSize','maximal'`

Data Types: `double` | `single` | `char` | `string`

`ClipAlphas` — Flag to clip alpha coefficients
`true` (default) | `false`

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of `'ClipAlphas'` and either `true` or `false`.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is C_j, $j = 1,...,n$, where n is the training sample size.

Value	Description
`true`	At each iteration, if α_j is near 0 or near C_j, then MATLAB sets α_j to 0 or to C_j, respectively.
`false`	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the `Alpha` property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: `'ClipAlphas',false`

Data Types: `logical`

`Nu` — ν parameter for one-class learning
`0.5` (default) | positive scalar

ν parameter for "One-Class Learning" on page 33-1863, specified as the comma-separated pair consisting of `'Nu'` and a positive scalar. `Nu` must be greater than `0` and at most `1`.

Set `Nu` to control the tradeoff between ensuring that most training examples are in the positive class and minimizing the weights in the score function.

Example: `'Nu',0.25`

Data Types: `double` | `single`

`NumPrint` — Number of iterations between optimization diagnostic message output
`1000` (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you specify `'Verbose',1` and `'NumPrint',numprint`, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: `'NumPrint',500`

Data Types: `double` | `single`

`OutlierFraction` — Expected proportion of outliers in training data
`0` (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of `'OutlierFraction'` and a numeric scalar in the interval [0,1).

Suppose that you set `'OutlierFraction',outlierfraction`, where `outlierfraction` is a value greater than 0.

- For two-class learning, the software implements robust learning. In other words, the software attempts to remove 100*`outlierfraction`% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that `outlierfraction` of the observations in the training set have negative scores.

Example: `'OutlierFraction',0.01`

Data Types: `double` | `single`

`RemoveDuplicates` — Flag to replace duplicate observations with single observations
`false` (default) | `true`

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of `'RemoveDuplicates'` and `true` or `false`.

If `RemoveDuplicates` is `true`, then `fitcsvm` replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see `Weights`).

Tip If your data set contains many duplicate observations, then specifying `'RemoveDuplicates',true` can decrease convergence time considerably.

Data Types: `logical`

`Verbose` — Verbosity level

`0` (default) | `1` | `2`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0`, `1`, or `2`. The value of `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software does not display or save convergence information.
`1`	The software displays diagnostic messages and saves convergence criteria every `numprint` iterations, where `numprint` is the value of the name-value pair argument `'NumPrint'`.
`2`	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: `'Verbose',1`

Data Types: `double` | `single`

Other Classification Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitcsvm` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.

Value	Description
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcsvm` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitcsvm` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitcsvm` creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For an unordered categorical variable, `fitcsvm` creates one dummy variable for each level of the categorical variable. For an ordered categorical variable, `fitcsvm` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Misclassification cost

square matrix | structure array

Misclassification cost specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure array.

- If you specify the square matrix `Cost` and the true class of an observation is `i`, then `Cost(i,j)` is the cost of classifying a point into class `j`. That is, rows correspond to the true classes and columns correspond to predicted classes. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then it must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
  - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. Consequently, the cost matrix resets to the default. For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 33-1865.

The default values are:

- `Cost = 0` for one-class learning
- `Cost(i,j) = 1` if `i ~= j` and `Cost(i,j) = 0` if `i = j` for two-class learning

Example: `'Cost',[0,1;2,0]`

Data Types: `double` | `single` | `struct`

`PredictorNames` — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitcsvm` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities
'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y.
'uniform'	All class prior probabilities are equal to 1/*K*, where *K* is the number of classes.
numeric vector	Each element in the vector is a class prior probability. Order the elements according to Mdl.ClassNames or specify the order using the ClassNames name-value pair argument. The software normalizes the elements to sum to 1.
structure	A structure S with two fields: • S.ClassNames contains the class names as a variable of the same type as Y. • S.ClassProbs contains a vector of corresponding prior probabilities. The software normalizes the elements of the vector to sum to 1.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. For more details on the relationships and algorithmic behavior of BoxConstraint, Cost, Prior, Standardize, and Weights, see “Algorithms” on page 33-1865.

Example: struct('ClassNames',
{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)

Data Types: char | string | double | single | struct

ResponseName — Response variable name
'Y' (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName','response'

Data Types: char | string

ScoreTransform — Score transformation
'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
numeric vector | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or the name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response variable when training the model.

By default, `Weights` is `ones(`*n*`,1)`, where *n* is the number of observations in `X` or `Tbl`.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class. For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 33-1865.

Data Types: `double` | `single` | `char` | `string`

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Cross-Validation Options

`CrossVal` — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair argument. You can use only one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.

2 For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.

3 Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1 Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.

2 Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Convergence Control Options

`DeltaGradientTolerance` — Tolerance for gradient difference

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

If `DeltaGradientTolerance` is `0`, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The default values are:

- `1e-3` if the solver is SMO (for example, you set `'Solver','SMO'`)
- `0` if the solver is ISDA (for example, you set `'Solver','ISDA'`)

Example: `'DeltaGradientTolerance',1e-2`

Data Types: `double` | `single`

`GapTolerance` — Feasibility gap tolerance

`0` (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of `'GapTolerance'` and a nonnegative scalar.

If `GapTolerance` is `0`, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: `'GapTolerance',1e-2`

Data Types: `double` | `single`

`IterationLimit` — Maximal number of numerical optimization iterations
`1e6` (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: `'IterationLimit',1e8`

Data Types: `double` | `single`

`KKTTolerance` — Karush-Kuhn-Tucker complementarity conditions violation tolerance
nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions on page 33-1862 violation tolerance, specified as the comma-separated pair consisting of `'KKTTolerance'` and a nonnegative scalar.

If `KKTTolerance` is `0`, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The default values are:

- `0` if the solver is SMO (for example, you set `'Solver','SMO'`)
- `1e-3` if the solver is ISDA (for example, you set `'Solver','ISDA'`)

Example: `'KKTTolerance',1e-2`

Data Types: `double` | `single`

`ShrinkagePeriod` — Number of iterations between reductions of active set
`0` (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of `'ShrinkagePeriod'` and a nonnegative integer.

If you set `'ShrinkagePeriod',0`, then the software does not shrink the active set.

Example: `'ShrinkagePeriod',1000`

Data Types: `double` | `single`

Hyperparameter Optimization Options

`OptimizeHyperparameters` — Parameters to optimize
`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of these values:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'BoxConstraint','KernelScale'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitcsvm` by varying the parameters. For information about cross-validation loss see “Classification Loss” on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair argument.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcsvm` are:

- `BoxConstraint` — `fitcsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `KernelScale` — `fitcsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `KernelFunction` — `fitcsvm` searches among `'gaussian'`, `'linear'`, and `'polynomial'`.
- `PolynomialOrder` — `fitcsvm` searches among integers in the range `[2,4]`.
- `Standardize` — `fitcsvm` searches among `'true'` and `'false'`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example:

```
load fisheriris
params = hyperparameters('fitcsvm',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize SVM Classifier” on page 33-1840.

Example: `'auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`

Field Name	Values	Default
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained SVM classification model

`ClassificationSVM` model object | `ClassificationPartitionedModel` cross-validated model object

Trained SVM classification model, returned as a `ClassificationSVM` model object or `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated classifier. Otherwise, `Mdl` is a `ClassificationSVM` classifier.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Alpha` in the Command Window to display the trained Lagrange multipliers.

Limitations

- `fitcsvm` trains SVM classifiers for one-class or two-class learning applications. To train SVM classifiers using data with more than two classes, use `fitcecoc`.
- `fitcsvm` supports low-dimensional and moderate-dimensional data sets. For high-dimensional data sets, use `fitclinear` instead.

More About

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, which helps to prevent overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

Gram Matrix

The Gram matrix of a set of n vectors $\{x_1,..,x_n;\ x_j \in R^p\}$ is an n-by-n matrix with element (j,k) defined as $G(x_j,x_k) = <\phi(x_j),\phi(x_k)>$, an inner product of the transformed predictors using the kernel function ϕ.

For nonlinear SVM, the algorithm forms a Gram matrix using the rows of the predictor data X. The dual formalization replaces the inner product of the observations in X with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Consequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.

Karush-Kuhn-Tucker (KKT) Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

$$\begin{cases} \alpha_j\left[y_j f\left(x_j\right) - 1 + \xi_j\right] = 0 \\ \xi_j\left(C - \alpha_j\right) = 0 \end{cases}$$

for all $j = 1,...,n$, where $f(x_j) = \phi(x_j)'\beta + b$, ϕ is a kernel function (see Gram matrix on page 33-1862), and ξ_j is a slack variable. If the classes are perfectly separable, then $\xi_j = 0$ for all $j = 1,...,n$.

One-Class Learning

One-class learning, or unsupervised SVM, aims to separate data from the origin in the high-dimensional predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification on page 33-1863. The objective is to minimize the dual expression

$$0.5\sum_{jk}\alpha_j\alpha_k G(x_j, x_k)$$

with respect to $\alpha_1, ..., \alpha_n$, subject to

$$\sum \alpha_j = n\nu$$

and $0 \le \alpha_j \le 1$ for all $j = 1,...,n$. The value of $G(x_j,x_k)$ is in element (j,k) of the Gram matrix on page 33-1862.

A small value of ν leads to fewer support vectors and, therefore, a smooth, crude decision boundary. A large value of ν leads to more support vectors and, therefore, a curvy, flexible decision boundary. The optimal value of ν should be large enough to capture the data complexity and small enough to avoid overtraining. Also, $0 < \nu \le 1$.

For more details, see [5].

Support Vector

Support vectors are observations corresponding to strictly positive estimates of $\alpha_1,...,\alpha_n$.

SVM classifiers that yield fewer support vectors for a given training set are preferred.

Support Vector Machines for Binary Classification

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a margin (space that does not contain any observations) surrounding itself, which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x'\beta + b,$$

where:

- x is an observation (corresponding to a row of `X`).
- The vector β contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to `Mdl.Beta`). For separable data, the optimal margin length is $2/\|\beta\|$.
- b is the bias term (corresponding to `Mdl.Bias`).

The root of $f(x)$ for particular coefficients defines a hyperplane. For a particular hyperplane, $f(z)$ is the distance from point z to the hyperplane.

The algorithm searches for the maximum margin length, while keeping observations in the positive ($y = 1$) and negative ($y = –1$) classes separate.

- For separable classes, the objective is to minimize $\|\beta\|$ with respect to the β and b subject to $y_j f(x_j) \geq 1$, for all $j = 1,..,n$. This is the primal formalization for separable classes.
- For inseparable classes, the algorithm uses slack variables (ξ_j) to penalize the objective function for observations that cross the margin boundary for their class. $\xi_j = 0$ for observations that do not cross the margin boundary for their class, otherwise $\xi_j \geq 0$.

  The objective is to minimize $0.5\|\beta\|^2 + C\sum \xi_j$ with respect to the β, b, and ξ_j subject to $y_j f(x_j) \geq 1 - \xi_j$ and $\xi_j \geq 0$ for all $j = 1,..,n$, and for a positive scalar box constraint on page 33-1862 C. This is the primal formalization for inseparable classes.

The algorithm uses the Lagrange multipliers method to optimize the objective, which introduces n coefficients $\alpha_1,...,\alpha_n$ (corresponding to `Mdl.Alpha`). The dual formalizations for linear SVM are as follows:

- For separable classes, minimize

  $$0.5 \sum_{j=1}^{n} \sum_{k=1}^{n} \alpha_j \alpha_k y_j y_k x_j' x_k - \sum_{j=1}^{n} \alpha_j$$

  with respect to $\alpha_1,...,\alpha_n$, subject to $\sum \alpha_j y_j = 0$, $\alpha_j \geq 0$ for all $j = 1,...,n$, and Karush-Kuhn-Tucker (KKT) complementarity conditions on page 33-1862.
- For inseparable classes, the objective is the same as for separable classes, except for the additional condition $0 \leq \alpha_j \leq C$ for all $j = 1,..,n$.

The resulting score function is

$$\widehat{f}(x) = \sum_{j=1}^{n} \widehat{\alpha}_j y_j x' x_j + \widehat{b} \ .$$

$\widehat{b}$ is the estimate of the bias and $\widehat{\alpha}_j$ is the jth estimate of the vector $\widehat{\alpha}$, $j = 1,...,n$. Written this way, the score function is free of the estimate of β as a result of the primal formalization.

The SVM algorithm classifies a new observation z using $\text{sign}\left(\widehat{f}(z)\right)$.

In some cases, a nonlinear boundary separates the classes. Nonlinear SVM works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^{n} \sum_{k=1}^{n} \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^{n} \alpha_j$$

with respect to $\alpha_1,...,\alpha_n$, subject to $\sum \alpha_j y_j = 0$, $0 \le \alpha_j \le C$ for all $j = 1,..,n$, and the KKT complementarity conditions. $G(x_k,x_j)$ are elements of the Gram matrix on page 33-1862. The resulting score function is

$$\widehat{f}(x) = \sum_{j=1}^{n} \widehat{\alpha}_j y_j G(x, x_j) + \widehat{b} .$$

For more details, see Understanding Support Vector Machines on page 18-150, [1], and [3].

Tips

- Unless your data set is large, always try to standardize the predictors (see `Standardize`). Standardization makes predictors insensitive to the scales on which they are measured.
- It is a good practice to cross-validate using the `KFold` name-value pair argument. The cross-validation results determine how well the SVM classifier generalizes.
- For one-class learning:
  - The default setting for the name-value pair argument `Alpha` can lead to long training times. To speed up training, set `Alpha` to a vector mostly composed of `0`s.
  - Set the name-value pair argument `Nu` to a value closer to `0` to yield fewer support vectors and, therefore, a smoother but crude decision boundary.
- Sparsity in support vectors is a desirable property of an SVM classifier. To decrease the number of support vectors, set `BoxConstraint` to a large value. This action increases the training time.
- For optimal training time, set `CacheSize` as high as the memory limit your computer allows.
- If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active set using the name-value pair argument `'ShrinkagePeriod'`. It is a good practice to specify `'ShrinkagePeriod',1000`.
- Duplicate observations that are far from the decision boundary do not affect convergence. However, just a few duplicate observations that occur near the decision boundary can slow down convergence considerably. To speed up convergence, specify `'RemoveDuplicates',true` if:
  - Your data set contains many duplicate observations.
  - You suspect that a few duplicate observations fall near the decision boundary.

  To maintain the original data set during training, `fitcsvm` must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify `true` for data sets containing few duplicates, then `fitcsvm` consumes close to double the memory of the original data.
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- For the mathematical formulation of the SVM binary classification algorithm, see “Support Vector Machines for Binary Classification” on page 33-1863 and “Understanding Support Vector Machines” on page 18-150.
- `NaN`, `<undefined>`, empty character vector (`''`), empty string (`""`), and `<missing>` values indicate missing values. `fitcsvm` removes entire rows of data corresponding to a missing

response. When computing total weights (see the next bullets), `fitcsvm` ignores any weight corresponding to an observation with at least one missing predictor. This action can lead to unbalanced prior probabilities in balanced-class problems. Consequently, observation box constraints might not equal `BoxConstraint`.

- `fitcsvm` removes observations that have zero weight or prior probability.
- For two-class learning, if you specify the cost matrix C (see `Cost`), then the software updates the class prior probabilities p (see `Prior`) to p_c by incorporating the penalties described in C.

  Specifically, `fitcsvm` completes these steps:

  1. Compute $p_c^* = p'\mathrm{C}$.
  2. Normalize p_c^* so that the updated prior probabilities sum to 1.

  $$p_c = \frac{1}{\sum_{j=1}^{K} p_{c,j}^*} p_c^* .$$

  K is the number of classes.
  3. Reset the cost matrix to the default

  $$\mathrm{C} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

  4. Remove observations from the training data corresponding to classes with zero prior probability.
- For two-class learning, `fitcsvm` normalizes all observation weights (see `Weights`) to sum to 1. The function then renormalizes the normalized weights to sum up to the updated prior probability of the class to which the observation belongs. That is, the total weight for observation j in class k is

  $$w_j^* = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_{c,k} .$$

  w_j is the normalized weight for observation j; $p_{c,k}$ is the updated prior probability of class k (see previous bullet).
- For two-class learning, `fitcsvm` assigns a box constraint to each observation in the training data. The formula for the box constraint of observation j is

  $$C_j = nC_0 w_j^* .$$

  n is the training sample size, C_0 is the initial box constraint (see the `'BoxConstraint'` name-value pair argument), and w_j^* is the total weight of observation j (see previous bullet).
- If you set `'Standardize',true` and the `'Cost'`, `'Prior'`, or `'Weights'` name-value pair argument, then `fitcsvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `fitcsvm` standardizes predictor j (x_j) using

  $$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*} .$$

$$\mu_j^* = \frac{1}{\sum_k w_k^*} \sum_k w_k^* x_{jk} .$$

x_{jk} is observation k (row) of predictor j (column).

$$\left(\sigma_j^*\right)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k^* \left(x_{jk} - \mu_j^*\right)^2 .$$

$$v_1 = \sum_j w_j^* .$$

$$v_2 = \sum_j \left(w_j^*\right)^2 .$$

- Assume that `p` is the proportion of outliers that you expect in the training data, and that you set `'OutlierFraction',p`.
  - For one-class learning, the software trains the bias term such that 100`p`% of the observations in the training data have negative scores.
  - The software implements robust learning for two-class learning. In other words, the software attempts to remove 100`p`% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.
  - The `PredictorNames` property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `PredictorNames` is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.
  - The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.
  - Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.
  - The `SupportVectors` property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then `SupportVectors` is an n-by-5 matrix.
  - The `X` property stores the training data as originally input and does not include the dummy variables. When the input is a table, `X` contains only the columns used as predictors.
- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
  - For a variable with k ordered levels, the software creates k – 1 dummy variables. The jth dummy variable is –1 for levels up to j, and +1 for levels j + 1 through k.

- The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value +1. The software stores k – 1 additional predictor names for the dummy variables, including the names of levels 2, 3, ..., k.

- All solvers implement $L1$ soft-margin minimization.
- For one-class learning, the software estimates the Lagrange multipliers, $\alpha_1,...,\alpha_n$, such that

$$\sum_{j=1}^{n} \alpha_j = n\nu .$$

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see "Parallel Bayesian Optimization" on page 10-7.

For general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'KernelFunction'` option must not specify a custom kernel.
- The `'Solver'` option can be set to only `'SMO'`.
- The `'OutlierFraction'` option is not supported.
- The `'Alpha'` option must specify a feasible starting point.
- The `'OptimizeHyperparameters'` option is not supported.
- One-class classification is not supported. The labels must contain two different classes.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2014a

fitctree

Fit binary decision tree for multiclass classification

Syntax

```
tree = fitctree(Tbl,ResponseVarName)
tree = fitctree(Tbl,formula)
tree = fitctree(Tbl,Y)

tree = fitctree(X,Y)

tree = fitctree(___,Name,Value)
```

Description

`tree = fitctree(Tbl,ResponseVarName)` returns a fitted binary classification decision tree based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `Tbl.ResponseVarName`. The returned binary tree splits branching nodes based on the values of a column of `Tbl`.

`tree = fitctree(Tbl,formula)` returns a fitted binary classification decision tree based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `tree`.

`tree = fitctree(Tbl,Y)` returns a fitted binary classification decision tree based on the input variables contained in the table `Tbl` and output in vector `Y`.

`tree = fitctree(X,Y)` returns a fitted binary classification decision tree based on the input variables contained in matrix `X` and output `Y`. The returned binary tree splits branching nodes based on the values of a column of `X`.

`tree = fitctree(___,Name,Value)` fits a tree with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the algorithm used to find the best split on a categorical predictor, grow a cross-validated tree, or hold out a fraction of the input data for validation.

Examples

Grow a Classification Tree

Grow a classification tree using the `ionosphere` data set.

```
load ionosphere
tc = fitctree(X,Y)
```

```
tc =
  ClassificationTree
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}
```

```
          ScoreTransform: 'none'
         NumObservations: 351

  Properties, Methods
```

Control Tree Depth

You can control the depth of the trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitctree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the `ionosphere` data set.

```
load ionosphere
```

The default values of the tree depth controllers for growing classification trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

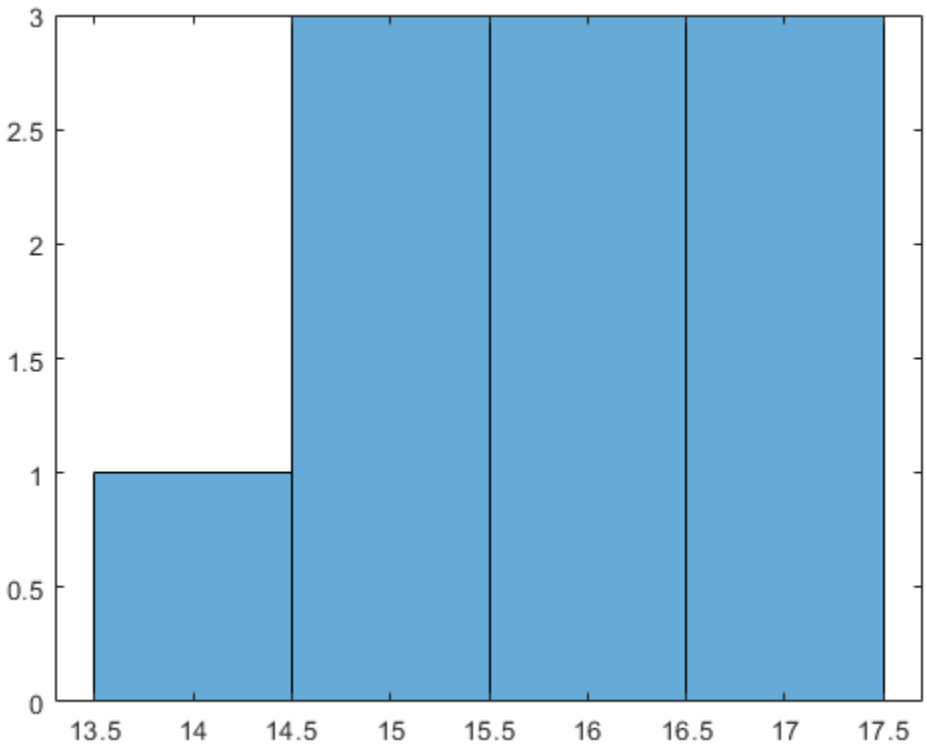
Train a classification tree using the default values for tree depth control. Cross-validate the model by using 10-fold cross-validation.

```
rng(1); % For reproducibility
MdlDefault = fitctree(X,Y,'CrossVal','on');
```

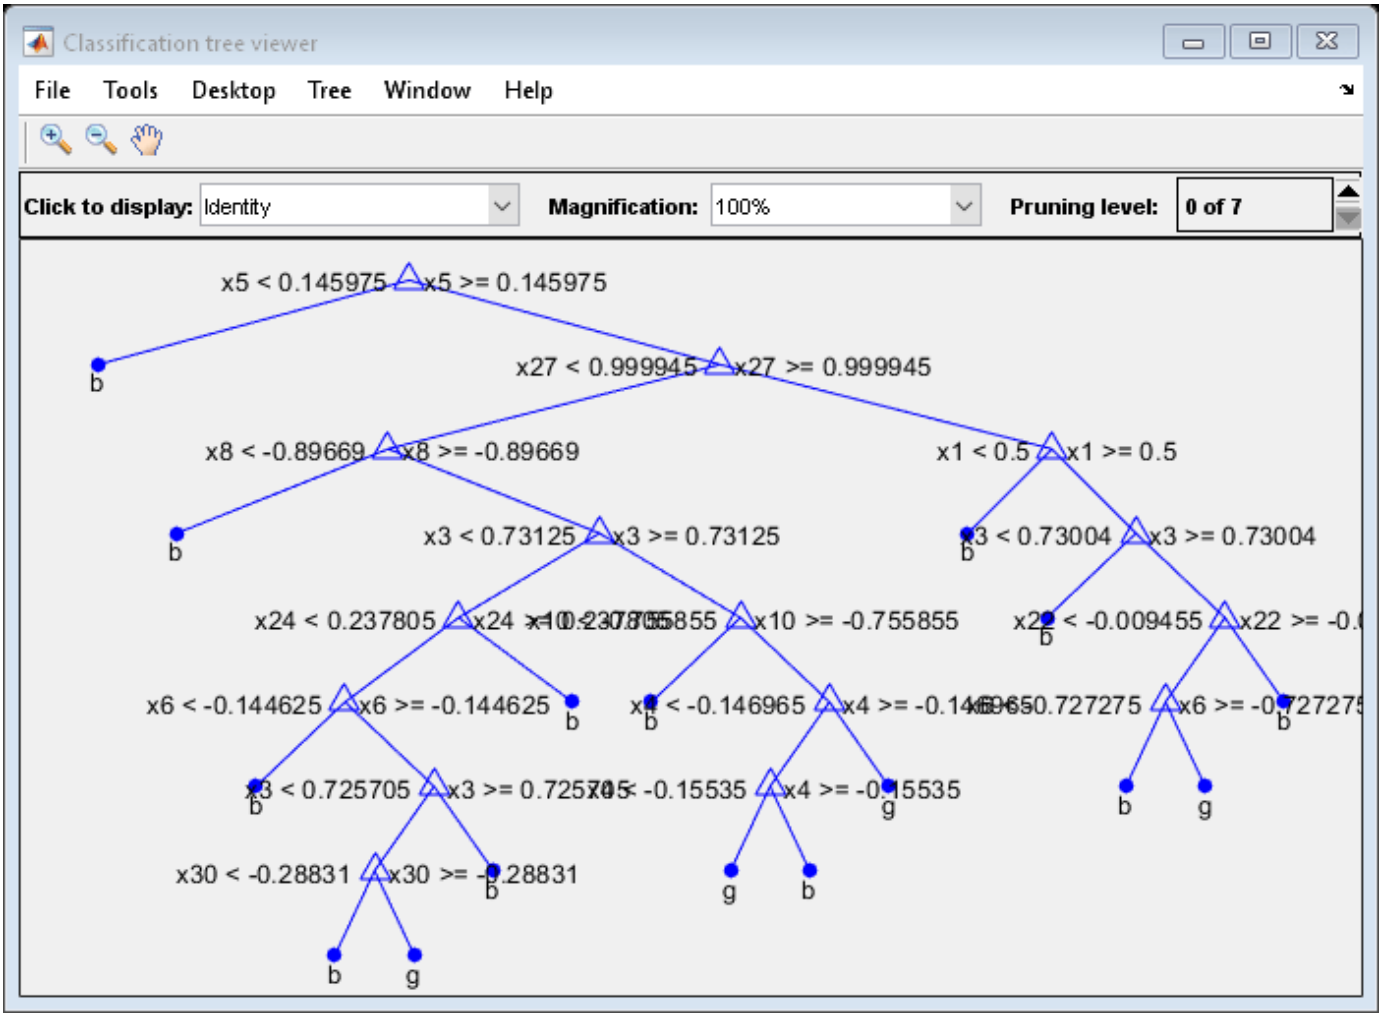
Draw a histogram of the number of imposed splits on the trees. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
```



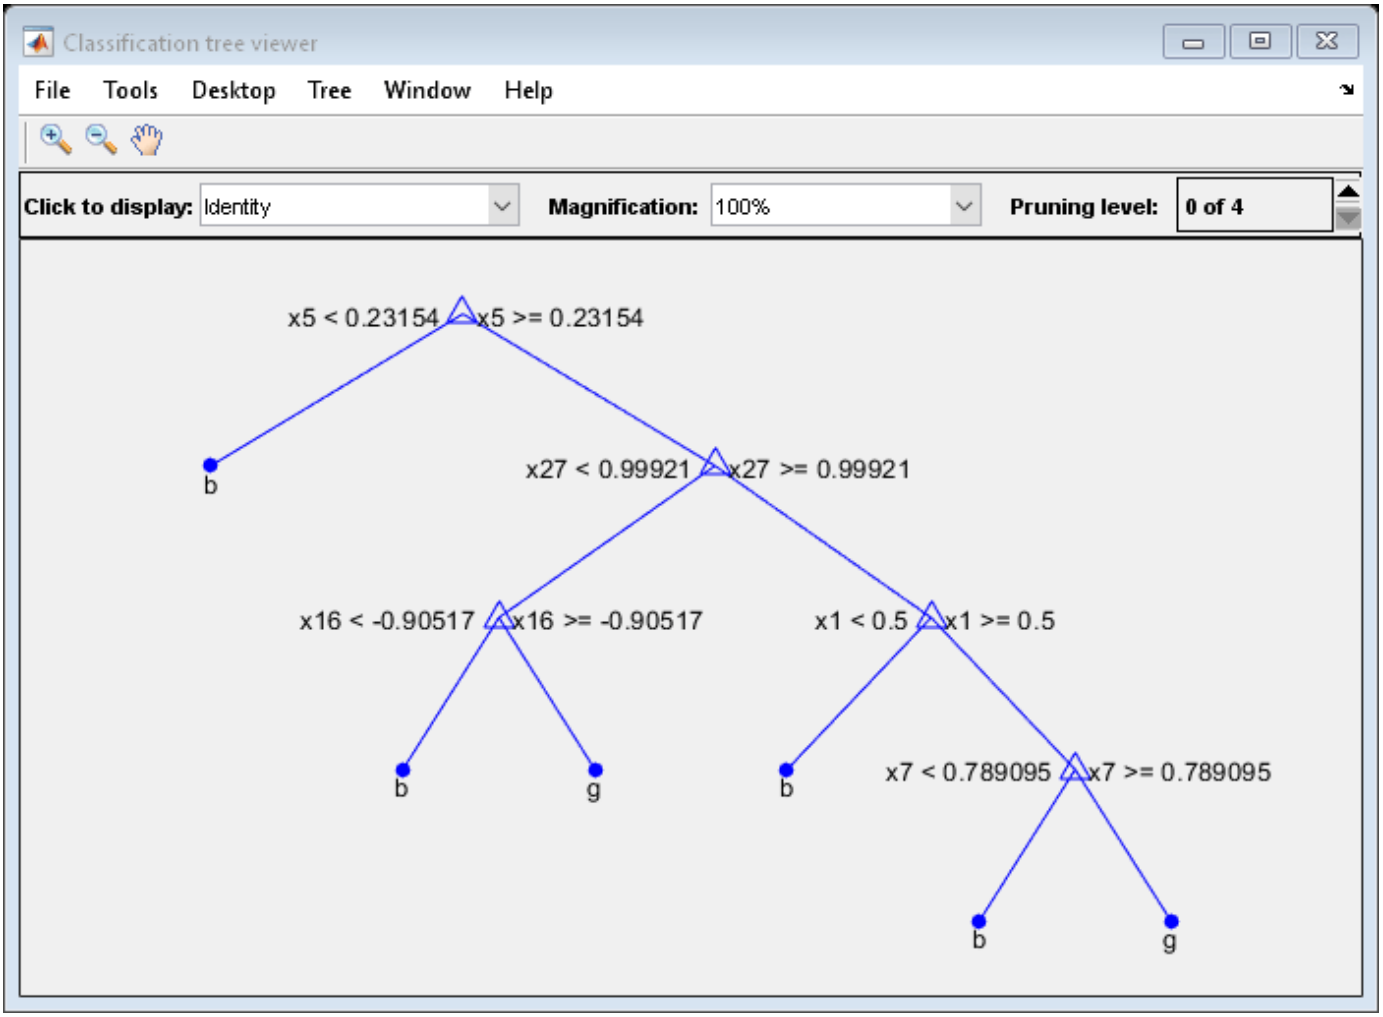
```
view(MdlDefault.Trained{1},'Mode','graph')
```



The average number of splits is around 15.

Suppose that you want a classification tree that is not as complex (deep) as the ones trained using the default number of splits. Train another classification tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default classification tree. Cross-validate the model by using 10-fold cross-validation.

```
Mdl7 = fitctree(X,Y,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```



Compare the cross-validation classification errors of the models.

```
classErrorDefault = kfoldLoss(MdlDefault)
```

```
classErrorDefault = 0.1168
```

```
classError7 = kfoldLoss(Mdl7)
```

```
classError7 = 0.1311
```

`Mdl7` is much less complex and performs only slightly worse than `MdlDefault`.

Optimize Classification Tree

This example shows how to optimize hyperparameters automatically using `fitctree`. The example uses Fisher's iris data.

Load Fisher's iris data.

```
load fisheriris
```

Optimize the cross-validation loss of the classifier, using the data in `meas` to predict the response in `species`.

```
X = meas;
Y = species;
Mdl = fitctree(X,Y,'OptimizeHyperparameters','auto')
```

```

Unbiased Predictor Importance Estimates

Load the `census1994` data set. Consider a model that predicts a person's salary category given their age, working class, education level, martial status, race, sex, capital gain and loss, and number of working hours per week.

```
load census1994
X = adultdata(:,{'age','workClass','education_num','marital_status','race',...
    'sex','capital_gain','capital_loss','hours_per_week','salary'});
```

Display the number of categories represented in the categorical variables using `summary`.

```
summary(X)
```

```
Variables:

        Min            0
        Median         0
        Max        99999

capital_loss: 32561x1 double

    Values:

        Min            0
        Median         0
        Max         4356

hours_per_week: 32561x1 double

    Values:

        Min           1
```

```
            Median       40
            Max          99

    salary: 32561x1 categorical

        Values:

            <=50K     24720
            >50K       7841
```

Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

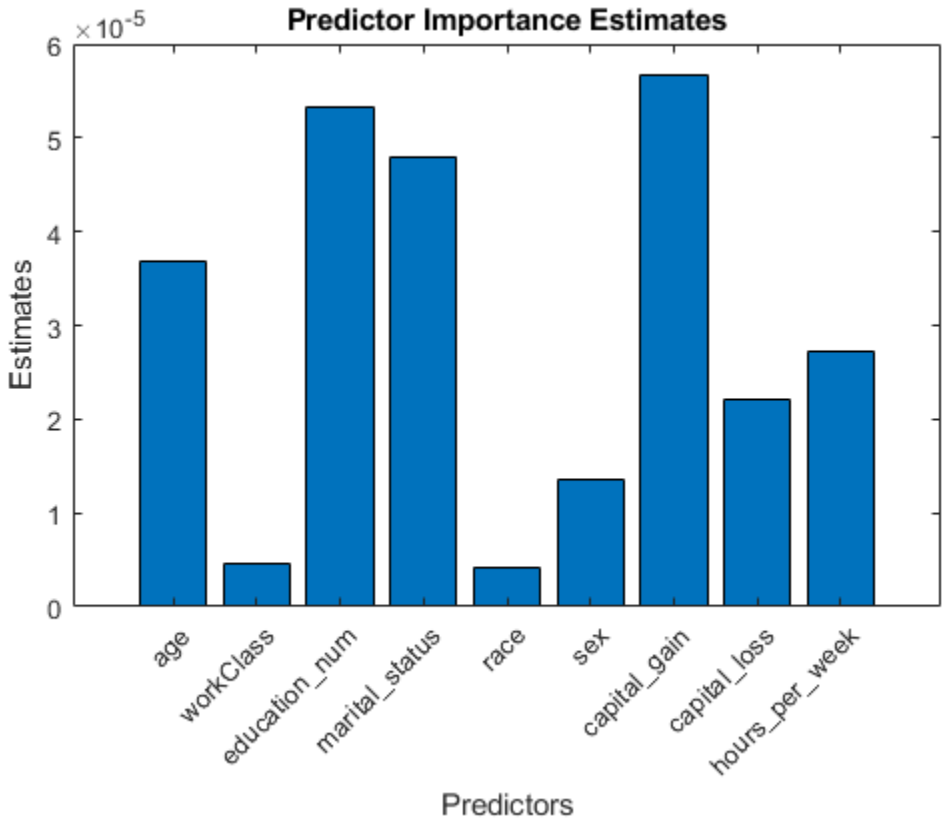
Train a classification tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing observations in the data, specify usage of surrogate splits.

```
Mdl = fitctree(X,'salary','PredictorSelection','curvature',...
    'Surrogate','on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```



In this case, `capital_gain` is the most important predictor, followed by `education_num`.

Optimize Classification Tree on Tall Array

This example shows how to optimize hyperparameters of a classification tree automatically using a tall array. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Create a datastore that references the folder location with the data. Select a subset of the variables to work with, and treat `'NA'` values as missing data so that `datastore` replaces them with `NaN` values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek',...
                            'DepTime','ArrDelay','Distance','DepDelay'};
ds.TreatAsMissing = 'NA';
tt  = tall(ds) % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

tt =

  M×7 tall table

    Month    DayofMonth    DayOfWeek    DepTime    ArrDelay    Distance    DepDelay

```

Determine the flights that are late by 10 minutes or more by defining a logical variable that is true for a late flight. This variable contains the class labels. A preview of this variable includes the first few rows.

```
Y = tt.DepDelay > 10 % Class labels
```

```
Y =

  M×1 tall logical array

   1
   0
   1
   1
   0
   1
   0
   0
   :
   :
```

Create a tall array for the predictor data.

```
X = tt{:,1:end-1} % Predictor data
```

```
X =

  M×6 tall double matrix

         10          21           3         642           8         308
         10          26           1        1021           8         296
         10          23           5        2055          21         480
         10          23           5        1332          13         296
         10          22           4         629           4         373
         10          28           3        1446          59         308
         10           8           4         928           3         447
         10          10           6         859          11         954
```

          :          :          :          :          :          :
          :          :          :          :          :          :
```

Remove rows in X and Y that contain missing data.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:end-1);
Y = R(:,end);
```

Standardize the predictor variables.

```
Z = zscore(X);
```

Optimize hyperparameters automatically using the `'OptimizeHyperparameters'` name-value pair argument. Find the optimal `'MinLeafSize'` value that minimizes holdout cross-validation loss. (Specifying `'auto'` uses `'MinLeafSize'`.) For reproducibility, use the `'expected-improvement-plus'` acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs”.

```
rng('default')
tallrng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitctree(Z,Y,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('Holdout',0.3,...
    'AcquisitionFunctionName','expected-improvement-plus'))
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: table

ResponseVarName — Response variable name
name of variable in Tbl

Response variable name, specified as the name of a variable in Tbl.

You must specify ResponseVarName as a character vector or string scalar. For example, if the response variable Y is stored as Tbl.Y, then specify it as 'Y'. Otherwise, the software treats all columns of Tbl, including Y, as predictors when training the model.

The response variable must be a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. If Y is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the ClassNames name-value argument.

Data Types: char | string

formula — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form 'Y~x1+x2+x3'. In this form, Y represents the response variable, and x1, x2, and x3 represent the predictor variables.

To specify a subset of variables in Tbl as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in Tbl that do not appear in formula.

The variable names in the formula must be both variable names in Tbl (Tbl.Properties.VariableNames) and valid MATLAB identifiers. You can verify the variable names in Tbl by using the isvarname function. If the variable names are not valid, then you can convert them by using the matlab.lang.makeValidName function.

Data Types: char | string

Y — Class labels
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class labels, specified as a numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

When fitting the tree, fitctree considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Y to be missing values. fitctree does not use observations with missing values for Y in the fit.

For numeric Y, consider fitting a regression tree using fitrtree instead.

Data Types: single | double | categorical | logical | char | string | cell

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

`fitctree` considers `NaN` values in `X` as missing values. `fitctree` does not use observations with all missing values for `X` in the fit. `fitctree` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'CrossVal','on','MinLeafSize',40` specifies a cross-validated classification tree with a minimum of 40 observations per leaf.

Model Parameters

`AlgorithmForCategorical` — Algorithm for best categorical predictor split
`'Exact'` | `'PullLeft'` | `'PCA'` | `'OVAbyClass'`

Algorithm to find the best split on a categorical predictor with C categories for data and $K \geq 3$ classes, specified as the comma-separated pair consisting of `'AlgorithmForCategorical'` and one of the following values.

Value	Description
`'Exact'`	Consider all $2^{C-1} - 1$ combinations.
`'PullLeft'`	Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.
`'PCA'`	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.

Value	Description
`'OVAbyClass'`	Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

`fitctree` automatically selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, `fitctree` always performs the exact search. To specify a particular algorithm, use the `'AlgorithmForCategorical'` name-value pair argument.

For more details, see “Splitting Categorical Predictors in Classification Trees” on page 19-25.

Example: `'AlgorithmForCategorical','PCA'`

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitctree` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitctree` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitctree` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for training
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Cost of misclassification
square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same data type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

`MaxDepth` — Maximum tree depth
positive integer

Maximum tree depth, specified as the comma-separated pair consisting of `'MaxDepth'` and a positive integer. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of `fitctree` takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

Note This option applies only when you use `fitctree` on tall arrays. See Tall Arrays on page 33-1931 for more information.

`MaxNumCategories` — Maximum category levels
`10` (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of `'MaxNumCategories'` and a nonnegative scalar value. `fitctree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxNumCategories` levels in the split node. Otherwise, `fitctree` finds the best categorical split using one of the inexact algorithms.

Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload.

Example: `'MaxNumCategories',8`

`MaxNumSplits` — Maximal number of decision splits
`size(X,1) - 1` (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of `'MaxNumSplits'` and a positive integer. `fitctree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see Algorithms on page 33-1928.

Example: `'MaxNumSplits',5`

Data Types: `single` | `double`

`MergeLeaves` — Leaf merge flag
`'on'` (default) | `'off'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and `'on'` or `'off'`.

If `MergeLeaves` is `'on'`, then `fitctree`:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the classification tree

Otherwise, `fitctree` does not merge leaves.

Example: `'MergeLeaves','off'`

`MinLeafSize` — Minimum number of leaf node observations
`1` (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of `'MinLeafSize'` and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitctree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

Example: `'MinLeafSize',3`

Data Types: `single` | `double`

`MinParentSize` — Minimum number of branch node observations
`10` (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParentSize'` and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitctree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

Example: `'MinParentSize',8`

Data Types: `single` | `double`

`NumBins` — Number of bins for numeric predictors
`[]` (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

- If the `'NumBins'` value is empty (default), then `fitctree` does not bin any predictors.
- If you specify the `'NumBins'` value as a positive integer scalar (`numBins`), then `fitctree` bins every numeric predictor into at most `numBins` equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - The number of bins can be less than `numBins` if a predictor has fewer than `numBins` unique values.
  - `fitctree` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but might cause a potential decrease in accuracy. You can try `'NumBins',50` first, and then change the value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single` | `double`

`NumVariablesToSample` — Number of predictors to select at random for each split
`'all'` (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. Alternatively, you can specify `'all'` to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify `'NumVariablesToSample'` as `'all'`. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

Example: `'NumVariablesToSample',3`

Data Types: `char` | `string` | `single` | `double`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitctree` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`PredictorSelection` — Algorithm used to select the best split predictor
`'allsplits'` (default) | `'curvature'` | `'interaction-curvature'`

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of `'PredictorSelection'` and a value in this table.

Value	Description
`'allsplits'`	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].
`'curvature'`	Curvature test on page 33-1925 — Selects the split predictor that minimizes the *p*-value of chi-square tests of independence between each predictor and the response [4]. Training speed is similar to standard CART.
`'interaction-curvature'`	Interaction test on page 33-1927 — Chooses the split predictor that minimizes the *p*-value of chi-square tests of independence between each predictor and the response, and that minimizes the *p*-value of a chi-square test of independence between each pair of predictors and response [3]. Training speed can be slower than standard CART.

For `'curvature'` and `'interaction-curvature'`, if all tests yield *p*-values greater than 0.05, then `fitctree` stops splitting nodes.

Tip

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. Consider specifying the curvature or interaction test if any of the following are true:
  - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
  - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `predictorImportance` and "Introduction to Feature Selection" on page 15-49.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [3].
- Prediction speed is unaffected by the value of `'PredictorSelection'`.

For details on how `fitctree` selects split predictors, see "Node Splitting Rules" on page 33-1928 and "Choose Split Predictor Selection Technique" on page 19-14.

Example: `'PredictorSelection','curvature'`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as one of the following:

- Character vector or string scalar.
  - `'empirical'` determines class probabilities from class frequencies in the response variable in `Y` or `Tbl`. If you pass observation weights, `fitctree` uses the weights to compute the class probabilities.
  - `'uniform'` sets all class probabilities to be equal.
- Vector (one scalar value for each class). To specify the class order for the corresponding elements of `'Prior'`, set the `'ClassNames'` name-value argument.
- Structure `S` with two fields.
  - `S.ClassNames` contains the class names as a variable of the same type as the response variable in `Y` or `Tbl`.
  - `S.ClassProbs` contains a vector of corresponding probabilities.

`fitctree` normalizes the weights in each class (`'Weights'`) to add up to the value of the prior probability of the respective class.

Example: `'Prior','uniform'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`Prune` — Flag to estimate optimal sequence of pruned subtrees
`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then `fitctree` grows the classification tree without pruning it, but estimates the optimal sequence of pruned subtrees. Otherwise, `fitctree` grows the classification tree without estimating the optimal sequence of pruned subtrees.

To prune a trained `ClassificationTree` model, pass it to `prune`.

Example: `'Prune','off'`

`PruneCriterion` — Pruning criterion
`'error'` (default) | `'impurity'`

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'error'` or `'impurity'`.

If you specify `'impurity'`, then `fitctree` uses the impurity measure specified by the `'SplitCriterion'` name-value pair argument.

For details, see “Impurity and Node Error” on page 33-1926.

Example: `'PruneCriterion','impurity'`

`Reproducible` — Flag to enforce reproducibility
`false` (logical `0`) (default) | `true` (logical `1`)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of `'Reproducible'` and either `false` or `true`.

If `'NumVariablesToSample'` is not `'all'`, then the software selects predictors at random for each split. To reproduce the random selections, you must specify `'Reproducible',true` and set the seed of the random number generator by using `rng`. Note that setting `'Reproducible'` to `true` can slow down training.

Example: `'Reproducible',true`

Data Types: `logical`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar representing the name of the response variable.

This name-value pair is not valid when using the `ResponseVarName` or `formula` input arguments.

Example: `'ResponseName','IrisType'`

Data Types: `char` | `string`

`ScoreTransform` — Score transformation
`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
`'doublelogit'`	$1/(1 + e^{-2x})$

Value	Description
`'invlogit'`	$\log(x / (1 - x))$
`'ismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
`'logit'`	$1/(1 + e^{-x})$
`'none'` or `'identity'`	x (no transformation)
`'sign'`	–1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
`'symmetric'`	$2x - 1$
`'symmetricismax'`	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to –1
`'symmetriclogit'`	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for the score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform','logit'`

Data Types: `char` | `string` | `function_handle`

`SplitCriterion` — Split criterion
`'gdi'` (default) | `'twoing'` | `'deviance'`

Split criterion, specified as the comma-separated pair consisting of `'SplitCriterion'` and `'gdi'` (Gini's diversity index), `'twoing'` for the twoing rule, or `'deviance'` for maximum deviance reduction (also known as cross entropy).

For details, see “Impurity and Node Error” on page 33-1926.

Example: `'SplitCriterion','deviance'`

`Surrogate` — Surrogate decision splits flag
`'off'` (default) | `'on'` | `'all'` | positive integer value

Surrogate decision splits on page 33-1928 flag, specified as the comma-separated pair consisting of `'Surrogate'` and `'on'`, `'off'`, `'all'`, or a positive integer value.

- When set to `'on'`, `fitctree` finds at most 10 surrogate splits at each branch node.
- When set to `'all'`, `fitctree` finds all surrogate splits at each branch node. The `'all'` setting can use considerable time and memory.
- When set to a positive integer value, `fitctree` finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors. For more details, see “Node Splitting Rules” on page 33-1928.

Example: `'Surrogate','on'`

Data Types: `single` | `double` | `char` | `string`

`Weights` — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values or the name of a variable in `Tbl`. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

`fitctree` normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation Options

`CrossVal` — Flag to grow cross-validated decision tree

`'off'` (default) | `'on'`

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of `'CrossVal'` and `'on'` or `'off'`.

If `'on'`, `fitctree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments. You can only use one of these four arguments at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

Example: `'CrossVal','on'`

`CVPartition` — Partition for cross-validated tree

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`.

If you use `'CVPartition'`, you cannot use any of the `'KFold'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

`Holdout` — Fraction of data for holdout validation

`0` (default) | scalar value in the range `[0,1]`

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range `[0,1]`. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use `'Holdout'`, you cannot use any of the `'CVPartition'`, `'KFold'`, or `'Leaveout'` name-value pair arguments.

Example: `'Holdout',0.1`

Data Types: `single` | `double`

KFold — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold',k`, then the software:

1. Randomly partitions the data into k sets
2. For each set, reserves the set as validation data, and trains the model using the other k – 1 sets
3. Stores the k compact, trained models in the cells of a k-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',8`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. Specify `'on'` to use leave-one-out cross-validation.

If you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

Hyperparameter Optimization Options

OptimizeHyperparameters — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'MinLeafSize'}`
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitctree` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitctree` are:

- `MaxNumSplits` — `fitctree` searches among integers, by default log-scaled in the range `[1,max(2,NumObservations-1)]`.
- `MinLeafSize` — `fitctree` searches among integers, by default log-scaled in the range `[1,max(2,floor(NumObservations/2))]`.
- `SplitCriterion` — For two classes, `fitctree` searches among `'gdi'` and `'deviance'`. For three or more classes, `fitctree` also searches among `'twoing'`.
- `NumVariablesToSample` — `fitctree` does not optimize over this hyperparameter. If you pass `NumVariablesToSample` as a parameter name, `fitctree` simply uses the full number of predictors. However, `fitcensemble` does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitctree',meas,species);
params(1).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Classification Tree” on page 33-1874.

Example: `'auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`

Field Name	Values	Default
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`tree` — Classification tree

classification tree object

Classification tree, returned as a classification tree object.

Using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldPredict` to predict responses for observations not used for training.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

More About

Curvature Test

The curvature test is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable x and y is conducted using this process.

1. If x is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
2. For each level in the partitioned predictor $j = 1..,J$ and class in the response $k = 1,...,K$, compute the weighted proportion of observations in class k

   $$\widehat{\pi}_{jk} = \sum_{i=1}^{n} I\{y_i = k\} w_i .$$

   w_i is the weight of observation i, $\sum w_i = 1$, I is the indicator function, and n is the sample size. If all observations have the same weight, then $\widehat{\pi}_{jk} = \frac{n_{jk}}{n}$, where n_{jk} is the number of observations in level j of the predictor that are in class k.
3. Compute the test statistic

   $$t = n \sum_{k=1}^{K} \sum_{j=1}^{J} \frac{\left(\widehat{\pi}_{jk} - \widehat{\pi}_{j+}\widehat{\pi}_{+k}\right)^2}{\widehat{\pi}_{j+}\widehat{\pi}_{+k}}$$

   $\widehat{\pi}_{j+} = \sum_{k} \widehat{\pi}_{jk}$, that is, the marginal probability of observing the predictor at level j. $\widehat{\pi}_{+k} = \sum_{j} \widehat{\pi}_{jk}$, that is the marginal probability of observing class k. If n is large enough, then t is distributed as a χ^2 with $(K - 1)(J - 1)$ degrees of freedom.
4. If the p-value for the test is less than 0.05, then reject the null hypothesis that there is no association between x and y.

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant *p*-values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

Note If levels of a predictor are pure for a particular class, then `fitctree` merges those levels. Therefore, in step 3 of the algorithm, J can be less than the actual number of levels in the predictor. For example, if x has 4 levels, and all observations in bins 1 and 2 belong to class 1, then those levels are pure for class 1. Consequently, `fitctree` merges the observations in bins 1 and 2, and J reduces to 3.

For more details on how the curvature test applies to growing classification trees, see “Node Splitting Rules” on page 33-1928 and [4].

Impurity and Node Error

A decision tree splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

  $$1 - \sum_i p^2(i),$$

  where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index `0`; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.
- Deviance (`'deviance'`) — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

  $$-\sum_i p(i)\log_2 p(i)\,.$$

  A pure node has deviance `0`; otherwise, the deviance is positive.
- Twoing rule (`'twoing'`) — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

  $$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

  where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.
- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

  $1 – p(j)$.

Interaction Test

The interaction test is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables x_1 and x_2 with respect to y is conducted using this process.

1. If x_1 or x_2 is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
2. Create the nominal variable z with $J = J_1J_2$ levels that assigns an index to observation i according to which levels of x_1 and x_2 it belongs. Remove any levels of z that do not correspond to any observations.
3. Conduct a curvature test on page 33-1925 between z and y.

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 33-1925, “Node Splitting Rules” on page 33-1928 and [3].

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 33-1928 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k, respectively, and $j \neq k$. At node t, the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - \left(1 - P_{L_jL_k} - P_{R_jR_k}\right)}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t, such that $x_j < u$. The subscript L stands for the left child of node t.
- P_R is the proportion of observations in node t, such that $x_j \geq u$. The subscript R stands for the right child of node t.
- $P_{L_jL_k}$ is the proportion of observations at node t, such that $x_j < u$ and $x_k < v$.
- $P_{R_jR_k}$ is the proportion of observations at node t, such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty,1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 33-2412.

Tip

- By default, `Prune` is `'on'`. However, this specification does not prune the classification tree. To prune a trained classification tree, pass the classification tree to `prune`.
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

Node Splitting Rules

`fitctree` uses these processes to determine how to split node t.

- For standard CART (that is, if `PredictorSelection` is `'allpairs'`) and for all predictors x_i, $i = 1,\ldots,p$:

  1. `fitctree` computes the weighted impurity of node t, i_t. For supported impurity measures, see `SplitCriterion`.
  2. `fitctree` estimates the probability that an observation is in node t using

     $$P(T) = \sum_{j \in T} w_j .$$

     w_j is the weight of observation j, and T is the set of all observation indices in node t. If you do not specify `Prior` or `Weights`, then $w_j = 1/n$, where n is the sample size.
  3. `fitctree` sorts x_i in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. `fitctree` stores any indices corresponding to missing values in the set T_U, which is the unsplit set.
  4. `fitctree` determines the best way to split node t using x_i by maximizing the impurity gain (ΔI) over all splitting candidates. That is, for all splitting candidates in x_i:

     a. `fitctree` splits the observations in node t into left and right child nodes (t_L and t_R, respectively).

     b. `fitctree` computes ΔI. Suppose that for a particular splitting candidate, t_L and t_R contain observation indices in the sets T_L and T_R, respectively.

        - If x_i does not contain any missing values, then the impurity gain for the current splitting candidate is

$\Delta I = P(T)i_t - P(T_L)i_{t_L} - P(T_R)i_{t_R}$.

- If x_i contains missing values then, assuming that the observations are missing at random, the impurity gain is

$\Delta I_U = P(T - T_U)i_t - P(T_L)i_{t_L} - P(T_R)i_{t_R}$.

$T - T_U$ is the set of all observation indices in node t that are not missing.

- If you use surrogate decision splits on page 33-1928, then:

  i `fitctree` computes the predictive measures of association on page 33-1927 between the decision split $x_j < u$ and all possible decision splits $x_k < v, j \neq k$.

  ii `fitctree` sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.

  iii `fitctree` decides the child node assignments for observations with a missing value for x_i using the surrogate split. If the surrogate predictor also contains a missing value, then `fitctree` uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for `fitctree` to split two different observations at node t using two different surrogate splits. For example, suppose the predictors x_1 and x_2 are the best and second best surrogates, respectively, for the predictor x_i, $i \notin \{1,2\}$, at node t. If observation m of predictor x_i is missing (i.e., x_{mi} is missing), but x_{m1} is not missing, then x_1 is the surrogate predictor for observation x_{mi}. If observations $x_{(m+1),i}$ and $x(m+1),1$ are missing, but $x_{(m+1),2}$ is not missing, then x_2 is the surrogate predictor for observation $m + 1$.

  iv `fitctree` uses the appropriate impurity gain formula. That is, if `fitctree` fails to assign all missing observations in node t to children nodes using surrogate splits, then the impurity gain is ΔI_U. Otherwise, `fitctree` uses ΔI for the impurity gain.

c `fitctree` chooses the candidate that yields the largest impurity gain.

`fitctree` splits the predictor variable at the cut point that maximizes the impurity gain.

- For the curvature test (that is, if `PredictorSelection` is `'curvature'`):

  1 `fitctree` conducts curvature tests on page 33-1925 between each predictor and the response for observations in node t.

  - If all p-values are at least 0.05, then `fitctree` does not split node t.
  - If there is a minimal p-value, then `fitctree` chooses the corresponding predictor to split node t.
  - If more than one p-value is zero due to underflow, then `fitctree` applies standard CART to the corresponding predictors to choose the split predictor.

  2 If `fitctree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

- For the interaction test (that is, if `PredictorSelection` is `'interaction-curvature'`):

  1 For observations in node t, `fitctree` conducts curvature tests on page 33-1925 between each predictor and the response and interaction tests on page 33-1927 between each pair of predictors and the response.

- If all *p*-values are at least 0.05, then `fitctree` does not split node *t*.
- If there is a minimal *p*-value and it is the result of a curvature test, then `fitctree` chooses the corresponding predictor to split node *t*.
- If there is a minimal *p*-value and it is the result of an interaction test, then `fitctree` chooses the split predictor using standard CART on the corresponding pair of predictors.
- If more than one *p*-value is zero due to underflow, then `fitctree` applies standard CART to the corresponding predictors to choose the split predictor.

2. If `fitctree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

Tree Depth Control

- If `MergeLeaves` is `'on'` and `PruneCriterion` is `'error'` (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using classification error. This specification amounts to merging leaves that share the most popular class per leaf.
- To accommodate `MaxNumSplits`, `fitctree` splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitctree` follows this procedure:

  1. Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
  2. Sort the branch nodes by their impurity gains.
  3. Unsplit the number of least successful branches.
  4. Return the decision tree grown so far.

  This procedure produces maximally balanced trees.
- The software splits branch nodes layer by layer until at least one of these events occurs:
  - There are `MaxNumSplits` branch nodes.
  - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
  - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.
  - The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
  - For values `'curvature'` or `'interaction-curvature'` of `PredictorSelection`, all tests yield *p*-values greater than 0.05.

  `MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set `'MaxNumSplits'`, splitting might stop due to the value of `MinParentSize`, before `MaxNumSplits` splits occur.

Parallelization

For dual-core systems and above, `fitctree` parallelizes training decision trees using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
  - `tree = fitctree(Tbl,Y)`
  - `tree = fitctree(X,Y)`
  - `tree = fitctree(___,Name,Value)`
  - `[tree,FitInfo,HyperparameterOptimizationResults] = fitctree(___,Name,Value)` — `fitctree` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the `'OptimizeHyperparameters'` name-value pair argument.
- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.
- The `HyperparameterOptimizationResults` output argument is a `BayesianOptimization` object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

  `'HyperparameterOptimizationResults'` is nonempty when the `'OptimizeHyperparameters'` name-value pair argument is nonempty at the time you create the model. The values in `'HyperparameterOptimizationResults'` depend on the value you specify for the `'HyperparameterOptimizationOptions'` name-value pair argument when you create the model.
  - If you specify `'bayesopt'` (default), then `HyperparameterOptimizationResults` is an object of class `BayesianOptimization`.
  - If you specify `'gridsearch'` or `'randomsearch'`, then `HyperparameterOptimizationResults` is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).
- Supported name-value pair arguments, and any differences, are:
  - `'AlgorithmForCategorical'`

- 'CategoricalPredictors'
- 'ClassNames'
- 'Cost'
- 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. By default, the software selects and reserves 20% of the data as holdout validation data, and trains the model using the rest of the data. You can specify a different value for the holdout fraction by using this argument. For example, specify 'HyperparameterOptimizationOptions',struct('Holdout',0.3) to reserve 30% of the data as validation data.
- 'MaxNumCategories'
- 'MaxNumSplits'— for tall optimization, fitctree searches among integers, by default log-scaled in the range [1,max(2,min(10000,NumObservations-1))].
- 'MergeLeaves'
- 'MinLeafSize'
- 'MinParentSize'
- 'NumVariablesToSample'
- 'OptimizeHyperparameters'
- 'PredictorNames'
- 'Prior'
- 'ResponseName'
- 'ScoreTransform'
- 'SplitCriterion'
- 'Weights'

- This additional name-value pair argument is specific to tall arrays:
  - 'MaxDepth' — A positive integer specifying the maximum depth of the output tree. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of fitctree takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

For more information, see “Tall Arrays”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptimizationOptions', struct('UseParallel',true) name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Splitting Categorical Predictors in Classification Trees” on page 19-25

Introduced in R2014a

fitglm

Create generalized linear regression model

Syntax

```
mdl = fitglm(tbl)
mdl = fitglm(X,y)
mdl = fitglm(___,modelspec)
mdl = fitglm(___,Name,Value)
```

Description

`mdl = fitglm(tbl)` returns a generalized linear model fit to variables in the table or dataset array `tbl`. By default, `fitglm` takes the last variable as the response variable.

`mdl = fitglm(X,y)` returns a generalized linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitglm(___,modelspec)` returns a generalized linear model of the type you specify in `modelspec`.

`mdl = fitglm(___,Name,Value)` returns a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, the distribution of the response variable, and the link function to use.

Examples

Fit a Logistic Regression Model

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the `hospital` dataset array.

```
load hospital
dsa = hospital;
```

Specify the model using a formula that allows up to two-way interactions between the variables age, weight, and sex. Smoker is the response variable.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Fit a logistic binomial model.

```
mdl = fitglm(dsa,modelspec,'Distribution','binomial')
```

```
mdl =
Generalized linear regression model:
    logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
```

```
    Distribution = Binomial

Estimated Coefficients:
                        Estimate         SE         tStat      pValue
                       ___________    _________    ________    _______

    (Intercept)            -6.0492       19.749     -0.3063    0.75938
    Sex_Male               -2.2859       12.424    -0.18399    0.85402
    Age                    0.11691      0.50977     0.22934    0.81861
    Weight                0.031109      0.15208     0.20455    0.83792
    Sex_Male:Age          0.020734      0.20681     0.10025    0.92014
    Sex_Male:Weight        0.01216     0.053168     0.22871     0.8191
    Age:Weight         -0.00071959    0.0038964    -0.18468    0.85348

100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535
```

All of the p-values (under `pValue`) are large. This means none of the coefficients are significant. The large *p*-value for the test of the model, 0.535, indicates that this model might not differ statistically from a constant model.

GLM for Poisson Response

Create sample data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,7);
mu = exp(X(:,[1 3 6])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl =  fitglm(X,y,'linear','Distribution','poisson')

mdl =
Generalized linear regression model:
    log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 + x6 + x7
    Distribution = Poisson

Estimated Coefficients:
                    Estimate        SE        tStat        pValue
                    _________    ________    ________    __________

    (Intercept)       0.88723    0.070969      12.502    7.3149e-36
    x1                0.44413    0.052337      8.4858    2.1416e-17
    x2              0.0083388    0.056527     0.14752       0.88272
    x3                0.21518    0.063416      3.3932    0.00069087
    x4               -0.058386    0.065503    -0.89135       0.37274
    x5               -0.060824    0.073441     -0.8282       0.40756
    x6                0.34267    0.056778      6.0352    1.5878e-09
    x7                0.04316     0.06146     0.70225       0.48252
```

```
100 observations, 92 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 119, p-value = 1.55e-22
```

The p-values of 2.14e-17, 0.00069, and 1.58e-09 indicate that the coefficients of the variables `x1`, `x3`, and `x6` are statistically significant.

Input Arguments

`tbl` — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if `'Distribution'` is `'binomial'`.

- By default, `fitglm` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.
- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

`X` — Predictor variables

matrix

Predictor variables, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

y — Response variable

vector | matrix

Response variable, specified as a vector or matrix.

- If `'Distribution'` is not `'binomial'`, then `y` must be an *n*-by-1 vector, where *n* is the number of observations. Each entry in `y` is the response for the corresponding row of `X`. The data type must be single or double.
- If `'Distribution'` is `'binomial'`, then `y` can be an *n*-by-1 vector or *n*-by-2 matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `logical` | `categorical`

modelspec — Model specification

`'linear'` (default) | character vector or string scalar naming the model | *t*-by-(*p* + 1) terms matrix | character vector or string scalar formula in the form `'y ~ terms'`

Model specification, specified as one of these values.

- A character vector or string scalar naming the model.

Value	Model Type
`'constant'`	Model contains only a constant (intercept) term.
`'linear'`	Model contains an intercept and linear term for each predictor.
`'interactions'`	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
`'purequadratic'`	Model contains an intercept term and linear and squared terms for each predictor.
`'quadratic'`	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
`'poly`*`ijk`*`'`	Model is a polynomial with all terms up to degree *`i`* in the first predictor, degree *`j`* in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, `'poly13'` has an intercept and x_1, x_2, x_2^2, x_2^3, x_1*x_2, and x_1*x_2^2 terms, where x_1 and x_2 are the first and second predictors, respectively.

- A *t*-by-(*p* + 1) matrix, or a “Terms Matrix” on page 33-1943, specifying terms in the model, where *t* is the number of terms and *p* is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar “Formula” on page 33-1943 in the form `'y ~ terms'`,

where the `terms` are in “Wilkinson Notation” on page 33-1944. The variable names in the formula must be variable names in `tbl` or variable names specified by `Varnames`. Also, the variable names must be valid MATLAB identifiers.

The software determines the order of terms in a fitted model by using the order of terms in `tbl` or `X`. Therefore, the order of terms in the model can be different from the order of terms in the specified formula.

Example: `'quadratic'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distribution','normal','link','probit','Exclude',[23,59]` specifies that the distribution of the response is normal, and instructs `fitglm` to use the probit link function and exclude the 23rd and 59th observations from the fit.

`BinomialSize` — Number of trials for binomial distribution

1 (default) | numeric scalar | numeric vector | character vector | string scalar

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of `'BinomialSize'` and the variable name in `tbl`, a numeric scalar, or a numeric vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `char` | `string`

`B0` — Initial values for coefficient estimates

numeric vector

Initial values for the coefficient estimates, specified as a numeric vector. The default values are initial fitted values derived from the input data.

Data Types: `single` | `double`

`CategoricalVars` — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `fitglm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the second and third variables out of six as categorical using either of the following:

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

`DispersionFlag` — Indicator to compute dispersion parameter
`false` for `'binomial'` and `'poisson'` distributions (default) | `true`

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

`true`	Estimate a dispersion parameter when computing standard errors. The estimated dispersion parameter value is the sum of squared Pearson residuals divided by the degrees of freedom for error (DFE).
`false`	Default. Use the theoretical value of 1 when computing standard errors.

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag',true`

`Distribution` — Distribution of the response variable
`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

`'normal'`	Normal distribution
`'binomial'`	Binomial distribution
`'poisson'`	Poisson distribution
`'gamma'`	Gamma distribution
`'inverse gaussian'`	Inverse Gaussian distribution

Example: `'Distribution','gamma'`

`Exclude` — Observations to exclude
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

`Intercept` — Indicator for constant term
`true` (default) | `false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept',false`

`Link` — Link function
canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of `'Link'` and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
`'identity'`	$f(\mu) = \mu$	$\mu = Xb$
`'log'`	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
`'logit'`	$f(\mu) = \log(\mu/(1–\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
`'probit'`	$f(\mu) = \Phi^{-1}(\mu)$, where Φ is the cumulative distribution function of the standard normal distribution.	$\mu = \Phi(Xb)$
`'comploglog'`	$f(\mu) = \log(–\log(1 – \mu))$	$\mu = 1 – \exp(–\exp(Xb))$
`'reciprocal'`	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
`p` (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
`S` (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: • `S.Link` — The link function • `S.Inverse` — The inverse link function • `S.Derivative` — The derivative of the link function	$f(\mu) =$ `S.Link`(μ)	$\mu =$ `S.Inverse`(Xb)

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see “Canonical Link Function” on page 33-1944.

Example: `'Link','probit'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`Options` — Optimization options
`statset('fitglm')` (default) | structure

Optimization options, specified as a structure. This argument determines the control parameters for the iterative algorithm that `fitglm` uses.

Create the `'Options'` value by using the function `statset` or by creating a structure array containing the fields and values described in this table.

Field Name	Value	Default Value
`Display`	Amount of information displayed by the algorithm • `'off'` — Displays no information • `'final'` — Displays the final output	`'off'`
`MaxIter`	Maximum number of iterations allowed, specified as a positive integer	`100`
`TolX`	Termination tolerance for the parameters, specified as a positive scalar	`1e-6`

You can also enter `statset('fitglm')` in the Command Window to see the names and default values of the fields that `fitglm` accepts in the `'Options'` name-value argument.

Example: `'Options',statset('Display','final','MaxIter',1000)` specifies to display the final information of the iterative algorithm results, and change the maximum number of iterations allowed to 1000.

Data Types: `struct`

`Offset` — Offset variable

[ ] (default) | numeric vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of `'Offset'` and the variable name in `tbl` or a numeric vector with the same length as the response.

`fitglm` uses `Offset` as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

$f(\mu)$ = Offset + $X*b$,

where f is the link function, μ is the mean response, and $X*b$ is the linear combination of predictors X. The `Offset` predictor has coefficient `1`.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char` | `string`

`PredictorVars` — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in X, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

`ResponseVar` — Response variable
last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

`VarNames` — Names of variables
`{'x1','x2',...,'xn','y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

Before specifying `'VarNames',varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string` | `cell`

`Weights` — Observation weights
`ones(n,1)` (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: `single` | `double`

Output Arguments

`mdl` — Generalized linear regression model
`GeneralizedLinearModel` object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

More About

Terms Matrix

A terms matrix `T` is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `x1`, `x2`, and `x3` and the response variable `y` in the order `x1`, `x2`, `x3`, and `y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `x2`; equivalently, `x1^0 * x2^1 * x3^0`
- `[1 0 1 0]` — `x1*x3`
- `[2 0 0 0]` — `x1^2`
- `[0 1 2 0]` — `x2*(x3^2)`

The `0` at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include `0` for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form `'`*`y ~ terms`*`'`.

- *`y`* is the response name.
- *`terms`* represents the predictor terms in a model using Wilkinson notation.

To represent predictor and response variables, use the variable names of the table input `tbl` or the variable names specified by using `VarNames`. The default value of `VarNames` is `{'x1','x2',...,'xn','y'}`.

For example:

- `'y ~ x1 + x2 + x3'` specifies a three-variable linear model with intercept.

- `'y ~ x1 + x2 + x3 − 1'` specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include −1 in the formula.

A formula includes a constant term unless you explicitly remove the term using −1.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- − means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- `( )` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
1	Constant (intercept) term
x1^k, where k is a positive integer	x1, $x1^2$, ..., $x1^k$
x1 + x2	x1, x2
x1*x2	x1, x2, x1*x2
x1:x2	x1*x2 only
−x2	Do not include x2
x1*x2 + x3	x1, x2, x3, x1*x2
x1 + x2 + x3 + x1:x2	x1, x2, x3, x1*x2
x1*x2*x3 − x1:x2:x3	x1, x2, x3, x1*x2, x1*x3, x2*x3
x1*(x2 + x3)	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

Distribution	Canonical Link Function Name	Link Function	Mean (Inverse) Function
`'normal'`	`'identity'`	$f(\mu) = \mu$	$\mu = Xb$
`'binomial'`	`'logit'`	$f(\mu) = \log(\mu/(1 - \mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
`'poisson'`	`'log'`	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$

Distribution	Canonical Link Function Name	Link Function	Mean (Inverse) Function
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For methods such as `plotResiduals` or `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- `fitglm` treats a categorical predictor as follows:
  - A model with a categorical predictor that has L levels (categories) includes L – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `fitglm` treats the group of L – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the L – 1 indicator variables with the continuous predictor.
  - Interaction terms between two categorical predictors with L and M levels consist of the (L – 1)*(M – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
  - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.
- `fitglm` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `fitglm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `fitglm` uses each observation in the fit.

Alternative Functionality

- Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If any input argument to `fitglm` is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the `'Weights'`, `'Exclude'`, `'Offset'`, and `'BinomialSize'` name-value pairs.
- The default number of iterations is 5. You can change the number of iterations using the `'Options'` name-value pair to pass in an options structure. Create an options structure using `statset` to specify a different value for `MaxIter`.
- For tall data, `fitglm` returns a `CompactGeneralizedLinearModel` object that contains most of the same properties as a `GeneralizedLinearModel` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `GeneralizedLinearModel` properties:

  - `Diagnostics`
  - `Fitted`
  - `Offset`
  - `ObservationInfo`
  - `ObservationNames`
  - `Residuals`
  - `Steps`
  - `Variables`

  You can compute the residuals directly from the compact object returned by `GLM = fitglm(X,Y)` using

```
RES = Y - predict(GLM,X);
S = sqrt(GLM.SSE/GLM.DFE);
histogram(RES,linspace(-3*S,3*S,51))
```

For more information, see “Tall Arrays for Out-of-Memory Data”.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2013b

fitglme

Fit generalized linear mixed-effects model

Syntax

```
glme = fitglme(tbl,formula)
glme = fitglme(tbl,formula,Name,Value)
```

Description

`glme = fitglme(tbl,formula)` returns a generalized linear mixed-effects model, `glme`. The model is specified by `formula` and fitted to the predictor variables in the table or dataset array, `tbl`.

`glme = fitglme(tbl,formula,Name,Value)` returns a generalized linear mixed-effects model using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the distribution of the response, the link function, or the covariance pattern of the random-effects terms.

Examples

Fit a Generalized Linear Mixed-Effects Model

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this

model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}\left(\mu_{ij}\right).$$

This corresponds to the generalized linear mixed-effects model

$$\log\left(\mu_{ij}\right) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ..
    'Distribution','Poisson','Link','log','FitMethod','Laplace', ...
    'DummyVarCoding','effects');
```

Display the model.

```
disp(glme)
```

```
Generalized linear mixed-effects model fit by ML

Model information:
    Number of observations             100
    Fixed effects coefficients           6
    Random effects coefficients         20
    Covariance parameters                1
    Distribution                   Poisson
    Link                           Log
    FitMethod                      Laplace

Formula:
    defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1 | factory)

Model fit statistics:
    AIC       BIC       LogLikelihood    Deviance
    416.35    434.58    -201.17          402.35

Fixed effects coefficients (95% CIs):

    -0.72019    -0.015134
     -1.7395       1.5505
     -2.1926       1.6263
    -0.22679     0.083051
    -0.082588     0.22473

Random effects covariance parameters:
Group: factory (20 Levels)
    Name1                  Name2                  Type           Estimate
    {'(Intercept)'}        {'(Intercept)'}        {'std'}        0.31381

Group: Error
    Name                        Estimate
    {'sqrt(Dispersion)'}        1
```

The `Model information` table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a `Poisson` distribution, the link function is `Log`, and the fit method is `Laplace`.

`Formula` indicates the model specification using Wilkinson's notation.

The `Model fit statistics` table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (`AIC`), Bayesian information criterion (`BIC`) values, log likelihood (`LogLikelihood`), and deviance (`Deviance`) values.

The `Fixed effects coefficients` table indicates that `fitglme` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (`Name`) contains the name of each fixed-effects coefficient, column 2 (`Estimate`) contains its estimated value, and column 3 (`SE`) contains the standard error of the coefficient. Column 4 (`tStat`) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (`DF`) and column 6 (`pValue`) contain the degrees of freedom and *p*-value that correspond to the *t*-statistic, respectively. The last two columns (`Lower` and `Upper`) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

`Random effects covariance parameters` displays a table for each grouping variable (here, only `factory`), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, `std` indicates that `fitglme` returns the standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglme` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

Input Arguments

`tbl` — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-45). You must specify the model for the variables using `formula`.

`formula` — Formula for model specification

character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The formula is case sensitive. For a full description, see “Formula” on page 33-1961.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects'` specifies the response variable distribution as Poisson, the link function as log, the fit method as Laplace, and dummy variable coding where the coefficients sum to 0.

`BinomialSize` — Number of trials for binomial distribution

1 (default) | scalar value | vector | variable name

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value, a vector of the same length as the response, or the name of a variable in the input table. If you specify the name of a variable, then the variable must be of the same length as the response. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

Data Types: `single` | `double`

`CheckHessian` — Indicator to check positive definiteness of Hessian

`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

If you specify 'FitMethod' as 'MPL' or 'REMPL', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CheckHessian',true

CovarianceMethod — Method to compute covariance of estimated parameters
'conditional' (default) | 'JointHessian'

Method to compute covariance of estimated parameters, specified as the comma-separated pair consisting of 'CovarianceMethod' and either 'conditional' or 'JointHessian'. If you specify 'conditional', then fitglme computes a fast approximation to the covariance of fixed effects given the estimated covariance parameters. It does not compute the covariance of covariance parameters. If you specify 'JointHessian', then fitglme computes the joint covariance of fixed effects and covariance parameters via the observed information matrix using the Laplacian loglikelihood.

If you specify 'FitMethod' as 'MPL' or 'REMPL', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CovarianceMethod','JointHessian'

CovariancePattern — Pattern of covariance matrix
'FullCholesky' | 'Isotropic' | 'Full' | 'Diagonal' | 'CompSymm' | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and 'FullCholesky', 'Isotropic', 'Full', 'Diagonal', 'CompSymm', a square symmetric logical matrix, a string array, or a cell array containing character vectors or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length R, where each element r of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the rth random-effects term. The options for each element follow.

Value	Description
'FullCholesky'	Full covariance matrix using the Cholesky parameterization. fitglme estimates all elements of the covariance matrix.

Value	Description
`'Isotropic'`	Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like $\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$ where σ^2_1 is the common variance of the random-effects terms.
`'Full'`	Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.
`'Diagonal'`	Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0. $\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$
`'CompSymm'`	Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like $\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$ where σ^2_{b1} is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .
`PAT`	Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

For scalar random-effects terms, the default is `'Isotropic'`. Otherwise, the default is `'FullCholesky'`.

Example: `'CovariancePattern','Diagonal'`

Example: `'CovariancePattern',{'Full','Diagonal'}`

Data Types: `char` | `string` | `logical` | `cell`

`DispersionFlag` — Indicator to compute dispersion parameter
`false` for `'binomial'` and `'poisson'` distributions (default) | `true`

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

Value	Description
`true`	Estimate a dispersion parameter when computing standard errors
`false`	Use the theoretical value of `1.0` when computing standard errors

`'DispersionFlag'` only applies if `'FitMethod'` is `'MPL'` or `'REMPL'`.

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag',true`

`Distribution` — Distribution of the response variable
`'Normal'` (default) | `'Binomial'` | `'Poisson'` | `'Gamma'` | `'InverseGaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

Value	Description
`'Normal'`	Normal distribution
`'Binomial'`	Binomial distribution
`'Poisson'`	Poisson distribution
`'Gamma'`	Gamma distribution
`'InverseGaussian'`	Inverse Gaussian distribution

Example: `'Distribution','Binomial'`

`DummyVarCoding` — Coding to use for dummy variables
`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the variables in this table.

Value	Description
`'reference'` (default)	`fitglme` creates dummy variables with a reference group. This scheme treats the first category as a reference group and creates one less dummy variables than the number of categories. You can check the category order of a categorical variable by using the `categories` function, and change the order by using the `reordercats` function.
`'effects'`	`fitglme` creates dummy variables using effects coding. This scheme uses –1 to represent the last category. This scheme creates one less dummy variables than the number of categories.
`'full'`	`fitglme` creates full dummy variables. This scheme creates one dummy variable for each category.

For more details about creating dummy variables, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'DummyVarCoding','effects'`

`EBMethod` — Method used to approximate empirical Bayes estimates of random effects
`'Auto'` (default) | `'LineSearchNewton'` | `'TrustRegion2D'` | `'fsolve'`

Method used to approximate empirical Bayes estimates of random effects, specified as the comma-separated pair consisting of `'EBMethod'` and one of the following.

- `'Auto'`
- `'LineSearchNewton'`
- `'TrustRegion2D'`
- `'fsolve'`

`'Auto'` is similar to `'LineSearchNewton'` but uses a different convergence criterion and does not display iterative progress. `'Auto'` and `'LineSearchNewton'` may fail for non-canonical link functions. For non-canonical link functions, `'TrustRegion2D'` or `'fsolve'` are recommended. You must have Optimization Toolbox to use `'fsolve'`.

Example: `'EBMethod','LineSearchNewton'`

`EBOptions` — Options for empirical Bayes optimization
structure

Options for empirical Bayes optimization, specified as the comma-separated pair consisting of `'EBOptions'` and a structure containing the following.

Value	Description
`'TolFun'`	Relative tolerance on the gradient norm. Default is 1e-6.
`'TolX'`	Absolute tolerance on the step size. Default is 1e-8.

Value	Description
'MaxIter'	Maximum number of iterations. Default is 100.
'Display'	'off', 'iter', or 'final'. Default is 'off'.

If EBMethod is 'Auto' and 'FitMethod' is 'Laplace', TolFun is the relative tolerance on the linear predictor of the model, and the 'Display' option does not apply.

If 'EBMethod' is 'fsolve', then 'EBOptions' must be specified as an object created by optimoptions('fsolve').

Data Types: struct

Exclude — Indices for rows to exclude
use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the generalized linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude',[13,67]

Data Types: single | double | logical

FitMethod — Method for estimating model parameters
'MPL' (default) | 'REMPL' | 'Laplace' | 'ApproximateLaplace

Method for estimating model parameters, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

- 'MPL' — Maximum pseudo likelihood
- 'REMPL' — Restricted maximum pseudo likelihood
- 'Laplace' — Maximum likelihood using Laplace approximation
- 'ApproximateLaplace' — Maximum likelihood using approximate Laplace approximation with fixed effects profiled out

Example: 'FitMethod','REMPL'

InitPLIterations — Initial number of pseudo likelihood iterations
10 (default) | integer value in the range [1,∞)

Initial number of pseudo likelihood iterations used to initialize parameters for ApproximateLaplace and Laplace fit methods, specified as the comma-separated pair consisting of 'InitPLIterations' and an integer value greater than or equal to 1.

Data Types: single | double

Link — Link function
'identity' | 'log' | 'logit' | 'probit' | 'comploglog' | 'reciprocal' | scalar value | structure

Link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Value	Description
`'identity'`	`g(mu) = mu` This is the default for the normal distribution.
`'log'`	`g(mu) = log(mu)` This is the default for the Poisson distribution.
`'logit'`	`g(mu) = log(mu/(1-mu))` This is the default for the binomial distribution.
`'loglog'`	`g(mu) = log(-log(mu))`
`'probit'`	`g(mu) = norminv(mu)`
`'comploglog'`	`g(mu) = log(-log(1-mu))`
`'reciprocal'`	`g(mu) = mu.^(-1)`
Scalar value `P`	`g(mu) = mu.^P`
Structure `S`	A structure containing four fields whose values are function handles with the following names: • `S.Link` — Link function • `S.Derivative` — Derivative • `S.SecondDerivative` — Second derivative • `S.Inverse` — Inverse of link Specification of `S.SecondDerivative` can be omitted if `FitMethod` is `MPL` or `REMPL`, or if `S` is the canonical link for the specified distribution.

The default link function used by `fitglme` is the canonical link that depends on the distribution of the response.

Response Distribution	Canonical Link Function
`'Normal'`	`'identity'`
`'Binomial'`	`'logit'`
`'Poisson'`	`'log'`
`'Gamma'`	`-1`
`'InverseGaussian'`	`-2`

Example: `'Link','log'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`MuStart` — Starting value for conditional mean
scalar value

Starting value for conditional mean, specified as the comma-separated pair consisting of `'MuStart'` and a scalar value. Valid values are as follows.

Response Distribution	Valid Values
'Normal'	(-Inf,Inf)
'Binomial'	(0,1)
'Poisson'	(0,Inf)
'Gamma'	(0,Inf)
'InverseGaussian'	(0,Inf)

Data Types: single | double

Offset — Offset
zeros(n,1) (default) | *n*-by-1 vector of scalar values

Offset, specified as the comma-separated pair consisting of 'Offset' and an *n*-by-1 vector of scalar values, where *n* is the length of the response vector. You can also specify the variable name of an *n*-by-1 vector of scalar values. 'Offset' is used as an additional predictor that has a coefficient value fixed at 1.0.

Data Types: single | double

Optimizer — Optimization algorithm
'quasinewton' (default) | 'fminsearch' | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

Value	Description
'quasinewton'	Uses a trust region based quasi-Newton optimizer. You can change the options of the algorithm using statset('fitglme'). If you do not specify the options, then fitglme uses the default options of statset('fitglme').
'fminsearch'	Uses a derivative-free Nelder-Mead method. You can change the options of the algorithm using optimset('fminsearch'). If you do not specify the options, then fitglme uses the default options of optimset('fminsearch').
'fminunc'	Uses a line search-based quasi-Newton method. You must have Optimization Toolbox to specify this option. You can change the options of the algorithm using optimoptions('fminunc'). If you do not specify the options, then fitglme uses the default options of optimoptions('fminunc') with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer','fminsearch'

OptimizerOptions — Options for optimization algorithm
structure returned by statset | structure returned by optimset | object returned by optimoptions

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('fitglme')`, a structure created by `optimset('fminsearch')`, or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminsearch'`, then use `optimset('fminsearch')` to change the options of the algorithm. If `'Optimizer'` is `'fminsearch'` and you do not supply `'OptimizerOptions'`, then the defaults used in `fitglme` are the default options created by `optimset('fminsearch')`.
- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the defaults used in `fitglme` are the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinewton'`, then use `statset('fitglme')` to change the optimization parameters. If `'Optimizer'` is `'quasinewton'` and you do not change the optimization parameters using `statset`, then `fitglme` uses the default options created by `statset('fitglme')`.

The `'quasinewton'` optimizer uses the following fields in the structure created by `statset('fitglme')`.

`TolFun` — Relative tolerance on gradient of objective function
`1e-6` (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

`TolX` — Absolute tolerance on step size
`1e-12` (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

`MaxIter` — Maximum number of iterations allowed
`10000` (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

`Display` — Level of display
`'off'` (default) | `'iter'` | `'final'`

Level of display, specified as one of `'off'`, `'iter'`, or `'final'`.

`PLIterations` — Maximum number of pseudo likelihood iterations
`100` (default) | positive integer value

Maximum number of pseudo likelihood (PL) iterations, specified as the comma-separated pair consisting of `'PLIterations'` and a positive integer value. PL is used for fitting the model if `'FitMethod'` is `'MPL'` or `'REMPL'`. For other `'FitMethod'` values, PL iterations are used to initialize parameters for subsequent optimization.

Example: `'PLIterations',200`

Data Types: `single` | `double`

`PLTolerance` — Relative tolerance factor for pseudo likelihood iterations
`1e–08` (default) | positive scalar value

Relative tolerance factor for pseudo likelihood iterations, specified as the comma-separated pair consisting of `'PLTolerance'` and a positive scalar value.

Example: `'PLTolerance',1e-06`

Data Types: `single` | `double`

`StartMethod` — Method to start iterative optimization
`'default'` (default) | `'random'`

Method to start iterative optimization, specified as the comma-separated pair consisting of `'StartMethod'` and either of the following.

Value	Description
`'default'`	An internally defined default value
`'random'`	A random initial value

Example: `'StartMethod','random'`

`UseSequentialFitting` — Initial fitting type
`false` (default) | `true`

, specified as the comma-separated pair consisting of `'UseSequentialFitting'` and either `false` or `true`. If `'UseSequentialFitting'` is `false`, all maximum likelihood methods are initialized using one or more pseudo likelihood iterations. If `'UseSequentialFitting'` is `true`, the initial values from pseudo likelihood iterations are refined using `'ApproximateLaplace'` for `'Laplace'` fitting.

Example: `'UseSequentialFitting',true`

`Verbose` — Indicator to display optimization process on screen
`0` (default) | `1` | `2`

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of `'Verbose'` and `0`, `1`, or `2`. If `'Verbose'` is specified as `1` or `2`, then `fitglme` displays the progress of the iterative model-fitting process. Specifying `'Verbose'` as `2` displays iterative optimization information from the individual pseudo likelihood iterations. Specifying `'Verbose'` as `1` omits this display.

The setting for `'Verbose'` overrides the field `'Display'` in `'OptimizerOptions'`.

Example: `'Verbose',1`

`Weights` — Observation weights
vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations. If the response distribution is binomial or Poisson, then `'Weights'` must be a vector of positive integers.

Data Types: `single` | `double`

Output Arguments

`glme` — Generalized linear mixed-effects model
`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

More About

Formula

In general, a formula for model specification is a character vector or string scalar of the form `'y ~ terms'`. For the generalized linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, X_j, which can be continuous or grouping variables
- Grouping variables, g_1, g_2, ..., g_R,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random`$_1$`|g`$_1$`) + ... + (random`$_R$`|g`$_R$`)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random`$_1$ is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1, and similarly `random`$_R$ is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
`1`	Constant (intercept) term
`X^k`, where `k` is a positive integer	`X`, X^2, ..., X^k
`X1 + X2`	`X1`, `X2`
`X1*X2`	`X1`, `X2`, `X1.*X2 (elementwise multiplication of X1 and X2)`
`X1:X2`	`X1.*X2` only
`- X2`	Do not include `X2`
`X1*X2 + X3`	`X1`, `X2`, `X3`, `X1*X2`
`X1 + X2 + X3 + X1:X2`	`X1`, `X2`, `X3`, `X1*X2`
`X1*X2*X3 - X1:X2:X3`	`X1`, `X2`, `X3`, `X1*X2`, `X1*X3`, `X2*X3`
`X1*(X2 + X3)`	`X1`, `X2`, `X3`, `X1*X2`, `X1*X3`

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for generalized linear mixed-effects model specification.

Examples:

Formula	Description
`'y ~ X1 + X2'`	Fixed effects for the intercept, `X1` and `X2`. This is equivalent to `'y ~ 1 + X1 + X2'`.
`'y ~ -1 + X1 + X2'`	No intercept and fixed effects for `X1` and `X2`. The implicit intercept term is suppressed by including `-1`.
`'y ~ 1 + (1 | g1)'`	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable `g1`.
`'y ~ X1 + (1 | g1)'`	Random intercept model with a fixed slope.
`'y ~ X1 + (X1 | g1)'`	Random intercept and slope, with possible correlation between them. This is equivalent to `'y ~ 1 + X1 + (1 + X1|g1)'`.
`'y ~ X1 + (1 | g1) + (-1 + X1 | g1)'`	Independent random effects terms for intercept and slope.
`'y ~ 1 + (1 | g1) + (1 | g2) + (1 | g1:g2)'`	Random intercept model with independent main effects for `g1` and `g2`, plus an independent interaction effect.

Introduced in R2014b

fitgmdist

Fit Gaussian mixture model to data

Syntax

```
GMModel = fitgmdist(X,k)
GMModel = fitgmdist(X,k,Name,Value)
```

Description

`GMModel = fitgmdist(X,k)` returns a Gaussian mixture distribution model (`GMModel`) with `k` components fitted to data (`X`).

`GMModel = fitgmdist(X,k,Name,Value)` returns a Gaussian mixture distribution model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a regularization value or the covariance type.

Examples

Cluster Data Using a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions.

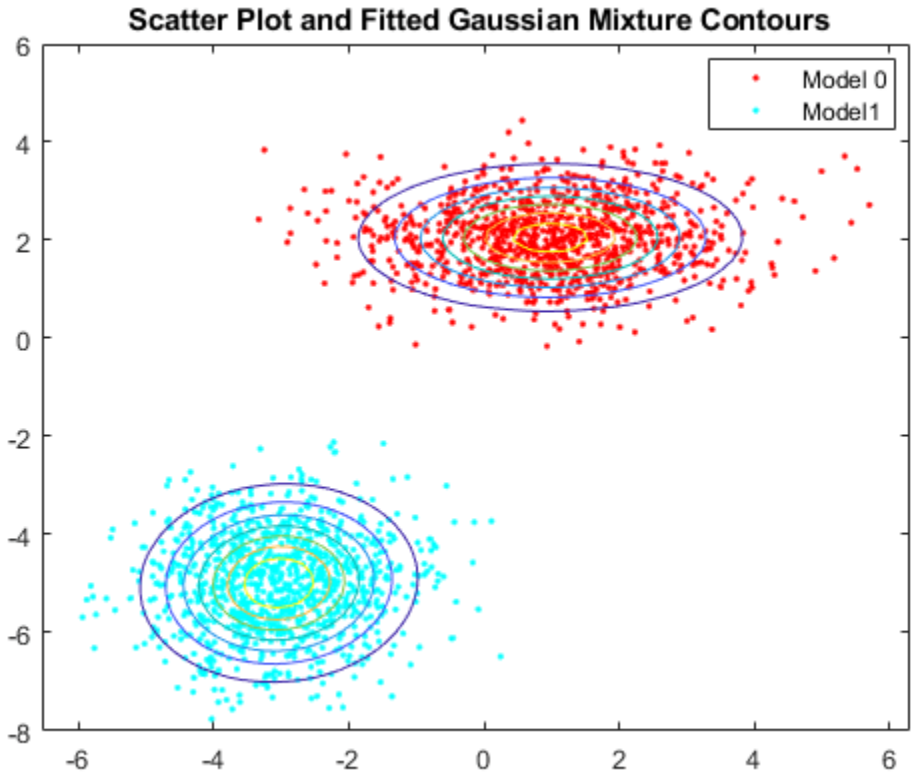
```
mu1 = [1 2];
Sigma1 = [2 0; 0 0.5];
mu2 = [-3 -5];
Sigma2 = [1 0;0 1];
rng(1); % For reproducibility
X = [mvnrnd(mu1,Sigma1,1000); mvnrnd(mu2,Sigma2,1000)];
```

Fit a Gaussian mixture model. Specify that there are two components.

```
GMModel = fitgmdist(X,2);
```

Plot the data over the fitted Gaussian mixture model contours.

```
figure
y = [zeros(1000,1);ones(1000,1)];
h = gscatter(X(:,1),X(:,2),y);
hold on
gmPDF = @(x,y) arrayfun(@(x0,y0) pdf(GMModel,[x0 y0]),x,y);
g = gca;
fcontour(gmPDF,[g.XLim g.YLim])
title('{\bf Scatter Plot and Fitted Gaussian Mixture Contours}')
legend(h,'Model 0','Model1')
hold off
```



Regularize Gaussian Mixture Model Estimation

Generate data from a mixture of two bivariate Gaussian distributions. Create a third predictor that is the sum of the first and second predictors.

```
mu1 = [1 2];
Sigma1 = [1 0; 0 1];
mu2 = [3 4];
Sigma2 = [0.5 0; 0 0.5];
rng(3); % For reproducibility
X1 = [mvnrnd(mu1,Sigma1,100);mvnrnd(mu2,Sigma2,100)];
X = [X1,X1(:,1)+X1(:,2)];
```

The columns of `X` are linearly dependent. This can cause ill-conditioned covariance estimates.

Fit a Gaussian mixture model to the data. You can use `try` / `catch` statements to help manage error messages.

```
rng(1); % Reset seed for common start values
try
    GMModel = fitgmdist(X,2)
catch exception
    disp('There was an error fitting the Gaussian mixture model')
    error = exception.message
end
```

```
There was an error fitting the Gaussian mixture model

error =
'Ill-conditioned covariance created at iteration 2.'
```

The covariance estimates are ill-conditioned. Consequently, optimization stops and an error appears.

Fit a Gaussian mixture model again, but use regularization.

```
rng(3); % Reset seed for common start values
GMModel = fitgmdist(X,2,'RegularizationValue',0.1)

GMModel =

Gaussian mixture distribution with 2 components in 3 dimensions
Component 1:
Mixing proportion: 0.536725
Mean:    2.8831    3.9506    6.8338

Component 2:
Mixing proportion: 0.463275
Mean:    0.8813    1.9758    2.8571
```

In this case, the algorithm converges to a solution due to regularization.

Select the Number of Gaussian Mixture Model Components Using PCA

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example shows how to explore the data, and try to get an initial guess at the number of components using principal component analysis.

Load Fisher's iris data set.

```
load fisheriris
classes = unique(species)

classes = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

The data set contains three classes of iris species. The analysis proceeds as if this is unknown.

Use principal component analysis to reduce the dimension of the data to two dimensions for visualization.

```
[~,score] = pca(meas,'NumComponents',2);
```

Fit three Gaussian mixture models to the data by specifying 1, 2, and 3 components. Increase the number of optimization iterations to `1000`. Use dot notation to store the final parameter estimates. By default, the software fits full and different covariances for each component.

```
GMModels = cell(3,1); % Preallocation
options = statset('MaxIter',1000);
```

```
rng(1); % For reproducibility

for j = 1:3
    GMModels{j} = fitgmdist(score,j,'Options',options);
    fprintf('\n GM Mean for %i Component(s)\n',j)
    Mu = GMModels{j}.mu
end
```

```
 GM Mean for 1 Component(s)

Mu = 1×2
10^-14 ×

    0.1051   -0.0438

 GM Mean for 2 Component(s)

Mu = 2×2

    1.3212   -0.0954
   -2.6424    0.1909

 GM Mean for 3 Component(s)

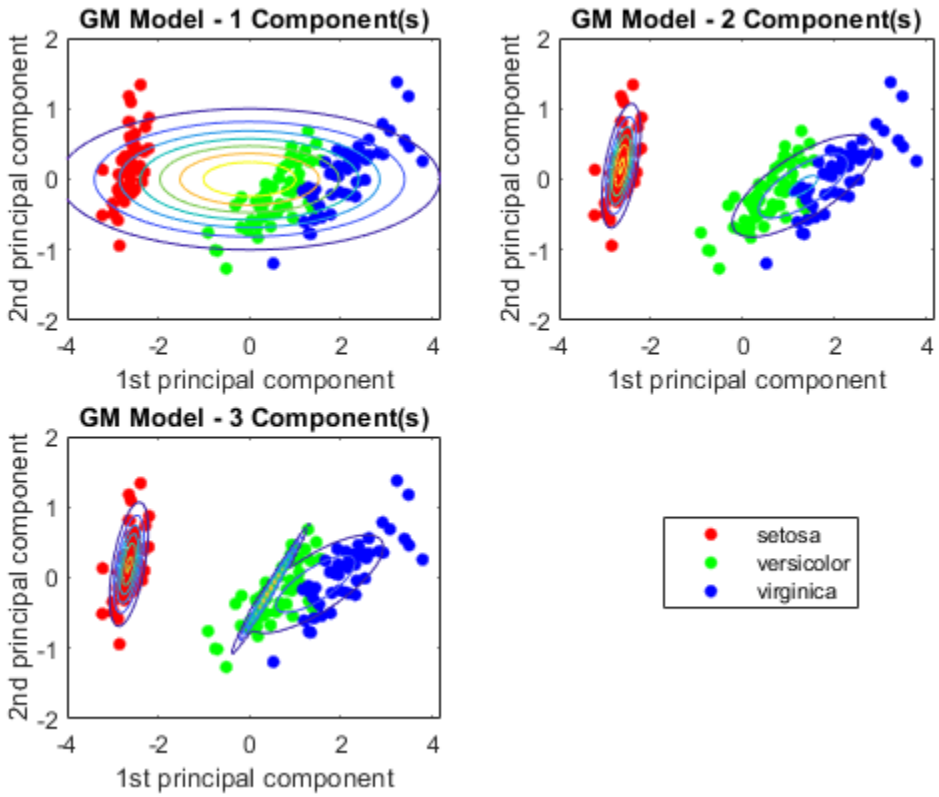
Mu = 3×2

    0.4856   -0.1287
    1.4484   -0.0904
   -2.6424    0.1909
```

`GMModels` is a cell array containing three, fitted `gmdistribution` models. The means in the three component models are different, suggesting that the model distinguishes among the three iris species.

Plot the scores over the fitted Gaussian mixture model contours. Since the data set includes labels, use `gscatter` to distinguish between the true number of components.

```
figure
for j = 1:3
    subplot(2,2,j)
    h1 = gscatter(score(:,1),score(:,2),species);
    h = gca;
    hold on
    gmPDF = @(x,y) arrayfun(@(x0,y0) pdf(GMModels{j},[x0 y0]),x,y);
    fcontour(gmPDF,[h.XLim h.YLim],'MeshDensity',100)
    title(sprintf('GM Model - %i Component(s)',j));
    xlabel('1st principal component');
    ylabel('2nd principal component');
    if(j ~= 3)
        legend off;
    end
    hold off
end
g = legend(h1);
g.Position = [0.7 0.25 0.1 0.1];
```



The three-component Gaussian mixture model, in conjunction with PCA, looks like it distinguishes between the three iris species.

There are other options you can use to help select the appropriate number of components for a Gaussian mixture model. For example,

- Compare multiple models with varying numbers of components using information criteria, e.g., AIC or BIC.
- Estimate the number of clusters using `evalclusters`, which supports, the Calinski-Harabasz criterion and the gap statistic, or other criteria.

Determine the Best Gaussian Mixture Fit Using AIC

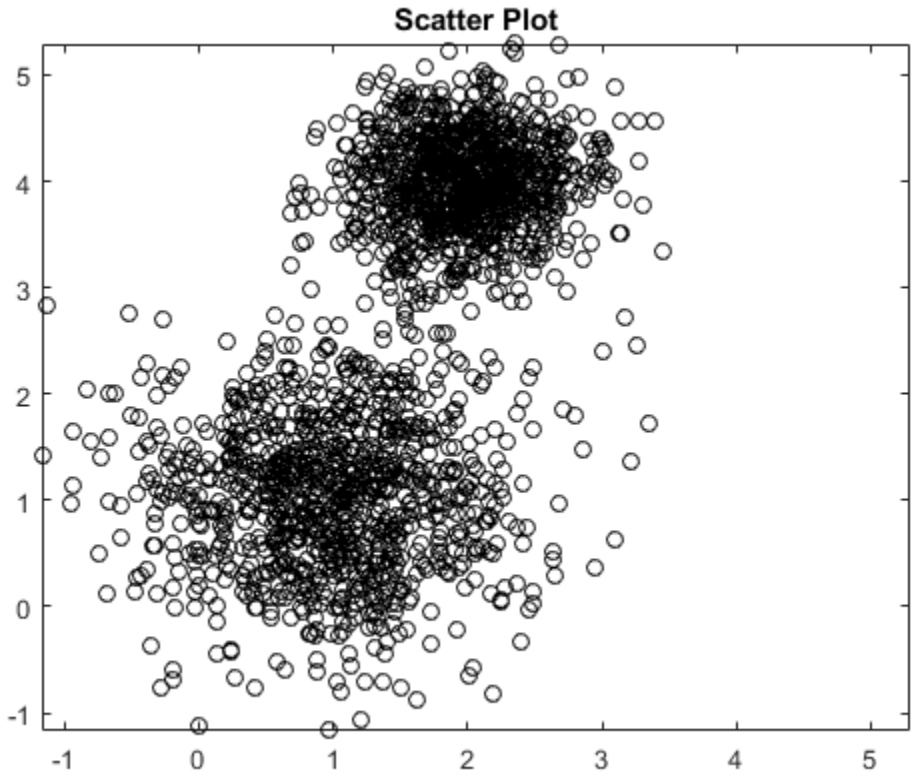
Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example uses the AIC fit statistic to help you choose the best fitting Gaussian mixture model over varying numbers of components.

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 1];
Sigma1 = [0.5 0; 0 0.5];
mu2 = [2 4];
```

```
Sigma2 = [0.2 0; 0 0.2];
rng(1);
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];

plot(X(:,1),X(:,2),'ko')
title('Scatter Plot')
xlim([min(X(:)) max(X(:))]) % Make axes have the same scale
ylim([min(X(:)) max(X(:))])
```



Supposing that you do not know the underlying parameter values, the scatter plots suggests:

- There are two components.
- The variances between the clusters are different.
- The variance within the clusters is the same.
- There is no covariance within the clusters.

Fit a two-component Gaussian mixture model. Based on the scatter plot inspection, specify that the covariance matrices are diagonal. Print the final iteration and loglikelihood statistic to the Command Window by passing a `statset` structure as the value of the `Options` name-value pair argument.

```
options = statset('Display','final');
GMModel = fitgmdist(X,2,'CovarianceType','diagonal','Options',options);
```

```
11 iterations, log-likelihood = -4787.38
```

`GMModel` is a fitted `gmdistribution` model.

Examine the AIC over varying numbers of components.

```
AIC = zeros(1,4);
GMModels = cell(1,4);
options = statset('MaxIter',500);
for k = 1:4
    GMModels{k} = fitgmdist(X,k,'Options',options,'CovarianceType','diagonal');
    AIC(k)= GMModels{k}.AIC;
end

[minAIC,numComponents] = min(AIC);
numComponents
```

```
numComponents = 2
```

```
BestModel = GMModels{numComponents}
```

```
BestModel =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.501719
Mean:    1.9824    4.0013

Component 2:
Mixing proportion: 0.498281
Mean:    0.9880    1.0511
```

The smallest AIC occurs when the software fits the two-component Gaussian mixture model.

Set Initial Values When Fitting Gaussian Mixture Models

Gaussian mixture model parameter estimates might vary with different initial values. This example shows how to control initial values when you fit Gaussian mixture models using `fitgmdist`.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);
```

Fit a Gaussian mixture model to the data using default initial values. There are three iris species, so specify $k = 3$ components.

```
rng(10); % For reproducibility
GMModel1 = fitgmdist(X,3);
```

By default, the software:

1. Implements the “k-means++ Algorithm for Initialization” on page 33-1976 to choose $k = 3$ initial cluster centers.
2. Sets the initial covariance matrices as diagonal, where element `(j, j)` is the variance of `X(:,j)`.
3. Treats the initial mixing proportions as uniform.

Fit a Gaussian mixture model by connecting each observation to its label.

```
y = ones(size(X,1),1);
y(strcmp(species,'setosa')) = 2;
y(strcmp(species,'virginica')) = 3;

GMModel2 = fitgmdist(X,3,'Start',y);
```

Fit a Gaussian mixture model by explicitly specifying the initial means, covariance matrices, and mixing proportions.

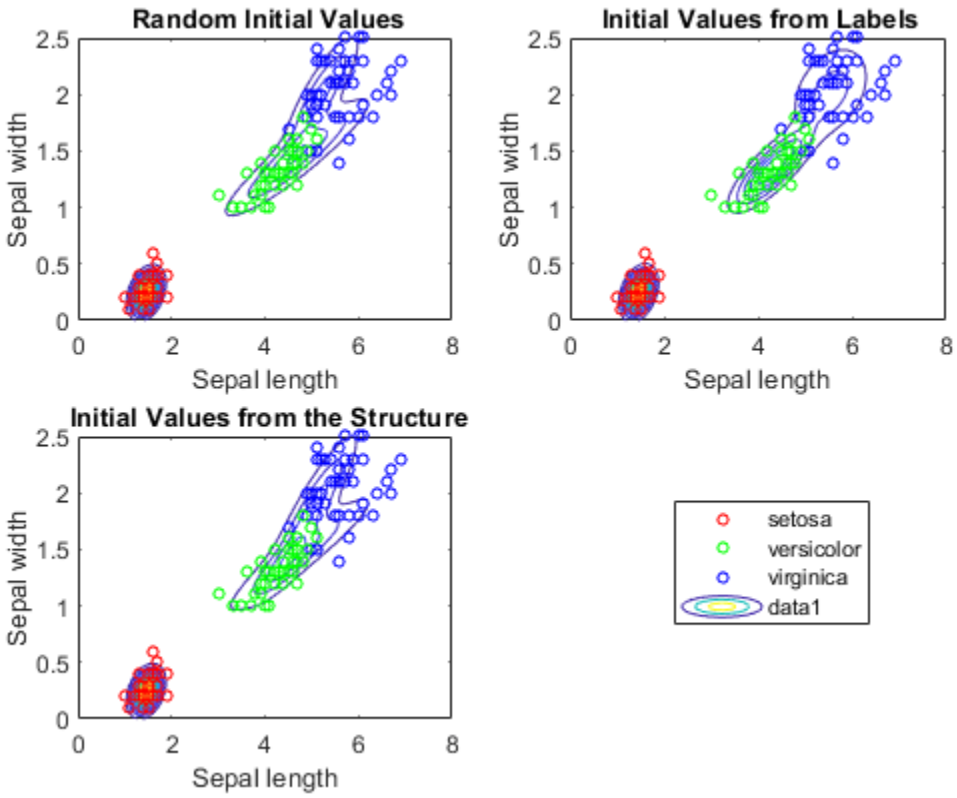
```
Mu = [1 1; 2 2; 3 3];
Sigma(:,:,1) = [1 1; 1 2];
Sigma(:,:,2) = 2*[1 1; 1 2];
Sigma(:,:,3) = 3*[1 1; 1 2];
PComponents = [1/2,1/4,1/4];
S = struct('mu',Mu,'Sigma',Sigma,'ComponentProportion',PComponents);

GMModel3 = fitgmdist(X,3,'Start',S);
```

Use `gscatter` to plot a scatter diagram that distinguishes between the iris species. For each model, plot the fitted Gaussian mixture model contours.

```
figure
subplot(2,2,1)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
haxis = gca;
xlim = haxis.XLim;
ylim = haxis.YLim;
d = (max([xlim ylim])-min([xlim ylim]))/1000;
[X1Grid,X2Grid] = meshgrid(xlim(1):d:xlim(2),ylim(1):d:ylim(2));
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel1,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Random Initial Values}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off;
hold off
subplot(2,2,2)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel2,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from Labels}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off
hold off
subplot(2,2,3)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel3,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from the Structure}');
xlabel('Sepal length');
ylabel('Sepal width');
```

```
legend('Location',[0.7,0.25,0.1,0.1]);
hold off
```



According to the contours, `GMModel2` seems to suggest a slight trimodality, while the others suggest bimodal distributions.

Display the estimated component means.

```
table(GMModel1.mu,GMModel2.mu,GMModel3.mu,'VariableNames',...
    {'Model1','Model2','Model3'})
```

```
ans=3×3 table
        Model1              Model2              Model3
    ________________    ________________    ________________

    5.2115     2.0119    4.2857    1.3339    1.4604    0.2429
     1.461    0.24423     1.462     0.246    4.7509    1.4629
    4.6829     1.4429    5.5507    2.0316    5.0158    1.8592
```

`GMModel2` seems to distinguish between the iris species the best.

Input Arguments

X — Data

numeric matrix

Data to which the Gaussian mixture model is fit, specified as a numeric matrix.

The rows of `X` correspond to observations, and the columns of `X` correspond to variables. The number of observations must be larger than each of the following: the number of variables and the number of components.

`NaN`s indicate missing values. The software removes rows of `X` containing at least one `NaN` before fitting, which decreases the effective sample size.

Data Types: `single` | `double`

`k` — Number of components
positive integer

Number of components to use when fitting Gaussian mixture model, specified as a positive integer. For example, if you specify `k = 3`, then the software fits a Gaussian mixture model with three distinct means, covariances matrices, and component proportions to the data (`X`).

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'RegularizationValue',0.1,'CovarianceType','diagonal'` specifies a regularization parameter value of 0.1 and to fit diagonal covariance matrices.

`CovarianceType` — Type of covariance matrix
`'full'` (default) | `'diagonal'`

Type of covariance matrix to fit to the data, specified as the comma-separated pair consisting of `'CovarianceType'` and either `'diagonal'` or `'full'`.

If you set `'diagonal'`, then the software fits diagonal covariance matrices. In this case, the software estimates `k*d` covariance parameters, where `d` is the number of columns in `X` (i.e., `d = size(X,2)`).

Otherwise, the software fits full covariance matrices. In this case, the software estimates `k*d*(d+1)/2` covariance parameters.

Example: `'CovarianceType','diagonal'`

`Options` — Iterative EM algorithm optimization options
`statset` options structure

Iterative EM algorithm optimization options, specified as the comma-separated pair consisting of `'Options'` and a `statset` options structure.

This table describes the available name-value pair arguments.

Name	Value
'Display'	'final': Display the final output. 'iter': Display iterative output to the Command Window for some functions; otherwise display the final output. 'off': Do not display optimization information.
'MaxIter'	Positive integer indicating the maximum number of iterations allowed. The default is 100
'TolFun'	Positive scalar indicating the termination tolerance for the loglikelihood function value. The default is 1e-6.

Example: 'Options',statset('Display','final','MaxIter',1500,'TolFun',1e-5)

ProbabilityTolerance — Tolerance for posterior probabilities
1e-8 (default) | nonnegative scalar value in range [0,1e-6]

Tolerance for posterior probabilities, specified as the comma-separated pair consisting of ProbabilityTolerance and a nonnegative scalar value in the range [0,1e-6].

In each iteration, after the estimation of posterior probabilities, fitgmdist sets any posterior probability that is not larger than the tolerance value to zero. Using a nonzero tolerance might speed up fitgmdist.

Example: 'ProbabilityTolerance',0.0000025

Data Types: single | double

RegularizationValue — Regularization parameter value
0 (default) | nonnegative scalar

Regularization parameter value, specified as the comma-separated pair consisting of 'RegularizationValue' and a nonnegative scalar.

Set RegularizationValue to a small positive scalar to ensure that the estimated covariance matrices are positive definite.

Example: 'RegularizationValue',0.01

Data Types: single | double

Replicates — Number of times to repeat EM algorithm
1 (default) | positive integer

Number of times to repeat the EM algorithm using a new set of initial values, specified as the comma-separated pair consisting of 'Replicates' and a positive integer.

If Replicates is greater than 1, then:

- The name-value pair argument Start must be plus (the default) or randSample.
- GMModel is the fit with the largest loglikelihood.

Example: 'Replicates',10

Data Types: `single` | `double`

`SharedCovariance` — Flag indicating whether all covariance matrices are identical
logical `false` (default) | logical `true`

Flag indicating whether all covariance matrices are identical (i.e., fit a pooled estimate), specified as the comma-separated pair consisting of `'SharedCovariance'` and either logical value `false` or `true`.

If `SharedCovariance` is `true`, then all `k` covariance matrices are equal, and the number of covariance parameters is scaled down by a factor of `k`.

`Start` — Initial value setting method
`'plus'` (default) | `'randSample'` | vector of integers | structure array

Initial value setting method, specified as the comma-separated pair consisting of `'Start'` and `'randSample'`, `'plus'`, a vector of integers, or a structure array.

The value of `Start` determines the initial values required by the optimization routine for each Gaussian component parameter — mean, covariance, and mixing proportion. This table summarizes the available options.

Value	Description
`'randSample'`	The software selects `k` observations from `X` at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element `j` on the diagonal is the variance of `X(:,j)`.
`'plus'`	The software selects `k` observations from `X` using the *k*-means++ algorithm on page 33-1976. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element `j` on the diagonal is the variance of `X(:,j)`.
Vector of integers	A vector of length *n* (the number of observations) containing an initial guess of the component index for each point. That is, each element is an integer from 1 to `k`, which corresponds to a component. The software collects all observations corresponding to the same component, computes means, covariances, and mixing proportions for each, and sets the initial values to these statistics.

Value	Description

Structure array	Suppose that there are `d` variables (i.e., `d = size(X,2)`). The structure array, e.g., `S`, must have three fields:
	• `S.mu`: A `k`-by-`d` matrix specifying the initial mean of each component
	• `S.Sigma`: A numeric array specifying the covariance matrix of each component. `Sigma` is one of the following:
	  • A `d`-by-`d`-by-`k` array. `Sigma(:,:,j)` is the initial covariance matrix of component `j`.
	  • A `1`-by-`d`-by-`k` array. `diag(Sigma(:,:,j))` is the initial covariance matrix of component `j`.
	  • A `d`-by-`d` matrix. `Sigma` is the initial covariance matrix for all components.
	  • A `1`-by-`d` vector. `diag(Sigma)` is the initial covariance matrix for all components.
	• `S.ComponentProportion`: A `1`-by-`k` vector of scalars specifying the initial mixing proportions of each component. The default is uniform.

Example: `'Start',ones(n,1)`

Data Types: `single` | `double` | `char` | `string` | `struct`

Output Arguments

`GMModel` — Fitted Gaussian mixture model

`gmdistribution` model

Fitted Gaussian mixture model, returned as a `gmdistribution` model.

Access properties of `GMModel` using dot notation. For example, display the AIC by entering `GMModel.AIC`.

Tips

`fitgmdist` might:

- Converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

  The following issues might result in an ill-conditioned covariance matrix:

  - The number of dimensions of your data is relatively high and there are not enough observations.
  - Some of the predictors (variables) of your data are highly correlated.
  - Some or all the features are discrete.
  - You tried to fit the data to too many components.

  In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Preprocess your data to remove correlated features.
- Set `'SharedCovariance'` to `true` to use an equal covariance matrix for every component.
- Set `'CovarianceType'` to `'diagonal'`.
- Use `'RegularizationValue'` to add a very small positive number to the diagonal of every covariance matrix.
- Try another set of initial values.

- Pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Try another set of initial values to avoid this issue without altering your data or model.

Algorithms

Gaussian Mixture Model Likelihood Optimization

The software optimizes the Gaussian mixture model likelihood using the iterative Expectation-Maximization (EM) algorithm.

`fitgmdist` fits GMMs to data using the iterative Expectation-Maximization (EM) algorithm. Using initial values for component means, covariance matrices, and mixing proportions, the EM algorithm proceeds using these steps.

1. For each observation, the algorithm computes posterior probabilities of component memberships. You can think of the result as an n-by-k matrix, where element (i,j) contains the posterior probability that observation i is from component j. This is the E-step of the EM algorithm.
2. Using the component-membership posterior probabilities as weights, the algorithm estimates the component means, covariance matrices, and mixing proportions by applying maximum likelihood. This is the M-step of the EM algorithm.

The algorithm iterates over these steps until convergence. The likelihood surface is complex, and the algorithm might converge to a local optimum. Also, the resulting local optimum might depend on the initial conditions. `fitgmdist` has several options for choosing initial conditions, including random component assignments for the observations and the k-means ++ algorithm.

k-means++ Algorithm for Initialization

The k-means++ algorithm uses an heuristic to find centroid seeds for k-means clustering. `fitgmdist` can apply the same principle to initialize the EM algorithm by using the k-means++ algorithm to select the initial parameter values for a fitted Gaussian mixture model.

The k-means++ algorithm assumes the number of clusters is k and chooses the initial parameter values as follows.

1. Select the component mixture probability to be the uniform probability $p_i = \frac{1}{k}$, where $i = 1, \ldots, k$.
2. Select the covariance matrices to be diagonal and identical, where $\sigma_i = diag(a_1, a_2, \ldots, a_k)$ and $a_j = \mathrm{var}(X_j)$.
3. Select the first initial component center μ_1 uniformly from all data points in X.
4. To choose center j:
   a. Compute the Mahalanobis distances from each observation to each centroid, and assign each observation to its closest centroid.

b For $m = 1,...,n$ and $p = 1,...,j - 1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, \mu_p)}{\sum_{h;\, x_h \in M_p} d^2(x_h, \mu_p)}$$

where $d(x_m, \mu_p)$ is the distance between observation m and μ_p, and M_p is the set of all observations closest to centroid μ_p and x_m belongs to M_p.

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

5 Repeat step 4 until k centroids are chosen.

Introduced in R2014a

fitlm

Fit linear regression model

Syntax

```
mdl = fitlm(tbl)
mdl = fitlm(X,y)
mdl = fitlm(___,modelspec)
mdl = fitlm(___,Name,Value)
```

Description

`mdl = fitlm(tbl)` returns a linear regression model fit to variables in the table or dataset array `tbl`. By default, `fitlm` takes the last variable as the response variable.

`mdl = fitlm(X,y)` returns a linear regression model of the responses `y`, fit to the data matrix `X`.

`mdl = fitlm(___,modelspec)` defines the model specification using any of the input argument combinations in the previous syntaxes.

`mdl = fitlm(___,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify which variables are categorical, perform robust regression, or use observation weights.

Examples

Fit Linear Regression Using Data in Matrix

Fit a linear regression model using a matrix input data set.

Load the `carsmall` data set, a matrix input data set.

```
load carsmall
X = [Weight,Horsepower,Acceleration];
```

Fit a linear regression model by using `fitlm`.

```
mdl = fitlm(X,MPG)
```

```
mdl =
Linear regression model:
    y ~ 1 + x1 + x2 + x3

Estimated Coefficients:
                   Estimate        SE          tStat        pValue
                  __________    _________    _________    __________

    (Intercept)        47.977       3.8785        12.37    4.8957e-21
    x1             -0.0065416    0.0011274      -5.8023    9.8742e-08
    x2              -0.042943     0.024313      -1.7663       0.08078
```

```
    x3              -0.011583      0.19333    -0.059913       0.95236

Number of observations: 93, Error degrees of freedom: 89
Root Mean Squared Error: 4.09
R-squared: 0.752,  Adjusted R-Squared: 0.744
F-statistic vs. constant model: 90, p-value = 7.38e-27
```

The model display includes the model formula, estimated coefficients, and model summary statistics.

The model formula in the display, `y ~ 1 + x1 + x2 + x3`, corresponds to $y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \epsilon$.

The model display also shows the estimated coefficient information, which is stored in the `Coefficients` property. Display the `Coefficients` property.

```
mdl.Coefficients
```

```
ans=4×4 table
                    Estimate        SE          tStat        pValue
                   __________    _________    _________    __________

    (Intercept)       47.977       3.8785        12.37    4.8957e-21
    x1             -0.0065416    0.0011274      -5.8023    9.8742e-08
    x2              -0.042943     0.024313      -1.7663       0.08078
    x3              -0.011583      0.19333    -0.059913       0.95236
```

The `Coefficient` property includes these columns:

- `Estimate` — Coefficient estimates for each corresponding term in the model. For example, the estimate for the constant term (`intercept`) is 47.977.
- `SE` — Standard error of the coefficients.
- `tStat` — *t*-statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that `tStat = Estimate/SE`. For example, the *t*-statistic for the intercept is 47.977/3.8785 = 12.37.
- `pValue` — *p*-value for the *t*-statistic of the hypothesis test that the corresponding coefficient is equal to zero or not. For example, the *p*-value of the *t*-statistic for `x2` is greater than 0.05, so this term is not significant at the 5% significance level given the other terms in the model.

The summary statistics of the model are:

- `Number of observations` — Number of rows without any `NaN` values. For example, `Number of observations` is 93 because the `MPG` data vector has six `NaN` values and the `Horsepower` data vector has one `NaN` value for a different observation, where the number of rows in `X` and `MPG` is 100.
- `Error degrees of freedom` — $n - p$, where n is the number of observations, and p is the number of coefficients in the model, including the intercept. For example, the model has four predictors, so the `Error degrees of freedom` is 93 – 4 = 89.
- `Root mean squared error` — Square root of the mean squared error, which estimates the standard deviation of the error distribution.

- `R-squared` and `Adjusted R-squared` — Coefficient of determination and adjusted coefficient of determination, respectively. For example, the `R-squared` value suggests that the model explains approximately 75% of the variability in the response variable `MPG`.
- `F-statistic vs. constant model` — Test statistic for the *F*-test on the regression model, which tests whether the model fits significantly better than a degenerate model consisting of only a constant term.
- `p-value` — *p*-value for the *F*-test on the model. For example, the model is significant with a *p*-value of 7.3816e-27.

You can find these statistics in the model properties (`NumObservations`, `DFE`, `RMSE`, and `Rsquared`) and by using the `anova` function.

```
anova(mdl,'summary')
```

```
ans=3×5 table
                SumSq     DF    MeanSq      F         pValue
                ______    __    ______    ______    __________

    Total       6004.8    92    65.269
    Model         4516     3    1505.3    89.987    7.3816e-27
    Residual    1488.8    89    16.728
```

Fit Linear Regression Using Data in Table

Load the sample data.

```
load carsmall
```

Store the variables in a table.

```
tbl = table(Weight,Acceleration,MPG,'VariableNames',{'Weight','Acceleration','MPG'});
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans=5×3 table
    Weight    Acceleration    MPG
    ______    ____________    ___

     3504           12         18
     3693         11.5         15
     3436           11         18
     3433           12         16
     3449         10.5         17
```

Fit a linear regression model for miles per gallon (MPG). Specify the model formula by using Wilkinson notation.

```
lm = fitlm(tbl,'MPG~Weight+Acceleration')
```

```
lm =
Linear regression model:
```

```
    MPG ~ 1 + Weight + Acceleration

Estimated Coefficients:
                    Estimate         SE         tStat       pValue
                   __________    __________    _______    __________

    (Intercept)         45.155        3.4659     13.028    1.6266e-22
    Weight          -0.0082475    0.00059836    -13.783    5.3165e-24
    Acceleration       0.19694       0.14743     1.3359       0.18493

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 4.12
R-squared: 0.743,  Adjusted R-Squared: 0.738
F-statistic vs. constant model: 132, p-value = 1.38e-27
```

The model `'MPG~Weight+Acceleration'` in this example is equivalent to set the model specification as `'linear'`. For example,

```
lm2 = fitlm(tbl,'linear');
```

If you use a character vector for model specification and you do not specify the response variable, then `fitlm` accepts the last variable in `tbl` as the response variable and the other variables as the predictor variables.

Fit Linear Regression Using Specified Model Formula

Fit a linear regression model using a model formula specified by Wilkinson notation.

Load the sample data.

```
load carsmall
```

Store the variables in a table.

```
tbl = table(Weight,Acceleration,Model_Year,MPG,'VariableNames',{'Weight','Acceleration','Model_Ye
```

Fit a linear regression model for miles per gallon (MPG) with weight and acceleration as the predictor variables.

```
lm = fitlm(tbl,'MPG~Weight+Acceleration')
```

```
lm =
Linear regression model:
    MPG ~ 1 + Weight + Acceleration

Estimated Coefficients:
                    Estimate         SE         tStat       pValue
                   __________    __________    _______    __________

    (Intercept)         45.155        3.4659     13.028    1.6266e-22
    Weight          -0.0082475    0.00059836    -13.783    5.3165e-24
    Acceleration       0.19694       0.14743     1.3359       0.18493
```

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 4.12
R-squared: 0.743,  Adjusted R-Squared: 0.738
F-statistic vs. constant model: 132, p-value = 1.38e-27
```

The *p*-value of 0.18493 indicates that `Acceleration` does not have a significant impact on `MPG`.

Remove `Acceleration` from the model, and try improving the model by adding the predictor variable `Model_Year`. First define `Model_Year` as a categorical variable.

```
tbl.Model_Year = categorical(tbl.Model_Year);
lm = fitlm(tbl,'MPG~Weight+Model_Year')
```

```
lm =
Linear regression model:
    MPG ~ 1 + Weight + Model_Year

Estimated Coefficients:
                       Estimate         SE         tStat       pValue
                      __________    __________    _______    __________

    (Intercept)           40.11        1.5418     26.016    1.2024e-43
    Weight           -0.0066475    0.00042802    -15.531    3.3639e-27
    Model_Year_76        1.9291       0.74761     2.5804      0.011488
    Model_Year_82        7.9093       0.84975     9.3078    7.8681e-15

Number of observations: 94, Error degrees of freedom: 90
Root Mean Squared Error: 2.92
R-squared: 0.873,  Adjusted R-Squared: 0.868
F-statistic vs. constant model: 206, p-value = 3.83e-40
```

Specifying `modelspec` using Wilkinson notation enables you to update the model without having to change the design matrix. `fitlm` uses only the variables that are specified in the formula. It also creates the necessary two dummy indicator variables for the categorical variable `Model_Year`.

Fit Linear Regression Using Terms Matrix

Fit a linear regression model using a terms matrix.

Terms Matrix for Table Input

If the model variables are in a table, then a column of `0`s in a terms matrix represents the position of the response variable.

Load the `hospital` data set.

```
load hospital
```

Store the variables in a table.

```
t = table(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,hospital.Smoker, ...
    'VariableNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model `'BloodPressure ~ 1 + Sex + Age + Smoker'` using a terms matrix. The response variable is in the second column of the table, so the second column of the terms matrix must be a column of `0`s for the response variable.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T = 4×4

     0     0     0     0
     1     0     0     0
     0     0     1     0
     0     0     0     1
```

Fit a linear model.

```
mdl1 = fitlm(t,T)
```

```
mdl1 =
Linear regression model:
    BloodPressure ~ 1 + Sex + Age + Smoker

Estimated Coefficients:
                   Estimate       SE        tStat        pValue
                   ________    ________    ________    __________

    (Intercept)      116.14      2.6107      44.485    7.1287e-66
    Sex_Male       0.050106     0.98364    0.050939       0.95948
    Age            0.085276    0.066945      1.2738        0.2058
    Smoker_1           9.87      1.0346      9.5395    1.4516e-15

Number of observations: 100, Error degrees of freedom: 96
Root Mean Squared Error: 4.78
R-squared: 0.507,  Adjusted R-Squared: 0.492
F-statistic vs. constant model: 33, p-value = 9.91e-15
```

Terms Matrix for Matrix Input

If the predictor and response variables are in a matrix and column vector, then you must include `0` for the response variable at the end of each row in a terms matrix.

Load the `carsmall` data set and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model `'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2'` using a terms matrix. This model includes the main effect and two-way interaction terms for the variables `Acceleration` and `Weight`, and a second-order term for the variable `Weight`.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T = 5×3

     0     0     0
     1     0     0
     0     1     0
```

```
     1     1     0
     0     2     0
```

Fit a linear model.

```
mdl2 = fitlm(X,MPG,T)
```

```
mdl2 =
Linear regression model:
    y ~ 1 + x1*x2 + x2^2

Estimated Coefficients:
                    Estimate          SE         tStat       pValue
                   ___________    __________    _______    __________

    (Intercept)         48.906        12.589     3.8847    0.00019665
    x1                 0.54418       0.57125    0.95261       0.34337
    x2                -0.012781     0.0060312    -2.1192      0.036857
    x1:x2          -0.00010892    0.00017925    -0.6076         0.545
    x2^2            9.7518e-07    7.5389e-07     1.2935       0.19917

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 4.1
R-squared: 0.751,  Adjusted R-Squared: 0.739
F-statistic vs. constant model: 67, p-value = 4.99e-26
```

Only the intercept and `x2` term, which corresponds to the `Weight` variable, are significant at the 5% significance level.

Linear Regression with Categorical Predictor

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use `anova` to test the significance of the categorical variable.

Model with Categorical Predictor

Load the `carsmall` data set and create a linear regression model of `MPG` as a function of `Model_Year`. To treat the numeric vector `Model_Year` as a categorical variable, identify the predictor using the `'CategoricalVars'` name-value pair argument.

```
load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Model_Year

Estimated Coefficients:
                    Estimate      SE      tStat       pValue
                   _________    ______    ______    __________

    (Intercept)        17.69    1.0328    17.127    3.2371e-30
    Model_Year_76     3.8839    1.4059    2.7625     0.0069402
```

```
    Model_Year_82      14.02     1.4369    9.7571    8.2164e-16

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531,  Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

The model formula in the display, `MPG ~ 1 + Model_Year`, corresponds to

$$\mathrm{MPG} = \beta_0 + \beta_1 I_{\mathrm{Year}=76} + \beta_2 I_{\mathrm{Year}=82} + \epsilon,$$

where $I_{\mathrm{Year}=76}$ and $I_{\mathrm{Year}=82}$ are indicator variables whose value is one if the value of `Model_Year` is 76 and 82, respectively. The `Model_Year` variable includes three distinct values, which you can check by using the `unique` function.

```
unique(Model_Year)
```

```
ans = 3×1

    70
    76
    82
```

`fitlm` chooses the smallest value in `Model_Year` as a reference level (`'70'`) and creates two indicator variables $I_{\mathrm{Year}=76}$ and $I_{\mathrm{Year}=82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

Model with Full Indicator Variables

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1=70} + (\beta_0 + \beta_1) I_{x_1=76} + (\beta_0 + \beta_2) I_{x_2=82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

```
mdl =
Linear regression model:
    MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82

Estimated Coefficients:
                    Estimate      SE       tStat       pValue
                    ________    _______    ______    __________

    Model_Year_70      17.69     1.0328    17.127    3.2371e-30
    Model_Year_76     21.574    0.95387    22.617    4.0156e-39
```

```
    Model_Year_82      31.71     0.99896    31.743    5.2234e-51

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
```

Choose Reference Level in Model

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```
categories(Year)
```

```
ans = 3x1 cell
    {'70'}
    {'76'}
    {'82'}
```

If you use `Year` as a predictor variable, then `fitlm` chooses the first category `'70'` as a reference level. Reorder `Year` by using the `reordercats` function.

```
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
```

```
ans = 3x1 cell
    {'76'}
    {'70'}
    {'82'}
```

The first category of `Year_reordered` is `'76'`. Create a linear regression model of `MPG` as a function of `Year_reordered`.

```
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

```
mdl2 =
Linear regression model:
    MPG ~ 1 + Model_Year

Estimated Coefficients:
                     Estimate      SE        tStat       pValue
                     ________    _______    _______    __________

    (Intercept)       21.574     0.95387     22.617    4.0156e-39
    Model_Year_70    -3.8839      1.4059    -2.7625     0.0069402
    Model_Year_82     10.136      1.3812     7.3385    8.7634e-11

Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531,  Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

`mdl2` uses `'76'` as a reference level and includes two indicator variables $I_{\text{Year = 70}}$ and $I_{\text{Year = 82}}$.

Evaluate Categorical Predictor

The model display of `mdl2` includes a *p*-value of each term to test whether or not the corresponding coefficient is equal to zero. Each *p*-value examines each indicator variable. To examine the categorical variable `Model_Year` as a group of indicator variables, use `anova`. Use the `'components'`(default) option to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```
anova(mdl2,'components')
```

```
ans=2×5 table
                SumSq     DF    MeanSq      F        pValue
                ______    __    ______    _____    __________

    Model_Year    3190.1     2    1595.1    51.56    1.0694e-15
    Error         2815.2    91    30.936
```

The component ANOVA table includes the *p*-value of the `Model_Year` variable, which is smaller than the *p*-values of the indicator variables.

Specify Response and Predictor Variables for Linear Model

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Specify weight as the response variable, and sex, age, and smoking status as the predictor variables. Also, specify that sex and smoking status are categorical variables.

```
mdl = fitlm(hospital,'interactions','ResponseVar','Weight',...
    'PredictorVars',{'Sex','Age','Smoker'},...
    'CategoricalVar',{'Sex','Smoker'})
```

```
mdl =
Linear regression model:
    Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker

Estimated Coefficients:
                        Estimate      SE        tStat        pValue
                        ________    _______    ________    __________

    (Intercept)            118.7     7.0718      16.785     6.821e-30
    Sex_Male               68.336     9.7153      7.0339    3.3386e-10
    Age                   0.31068    0.18531      1.6765      0.096991
    Smoker_1               3.0425     10.446     0.29127       0.77149
    Sex_Male:Age          -0.49094    0.24764     -1.9825      0.050377
    Sex_Male:Smoker_1       0.9509     3.8031     0.25003       0.80312
    Age:Smoker_1          -0.07288    0.26275    -0.27737       0.78211

Number of observations: 100, Error degrees of freedom: 93
```

```
Root Mean Squared Error: 8.75
R-squared: 0.898,  Adjusted R-Squared: 0.892
F-statistic vs. constant model: 137, p-value = 6.91e-44
```

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

Fit Robust Linear Regression Model

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a robust linear regression model to the data.

```
mdl = fitlm(ingredients,heat,'RobustOpts','on')
```

```
mdl =
Linear regression model (robust fit):
    y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
                   Estimate      SE        tStat       pValue
                   ________    _______    ________    ________

    (Intercept)       60.09     75.818     0.79256      0.4509
    x1               1.5753    0.80585      1.9548    0.086346
    x2               0.5322    0.78315     0.67957     0.51596
    x3              0.13346     0.8166     0.16343     0.87424
    x4             -0.12052     0.7672    -0.15709     0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979,  Adjusted R-Squared: 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

For more details, see the topic “Reduce Outlier Effects Using Robust Regression” on page 11-104, which compares the results of a robust fit to a standard least-squares fit.

Compute Mean Absolute Error Using Cross-Validation

Compute the mean absolute error of a regression model by using 10-fold cross-validation.

Load the `carsmall` data set. Specify the `Acceleration` and `Displacement` variables as predictors and the `Weight` variable as the response.

```
load carsmall
X1 = Acceleration;
```

```
X2 = Displacement;
y = Weight;
```

Create the custom function `regf` (shown at the end of this example). This function fits a regression model to training data and then computes predicted car weights on a test set. The function compares the predicted car weight values to the true values, and then computes the mean absolute error (MAE) and the MAE adjusted to the range of the test set car weights.

Note: If you use the live script file for this example, the `regf` function is already included at the end of the file. Otherwise, you need to create this function at the end of your .m file or add it as a file on the MATLAB® path.

By default, `crossval` performs 10-fold cross-validation. For each of the 10 training and test set partitions of the data in `X1`, `X2`, and `y`, compute the MAE and adjusted MAE values using the `regf` function. Find the mean MAE and mean adjusted MAE.

```
rng('default') % For reproducibility
values = crossval(@regf,X1,X2,y)
```

```
values = 10×2

  319.2261    0.1132
  342.3722    0.1240
  214.3735    0.0902
  174.7247    0.1128
  189.4835    0.0832
  249.4359    0.1003
  194.4210    0.0845
  348.7437    0.1700
  283.1761    0.1187
  210.7444    0.1325
```

```
mean(values)
```

```
ans = 1×2

  252.6701    0.1129
```

This code creates the function `regf`.

```
function errors = regf(X1train,X2train,ytrain,X1test,X2test,ytest)
tbltrain = table(X1train,X2train,ytrain, ...
    'VariableNames',{'Acceleration','Displacement','Weight'});
tbltest = table(X1test,X2test,ytest, ...
    'VariableNames',{'Acceleration','Displacement','Weight'});
mdl = fitlm(tbltrain,'Weight ~ Acceleration + Displacement');
yfit = predict(mdl,tbltest);
MAE = mean(abs(yfit-tbltest.Weight));
adjMAE = MAE/range(tbltest.Weight);
errors = [MAE adjMAE];
end
```

Input Arguments

`tbl` — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

- By default, `fitlm` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.
- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

`X` — Predictor variables

matrix

Predictor variables, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

`y` — Response variable

vector

Response variable, specified as an *n*-by-1 vector, where *n* is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double` | `logical`

`modelspec` — Model specification

`'linear'` (default) | character vector or string scalar naming the model | *t*-by-(*p* + 1) terms matrix | character vector or string scalar formula in the form `'y ~ terms'`

Model specification, specified as one of these values.

- A character vector or string scalar naming the model.

Value	Model Type
`'constant'`	Model contains only a constant (intercept) term.
`'linear'`	Model contains an intercept and linear term for each predictor.
`'interactions'`	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
`'purequadratic'`	Model contains an intercept term and linear and squared terms for each predictor.
`'quadratic'`	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
`'poly`*`ijk`*`'`	Model is a polynomial with all terms up to degree *`i`* in the first predictor, degree *`j`* in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, `'poly13'` has an intercept and x_1, x_2, x_2^2, x_2^3, x_1*x_2, and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A *t*-by-(*p* + 1) matrix, or a “Terms Matrix” on page 33-1995, specifying terms in the model, where *t* is the number of terms and *p* is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar “Formula” on page 33-1996 in the form
  `'y ~ terms'`,
  where the `terms` are in “Wilkinson Notation” on page 33-1996. The variable names in the formula must be variable names in `tbl` or variable names specified by `Varnames`. Also, the variable names must be valid MATLAB identifiers.

  The software determines the order of terms in a fitted model by using the order of terms in `tbl` or `X`. Therefore, the order of terms in the model can be different from the order of terms in the specified formula.

Example: `'quadratic'`

Example: `'y ~ x1 + x2^2 + x1:x2'`

Data Types: `single` | `double` | `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Intercept',false,'PredictorVars',[1,3],'ResponseVar',5,'RobustOpts','logistic'` specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning constant, first and third variables are the predictor variables, and fifth variable is the response variable.

`CategoricalVars` — Categorical variable list
string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `fitlm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the second and third variables out of six as categorical using either of the following:

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

`Exclude` — Observations to exclude
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

`Intercept` — Indicator for constant term
`true` (default) | `false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept',false`

`PredictorVars` — Predictor variables
string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

`ResponseVar` — Response variable
last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

`RobustOpts` — Indicator of robust fitting type
`'off'` (default) | `'on'` | character vector | string scalar | structure

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of `'RobustOpts'` and one of these values.

- `'off'` — No robust fitting. `fitlm` uses ordinary least squares.
- `'on'` — Robust fitting using the `'bisquare'` weight function with the default tuning constant.
- Character vector or string scalar — Name of a robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant specified in the table.
- Structure with the two fields `RobustWgtFun` and `Tune`.
  - The `RobustWgtFun` field contains the name of a robust fitting weight function from the following table or a function handle of a custom weight function.
  - The `Tune` field contains a tuning constant. If you do not set the `Tune` field, `fitlm` uses the corresponding default tuning constant.

Weight Function	Description	Default Tuning Constant
'andrews'	w = (abs(r)<pi) .* sin(r) ./ r	1.339
'bisquare'	w = (abs(r)<1) .* (1 - r.^2).^2 (also called biweight)	4.685
'cauchy'	w = 1 ./ (1 + r.^2)	2.385
'fair'	w = 1 ./ (1 + abs(r))	1.400
'huber'	w = 1 ./ max(1, abs(r))	1.345
'logistic'	w = tanh(r) ./ r	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	w = 1 * (abs(r)<1)	2.795
'welsch'	w = exp(-(r.^2))	2.985
function handle	Custom weight function that accepts a vector r of scaled residuals, and returns a vector of weights the same size as r	1

- The default tuning constants of built-in weight functions give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.
- The value *r* in the weight functions is

  r = resid/(tune*s*sqrt(1—h)),

  where resid is the vector of residuals from the previous iteration, tune is the tuning constant, h is the vector of leverage values from a least-squares fit, and s is an estimate of the standard deviation of the error term given by

  s = MAD/0.6745.

  MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If X has *p* columns, the software excludes the smallest *p* absolute deviations when computing the median.

For robust fitting, fitlm uses M-estimation to formulate estimating equations and solves them using the method of “Iteratively Reweighted Least Squares” on page 11-104 (IRLS).

Example: 'RobustOpts','andrews'

VarNames — Names of variables
{'x1','x2',...,'xn','y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

Before specifying `'VarNames',varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string` | `cell`

`Weights` — Observation weights
`ones(n,1)` (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: `single` | `double`

Output Arguments

`mdl` — Linear model
`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

If the value of the `'RobustOpts'` name-value pair is not `[]` or `'ols'`, the model is not a least-squares fit, but uses the robust fitting function.

More About

Terms Matrix

A terms matrix `T` is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `x1`, `x2`, and `x3` and the response variable `y` in the order `x1`, `x2`, `x3`, and `y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `x2`; equivalently, `x1^0 * x2^1 * x3^0`
- `[1 0 1 0]` — `x1*x3`
- `[2 0 0 0]` — `x1^2`
- `[0 1 2 0]` — `x2*(x3^2)`

The `0` at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include `0` for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form `'y ~ terms'`.

- *y* is the response name.
- *terms* represents the predictor terms in a model using Wilkinson notation.

To represent predictor and response variables, use the variable names of the table input `tbl` or the variable names specified by using `VarNames`. The default value of `VarNames` is `{'x1','x2',...,'xn','y'}`.

For example:

- `'y ~ x1 + x2 + x3'` specifies a three-variable linear model with intercept.
- `'y ~ x1 + x2 + x3 − 1'` specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include `−1` in the formula.

A formula includes a constant term unless you explicitly remove the term using `−1`.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- `+` means include the next variable.
- `−` means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- `*` defines an interaction and all lower-order terms.
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
`1`	Constant (intercept) term
`x1^k`, where `k` is a positive integer	`x1`, $x1^2$, ..., $x1^k$
`x1 + x2`	`x1`, `x2`
`x1*x2`	`x1`, `x2`, `x1*x2`
`x1:x2`	`x1*x2` only
`−x2`	Do not include `x2`
`x1*x2 + x3`	`x1`, `x2`, `x3`, `x1*x2`

Wilkinson Notation	Terms in Standard Notation
`x1 + x2 + x3 + x1:x2`	x1, x2, x3, x1*x2
`x1*x2*x3 − x1:x2:x3`	x1, x2, x3, x1*x2, x1*x3, x2*x3
`x1*(x2 + x3)`	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Tips

- To access the model properties of the `LinearModel` object `mdl`, you can use dot notation. For example, `mdl.Residuals` returns a table of the raw, Pearson, Studentized, and standardized residual values for the model.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- The main fitting algorithm is QR decomposition. For robust fitting, `fitlm` uses M-estimation to formulate estimating equations and solves them using the method of “Iteratively Reweighted Least Squares” on page 11-104 (IRLS).
- `fitlm` treats a categorical predictor as follows:
  - A model with a categorical predictor that has L levels (categories) includes L – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `fitlm` treats the group of L – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the L – 1 indicator variables with the continuous predictor.
  - Interaction terms between two categorical predictors with L and M levels consist of the (L – 1)*(M – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
  - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.
- `fitlm` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `fitlm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `fitlm` uses each observation in the fit.

Alternative Functionality

- For reduced computation time on high-dimensional data sets, fit a linear regression model using the `fitrlinear` function.
- To regularize a regression, use `fitrlinear`, `lasso`, `ridge`, or `plsregress`.
  - `fitrlinear` regularizes a regression for high-dimensional data sets using lasso or ridge regression.
  - `lasso` removes redundant predictors in linear regression using lasso or elastic net.
  - `ridge` regularizes a regression with correlated terms using ridge regression.
  - `plsregress` regularizes a regression with correlated terms using partial least squares.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If any input argument to `fitlm` is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the `'Weights'` and `'Exclude'` name-value pairs.
- The `'RobustOpts'` name-value pair is not supported with tall arrays.
- For tall data, `fitlm` returns a `CompactLinearModel` object that contains most of the same properties as a `LinearModel` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `LinearModel` properties:
  - `Diagnostics`
  - `Fitted`
  - `ObservationInfo`
  - `ObservationNames`
  - `Residuals`
  - `Steps`

- `Variables`

  You can compute the residuals directly from the compact object returned by `LM = fitlm(X,Y)` using

  ```
  RES = Y - predict(LM,X);
  S = LM.RMSE;
  histogram(RES,linspace(-3*S,3*S,51))
  ```

- If the `CompactLinearModel` object is missing lower order terms that include categorical factors:
  - The `plotEffects` and `plotInteraction` methods are not supported.
  - The `anova` method with the `'components'` option is not supported.

For more information, see “Tall Arrays for Out-of-Memory Data”.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2013b

fitlme

Fit linear mixed-effects model

Syntax

```
lme = fitlme(tbl,formula)
lme = fitlme(tbl,formula,Name,Value)
```

Description

`lme = fitlme(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = fitlme(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Examples

Fit Linear Mixed-Effects Model

Load the sample data.

```
load imports-85
```

Store the variables in a table.

```
tbl = table(X(:,12),X(:,14),X(:,24),'VariableNames',{'Horsepower','CityMPG','EngineType'});
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans=5×3 table
    Horsepower    CityMPG    EngineType
    __________    _______    __________

       111          21           13
       111          21           13
       154          19           37
       102          24           35
       115          18           35
```

Fit a linear mixed-effects model for miles per gallon in the city, with fixed effects for horsepower, and uncorrelated random effect for intercept and horsepower grouped by the engine type.

```
lme = fitlme(tbl,'CityMPG~Horsepower+(1|EngineType)+(Horsepower-1|EngineType)');
```

In this model, `CityMPG` is the response variable, horsepower is the predictor variable, and engine type is the grouping variable. The fixed-effects portion of the model corresponds to `1 + Horsepower`, because the intercept is included by default.

Since the random-effect terms for intercept and horsepower are uncorrelated, these terms are specified separately. Because the second random-effect term is only for horsepower, you must include a `−1` to eliminate the intercept from the second random-effect term.

Display the model.

```
lme
```

```
lme =
Linear mixed-effects model fit by ML

Model information:
    Number of observations             203
    Fixed effects coefficients           2
    Random effects coefficients         14
    Covariance parameters                3

Formula:
    CityMPG ~ 1 + Horsepower + (1 | EngineType) + (Horsepower | EngineType)

Model fit statistics:
    AIC       BIC     LogLikelihood    Deviance
    1099.5    1116    -544.73          1089.5

Fixed effects coefficients (95% CIs):
    Name                   Estimate    SE         tStat     DF     pValue
    {'(Intercept)'}          37.276     2.8556    13.054    201    1.3147e-28
    {'Horsepower' }        -0.12631    0.02284     -5.53    201    9.8848e-08

    Lower       Upper
      31.645       42.906
    -0.17134    -0.081269

Random effects covariance parameters (95% CIs):
Group: EngineType (7 Levels)
    Name1                  Name2                  Type           Estimate
    {'(Intercept)'}        {'(Intercept)'}        {'std'}        5.7338

    Lower     Upper
    2.3773    13.829

Group: EngineType (7 Levels)
    Name1                 Name2                 Type           Estimate
    {'Horsepower'}        {'Horsepower'}        {'std'}        0.050357

    Lower      Upper
    0.02307    0.10992

Group: Error
    Name               Estimate    Lower     Upper
```

```
    {'Res Std'}        3.226       2.9078    3.5789
```

Note that the random-effects covariance parameters for intercept and horsepower are separate in the display.

Now, fit a linear mixed-effects model for miles per gallon in the city, with the same fixed-effects term and potentially correlated random effect for intercept and horsepower grouped by the engine type.

```
lme2 = fitlme(tbl,'CityMPG~Horsepower+(Horsepower|EngineType)');
```

Because the random-effect term includes the intercept by default, you do not have to add `1`, the random effect term is equivalent to `(1 + Horsepower|EngineType)`.

Display the model.

```
lme2
```

```
lme2 =

    {'Res Std'}        3.1845      2.8774    3.5243
```

Note that the random effects covariance parameters for intercept and horsepower are together in the display, and it includes the correlation (`'corr'`) between the intercept and horsepower.

Fit Random Intercept LME Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the new response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate', ...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Display the first six rows of `flu2`.

```
flu2(1:6,:)
```

```
ans =
    Date         WtdILI    Region       FluRate
    10/9/2005    1.182     NE            0.97
    10/9/2005    1.182     MidAtl       1.025
    10/9/2005    1.182     ENCentral    1.232
    10/9/2005    1.182     WNCentral    1.286
    10/9/2005    1.182     SAtl         1.082
    10/9/2005    1.182     ESCentral    1.457
```

Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, `WtdILI`, and a random intercept that varies by `Date`. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 \mathrm{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \ldots, 468, \quad m = 1, 2, \ldots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i. The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2,'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
Linear mixed-effects model fit by ML

    {'(Intercept)'}       0.16385     0.057525    2.8484    466     0.0045885
    {'WtdILI'     }        0.7236     0.032219    22.459    466    3.0502e-76

    Lower       Upper
    0.050813    0.27689
     0.66028    0.78691

Random effects covariance parameters (95% CIs):
Group: Date (52 Levels)
    Name1                 Name2                 Type          Estimate
    {'(Intercept)'}       {'(Intercept)'}       {'std'}       0.17146

    Lower      Upper
    0.13227    0.22226

Group: Error
    Name              Estimate    Lower      Upper
    {'Res Std'}       0.30201     0.28217    0.32324
```

Estimated covariance parameters are displayed in the section titled "Random effects covariance parameters". The estimated value of σ_b is 0.17146 and its 95% confidence interval is [0.13227, 0.22226]. Since this interval does not include 0, the random-effects term is significant. You can formally test the significance of any random-effects term using a likelihood ratio test via the `compare` method.

The estimated response at an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \mathrm{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236*(1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where $\hat{b}$ is the estimated best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
```

```
y_hat = 1.4674
```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(28)
```

```
ans = 1.4674
```

LME Model for Randomized Block Design

Load the sample data.

```
load('shift.mat')
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and `'effects'` contrasts.

`'effects'` contrasts mean that the coefficients sum to 0, and `fitlme` creates a matrix called a *fixed effects design matrix* to describe the effect of shift. This matrix has two columns, Shift_Evening and Shift_Morning, where

$$\text{Shift\_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift\_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\text{Morning Shift:} \quad \text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im},$$
$$\text{Evening Shift:} \quad \text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + \epsilon_{im},$$
$$\text{Night Shift:} \quad \text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im},$$

where i represents the observations, and m represents the operators, i = 1, 2, ..., 15, and m = 1, 2, ..., 5. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)',...
'FitMethod','REML','DummyVarCoding','effects')
```

```
lme =
Linear mixed-effects model fit by REML

    {'Res Std'}        0.85462     0.52357    1.395
```

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B = 5×1

    0.5775
    1.1757
   -2.1715
    2.3655
   -1.9472
```

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift\_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans = 0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

$$\begin{aligned}\hat{y}_{\text{Morning, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_2 \text{Shift\_Morning} + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value as follows.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
```

```
ans = 0.5613
```

The operator tends to make a smaller magnitude of error during the morning shift.

LME Model for Split-Plot Experiment

Load the sample data.

```
load('fertilizer.mat')
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of

tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^{4} \beta_{1m} I[F]_{im} + \sum_{j=2}^{5} \beta_{2j} I[T]_{ij} + \sum_{j=2}^{5} \sum_{m=2}^{4} \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S*T)_{jk} + \varepsilon_{imjk},$$

where $i = 1, 2, \ldots, 60$, index m corresponds to the fertilizer types, j corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil type, and $(S*T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[F]_{im}$ is the dummy variable representing level m of the fertilizer. Similarly, $I[T]_{ij}$ is the dummy variable representing level j of the tomato type.

The random effects and observation error have these prior distributions: $b_{0k} \sim N(0, \sigma_S^2)$, $b_{0jk} \sim N(0, \sigma_{S*T}^2)$, and $\epsilon_{imjk} \sim N(0, \sigma^2)$.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

```
lme =
Linear mixed-effects model fit by ML

Model information:
    Number of observations             60
    Fixed effects coefficients         20
    Random effects coefficients        18
    Covariance parameters               3

Formula:
    Yield ~ 1 + Tomato*Fertilizer + (1 | Soil) + (1 | Soil:Tomato)

Model fit statistics:
    AIC       BIC       LogLikelihood    Deviance

```

The *p*-values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova` method after refitting the model using `'effects'` contrasts.

The confidence interval for the standard deviations of the random-effects terms (σ_S^2), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1 | Soil)`.

```
lme = fitlme(ds,'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)')
```

```
lme =

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

Longitudinal Study with a Covariate

Load the sample data.

```
load('weight.mat')
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables $I[.]$. Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the `'reference'` method of coding dummy variables.

This model corresponds to

$$\begin{aligned} y_{im} = {} & \beta_0 + \beta_1 \mathrm{IW}_i + \beta_2 \mathrm{Week}_i + \beta_3 I[\mathrm{PB}]_i + \beta_4 I[\mathrm{PC}]_i + \beta_5 I[\mathrm{PD}]_i \\ & + \beta_6(\mathrm{Week}_i * I[\mathrm{PB}]_i) + \beta_7(\mathrm{Week}_i * I[\mathrm{PC}]_i) + \beta_8(\mathrm{Week}_i * I[\mathrm{PD}]_i) \\ & + b_{0m} + b_{1m}\mathrm{Week}_{im} + \varepsilon_{im}, \end{aligned}$$

where $i = 1, 2, \ldots, 120$, and $m = 1, 2, \ldots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \ldots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\mathrm{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme =
Linear mixed-effects model fit by ML

```

The *p*-values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

Input Arguments

`tbl` — Input data

table | `dataset` array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or `dataset` array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-45). You must specify the model for the variables using `formula`.

Data Types: `table`

`formula` — Formula for model specification

character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The formula is case sensitive. For a full description, see “Formula” on page 33-2018.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CovariancePattern','Diagonal','Optimizer','fminunc','OptimizerOptions',opt` specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and `fitlme` uses the `fminunc` optimization algorithm with the custom optimization parameters defined in variable `opt`.

`CovariancePattern` — Pattern of covariance matrix

`'FullCholesky'` (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are *R* random-effects terms, then the value of `'CovariancePattern'` must be a string array or cell array of length *R*, where each element *r* of the array specifies the pattern of the covariance

matrix of the random-effects vector associated with the *r*th random-effects term. The options for each element follow.

`'FullCholesky'`	Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.
`'Full'`	Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.
`'Diagonal'`	Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0. $\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$
`'Isotropic'`	Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like $\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$ where σ^2_b is the common variance of the random-effects terms.
`'CompSymm'`	Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like $\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$ where σ^2_{b1} is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

`PAT`	Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern','Diagonal'`

Example: `'CovariancePattern',{'Full','Diagonal'}`

Data Types: `char` | `string` | `logical` | `cell`

`FitMethod` — Method for estimating parameters
`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`	Default. Maximum likelihood estimation
`'REML'`	Restricted maximum likelihood estimation

Example: `'FitMethod','REML'`

`Weights` — Observation weights
vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length n, where n is the number of observations.

Data Types: `single` | `double`

`Exclude` — Indices for rows to exclude
use all rows without `NaNs` (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude',[13,67]`

Data Types: `single` | `double` | `logical`

`DummyVarCoding` — Coding to use for dummy variables
`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the variables in this table.

Value	Description
`'reference'` (default)	`fitlme` creates dummy variables with a reference group. This scheme treats the first category as a reference group and creates one less dummy variables than the number of categories. You can check the category order of a categorical variable by using the `categories` function, and change the order by using the `reordercats` function.
`'effects'`	`fitlme` creates dummy variables using effects coding. This scheme uses –1 to represent the last category. This scheme creates one less dummy variables than the number of categories.
`'full'`	`fitlme` creates full dummy variables. This scheme creates one dummy variable for each category.

For more details about creating dummy variables, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'DummyVarCoding','effects'`

`Optimizer` — Optimization algorithm
`'quasinewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

`'quasinewton'`	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using `statset('LinearMixedModel')`. If you don’t specify the options, then `LinearMixedModel` uses the default options of `statset('LinearMixedModel')`.
`'fminunc'`	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using `optimoptions('fminunc')`. If you don’t specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.

Example: `'Optimizer','fminunc'`

`OptimizerOptions` — Options for optimization algorithm
structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'`

is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.

- If `'Optimizer'` is `'quasinewton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinewton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

`TolFun` — Relative tolerance on gradient of objective function
`1e-6` (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

`TolX` — Absolute tolerance on step size
`1e-12` (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

`MaxIter` — Maximum number of iterations allowed
`10000` (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

`Display` — Level of display
`'off'` (default) | `'iter'` | `'final'`

Level of display, specified as one of `'off'`, `'iter'`, or `'final'`.

`StartMethod` — Method to start iterative optimization
`'default'` (default) | `'random'`

Method to start iterative optimization, specified as the comma-separated pair consisting of `'StartMethod'` and either of the following.

Value	Description
`'default'`	An internally defined default value
`'random'`	A random initial value

Example: `'StartMethod','random'`

`Verbose` — Indicator to display optimization process on screen
`false` (default) | `true`

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of `'Verbose'` and either `false` or `true`. Default is `false`.

The setting for `'Verbose'` overrides the field `'Display'` in `'OptimizerOptions'`.

Example: `'Verbose',true`

`CheckHessian` — Indicator to check positive definiteness of Hessian
`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: `'CheckHessian',true`

Output Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

More About

Formula

In general, a formula for model specification is a character vector or string scalar of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, X_j, which can be continuous or grouping variables
- Grouping variables, g_1, g_2, ..., g_R,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random`$_1$`|g`$_1$`) + ... + (random`$_R$`|g`$_R$`)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random`$_1$ is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1, and similarly `random`$_R$ is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
`1`	Constant (intercept) term
`X^k`, where `k` is a positive integer	`X`, X^2, ..., X^k
`X1 + X2`	`X1`, `X2`
`X1*X2`	`X1`, `X2`, `X1.*X2 (elementwise multiplication of X1 and X2)`
`X1:X2`	`X1.*X2` only

Wilkinson Notation	Factors in Standard Notation
`- X2`	Do not include X2
`X1*X2 + X3`	X1, X2, X3, X1*X2
`X1 + X2 + X3 + X1:X2`	X1, X2, X3, X1*X2
`X1*X2*X3 - X1:X2:X3`	X1, X2, X3, X1*X2, X1*X3, X2*X3
`X1*(X2 + X3)`	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
`'y ~ X1 + X2'`	Fixed effects for the intercept, X1 and X2. This is equivalent to `'y ~ 1 + X1 + X2'`.
`'y ~ -1 + X1 + X2'`	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including `-1`.
`'y ~ 1 + (1 | g1)'`	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable `g1`.
`'y ~ X1 + (1 | g1)'`	Random intercept model with a fixed slope.
`'y ~ X1 + (X1 | g1)'`	Random intercept and slope, with possible correlation between them. This is equivalent to `'y ~ 1 + X1 + (1 + X1|g1)'`.
`'y ~ X1 + (1 | g1) + (-1 + X1 | g1)'`	Independent random effects terms for intercept and slope.
`'y ~ 1 + (1 | g1) + (1 | g2) + (1 | g1:g2)'`	Random intercept model with independent main effects for `g1` and `g2`, plus an independent interaction effect.

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N\left(0, \sigma^2 D(\theta)\right),$$

where D is a q-by-q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ, q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D, is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q*(q+1)/2$-by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L.

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternatives

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

Introduced in R2013b

fitlmematrix

Fit linear mixed-effects model

Syntax

```
lme = fitlmematrix(X,y,Z,[])
lme = fitlmematrix(X,y,Z,G)
lme = fitlmematrix( ___ ,Name,Value)
```

Description

`lme = fitlmematrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where *n* is the number of observations. Using `fitlmematrix(X,Y,Z,[])` without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using the `'CovariancePattern'` name-value pair argument.

`lme = fitlmematrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = fitlmematrix( ___ ,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = fitlmematrix(X,y,Z,Model_Year)
```

```
lme =
Linear mixed-effects model fit by ML

```

Longitudinal Study with a Covariate

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned} y_{im} = {} & \beta_0 + \beta_1 \mathrm{IW}_i + \beta_2 \mathrm{Week}_i + \beta_3 I[\mathrm{PB}]_i + \beta_4 I[\mathrm{PC}]_i + \beta_5 I[\mathrm{PD}]_i \\ & + \beta_6 (\mathrm{Week}_i * I[\mathrm{PB}]_i) + \beta_7 (\mathrm{Week}_i * I[\mathrm{PC}]_i) + \beta_8 (\mathrm{Week}_i * I[\mathrm{PD}]_i) \\ & + b_{0m} + b_{1m} \mathrm{Week}_{im} + \varepsilon_{im}, \end{aligned}$$

where $i = 1, 2, \ldots, 120$, and $m = 1, 2, \ldots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \ldots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\mathrm{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
```

```
X = [ones(120,1), InitialWeight, D(:,2:4), Week,...
        D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;
```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the `'reference'` method of coding dummy variables.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD'},...
'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'})
```

```
lme =

      -0.15026       0.2278
      -0.15849      0.21957
      -0.15592      0.22214

Random effects covariance parameters (95% CIs):
Group: Subject (20 Levels)
    Name1               Name2               Type            Estimate
    {'Intercept'}       {'Intercept'}       {'std' }        0.18407
```

```
    {'Week'     }        {'Intercept'}        {'corr'}        0.66841
    {'Week'     }        {'Week'     }        {'std' }        0.15033

    Lower      Upper
    0.12281    0.27587
    0.21076    0.88573
    0.11004    0.20537

Group: Error
    Name               Estimate    Lower       Upper
    {'Res Std'}        0.10261     0.087882    0.11981
```

Examine the fixed effects coefficients table. The row labeled `'InitWeight'` has a *p*-value of 0.0228, and the row labeled `'Week'` has a *p*-value of 0.0115. These *p*-values indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 \mathrm{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \ldots, 468, \quad m = 1, 2, \ldots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i. The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$\varepsilon_{im} \sim N(0, \sigma^2)$.

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept','NationalRate'},...
'RandomEffectPredictors',{{'Intercept'}},'RandomEffectGroups',{'Date'})
```

```
lme =
Linear mixed-effects model fit by ML

Model information:

    {'Intercept'   }        0.16385    0.057525    2.8484    466     0.0045885
    {'NationalRate'}         0.7236    0.032219    22.459    466    3.0502e-76

    Lower       Upper
    0.050813    0.27689
     0.66028    0.78691

Random effects covariance parameters (95% CIs):
Group: Date (52 Levels)
    Name1               Name2               Type           Estimate    Lower
    {'Intercept'}       {'Intercept'}       {'std'}        0.17146     0.13227

    Upper
    0.22226

Group: Error
    Name              Estimate    Lower      Upper
    {'Res Std'}       0.30201     0.28217    0.32324
```

The confidence limits of the standard deviation of the random-effects term σ_b, do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \mathrm{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236*(1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where $\hat{b}$ is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
```

```
y_hat = 1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)
```

```
ans = 1.4674
```

Randomized Block Design

Load the sample data.

```
load('shift.mat');
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the `'effects'` contrasts. `'effects'` contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix, `X1` and `X2`, where

$$\text{Shift\_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift\_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\text{Morning Shift:}\quad \text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im},$$
$$\text{Evening Shift:}\quad \text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + \epsilon_{im},$$
$$\text{Night Shift:}\quad \text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + \epsilon_{im},$$

where i represents the observations, and m represents the operators, i = 1, 2, ..., 15, and m = 1, 2, ..., 5. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```
lme = fitlmematrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',....
{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{{'Intercept'}},...
'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')
```

```
lme =

```

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift\_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans = 0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

$$\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2),$$

$$b_{1m} \sim N(0, \sigma_1^2),$$

where m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'})
```

```
lme =
Linear mixed-effects model fit by ML

Model information:

    {'Res Std'}        3.7258      3.4698    4.0007
```

Note that the random effects covariance parameters for intercept and acceleration are separate in the display. The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case, the random-effects terms has this prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix}\right),$$

where m represents the model year.

First, prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})

lme =
Linear mixed-effects model fit by ML

    7.7727e-71      45.679      54.586
```

```
    1.7075e-05    -0.84661    -0.31992
     5.188e-76    -0.18382    -0.15527

Random effects covariance parameters (95% CIs):
Group: Model_Year (13 Levels)
    Name1                  Name2                  Type            Estimate
    {'Intercept'   }       {'Intercept'   }       {'std' }          3.3475
    {'Acceleration'}       {'Intercept'   }       {'corr'}        -0.87971
    {'Acceleration'}       {'Acceleration'}       {'std' }         0.33789

    Lower       Upper
      1.2862      8.7119
    -0.98501    -0.29675
      0.1825     0.62558

Group: Error
    Name               Estimate    Lower     Upper
    {'Res Std'}        3.6874      3.4298    3.9644
```

Note that the random effects covariance parameters for intercept and acceleration are together in the display, with an addition of the correlation between the intercept and acceleration. The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the `compare` method.

Specify the Covariance Pattern

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$\begin{aligned} y_{im} = {} & \beta_0 + \beta_1 \mathrm{IW}_i + \beta_2 \mathrm{Week}_i + \beta_3 I[\mathrm{PB}]_i + \beta_4 I[\mathrm{PC}]_i + \beta_5 I[\mathrm{PD}]_i \\ & + b_{0m} + b_{1m}\mathrm{Week2}_{im} + b_{2m}\mathrm{Week4}_{im} + b_{3m}\mathrm{Week6}_{im} + b_{4m}\mathrm{Week8}_{im} \\ & + b_{5m}\mathrm{Week10}_{im} + b_{6m}\mathrm{Week12}_{im} + \varepsilon_{im}, \end{aligned}$$

where i = 1, 2, ..., 120, and m = 1, 2, ..., 20.

β_j are the fixed-effects coefficients, j = 0, 1, ...,8, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\,.\,]$ is a dummy variable representing a type of program. For example, $I[\mathrm{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2)\,.$$

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{{'Intercept','Week'}},...
'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')
```

```
lme =

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of X corresponds to one observation, and each column of X corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, $r = 1, 2, ..., R$

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then Z must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then Z must be a cell array of length *R*. Each cell of Z contains an *n*-by-*q*(*r*) design matrix `Z{r}`, $r = 1, 2, ..., R$, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, `Z{r}`.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables on page 2-45, specified as either of the following.

- If there is one random-effects term, then G must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.

  G can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

- If there are multiple random-effects terms, then `G` must be a cell array of length R. Each cell of `G` contains a grouping variable `G{r}`, $r = 1, 2, ..., R$, with $M(r)$ levels.

  `G{r}` can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CovariancePattern','Diagonal','DummyVarCoding','full','Optimizer','fminunc'` specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the `fminunc` optimization algorithm.

`FixedEffectPredictors` — Names of columns in fixed-effects design matrix
`{'x1','x2',...,'xP'}` (default) | string array or cell array of length p

Names of columns in the fixed-effects design matrix `X`, specified as the comma-separated pair consisting of `'FixedEffectPredictors'` and a string array or cell array of length p.

For example, if you have a constant term and two predictors, say `TimeSpent` and `Gender`, where `Female` is the reference level for `Gender`, as the fixed effects, then you can specify the names of your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

Example: `'FixedEffectPredictors',{'Intercept','TimeSpent','Gender_Male'},`

Data Types: `string` | `cell`

`RandomEffectPredictors` — Names of columns in random-effects design matrix or cell array
string array or cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, ..., R$

Names of columns in the random-effects design matrix or cell array `Z`, specified as the comma-separated pair consisting of `'RandomEffectPredictors'` and either of the following:

- A string array or cell array of length q when `Z` is an n-by-q design matrix. In this case, the default is `{'z1','z2',...,'zQ'}`.
- A cell array of length R, when `Z` is a cell array of length R with each element `Z{r}` of length $q(r)$, $r = 1, 2, ..., R$. In this case, the default is `{'z11','z12',...,'z1Q(1)'},...,{'zr1','zr2',...,'zrQ(r)'}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors',{'Intercept','Acceleration'}`

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors',{{'Intercept','Acceleration'},{'Intercept'}}`

Data Types: `string` | `cell`

`ResponseVarName` — Name of response variable
`'y'` (default) | character vector | string scalar

Name of response variable, specified as the comma-separated pair consisting of `'ResponseVarName'` and a character vector or string scalar.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: `'ResponseVarName','score'`

Data Types: `char` | `string`

`RandomEffectGroups` — Names of random effects grouping variables
`'g'` or `{'g1','g2',...,'gR'}` (default) | character vector | string scalar | string array | cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair `'RandomEffectGroups'` and either of the following:

- Character vector or string scalar — If there is only one random-effects term, that is, if `G` is a vector, then the value of `'RandomEffectGroups'` is the name for the grouping variable `G`. The default is `'g'`.
- String array or cell array of character vectors — If there are multiple random-effects terms, that is, if `G` is a cell array of length *R*, then the value of `'RandomEffectGroups'` is a string array or cell array of length *R*, where each element is the name for the grouping variable `G{r}`. The default is `{'g1','g2',...,'gR'}`.

For example, if you have two random-effects terms, `z1` and `z2`, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

Example: `'RandomEffectGroups',{'sex','subject'}`

Data Types: `char` | `string` | `cell`

`CovariancePattern` — Pattern of covariance matrix
`'FullCholesky'` (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are *R* random-effects terms, then the value of `'CovariancePattern'` must be a string array or cell array of length *R*, where each element *r* of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the *r*th random-effects term. The options for each element follow.

`'FullCholesky'`	Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

`'Full'`	Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.
`'Diagonal'`	Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0. $\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$
`'Isotropic'`	Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like $\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$ where σ^2_b is the common variance of the random-effects terms.
`'CompSymm'`	Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like $\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$ where σ^2_{b1} is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .
`PAT`	Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern','Diagonal'`

Example: `'CovariancePattern',{'Full','Diagonal'}`

Data Types: `char` | `string` | `logical` | `cell`

`FitMethod` — Method for estimating parameters
`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`	Default. Maximum likelihood estimation
`'REML'`	Restricted maximum likelihood estimation

Example: `'FitMethod','REML'`

`Weights` — Observation weights
vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of length *n*, where *n* is the number of observations.

Data Types: `single` | `double`

`Exclude` — Indices for rows to exclude
use all rows without `NaN`s (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of `'Exclude'` and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: `'Exclude',[13,67]`

Data Types: `single` | `double` | `logical`

`DummyVarCoding` — Coding to use for dummy variables
`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the variables in this table.

Value	Description
`'reference'` (default)	`fitlmematrix` creates dummy variables with a reference group. This scheme treats the first category as a reference group and creates one less dummy variables than the number of categories. You can check the category order of a categorical variable by using the `categories` function, and change the order by using the `reordercats` function.
`'effects'`	`fitlmematrix` creates dummy variables using effects coding. This scheme uses –1 to represent the last category. This scheme creates one less dummy variables than the number of categories.

Value	Description
`'full'`	`fitlmematrix` creates full dummy variables. This scheme creates one dummy variable for each category.

For more details about creating dummy variables, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'DummyVarCoding','effects'`

`Optimizer` — Optimization algorithm
`'quasinewton'` (default) | `'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

`'quasinewton'`	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using `statset('LinearMixedModel')`. If you don’t specify the options, then `LinearMixedModel` uses the default options of `statset('LinearMixedModel')`.
`'fminunc'`	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using `optimoptions('fminunc')`. If you don’t specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.

Example: `'Optimizer','fminunc'`

`OptimizerOptions` — Options for optimization algorithm
structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinewton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don’t change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinewton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

`TolFun` — Relative tolerance on gradient of objective function
`1e-6` (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

`TolX` — Absolute tolerance on step size
`1e-12` (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

`MaxIter` — Maximum number of iterations allowed
`10000` (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

`Display` — Level of display
`'off'` (default) | `'iter'` | `'final'`

Level of display, specified as one of `'off'`, `'iter'`, or `'final'`.

`StartMethod` — Method to start iterative optimization
`'default'` (default) | `'random'`

Method to start iterative optimization, specified as the comma-separated pair consisting of `'StartMethod'` and either of the following.

Value	Description
`'default'`	An internally defined default value
`'random'`	A random initial value

Example: `'StartMethod','random'`

`Verbose` — Indicator to display optimization process on screen
`false` (default) | `true`

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of `'Verbose'` and either `false` or `true`. Default is `false`.

The setting for `'Verbose'` overrides the field `'Display'` in `'OptimizerOptions'`.

Example: `'Verbose',true`

`CheckHessian` — Indicator to check positive definiteness of Hessian
`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: `'CheckHessian',true`

Output Arguments

`lme` — Linear mixed-effects model
`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

More About

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N\left(0, \sigma^2 D(\theta)\right),$$

where D is a q-by-q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ, q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D, is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q*(q+1)/2$-by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L.

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternative Functionality

You can also fit a linear mixed-effects model using `fitlme(tbl,formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random`$_1$`|g`$_1$`) + ... + (random`$_R$`|g`$_R$`)'`.

Introduced in R2013b

fitsemigraph

Label data using semi-supervised graph-based method

Syntax

```
Mdl = fitsemigraph(Tbl,ResponseVarName,UnlabeledTbl)
Mdl = fitsemigraph(Tbl,formula,UnlabeledTbl)
Mdl = fitsemigraph(Tbl,Y,UnlabeledTbl)

Mdl = fitsemigraph(X,Y,UnlabeledX)

Mdl = fitsemigraph( ___ ,Name,Value)
```

Description

`fitsemigraph` creates a semi-supervised graph-based model given labeled data, labels, and unlabeled data. The returned model contains the fitted labels for the unlabeled data and the corresponding scores. This model can also predict labels for unseen data using the `predict` object function. For more information on the different labeling algorithms, see “Algorithms” on page 33-2062.

`Mdl = fitsemigraph(Tbl,ResponseVarName,UnlabeledTbl)` uses the labeled data in `Tbl`, where `Tbl.ResponseVarName` contains the labels for the labeled data, and returns fitted labels for the unlabeled data in `UnlabeledTbl`. The function stores the fitted labels and the corresponding scores in the `FittedLabels` and `LabelScores` properties of the object `Mdl`, respectively.

`Mdl = fitsemigraph(Tbl,formula,UnlabeledTbl)` uses `formula` to specify the response variable (vector of labels) and the predictor variables to use among the variables in `Tbl`. The function uses these variables to label the data in `UnlabeledTbl`.

`Mdl = fitsemigraph(Tbl,Y,UnlabeledTbl)` uses the predictor data in `Tbl` and the labels in `Y` to label the data in `UnlabeledTbl`.

`Mdl = fitsemigraph(X,Y,UnlabeledX)` uses the predictor data in `X` and the labels in `Y` to label the data in `UnlabeledX`.

`Mdl = fitsemigraph( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify the labeling method, number of iterations, and score threshold to use in the labeling algorithm.

Examples

Fit Labels to Unlabeled Data

Fit labels to unlabeled data by using a semi-supervised graph-based method.

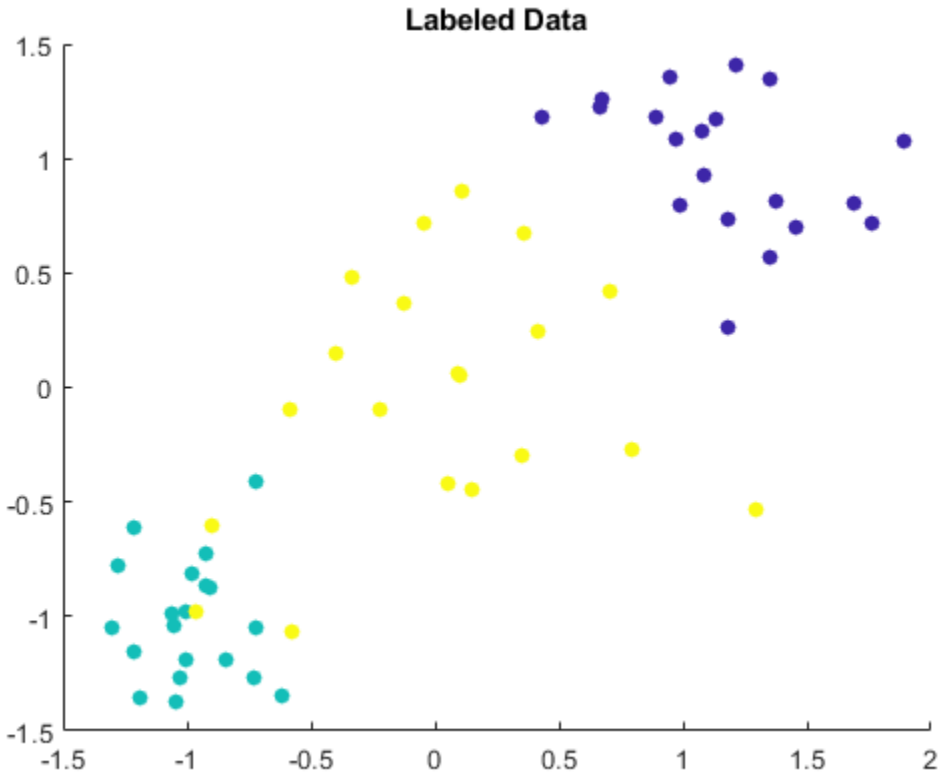
Randomly generate 60 observations of labeled data, with 20 observations in each of three classes.

```
rng('default') % For reproducibility

labeledX = [randn(20,2)*0.25 + ones(20,2);
            randn(20,2)*0.25 - ones(20,2);
            randn(20,2)*0.5];
Y = [ones(20,1); ones(20,1)*2; ones(20,1)*3];
```

Visualize the labeled data by using a scatter plot. Observations in the same class have the same color. Notice that the data is split into three clusters with very little overlap.

```
scatter(labeledX(:,1),labeledX(:,2),[],Y,'filled')
title('Labeled Data')
```



Randomly generate 300 additional observations of unlabeled data, with 100 observations per class. For the purposes of validation, keep track of the true labels for the unlabeled data.

```
unlabeledX = [randn(100,2)*0.25 + ones(100,2);
              randn(100,2)*0.25 - ones(100,2);
              randn(100,2)*0.5];
trueLabels = [ones(100,1); ones(100,1)*2; ones(100,1)*3];
```

Fit labels to the unlabeled data by using a semi-supervised graph-based method. The function `fitsemigraph` returns a `SemiSupervisedGraphModel` object whose `FittedLabels` property contains the fitted labels for the unlabeled data and whose `LabelScores` property contains the associated label scores.

```
Mdl = fitsemigraph(labeledX,Y,unlabeledX)
```

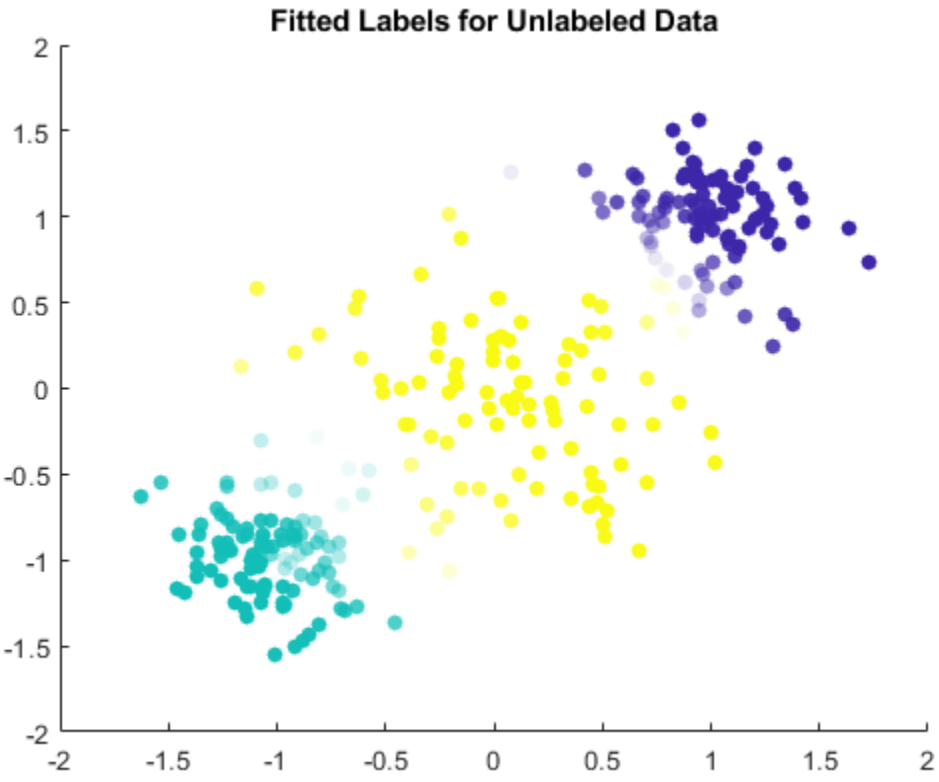
```
Mdl =
  SemiSupervisedGraphModel with properties:

            FittedLabels: [300x1 double]
             LabelScores: [300x3 double]
              ClassNames: [1 2 3]
            ResponseName: 'Y'
    CategoricalPredictors: []
                  Method: 'labelpropagation'

  Properties, Methods
```

Visualize the fitted label results by using a scatter plot. Use the fitted labels to set the color of the observations, and use the maximum label scores to set the transparency of the observations. Observations with less transparency are labeled with greater confidence. Notice that observations that lie closer to the cluster boundaries are labeled with more uncertainty.

```
maxLabelScores = max(Mdl.LabelScores,[],2);
rescaledScores = rescale(maxLabelScores,0.05,0.95);
scatter(unlabeledX(:,1),unlabeledX(:,2),[],Mdl.FittedLabels,'filled', ...
    'MarkerFaceAlpha','flat','AlphaData',rescaledScores);
title('Fitted Labels for Unlabeled Data')
```



Determine the accuracy of the labeling by using the true labels for the unlabeled data.

```
numWrongLabels = sum(trueLabels ~= Mdl.FittedLabels)
```

```
numWrongLabels = 10
```

Only 10 of the 300 observations in `unlabeledX` are mislabeled.

Specify Graph Type Used to Fit Labels

Fit labels to unlabeled data by using a semi-supervised graph-based method. Specify the type of nearest neighbor graph.

Load the `patients` data set. Create a table from the variables `Distolic`, `Gender`, and so on. For each observation, or row in the table, treat the `Smoker` value as the label for that observation.

```
load patients
Tbl = table(Diastolic,Gender,Height,Systolic,Weight,Smoker);
```

Suppose only 20% of the observations are labeled. To recreate this scenario, randomly sample 20 labeled observations and store them in the table `unlabeledTbl`. Remove the label from the rest of the observations and store them in the table `unlabeledTbl`. To verify the accuracy of the label fitting at the end of the example, retain the true labels for the unlabeled data in the variable `trueLabels`.

```
rng('default') % For reproducibility of the sampling
[labeledTbl,Idx] = datasample(Tbl,20,'Replace',false);

unlabeledTbl = Tbl;
unlabeledTbl(Idx,:) = [];
trueLabels = unlabeledTbl.Smoker;
unlabeledTbl.Smoker = [];
```

Fit labels to the unlabeled data by using a semi-supervised graph-based method. Use a mutual type of nearest neighbor graph, where two points are connected when they are nearest neighbors of each other. Specify to standardize the numeric predictors. The function `fitsemigraph` returns an object whose `FittedLabels` property contains the fitted labels for the unlabeled data.

```
Mdl = fitsemigraph(labeledTbl,'Smoker',unlabeledTbl,'KNNGraphType','mutual', ...
    'Standardize',true);
fittedLabels = Mdl.FittedLabels;
```

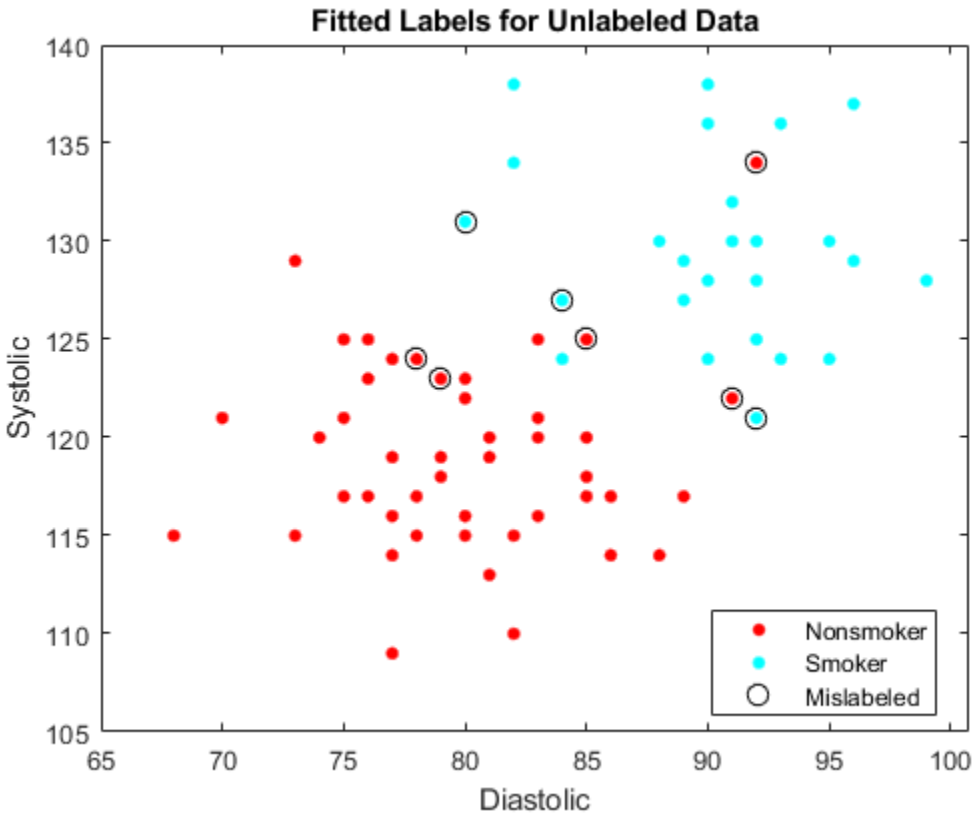
Identify the observations that are incorrectly labeled by comparing the stored true labels for the unlabeled data to the fitted labels returned by the semi-supervised graph-based method.

```
wrongIdx = (trueLabels ~= fittedLabels);
wrongTbl = unlabeledTbl(wrongIdx,:);
```

Visualize the fitted label results for the unlabeled data. Mislabeled observations are circled in the plot.

```
gscatter(unlabeledTbl.Diastolic,unlabeledTbl.Systolic, ...
    fittedLabels)
hold on
plot(wrongTbl.Diastolic,wrongTbl.Systolic, ...
    'ko','MarkerSize',8)
xlabel('Diastolic')
```

```
ylabel('Systolic')
legend('Nonsmoker','Smoker','Mislabeled')
title('Fitted Labels for Unlabeled Data')
```



Input Arguments

`Tbl` — Labeled sample data

table

Labeled sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor. Optionally, `Tbl` can contain one additional column for the response variable (vector of labels). Multicolumn variables, cell arrays other than cell arrays of character vectors, and ordinal categorical variables are not supported.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, specify a formula using `formula`.

If `Tbl` does not contain the response variable, specify a response variable using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`UnlabeledTbl` — Unlabeled sample data
table

Unlabeled sample data, specified as a table. Each row of `UnlabeledTbl` corresponds to one observation, and each column corresponds to one predictor. `UnlabeledTbl` must contain the same predictors as those contained in `Tbl`.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable contains the class labels for the sample data in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Class labels
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class labels, specified as a numeric, categorical, or logical vector, a character or string array, or a cell array of character vectors.

- If `Y` is a character array, then each element of the class labels must correspond to one row of the array.
- The length of `Y` must be equal to the number of rows in `Tbl` or `X`.

- A good practice is to specify the class order by using the `ClassNames` name-value pair argument.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`X` — Labeled predictor data
numeric matrix

Labeled predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation, and each column corresponds to one predictor.

The length of `Y` and the number of rows in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

`UnlabeledX` — Unlabeled predictor data
numeric matrix

Unlabeled predictor data, specified as a numeric matrix. Each row of `UnlabeledX` corresponds to one observation, and each column corresponds to one predictor. `UnlabeledX` must have the same predictors as `X`, in the same order.

Data Types: `single` | `double`

Note The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing data. The software removes rows of the predictor data (observations) with missing values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitsemigraph(Tbl,'Y',UnlabeledTbl,'Method','labelspreading','IterationLimit',2e3)` specifies to use a label spreading labeling technique and run a maximum of 2000 iterations.

Labeling Algorithm Options

`Method` — Labeling technique
`'labelpropagation'` (default) | `'labelpropagationexact'` | `'labelspreading'` | `'labelspreadingexact'`

Labeling technique, specified as the comma-separated pair consisting of `'Method'` and one of these values.

Value	Description	Method-Specific Name-Value Pair Arguments
`'labelpropagation'`	Iteratively propagate labels across the nodes in the similarity graph. For more information, see "Label Propagation" on page 33-2062.	`'IterationLimit'` — Maximum number of iterations `'Tolerance'` — Tolerance for the score absolute difference in subsequent iterations
`'labelpropagationexact'`	Use an exact formula to propagate labels. For more information, see "Label Propagation" on page 33-2062.	None
`'labelspreading'`	Iteratively spread labels across the nodes in the similarity graph. For more information, see "Label Spreading" on page 33-2063.	`'Alpha'` — Relative weight of neighboring labels to the initial label `'IterationLimit'` — Maximum number of iterations `'Tolerance'` — Tolerance for the score absolute difference in subsequent iterations
`'labelspreadingexact'`	Use an exact formula to spread labels. For more information, see "Label Spreading" on page 33-2063.	`'Alpha'` — Relative weight of neighboring labels to the initial label

Example: `'Method','labelspreading'`

Data Types: `char` | `string`

`Alpha` — Relative weight of neighboring labels to initial label
`0.01` (default) | scalar value in the range (0,1)

Relative weight of neighboring labels to the initial label for labeled observations in `X` or `Tbl`, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). A value close to 0 indicates that `fitsemigraph` treats labels of initially labeled observations almost like ground truth. A value close to 1 indicates that `fitsemigraph` treats labels of initially labeled observations almost like noise.

Note This argument is valid only when the `Method` value is `'labelspreading'` or `'labelspreadingexact'`.

Example: `'Alpha',0.05`

Data Types: `single` | `double`

`IterationLimit` — Maximum number of iterations
`1e3` (default) | positive integer scalar

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer scalar. The `fitsemigraph` function returns `Mdl`, which

contains the fitted labels and scores, when this limit is reached, even if the algorithm does not converge.

Note This argument is valid only when the `Method` value is `'labelpropagation'` or `'labelspreading'`.

Example: `'IterationLimit',2e3`

Data Types: `single` | `double`

`Tolerance` — Tolerance for score absolute difference in subsequent iterations
`1e-3` (default) | nonnegative scalar

Tolerance for score absolute difference in subsequent iterations, specified as the comma-separated pair consisting of `'Tolerance'` and a nonnegative scalar.

Note This argument is valid only when the `Method` value is `'labelpropagation'` or `'labelspreading'`.

Example: `'Tolerance',1e-4`

Data Types: `single` | `double`

Classification Options

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitsemigraph` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.

Value	Description
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table, `fitsemigraph` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. Ordinal categorical variables are not supported. If the predictor data is a matrix, `fitsemigraph` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value pair argument.

`fitsemigraph` encodes categorical variables as numeric variables by assigning a positive integer value to each category. When you use categorical predictors, ensure that you use an appropriate distance metric (`Distance`).

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for labeling

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of the classes to use for labeling, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `'ClassNames'` to:

- Order the classes.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `'ClassNames'` to specify the column order of classification scores in `Mdl.LabelScores`.
- Select a subset of classes for labeling. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To use observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`PredictorNames` — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the predictor data.

- If you supply `X`, `Y`, and `UnlabeledX`, then you can use `'PredictorNames'` to assign names to the predictor variables in `X` and `UnlabeledX`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl` and `UnlabeledTbl`, then you can use `'PredictorNames'` to choose which predictor variables to use. That is, `fitsemigraph` uses only the predictor variables in `PredictorNames` and the response variable to label the unlabeled data.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`Standardize` — Flag to standardize predictor data
`false` or `0` (default) | `true` or `1`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and a numeric or logical `0` (`false`) or `1` (`true`). If you set `'Standardize',true`, the software combines the labeled and unlabeled predictor data, and then centers and scales each numeric predictor variable by the corresponding column mean and standard deviation. The software does not standardize the categorical predictors.

Example: `'Standardize',true`

Data Types: `double` | `logical`

Distance Metric Options

`Distance` — Distance metric
character vector | string scalar

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a character vector or string scalar.

- If all the predictor variables are continuous (numeric) variables, then you can specify one of these distance metrics.

Value	Description
`'euclidean'`	Euclidean distance
`'seuclidean'`	Standardized Euclidean distance — Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation `S = std(PD,'omitnan')`, where `PD` is the predictor data, both labeled and unlabeled. To specify another scale parameter, use the `'Scale'` name-value pair argument.
`'mahalanobis'`	Mahalanobis distance — By default, the distance is computed using `C = cov(PD,'omitrows')`, the covariance of `PD`. To change the value of the covariance matrix, use the `'Cov'` name-value pair argument.
`'minkowski'`	Minkowski distance — The default exponent is 2. To specify a different exponent, use the `'P'` name-value pair argument.
`'chebychev'`	Chebychev distance (maximum coordinate difference)
`'cityblock'`	City block distance
`'correlation'`	One minus the sample correlation between observations (treated as sequences of values)
`'cosine'`	One minus the cosine of the included angle between observations (treated as vectors)
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)

Note If you specify one of these distance metrics and the predictor data includes categorical predictors, then the software treats each categorical predictor as a numeric variable, with each category represented by a positive integer.

- If all the predictor variables are categorical variables, then you can specify one of these distance metrics.

Value	Description
`'hamming'`	Hamming distance, which is the percentage of coordinates that differ
`'jaccard'`	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ

Note If you specify one of these distance metrics and the predictor data includes continuous (numeric) predictors, then the software treats each continuous predictor as a categorical variable.

- If the predictor variables are a mix of continuous (numeric) and categorical variables, then you can specify one of these distance metrics.

Value	Description
`'goodall3'`	Modified Goodall distance
`'ofd'`	Occurrence frequency distance

The default value is `'euclidean'` if all the predictor variables are continuous, and `'goodall3'` if any of the predictor variables are categorical. For more information on the various distance metrics, see “Distance Metrics” on page 33-2059.

Example: `'Distance','ofd'`

Data Types: `char` | `string`

`Scale` — Scale parameter for standardized Euclidean distance metric
nonnegative vector

Scale parameter for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of `'Scale'` and a nonnegative vector. The length of `Scale` is equal to the number of predictors. Each coordinate difference between two observations is scaled by the corresponding element of `Scale`.

The default scale parameter is `std(PD,'omitnan')`, where `PD` is the predictor data, both labeled and unlabeled.

Note This argument is valid only if `Distance` is `'seuclidean'`.

Example: `'Scale',iqr(X)`

Data Types: `single` | `double`

`Cov` — Covariance matrix for Mahalanobis distance metric
positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a *p*-by-*p* positive definite matrix, where *p* is the number of predictors.

The default covariance matrix is `cov(PD,'omitrows')`, where `PD` is the predictor data, both labeled and unlabeled.

Note This argument is valid only if `Distance` is `'mahalanobis'`.

Example: `'Cov',eye(3)`

Data Types: `single` | `double`

`P` — Exponent for Minkowski distance metric
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar.

Note This argument is valid only if `Distance` is `'minkowski'`.

Example: `'P',3`

Data Types: `single` | `double`

Graph Options

`SimilarityGraph` — Type of similarity graph
`'knn'` (default) | `'epsilon'`

Type of similarity graph used in the labeling algorithm, specified as the comma-separated pair consisting of `'SimilarityGraph'` and one of these values.

Value	Description	Graph-Specific Name-Value Pair Arguments
`'knn'`	Construct the graph using nearest neighbors.	`'NumNeighbors'` — Number of nearest neighbors used to construct the similarity graph `'KNNGraphType'` — Type of nearest neighbor graph
`'epsilon'`	Construct the graph by using radius search. You must specify a value for `Radius` if you use this option.	`'Radius'` — Search radius for the nearest neighbors used to construct the similarity graph

For more information, see “Similarity Graph” on page 33-2061.

Example: `'SimilarityGraph','epsilon','Radius',2`

Data Types: `char` | `string`

`NumNeighbors` — Number of nearest neighbors
positive integer scalar

Number of nearest neighbors used to construct the similarity graph, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer scalar.

The default number of neighbors is `log(n)`, where `n` is the number of observations in the predictor data, both labeled and unlabeled.

Note This argument is valid only if `SimilarityGraph` is `'knn'`.

Example: `'NumNeighbors',10`

Data Types: `single` | `double`

`KNNGraphType` — Type of nearest neighbor graph
`'complete'` (default) | `'mutual'`

Type of nearest neighbor graph, specified as the comma-separated pair consisting of `'KNNGraphType'` and one of these values.

Value	Description
`'complete'`	Connects two points *i* and *j*, when either *i* is a nearest neighbor of *j* or *j* is a nearest neighbor of *i*. This option leads to a denser representation of the similarity matrix.
`'mutual'`	Connects two points *i* and *j*, when *i* is a nearest neighbor of *j* and *j* is a nearest neighbor of *i*. This option leads to a sparser representation of the similarity matrix.

Note This argument is valid only if `SimilarityGraph` is `'knn'`.

Example: `'KNNGraphType','mutual'`

Data Types: `char` | `string`

`Radius` — Search radius
nonnegative scalar

Search radius for the nearest neighbors used to construct the similarity graph, specified as the comma-separated pair consisting of `'Radius'` and a nonnegative scalar.

Note You must specify this argument if `SimilarityGraph` is `'epsilon'`.

Example: `'Radius',5`

Data Types: `single` | `double`

`KernelScale` — Scale factor
1 (default) | `'auto'` | positive scalar

Scale factor for the kernel, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar. The software uses the scale factor to transform distances to similarity measures.

- The `'auto'` option is supported only for the `'euclidean'` and `'seuclidean'` distance metrics.
- If you specify `'auto'`, then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. To reproduce results, set a random number seed using `rng` before calling `fitsemigraph`.

Example: `'KernelScale','auto'`

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`Mdl` — Semi-supervised graph-based classifier

`SemiSupervisedGraphModel` object

Semi-supervised graph-based classifier, returned as a `SemiSupervisedGraphModel` object. Use dot notation to access the object properties. For example, to get the fitted labels for the unlabeled data and their corresponding scores, enter `Mdl.FittedLabels` and `Mdl.LabelScores`, respectively.

More About

Distance Metrics

A distance metric is a function that defines a distance between two observations. `fitsemigraph` supports various distance metrics for continuous (numeric) predictors, categorical predictors, and a mix of continuous and categorical predictors.

Given an mx-by-n data matrix X, which is treated as mx (1-by-n) row vectors x_1, x_2, ..., x_{mx}, and an my-by-n data matrix Y, which is treated as my (1-by-n) row vectors y_1, y_2, ...,y_{my}, the various distances between the vector x_s and y_t are defined as follows:

- Distance metrics for continuous (numeric) variables
  - Euclidean distance

    $$d_{st}^2 = (x_s - y_t)(x_s - y_t)'.$$

    The Euclidean distance is a special case of the Minkowski distance, where $p = 2$.
  - Standardized Euclidean distance

    $$d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)',$$

    where V is the n-by-n diagonal matrix whose jth diagonal element is $(S(j))^2$, where S is a vector of scaling factors for each dimension.
  - Mahalanobis distance

    $$d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)',$$

    where C is the covariance matrix.
  - Minkowski distance

    $$d_{st} = \sqrt[p]{\sum_{j=1}^{n} \left|x_{sj} - y_{tj}\right|^p}.$$

    For the special case of $p = 1$, the Minkowski distance gives the city block distance. For the special case of $p = 2$, the Minkowski distance gives the Euclidean distance. For the special case of $p = \infty$, the Minkowski distance gives the Chebychev distance.
  - Chebychev distance

    $$d_{st} = \max_j\left\{\left|x_{sj} - y_{tj}\right|\right\}.$$

    The Chebychev distance is a special case of the Minkowski distance, where $p = \infty$.

- City block distance

$$d_{st} = \sum_{j=1}^{n} \left| x_{sj} - y_{tj} \right|.$$

The city block distance is a special case of the Minkowski distance, where $p = 1$.

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'}\sqrt{(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}},$$

where

$$\bar{x}_s = \frac{1}{n}\sum_j x_{sj}$$

and

$$\bar{y}_t = \frac{1}{n}\sum_j y_{tj}.$$

- Cosine distance

$$d_{st} = \left(1 - \frac{x_s y'_t}{\sqrt{(x_s x'_s)(y_t y'_t)}}\right).$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'}\sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}},$$

where

  - r_{sj} is the rank of x_{sj} taken over x_{1j}, x_{2j}, ...$x_{mx,j}$, as computed by `tiedrank`.
  - r_{tj} is the rank of y_{tj} taken over y_{1j}, y_{2j}, ...$y_{my,j}$, as computed by `tiedrank`.
  - r_s and r_t are the coordinate-wise rank vectors of x_s and y_t, that is, $r_s = (r_{s1}, r_{s2}, \ldots r_{sn})$ and $r_t = (r_{t1}, r_{t2}, \ldots r_{tn})$.
  - $\bar{r}_s = \frac{1}{n}\sum_j r_{sj} = \frac{(n+1)}{2}$.
  - $\bar{r}_t = \frac{1}{n}\sum_j r_{tj} = \frac{(n+1)}{2}$.

- Distance metrics for categorical variables

  - Hamming distance

$$d_{st} = \left(\#\,(x_{sj} \neq y_{tj})/n \right).$$

  - Jaccard distance

$$d_{st} = \frac{\#\left[\left(x_{sj} \neq y_{tj}\right) \cap \left(\left(x_{sj} \neq 0\right) \cup \left(y_{tj} \neq 0\right)\right)\right]}{\#\left[\left(x_{sj} \neq 0\right) \cup \left(y_{tj} \neq 0\right)\right]}.$$

- Distance metrics for a mix of continuous (numeric) and categorical variables
  - Modified Goodall distance

    This distance is a variant of the Goodall distance, which assigns a small distance if the matching values are infrequent regardless of the frequencies of the other values. For mismatches, the distance contribution of the predictor is 1/(number of variables).
  - Occurrence frequency distance

    For a match, the occurrence frequency distance assigns zero distance. For a mismatch, the occurrence frequency distance assigns a higher distance on a less frequent value and a lower distance on a more frequent value.

Similarity Graph

A similarity graph models the local neighborhood relationships between observations in the predictor data, both labeled and unlabeled, as an undirected graph. The nodes in the graph represent observations, and the edges, which are directionless, represent the connections between the observations.

If the pairwise distance $Dist_{i,j}$ between any two nodes i and j is positive (or larger than a certain threshold), then the similarity graph connects the two nodes using an edge. The edge between the two nodes is weighted by the pairwise similarity $S_{i,j}$, where $S_{i,\,j} = \exp\left(-\left(\frac{Dist_{i,\,j}}{\sigma}\right)^2\right)$, for a specified kernel scale σ value.

`fitsemigraph` supports these two methods of constructing a similarity graph:

- *Nearest neighbor* method (if `SimilarityGraph` is `'knn'` (default)): `fitsemigraph` connects observations in the predictor data, both labeled and unlabeled, that are nearest neighbors.
  - Use the `'NumNeighbors'` name-value pair argument to specify the number of nearest neighbors.
  - Use the `'KNNGraphType'` name-value pair argument to specify whether to make a `'complete'` or `'mutual'` connection of points.
- *Radius search* method (if `SimilarityGraph` is `'epsilon'`): `fitsemigraph` connects observations whose pairwise distances are smaller than the specified search radius. You must specify the search radius for nearest neighbors used to construct the similarity graph by using the `'Radius'` name-value pair argument.

Similarity Matrix

A similarity matrix is a matrix representation of a similarity graph on page 33-2061. The n-by-n matrix $S = (S_{i,\,j})_{i,\,j\,=\,1,\,\ldots,\,n}$ contains pairwise similarity values between connected nodes in the similarity graph. The similarity matrix of a graph is also called an adjacency matrix.

The similarity matrix is symmetric because the edges of the similarity graph are directionless. A value of $S_{i,\,j} = 0$ means that nodes i and j of the similarity graph are not connected.

Algorithms

The software constructs a similarity graph (`SimilarityGraph`) with both labeled and unlabeled observations as nodes, and distributes label information from labeled observations to unlabeled observations by using either label propagation or label spreading.

Label Propagation

To propagate labels across the nodes in the similarity graph, the iterative label propagation algorithm (where `Method` is `'labelpropagation'`) follows these steps:

1. Initialize an n-by-K matrix $F(0)$, where n is the number of nodes (or observations) and K is the number of classes.
   - The first l rows correspond to labeled observations. Each row contains a 1 in the column corresponding to the true class label for that observation, and a 0 in every other column.
   - The last u rows correspond to the unlabeled observations, and contain a 0 in all columns.
2. At iteration t (starting with $t = 1$), update the F matrix by using the probabilistic transition matrix P, so that $F(t) = PF(t-1)$, where $P_{i,j} = \frac{S_{i,j}}{\sum_{k=1}^{n} S_{i,k}}$.
   - $P_{i,j}$ is the probability of transmitting label information from node i to node j.
   - $S_{i,j}$ is the weight of the edge between node i and node j. For the definition of $S_{i,j}$, see “Similarity Graph” on page 33-2061.
3. To complete iteration t, clamp the labels for the labeled observations. That is, keep the first l rows of $F(t)$ equal to their initial values in $F(0)$.
4. Repeat the second and third steps until the F values converge. You can use the `IterationLimit` and `Tolerance` values to control the convergence.

   The final F matrix corresponds to the scores for the labeled data and the unlabeled data (`LabelScores`). For each observation, or row in F, the column with the maximum score corresponds to the fitted class label (`FittedLabels`).

For more details, see [2].

Instead of using an iterative label propagation algorithm, you can use an exact method for label propagation (where `Method` is `'labelpropagationexact'`). In this case, the u-by-K matrix of label information for the unlabeled data is $F_U = (I - P_{UU})^{-1}P_{UL}F_L$ where:

- I is the identity matrix.
- P_{UU} and P_{UL} are the labeled (L) and unlabeled (U) submatrices of P such that $P = \begin{bmatrix} P_{LL} & P_{LU} \\ P_{UL} & P_{UU} \end{bmatrix}$.
- F_L is the l-by-K matrix of label information for the labeled data. Each row contains a 1 in the column corresponding to the true class label for that observation, and a 0 in every other column.

The F_U matrix corresponds to the scores for the unlabeled data (`LabelScores`). For each observation, or row in F_U, the column with the maximum score corresponds to the fitted class label (`FittedLabels`). For more details, see [3].

Label Spreading

To spread labels across the nodes in the similarity graph, the iterative spreading propagation algorithm (where `Method` is `'labelspreading'`) follows these steps:

1. Create an n-by-K matrix Y, where n is the number of nodes (or observations) and K is the number of classes.
   - The first l rows correspond to labeled observations. Each row contains a 1 in the column corresponding to the true class label for that observation, and a 0 in every other column.
   - The last u rows correspond to the unlabeled observations, and contain a 0 in all columns.
2. Create a matrix A that is a normalized version of the n-by-n similarity matrix on page 33-2061 S, with pairwise similarity values $S_{i,j}$ as defined in "Similarity Graph" on page 33-2061. Let $A = D^{-1/2}SD^{-1/2}$, where D is the n-by-n diagonal matrix $D = \begin{bmatrix} \sum_{j=1}^{n} S_{1,n} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sum_{j=1}^{n} S_{n,n} \end{bmatrix}$.
3. At iteration t (starting with $t = 1$), update the F matrix by using the matrix A and the neighboring label weight parameter α (`Alpha`), so that $F(t) = \alpha AF(t - 1) + (1 - \alpha)Y$. Let $F(0)$ equal Y.
4. Repeat the third step until the F values converge. You can use the `IterationLimit` and `Tolerance` values to control the convergence.
5. Take the limit of the sequence $\{F(t)\}_{t=1,..,T}$. This final matrix corresponds to the scores for the labeled data and the unlabeled data (`LabelScores`). For each observation, or row in the matrix, the column with the maximum score corresponds to the fitted class label (`FittedLabels`).

Instead of using an iterative label spreading algorithm, you can use an exact method for label spreading (where `Method` is `'labelspreadingexact'`). In this case, the n-by-K matrix of label information for the labeled and unlabeled data is $F = (I - \alpha A)^{-1}Y$, where I is the identity matrix. The F matrix corresponds to the scores for the labeled data and the unlabeled data (`LabelScores`). For each observation, or row in F, the column with the maximum score corresponds to the fitted class label (`FittedLabels`).

For more details, see [1].

Topics
“Label Data Using Semi-Supervised Learning Techniques” on page 18-250

Introduced in R2020b

fitsemiself

Label data using semi-supervised self-training method

Syntax

```
Mdl = fitsemiself(Tbl,ResponseVarName,UnlabeledTbl)
Mdl = fitsemiself(Tbl,formula,UnlabeledTbl)
Mdl = fitsemiself(Tbl,Y,UnlabeledTbl)

Mdl = fitsemiself(X,Y,UnlabeledX)

Mdl = fitsemiself( ___ ,Name,Value)
```

Description

`fitsemiself` creates a semi-supervised self-training model given labeled data, labels, and unlabeled data. The returned model contains the fitted labels for the unlabeled data and the corresponding scores. This model can also predict labels for unseen data using the `predict` object function. For more information on the labeling algorithm, see “Algorithms” on page 33-2076.

`Mdl = fitsemiself(Tbl,ResponseVarName,UnlabeledTbl)` uses the labeled data in `Tbl`, where `Tbl.ResponseVarName` contains the labels for the labeled data, and returns fitted labels for the unlabeled data in `UnlabeledTbl`. The function stores the fitted labels and the corresponding scores in the `FittedLabels` and `LabelScores` properties of the object `Mdl`, respectively.

`Mdl = fitsemiself(Tbl,formula,UnlabeledTbl)` uses `formula` to specify the response variable (vector of labels) and the predictor variables to use among the variables in `Tbl`. The function uses these variables to label the data in `UnlabeledTbl`.

`Mdl = fitsemiself(Tbl,Y,UnlabeledTbl)` uses the predictor data in `Tbl` and the labels in `Y` to label the data in `UnlabeledTbl`.

`Mdl = fitsemiself(X,Y,UnlabeledX)` uses the predictor data in `X` and the labels in `Y` to label the data in `UnlabeledX`.

`Mdl = fitsemiself( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify the type of learner, number of iterations, and score threshold to use in the labeling algorithm.

Examples

Fit Labels to Unlabeled Data

Fit labels to unlabeled data by using a semi-supervised self-training method.

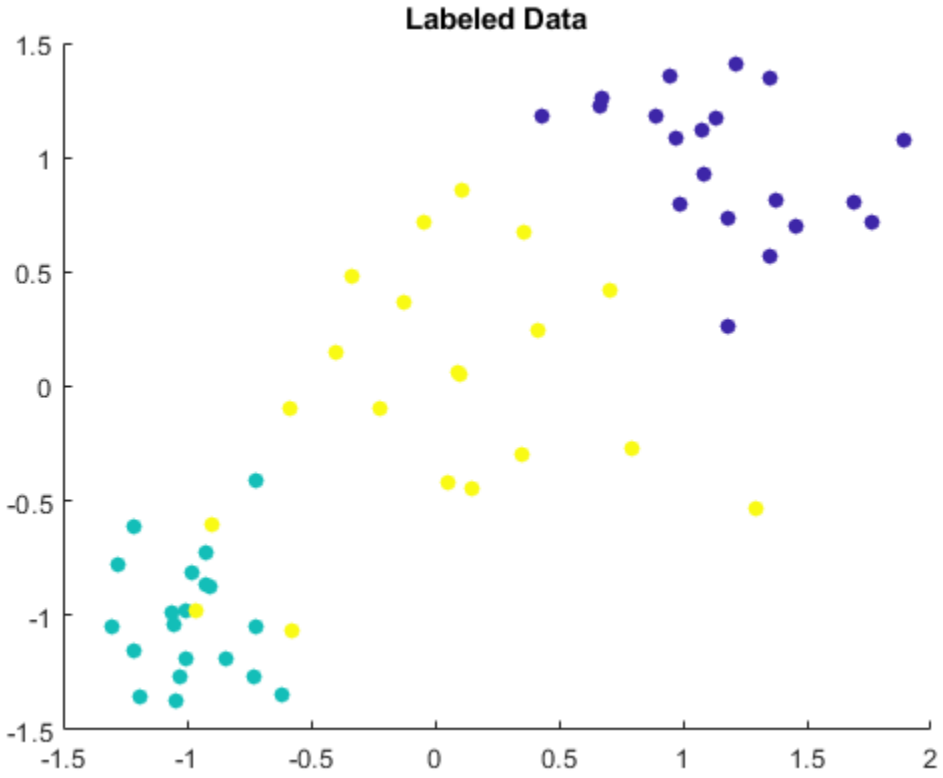
Randomly generate 60 observations of labeled data, with 20 observations in each of three classes.

```
rng('default') % For reproducibility
```

```
labeledX = [randn(20,2)*0.25 + ones(20,2);
            randn(20,2)*0.25 - ones(20,2);
            randn(20,2)*0.5];
Y = [ones(20,1); ones(20,1)*2; ones(20,1)*3];
```

Visualize the labeled data by using a scatter plot. Observations in the same class have the same color. Notice that the data is split into three clusters with very little overlap.

```
scatter(labeledX(:,1),labeledX(:,2),[],Y,'filled')
title('Labeled Data')
```



Randomly generate 300 additional observations of unlabeled data, with 100 observations per class. For the purposes of validation, keep track of the true labels for the unlabeled data.

```
unlabeledX = [randn(100,2)*0.25 + ones(100,2);
              randn(100,2)*0.25 - ones(100,2);
              randn(100,2)*0.5];
trueLabels = [ones(100,1); ones(100,1)*2; ones(100,1)*3];
```

Fit labels to the unlabeled data by using a semi-supervised self-training method. The function `fitsemiself` returns a `SemiSupervisedSelfTrainingModel` object whose `FittedLabels` property contains the fitted labels for the unlabeled data and whose `LabelScores` property contains the associated label scores.

```
Mdl = fitsemiself(labeledX,Y,unlabeledX)
```

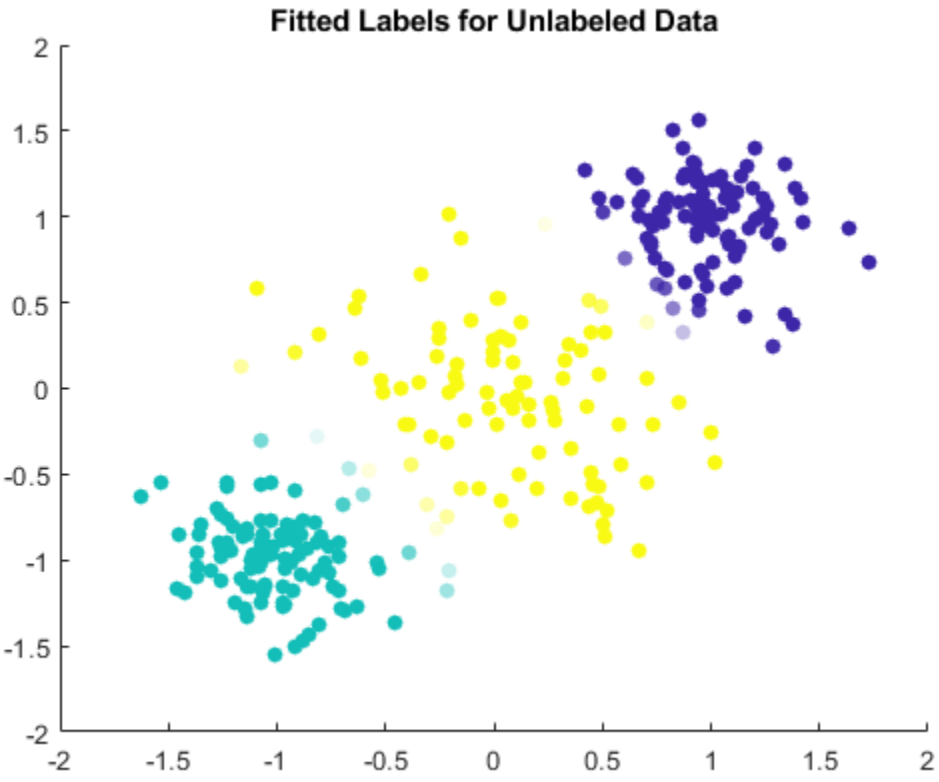
```
Mdl =
  SemiSupervisedSelfTrainingModel with properties:
```

```
            FittedLabels: [300x1 double]
             LabelScores: [300x3 double]
              ClassNames: [1 2 3]
            ResponseName: 'Y'
  CategoricalPredictors: []
                Learner: [1x1 classreg.learning.classif.CompactClassificationECOC]

  Properties, Methods
```

Visualize the fitted label results by using a scatter plot. Use the fitted labels to set the color of the observations, and use the maximum label scores to set the transparency of the observations. Observations with less transparency are labeled with greater confidence. Notice that observations that lie closer to the cluster boundaries are labeled with more uncertainty.

```
maxLabelScores = max(Mdl.LabelScores,[],2);
rescaledScores = rescale(maxLabelScores,0.05,0.95);
scatter(unlabeledX(:,1),unlabeledX(:,2),[],Mdl.FittedLabels,'filled', ...
    'MarkerFaceAlpha','flat','AlphaData',rescaledScores);
title('Fitted Labels for Unlabeled Data')
```



Determine the accuracy of the labeling by using the true labels for the unlabeled data.

```
numWrongLabels = sum(trueLabels ~= Mdl.FittedLabels)
```

```
numWrongLabels = 8
```

Only 8 of the 300 observations in `unlabeledX` are mislabeled.

Specify Learner Used to Fit Labels

Fit labels to unlabeled data by using a semi-supervised self-training method. Specify the type of learner used to fit the labels.

Load the `carsmall` data set. Create a table from the variables `Acceleration`, `Displacement`, and so on. For each observation, or row in the table, treat the `Cylinders` value as the label for that observation.

```
load carsmall
Tbl = table(Acceleration,Displacement,Horsepower,Weight,Cylinders);
```

Suppose only 20% of the observations are labeled. To recreate this scenario, randomly sample 20 labeled observations and store them in the table `unlabeledTbl`. Remove the label from the rest of the observations and store them in the table `unlabeledTbl`. To verify the accuracy of the label fitting at the end of the example, retain the true labels for the unlabeled data in the variable `trueLabels`.

```
rng('default') % For reproducibility of the sampling
[labeledTbl,Idx] = datasample(Tbl,20,'Replace',false);

unlabeledTbl = Tbl;
unlabeledTbl(Idx,:) = [];
trueLabels = unlabeledTbl.Cylinders;
unlabeledTbl.Cylinders = [];
```

Fit labels to the unlabeled data by using a semi-supervised self-training method. Use a multiclass SVM (ECOC) model to iteratively label the unlabeled observations. Specify to standardize the numeric predictors and use a linear kernel function for the SVM binary learners. The function `fitsemiself` returns an object whose `FittedLabels` property contains the fitted labels for the unlabeled data.

```
Mdl = fitsemiself(labeledTbl,'Cylinders',unlabeledTbl, ...
    'Learner',templateECOC('Learner',templateSVM('Standardize',true, ...
    'KernelFunction','linear')));
fittedLabels = Mdl.FittedLabels;
```

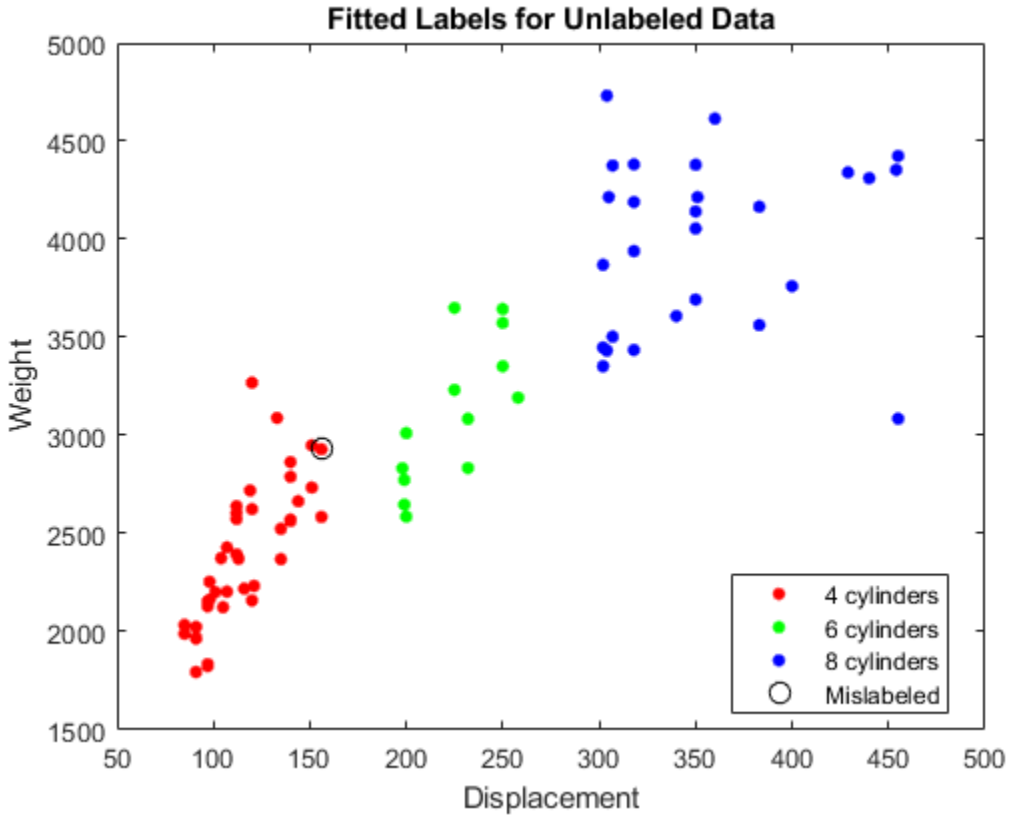
Identify the observations that are incorrectly labeled by comparing the stored true labels for the unlabeled data to the fitted labels returned by the semi-supervised self-training method.

```
wrongIdx = (trueLabels ~= fittedLabels);
wrongTbl = unlabeledTbl(wrongIdx,:);
```

Visualize the fitted label results for the unlabeled data. Mislabeled observations are circled in the plot.

```
gscatter(unlabeledTbl.Displacement,unlabeledTbl.Weight, ...
    fittedLabels)
hold on
plot(wrongTbl.Displacement,wrongTbl.Weight, ...
```

```
    'ko','MarkerSize',8)
xlabel('Displacement')
ylabel('Weight')
legend('4 cylinders','6 cylinders','8 cylinders','Mislabeled')
title('Fitted Labels for Unlabeled Data')
```



Input Arguments

`Tbl` — Labeled sample data

table

Labeled sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor. Optionally, `Tbl` can contain one additional column for the response variable (vector of labels). Multicolumn variables and cell arrays other than cell arrays of character vectors are not supported.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, specify a formula using `formula`.

If `Tbl` does not contain the response variable, specify a response variable using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`UnlabeledTbl` — Unlabeled sample data
table

Unlabeled sample data, specified as a table. Each row of `UnlabeledTbl` corresponds to one observation, and each column corresponds to one predictor. `UnlabeledTbl` must contain the same predictors as those contained in `Tbl`.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable contains the class labels for the sample data in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

A good practice is to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Class labels
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class labels, specified as a numeric, categorical, or logical vector, a character or string array, or a cell array of character vectors.

- If `Y` is a character array, then each element of the class labels must correspond to one row of the array.
- The length of `Y` must be equal to the number of rows in `Tbl` or `X`.

- A good practice is to specify the class order by using the `ClassNames` name-value pair argument.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`X` — Labeled predictor data

numeric matrix

Labeled predictor data, specified as a numeric matrix.

By default, each row of `X` corresponds to one observation, and each column corresponds to one predictor.

The length of `Y` and the number of observations in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

`UnlabeledX` — Unlabeled predictor data

numeric matrix

Unlabeled predictor data, specified as a numeric matrix. By default, each row of `UnlabeledX` corresponds to one observation, and each column corresponds to one predictor. `UnlabeledX` must have the same predictors as `X`, in the same order.

Data Types: `single` | `double`

Note The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing data. Whether the software removes observations with missing values depends on the underlying classifier type (`Learner`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitsemiself(Tbl,'Y',UnlabeledTbl,'Learner',templateSVM('Standardize',true),'IterationLimit',2e3)` specifies to use a binary support vector machine (SVM) learner, standardize the numeric predictors, and run a maximum of 2000 iterations.

`Learner` — Underlying classifier type

`'svm'` | `'discriminant'` | `'kernel'` | `'knn'` | `'linear'` | `'naivebayes'` | `'tree'` | ...

Underlying classifier type, specified as the comma-separated pair consisting of `'Learner'` and one of the values in this table.

Value	Description
`'discriminant'` or `templateDiscriminant` object	Discriminant analysis classifier

Value	Description
`templateECOC` object	Multiclass error-correcting output codes (ECOC) model — `templateECOC('Learners',templateSVM('KernelFunction','gaussian'))` is the default for multiclass classification.
`templateEnsemble` object	Ensemble classification model
`'kernel'` or `templateKernel` object	Kernel classification model (for binary classification only)
`'knn'` or `templateKNN` object	k-nearest neighbor model
`'linear'` or `templateLinear` object	Linear classification model (for binary classification only)
`'svm'` or `templateSVM` object	Support vector machine (SVM) classifier (for binary classification only) — `templateSVM('KernelFunction','gaussian')` is the default for binary classification.
`'tree'` or `templateTree` object	Binary decision classification tree

Example: `'Learner','tree'`

Example: `'Learner',templateEnsemble('AdaBoostM1',100,'tree')`

`IterationLimit` — Maximum number of self-training iterations
`1e3` (default) | positive integer scalar

Maximum number of self-training iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer scalar. The `fitsemiself` function returns `Mdl`, which contains the fitted labels and scores, when this limit is reached, even if the algorithm does not converge.

Example: `'IterationLimit',2e3`

Data Types: `single` | `double`

`ScoreThreshold` — Score threshold for fitted labels
numeric scalar

Score threshold for fitted labels, specified as the comma-separated pair consisting of `'ScoreThreshold'` and a numeric scalar. At each iteration of the algorithm, the software makes label predictions for the unlabeled observations by using the specified `Learner`, and calculates scores for these predictions. Unlabeled observations with prediction scores greater than or equal to the score threshold are treated as labeled observations in the next iteration, where the label is the predicted label. By default, `ScoreThreshold` is `0.1` for binary classification and `–0.1` for multiclass classification.

Example: `'ScoreThreshold',0.2`

Data Types: `single` | `double`

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table. The descriptions assume that the predictor data has observations in rows and predictors in columns.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitsemiself` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table, `fitsemiself` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. However, learners that use decision trees assume that mathematically ordered categorical vectors are continuous variables. If the predictor data is a matrix, `fitsemiself` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value pair argument.

For more information on how different fitting functions and, therefore, different learners treat categorical predictors, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for labeling

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of the classes to use for labeling, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `'ClassNames'` to:

- Order the classes.

- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `'ClassNames'` to specify the column order of classification scores in `Mdl.LabelScores`.
- Select a subset of classes for labeling. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the underlying classifier `Learner` using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply predictor data.

- If you supply `X`, `Y`, and `UnlabeledX`, then you can use `'PredictorNames'` to assign names to the predictor variables in `X` and `UnlabeledX`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. Assuming that `X` has the default orientation, with observations in rows and predictors in columns, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl` and `UnlabeledTbl`, then you can use `'PredictorNames'` to choose which predictor variables to use. That is, `fitsemiself` uses only the predictor variables in `PredictorNames` and the response variable to label the unlabeled data.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',`
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`NumBins` — Number of bins for numeric predictors
`[]` (default) | positive integer scalar

Number of bins for the numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

- If the `'NumBins'` value is empty (default), then the software does not bin any predictors.
- If you specify the `'NumBins'` value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.

  - If the `'NumBins'` value exceeds the number (u) of unique values for a predictor, then `fitsemiself` bins the predictor into u bins.
  - `fitsemiself` does not bin categorical predictors.

  When you use a large data set, this binning option speeds up classifier training, but causes a potential decrease in accuracy. You can try `'NumBins',50` first, and then change the `'NumBins'` value depending on the accuracy and training speed.

Note This argument is valid only when the `Learner` value is a `templateECOC` or `templateEnsemble` object that uses tree learners.

Example: `'NumBins',50`

Data Types: `single` | `double`

`ObservationsIn` — Observation dimension for predictor data `X` and `UnlabeledX`
`'rows'` (default) | `'columns'`

Observation dimension for the predictor data `X` and `UnlabeledX`, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'rows'` or `'columns'`. For linear classification models, if you orient `X` and `UnlabeledX` so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you can experience a reduction in execution time.

Note The `'columns'` value is valid only when the `Learner` value is a binary linear classification model (`'linear'` or `templateLinear`) or an ECOC model with linear binary learners (for example, `templateECOC('Learners','linear')`).

Example: `'ObservationsIn','columns'`

Data Types: `char` | `string`

Output Arguments

`Mdl` — Semi-supervised self-training classifier
`SemiSupervisedSelfTrainingModel` object

Semi-supervised self-training classifier, returned as a `SemiSupervisedSelfTrainingModel` object. Use dot notation to access the object properties. For example, to get the fitted labels for the unlabeled data and their corresponding scores, enter `Mdl.FittedLabels` and `Mdl.LabelScores`, respectively.

Algorithms

The algorithm begins by training a user-specified classifier (`Learner`), first trained on the labeled data alone, and then uses that classifier to make label predictions for the unlabeled data. Next, the algorithm provides scores for the predictions, and then treats the predictions as true labels for the next training cycle of the classifier if the scores are above a threshold (`ScoreThreshold`). This process repeats until the label predictions converge or the iteration limit (`IterationLimit`) is reached.

fitrauto

Automatically select regression model with optimized hyperparameters

Syntax

```
Mdl = fitrauto(Tbl,ResponseVarName)
Mdl = fitrauto(Tbl,formula)
Mdl = fitrauto(Tbl,Y)

Mdl = fitrauto(X,Y)

Mdl = fitrauto( ___ ,Name,Value)
[Mdl,OptimizationResults] = fitrauto( ___ )
```

Description

Given predictor and response data, `fitrauto` automatically tries a selection of regression model types with different hyperparameter values. The function uses Bayesian optimization to select models and their hyperparameter values, and computes the following for each model: log(1 + *valLoss*), where *valLoss* is the cross-validation mean squared error (MSE). After the optimization is complete, `fitrauto` returns the model, trained on the entire data set, that is expected to best predict the responses for new data. You can use the `predict` and `loss` object functions of the returned model to predict on new data and compute the test set MSE, respectively.

Use `fitrauto` when you are uncertain which model types best suit your data. For information on alternative methods for tuning hyperparameters of regression models, see “Alternative Functionality” on page 33-2114.

`Mdl = fitrauto(Tbl,ResponseVarName)` returns a regression model `Mdl` with tuned hyperparameters. The table `Tbl` contains the predictor variables and the response variable, where `ResponseVarName` is the name of the response variable.

`Mdl = fitrauto(Tbl,formula)` uses `formula` to specify the response variable and the predictor variables to consider among the variables in `Tbl`.

`Mdl = fitrauto(Tbl,Y)` uses the predictor variables in table `Tbl` and the response values in vector `Y`.

`Mdl = fitrauto(X,Y)` uses the predictor variables in matrix `X` and the response values in vector `Y`.

`Mdl = fitrauto( ___ ,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, use the `HyperparameterOptimizationOptions` name-value pair argument to specify how the Bayesian optimization is performed.

`[Mdl,OptimizationResults] = fitrauto( ___ )` additionally returns `OptimizationResults`, a `BayesianOptimization` object containing the results of the model selection and hyperparameter tuning process.

Examples

Automatically Select Regression Model Using Table Data

Use `fitrauto` to automatically select a regression model with optimized hyperparameters, given predictor and response data stored in a table.

Load Data

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table containing the predictor variables `Acceleration`, `Displacement`, and so on, as well as the response variable `MPG`.

```
cars = table(Acceleration,Displacement,Horsepower, ...
    Model_Year,Origin,Weight,MPG);
```

Partition Data

Partition the data into training and test sets. Use approximately 80% of the observations for the model selection and hyperparameter tuning process, and 20% of the observations to test the performance of the final model returned by `fitrauto`. Use `cvpartition` to partition the data.

```
rng('default') % For reproducibility of the data partition
c = cvpartition(length(MPG),'Holdout',0.2);
trainingIdx = training(c); % Training set indices
carsTrain = cars(trainingIdx,:);
testIdx = test(c); % Test set indices
carsTest = cars(testIdx,:);
```

Run `fitrauto`

Pass the training data to `fitrauto`. By default, `fitrauto` determines appropriate model types to try, uses Bayesian optimization to find good hyperparameter values, and returns a trained model `Mdl` with the best expected performance. Additionally, `fitrauto` provides a plot of the optimization and an iterative display of the optimization results. For more information on how to interpret these results, see “Verbose Display” on page 33-2111.

Expect this process to take some time. To speed up the optimization process, consider running the optimization in parallel, if you have a Parallel Computing Toolbox™ license. To do so, pass `'HyperparameterOptimizationOptions',struct('UseParallel',true)` to `fitrauto` as a name-value pair argument.

```
Mdl = fitrauto(carsTrain,'MPG');
```

```

```

```
Optimization completed.
Total iterations: 90
Total elapsed time: 589.6892 seconds
Total time for training and validation: 245.2123 seconds

Best observed learner is an ensemble model with:
    Method:             LSBoost
    NumLearningCycles:      278
    MinLeafSize:             13
Observed log(1 + valLoss): 2.1916
Time for training and validation: 6.4368 seconds

Best estimated learner (returned model) is an ensemble model with:
    Method:             LSBoost
    NumLearningCycles:      278
    MinLeafSize:             13
Estimated log(1 + valLoss): 2.1928
Estimated time for training and validation: 5.8977 seconds

Documentation for fitrauto display
```

The final model returned by `fitrauto` corresponds to the best estimated learner. Before returning the model, the function retrains it using the entire training data (`carsTrain`), the listed `Learner` (or model) type, and the displayed hyperparameter values.

Evaluate Test Set Performance

Evaluate the performance of the model on the test set. `testError` is based on the test set mean squared error (MSE). Smaller MSE values indicate better performance.

```
testMSE = loss(Mdl,carsTest,'MPG');
testError = log(1 + testMSE)
```

```
testError = 2.3194
```

Automatically Select Regression Model Using Matrix Data

Use `fitrauto` to automatically select a regression model with optimized hyperparameters, given predictor and response data stored in separate variables.

Load Data

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a matrix `X` containing the predictor variables `Acceleration`, `Cylinders`, and so on. Store the response variable `MPG` in the variable `Y`.

```
X = [Acceleration Cylinders Displacement Weight];
Y = MPG;
```

Create a variable indicating which predictors are categorical. `Cylinders` is the only categorical variable in `X`.

```
categoricalVars = [false true false false];
```

Partition Data

Partition the data into training and test sets. Use approximately 80% of the observations for the model selection and hyperparameter tuning process, and 20% of the observations to test the performance of the final model returned by `fitrauto`. Use `cvpartition` to partition the data.

```
rng('default') % For reproducibility of the partition
c = cvpartition(length(Y),'Holdout',0.20);
trainingIdx = training(c); % Indices for the training set
XTrain = X(trainingIdx,:);
YTrain = Y(trainingIdx);
testIdx = test(c); % Indices for the test set
XTest = X(testIdx,:);
YTest = Y(testIdx);
```

Run `fitrauto`

Pass the training data to `fitrauto`. By default, `fitrauto` determines appropriate model (or learner) types to try, uses Bayesian optimization to find good hyperparameter values for those models, and returns a trained model `Mdl` with the best expected performance. Specify the categorical predictors, and run the optimization in parallel (requires Parallel Computing Toolbox™). Return a second output `OptimizationResults` that contains the details of the Bayesian optimization.

Expect this process to take some time. By default, `fitrauto` provides a plot of the optimization and an iterative display of the optimization results. For more information on how to interpret these results, see “Verbose Display” on page 33-2111.

```
options = struct('UseParallel',true);
[Mdl,OptimizationResults] = fitrauto(XTrain,YTrain, ...
    'CategoricalPredictors',categoricalVars, ...
    'HyperparameterOptimizationOptions',options);
```

_____________________________________________________________
Optimization completed.
Total iterations: 91
Total elapsed time: 201.923 seconds
Total time for training and validation: 436.1019 seconds

Best observed learner is an ensemble model with:
    Method:                Bag
    NumLearningCycles:     202
    MinLeafSize:             9
Observed log(1 + valLoss): 2.8217
Time for training and validation: 4.2702 seconds

Best estimated learner (returned model) is an svm model with:
    BoxConstraint:    0.0013447
    KernelScale:         362.68
    Epsilon:           0.096474
Estimated log(1 + valLoss): 2.7363
Estimated time for training and validation: 0.29514 seconds

Documentation for fitrauto display
```

The final model returned by `fitrauto` corresponds to the best estimated learner. Before returning the model, the function retrains it using the entire training data (`XTrain` and `YTrain`), the listed `Learner` (or model) type, and the displayed hyperparameter values.

Evaluate Test Set Performance

Evaluate the performance of the model on the test set. `testError` is based on the test set mean squared error (MSE). Smaller MSE values indicate better performance.

```
testMSE = loss(Mdl,XTest,YTest);
testError = log(1 + testMSE)
```

```
testError = 2.9873
```

Compare Optimized and Simple Linear Regression Model

Use `fitrauto` to automatically select a regression model with optimized hyperparameters, given predictor and response data stored in a table. Compare the performance of the resulting regression model to the performance of a simple linear regression model created with `fitlm`.

Load and Partition Data

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s. Convert the `Cylinders` variable to a `categorical` variable. Create a table containing the predictor variables `Acceleration`, `Cylinders`, `Displacement`, and so on, as well as the response variable `MPG`.

```
load carbig
Cylinders = categorical(Cylinders);
cars = table(Acceleration,Cylinders,Displacement, ...
    Horsepower,Model_Year,Origin,Weight,MPG);
```

Partition the data into training and test sets. Use approximately 80% of the observations for training, and 20% of the observations for testing. Use `cvpartition` to partition the data.

```
rng('default') % For reproducibility of the data partition
c = cvpartition(length(MPG),'Holdout',0.2);
trainingIdx = training(c); % Training set indices
carsTrain = cars(trainingIdx,:);
testIdx = test(c); % Test set indices
carsTest = cars(testIdx,:);
```

Run `fitrauto`

Pass the training data to `fitrauto`. By default, `fitrauto` determines appropriate model types to try, uses Bayesian optimization to find good hyperparameter values, and returns a trained model `autoMdl` with the best expected performance. Specify to optimize over all optimizable hyperparameters and run the optimization in parallel (requires Parallel Computing Toolbox™).

Expect this process to take some time. By default, `fitrauto` provides a plot of the optimization and an iterative display of the optimization results. For more information on how to interpret these results, see “Verbose Display” on page 33-2111.

```
options = struct('UseParallel',true);
autoMdl = fitrauto(carsTrain,'MPG','OptimizeHyperparameters','all', ...
    'HyperparameterOptimizationOptions',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
Copying objective function to workers...
Done copying objective function to workers.
Learner types to explore: ensemble, svm, tree
Total iterations (MaxObjectiveEvaluations): 90
Total time (MaxTime): Inf
```

__________________________________________________________
Optimization completed.
Total iterations: 91
Total elapsed time: 235.4082 seconds
Total time for training and validation: 426.1606 seconds

Best observed learner is an ensemble model with:
    Method:             LSBoost
    LearnRate:         0.079786
    MinLeafSize:             16
    NumVariablesToSample:   NaN
Observed log(1 + valLoss): 2.1839
Time for training and validation: 5.4291 seconds

Best estimated learner (returned model) is an ensemble model with:
    Method:             LSBoost
    LearnRate:         0.079786
    MinLeafSize:             16
    NumVariablesToSample:   NaN
Estimated log(1 + valLoss): 2.1981
Estimated time for training and validation: 5.3328 seconds

Documentation for fitrauto display
```

The final model returned by `fitrauto` corresponds to the best estimated learner. Before returning the model, the function retrains it using the entire training data (`carsTrain`), the listed `Learner` (or model) type, and the displayed hyperparameter values.

Create Simple Model

Create a simple linear regression model `linearMdl` by using the `fitlm` function.

```
linearMdl = fitlm(carsTrain);
```

Although the `linearMdl` object does not have the exact same properties and methods as the `autoMdl` object, you can use both models to predict response values for new data by using the `predict` object function.

Compare Test Set Performance of Models

Compare the performance of the `linearMdl` and `autoMdl` models on the test data set. For each model, compute the test set mean squared error (MSE). Smaller MSE values indicate better performance.

```
ypred = predict(linearMdl,carsTest);
linearMSE = mean((carsTest.MPG-ypred).^2,'omitnan')
```

```
linearMSE = 11.0981
```

```
autoMSE = loss(autoMdl,carsTest,'MPG')
```

```
autoMSE = 8.8024
```

The `autoMdl` model seems to outperform the `linearMdl` model.

Input Arguments

`Tbl` — Sample data

table

Sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not accepted.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, specify a formula using `formula`.

If `Tbl` does not contain the response variable, specify a response variable using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training a model.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables

character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

Y — Response data
numeric vector

Response data, specified as a numeric vector. The length of `Y` must be equal to the number of rows in `Tbl` or `X`.

To specify the response variable name, use the `ResponseName` name-value pair argument.

Data Types: `single` | `double`

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation, and each column corresponds to one predictor.

The length of `Y` and the number of rows in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Note The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing data. The software removes rows of data corresponding to missing values in the response variable. However, the treatment of missing values in the predictor data `X` or `Tbl` varies among models (or learners).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',200,'Verbose',2)` specifies to run 200 iterations of the optimization process (that is, try 200 model hyperparameter combinations), and to display information in the Command Window about the next model hyperparameter combination to be evaluated.

Optimizer Options

Learners — Types of regression models

'auto' (default) | 'all' | 'all-linear' | 'all-nonlinear' | one or more learner names

Types of regression models to try during the optimization, specified as the comma-separated pair consisting of 'Learners' and a value in the first table below or one or more learner names in the second table. Specify multiple learner names as a string or cell array.

Value	Description
'auto'	fitrauto automatically selects a subset of learners, suitable for the given predictor and response data. The learners can have model hyperparameter values that differ from the default. For more information, see "Automatic Selection of Learners" on page 33-2113.
'all'	fitrauto selects all possible learners.
'all-linear'	fitrauto selects linear ('linear') learners.
'all-nonlinear'	fitrauto selects all nonlinear learners: 'ensemble', 'gp', 'kernel', 'svm' (with a Gaussian or polynomial kernel), and 'tree'.

Note For greater efficiency, fitrauto does not select the following combinations of models when you specify one of the previous values.

- 'kernel' and 'svm' (with a Gaussian kernel) — fitrauto chooses the first when the predictor data has more than 11,000 observations, and the second otherwise.
- 'linear' and 'svm' (with a linear kernel) — fitrauto chooses the first.

Learner Name	Description
'ensemble'	Ensemble regression model
'gp'	Gaussian process regression model
'kernel'	Kernel regression model
'linear'	Linear regression model for high-dimensional data
'svm'	Support vector machine regression model
'tree'	Binary decision regression tree

Example: 'Learners','all'

Example: 'Learners','ensemble'

Example: 'Learners',{'gp','svm'}

OptimizeHyperparameters — Hyperparameters to optimize

'auto' (default) | 'all'

Hyperparameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and 'auto' or 'all'. The optimizable hyperparameters depend on the model (or learner), as described in this table.

Learner Name	Hyperparameters for 'auto'	Additional Hyperparameters for 'all'	Notes
'ensemble'	Method, NumLearningCycles, LearnRate, MinLeafSize	MaxNumSplits, NumVariablesToSample	When the ensemble Method value is a boosting method, the ensemble NumBins value is 50. For more information, including hyperparameter search ranges, see OptimizeHyperparameters. Note that you cannot change hyperparameter search ranges when you use fitrauto.
'gp'	Sigma	BasisFunction, KernelFunction, KernelScale (KernelParameters), Standardize	The fitrauto function ignores all ARD kernel options and, therefore, chooses among the KernelFunction values of 'exponential', 'matern32', 'matern52', 'rationalquadratic', and 'squaredexponential' when the OptimizeHyperparameters value is 'all'. For more information, including hyperparameter search ranges, see OptimizeHyperparameters. Note that you cannot change hyperparameter search ranges when you use fitrauto.
'kernel'	Epsilon, KernelScale, Lambda	Learner, NumExpansionDimensions	For more information, including hyperparameter search ranges, see OptimizeHyperparameters. Note that you cannot change hyperparameter search ranges when you use fitrauto.

Learner Name	Hyperparameters for 'auto'	Additional Hyperparameters for 'all'	Notes
'linear'	Lambda, Learner	Regularization	For more information, including hyperparameter search ranges, see OptimizeHyperparameters. Note that you cannot change hyperparameter search ranges when you use fitrauto.
'svm'	BoxConstraint, Epsilon, KernelScale	KernelFunction, PolynomialOrder, Standardize	• When the Learners value is 'all-linear', the fitrauto function does not optimize the KernelFunction or PolynomialOrder hyperparameters when the OptimizeHyperparameters value is 'all'. • When the Learners value is 'all-nonlinear', the fitrauto function chooses among the KernelFunction values of 'gaussian' and 'polynomial', regardless of the OptimizeHyperparameters value. • The Standardize value is true when the OptimizeHyperparameters value is 'auto'. For more information, including hyperparameter search ranges, see OptimizeHyperparameters. Note that you cannot change hyperparameter search ranges when you use fitrauto.

Learner Name	Hyperparameters for 'auto'	Additional Hyperparameters for 'all'	Notes
'tree'	MinLeafSize	MaxNumSplits	For more information, including hyperparameter search ranges, see OptimizeHyperparameters. Note that you cannot change hyperparameter search ranges when you use fitrauto.

Note When 'Learners' is set to a value other than 'auto', the default values for the model hyperparameters not being optimized match the default fit function values, unless otherwise indicated in the table notes. When 'Learners' is set to 'auto', the optimized hyperparameter search ranges and nonoptimized hyperparameter values can vary, depending on the characteristics of the training data. For more information, see "Automatic Selection of Learners" on page 33-2113.

Example: 'OptimizeHyperparameters','all'

HyperparameterOptimizationOptions — Options for optimization
structure

Options for the optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. All fields in the structure are optional.

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of iterations (objective function evaluations)	30*L, where L is the number of learners (see Learners)
MaxTime	Time limit, specified as a positive real number. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best observed and estimated objective function values (so far) against the iteration number.	true
SaveIntermediateResults	Logical value indicating whether to save results. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
`Verbose`	Display at the command line: • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with additional information about the next point to be evaluated	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Specify only one of the following three options.		
`CVPartition`	`cvpartition` object, created by `cvpartition`	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	Scalar in the range `(0,1)` representing the holdout fraction	
`Kfold`	Integer greater than 1	

Example: `'HyperparameterOptimizationOptions',struct('UseParallel',true)`

Regression Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitrauto` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrauto` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. However, learners that use decision trees assume that mathematically ordered categorical vectors are continuous variables. If the predictor data is a matrix (`X`), `fitrauto` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value pair argument.

For more information on how fitting functions treat categorical predictors, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`PredictorNames` — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitrauto` uses only the predictor variables in `PredictorNames` and the response variable during training.

- `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
- By default, `PredictorNames` contains the names of all predictor variables.
- A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`Weights` — Observation weights
positive numeric vector | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a positive numeric vector or the name of a variable in `Tbl`. The software weights each observation in `X` or `Tbl` with the corresponding value in `Weights`. The length of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response variable when training the model.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

The software normalizes `Weights` to sum to 1.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`Mdl` — Trained regression model
regression model object

Trained regression model, returned as one of the regression model objects in this table.

Learner Name	Returned Model Object
`'ensemble'`	`CompactRegressionEnsemble`
`'gp'`	`CompactRegressionGP`

Learner Name	Returned Model Object
'kernel'	RegressionKernel
'linear'	RegressionLinear
'svm'	CompactRegressionSVM
'tree'	CompactRegressionTree

OptimizationResults — Optimization results
BayesianOptimization object

Optimization results, returned as a BayesianOptimization object. For more information on the Bayesian optimization process, see “Bayesian Optimization” on page 33-2113.

More About

Verbose Display

When you set the Verbose field of the HyperparameterOptimizationOptions name-value pair argument to 1 or 2, the fitrauto function provides an iterative display of the optimization results.

The following table describes the columns in the display and their entries.

Column Name	Description
Iter	Iteration number — You can set a limit to the number of iterations by using the MaxObjectiveEvaluations field of the 'HyperparameterOptimizationOptions' name-value pair argument.
Active workers	Number of active parallel workers — This column appears only when you run the optimization in parallel by setting the UseParallel field of the 'HyperparameterOptimizationOptions' name-value pair argument to true.
Eval result	One of the following evaluation results: • Best — The learner and hyperparameter values at this iteration give the minimum observed validation loss computed so far. That is, the log(1 + valLoss) value is the smallest computed so far. • Accept — The learner and hyperparameter values at this iteration give meaningful (for example, non-NaN) observed and estimated validation loss values. • Error — The learner and hyperparameter values at this iteration result in an error (for example, a log(1 + valLoss) value of NaN).

Column Name	Description
`log(1 + valLoss)`	Log-transformed validation loss computed for the learner and hyperparameter values at this iteration — In particular, `fitrauto` computes log(1 + *valLoss*), where *valLoss* is the cross-validation mean squared error (MSE) by default. You can change the validation scheme by using the `CVPartition`, `Holdout`, or `Kfold` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.
`Time for training & validation (sec)`	Time taken to train and compute the validation loss for the model with the learner and hyperparameter values at this iteration (in seconds) — In particular, this value excludes the time required to update the objective function model maintained by the Bayesian optimization process. For more details, see “Bayesian Optimization” on page 33-2113.
`Observed min log(1 + valLoss)`	Observed minimum log-transformed validation loss computed so far — This value corresponds to the smallest `log(1 + valLoss)` value computed so far in the optimization process. By default, `fitrauto` returns a plot of the optimization that displays dark blue points for the observed minimum log-transformed validation loss values. This plot does not appear when the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument is set to `false`.
`Estimated min log(1 + valLoss)`	Estimated minimum log-transformed validation loss — At each iteration, `fitrauto` updates an objective function model maintained by the Bayesian optimization process and uses this model to estimate the minimum log-transformed validation loss. For more details, see “Bayesian Optimization” on page 33-2113. By default, `fitrauto` returns a plot of the optimization that displays light blue points for the estimated minimum log-transformed validation loss values. This plot does not appear when the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument is set to `false`.
`Learner`	Model type evaluated at this iteration — Specify the learners used in the optimization by using the `'Learners'` name-value pair argument.

Column Name	Description
`Hyperparameter: Value`	Hyperparameter values at this iteration — Specify the hyperparameters used in the optimization by using the `'OptimizeHyperparameters'` name-value pair argument.

The display also includes a description of two models:

- `Best observed learner` — This model, with the listed learner type and hyperparameter values, yields the final observed minimum validation loss (log-transformed).
- `Best estimated learner` — This model, with the listed learner type and hyperparameter values, yields the final estimated minimum validation loss (log-transformed). `fitrauto` retrains the model on the entire training data set and returns it as the `Mdl` output.

Tips

- Depending on the size of your data and the number of learners you specify, `fitrauto` can take some time to run. If you have a Parallel Computing Toolbox license, you can speed up computations by running the optimization in parallel. To do so, specify `'HyperparameterOptimizationOptions',struct('UseParallel',true)`. You can include other fields in the structure to control other aspects of the optimization. See `HyperparameterOptimizationOptions`.

Algorithms

Automatic Selection of Learners

When you specify `'Learners','auto'`, the `fitrauto` function analyzes the predictor and response data in order to choose appropriate learners. The function considers whether the data set has any of these characteristics:

- Categorical predictors
- Missing values for more than 5% of the data
- Wide data, where the number of predictors is greater than or equal to the number of observations
- High-dimensional data, where the number of predictors is greater than 100
- Large data, where the number of observations is greater than 50,000

The selected learners are always a subset of those listed in the `Learners` table. However, the associated models tried during the optimization process can have different default values for hyperparameters not being optimized, as well as different search ranges for hyperparameters being optimized.

Bayesian Optimization

The goal of Bayesian optimization, and optimization in general, is to find a point that minimizes an objective function. In the context of `fitrauto`, a point is a learner type together with a set of hyperparameter values for the learner (see `Learners` and `OptimizeHyperparameters`), and the objective function is log(1 + *valLoss*), where *valLoss* is the cross-validation mean squared error (MSE), by default. The Bayesian optimization implemented in `fitrauto` internally maintains a multi-

RegressionGP model of the objective function. That is, the objective function model splits along the learner type and, for a given learner, the model is a Gaussian process regression (GPR) model. (This underlying model differs from the single GPR model employed by other Statistics and Machine Learning Toolbox functions that use Bayesian optimization.) Bayesian optimization trains the underlying model by using objective function evaluations, and determines the next point to evaluate by using an acquisition function ('expected-improvement'). For more information, see "Expected Improvement" on page 10-4. The acquisition function balances between sampling at points with low modeled objective function values and exploring areas that are not well modeled yet. At the end of the optimization, fitrauto chooses the point with the minimum objective function model value, among the points evaluated during the optimization. For more information, see the 'Criterion','min-visited-mean' name-value pair argument of bestPoint.

Alternative Functionality

- If you are unsure which models work best for your data set, you can alternatively use the **Regression Learner** app. Using the app, you can perform hyperparameter tuning for different models, and choose the optimized model that performs best. Although you must select a specific model before you can tune the model hyperparameters, **Regression Learner** provides greater flexibility for selecting optimizable hyperparameters and setting hyperparameter values. The app also allows you to train a variety of linear regression models (see "Linear Regression Models" on page 24-14). However, you cannot optimize in parallel, choose 'linear' or 'kernel' learners, or specify observation weights in the app. For more information, see "Hyperparameter Optimization in Regression Learner App" on page 24-30.
- If you know which models might suit your data, you can alternatively use the corresponding model fit functions and specify the 'OptimizeHyperparameters' name-value pair argument to tune hyperparameters. You can compare the results across the models to select the best regression model. For an example of this process applied to classification models, see "Moving Towards Automating Model Selection Using Bayesian Optimization" on page 18-197.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptimizationOptions',struct('UseParallel',true) name-value pair argument in the call to this function.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

Introduced in R2020b

fitrgam

Fit generalized additive model (GAM) for regression

Syntax

```
Mdl = fitrgam(Tbl,ResponseVarName)
Mdl = fitrgam(Tbl,formula)
Mdl = fitrgam(Tbl,Y)
Mdl = fitrgam(X,Y)
Mdl = fitrgam(___,Name,Value)
```

Description

`Mdl = fitrgam(Tbl,ResponseVarName)` returns a generalized additive model on page 33-2133 `Mdl` trained using the sample data contained in the table `Tbl`. The input argument `ResponseVarName` is the name of the variable in `Tbl` that contains the response values for regression.

`Mdl = fitrgam(Tbl,formula)` uses the model specification argument `formula` to specify the response variable and predictor variables in `Tbl`. You can specify a subset of predictor variables and interaction terms for predictor variables by using `formula`.

`Mdl = fitrgam(Tbl,Y)` uses the predictor variables in the table `Tbl` and the response values in the vector `Y`.

`Mdl = fitrgam(X,Y)` uses the predictors in the matrix `X` and the response values in the vector `Y`.

`Mdl = fitrgam(___,Name,Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in the previous syntaxes. For example, `'Interactions',5` specifies to include five interaction terms in the model. You can also specify a list of interaction terms using the `'Interactions'` name-value argument.

Examples

Train Generalized Additive Model

Train a univariate GAM, which contains linear terms for predictors. Then, interpret the prediction for a specified data instance by using the `plotLocalEffects` function.

Load the data set `NYCHousing2015`.

```
load NYCHousing2015
```

The data set includes 10 variables with information on the sales of properties in New York City in 2015. This example uses these variables to analyze the sale prices (`SALEPRICE`).

Preprocess the data set. Remove outliers, convert the `datetime` array (`SALEDATE`) to the month numbers, and move the response variable (`SALEPRICE`) to the last column.

```
idx = isoutlier(NYCHousing2015.SALEPRICE);
NYCHousing2015(idx,:) = [];
NYCHousing2015.SALEDATE = month(NYCHousing2015.SALEDATE);
NYCHousing2015 = movevars(NYCHousing2015,'SALEPRICE','After','SALEDATE');
```

Display the first three rows of the table.

```
head(NYCHousing2015,3)
```

```
ans=3×10 table
    BOROUGH    NEIGHBORHOOD       BUILDINGCLASSCATEGORY        RESIDENTIALUNITS    COMMERCIALUNI
    _______    ____________    ___________________________    ________________    _____________

       2       {'BATHGATE'}    {'01  ONE FAMILY DWELLINGS'}           1                   0
       2       {'BATHGATE'}    {'01  ONE FAMILY DWELLINGS'}           1                   0
       2       {'BATHGATE'}    {'01  ONE FAMILY DWELLINGS'}           1                   1
```

Train a univariate GAM for the sale prices. Specify the variables for `BOROUGH`, `NEIGHBORHOOD`, `BUILDINGCLASSCATEGORY`, and `SALEDATE` as categorical predictors.

```
Mdl = fitrgam(NYCHousing2015,'SALEPRICE','CategoricalPredictors',[1 2 3 9])
```

```
Mdl =
  RegressionGAM
           PredictorNames: {1x9 cell}
             ResponseName: 'SALEPRICE'
    CategoricalPredictors: [1 2 3 9]
        ResponseTransform: 'none'
                Intercept: 3.7518e+05
          NumObservations: 83517

  Properties, Methods
```

`Mdl` is a `RegressionGAM` model object. The model display shows a partial list of the model properties. To view the full list of properties, double-click the variable name `Mdl` in the Workspace. The Variables editor opens for `Mdl`. Alternatively, you can display the properties in the Command Window by using dot notation. For example, display the estimated intercept (constant) term of `Mdl`.

```
Mdl.Intercept
```

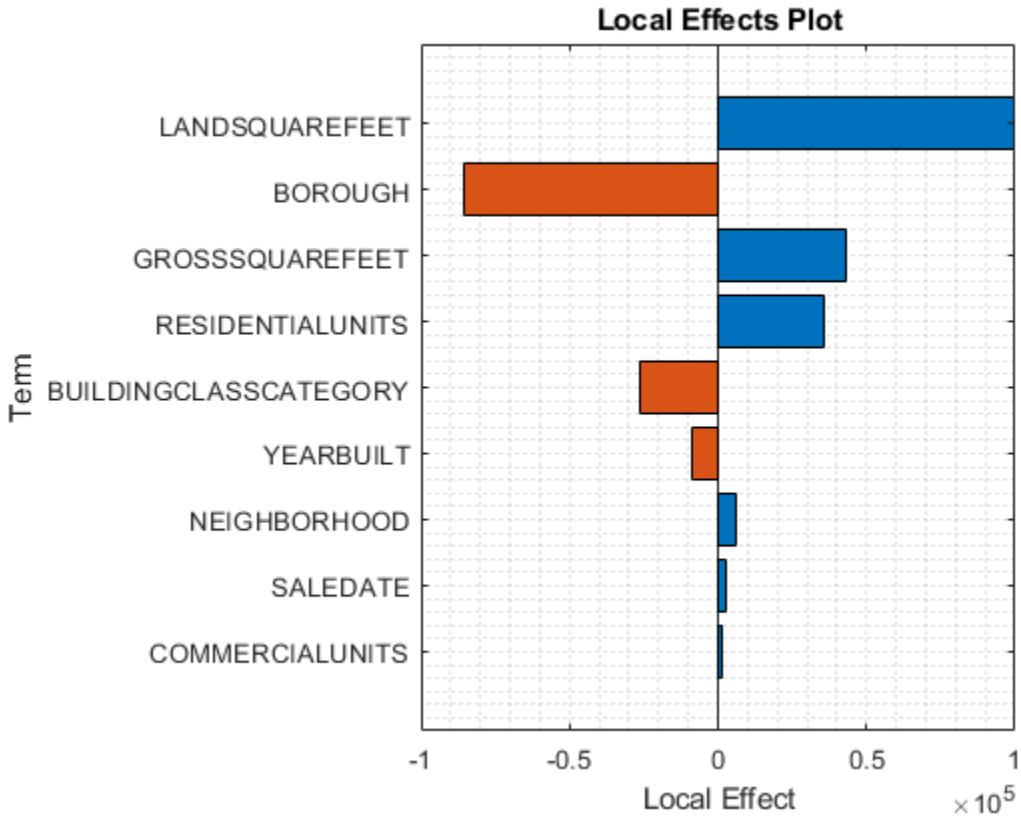
```
ans = 3.7518e+05
```

Predict the sale price for the first observation of the training data, and plot the local effects of the terms in `Mdl` on the prediction.

```
yFit = predict(Mdl,NYCHousing2015(1,:))
```

```
yFit = 4.4421e+05
```

```
plotLocalEffects(Mdl,NYCHousing2015(1,:))
```



The `predict` function predicts the sale price for the first observation as `4.4421e5`. The `plotLocalEffects` function creates a horizontal bar graph that shows the local effects of the terms in `Mdl` on the prediction. Each local effect value shows the contribution of each term to the predicted sale price.

Train GAM with Interaction Terms

Train a generalized additive model that contains linear and interaction terms for predictors in three different ways:

- Specify the interaction terms using the `formula` input argument.
- Specify the `'Interactions'` name-value argument.
- Build a model with linear terms first and add interaction terms to the model by using the `addInteractions` function.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table that contains the predictor variables (`Acceleration`, `Displacement`, `Horsepower`, and `Weight`) and the response variable (`MPG`).

```
tbl = table(Acceleration,Displacement,Horsepower,Weight,MPG);
```

Specify formula

Train a GAM that contains the four linear terms (Acceleration, Displacement, Horsepower, and Weight) and two interaction terms (Acceleration*Displacement and Displacement*Horsepower). Specify the terms using a formula in the form 'Y ~ terms'.

```
Mdl1 = fitrgam(tbl,'MPG ~ Acceleration + Displacement + Horsepower + Weight + Acceleration:Displa
```

The function adds interaction terms to the model in the order of importance. You can use the Interactions property to check the interaction terms in the model and the order in which fitrgam adds them to the model. Display the Interactions property.

```
Mdl1.Interactions
```

```
ans = 2×2

     2     3
     1     2
```

Each row of Interactions represents one interaction term and contains the column indexes of the predictor variables for the interaction term.

Specify 'Interactions'

Pass the training data (tbl) and the name of the response variable in tbl to fitrgam, so that the function includes the linear terms for all the other variables as predictors. Specify the 'Interactions' name-value argument using a logical matrix to include the two interaction terms, x1*x2 and x2*x3.

```
Mdl2 = fitrgam(tbl,'MPG','Interactions',logical([1 1 0 0; 0 1 1 0]));
Mdl2.Interactions
```

```
ans = 2×2

     2     3
     1     2
```

You can also specify 'Interactions' as the number of interaction terms or as 'all' to include all available interaction terms. Among the specified interaction terms, fitrgam identifies those whose *p*-values are not greater than the 'MaxPValue' value and adds them to the model. The default 'MaxPValue' is 1 so that the function adds all specified interaction terms to the model.

Specify 'Interactions','all' and set the 'MaxPValue' name-value argument to 0.05.

```
Mdl3 = fitrgam(tbl,'MPG','Interactions','all','MaxPValue',0.05);
```

```
Warning: Model does not include interaction terms because all interaction terms have p-values gre
```

```
Mdl3.Interactions
```

```
ans =

  0x2 empty double matrix
```

Mdl3 includes no interaction terms, which implies one of the following: all interaction terms have *p*-values greater than 0.05, or adding the interaction terms does not improve the model fit.

Use `addInteractions` Function

Train a univariate GAM that contains linear terms for predictors, and then add interaction terms to the trained model by using the `addInteractions` function. Specify the second input argument of `addInteractions` in the same way you specify the `'Interactions'` name-value argument of `fitrgam`. You can specify the list of interaction terms using a logical matrix, the number of interaction terms, or `'all'`.

Specify the number of interaction terms as 3 to add the three most important interaction terms to the trained model.

```
Mdl4 = fitrgam(tbl,'MPG');
UpdatedMdl4 = addInteractions(Mdl4,3);
UpdatedMdl4.Interactions
```

```
ans = 3×2

     2     3
     1     2
     3     4
```

`Mdl4` is a univariate GAM, and `UpdatedMdl4` is an updated GAM that contains all the terms in `Mdl4` and three additional interaction terms.

Create Cross-Validated GAM Using `fitrgam`

Train a cross-validated GAM with 10 folds, which is the default cross-validation option, by using `fitrgam`. Then, use `kfoldPredict` to predict responses for validation-fold observations using a model trained on training-fold observations.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table that contains the predictor variables (`Acceleration`, `Displacement`, `Horsepower`, and `Weight`) and the response variable (`MPG`).

```
tbl = table(Acceleration,Displacement,Horsepower,Weight,MPG);
```

Create a cross-validated GAM by using the default cross-validation option. Specify the `'CrossVal'` name-value argument as `'on'`.

```
rng('default') % For reproducibility
CVMdl = fitrgam(tbl,'MPG','CrossVal','on')
```

```
CVMdl =
  RegressionPartitionedGAM
    CrossValidatedModel: 'GAM'
         PredictorNames: {1x4 cell}
           ResponseName: 'MPG'
        NumObservations: 398
                  KFold: 10
              Partition: [1x1 cvpartition]
      NumTrainedPerFold: [1x1 struct]
      ResponseTransform: 'none'
```

```
  Properties, Methods
```

The `fitrgam` function creates a `RegressionPartitionedGAM` model object `CVMdl` with 10 folds. During cross-validation, the software completes these steps:

1. Randomly partition the data into 10 sets.
2. For each set, reserve the set as validation data, and train the model using the other 9 sets.
3. Store the 10 compact, trained models a in a 10-by-1 cell vector in the `Trained` property of the cross-validated model object `RegressionPartitionedGAM`.

You can override the default cross-validation setting by using the `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'` name-value argument.

Predict responses for the observations in `tbl` by using `kfoldPredict`. The function predicts responses for every observation using the model trained without that observation.

```
yHat = kfoldPredict(CVMdl);
```

`yHat` is a numeric vector. Display the first five predicted responses.

```
yHat(1:5)
```

```
ans = 5×1

   19.4848
   15.7203
   15.5742
   15.3185
   17.8223
```

Compute the regression loss (mean squared error).

```
L = kfoldLoss(CVMdl)
```

```
L = 17.7248
```

`kfoldLoss` returns the average mean squared error over 10 folds.

Optimize Cross-Validated GAM Using bayesopt

Optimize the parameters of a GAM with respect to cross-validation by using the `bayesopt` function.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Specify `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Acceleration,Displacement,Horsepower,Weight];
Y = MPG;
```

Prepare `optimizableVariable` objects for the name-value arguments that you want to optimize using Bayesian optimization. This example finds optimal values for the `MaxNumSplitsPerPredictor` and `NumTreesPerPredictor` arguments of `fitrgam`.

```
maxNumSplits = optimizableVariable('maxNumSplits',[1,10],'Type','integer');
numTrees = optimizableVariable('numTrees',[1,500],'Type','integer');
```

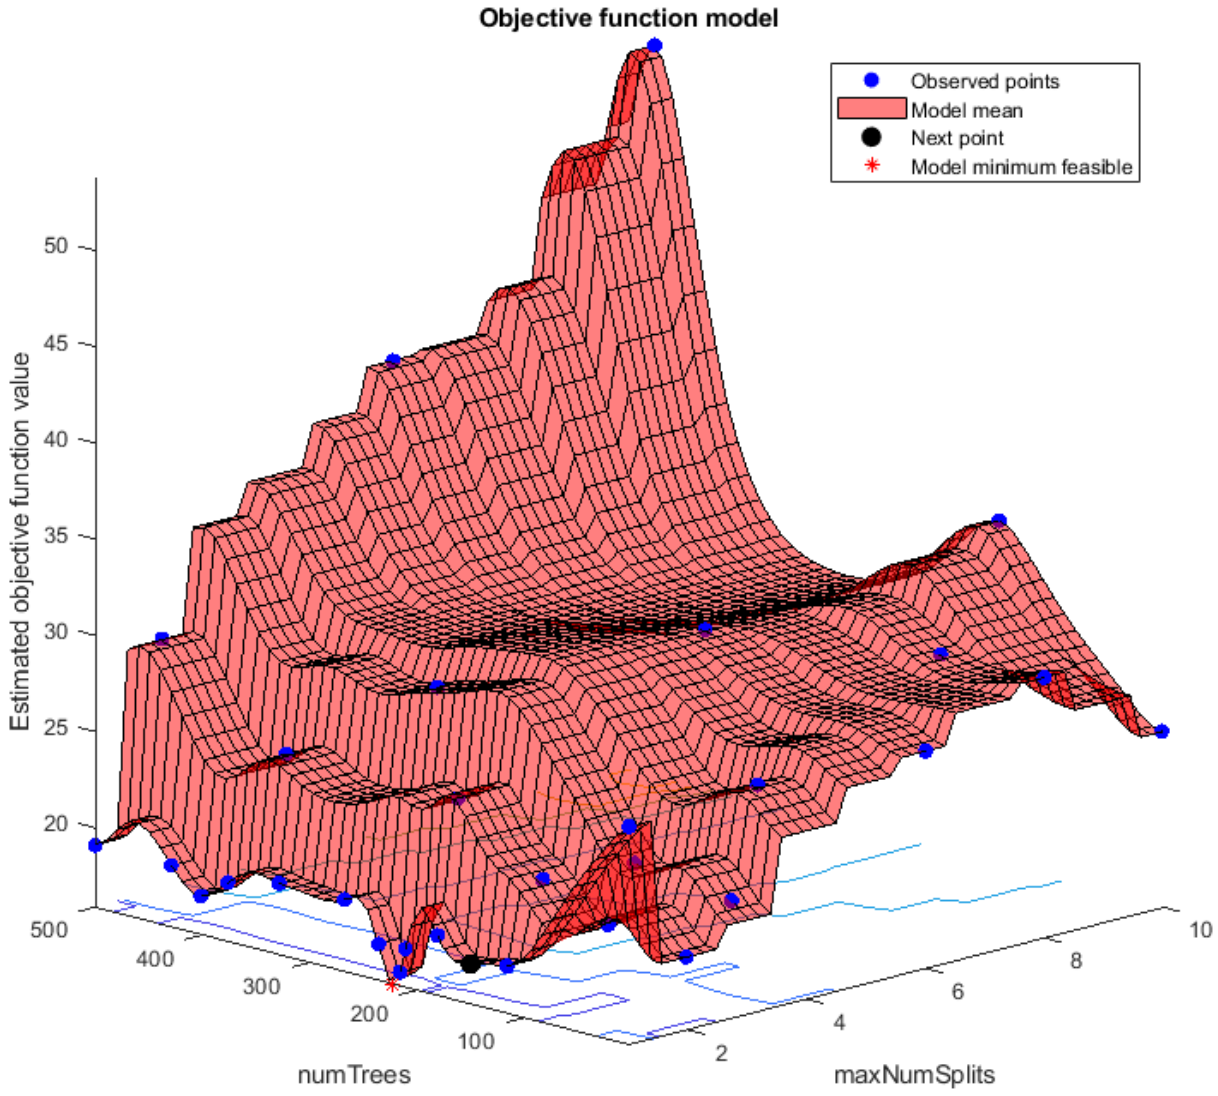
Create an objective function that takes an input `z = [maxNumSplits,numTrees]` and returns the cross-validated loss value of `z`.

```
minfun = @(z)kfoldLoss(fitrgam(X,Y,'CrossVal','on', ...
    'MaxNumSplitsPerPredictor',z.maxNumSplits, ...
    'NumTreesPerPredictor',z.numTrees));
```

If you specify the cross-validation option (`'CrossVal','on'`), then the `fitrgam` function returns a cross-validated model object `RegressionPartitionedGAM`. The `kfoldLoss` function returns the regression loss (mean squared error) obtained by the cross-validated model. Therefore, the function handle `minfun` computes the cross-validation loss at the parameters in `z`.

Search for the best parameters `[maxNumSplits,numTrees]` using `bayesopt`. For reproducibility, choose the `'expected-improvement-plus'` acquisition function. The default acquisition function depends on run time and, therefore, can give varying results.

```
rng('default')
results = bayesopt(minfun,[maxNumSplits,numTrees],'Verbose',0, ...
    'IsObjectiveDeterministic',true, ...
    'AcquisitionFunctionName','expected-improvement-plus');
```



Objective function model

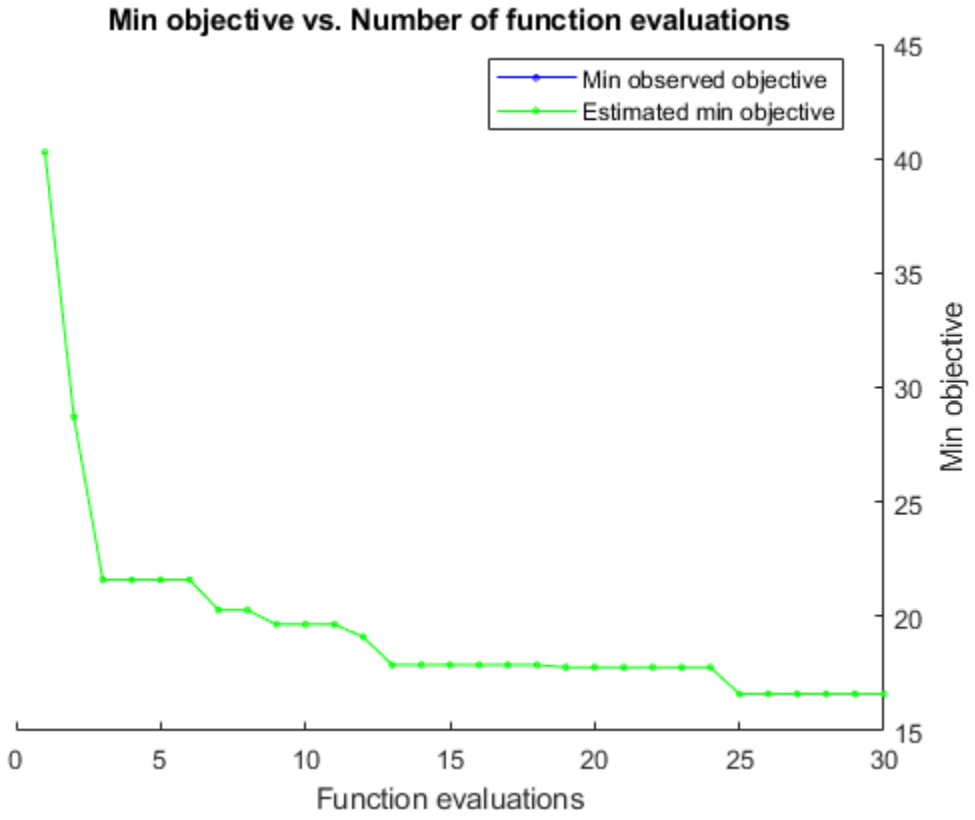
maxNumSplits



Obtain the best point from `results`.

```
zbest = bestPoint(results)
```

```
zbest=1×2 table
    maxNumSplits    numTrees
    ____________    ________

          1             215
```

Train an optimized GAM using the `zbest` values.

```
Mdl = fitrgam(X,Y, ...
    'MaxNumSplitsPerPredictor',zbest.maxNumSplits, ...
    'NumTreesPerPredictor',zbest.numTrees);
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- Optionally, `Tbl` can contain a column for the response variable and a column for the observation weights. The response variable and the weight values must be numeric vectors.

  You must specify the response variable in `Tbl` by using `ResponseVarName` or `formula` and specify the observation weights in `Tbl` by using `'Weights'`.

  - Specify the response variable by using `ResponseVarName` — `fitrgam` uses the remaining variables as predictors. To use a subset of the remaining variables in `Tbl` as predictors, specify predictor variables by using `'PredictorNames'`.
  - Define a model specification by using `formula` — `fitrgam` uses a subset of the variables in `Tbl` as predictor variables and the response variable, as specified in `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable `Y` and the number of rows in `Tbl` must be equal. To use a subset of the variables in `Tbl` as predictors, specify predictor variables by using `'PredictorNames'`.

`fitrgam` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Tbl` to be missing values.

- `fitrgam` does not use observations with all missing values in the fit.
- `fitrgam` does not use observations with missing response values in the fit.
- `fitrgam` uses observations with some missing values for predictors to find splits on variables for which these observations have valid values.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as a character vector or string scalar containing the name of the response variable in `Tbl`. For example, if the response variable `Y` is stored in `Tbl.Y`, then specify it as `'Y'`.

Data Types: `char` | `string`

`formula` — Model specification
character vector | string scalar

Model specification, specified as a character vector or string scalar in the form `'Y ~ terms'`. The `formula` argument specifies a response variable and linear and interaction terms for predictor variables. Use `formula` to specify a subset of variables in `Tbl` as predictors for training the model. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

For example, specify `'Y~x1+x2+x3+x1:x2'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the linear terms for the predictor variables. `x1:x2` represents the interaction term for `x1` and `x2`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Alternatively, you can specify a response variable and linear terms for predictors using `formula`, and specify interaction terms for predictors using `'Interactions'`.

`fitrgam` builds a set of interaction trees using only the terms whose *p*-values are not greater than the `'MaxPValue'` value.

Example: `'Y~x1+x2+x3+x1:x2'`

Data Types: `char` | `string`

Y — Response data

numeric column vector

Response data, specified as a numeric column vector. Each entry in `Y` is the response to the data in the corresponding row of `X` or `Tbl`.

The software considers `NaN` values in `Y` to be missing values. `fitrgam` does not use observations with missing response values in the fit.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

`fitrgam` considers `NaN` values in `X` as missing values. The function does not use observations with all missing values in the fit. `fitrgam` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Interactions','all','MaxPValue',0.05` specifies to include all available interaction terms whose *p*-values are not greater than 0.05.

GAM Options

InitialLearnRateForInteractions — Initial learning rate of gradient boosting for interaction terms

1 (default) | numeric scalar in (0,1]

Initial learning rate of gradient boosting for interaction terms, specified as a numeric scalar in the interval (0,1].

For each boosting iteration for interaction trees, `fitrgam` starts fitting with the initial learning rate. The function halves the learning rate until it finds a rate that improves the model fit.

Training a model using a small learning rate requires more learning iterations, but often achieves better accuracy.

For more details about gradient boosting, see “Gradient Boosting Algorithm” on page 33-2134.

Example: `'InitialLearnRateForInteractions',0.1`

Data Types: `single` | `double`

`InitialLearnRateForPredictors` — Initial learning rate of gradient boosting for linear terms
`1` (default) | numeric scalar in (0,1]

Initial learning rate of gradient boosting for linear terms, specified as a numeric scalar in the interval (0,1].

For each boosting iteration for predictor trees, `fitrgam` starts fitting with the initial learning rate. The function halves the learning rate until it finds a rate that improves the model fit.

Training a model using a small learning rate requires more learning iterations, but often achieves better accuracy.

For more details about gradient boosting, see “Gradient Boosting Algorithm” on page 33-2134.

Example: `'InitialLearnRateForPredictors',0.1`

Data Types: `single` | `double`

`Interactions` — Number or list of interaction terms
`0` (default) | nonnegative integer scalar | logical matrix | `'all'`

Number or list of interaction terms to include in the candidate set *S*, specified as a nonnegative integer scalar, a logical matrix, or `'all'`.

- Number of interaction terms, specified as a nonnegative integer — *S* includes the specified number of important interaction terms, selected based on the *p*-values of the terms.
- List of interaction terms, specified as a logical matrix — *S* includes the terms specified by a `t`-by-`p` logical matrix, where `t` is the number of interaction terms, and `p` is the number of predictors used to train the model. For example, `logical([1 1 0; 0 1 1])` represents two pairs of interaction terms: a pair of the first and second predictors, and a pair of the second and third predictors.

  If `fitrgam` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. That is, the column indexes of the logical matrix do not count the response and observation weight variables. The indexes also do not count any variables not used by the function.
- `'all'` — *S* includes all possible pairs of interaction terms, which is `p*(p − 1)/2` number of terms in total.

Among the interaction terms in *S*, the `fitrgam` function identifies those whose *p*-values are not greater than the `'MaxPValue'` value and uses them to build a set of interaction trees. Use the default value (`'MaxPValue'`,1) to build interaction trees using all terms in *S*.

Example: `'Interactions','all'`

Data Types: `single` | `double` | `logical` | `char` | `string`

`MaxNumSplitsPerInteraction` — Maximum number of decision splits per interaction tree
4 (default) | positive integer scalar

Maximum number of decision splits (or branch nodes) for each interaction tree (boosted tree for an interaction term), specified as a positive integer scalar.

Example: `'MaxNumSplitsPerInteraction',5`

Data Types: `single` | `double`

`MaxNumSplitsPerPredictor` — Maximum number of decision splits per predictor tree
1 (default) | positive integer scalar

Maximum number of decision splits (or branch nodes) for each predictor tree (boosted tree for a linear term), specified as a positive integer scalar. By default, `fitrgam` uses a tree stump for a predictor tree.

Example: `'MaxNumSplitsPerPredictor',5`

Data Types: `single` | `double`

`MaxPValue` — Maximum *p*-value for detecting interaction terms
1 (default) | numeric scalar in [0,1]

Maximum *p*-value for detecting interaction terms, specified as a numeric scalar in the interval [0,1].

`fitrgam` first finds the candidate set *S* of interaction terms from `formula` or `'Interactions'`. Then the function identifies the interaction terms whose *p*-values are not greater than the `'MaxPValue'` value and uses them to build a set of interaction trees.

The default value (`'MaxPValue',1`) builds interaction trees for all interaction terms in the candidate set *S*.

For more details about detecting interaction terms, see “Interaction Term Detection” on page 33-2135.

Example: `'MaxPValue',0.05`

Data Types: `single` | `double`

`NumBins` — Number of bins for numeric predictors
`256` (default) | positive integer scalar | `[]` (empty)

Number of bins for numeric predictors, specified as a positive integer scalar or `[]` (empty).

- If you specify the `'NumBins'` value as a positive integer scalar (`numBins`), then `fitrgam` bins every numeric predictor into at most `numBins` equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - The number of bins can be less than `numBins` if a predictor has fewer than `numBins` unique values.
  - `fitrgam` does not bin categorical predictors.
- If the `'NumBins'` value is empty (`[]`), then `fitrgam` does not bin any predictors.

When you use a large training data set, this binning option speeds up training but might cause a decrease in accuracy. You can first use the default value of `'NumBins'`, and then change the value depending on the accuracy and training speed.

The trained model `Mdl` stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single` | `double`

`NumTreesPerInteraction` — Number of trees per interaction term
100 (default) | positive integer scalar

Number of trees per interaction term, specified as a positive integer scalar.

The `'NumTreesPerInteraction'` value is equivalent to the number of gradient boosting iterations for the interaction terms for predictors. For each iteration, `fitrgam` adds a set of interaction trees to the model, one tree for each interaction term. To learn about the gradient boosting algorithm, see “Gradient Boosting Algorithm” on page 33-2134.

You can determine whether the fitted model has the specified number of trees by viewing the diagnostic message displayed when `'Verbose'` is 1 or 2, or by checking the `ReasonForTermination` property value of the model `Mdl`.

Example: `'NumTreesPerInteraction',500`

Data Types: `single` | `double`

`NumTreesPerPredictor` — Number of trees per linear term
300 (default) | positive integer scalar

Number of trees per linear term, specified as a positive integer scalar.

The `'NumTreesPerPredictor'` value is equivalent to the number of gradient boosting iterations for the linear terms for predictors. For each iteration, `fitrgam` adds a set of predictor trees to the model, one tree for each predictor. To learn about the gradient boosting algorithm, see “Gradient Boosting Algorithm” on page 33-2134.

You can determine whether the fitted model has the specified number of trees by viewing the diagnostic message displayed when `'Verbose'` is 1 or 2, or by checking the `ReasonForTermination` property value of the model `Mdl`.

Example: `'NumTreesPerPredictor',500`

Data Types: `single` | `double`

Other Regression Options

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitrgam` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.

Value	Description
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrgam` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitrgam` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`NumPrint` — Number of iterations between diagnostic message printouts
`10` (default) | nonnegative integer scalar

Number of iterations between diagnostic message printouts, specified as a nonnegative integer scalar. This argument is valid only when you specify `'Verbose'` as 1.

If you specify `'Verbose',1` and `'NumPrint',numPrint`, then the software displays diagnostic messages every `numPrint` iterations in the Command Window.

Example: `'NumPrint',500`

Data Types: `single` | `double`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitrgam` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.

- A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ResponseTransform` — Response transformation
`'none'` (default) | function handle

Response transformation, specified as either `'none'` or a function handle. The default is `'none'`, which means `@(y)y`, or no transformation. For a MATLAB function or a function you define, use its function handle for the response transformation. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as `'ResponseTransform',myfunction`.

Data Types: `char` | `string` | `function_handle`

`Verbose` — Verbosity level
`0` (default) | `1` | `2`

Verbosity level, specified as `0`, `1`, or `2`. The `Verbose` value controls the amount of information that the software displays in the Command Window.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software displays no information.
`1`	The software displays diagnostic messages every `numPrint` iterations, where `numPrint` is the `'NumPrint'` value.
`2`	The software displays diagnostic messages at every iteration.

Each line of the diagnostic messages shows the information about each boosting iteration and includes the following columns:

- `Type` — Type of trained trees, `1D` (predictor trees, or boosted trees for linear terms for predictors) or `2D` (interaction trees, or boosted trees for interaction terms for predictors)
- `NumTrees` — Number of trees per linear term or interaction term that `fitrgam` added to the model so far

- `Deviance` — "Deviance" on page 33-2134 of the model
- `RelTol` — Relative change of model predictions: $(\widehat{y}_k - \widehat{y}_{k-1})'(\widehat{y}_k - \widehat{y}_{k-1})/\widehat{y}_k'\widehat{y}_k$, where $\widehat{y}_k$ is a column vector of model predictions at iteration k
- `LearnRate` — Learning rate used for the current iteration

Example: `'Verbose',1`

Data Types: `single` | `double`

`Weights` — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as a vector of scalar values or the name of a variable in `Tbl`. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`.

`fitrgam` normalizes the values of `Weights` to sum to 1.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation Options

`CrossVal` — Flag to train cross-validated model

`'off'` (default) | `'on'`

Flag to train a cross-validated model, specified as `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated model with 10 folds.

You can override this cross-validation setting using the `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'` name-value argument. You can use only one cross-validation name-value argument at a time to create a cross-validated model.

Alternatively, cross-validate after creating a model by passing `Mdl` to `crossval`.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.
2. Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Output Arguments

`Mdl` — Trained generalized additive model
`RegressionGAM` model object | `RegressionPartitionedGAM` cross-validated model object

Trained generalized additive model, returned as one of the model objects in this table.

Model Object	Cross-Validation Options to Train Model Object	Ways to Predict Responses Using Model Object
`RegressionGAM`	None	Use `predict` to predict responses for new observations, and use `resubPredict` to predict responses for training observations.
`RegressionPartitionedGAM`	Specify the name-value argument `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`	Use `kfoldPredict` to predict responses for observations that `fitrgam` holds out during training. `kfoldPredict` predicts a response for every observation by using the model trained without that observation.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Interactions` in the Command Window to display the interaction terms in `Mdl`.

More About

Generalized Additive Model (GAM) for Regression

A generalized additive model (GAM) is an interpretable model that explains a response variable using a sum of univariate and bivariate shape functions of predictors.

`fitrgam` uses a boosted tree as a shape function for each predictor and, optionally, each pair of predictors; therefore, the function can capture a nonlinear relation between a predictor and the response variable. Because contributions of individual shape functions to the prediction (response value) are well separated, the model is easy to interpret.

The standard GAM uses a univariate shape function for each predictor.

$$y \sim N\left(\mu, \sigma^2\right)$$
$$g(\mu) = \mu = c + f_1(x_1) + f_2(x_2) + \cdots + f_p(x_p),$$

where y is a response variable that follows the normal distribution with mean μ and standard deviation σ. $g(\mu)$ is an identity link function, and c is an intercept (constant) term. $f_i(x_i)$ is a univariate shape function for the ith predictor, which is a boosted tree for a linear term for the predictor (predictor tree).

You can include interactions between predictors in a model by adding bivariate shape functions of important interaction terms to the model.

$$\mu = c + f_1(x_1) + f_2(x_2) + \cdots + f_p(x_p) + \sum_{i,\, j \in \{1, 2, \cdots, p\}} f_{ij}(x_i x_j),$$

where $f_{ij}(x_i x_j)$ is a bivariate shape function for the ith and jth predictors, which is a boosted tree for an interaction term for the predictors (interaction tree).

`fitrgam` finds important interaction terms based on the *p*-values of *F*-tests. For details, see “Interaction Term Detection” on page 33-2135.

Deviance

Deviance is a generalization of the residual sum of squares. It measures the goodness of fit compared to the saturated model.

The deviance of a fitted model is twice the difference between the loglikelihoods of the model and the saturated model:

$$-2(\log L - \log L_s),$$

where L and L_s are the likelihoods of the fitted model and the saturated model, respectively. The saturated model is the model with the maximum number of parameters that you can estimate.

`fitrgam` uses the deviance to measure the goodness of model fit and finds a learning rate that reduces the deviance at each iteration. Specify `'Verbose'` as 1 or 2 to display the deviance and learning rate in the Command Window.

Algorithms

Gradient Boosting Algorithm

`fitrgam` fits a generalized additive model using a gradient boosting algorithm (“Least-Squares Boosting” on page 18-50).

`fitrgam` first builds sets of predictor trees (boosted trees for linear terms for predictors) and then builds sets of interaction trees (boosted trees for interaction terms for predictors). The boosting algorithm iterates for at most `'NumTreesPerPredictor'` times for predictor trees, and then iterates for at most `'NumTreesPerInteraction'` times for interaction trees.

For each boosting iteration, `fitrgam` builds a set of predictor trees with the initial learning rate `'InitialLearnRateForPredictors'`, or builds a set of interaction trees with the initial learning rate `'InitialLearnRateForInteractions'`.

- When building a set of trees, the function trains one tree at a time. It fits a tree to the residual that is the difference between the response and the aggregated prediction from all trees grown previously. To control the boosting learning speed, the function shrinks the tree by the learning rate and then adds the tree to the model and updates the residual.
  - Updated model = current model + (learning rate)·(new tree)
  - Updated residual = current residual – (learning rate)·(response explained by new tree)
- If adding the set of trees improves the model fit (that is, reduces the deviance of the fit), then `fitrgam` moves to the next iteration.
- Otherwise, `fitrgam` halves the learning rate and uses it to update the model and residual. The function continues to halve the learning rate until it finds a rate that improves the model fit.
  - If the function cannot find such a learning rate for predictor trees, then it stops boosting iterations for linear terms and starts boosting iterations for interaction terms.
  - If the function cannot find such a learning rate for interaction trees, then it terminates the model fitting.

  You can determine why training stopped by checking the `ReasonForTermination` property of the trained model.

Interaction Term Detection

For each pairwise interaction term $x_i x_j$ (specified by `formula` or `'Interactions'`), the software performs an *F*-test to examine whether the term is statistically significant.

To speed up the process, `fitrgam` bins numeric predictors into at most 8 equiprobable bins. The number of bins can be less than 8 if a predictor has fewer than 8 unique values. The *F*-test examines the null hypothesis that the bins created by x_i and x_j have equal responses versus the alternative that at least one bin has a different response value from the others. A small *p*-value indicates that differences are significant, which implies that the corresponding interaction term is significant and, therefore, including the term can improve the model fit.

`fitrgam` builds a set of interaction trees using the terms whose *p*-values are not greater than the `'MaxPValue'` value. You can use the default `'MaxPValue'` value `1` to build interaction trees using all terms specified by `formula` or `'Interactions'`.

`fitrgam` adds interaction terms to the model in the order of importance based on the *p*-values. Use the `Interactions` property of the returned model to check the order of the interaction terms added to the model.

"Train Generalized Additive Model for Regression" on page 12-91

Introduced in R2021a

fitrgp

Fit a Gaussian process regression (GPR) model

Syntax

```
gprMdl = fitrgp(Tbl,ResponseVarName)
gprMdl = fitrgp(Tbl,formula)
gprMdl = fitrgp(Tbl,y)

gprMdl = fitrgp(X,y)

gprMdl = fitrgp(___,Name,Value)
```

Description

`gprMdl = fitrgp(Tbl,ResponseVarName)` returns a Gaussian process regression (GPR) model trained using the sample data in `Tbl`, where `ResponseVarName` is the name of the response variable in `Tbl`.

`gprMdl = fitrgp(Tbl,formula)` returns a Gaussian process regression (GPR) model, trained using the sample data in `Tbl`, for the predictor variables and response variables identified by `formula`.

`gprMdl = fitrgp(Tbl,y)` returns a GPR model for the predictors in table `Tbl` and continuous response vector `y`.

`gprMdl = fitrgp(X,y)` returns a GPR model for predictors `X` and continuous response vector `y`.

`gprMdl = fitrgp(___,Name,Value)` returns a GPR model for any of the input arguments in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the fitting method, the prediction method, the covariance function, or the active set selection method. You can also train a cross-validated model.

`gprMdl` is a `RegressionGP` object. For methods and properties of this class, see `RegressionGP` class page.

If you train a cross-validated model, then `gprMdl` is a `RegressionPartitionedModel` object. For further analysis on the cross-validated object, use the methods of `RegressionPartitionedModel` class. For the methods of this class, see the `RegressionPartitionedModel` class page.

Examples

Train GPR Model Using Data in Table

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3] . Download the data and save it in your current folder with the name `abalone.data`.

Store the data into a table. Display the first seven rows.

```
tbl = readtable('abalone.data','Filetype','text',...
     'ReadVariableNames',false);
tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height',...
     'WWeight','SWeight','VWeight','ShWeight','NoShellRings'};
tbl(1:7,:)
```

```
ans =

    Sex    Length    Diameter    Height    WWeight    SWeight    VWeight    ShWeight    NoShellRi
    ___    ______    ________    ______    _______    _______    _______    ________    _________

    'M'    0.455     0.365       0.095      0.514     0.2245      0.101      0.15       15
    'M'     0.35     0.265        0.09     0.2255     0.0995     0.0485      0.07        7
    'F'     0.53      0.42       0.135      0.677     0.2565     0.1415      0.21        9
    'M'     0.44     0.365       0.125      0.516     0.2155      0.114     0.155       10
    'I'     0.33     0.255        0.08      0.205     0.0895     0.0395     0.055        7
    'I'    0.425       0.3       0.095     0.3515      0.141     0.0775      0.12        8
    'F'     0.53     0.415        0.15     0.7775      0.237     0.1415      0.33       20
```

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Fit a GPR model using the subset of regressors method for parameter estimation and fully independent conditional method for prediction. Standardize the predictors.

```
gprMdl = fitrgp(tbl,'NoShellRings','KernelFunction','ardsquaredexponential',...
      'FitMethod','sr','PredictMethod','fic','Standardize',1)
```

```
grMdl =

  RegressionGP
       PredictorNames: {1x8 cell}
         ResponseName: 'Var9'
    ResponseTransform: 'none'
      NumObservations: 4177
       KernelFunction: 'ARDSquaredExponential'
    KernelInformation: [1x1 struct]
        BasisFunction: 'Constant'
                 Beta: 10.9148
                Sigma: 2.0243

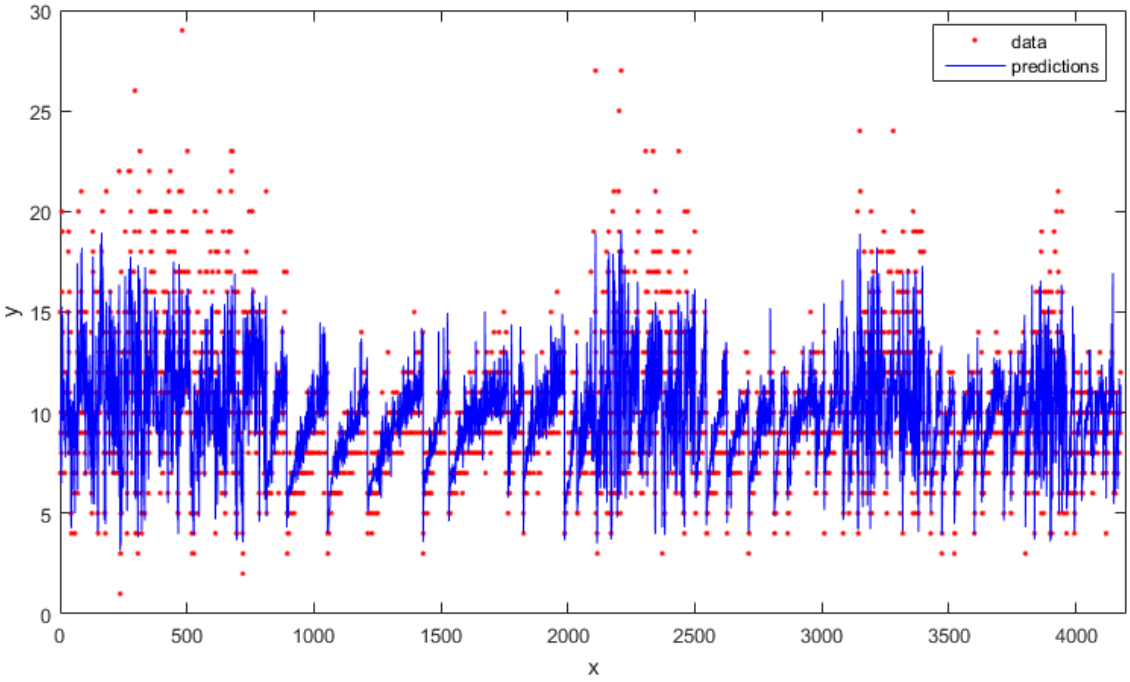
      ActiveSetMethod: 'Random'
    IsActiveSetVector: [4177x1 logical]
        LogLikelihood: -9.0013e+03
     ActiveSetHistory: [1x1 struct]
       BCDInformation: []
```

Predict the responses using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response and the predicted responses.

```
figure();
plot(tbl.NoShellRings,'r.');
hold on
plot(ypred,'b');
xlabel('x');
ylabel('y');
legend({'data','predictions'},'Location','Best');
axis([0 4300 0 30]);
hold off;
```



Compute the regression loss on the training data (resubstitution loss) for the trained model.

```
L = resubLoss(gprMdl)
```

```
L =

    4.0064
```

Train GPR Model and Plot Predictions

Generate sample data.

```
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Fit a GPR model using a linear basis function and the exact fitting method to estimate the parameters. Also use the exact prediction method.

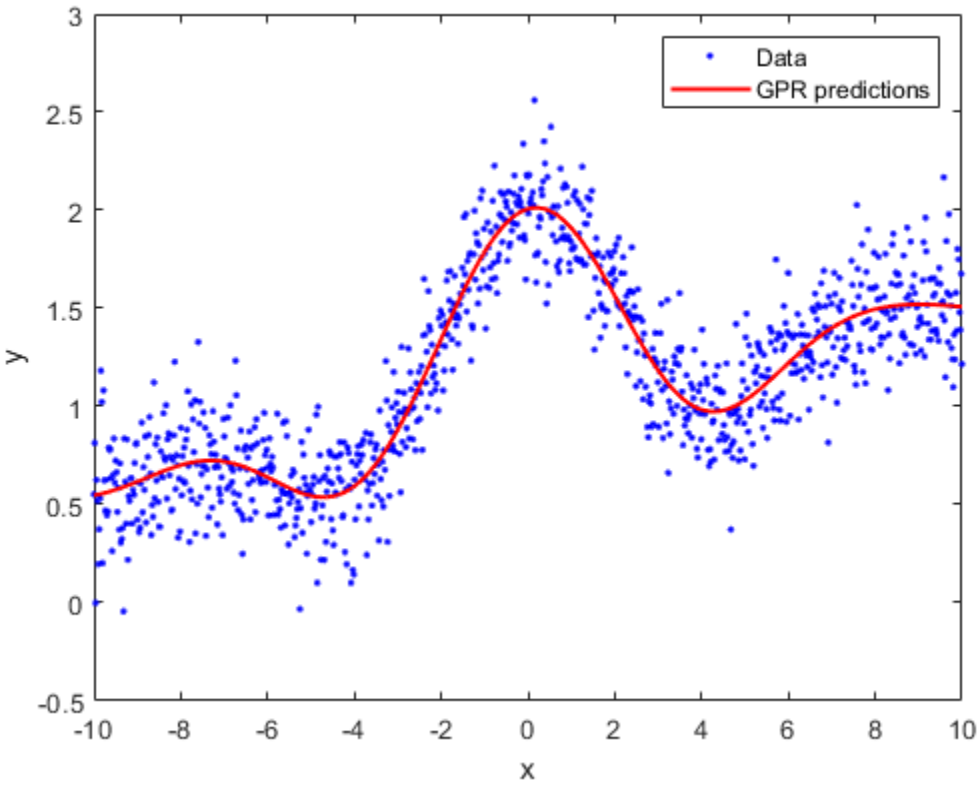
```
gprMdl = fitrgp(x,y,'Basis','linear',...
      'FitMethod','exact','PredictMethod','exact');
```

Predict the response corresponding to the rows of x (resubstitution predictions) using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response with the predicted values.

```
plot(x,y,'b.');
hold on;
plot(x,ypred,'r','LineWidth',1.5);
xlabel('x');
ylabel('y');
legend('Data','GPR predictions');
hold off
```



Impact of Specifying Initial Kernel Parameter Values

Load the sample data.

```
load('gprdata2.mat')
```

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```
gprMdl1 = fitrgp(x,y,'KernelFunction','squaredexponential');
```

Now, fit a second model, where you specify the initial values for the kernel parameters.

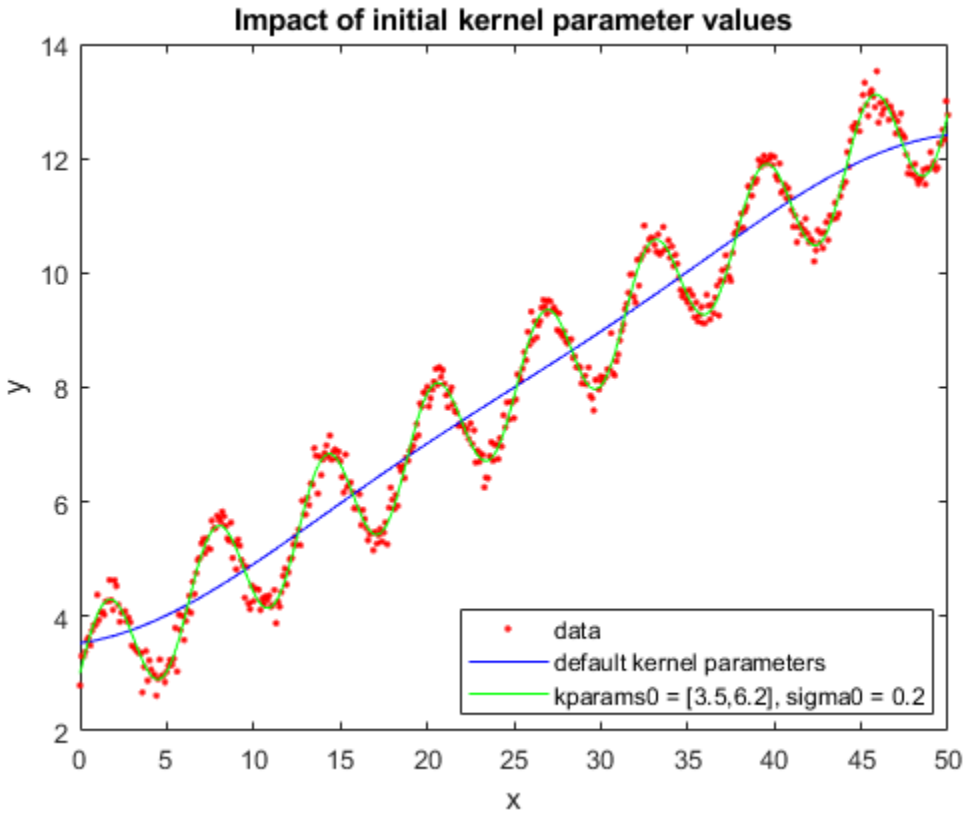
```
sigma0 = 0.2;
kparams0 = [3.5, 6.2];
gprMdl2 = fitrgp(x,y,'KernelFunction','squaredexponential',...
     'KernelParameters',kparams0,'Sigma',sigma0);
```

Compute the resubstitution predictions from both models.

```
ypred1 = resubPredict(gprMdl1);
ypred2 = resubPredict(gprMdl2);
```

Plot the response predictions from both models and the responses in training data.

```
figure();
plot(x,y,'r.');
hold on
plot(x,ypred1,'b');
plot(x,ypred2,'g');
xlabel('x');
ylabel('y');
legend({'data','default kernel parameters',...
'kparams0 = [3.5,6.2], sigma0 = 0.2'},...
'Location','Best');
title('Impact of initial kernel parameter values');
hold off
```



The marginal log likelihood that `fitrgp` maximizes to estimate GPR parameters has multiple local solutions; the solution that it converges to depends on the initial point. Each local solution corresponds to a particular interpretation of the data. In this example, the solution with the default initial kernel parameters corresponds to a low frequency signal with high noise whereas the second solution with custom initial kernel parameters corresponds to a high frequency signal with low noise.

Use Separate Length Scales for Predictors

Load the sample data.

```
load('gprdata.mat')
```

There are six continuous predictor variables. There are 500 observations in the training data set and 100 observations in the test data set. This is simulated data.

Fit a GPR model using the squared exponential kernel function with a separate length scale for each predictor. This covariance function is defined as:

$$k(x_i,x_j|\theta)=\sigma_f^2\exp\left[-\frac{1}{2}\sum_{m=1}^{d}\frac{(x_{im}-x_{jm})^2}{\sigma_m^2}\right].$$

where σ_m represents the length scale for predictor m, $m = 1, 2, \ldots, d$ and σ_f is the signal standard deviation. The unconstrained parametrization θ is

$\theta_m = \log\sigma_m, \quad \text{for } m = 1, 2, \ldots, d$

$\theta_{d+1} = \log\sigma_f .$

Initialize length scales of the kernel function at 10 and signal and noise standard deviations at the standard deviation of the response.

```
sigma0 = std(ytrain);
sigmaF0 = sigma0;
d = size(Xtrain,2);
sigmaM0 = 10*ones(d,1);
```

Fit the GPR model using the initial kernel parameter values. Standardize the predictors in the training data. Use the exact fitting and prediction methods.

```
gprMdl = fitrgp(Xtrain,ytrain,'Basis','constant','FitMethod','exact',...
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression loss on the test data.

```
L = loss(gprMdl,Xtest,ytest)
```

```
L = 0.6919
```

Access the kernel information.

```
gprMdl.KernelInformation
```

```
ans = struct with fields:
                    Name: 'ARDSquaredExponential'
        KernelParameters: [7x1 double]
    KernelParameterNames: {7x1 cell}
```

Display the kernel parameter names.

```
gprMdl.KernelInformation.KernelParameterNames
```

```
ans = 7x1 cell
    {'LengthScale1'}
    {'LengthScale2'}
    {'LengthScale3'}
    {'LengthScale4'}
    {'LengthScale5'}
    {'LengthScale6'}
    {'SigmaF'      }
```

Display the kernel parameters.

```
sigmaM = gprMdl.KernelInformation.KernelParameters(1:end-1,1)
```

```
sigmaM = 6×1
10^4 ×

    0.0004
    0.0007
    0.0004
```

```
    5.2711
    0.1018
    0.0056
```

```
sigmaF = gprMdl.KernelInformation.KernelParameters(end)
```

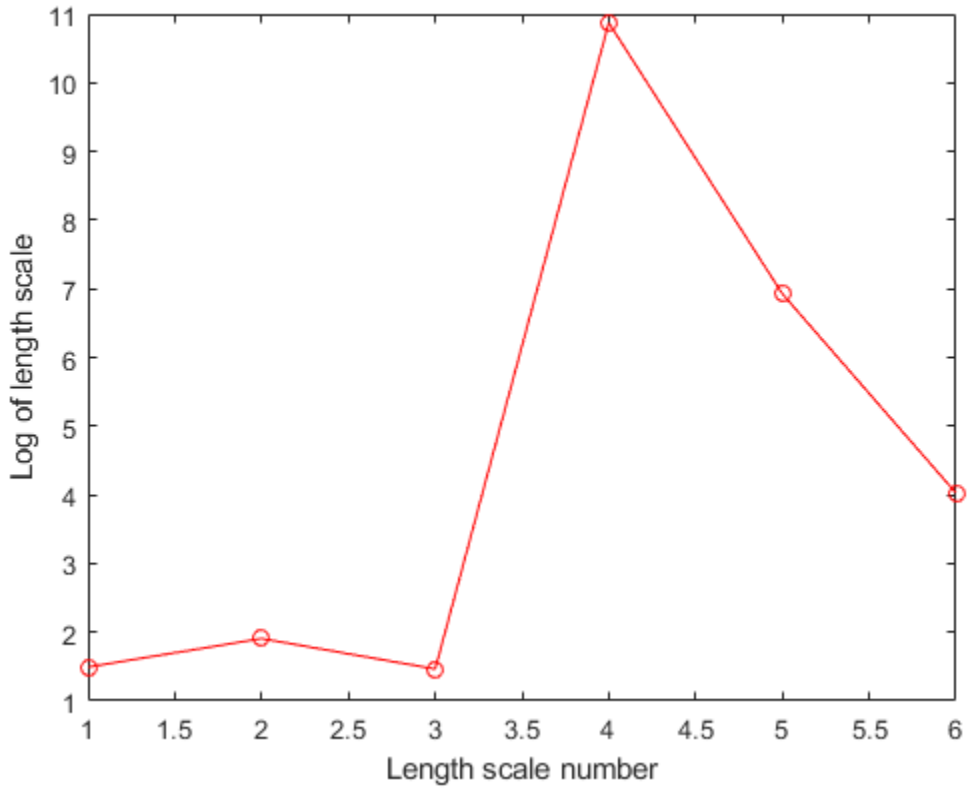
```
sigmaF = 28.1721
```

```
sigma  = gprMdl.Sigma
```

```
sigma = 0.8162
```

Plot the log of learned length scales.

```
figure()
plot((1:d)',log(sigmaM),'ro-');
xlabel('Length scale number');
ylabel('Log of length scale');
```



The log of length scale for the 4th and 5th predictor variables are high relative to the others. These predictor variables do not seem to be as influential on the response as the other predictor variables.

Fit the GPR model without using the 4th and 5th variables as the predictor variables.

```
X = [Xtrain(:,1:3) Xtrain(:,6)];
sigma0 = std(ytrain);
sigmaF0 = sigma0;
```

```
d = size(X,2);
sigmaM0 = 10*ones(d,1);

gprMdl = fitrgp(X,ytrain,'Basis','constant','FitMethod','exact',...
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression error on the test data.

```
xtest = [Xtest(:,1:3) Xtest(:,6)];
L = loss(gprMdl,xtest,ytest)
```

```
L = 0.6928
```

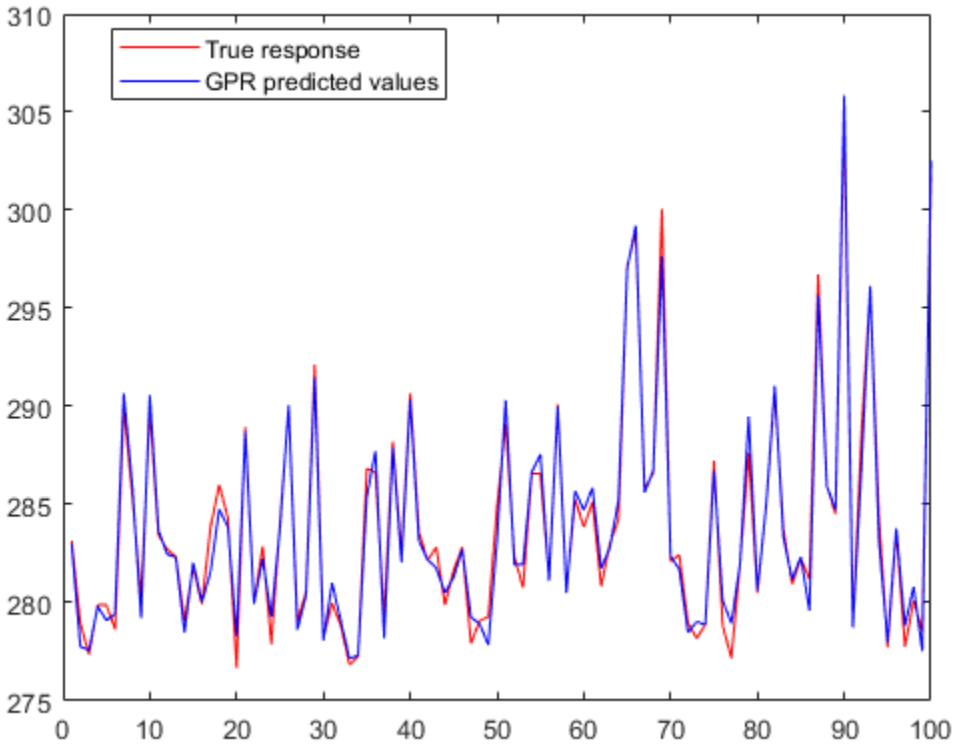
The loss is similar to the one when all variables are used as predictor variables.

Compute the predicted response for the test data.

```
 ypred = predict(gprMdl,xtest);
```

Plot the original response along with the fitted values.

```
figure;
plot(ytest,'r');
hold on;
plot(ypred,'b');
legend('True response','GPR predicted values','Location','Best');
hold off
```



Optimize GPR Regression

This example shows how to optimize hyperparameters automatically using `fitrgp`. The example uses the `gprdata2` data that ships with your software.

Load the data.

```
load('gprdata2.mat')
```

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```
gprMdl1 = fitrgp(x,y,'KernelFunction','squaredexponential');
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng default
gprMdl2 = fitrgp(x,y,'KernelFunction','squaredexponential',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'));
```

```

Train GPR Model Using Cross-Validation

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name `abalone.data`.

Store the data into a `table`. Display the first seven rows.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height','WWeight','SWeight','VWeight'
tbl(1:7,:)
```

```
ans =

    Sex    Length    Diameter    Height    WWeight    SWeight    VWeight    ShWeight    NoShellRi
    ___    ______    ________    ______    _______    _______    _______    ________    _________

    'F'     0.53     0.415        0.15     0.7775      0.237     0.1415      0.33       20
```

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Train a cross-validated GPR model using the 25% of the data for validation.

```
rng('default') % For reproducibility
cvgprMdl = fitrgp(tbl,'NoShellRings','Standardize',1,'Holdout',0.25);
```

Compute the average loss on folds using models trained on out-of-fold observations.

```
kfoldLoss(cvgprMdl)
```

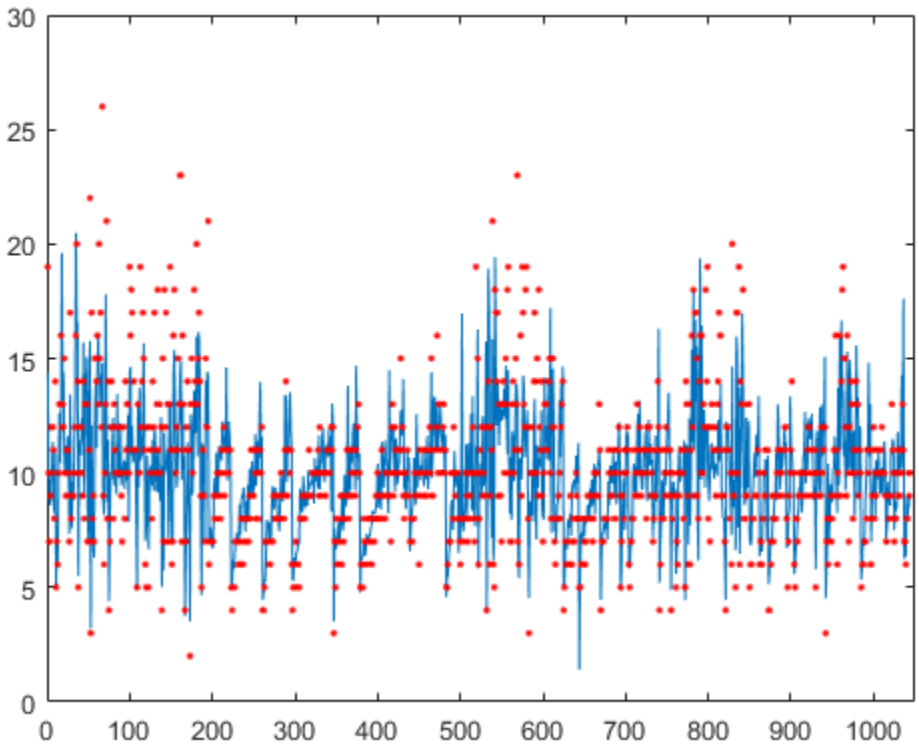
```
ans =
   4.6409
```

Predict the responses for out-of-fold data.

```
ypred = kfoldPredict(cvgprMdl);
```

Plot the true responses used for testing and the predictions.

```
figure();
plot(ypred(cvgprMdl.Partition.test));
hold on;
y = table2array(tbl(:,end));
plot(y(cvgprMdl.Partition.test),'r.');
axis([0 1050 0 30]);
xlabel('x')
ylabel('y')
hold off;
```



Fit GPR Model Using Custom Kernel Function

Generate the sample data.

```
rng(0,'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Define the squared exponential kernel function as a custom kernel function.

You can compute the squared exponential kernel function as

$$k(x_i,x_j|\theta) = \sigma_f^2 \exp\left(-\frac{1}{2}\frac{(x_i-x_j)^T(x_i-x_j)}{\sigma_l^2}\right),$$

where σ_f is the signal standard deviation, σ_l is the length scale. Both σ_f and σ_l must be greater than zero. This condition can be enforced by the unconstrained parametrization, $\sigma_l = \exp(\theta(1))$ and $\sigma_f = \exp(\theta(2))$, for some unconstrained parametrization vector θ.

Hence, you can define the squared exponential kernel function as a custom kernel function as follows:

```
kfcn = @(XN,XM,theta) (exp(theta(2))^2)*exp(-(pdist2(XN,XM).^2)/(2*exp(theta(1))^2));
```

Here `pdist2(XN,XM).^2` computes the distance matrix.

Fit a GPR model using the custom kernel function, `kfcn`. Specify the initial values of the kernel parameters (Because you use a custom kernel function, you must provide initial values for the unconstrained parametrization vector, `theta`).

```
theta0 = [1.5,0.2];
gprMdl = fitrgp(x,y,'KernelFunction',kfcn,'KernelParameters',theta0);
```

`fitrgp` uses analytical derivatives to estimate parameters when using a built-in kernel function, whereas when using a custom kernel function it uses numerical derivatives.

Compute the resubstitution loss for this model.

```
L = resubLoss(gprMdl)
```

```
L = 0.0391
```

Fit the GPR model using the built-in squared exponential kernel function option. Specify the initial values of the kernel parameters (Because you use the built-in custom kernel function and specifying initial parameter values, you must provide the initial values for the signal standard deviation and length scale(s) directly).

```
sigmaL0 = exp(1.5);
sigmaF0 = exp(0.2);
gprMdl2 = fitrgp(x,y,'KernelFunction','squaredexponential','KernelParameters',[sigmaL0,sigmaF0]);
```

Compute the resubstitution loss for this model.

```
L2 = resubLoss(gprMdl2)
```

```
L2 = 0.0391
```

The two loss values are the same as expected.

Specify Initial Step Size for LBFGS Optimization

Train a GPR model on generated data with many predictors. Specify the initial step size for the LBFGS optimizer.

Set the seed and type of the random number generator for reproducibility of the results.

```
rng(0,'twister'); % For reproducibility
```

Generate sample data with 300 observations and 3000 predictors, where the response variable depends on the 4th, 7th, and 13th predictors.

```
N = 300;
P = 3000;
X = rand(N,P);
y = cos(X(:,7)) + sin(X(:,4).*X(:,13)) + 0.1*randn(N,1);
```

Set initial values for the kernel parameters.

```
sigmaL0 = sqrt(P)*ones(P,1); % Length scale for predictors
sigmaF0 = 1; % Signal standard deviation
```

Set initial noise standard deviation to 1.

```
sigmaN0 = 1;
```

Specify `1e-2` as the termination tolerance for the relative gradient norm.

```
opts = statset('fitrgp');
opts.TolFun = 1e-2;
```

Fit a GPR model using the initial kernel parameter values, initial noise standard deviation, and an automatic relevance determination (ARD) squared exponential kernel function.

Specify the initial step size as 1 for determining the initial Hessian approximation for an LBFGS optimizer.

```
gpr = fitrgp(X,y,'KernelFunction','ardsquaredexponential','Verbose',1, ...
    'Optimizer','lbfgs','OptimizerOptions',opts, ...
    'KernelParameters',[sigmaL0;sigmaF0],'Sigma',sigmaN0,'InitialStepSize',1);
```

```
o Parameter estimation: FitMethod = Exact, Optimizer = lbfgs

 o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

Relative infinity norm of the final gradient = 6.016e-03, TolFun = 1.000e-02
EXIT: Local minimum found.

o Alpha estimation: PredictMethod = Exact
```

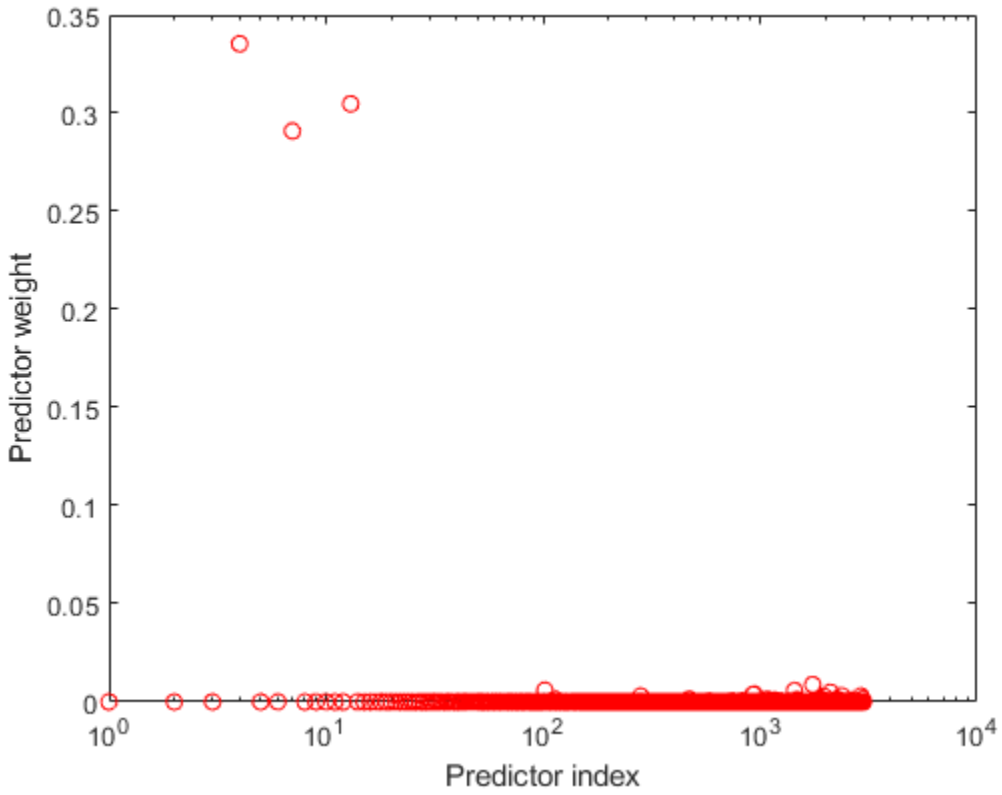
Because the GPR model uses an ARD kernel with many predictors, using an LBFGS approximation to the Hessian is more memory efficient than storing the full Hessian matrix. Also, using the initial step size to determine the initial Hessian approximation may help speed up optimization.

Find the predictor weights by taking the exponential of the negative learned length scales. Normalize the weights.

```
sigmaL = gpr.KernelInformation.KernelParameters(1:end-1); % Learned length scales
weights = exp(-sigmaL); % Predictor weights
weights = weights/sum(weights); % Normalized predictor weights
```

Plot the normalized predictor weights.

```
figure;
semilogx(weights,'ro');
xlabel('Predictor index');
ylabel('Predictor weight');
```



The trained GPR model assigns the largest weights to the 4th, 7th, and 13th predictors. The irrelevant predictors have weights close to zero.

Input Arguments

`Tbl` — Sample data

`table`

Sample data used to train the model, specified as a `table`. Each row of `Tbl` corresponds to one observation, and each column corresponds to one variable. `Tbl` contains the predictor variables, and optionally it can also contain one column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all the remaining variables as predictors, then specify the response variable using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the predictors in training the model, then specify the response variable and the predictor variables using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable using `y`. The length of the response variable and the number of rows in `Tbl` must be equal.

For more information on the `table` data type, see `table`.

If your predictor data contains categorical variables, then `fitrgp` creates dummy variables. For details, see `CategoricalPredictors`.

Data Types: `table`

`ResponseVarName` — Response variable name
name of a variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored in `Tbl` (as `Tbl.y`), then specify it as `'y'`. Otherwise, the software treats all the columns of `Tbl`, including `y`, as predictors when training the model.

Data Types: `char` | `string`

`formula` — Response and predictor variables to use in model training
character vector or string scalar in the form of `'y~x1+x2+x3'`

Response and predictor variables to use in model training, specified as a character vector or string scalar in the form of `'y~x1+x2+x3'`. In this form, `y` represents the response variable; `x1`, `x2`, `x3` represent the predictor variables to use in training the model.

Use a formula if you want to specify a subset of variables in `Tbl` as predictors to use when training the model. If you specify a formula, then any variables that do not appear in `formula` are not used to train the model.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

The formula does not indicate the form of the `BasisFunction`.

Example: `'PetalLength~PetalWidth+Species'` identifies the variable `PetalLength` as the response variable, and `PetalWidth` and `Species` as the predictor variables.

Data Types: `char` | `string`

`X` — Predictor data for the GPR model
n-by-*d* matrix

Predictor data for the GPR model, specified as an *n*-by-*d* matrix. *n* is the number of observations (rows), and *d* is the number of predictors (columns).

The length of `y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `double`

`y` — Response data for the GPR model
n-by-1 vector

Response data for the GPR model, specified as an *n*-by-1 vector. You can omit `y` if you provide the `Tbl` training data that also includes `y`. In that case, use `ResponseVarName` to identify the response variable or use `formula` to identify the response and predictor variables.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'FitMethod','sr','BasisFunction','linear','ActiveSetMethod','sgma','PredictMethod','fic'` trains the GPR model using the subset of regressors approximation method for parameter estimation, uses a linear basis function, uses sparse greedy matrix approximation for active selection, and fully independent conditional approximation method for prediction.

Fitting

`FitMethod` — Method to estimate parameters of the GPR model

`'none'` | `'exact'` | `'sd'` | `'sr'` | `'fic'`

Method to estimate parameters of the GPR model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following.

Fit Method	Description
`'none'`	No estimation, use the initial parameter values as the known parameter values.
`'exact'`	Exact Gaussian process regression. Default if $n \le 2000$, where n is the number of observations.
`'sd'`	Subset of data points approximation. Default if $n > 2000$, where n is the number of observations.
`'sr'`	Subset of regressors approximation.
`'fic'`	Fully independent conditional approximation.

Example: `'FitMethod','fic'`

`BasisFunction` — Explicit basis in the GPR model

`'constant'` (default) | `'none'` | `'linear'` | `'pureQuadratic'` | function handle

Explicit basis in the GPR model, specified as the comma-separated pair consisting of `'BasisFunction'` and one of the following. If n is the number of observations, the basis function adds the term $\boldsymbol{H}*\boldsymbol{\beta}$ to the model, where $\boldsymbol{H}$ is the basis matrix and $\boldsymbol{\beta}$ is a p-by-1 vector of basis coefficients.

Explicit Basis	Basis Matrix
`'none'`	Empty matrix.

Explicit Basis	Basis Matrix
`'constant'`	$H = 1$ (n-by-1 vector of 1s, where n is the number of observations)
`'linear'`	$H = [1, X]$
`'pureQuadratic'`	$H = [1, X, X_2]$, where $X_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \cdots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \cdots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \cdots & x_{nd}^2 \end{bmatrix}$.
Function handle	Function handle, `hfcn`, that `fitrgp` calls as: $H = hfcn(X)$, where X is an n-by-d matrix of predictors and H is an n-by-p matrix of basis functions.

Example: `'BasisFunction','pureQuadratic'`

Data Types: `char` | `string` | `function_handle`

`Beta` — Initial value of the coefficients
p-by-1 vector

Initial value of the coefficients for the explicit basis, specified as the comma-separated pair consisting of `'Beta'` and *p*-by-1 vector, where *p* is the number of columns in the basis matrix $\boldsymbol{H}$.

The basis matrix depends on the choice of the explicit basis function as follows (also see `BasisFunction`).

`fitrgp` uses the coefficient initial values as the known coefficient values, only when `FitMethod` is `'none'`.

Data Types: `double`

`Sigma` — Initial value for the noise standard deviation of the Gaussian process model
`std(y)/sqrt(2)` (default) | positive scalar value

Initial value for the noise standard deviation of the Gaussian process model, specified as the comma-separated pair consisting of `'Sigma'` and a positive scalar value.

Example: `'Sigma',2`

Data Types: `double`

`ConstantSigma` — Constant value of `Sigma` for the noise standard deviation of the Gaussian process model
`false` (default) | `true`

Constant value of `Sigma` for the noise standard deviation of the Gaussian process model, specified as a logical scalar. When `ConstantSigma` is `true`, `fitrgp` does not optimize the value of `Sigma`, but instead takes the initial value as the value throughout its computations.

Example: `'ConstantSigma',true`

Data Types: `logical`

`SigmaLowerBound` — Lower bound on the noise standard deviation
`1e-2*std(y)` (default) | positive scalar value

Lower bound on the noise standard deviation, specified as the comma-separated pair consisting of `'SigmaLowerBound'` and a positive scalar value.

Example: `'SigmaLowerBound',0.02`

Data Types: `double`

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitrgp` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrgp` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitrgp` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitrgp` creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For an unordered

categorical variable, `fitrgp` creates one dummy variable for each level of the categorical variable. For an ordered categorical variable, `fitrgp` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`Standardize` — Indicator to standardize data
`0 (false)` (default) | logical value

Indicator to standardize data, specified as the comma-separated pair consisting of `'Standardize'` and a logical value.

If you set `'Standardize',1`, then the software centers and scales each column of the predictor data, by the column mean and standard deviation, respectively. The software does not standardize the data contained in the dummy variable columns that it generates for categorical predictors.

Example: `'Standardize',1`

Example: `'Standardize',true`

Data Types: `logical`

`Regularization` — Regularization standard deviation
`1e-2*std(y)` (default) | positive scalar value

Regularization standard deviation for sparse methods subset of regressors (`'sr'`) and fully independent conditional (`'fic'`), specified as the comma-separated pair consisting of `'Regularization'` and a positive scalar value.

Example: `'Regularization',0.2`

Data Types: `double`

`ComputationMethod` — Method for computing log likelihood and gradient
`'qr'` (default) | `'v'`

Method for computing the log likelihood and gradient for parameter estimation using subset of regressors (`'sr'`) and fully independent conditional (`'fic'`) approximation methods, specified as the comma-separated pair consisting of `'ComputationMethod'` and one of the following.

- `'qr'` — Use QR factorization based approach, this option provides better accuracy.
- `'v'` — Use V-method-based approach. This option provides faster computation of log likelihood gradients.

Example: `'ComputationMethod','v'`

Kernel (Covariance) Function

`KernelFunction` — Form of the covariance function
`'squaredexponential'` (default) | `'exponential'` | `'matern32'` | `'matern52'` | `'rationalquadratic'` | `'ardsquaredexponential'` | `'ardexponential'` | `'ardmatern32'` | `'ardmatern52'` | `'ardrationalquadratic'` | function handle

Form of the covariance function, specified as the comma-separated pair consisting of `'KernelFunction'` and one of the following.

Function	Description
`'exponential'`	Exponential kernel.
`'squaredexponential'`	Squared exponential kernel.
`'matern32'`	Matern kernel with parameter 3/2.
`'matern52'`	Matern kernel with parameter 5/2.
`'rationalquadratic'`	Rational quadratic kernel.
`'ardexponential'`	Exponential kernel with a separate length scale per predictor.
`'ardsquaredexponential'`	Squared exponential kernel with a separate length scale per predictor.
`'ardmatern32'`	Matern kernel with parameter 3/2 and a separate length scale per predictor.
`'ardmatern52'`	Matern kernel with parameter 5/2 and a separate length scale per predictor.
`'ardrationalquadratic'`	Rational quadratic kernel with a separate length scale per predictor.
Function handle	A function handle that can be called like this: `Kmn = kfcn(Xm,Xn,theta)` where `Xm` is an *m*-by-*d* matrix, `Xn` is an *n*-by-*d* matrix and `Kmn` is an *m*-by-*n* matrix of kernel products such that `Kmn`(*i*,*j*) is the kernel product between `Xm`(*i*,:) and `Xn`(*j*,:). `theta` is the *r*-by-1 unconstrained parameter vector for `kfcn`.

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-6.

Example: `'KernelFunction','matern32'`

Data Types: `char` | `string` | `function_handle`

`KernelParameters` — Initial values for the kernel parameters
vector

Initial values for the kernel parameters, specified as the comma-separated pair consisting of `'KernelParameters'` and a vector. The size of the vector and the values depend on the form of the covariance function, specified by the `KernelFunction` name-value pair argument.

'KernelFunction'	'KernelParameters'
'exponential', 'squaredexponential', 'matern32', or 'matern52'	2-by-1 vector phi, where phi(1) contains the length scale and phi(2) contains the signal standard deviation. Default initial value of the length scale parameter is the mean of standard deviations of the predictors, and the signal standard deviation is the standard deviation of the responses divided by square root of 2. That is, phi = [mean(std(X));std(y)/sqrt(2)]
'rationalquadratic'	3-by-1 vector phi, where phi(1) contains the length scale, phi(2) contains the scale-mixture parameter, and phi(3) contains the signal standard deviation. Default initial value of the length scale parameter is the mean of standard deviations of the predictors, and the signal standard deviation is the standard deviation of the responses divided by square root of 2. Default initial value for the scale-mixture parameter is 1. That is, phi = [mean(std(X));1;std(y)/sqrt(2)]
'ardexponential', 'ardsquaredexponential', 'ardmatern32', or 'ardmatern52'	(d+1)-by-1 vector phi, where phi(i) contains the length scale for predictor i, and phi(d+1) contains the signal standard deviation. d is the number of predictor variables after dummy variables are created for categorical variables. For details about creating dummy variables, see CategoricalPredictors. Default initial value of the length scale parameters are the standard deviations of the predictors and the signal standard deviation is the standard deviation of the responses divided by square root of 2. That is, phi = [std(X)';std(y)/sqrt(2)]
'ardrationalquadratic'	(d+2)-by-1 vector phi, where phi(i) contains the length scale for predictor i, phi(d+1) contains the scale-mixture parameter, and phi(d+2) contains signal standard deviation. Default initial value of the length scale parameters are the standard deviations of the predictors and the signal standard deviation is the standard deviation of the responses divided by square root of 2. Default initial value for the scale-mixture parameter is 1. That is, phi = [std(X)';1;std(y)/sqrt(2)]

'KernelFunction'	'KernelParameters'
Function handle	*r*-by-1 vector as the initial value of the unconstrained parameter vector `phi` for the custom kernel function `kfcn`. When `KernelFunction` is a function handle, you must supply initial values for the kernel parameters.

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-6.

Example: `'KernelParameters',theta`

Data Types: `double`

`DistanceMethod` — Method for computing inter-point distances
`'fast'` (default) | `'accurate'`

Method for computing inter-point distances to evaluate built-in kernel functions, specified as the comma-separated pair consisting of `'DistanceMethod'` and either `'fast'` or `'accurate'`.

`fitrgp` computes $(x-y)^2$ as $x^2+y^2-2*x*y$ when you choose the `fast` option and as $(x-y)^2$ when you choose the `accurate` option.

Example: `'DistanceMethod','accurate'`

Active Set Selection

`ActiveSet` — Observations in the active set
`[]` (default) | *m*-by-1 vector of integers ranging from 1 to *n* ($m \le n$) | logical vector of length *n*

Observations in the active set, specified as the comma-separated pair consisting of `'ActiveSet'` and an *m*-by-1 vector of integers ranging from 1 to *n* ($m \le n$) or a logical vector of length *n* with at least one `true` element. *n* is the total number of observations in the training data.

`fitrgp` uses the observations indicated by `ActiveSet` to train the GPR model. The active set cannot have duplicate elements.

If you supply `ActiveSet`, then:

- `fitrgp` does not use `ActiveSetSize` and `ActiveSetMethod`.
- You cannot perform cross-validation on this model.

Data Types: `double` | `logical`

`ActiveSetSize` — Size of the active set for sparse methods
an integer *m* ($1 \le m \le n$)

Size of the active set for sparse methods (`'sd'`, `'sr'`, `'fic'`), specified as the comma-separated pair consisting of `'ActiveSetSize'` and an integer *m*, $1 \le m \le n$, where *n* is the number of observations.

Default is min(1000,*n*) when `FitMethod` is `'sr'` or `'fic'`, and min(2000,*n*), otherwise.

Example: `'ActiveSetSize',100`

Data Types: `double`

`ActiveSetMethod` — Active set selection method
`'random'` (default) | `'sgma'` | `'entropy'` | `'likelihood'`

Active set selection method, specified as the comma-separated pair consisting of `'ActiveSetMethod'` and one of the following.

Method	Description
`'random'`	Random selection
`'sgma'`	Sparse greedy matrix approximation
`'entropy'`	Differential entropy-based selection
`'likelihood'`	Subset of regressors log likelihood-based selection

All active set selection methods (except `'random'`) require the storage of an *n*-by-*m* matrix, where *m* is the size of the active set and *n* is the number of observations.

Example: `'ActiveSetMethod','entropy'`

`RandomSearchSetSize` — Random search set size
59 (default) | integer value

Random search set size per greedy inclusion for active set selection, specified as the comma-separated pair consisting of `'RandomSearchSetSize'` and an integer value.

Example: `'RandomSearchSetSize',30`

Data Types: `double`

`ToleranceActiveSet` — Relative tolerance for terminating active set selection
1e-06 (default) | positive scalar

Relative tolerance for terminating active set selection, specified as the comma-separated pair consisting of `'ToleranceActiveset'` and a positive scalar value.

Example: `'ToleranceActiveset',0.0002`

Data Types: `double`

`NumActiveSetRepeats` — Number of repetitions
3 (default) | integer value

Number of repetitions for interleaved active set selection and parameter estimation on page 33-2172 when `ActiveSetMethod` is not `'random'`, specified as the comma-separated pair consisting of `'NumActiveSetRepeats'` and an integer value.

Example: `'NumActiveSetRepeats',5`

Data Types: `double`

Prediction

`PredictMethod` — Method used to make predictions
`'exact'` | `'bcd'` | `'sd'` | `'sr'` | `'fic'`

Method used to make predictions from a Gaussian process model given the parameters, specified as the comma-separated pair consisting of `'PredictMethod'` and one of the following.

Method	Description
'exact'	Exact Gaussian process regression method. Default, if $n \le 10000$.
'bcd'	Block coordinate descent. Default, if $n > 10000$.
'sd'	Subset of data points approximation.
'sr'	Subset of regressors approximation.
'fic'	Fully independent conditional approximation.

Example: 'PredictMethod','bcd'

BlockSizeBCD — Block size
minimum of 1000 or *n* (default) | integer in the range from 1 to *n*

Block size for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'BlockSizeBCD' and an integer in the range from 1 to *n*, where *n* is the number of observations.

Example: 'BlockSizeBCD',1500

Data Types: double

NumGreedyBCD — Number of greedy selections
minimum of 100 and BlockSizeBCD (default) | integer value in the range from 1 to BlockSizeBCD

Number of greedy selections for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'NumGreedyBCD' and an integer in the range from 1 to BlockSizeBCD.

Example: 'NumGreedyBCD',150

Data Types: double

ToleranceBCD — Relative tolerance on gradient norm
1e-3 (default) | positive scalar

Relative tolerance on gradient norm for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'ToleranceBCD' and a positive scalar.

Example: 'ToleranceBCD',0.002

Data Types: double

StepToleranceBCD — Absolute tolerance on step size
1e-3 (default) | positive scalar

Absolute tolerance on step size for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'StepToleranceBCD' and a positive scalar.

Example: 'StepToleranceBCD',0.002

Data Types: double

IterationLimitBCD — Maximum number of BCD iterations
1000000 (default) | integer value

Maximum number of block coordinate descent method (`'bcd'`) iterations, specified as the comma-separated pair consisting of `'IterationLimitBCD'` and an integer value.

Example: `'IterationLimitBCD',10000`

Data Types: `double`

Optimization

`Optimizer` — Optimizer to use for parameter estimation

`'quasinewton'` (default) | `'lbfgs'` | `'fminsearch'` | `'fminunc'` | `'fmincon'`

Optimizer to use for parameter estimation, specified as the comma-separated pair consisting of `'Optimizer'` and one of the values in this table.

Value	Description
`'quasinewton'`	Dense, symmetric rank-1-based, quasi-Newton approximation to the Hessian
`'lbfgs'`	LBFGS-based quasi-Newton approximation to the Hessian
`'fminsearch'`	Unconstrained nonlinear optimization using the simplex search method of Lagarias et al. [5]
`'fminunc'`	Unconstrained nonlinear optimization (requires an Optimization Toolbox license)
`'fmincon'`	Constrained nonlinear optimization (requires an Optimization Toolbox license)

For more information on the optimizers, see Algorithms on page 33-2173.

Example: `'Optimizer','fmincon'`

`OptimizerOptions` — Options for the optimizer

structure | object

Options for the optimizer you choose using the `Optimizer` name-value pair argument, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure or object created by `optimset`, `statset('fitrgp')`, or `optimoptions`.

Optimizer	Create Optimizer Options Using
`'fminsearch'`	`optimset` (structure)
`'quasinewton'` or `'lbfgs'`	`statset('fitrgp')` (structure)
`'fminunc'` or `'fmincon'`	`optimoptions` (object)

The default options depend on the type of optimizer.

Example: `'OptimizerOptions',opt`

`InitialStepSize` — Initial step size

`[]` (default) | real positive scalar | `'auto'`

Initial step size, specified as the comma-separated pair consisting of `'InitialStepSize'` and a real positive scalar or `'auto'`.

'InitialStepSize' is the approximate maximum absolute value of the first optimization step when the optimizer is 'quasinewton' or 'lbfgs'. The initial step size can determine the initial Hessian approximation during optimization.

By default, fitrgp does not use the initial step size to determine the initial Hessian approximation. To use the initial step size, set a value for the 'InitialStepSize' name-value pair argument, or specify 'InitialStepSize','auto' to have fitrgp determine a value automatically. For more information on 'auto', see Algorithms on page 33-2173.

Example: 'InitialStepSize','auto'

Cross-Validation

CrossVal — Indicator for cross-validation

'off' (default) | 'on'

Indicator for cross-validation, specified as the comma-separated pair consisting of 'CrossVal' and either 'off' or 'on'. If it is 'on', then fitrgp returns a GPR model cross-validated with 10 folds.

You can use one of the KFold, Holdout, Leaveout or CVPartition name-value pair arguments to change the default cross-validation settings. You can use only one of these name-value pairs at a time.

As an alternative, you can use the crossval method for your model.

Example: 'CrossVal','on'

CVPartition — Random partition for a stratified *k*-fold cross-validation

cvpartition object

Random partition for a stratified *k*-fold cross-validation, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition object.

Example: 'CVPartition',cvp uses the random partition defined by cvp.

If you specify CVPartition, then you cannot specify Holdout, KFold, or Leaveout.

Holdout — Fraction of data to use for testing

scalar value in the range from 0 to 1

Fraction of the data to use for testing in holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range from 0 to 1. If you specify 'Holdout',p, then the software:
1. Randomly reserves around *p**100% of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in cvgprMdl.Trained.

Example: 'Holdout', 0.3 uses 30% of the data for testing and 70% of the data for training.

If you specify Holdout, then you cannot specify CVPartition, KFold, or Leaveout.

Data Types: double

KFold — Number of folds

10 (default) | positive integer value

Number of folds to use in cross-validated GPR model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. KFold must be greater than 1. If you specify 'KFold',k then the software:

1. Randomly partitions the data into *k* sets.
2. For each set, reserves the set as test data, and trains the model using the other *k* – 1 sets.
3. Stores the *k* compact, trained models in the cells of a *k*-by-1 cell array in `cvgprMdl.Trained`.

Example: `'KFold',5` uses 5 folds in cross-validation. That is, for each fold, uses that fold as test data, and trains the model on the remaining 4 folds.

If you specify `KFold`, then you cannot specify `CVPartition`, `Holdout`, or `Leaveout`.

Data Types: `double`

`Leaveout` — Indicator for leave-one-out cross-validation
`'off'` (default) | `'on'`

Indicator for leave-one-out cross-validation, specified as the comma-separated pair consisting of `'Leaveout'` and either `'off'` or `'on'`.

If you specify `'Leaveout','on'`, then, for each of the *n* observations, the software:
1. Reserves the observation as test data, and trains the model using the other *n* – 1 observations.
2. Stores the compact, trained model in a cell in the *n*-by-1 cell array `cvgprMdl.Trained`.

Example: `'Leaveout','on'`

If you specify `Leaveout`, then you cannot specify `CVPartition`, `Holdout`, or `KFold`.

Hyperparameter Optimization

`OptimizeHyperparameters` — Parameters to optimize
`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Sigma'}`.
- `'all'` — Optimize all eligible parameters, equivalent to`{'BasisFunction','KernelFunction','KernelScale','Sigma','Standardize'}`.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitrgp` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 33-3184. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitrgp` are:

- `BasisFunction` — `fitrgp` searches among `'constant'`, `'none'`, `'linear'`, and `'pureQuadratic'`.

- `KernelFunction` — `fitrgp` searches among `'ardexponential'`, `'ardmatern32'`, `'ardmatern52'`, `'ardrationalquadratic'`, `'ardsquaredexponential'`, `'exponential'`, `'matern32'`, `'matern52'`, `'rationalquadratic'`, and `'squaredexponential'`.
- `KernelScale` — `fitrgp` uses the `KernelParameters` argument to specify the value of the kernel scale parameter, which is held constant during fitting. In this case, all input dimensions are constrained to have the same `KernelScale` value. `fitrgp` searches among real value in the range `[1e-3*MaxPredictorRange,MaxPredictorRange]`, where

  `MaxPredictorRange = max(max(X) - min(X))`.

  `KernelScale` cannot be optimized for any of the ARD kernels.
- `Sigma` — `fitrgp` searches among real value in the range `[1e-4, max(1e-3,10*ResponseStd)]`, where

  `ResponseStd = std(y)`.

  Internally, `fitrgp` sets the `ConstantSigma` name-value pair to `true` so the value of `Sigma` is constant during the fitting.
- `Standardize` — `fitrgp` searches among `true` and `false`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitrgp',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize GPR Regression” on page 33-2145.

Example: `'auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`

Field Name	Values	Default
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Other

`PredictorNames` — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array of unique names or a cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrgp` uses the predictor variables in `PredictorNames` and the response only in training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames',{'PedalLength','PedalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`Verbose` — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and one of the following.

- 0 — `fitrgp` suppresses diagnostic messages related to active set selection and block coordinate descent but displays the messages related to parameter estimation, depending on the value of `'Display'` in `OptimizerOptions`.
- 1 — `fitrgp` displays the iterative diagnostic messages related to parameter estimation, active set selection, and block coordinate descent.

Example: `'Verbose',1`

`CacheSize` — Cache size in megabytes
1000 MB (default) | positive scalar

Cache size in megabytes (MB), specified as the comma-separated pair consisting of `'CacheSize'` and a positive scalar. Cache size is the extra memory that is available in addition to that required for fitting and active set selection. `fitrgp` uses `CacheSize` to:

- Decide whether interpoint distances should be cached when estimating parameters.
- Decide how matrix vector products should be computed for block coordinate descent method and for making predictions.

Example: `'CacheSize',2000`

Data Types: `double`

Output Arguments

`gprMdl` — Gaussian process regression model
`RegressionGP` object | `RegressionPartitionedModel` object

Gaussian process regression model, returned as a `RegressionGP` or a `RegressionPartitionedModel` object.

- If you cross-validate, that is, if you use one of the `'Crossval'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pairs, then `gprMdl` is a `RegressionPartitionedModel` object. You cannot use a `RegressionPartitionedModel` object to make predictions using `predict`. For more information on the methods and properties of this object, see `RegressionPartitionedModel`.
- If you do not cross-validate, then `gprMdl` is a `RegressionGP` object. You can use this object for predictions using the `predict` method. For more information on the methods and properties of this object, see `RegressionGP`.

More About

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (`FitMethod` equal to `'sd'`, `'sr'`, or `'fic'`), if you do not provide the active set, `fitrgp` selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector $\eta_0 = [\beta_0,\sigma_0,\theta_0]$ to select an active set A_1. It maximizes the GPR marginal log likelihood or its approximation using η_0 as the initial values and A_1 to compute the new parameter estimates η_1. Next, it computes the new log likelihood L_1 using η_1 and A_1.

In the second iteration, the software selects the active set A_2 using the parameter values in η_1. Then, using η_1 as the initial values and A_2, it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values η_2. Then using η_2 and A_2, computes the new log likelihood value L_2.

The following table summarizes the iterations and what is computed at each iteration.

Iteration Number	Active Set	Parameter Vector	Log Likelihood
1	A_1	η_1	L_1
2	A_2	η_2	L_2
3	A_3	η_3	L_3
…	…	…	…

The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the `NumActiveSetRepeats` name-value pair argument.

Tips

- `fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See `predict`. And in some cases, using the exact method might be expensive due to the size of the training data.
- The `PredictorNames` property stores one element for each of the original predictor variable names. For example, if there are three predictors, one of which is a categorical variable with three levels, `PredictorNames` is a 1-by-3 cell array of character vectors.
- The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors.
- Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.
- The `X` property stores the training data as originally input. It does not include the dummy variables.
- The default approach to initializing the Hessian approximation in `fitrgp` can be slow when you have a GPR model with many kernel parameters, such as when using an ARD kernel with many predictors. In this case, consider specifying `'auto'` or a value for the initial step size.

  You can set `'Verbose',1` for display of iterative diagnostic messages, and begin training a GPR model using an LBFGS or quasi-Newton optimizer with the default `fitrgp` optimization. If the iterative diagnostic messages are not displayed after a few seconds, it is possible that initialization of the Hessian approximation is taking too long. In this case, consider restarting training and using the initial step size to speed up optimization.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2..

Algorithms

- Fitting a GPR model involves estimating the following model parameters from the data:
  - Covariance function $k\left(x_i, x_j \middle| \theta\right)$ parameterized in terms of kernel parameters in vector θ (see “Kernel (Covariance) Function Options” on page 6-6)
  - Noise variance, σ^2
  - Coefficient vector of fixed basis functions, β

The value of the `'KernelParameters'` name-value pair argument is a vector that consists of initial values for the signal standard deviation σ_f and the characteristic length scales σ_l. The `fitrgp` function uses these values to determine the kernel parameters. Similarly, the `'Sigma'` name-value pair argument contains the initial value for the noise standard deviation σ.

- During optimization, `fitrgp` creates a vector of unconstrained initial parameter values η_0 by using the initial values for the noise standard deviation and the kernel parameters.
- `fitrgp` analytically determines the explicit basis coefficients β, specified by the `'Beta'` name-value pair argument, from estimated values of θ and σ^2. Therefore, β does not appear in the η_0 vector when `fitrgp` initializes numerical optimization.

Note If you specify no estimation of parameters for the GPR model, `fitrgp` uses the value of the `'Beta'` name-value pair argument and other initial parameter values as the known GPR parameter values (see `Beta`). In all other cases, the value of the `'Beta'` argument is optimized analytically from the objective function.

- The quasi-Newton optimizer uses a trust-region method with a dense, symmetric rank-1-based (SR1), quasi-Newton approximation to the Hessian, while the LBFGS optimizer uses a standard line-search method with a limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) quasi-Newton approximation to the Hessian. See Nocedal and Wright [6].
- If you set the `'InitialStepSize'` name-value pair argument to `'auto'`, `fitrgp` determines the initial step size, $\|s_0\|_\infty$, by using $\|s_0\|_\infty = 0.5\|\eta_0\|_\infty + 0.1$.

  s_0 is the initial step vector, and η_0 is the vector of unconstrained initial parameter values.
- During optimization, `fitrgp` uses the initial step size, $\|s_0\|_\infty$, as follows:

  If you use `'Optimizer','quasinewton'` with the initial step size, then the initial Hessian approximation is $\frac{\|g_0\|_\infty}{\|s_0\|_\infty} I$.

  If you use `'Optimizer','lbfgs'` with the initial step size, then the initial inverse-Hessian approximation is $\frac{\|s_0\|_\infty}{\|g_0\|_\infty} I$.

  g_0 is the initial gradient vector, and I is the identity matrix.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2015b

fitrlinear

Fit linear regression model to high-dimensional data

Syntax

```
Mdl = fitrlinear(X,Y)

Mdl = fitrlinear(Tbl,ResponseVarName)
Mdl = fitrlinear(Tbl,formula)
Mdl = fitrlinear(Tbl,Y)

Mdl = fitrlinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitrlinear(___)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(___)
```

Description

`fitrlinear` efficiently trains linear regression models with high-dimensional, full or sparse predictor data. Available linear regression models include regularized support vector machines (SVM) and least-squares regression methods. `fitrlinear` minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

For reduced computation time on a high-dimensional data set that includes many predictor variables, train a linear regression model by using `fitrlinear`. For low- through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 33-2208.

`Mdl = fitrlinear(X,Y)` returns a trained regression model object `Mdl` that contains the results of fitting a support vector machine regression model to the predictors `X` and response `Y`.

`Mdl = fitrlinear(Tbl,ResponseVarName)` returns a linear regression model using the predictor variables in the table `Tbl` and the response values in `Tbl.ResponseVarName`.

`Mdl = fitrlinear(Tbl,formula)` returns a linear regression model using the sample data in the table `Tbl`. The input argument `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitrlinear(Tbl,Y)` returns a linear regression model using the predictor variables in the table `Tbl` and the response values in vector `Y`.

`Mdl = fitrlinear(X,Y,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify to cross-validate, implement least-squares regression, or specify the type of regularization. A good practice is to cross-validate using the `'Kfold'` name-value pair argument. The cross-validation results determine how well the model generalizes.

`[Mdl,FitInfo] = fitrlinear(___)` also returns optimization details using any of the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

`[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(___)` also returns hyperparameter optimization details when you pass an `OptimizeHyperparameters` name-value pair.

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = x_1, \ldots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. By default, `fitrlinear` uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
[Mdl,FitInfo] = fitrlinear(X,Y)
```

```
Mdl =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x1 double]
                 Bias: -0.0056
               Lambda: 1.0000e-04
              Learner: 'svm'

  Properties, Methods

FitInfo = struct with fields:
                    Lambda: 1.0000e-04
                 Objective: 0.2725
                 PassLimit: 10

                   History: []
```

```
                FitTime: 0.1318
                 Solver: {'dual'}
```

`Mdl` is a `RegressionLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample mean-squared error. Or, you can pass `Mdl` and new predictor data to `predict` to predict responses for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. In this case, `fitrlinear` reached the maximum number of iterations. Because training time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as LBFGS.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = \{x_1, \ldots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1}.

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpaRSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');

numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

`CVMdl` is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, `CVMdl` contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x15 double]
                 Bias: [1x15 double]
               Lambda: [1x15 double]
              Learner: 'leastsquares'

  Properties, Methods
```

`Mdl1` is a `RegressionLinear` model object. `fitrlinear` constructed `Mdl1` by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 15 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

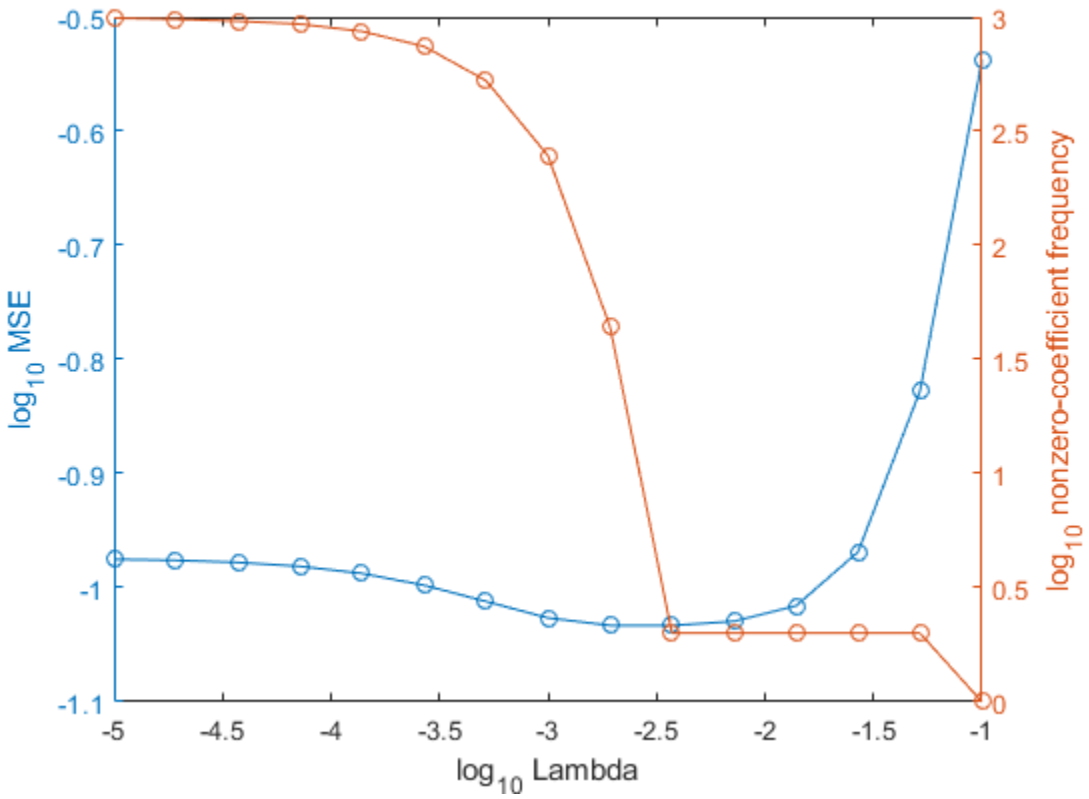
```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```



Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, `Lambda(10)`).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x1 double]
                 Bias: -0.0050
               Lambda: 0.0037
              Learner: 'leastsquares'

  Properties, Methods
```

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2×1

   100
   200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1

    1.0051
    1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Optimize a Linear Regression

This example shows how to optimize hyperparameters automatically using `fitrlinear`. The example uses artificial (simulated) data for the model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = \{x_1, \ldots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Find hyperparameters that minimize five-fold cross validation loss by using automatic hyperparameter optimization.

For reproducibility, use the `'expected-improvement-plus'` acquisition function.

```
hyperopts = struct('AcquisitionFunctionName','expected-improvement-plus');
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(X,Y,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',hyperopts)
```

```

This optimization technique is simpler than that shown in “Find Good Lasso Penalty Using Cross-Validation” on page 33-2178, but does not allow you to trade off model complexity and cross-validation loss.

Input Arguments

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an *n*-by-*p* full or sparse matrix.

The length of `Y` and the number of observations in `X` must be equal.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in optimization execution time.

Data Types: `single` | `double`

Y — Response data

numeric vector

Response data, specified as an *n*-dimensional numeric vector. The length of `Y` must be equal to the number of observations in `X` or `Tbl`.

Data Types: `single` | `double`

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

Note The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing values, and removes observations with any of these characteristics:

- Missing value in the response (for example, `Y` or `ValidationData{2}`)
- At least one missing value in a predictor observation (for example, row in `X` or `ValidationData{1}`)
- `NaN` value or `0` weight (for example, value in `Weights` or `ValidationData{3}`)

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `Mdl = fitrlinear(X,Y,'Learner','leastsquares','CrossVal','on','Regularization','lasso')` specifies to implement least-squares regression, implement 10-fold cross-validation, and specifies to include a lasso regularization term.

Linear Regression Options

Epsilon — Half the width of epsilon-insensitive band

`iqr(Y)/13.49` (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of `'Epsilon'` and a nonnegative scalar value. `'Epsilon'` applies to SVM learners only.

The default `Epsilon` value is `iqr(Y)/13.49`, which is an estimate of standard deviation using the interquartile range of the response variable `Y`. If `iqr(Y)` is equal to zero, then the default `Epsilon` value is 0.1.

Example: `'Epsilon',0.3`

Data Types: `single` | `double`

Lambda — Regularization term strength

`'auto'` (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and `'auto'`, a nonnegative scalar, or a vector of nonnegative values.

- For `'auto'`, `Lambda` = $1/n$.
  - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then n is the number of in-fold observations.
  - Otherwise, n is the training sample size.
- For a vector of nonnegative values, `fitrlinear` sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.
  - If `Solver` is `'sgd'` or `'asgd'` and `Regularization` is `'lasso'`, `fitrlinear` does not use the previous coefficient estimates as a warm start on page 33-1767 for the next optimization iteration. Otherwise, `fitrlinear` uses warm starts.
  - If `Regularization` is `'lasso'`, then any coefficient estimate of 0 retains its value when `fitrlinear` optimizes using subsequent values in `Lambda`.
  - `fitrlinear` returns coefficient estimates for each specified regularization strength.

Example: `'Lambda',10.^(-(10:-2:2))`

Data Types: `char` | `string` | `double` | `single`

Learner — Linear regression model type

`'svm'` (default) | `'leastsquares'`

Linear regression model type, specified as the comma-separated pair consisting of `'Learner'` and `'svm'` or `'leastsquares'`.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.

- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response range	Loss function
`'leastsquares'`	Linear regression via ordinary least squares	$y \in (-\infty,\infty)$	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$
`'svm'`	Support vector machine regression	Same as `'leastsquares'`	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, \lvert y - f(x)\rvert - \varepsilon]$

Example: `'Learner','leastsquares'`

`ObservationsIn` — Predictor data observation dimension
`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as `'rows'` or `'columns'`.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time. You cannot specify `'ObservationsIn','columns'` for predictor data in a table.

Example: `'ObservationsIn','columns'`

Data Types: `char` | `string`

`Regularization` — Complexity penalty type
`'lasso'` | `'ridge'`

Complexity penalty type, specified as the comma-separated pair consisting of `'Regularization'` and `'lasso'` or `'ridge'`.

The software composes the objective function for minimization from the sum of the average loss function (see `Learner`) and the regularization term in this table.

Value	Description
`'lasso'`	Lasso (L1) penalty: $\lambda \sum_{j=1}^{p} \lvert\beta_j\rvert$
`'ridge'`	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^{p} \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use `Lambda`.

The software excludes the bias term (β_0) from the regularization penalty.

If `Solver` is `'sparsa'`, then the default value of `Regularization` is `'lasso'`. Otherwise, the default is `'ridge'`.

Tip

- For predictor variable selection, specify `'lasso'`. For more on variable selection, see “Introduction to Feature Selection” on page 15-49.
- For optimization accuracy, specify `'ridge'`.

Example: `'Regularization','lasso'`

`Solver` — Objective function minimization technique
`'sgd'` | `'asgd'` | `'dual'` | `'bfgs'` | `'lbfgs'` | `'sparsa'` | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description	Restrictions
`'sgd'`	Stochastic gradient descent (SGD) [5][3]	
`'asgd'`	Average stochastic gradient descent (ASGD) [8]	
`'dual'`	Dual SGD for SVM [2][7]	`Regularization` must be `'ridge'` and `Learner` must be `'svm'`.
`'bfgs'`	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]	Inefficient if `X` is very high-dimensional.
`'lbfgs'`	Limited-memory BFGS (LBFGS) [4]	`Regularization` must be `'ridge'`.
`'sparsa'`	Sparse Reconstruction by Separable Approximation (SpaRSA) [6]	`Regularization` must be `'lasso'`.

If you specify:

- A ridge penalty (see `Regularization`) and `size(X,1) <= 100` (100 or fewer predictor variables), then the default solver is `'bfgs'`.
- An SVM regression model (see `Learner`), a ridge penalty, and `size(X,1) > 100` (more than 100 predictor variables), then the default solver is `'dual'`.
- A lasso penalty and `X` contains 100 or fewer predictor variables, then the default solver is `'sparsa'`.

Otherwise, the default solver is `'sgd'`.

If you specify a string array or cell array of solver names, then the software uses all solvers in the specified order for each `Lambda`.

For more details on which solver to choose, see “Tips” on page 33-2209.

Example: `'Solver',{'sgd','lbfgs'}`

Beta — Initial linear coefficient estimates
`zeros(p,1)` (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of `'Beta'` and a p-dimensional numeric vector or a p-by-L numeric matrix. p is the number of predictor variables in `X` and L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a p-dimensional vector, then the software optimizes the objective function L times using this process.
  1. The software optimizes using `Beta` as the initial value and the minimum value of `Lambda` as the regularization strength.
  2. The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 33-1767, and the next smallest value in `Lambda` as the regularization strength.
  3. The software implements step 2 until it exhausts all values in `Lambda`.
- If you specify a p-by-L matrix, then the software optimizes the objective function L times. At iteration j, the software uses `Beta(:,j)` as the initial value and, after it sorts `Lambda` in ascending order, uses `Lambda(j)` as the regularization strength.

If you set `'Solver','dual'`, then the software ignores `Beta`.

Data Types: `single` | `double`

Bias — Initial intercept estimate
numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of `'Bias'` and a numeric scalar or an L-dimensional numeric vector. L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
  1. The software optimizes using `Bias` as the initial value and the minimum value of `Lambda` as the regularization strength.
  2. The uses the resulting estimate as a warm start on page 33-2208 to the next optimization iteration, and uses the next smallest value in `Lambda` as the regularization strength.
  3. The software implements step 2 until it exhausts all values in `Lambda`.
- If you specify an L-dimensional vector, then the software optimizes the objective function L times. At iteration j, the software uses `Bias(j)` as the initial value and, after it sorts `Lambda` in ascending order, uses `Lambda(j)` as the regularization strength.
- By default:
  - If `Learner` is `'leastsquares'`, then `Bias` is the weighted average of `Y` for training or, for cross-validation, in-fold responses.
  - If `Learner` is `'svm'`, then `Bias` is the weighted median of `Y` for all training or, for cross-validation, in-fold observations that are greater than `Epsilon`.

Data Types: `single` | `double`

FitBias — Linear model intercept inclusion flag
`true` (default) | `false`

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of `'FitBias'` and `true` or `false`.

Value	Description
`true`	The software includes the bias term b in the linear model, and then estimates it.
`false`	The software sets $b = 0$ during estimation.

Example: `'FitBias',false`

Data Types: `logical`

`PostFitBias` — Flag to fit linear model intercept after optimization

`false` (default) | `true`

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of `'PostFitBias'` and `true` or `false`.

Value	Description
`false`	The software estimates the bias term b and the coefficients β during optimization.
`true`	To estimate b, the software: **1** Estimates β and b using the model. **2** Computes residuals. **3** Refits b. For least squares, b is the weighted average of the residuals. For SVM regression, b is the weighted median between all residuals with magnitude greater than `Epsilon`.

If you specify `true`, then `FitBias` must be true.

Example: `'PostFitBias',true`

Data Types: `logical`

`Verbose` — Verbosity level

`0` (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitrlinear` displays at the command line.

Value	Description
`0`	`fitrlinear` does not display diagnostic information.

Value	Description
1	`fitrlinear` periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. `FitInfo.History` contains the diagnostic information.
Any other positive integer	`fitrlinear` displays and stores diagnostic information at each optimization iteration. `FitInfo.History` contains the diagnostic information.

Example: `'Verbose',1`

Data Types: `double` | `single`

SGD and ASGD Solver Options

`BatchSize` — Mini-batch size
positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration, the software estimates the subgradient using `BatchSize` observations from the training data.

- If `X` is a numeric matrix, then the default value is `10`.
- If `X` is a sparse matrix, then the default value is `max([10,ceil(sqrt(ff))])`, where `ff = numel(X)/nnz(X)` (the fullness factor of `X`).

Example: `'BatchSize',100`

Data Types: `single` | `double`

`LearnRate` — Learning rate
positive scalar

Learning rate, specified as the comma-separated pair consisting of `'LearnRate'` and a positive scalar. `LearnRate` specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If `Regularization` is `'ridge'`, then `LearnRate` specifies the initial learning rate γ_0. The software determines the learning rate for iteration t, γ_t, using

  $$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

  - λ is the value of `Lambda`.
  - If `Solver` is `'sgd'`, $c = 1$.
  - If `Solver` is `'asgd'`:
    - $c = 2/3$ if `Learner` is `'leastsquares'`
    - $c = 3/4$ if `Learner` is `'svm'` [8]
- If `Regularization` is `'lasso'`, then, for all iterations, `LearnRate` is constant.

By default, `LearnRate` is `1/sqrt(1+max((sum(X.^2,obsDim))))`, where `obsDim` is `1` if the observations compose the columns of `X`, and `2` otherwise.

Example: `'LearnRate',0.01`

Data Types: `single` | `double`

`OptimizeLearnRate` — Flag to decrease learning rate
`true` (default) | `false`

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of `'OptimizeLearnRate'` and `true` or `false`.

If `OptimizeLearnRate` is `'true'`, then:

1. For the few optimization iterations, the software starts optimization using `LearnRate` as the learning rate.
2. If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
3. The software iterates step 2 until the objective function decreases.

Example: `'OptimizeLearnRate',true`

Data Types: `logical`

`TruncationPeriod` — Number of mini-batches between lasso truncation runs
`10` (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of `'TruncationPeriod'` and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing k = `TruncationPeriod` mini-batches, the software truncates the estimated coefficient j using

$$\widehat{\beta}_j^* = \begin{cases} \widehat{\beta}_j - u_t & \text{if } \widehat{\beta}_j > u_t, \\ 0 & \text{if } \left|\widehat{\beta}_j\right| \le u_t, \\ \widehat{\beta}_j + u_t & \text{if } \widehat{\beta}_j < -u_t. \end{cases}$$

- For SGD, $\widehat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t. λ is the value of `Lambda`.
- For ASGD, $\widehat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If `Regularization` is `'ridge'`, then the software ignores `TruncationPeriod`.

Example: `'TruncationPeriod',100`

Data Types: `single` | `double`

Other Regression Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table. The descriptions assume that the predictor data has observations in rows and predictors in columns.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitrlinear` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrlinear` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitrlinear` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitrlinear` creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For an unordered categorical variable, `fitrlinear` creates one dummy variable for each level of the categorical variable. For an ordered categorical variable, `fitrlinear` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`PredictorNames` — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the predictor order in `X`. Assuming that `X` has the default orientation, with observations in rows and predictors in columns, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrlinear` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ResponseTransform` — Response transformation
`'none'` (default) | function handle

Response transformation, specified as either `'none'` or a function handle. The default is `'none'`, which means `@(y)y`, or no transformation. For a MATLAB function or a function you define, use its function handle for the response transformation. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as `'ResponseTransform',myfunction`.

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
positive numeric vector | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a positive numeric vector or the name of a variable in `Tbl`. The software weights each observation in `X` or `Tbl`

with the corresponding value in `Weights`. The length of `Weights` must equal the number of observations in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

`fitrlinear` normalizes the weights to sum to 1.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation Options

`CrossVal` — Cross-validation flag
`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, or `KFold`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout',`*p*, then the software:

1. Randomly reserves *p*`*100`% of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

KFold — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold',k`, then the software:

1. Randomly partitions the data into k sets
2. For each set, reserves the set as validation data, and trains the model using the other k – 1 sets
3. Stores the k compact, trained models in the cells of a k-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'KFold',8`

Data Types: `single` | `double`

SGD and ASGD Convergence Controls

BatchLimit — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of `'BatchLimit'` and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
  - The software passes through the data `PassLimit` times.
  - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is `ceil(1e6/BatchSize)`. `BatchSize` is the value of the `'BatchSize'` name-value pair argument.
- If you specify `'BatchLimit'` and `'PassLimit'`, then the software chooses the argument that results in processing the fewest observations.
- If you specify `'BatchLimit'` but not `'PassLimit'`, then the software processes enough batches to complete up to one entire pass through the data.

Example: `'BatchLimit',100`

Data Types: `single` | `double`

BetaTolerance — Relative tolerance on linear coefficients and bias term

`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance',1e-6

Data Types: single | double

NumCheckConvergence — Number of batches to process before next convergence check
positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

To specify the batch size, see BatchSize.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: 'NumCheckConvergence',100

Data Types: single | double

PassLimit — Maximal number of passes
1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

fitrlinear processes all observations when it completes one pass through the data.

When fitrlinear passes through the data PassLimit times, it terminates optimization.

If you specify 'BatchLimit' and PassLimit, then fitrlinear chooses the argument that results in processing the fewest observations. For more details, see “Algorithms” on page 33-2210.

Example: 'PassLimit',5

Data Types: single | double

ValidationData — Validation data for optimization convergence detection
cell array | table

Validation data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array or table.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 33-2210. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

You can specify ValidationData as a table if you use a table Tbl of predictor data that contains the response variable. In this case, ValidationData must contain the same predictors and response contained in Tbl. The software does not apply weights to observations, even if Tbl contains a vector of weights. To specify weights, you must specify ValidationData as a cell array.

If you specify ValidationData as a cell array, then it must have the following format:

- ValidationData{1} must have the same data type and orientation as the predictor data. That is, if you use a predictor matrix X, then ValidationData{1} must be an *m*-by-*p* or *p*-by-*m* full or sparse matrix of predictor data that has the same orientation as X. The predictor variables in the training data X and ValidationData{1} must correspond. Similarly, if you use a predictor table

`Tbl` of predictor data, then `ValidationData{1}` must be a table containing the same predictor variables contained in `Tbl`. The number of observations in `ValidationData{1}` and the predictor data can vary.

- `ValidationData{2}` must match the data type and format of the response variable, either `Y` or `ResponseVarName`. If `ValidationData{2}` is an array of responses, then it must have the same number of elements as the number of observations in `ValidationData{1}`. If `ValidationData{1}` is a table, then `ValidationData{2}` can be the name of the response variable in the table. If you want to use the same `ResponseVarName` or `formula`, you can specify `ValidationData{2}` as `[]`.
- Optionally, you can specify `ValidationData{3}` as an *m*-dimensional numeric vector of observation weights or the name of a variable in the table `ValidationData{1}` that contains observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData` and want to display the validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

`GradientTolerance` — Absolute gradient tolerance

`1e-6` (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar. `GradientTolerance` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Let $\nabla\mathscr{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t. If $\|\nabla\mathscr{L}_t\|_\infty = \max|\nabla\mathscr{L}_t| <$ GradientTolerance, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when `fitrlinear` satisfies either stopping criterion.

If `fitrlinear` converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, `fitrlinear` uses the next solver specified in `Solver`.

Example: `'GradientTolerance',eps`

Data Types: `single` | `double`

`IterationLimit` — Maximal number of optimization iterations

`1000` (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. `IterationLimit` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Example: `'IterationLimit',1e7`

Data Types: `single` | `double`

Dual SGD Optimization Convergence Controls

`BetaTolerance` — Relative tolerance on linear coefficients and bias term

`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`DeltaGradientTolerance` — Gradient-difference tolerance

`0.1` (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 33-1862 violators, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar. `DeltaGradientTolerance` applies to the `'dual'` value of `Solver` only.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then `fitrlinear` terminates optimization.
- If `fitrlinear` converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, `fitrlinear` uses the next solver specified in `Solver`.

Example: `'DeltaGapTolerance',1e-2`

Data Types: `double` | `single`

`NumCheckConvergence` — Number of passes through entire data set to process before next convergence check

`5` (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

Example: `'NumCheckConvergence',100`

Data Types: `single` | `double`

`PassLimit` — Maximal number of passes

`10` (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PassLimit` times, it terminates optimization.

Example: `'PassLimit',5`

Data Types: `single` | `double`

`ValidationData` — Validation data for optimization convergence detection

cell array | table

Validation data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array or table.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 33-2210. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

You can specify `ValidationData` as a table if you use a table `Tbl` of predictor data that contains the response variable. In this case, `ValidationData` must contain the same predictors and response contained in `Tbl`. The software does not apply weights to observations, even if `Tbl` contains a vector of weights. To specify weights, you must specify `ValidationData` as a cell array.

If you specify `ValidationData` as a cell array, then it must have the following format:

- `ValidationData{1}` must have the same data type and orientation as the predictor data. That is, if you use a predictor matrix `X`, then `ValidationData{1}` must be an *m*-by-*p* or *p*-by-*m* full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. Similarly, if you use a predictor table `Tbl` of predictor data, then `ValidationData{1}` must be a table containing the same predictor variables contained in `Tbl`. The number of observations in `ValidationData{1}` and the predictor data can vary.
- `ValidationData{2}` must match the data type and format of the response variable, either `Y` or `ResponseVarName`. If `ValidationData{2}` is an array of responses, then it must have the same number of elements as the number of observations in `ValidationData{1}`. If `ValidationData{1}` is a table, then `ValidationData{2}` can be the name of the response variable in the table. If you want to use the same `ResponseVarName` or `formula`, you can specify `ValidationData{2}` as `[]`.
- Optionally, you can specify `ValidationData{3}` as an *m*-dimensional numeric vector of observation weights or the name of a variable in the table `ValidationData{1}` that contains observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData` and want to display the validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

BFGS, LBFGS, and SpaRSA Convergence Controls

`BetaTolerance` — Relative tolerance on linear coefficients and bias term

`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`GradientTolerance` — Absolute gradient tolerance
`1e-6` (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let $\nabla \mathscr{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t. If $\|\nabla \mathscr{L}_t\|_\infty = \max|\nabla \mathscr{L}_t| <$ GradientTolerance, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'GradientTolerance',1e-5`

Data Types: `single` | `double`

`HessianHistorySize` — Size of history buffer for Hessian approximation
`15` (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest `HessianHistorySize` iterations.

The software does not support `'HessianHistorySize'` for SpaRSA.

Example: `'HessianHistorySize',10`

Data Types: `single` | `double`

`IterationLimit` — Maximal number of optimization iterations
`1000` (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. `IterationLimit` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Example: `'IterationLimit',500`

Data Types: `single` | `double`

`ValidationData` — Validation data for optimization convergence detection

cell array | table

Validation data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array or table.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 33-2210. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

You can specify `ValidationData` as a table if you use a table `Tbl` of predictor data that contains the response variable. In this case, `ValidationData` must contain the same predictors and response contained in `Tbl`. The software does not apply weights to observations, even if `Tbl` contains a vector of weights. To specify weights, you must specify `ValidationData` as a cell array.

If you specify `ValidationData` as a cell array, then it must have the following format:

- `ValidationData{1}` must have the same data type and orientation as the predictor data. That is, if you use a predictor matrix `X`, then `ValidationData{1}` must be an *m*-by-*p* or *p*-by-*m* full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. Similarly, if you use a predictor table `Tbl` of predictor data, then `ValidationData{1}` must be a table containing the same predictor variables contained in `Tbl`. The number of observations in `ValidationData{1}` and the predictor data can vary.
- `ValidationData{2}` must match the data type and format of the response variable, either `Y` or `ResponseVarName`. If `ValidationData{2}` is an array of responses, then it must have the same number of elements as the number of observations in `ValidationData{1}`. If `ValidationData{1}` is a table, then `ValidationData{2}` can be the name of the response variable in the table. If you want to use the same `ResponseVarName` or `formula`, you can specify `ValidationData{2}` as `[]`.
- Optionally, you can specify `ValidationData{3}` as an *m*-dimensional numeric vector of observation weights or the name of a variable in the table `ValidationData{1}` that contains observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData` and want to display the validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Hyperparameter Optimization

`OptimizeHyperparameters` — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Lambda','Learner'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitrlinear by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrlinear are:

- Lambda — fitrlinear searches among positive values, by default log-scaled in the range [1e-5/NumObservations,1e5/NumObservations].
- Learner — fitrlinear searches among 'svm' and 'leastsquares'.
- Regularization — fitrlinear searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of optimizableVariable objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrlinear',[Horsepower,Weight],MPG);
params(1).Range = [1e-3,2e4];
```

Pass params as the value of OptimizeHyperparameters.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the Verbose field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the ShowPlots field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize a Linear Regression” on page 33-2181.

Example: 'OptimizeHyperparameters','auto'

HyperparameterOptimizationOptions — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the OptimizeHyperparameters name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`

Field Name	Values	Default
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained linear regression model

`RegressionLinear` model object | `RegressionPartitionedLinear` cross-validated model object

Trained linear regression model, returned as a `RegressionLinear` model object or `RegressionPartitionedLinear` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `RegressionPartitionedLinear` cross-validated model object. Otherwise, `Mdl` is a `RegressionLinear` model object.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Beta` in the Command Window to display the vector or matrix of estimated coefficients.

Note Unlike other regression models, and for economical memory usage, `RegressionLinear` and `RegressionPartitionedLinear` model objects do not store the training data or optimization details (for example, convergence history).

`FitInfo` — Optimization details

structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, `Objective` is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of `Lambda` and columns correspond to values of `Solver`.

This table describes some notable fields.

Field	Description
`TerminationStatus`	• Reason for optimization termination • Corresponds to a value in `TerminationCode`
`FitTime`	Elapsed, wall-clock time in seconds
`History`	A structure array of optimization information for each iteration. The field `Solver` stores solver types using integer coding. **Integer** / **Solver** 1 / SGD 2 / ASGD 3 / Dual SGD for SVM 4 / LBFGS 5 / BFGS 6 / SpaRSA

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

`HyperparameterOptimizationResults` — Cross-validation optimization of hyperparameters
`BayesianOptimization` object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. The output is nonempty when the value of `'OptimizeHyperparameters'` is not `'none'`. The output value depends on the `Optimizer` field value of the `'HyperparameterOptimizationOptions'` name-value pair argument:

Value of `Optimizer` Field	Value of `HyperparameterOptimizationResults`
`'bayesopt'` (default)	Object of class `BayesianOptimization`
`'gridsearch'` or `'randomsearch'`	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Note If `Learner` is `'leastsquares'`, then the loss term in the objective function is half of the MSE. `loss` returns the MSE by default. Therefore, if you use `loss` to check the resubstitution, or training, error then there is a discrepancy between the MSE returned by `loss` and optimization results in `FitInfo` or returned to the command line by setting a positive verbosity level using `Verbose`.

More About

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Alternatives for Lower-Dimensional Data

High-dimensional linear classification and regression models minimize objective functions relatively quickly, but at the cost of some accuracy, the numeric-only predictor variables restriction, and the model must be linear with respect to the parameters. If your predictor data set is low- through medium-dimensional, or contains heterogeneous variables, then you should use the appropriate classification or regression fitting function. To help you decide which fitting function is appropriate for your low-dimensional data set, use this table.

Model to Fit	Function	Notable Algorithmic Differences
SVM	• Binary classification: `fitcsvm` • Multiclass classification: `fitcecoc` • Regression: `fitrsvm`	• Computes the Gram matrix of the predictor variables, which is convenient for nonlinear kernel transformations. • Solves dual problem using SMO, ISDA, or *L*1 minimization via quadratic programming using `quadprog`.

Model to Fit	Function	Notable Algorithmic Differences
Linear regression	• Least-squares without regularization: `fitlm` • Regularized least-squares using a lasso penalty: `lasso` • Ridge regression: `ridge` or `lasso`	• `lasso` implements cyclic coordinate descent.
Logistic regression	• Logistic regression without regularization: `fitglm`. • Regularized logistic regression using a lasso penalty: `lassoglm`	• `fitglm` implements iteratively reweighted least squares. • `lassoglm` implements cyclic coordinate descent.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn','columns'`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy when you have high-dimensional predictor data and the `Regularization` value is `'ridge'`, set any of these options for `Solver`:
  - `'sgd'`
  - `'asgd'`
  - `'dual'` if `Learner` is `'svm'`
  - `{'sgd','lbfgs'}`
  - `{'asgd','lbfgs'}`
  - `{'dual','lbfgs'}` if `Learner` is `'svm'`

  Other options can result in poor optimization accuracy.
- For better optimization accuracy when you have moderate- to low-dimensional predictor data and the `Regularization` value is `'ridge'`, set `Solver` to `'bfgs'`.
- If `Regularization` is `'lasso'`, set any of these options for `Solver`:
  - `'sgd'`
  - `'asgd'`
  - `'sparsa'`
  - `{'sgd','sparsa'}`
  - `{'asgd','sparsa'}`
- When choosing between SGD and ASGD, consider that:
  - SGD takes less time per iteration, but requires more iterations to converge.
  - ASGD requires fewer iterations to converge, but takes more time per iteration.
- If your predictor data has few observations but many predictor variables, then:

  - Specify `'PostFitBias',true`.
  - For SGD or ASGD solvers, set `PassLimit` to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, `BatchSize` affects the rate of convergence.
  - If `BatchSize` is too small, then `fitrlinear` achieves the minimum in many iterations, but computes the gradient per iteration quickly.
  - If `BatchSize` is too large, then `fitrlinear` achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rates (see `LearnRate`) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- When using lasso penalties, experiment with various values of `TruncationPeriod`. For example, set `TruncationPeriod` to `1`, `10`, and then `100`.
- For efficiency, `fitrlinear` does not standardize predictor data. To standardize `X`, enter

  ```
  X = bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2));
  ```

  The code requires that you orient the predictors and observations as the rows and columns of `X`, respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- If you specify `ValidationData`, then, during objective-function optimization:
  - `fitrlinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.
  - When `fitrlinear` estimates a validation loss, it compares the estimate to the minimal estimate.
  - When subsequent, validation loss estimates exceed the minimal estimate five times, `fitrlinear` terminates optimization.
- If you specify `ValidationData` and to implement a cross-validation routine (`CrossVal`, `CVPartition`, `Holdout`, or `KFold`), then:

  1. `fitrlinear` randomly partitions `X` and `Y` (or `Tbl`) according to the cross-validation routine that you choose.
  2. `fitrlinear` trains the model using the training-data partition. During objective-function optimization, `fitrlinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
  3. Once `fitrlinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
     a. If you implement *k*-fold cross-validation, and `fitrlinear` has not exhausted all training-set folds, then `fitrlinear` returns to Step 2 to train using the next training-set fold.

   b Otherwise, `fitrlinear` terminates training, and then returns the cross-validated model.

4 You can determine the quality of the cross-validated model. For example:

   - To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
   - To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `fitrlinear` does not support tall `table` data.
- Some name-value pair arguments have different defaults and values compared to the in-memory `fitrlinear` function. Supported name-value pair arguments, and any differences, are:
  - `'Epsilon'`
  - `'ObservationsIn'` — Supports only `'rows'`.
  - `'Lambda'` — Can be `'auto'` (default) or a scalar.
  - `'Learner'`
  - `'Regularization'` — Supports only `'ridge'`.

- `'Solver'` — Supports only `'lbfgs'`.
- `'Verbose'` — Default value is `1`
- `'Beta'`
- `'Bias'`
- `'FitBias'` — Supports only `true`.
- `'Weights'` — Value must be a tall array.
- `'HessianHistorySize'`
- `'BetaTolerance'` — Default value is relaxed to `1e-3`.
- `'GradientTolerance'` — Default value is relaxed to `1e-3`.
- `'IterationLimit'` — Default value is relaxed to `20`.
- `'OptimizeHyperparameters'` — Value of `'Regularization'` parameter must be `'ridge'`.
- `'HyperparameterOptimizationOptions'` — For cross-validation, tall optimization supports only `'Holdout'` validation. By default, the software selects and reserves 20% of the data as holdout validation data, and trains the model using the rest of the data. You can specify a different value for the holdout fraction by using this argument. For example, specify `'HyperparameterOptimizationOptions',struct('Holdout',0.3)` to reserve 30% of the data as validation data.

- For tall arrays `fitrlinear` implements LBFGS by distributing the calculation of the loss and the gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

  When initial values for `Beta` and `Bias` are not given, `fitrlinear` first refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016a

fitrm

Fit repeated measures model

Syntax

```
rm = fitrm(t,modelspec)
rm = fitrm(t,modelspec,Name,Value)
```

Description

`rm = fitrm(t,modelspec)` returns a repeated measures model, specified by `modelspec`, fitted to the variables in the table or dataset array `t`.

`rm = fitrm(t,modelspec,Name,Value)` returns a repeated measures model, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the hypothesis for the within-subject factors.

Examples

Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas)
```

```
rm =
  RepeatedMeasuresModel with properties:

   Between Subjects:
         BetweenDesign: [150x5 table]
         ResponseNames: {'meas1'  'meas2'  'meas3'  'meas4'}
    BetweenFactorNames: {'species'}
          BetweenModel: '1 + species'

   Within Subjects:
```

```
          WithinDesign: [4x1 table]
     WithinFactorNames: {'Measurements'}
           WithinModel: 'separatemeans'

   Estimates:
          Coefficients: [3x4 table]
            Covariance: [4x4 table]
```

Display the coefficients.

```
rm.Coefficients
```

```
ans=3×4 table
                          meas1       meas2      meas3      meas4
                        ________    ________    ______    ________

    (Intercept)           5.8433      3.0573     3.758      1.1993
    species_setosa       -0.83733     0.37067   -2.296     -0.95333
    species_versicolor    0.092667   -0.28733    0.502      0.12667
```

`fitrm` uses the `'effects'` contrasts which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species\_setosa} = \begin{cases} 1 & \text{if setosa} \\ 0 & \text{if versicolor} \\ -1 & \text{if virginica} \end{cases} \quad \text{and} \quad \text{species\_versicolor} = \begin{cases} 0 & \text{if setosa} \\ 1 & \text{if versicolor} \\ -1 & \text{if virginica} \end{cases}$$

Display the covariance matrix.

```
rm.Covariance

```

Specify the Within-Subject Hypothesis

Load the sample data.

```
load('longitudinalData.mat');
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M']';
```

Store the data in a proper table array format to conduct repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable. Also define the hypothesis for within-subject factors.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time,'WithinModel','orthogonalcontrasts')
```

```
rm =
  RepeatedMeasuresModel with properties:

   Between Subjects:
         BetweenDesign: [16x6 table]
         ResponseNames: {'t0'  't2'  't4'  't6'  't8'}
    BetweenFactorNames: {'Gender'}
          BetweenModel: '1 + Gender'

   Within Subjects:
          WithinDesign: [5x1 table]
     WithinFactorNames: {'Time'}
           WithinModel: 'orthogonalcontrasts'

   Estimates:
          Coefficients: [2x5 table]
            Covariance: [5x5 table]
```

Fit a Model with Covariates

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the eight repeated measurements, `y1` through `y8`, as responses and the between-subject factors `Group`, `Gender`, `IQ`, and `Age`. `IQ` and `Age` as continuous variables. The table `within` includes the within-subject factors `w1` and `w2`.

Fit a repeated measures model, where age, IQ, group, and gender are the predictor variables, and the model includes the interaction effect of group and gender. Also define the within-subject factors.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender+Age+IQ','WithinDesign',within)
```

```
rm =
  RepeatedMeasuresModel with properties:

   Between Subjects:
```

```

```

The display shows the coefficients for fitting the repeated measures as a function of the terms in the between-subjects model.

Input Arguments

`t` — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

The variable names in `t` must be valid MATLAB identifiers. You can verify the variable names by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `table`

`modelspec` — Formula for model specification

character vector or string scalar of the form `'y1-yk ~ terms'`

Formula for model specification, specified as a character vector or string scalar of the form `'y1-yk ~ terms'`. The responses and terms are specified using Wilkinson notation on page 33-2218. `fitrm`

treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, character arrays, string arrays, or cell arrays of character vectors.

For example, if you have four repeated measures as responses and the factors `x1`, `x2`, and `x3` as the predictor variables, then you can define a repeated measures model as follows.

Example: `'y1-y4 ~ x1 + x2 * x3'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'WithinDesign','W','WithinModel','w1+w2'` specifies the matrix `w` as the design matrix for within-subject factors, and the model for within-subject factors `w1` and `w2` is `'w1+w2'`.

`WithinDesign` — Design for within-subject factors

numeric vector of length *r* (default) | *r*-by-*k* numeric matrix | *r*-by-*k* table

Design for within-subject factors, specified as the comma-separated pair consisting of `'WithinDesign'` and one of the following:

- Numeric vector of length *r*, where *r* is the number of repeated measures.

  In this case, `fitrm` treats the values in the vector as continuous, and these are typically time values.
- *r*-by-*k* numeric matrix of the values of the *k* within-subject factors, w_1, w_2, ..., w_k.

  In this case,`fitrm` treats all *k* variables as continuous.
- *r*-by-*k* table that contains the values of the *k* within-subject factors.

  In this case, `fitrm` treats all numeric variables as continuous, and all categorical variables as categorical.

For example, if the table `weeks` contains the values of the within-subject factors, then you can define the design table as follows.

Example: `'WithinDesign',weeks`

Data Types: `single` | `double` | `table`

`WithinModel` — Model specifying within-subject hypothesis test

`'separatemeans'` (default) | `'orthogonalcontrasts'` | character vector or string scalar that defines a model

Model specifying the within-subject hypothesis test, specified as the comma-separated pair consisting of `'WithinModel'` and one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `'orthogonalcontrasts'` — This is valid only when the within-subject model has a single numeric factor *T*. Responses are the average, the slope of centered *T*, and, in general, all orthogonal contrasts for a polynomial up to *T*^(*p* – 1), where *p* is the number if rows in the within-subject model.
- A character vector or string scalar that defines a model specification in the within-subject factors. You can define the model based on the rules for the `terms` in `modelspec`.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: `'WithinModel','w1+w2+w2*w3'`

Data Types: `char` | `string`

Output Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

More About

Model Specification Using Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

The following rules specify the responses in `modelspec`.

Wilkinson Notation	Meaning
`Y1,Y2,Y3`	Specific list of variables
`Y1-Y5`	All table variables from `Y1` through `Y5`

The following rules specify terms in `modelspec`.

Wilkinson notation	Factors in Standard Notation
`1`	Constant (intercept) term
`X^k`, where `k` is a positive integer	X, X^2, ..., X^k
`X1 + X2`	X1, X2
`X1*X2`	X1, X2, X1*X2
`X1:X2`	X1*X2 only
`-X2`	Do not include X2
`X1*X2 + X3`	X1, X2, X3, X1*X2
`X1 + X2 + X3 + X1:X2`	X1, X2, X3, X1*X2
`X1*X2*X3 - X1:X2:X3`	X1, X2, X3, X1*X2, X1*X3, X2*X3
`X1*(X2 + X3)`	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

`RepeatedMeasuresModel`

Introduced in R2014a

fitrnet

Train neural network regression model

Syntax

```
Mdl = fitrnet(Tbl,ResponseVarName)
Mdl = fitrnet(Tbl,formula)
Mdl = fitrnet(Tbl,Y)

Mdl = fitrnet(X,Y)

Mdl = fitrnet( ___ ,Name,Value)
```

Description

Use `fitrnet` to train a feedforward, fully connected neural network for regression. The first fully connected layer of the neural network has a connection from the network input (predictor data), and each subsequent layer has a connection from the previous layer. Each fully connected layer multiplies the input by a weight matrix and then adds a bias vector. An activation function follows each fully connected layer, excluding the last. The final fully connected layer produces the network's output, namely predicted response values. For more information, see “Neural Network Structure” on page 33-2239.

`Mdl = fitrnet(Tbl,ResponseVarName)` returns a neural network regression model `Mdl` trained using the predictors in the table `Tbl` and the response values in the `ResponseVarName` table variable.

`Mdl = fitrnet(Tbl,formula)` returns a neural network regression model trained using the sample data in the table `Tbl`. The input argument `formula` is an explanatory model of the response and a subset of the predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitrnet(Tbl,Y)` returns a neural network regression model using the predictor variables in the table `Tbl` and the response values in vector `Y`.

`Mdl = fitrnet(X,Y)` returns a neural network regression model trained using the predictors in the matrix `X` and the response values in vector `Y`.

`Mdl = fitrnet( ___ ,Name,Value)` specifies options using one or more name-value arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can adjust the number of outputs and the activation functions for the fully connected layers by specifying the `LayerSizes` and `Activations` name-value arguments.

Examples

Train Neural Network Regression Model

Train a neural network regression model, and assess the performance of the model on a test set.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s. Create a table containing the predictor variables `Acceleration`, `Displacement`, and so on, as well as the response variable `MPG`.

```
load carbig
cars = table(Acceleration,Displacement,Horsepower, ...
    Model_Year,Origin,Weight,MPG);
```

Partition the data into training and test sets. Use approximately 80% of the observations to train a neural network model, and 20% of the observations to test the performance of the trained model on new data. Use `cvpartition` to partition the data.

```
rng("default") % For reproducibility of the data partition
c = cvpartition(length(MPG),"Holdout",0.20);
trainingIdx = training(c); % Training set indices
carsTrain = cars(trainingIdx,:);
testIdx = test(c); % Test set indices
carsTest = cars(testIdx,:);
```

Train a neural network regression model by passing the `carsTrain` training data to the `fitrnet` function. For better results, specify to standardize the predictor data.

```
Mdl = fitrnet(carsTrain,"MPG","Standardize",true)
```

```
Mdl =
  RegressionNeuralNetwork
           PredictorNames: {'Acceleration'  'Displacement'  'Horsepower'  'Model_Year'  'Origin'
             ResponseName: 'MPG'
    CategoricalPredictors: 5
        ResponseTransform: 'none'
          NumObservations: 314
               LayerSizes: 10
              Activations: 'relu'
    OutputLayerActivation: 'linear'
                   Solver: 'LBFGS'
          ConvergenceInfo: [1×1 struct]
          TrainingHistory: [1000×7 table]

  Properties, Methods
```

`Mdl` is a trained `RegressionNeuralNetwork` model. You can use dot notation to access the properties of `Mdl`. For example, you can specify `Mdl.TrainingHistory` to get more information about the training history of the neural network model.

Evaluate the performance of the regression model on the test set by computing the test mean squared error (MSE). Smaller MSE values indicate better performance.

```
testMSE = loss(Mdl,carsTest,"MPG")
```

```
testMSE = 16.6154
```

Specify Neural Network Regression Model Architecture

Specify the structure of the neural network regression model, including the size of the fully connected layers.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s. Create a matrix `X` containing the predictor variables `Acceleration`, `Cylinders`, and so on. Store the response variable `MPG` in the variable `Y`.

```
load carbig
X = [Acceleration Cylinders Displacement Weight];
Y = MPG;
```

Partition the data into training data (`XTrain` and `YTrain`) and test data (`XTest` and `YTest`). Reserve approximately 20% of the observations for testing, and use the rest of the observations for training.

```
rng("default") % For reproducibility of the partition
c = cvpartition(length(Y),"Holdout",0.20);
trainingIdx = training(c); % Indices for the training set
XTrain = X(trainingIdx,:);
YTrain = Y(trainingIdx);
testIdx = test(c); % Indices for the test set
XTest = X(testIdx,:);
YTest = Y(testIdx);
```

Train a neural network regression model. Specify to standardize the predictor data, and to have 30 outputs in the first fully connected layer and 10 outputs in the second fully connected layer. By default, both layers use a rectified linear unit (ReLU) activation function. You can change the activation functions for the fully connected layers by using the `Activations` name-value argument.

```
Mdl = fitrnet(XTrain,YTrain,"Standardize",true, ...
    "LayerSizes",[30 10])
```

```
Mdl =
  RegressionNeuralNetwork
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
          NumObservations: 318
              LayerSizes: [30 10]
             Activations: 'relu'
    OutputLayerActivation: 'linear'
                  Solver: 'LBFGS'
          ConvergenceInfo: [1×1 struct]
          TrainingHistory: [1000×7 table]

  Properties, Methods
```

Access the weights and biases for the fully connected layers of the trained model by using the `LayerWeights` and `LayerBiases` properties of `Mdl`. The first two elements of each property correspond to the values for the first two fully connected layers, and the third element corresponds to the values for the final fully connected layer for regression. For example, display the weights and biases for the first fully connected layer.

```
Mdl.LayerWeights{1}
```

```
ans = 30×4

   -1.0617    0.1287    0.0797    0.4648
   -0.6497   -1.4565   -2.6026    2.6962
   -0.6420    0.2744   -0.0234   -0.0252
   -1.9727   -0.4665   -0.5833    0.9371
   -0.4373    0.1607    0.3930    0.7859
    0.5091   -0.0032   -0.6503   -1.6694
    0.0123   -0.2624   -2.2928   -1.0965
   -0.1386    1.2747    0.4085    0.5395
   -0.1755    1.5641   -3.1896   -1.1336
    0.4401    0.4942    1.8957   -1.1617
      ⋮
```

```
Mdl.LayerBiases{1}
```

```
ans = 30×1

   -1.3086
   -1.6205
   -0.7815
    1.5382
   -0.5256
    1.2394
   -2.3078
   -1.0709
   -1.8898
    1.9443
      ⋮
```

The final fully connected layer has one output. The number of layer outputs corresponds to the first dimension of the layer weights and layer biases.

```
size(Mdl.LayerWeights{end})
```

```
ans = 1×2

     1    10
```

```
size(Mdl.LayerBiases{end})
```

```
ans = 1×2

     1     1
```

To estimate the performance of the trained model, compute the test set mean squared error (MSE) for `Mdl`. Smaller MSE values indicate better performance.

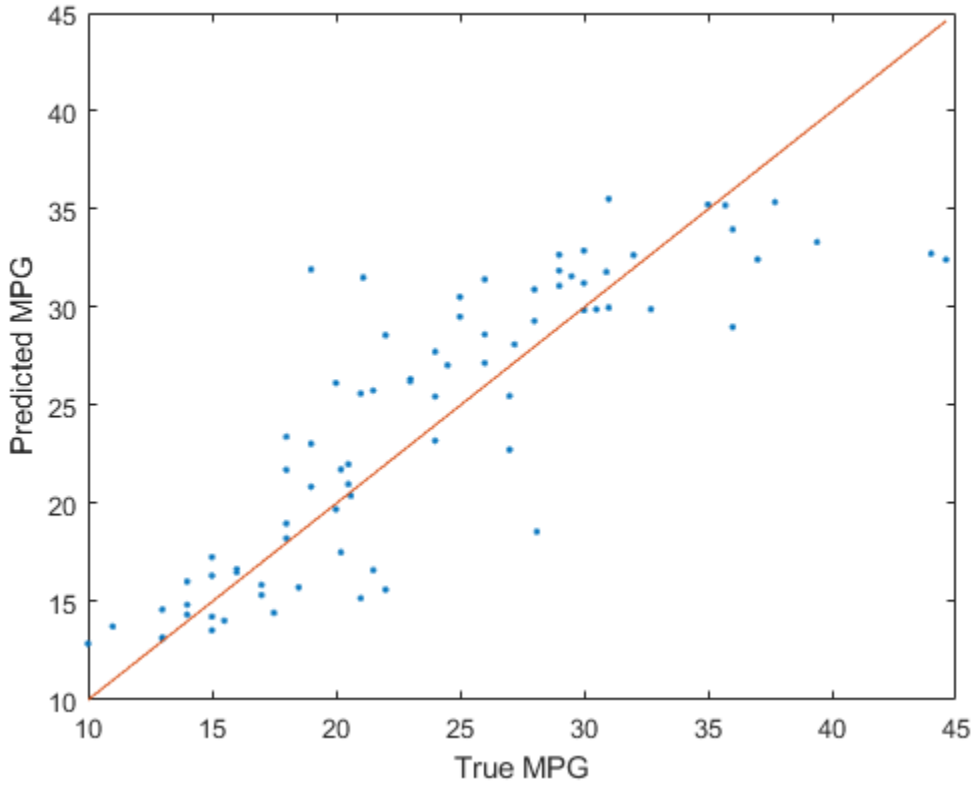
```
testMSE = loss(Mdl,XTest,YTest)
```

```
testMSE = 17.2022
```

Compare the predicted test set response values to the true response values. Plot the predicted miles per gallon (MPG) along the vertical axis and the true MPG along the horizontal axis. Points on the

reference line indicate correct predictions. A good model produces predictions that are scattered near the line.

```
testPredictions = predict(Mdl,XTest);
plot(YTest,testPredictions,".")
hold on
plot(YTest,YTest)
hold off
xlabel("True MPG")
ylabel("Predicted MPG")
```



Stop Neural Network Training Early Using Validation Data

At each iteration of the training process, compute the validation loss of the neural network. Stop the training process early if the validation loss reaches a reasonable minimum.

Load the `patients` data set. Create a table from the data set. Each row corresponds to one patient, and each column corresponds to a diagnostic variable. Use the `Systolic` variable as the response variable, and the rest of the variables as predictors.

```
load patients
tbl = table(Age,Diastolic,Gender,Height,Smoker,Weight,Systolic);
```

Separate the data into a training set `tblTrain` and a validation set `tblValidation`. The software reserves approximately 30% of the observations for the validation data set and uses the rest of the observations for the training data set.

```
rng("default") % For reproducibility of the partition
c = cvpartition(size(tbl,1),"Holdout",0.30);
trainingIndices = training(c);
validationIndices = test(c);
tblTrain = tbl(trainingIndices,:);
tblValidation = tbl(validationIndices,:);
```

Train a neural network regression model by using the training set. Specify the `Systolic` column of `tblTrain` as the response variable. Evaluate the model at each iteration by using the validation set. Specify to display the training information at each iteration by using the `Verbose` name-value argument. By default, the training process ends early if the validation loss is greater than or equal to the minimum validation loss computed so far, six times in a row. To change the number of times the validation loss is allowed to be greater than or equal to the minimum, specify the `ValidationPatience` name-value argument.

```
Mdl = fitrnet(tblTrain,"Systolic", ...
    "ValidationData",tblValidation, ...
    "Verbose",1);
```

```

|=========================================================================================|
```

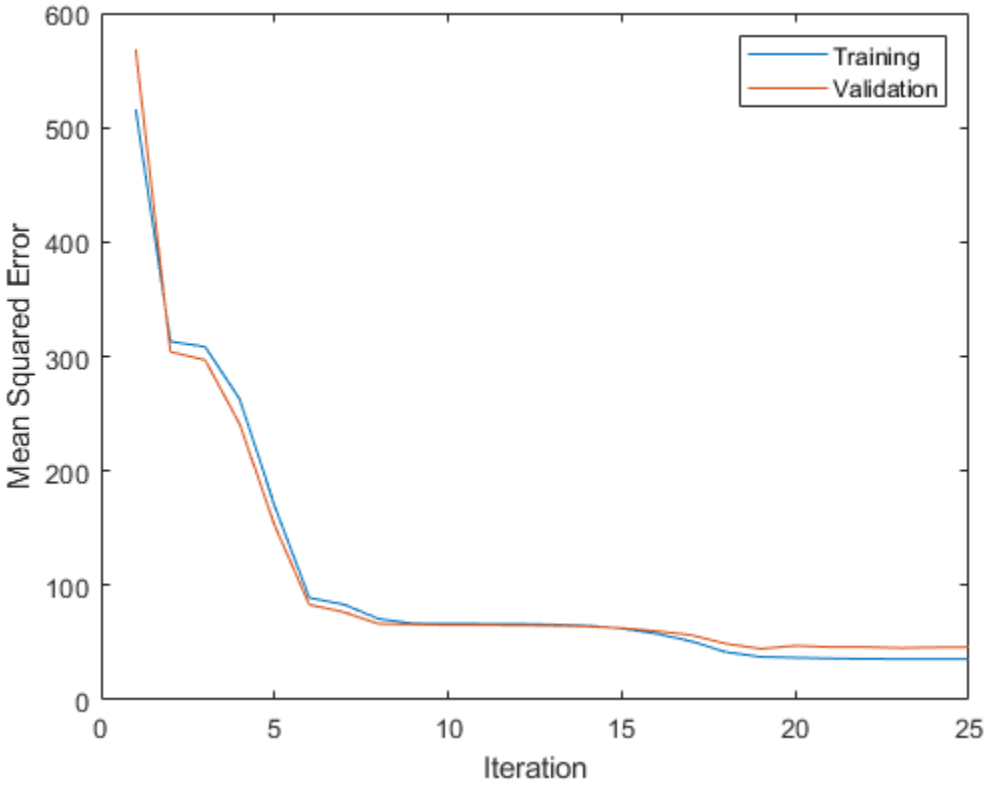
Create a plot that compares the training mean squared error (MSE) and the validation MSE at each iteration. By default, `fitrnet` stores the loss information inside the `TrainingHistory` property of the object `Mdl`. You can access this information by using dot notation.

```
iteration = Mdl.TrainingHistory.Iteration;
trainLosses = Mdl.TrainingHistory.TrainingLoss;
valLosses = Mdl.TrainingHistory.ValidationLoss;
plot(iteration,trainLosses,iteration,valLosses)
legend(["Training","Validation"])
xlabel("Iteration")
ylabel("Mean Squared Error")
```



Check the iteration that corresponds to the minimum validation MSE. The final returned model `Mdl` is the model trained at this iteration.

```
[~,minIdx] = min(valLosses);
iteration(minIdx)
```

```
ans = 19
```

Find Good Regularization Strength for Neural Network Using Cross-Validation

Assess the cross-validation loss of neural network models with different regularization strengths, and choose the regularization strength corresponding to the best performing model.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s. Create a table containing the predictor variables `Acceleration`, `Displacement`, and so on, as well as the response variable `MPG`. Remove observations from the table with missing values.

```
load carbig
tbl = table(Acceleration,Displacement,Horsepower, ...
    Model_Year,Origin,Weight,MPG);
cars = rmmissing(tbl);
```

Create a `cvpartition` object for 5-fold cross-validation. `cvp` partitions the data into five folds, where each fold has roughly the same number of observations. Set the random seed to the default value for reproducibility of the partition.

```
rng("default")
n = size(cars,1);
cvp = cvpartition(n,"KFold",5);
```

Compute the cross-validation mean squared error (MSE) for neural network regression models with different regularization strengths. Try regularization strengths on the order of $1/n$, where n is the number of observations. Specify to standardize the data before training the neural network models.

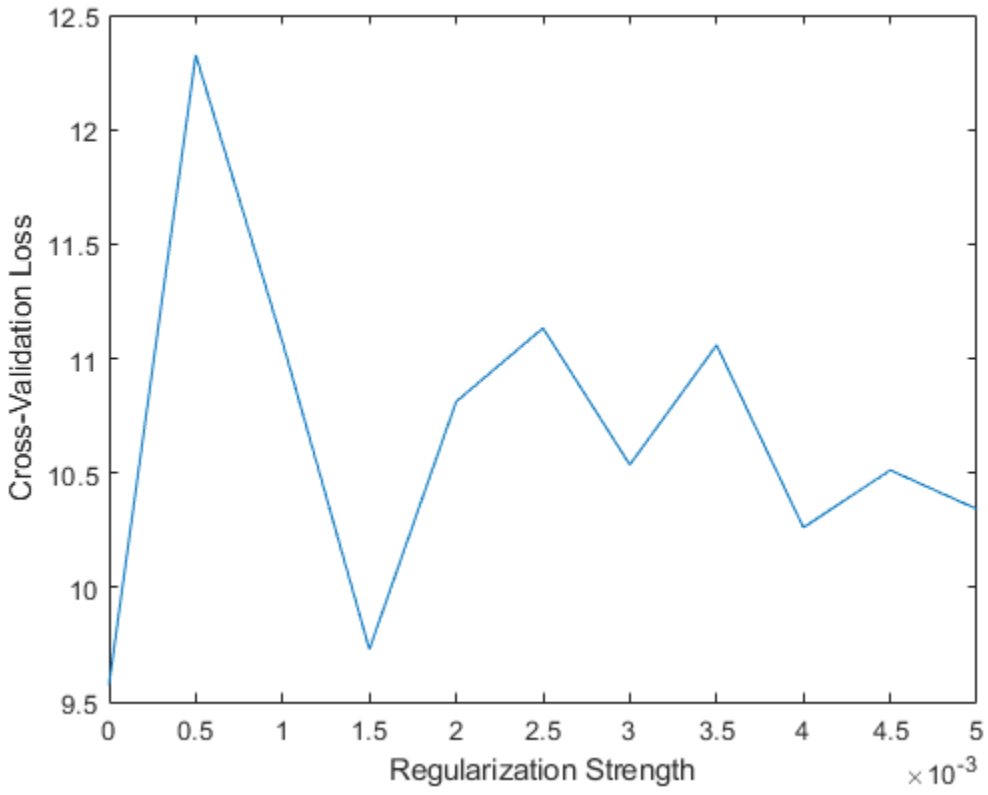
```
1/n
```

```
ans = 0.0026
```

```
lambda = (0:0.5:5)*1e-3;
cvloss = zeros(length(lambda),1);
for i = 1:length(lambda)
    cvMdl = fitrnet(cars,"MPG","Lambda",lambda(i), ...
        "CVPartition",cvp,"Standardize",true);
    cvloss(i) = kfoldLoss(cvMdl);
end
```

Plot the results. Find the regularization strength corresponding to the lowest cross-validation MSE.

```
plot(lambda,cvloss)
xlabel("Regularization Strength")
ylabel("Cross-Validation Loss")
```



```
[~,idx] = min(cvloss);
bestLambda = lambda(idx)
```

```
bestLambda = 0
```

Train a neural network regression model using the `bestLambda` regularization strength.

```
Mdl = fitrnet(cars,"MPG","Lambda",bestLambda, ...
    "Standardize",true)
```

```
Mdl =
  RegressionNeuralNetwork
           PredictorNames: {'Acceleration'  'Displacement'  'Horsepower'  'Model_Year'  'Origin'
             ResponseName: 'MPG'
    CategoricalPredictors: 5
        ResponseTransform: 'none'
          NumObservations: 392
               LayerSizes: 10
              Activations: 'relu'
    OutputLayerActivation: 'linear'
                   Solver: 'LBFGS'
          ConvergenceInfo: [1×1 struct]
          TrainingHistory: [1000×7 table]

  Properties, Methods
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables

character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Response data

numeric vector

Response data, specified as a numeric vector. The length of `Y` must be equal to the number of observations in `X` or `Tbl`.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data used to train the model, specified as a numeric matrix.

By default, the software treats each row of `X` as one observation, and each column as one predictor.

The length of `Y` and the number of observations in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value argument.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time.

Data Types: `single` | `double`

Note The software treats `NaN`, empty character vector (`''`), empty string (`""`), `<missing>`, and `<undefined>` elements as missing values, and removes observations with any of these characteristics:

- Missing value in the response (for example, `Y` or `ValidationData{2}`)
- At least one missing value in a predictor observation (for example, row in `X` or `ValidationData{1}`)
- `NaN` value or `0` weight (for example, value in `Weights` or `ValidationData{3}`)

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitrnet(X,Y,'LayerSizes',[10 10],'Activations',["relu","tanh"])` specifies to create a neural network with two fully connected layers, each with 10 outputs. The first layer uses a rectified linear unit (ReLU) activation function, and the second uses a hyperbolic tangent activation function.

Neural Network Options

LayerSizes — Sizes of fully connected layers

`10` (default) | positive integer vector

Sizes of the fully connected layers in the neural network model, specified as a positive integer vector. The *i*th element of `LayerSizes` is the number of outputs in the *i*th fully connected layer of the neural network model.

`LayerSizes` does not include the size of the final fully connected layer. For more information, see “Neural Network Structure” on page 33-2239.

Example: `'LayerSizes',[100 25 10]`

`Activations` — Activation functions for fully connected layers
`'relu'` (default) | `'tanh'` | `'sigmoid'` | `'none'` | string array | cell array of character vectors

Activation functions for the fully connected layers of the neural network model, specified as a character vector, string scalar, string array, or cell array of character vectors with values from this table.

Value	Description
`'relu'`	Rectified linear unit (ReLU) function — Performs a threshold operation on each element of the input, where any value less than zero is set to zero, that is, $$f(x) = \begin{cases} x, & x \geq 0 \\ 0, & x < 0 \end{cases}$$
`'tanh'`	Hyperbolic tangent (tanh) function — Applies the `tanh` function to each input element
`'sigmoid'`	Sigmoid function — Performs the following operation on each input element: $$f(x) = \frac{1}{1 + e^{-x}}$$
`'none'`	Identity function — Returns each input element without performing any transformation, that is, $f(x) = x$

- If you specify one activation function only, then `Activations` is the activation function for every fully connected layer of the neural network model, excluding the final fully connected layer (see “Neural Network Structure” on page 33-2239).
- If you specify an array of activation functions, then the *i*th element of `Activations` is the activation function for the *i*th layer of the neural network model.

Example: `'Activations','sigmoid'`

`LayerWeightsInitializer` — Function to initialize fully connected layer weights
`'glorot'` (default) | `'he'`

Function to initialize the fully connected layer weights, specified as `'glorot'` or `'he'`.

Value	Description
`'glorot'`	Initialize the weights with the Glorot initializer [1] (also known as the Xavier initializer). For each layer, the Glorot initalizer independently samples from a uniform distribution with zero mean and variable `2/(I+O)`, where `I` is the input size and `O` is the output size for the layer.

Value	Description
`'he'`	Initialize the weights with the He initializer [2]. For each layer, the He initializer samples from a normal distribution with zero mean and variance `2/I`, where `I` is the input size for the layer.

Example: `'LayerWeightsFunction','he'`

`LayerBiasesInitializer` — Type of initial fully connected layer biases
`'zeros'` (default) | `'ones'`

Type of initial fully connected layer biases, specified as `'zeros'` or `'ones'`.

- If you specify the value `'zeros'`, then each fully connected layer has an initial bias of 0.
- If you specify the value `'ones'`, then each fully connected layer has an initial bias of 1.

Example: `'LayerBiasesInitializer','ones'`

Data Types: `char` | `string`

`ObservationsIn` — Predictor data observation dimension
`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as `'rows'` or `'columns'`.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn','columns'`, then you might experience a significant reduction in computation time. You cannot specify `'ObservationsIn','columns'` for predictor data in a table.

Example: `'ObservationsIn','columns'`

Data Types: `char` | `string`

`Lambda` — Regularization term strength
`0` (default) | nonnegative scalar

Regularization term strength, specified as a nonnegative scalar. The software composes the objective function for minimization from the mean squared error (MSE) loss function and the ridge (L2) penalty term.

Example: `'Lambda',1e-4`

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictor data
`false` or `0` (default) | `true` or `1`

Flag to standardize the predictor data, specified as a numeric or logical `0` (`false`) or `1` (`true`). If you set `Standardize` to `true`, then the software centers and scales each numeric predictor variable by the corresponding column mean and standard deviation. The software does not standardize the categorical predictors.

Example: `'Standardize',true`

Data Types: `single` | `double` | `logical`

Convergence Control Options

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as `0` or `1`. The `'Verbose'` name-value argument controls the amount of diagnostic information that `fitrnet` displays at the command line.

Value	Description
`0`	`fitrnet` does not display diagnostic information.
`1`	`fitrnet` periodically displays diagnostic information.

By default, `StoreHistory` is set to `true` and `fitrnet` stores the diagnostic information inside of `Mdl`. Use `Mdl.TrainingHistory` to access the diagnostic information.

Example: `'Verbose',1`

Data Types: `single` | `double`

`VerboseFrequency` — Frequency of verbose printing
`1` (default) | positive integer scalar

Frequency of verbose printing, which is the number of iterations between printing to the command window, specified as a positive integer scalar. A value of 1 indicates to print diagnostic information at every iteration.

Note To use this name-value argument, set `Verbose` to `1`.

Example: `'VerboseFrequency',5`

Data Types: `single` | `double`

`StoreHistory` — Flag to store training history
`true` or `1` (default) | `false` or `0`

Flag to store the training history, specified as a numeric or logical `0` (`false`) or `1` (`true`). If `StoreHistory` is set to `true`, then the software stores diagnostic information inside of `Mdl`, which you can access by using `Mdl.TrainingHistory`.

Example: `'StoreHistory',false`

Data Types: `single` | `double` | `logical`

`IterationLimit` — Maximum number of training iterations
`1e3` (default) | positive integer scalar

Maximum number of training iterations, specified as a positive integer scalar.

The software returns a trained model regardless of whether the training routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: `'IterationLimit',1e8`

Data Types: `single` | `double`

`GradientTolerance` — Relative gradient tolerance
`1e-6` (default) | nonnegative scalar

Relative gradient tolerance, specified as a nonnegative scalar.

Let $\mathscr{L}_t$ be the loss function at training iteration t, $\nabla\mathscr{L}_t$ be the gradient of the loss function with respect to the weights and biases at iteration t, and $\nabla\mathscr{L}_0$ be the gradient of the loss function at an initial point. If $\max|\nabla\mathscr{L}_t| \le a \cdot \text{GradientTolerance}$, where $a = \max(1, \min|\mathscr{L}_t|, \max|\nabla\mathscr{L}_0|)$, then the training process terminates.

Example: `'GradientTolerance',1e-5`

Data Types: `single` | `double`

`LossTolerance` — Loss tolerance
`1e-6` (default) | nonnegative scalar

Loss tolerance, specified as a nonnegative scalar.

If the function loss at some iteration is smaller than `LossTolerance`, then the training process terminates.

Example: `'LossTolerance',1e-8`

Data Types: `single` | `double`

`StepTolerance` — Step size tolerance
`1e-6` (default) | nonnegative scalar

Step size tolerance, specified as a nonnegative scalar.

If the step size at some iteration is smaller than `StepTolerance`, then the training process terminates.

Example: `'StepTolerance',1e-4`

Data Types: `single` | `double`

`ValidationData` — Validation data for training convergence detection
cell array | table

Validation data for training convergence detection, specified as a cell array or table.

During the training process, the software periodically estimates the validation loss by using `ValidationData`. If the validation loss increases more than `ValidationPatience` times in a row, then the software terminates the training.

You can specify `ValidationData` as a table if you use a table `Tbl` of predictor data that contains the response variable. In this case, `ValidationData` must contain the same predictors and response contained in `Tbl`. The software does not apply weights to observations, even if `Tbl` contains a vector of weights. To specify weights, you must specify `ValidationData` as a cell array.

If you specify `ValidationData` as a cell array, then it must have the following format:

- `ValidationData{1}` must have the same data type and orientation as the predictor data. That is, if you use a predictor matrix `X`, then `ValidationData{1}` must be an *m*-by-*p* or *p*-by-*m* matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X`

and `ValidationData{1}` must correspond. Similarly, if you use a predictor table `Tbl` of predictor data, then `ValidationData{1}` must be a table containing the same predictor variables contained in `Tbl`. The number of observations in `ValidationData{1}` and the predictor data can vary.

- `ValidationData{2}` must match the data type and format of the response variable, either `Y` or `ResponseVarName`. If `ValidationData{2}` is an array of responses, then it must have the same number of elements as the number of observations in `ValidationData{1}`. If `ValidationData{1}` is a table, then `ValidationData{2}` can be the name of the response variable in the table. If you want to use the same `ResponseVarName` or `formula`, you can specify `ValidationData{2}` as `[]`.
- Optionally, you can specify `ValidationData{3}` as an *m*-dimensional numeric vector of observation weights or the name of a variable in the table `ValidationData{1}` that contains observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData` and want to display the validation loss at the command line, set `Verbose` to `1`.

`ValidationFrequency` — Number of iterations between validation evaluations

`1` (default) | positive integer scalar

Number of iterations between validation evaluations, specified as a positive integer scalar. A value of 1 indicates to evaluate validation metrics at every iteration.

Note To use this name-value argument, you must specify `ValidationData`.

Example: `'ValidationFrequency',5`

Data Types: `single` | `double`

`ValidationPatience` — Stopping condition for validation evaluations

`6` (default) | nonnegative integer scalar

Stopping condition for validation evaluations, specified as a nonnegative integer scalar. Training stops if the validation loss is greater than or equal to the minimum validation loss computed so far, `ValidationPatience` times in a row. You can check the `Mdl.TrainingHistory` table to see the running total of times that the validation loss is greater than or equal to the minimum (`Validation Checks`).

Example: `'ValidationPatience',10`

Data Types: `single` | `double`

Other Regression Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table. The descriptions assume that the predictor data has observations in rows and predictors in columns.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitrnet` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrnet` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitrnet` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitrnet` creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For an unordered categorical variable, `fitrnet` creates one dummy variable for each level of the categorical variable. For an ordered categorical variable, `fitrnet` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`PredictorNames` — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the predictor order in `X`. Assuming that `X` has the default orientation, with observations in rows and predictors in columns, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.

  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrnet` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`Weights` — Observation weights
nonnegative numeric vector | name of variable in `Tbl`

Observation weights, specified as a nonnegative numeric vector or the name of a variable in `Tbl`. The software weights each observation in `X` or `Tbl` with the corresponding value in `Weights`. The length of `Weights` must equal the number of observations in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

By default, `Weights` is `ones(n,1)`, where `n` is the number of observations in `X` or `Tbl`.

`fitrnet` normalizes the weights to sum to 1.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation Options

`CrossVal` — Flag to train cross-validated model
`'off'` (default) | `'on'`

Flag to train a cross-validated model, specified as `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated model with 10 folds.

You can override this cross-validation setting using the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value argument. You can use only one cross-validation name-value argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'Crossval','on'`

Data Types: `char` | `string`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.
2. Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Output Arguments

`Mdl` — Trained neural network regression model
`RegressionNeuralNetwork` object | `RegressionPartitionedModel` object

Trained neural network regression model, returned as a `RegressionNeuralNetwork` or `RegressionPartitionedModel`object.

If you set any of the name-value arguments `CrossVal`, `CVPartition`, `Holdout`, `KFold`, or `Leaveout`, then `Mdl` is a `RegressionPartitionedModel` object. Otherwise, `Mdl` is a `RegressionNeuralNetwork` model.

To reference properties of `Mdl`, use dot notation.

More About

Neural Network Structure

The default neural network regression model has the following layer structure.

Structure	Description
	Input — This layer corresponds to the predictor data in `Tbl` or `X`.
	First fully connected layer — This layer has 10 outputs by default. • You can widen the layer or add more fully connected layers to the network by specifying the `LayerSizes` name-value argument. • You can find the weights and biases for this layer in the `Mdl.LayerWeights{1}` and `Mdl.LayerBiases{1}` properties of `Mdl`, respectively.
	ReLU activation function — `fitrnet` applies this activation function to the first fully connected layer. • You can change the activation function by specifying the `Activations` name-value argument.
	Final fully connected layer — This layer has one output. • You can find the weights and biases for this layer in the `Mdl.LayerWeights{end}` and `Mdl.LayerBiases{end}` properties of `Mdl`, respectively.
	Output — This layer corresponds to the predicted response values.

For an example that shows how a regression neural network model with this layer structure returns predictions, see “Predict Using Layer Structure of Regression Neural Network Model” on page 33-4889.

Tips

- Always try to standardize the numeric predictors (see `Standardize`). Standardization makes predictors insensitive to the scales on which they are measured.

Algorithms

Training Solver

`fitrnet` uses a limited-memory Broyden-Flecter-Goldfarb-Shanno quasi-Newton algorithm (LBFGS) [3] as its loss function minimization technique, where the software minimizes the mean squared error (MSE).

Introduced in R2021a

fitdist

Fit probability distribution object to data

Syntax

```
pd = fitdist(x,distname)
pd = fitdist(x,distname,Name,Value)

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)
[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)
```

Description

`pd = fitdist(x,distname)` creates a probability distribution object by fitting the distribution specified by `distname` to the data in column vector `x`.

`pd = fitdist(x,distname,Name,Value)` creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)` creates probability distribution objects by fitting the distribution specified by `distname` to the data in `x` based on the grouping variable `groupvar`. It returns a cell array of fitted probability distribution objects, `pdca`, a cell array of group labels, `gn`, and a cell array of grouping variable levels, `gl`.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)` returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

Examples

Fit a Normal Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

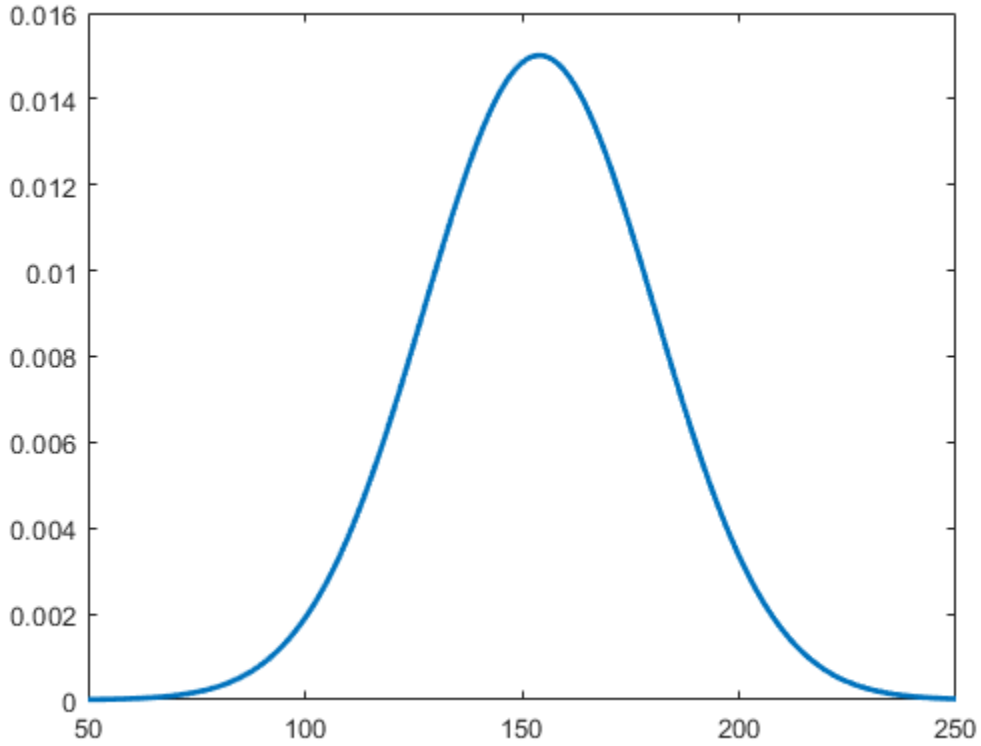
```
pd =
  NormalDistribution

  Normal distribution
       mu =     154   [148.728, 159.272]
    sigma = 26.5714   [23.3299, 30.8674]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Plot the pdf of the distribution.

```
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y,'LineWidth',2)
```



Fit a Kernel Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

```
pd = fitdist(x,'Kernel','Kernel','epanechnikov')
```

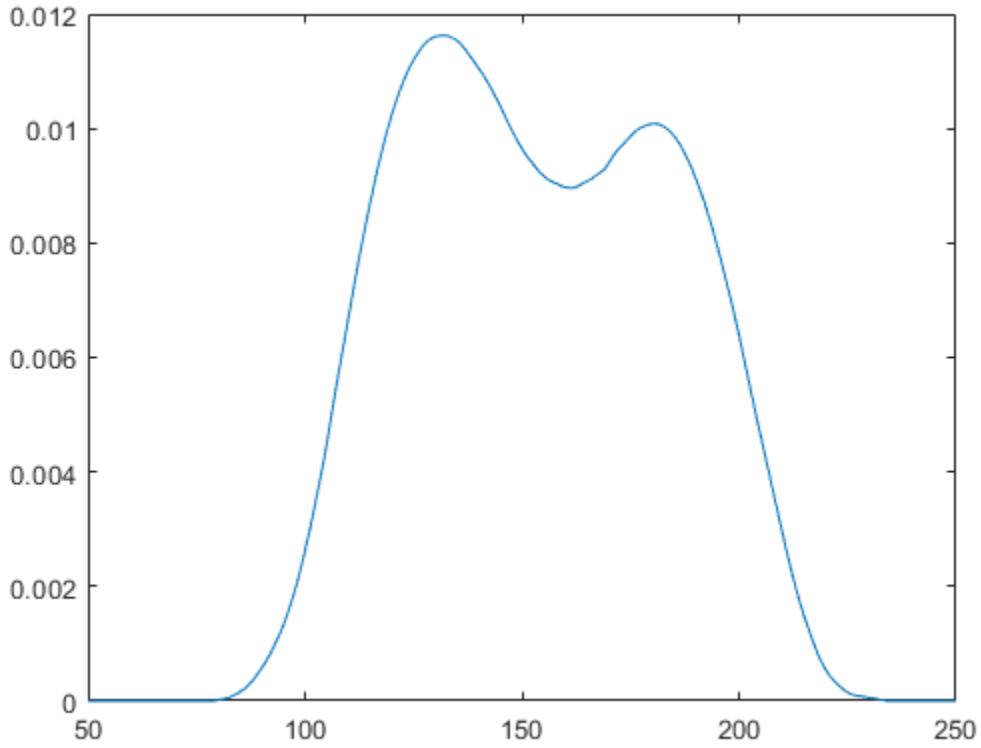
```
pd =
  KernelDistribution

    Kernel = epanechnikov
    Bandwidth = 14.3792
```

```
    Support = unbounded
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y)
```



Fit Normal Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)
```

```
pdca=1×2 cell array
    {1x1 prob.NormalDistribution}    {1x1 prob.NormalDistribution}
```

```
gn = 2x1 cell
    {'Female'}
    {'Male'  }

gl = 2x1 cell
    {'Female'}
    {'Male'  }
```

The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two group labels. The cell array `gl` contains two group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender.

```
female = pdca{1}  % Distribution for females
```

```
female =
  NormalDistribution

  Normal distribution
       mu = 130.472   [128.183, 132.76]
    sigma = 8.30339   [6.96947, 10.2736]
```

```
male = pdca{2}  % Distribution for males
```

```
male =
  NormalDistribution

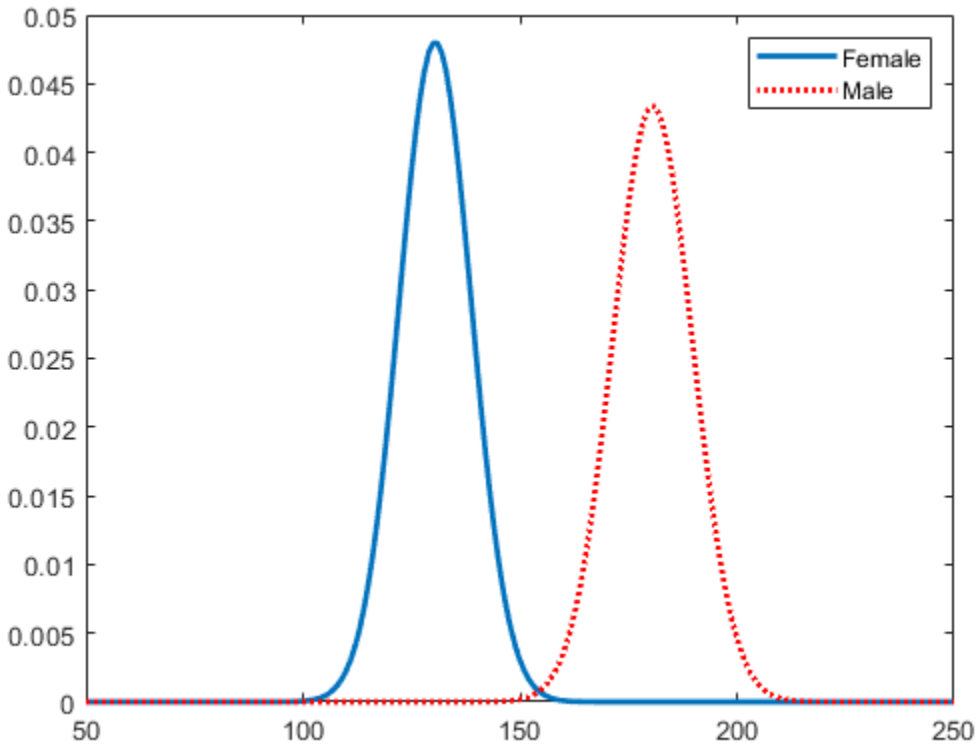
  Normal distribution
       mu = 180.532   [177.833, 183.231]
    sigma = 9.19322   [7.63933, 11.5466]
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure
plot(x_values,femalepdf,'LineWidth',2)
hold on
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
legend(gn,'Location','NorthEast')
hold off
```



Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');
```

View each distribution in the cell array `pdca` to see the kernel distributions for each gender.

```
female = pdca{1}  % Distribution for females
```

```
female =
  KernelDistribution

    Kernel = triangle
    Bandwidth = 4.25894
    Support = unbounded
```

```
male = pdca{2}  % Distribution for males
```

```
male =
  KernelDistribution

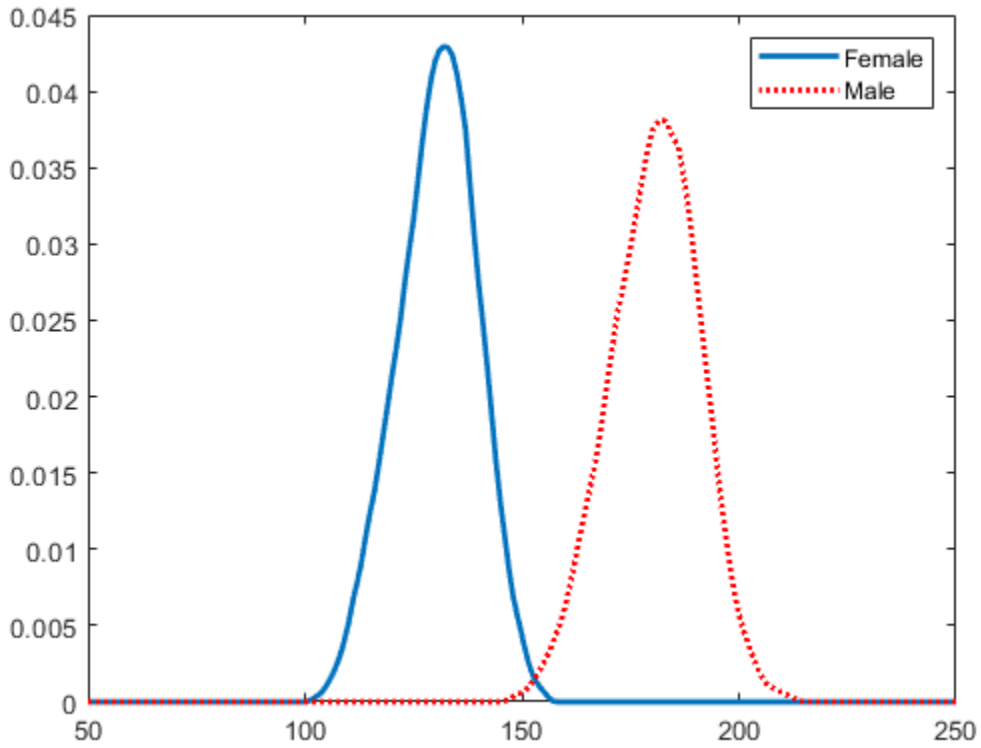
    Kernel = triangle
    Bandwidth = 5.08961
    Support = unbounded
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure
plot(x_values,femalepdf,'LineWidth',2)
hold on
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
legend(gn,'Location','NorthEast')
hold off
```



Input Arguments

x — Input data

column vector

Input data, specified as a column vector. `fitdist` ignores `NaN` values in `x`. Additionally, any `NaN` values in the censoring vector or frequency vector cause `fitdist` to ignore the corresponding values in `x`.

Data Types: `double`

`distname` — Distribution name
character vector | string scalar

Distribution name, specified as one of the following character vectors or string scalars. The distribution specified by `distname` determines the type of the returned probability distribution object.

Distribution Name	Description	Distribution Object
`'Beta'`	Beta distribution	`BetaDistribution`
`'Binomial'`	Binomial distribution	`BinomialDistribution`
`'BirnbaumSaunders'`	Birnbaum-Saunders distribution	`BirnbaumSaundersDistribution`
`'Burr'`	Burr distribution	`BurrDistribution`
`'Exponential'`	Exponential distribution	`ExponentialDistribution`
`'ExtremeValue'`	Extreme Value distribution	`ExtremeValueDistribution`
`'Gamma'`	Gamma distribution	`GammaDistribution`
`'GeneralizedExtremeValue'`	Generalized Extreme Value distribution	`GeneralizedExtremeValueDistribution`
`'GeneralizedPareto'`	Generalized Pareto distribution	`GeneralizedParetoDistribution`
`'HalfNormal'`	Half-normal distribution	`HalfNormalDistribution`
`'InverseGaussian'`	Inverse Gaussian distribution	`InverseGaussianDistribution`
`'Kernel'`	Kernel distribution	`KernelDistribution`
`'Logistic'`	Logistic distribution	`LogisticDistribution`
`'Loglogistic'`	Loglogistic distribution	`LoglogisticDistribution`
`'Lognormal'`	Lognormal distribution	`LognormalDistribution`
`'Nakagami'`	Nakagami distribution	`NakagamiDistribution`
`'NegativeBinomial'`	Negative Binomial distribution	`NegativeBinomialDistribution`
`'Normal'`	Normal distribution	`NormalDistribution`
`'Poisson'`	Poisson distribution	`PoissonDistribution`
`'Rayleigh'`	Rayleigh distribution	`RayleighDistribution`
`'Rician'`	Rician distribution	`RicianDistribution`
`'Stable'`	Stable distribution	`StableDistribution`
`'tLocationScale'`	*t* Location-Scale distribution	`tLocationScaleDistribution`

Distribution Name	Description	Distribution Object
`'Weibull'`	Weibull distribution	`WeibullDistribution`

`groupvar` — Grouping variable

categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of character vectors with values `'Male'` and `'Female'`, you can use `Gender` as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variables. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values `0` for nonsmokers and `1` for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: `{Gender,Smoker}`

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitdist(x,'Kernel','Kernel','triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

`Censoring` — Logical flag for censored data

`0` (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of `'Censoring'` and a vector of logical values that is the same size as input vector `x`. The value is `1` when the corresponding element in `x` is a right-censored observation and `0` when the corresponding element is an exact observation. The default is a vector of `0`s, indicating that all observations are exact.

`fitdist` ignores any `NaN` values in this censoring vector. Additionally, any `NaN` values in `x` or the frequency vector cause `fitdist` to ignore the corresponding values in the censoring vector.

This argument is valid only if `distname` is `'BirnbaumSaunders'`, `'Burr'`, `'Exponential'`, `'ExtremeValue'`, `'Gamma'`, `'InverseGaussian'`, `'Kernel'`, `'Logistic'`, `'Loglogistic'`, `'Lognormal'`, `'Nakagami'`, `'Normal'`, `'Rician'`, `'tLocationScale'`, or `'Weibull'`.

Data Types: `logical`

`Frequency` — Observation frequency

`1` (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of `'Frequency'` and a vector of nonnegative integer values that is the same size as input vector `x`. Each element of the

frequency vector specifies the frequencies for the corresponding elements in `x`. The default is a vector of `1`s, indicating that each value in `x` only appears once.

`fitdist` ignores any `NaN` values in this frequency vector. Additionally, any `NaN` values in `x` or the censoring vector cause `fitdist` to ignore the corresponding values in the frequency vector.

Data Types: `single` | `double`

`Options` — Control parameters
structure

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of `'Options'` and a structure you create using `statset`.

Data Types: `struct`

`NTrials` — Number of trials
positive integer value

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of `'NTrials'` and a positive integer value. You must specify `distname` as `'Binomial'` to use this option.

Data Types: `single` | `double`

`Theta` — Threshold parameter
`0` (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of `'Theta'` and a scalar value. You must specify `distname` as `'GeneralizedPareto'` to use this option.

Data Types: `single` | `double`

`mu` — Location parameter
0 (default) | scalar value

Location parameter for the half-normal distribution, specified as the comma-separated pair consisting of `'mu'` and a scalar value. You must specify `distname` as `'HalfNormal'` to use this option.

Data Types: `single` | `double`

`Kernel` — Kernel smoother type
`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'`

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and one of the following:

- `'normal'`
- `'box'`
- `'triangle'`
- `'epanechnikov'`

You must specify `distname` as `'Kernel'` to use this option.

`Support` — Kernel density support
`'unbounded'` (default) | `'positive'` | two-element vector

Kernel density support, specified as the comma-separated pair consisting of `'Support'` and `'unbounded'`, `'positive'`, or a two-element vector.

`'unbounded'`	Density can extend over the whole real line.
`'positive'`	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify `distname` as `'Kernel'` to use this option.

Data Types: `single` | `double` | `char` | `string`

`Width` — Bandwidth of kernel smoothing window
scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of `'Width'` and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes. You must specify `distname` as `'Kernel'` to use this option.

Data Types: `single` | `double`

Output Arguments

`pd` — Probability distribution
probability distribution object

Probability distribution, returned as a probability distribution object. The distribution specified by `distname` determines the class type of the returned probability distribution object. For the list of `distname` values and corresponding probability distribution objects, see `distname`.

`pdca` — Probability distribution objects
cell array

Probability distribution objects of the type specified by `distname`, returned as a cell array. For the list of `distname` values and corresponding probability distribution objects, see `distname`.

`gn` — Group labels
cell array of character vectors

Group labels, returned as a cell array of character vectors.

`gl` — Grouping variable levels
cell array of character vectors

Grouping variable levels, returned as a cell array of character vectors containing one column for each grouping variable.

Algorithms

The `fitdist` function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.
- For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

Alternative Functionality

App

The **Distribution Fitter** app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitter app using `distributionFitter`, or click Distribution Fitter on the Apps tab.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Supported syntaxes are:

  ```
  pd = fitdist(x,distname)
  pd = fitdist(x,distname,Name,Value)
  ```

  Code generation does not support the syntaxes that include the grouping variable `'By',groupvar` and the related output arguments `pdca`, `gn`, and `gl`.
- `fitdist` supports code generation for beta, exponential, extreme value, lognormal, normal, and Weibull distributions.
  - The value of `distname` can be `'Beta'`, `'Exponential'`, `'ExtremeValue'`, `'Lognormal'`, `'Normal'` or `'Weibull'`.
  - The value of `distname` must be a compile-time constant.
- The values of `x`, `'Censoring'`, and `'Frequency'` must not contain `NaN` values.
- Code generation ignores the `'Frequency'` value for the beta distribution. Instead of specifying the `'Frequency'` value, manually add duplicated values to `x` so that the values in `x` have the frequency you want.
- Code generation does not support these input arguments: `groupvar`, `NTrials`, `Theta`, `mu`, `Kernel`, `Support`, and `Width`.

- Names in name-value pair arguments must be compile-time constants.
- These object functions of `pd` support code generation: `cdf`, `icdf`, `iqr`, `mean`, `median`, `pdf`, `std`, `truncate`, and `var`.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “Code Generation for Probability Distribution Objects” on page 32-82.

Introduced in R2009a

fitensemble

Fit ensemble of learners for classification and regression

Syntax

```
Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)
Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)
Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)

Mdl = fitensemble(X,Y,Method,NLearn,Learners)

Mdl = fitensemble( ___ ,Name,Value)
```

Description

`fitensemble` can boost or bag decision tree learners or discriminant analysis classifiers. The function can also train random subspace ensembles of KNN or discriminant analysis classifiers.

For simpler interfaces that fit classification and regression ensembles, instead use `fitcensemble` and `fitrensemble`, respectively. Also, `fitcensemble` and `fitrensemble` provide options for Bayesian optimization.

`Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)` returns a trained ensemble model object that contains the results of fitting an ensemble of `NLearn` classification or regression learners (`Learners`) to all variables in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`. `Method` is the ensemble-aggregation method.

`Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)` fits the model specified by `formula`.

`Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)` treats all variables in `Tbl` as predictor variables. `Y` is the response variable that is not in `Tbl`.

`Mdl = fitensemble(X,Y,Method,NLearn,Learners)` trains an ensemble using the predictor data in `X` and response data in `Y`.

`Mdl = fitensemble( ___ ,Name,Value)` trains an ensemble using additional options specified by one or more `Name,Value` pair arguments and any of the previous syntaxes. For example, you can specify the class order, to implement 10–fold cross-validation, or the learning rate.

Examples

Estimate the Resubstitution Loss of a Boosting Ensemble

Estimate the resubstitution loss of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using AdaBoost, 100 learning cycles, and the entire data set.

```
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

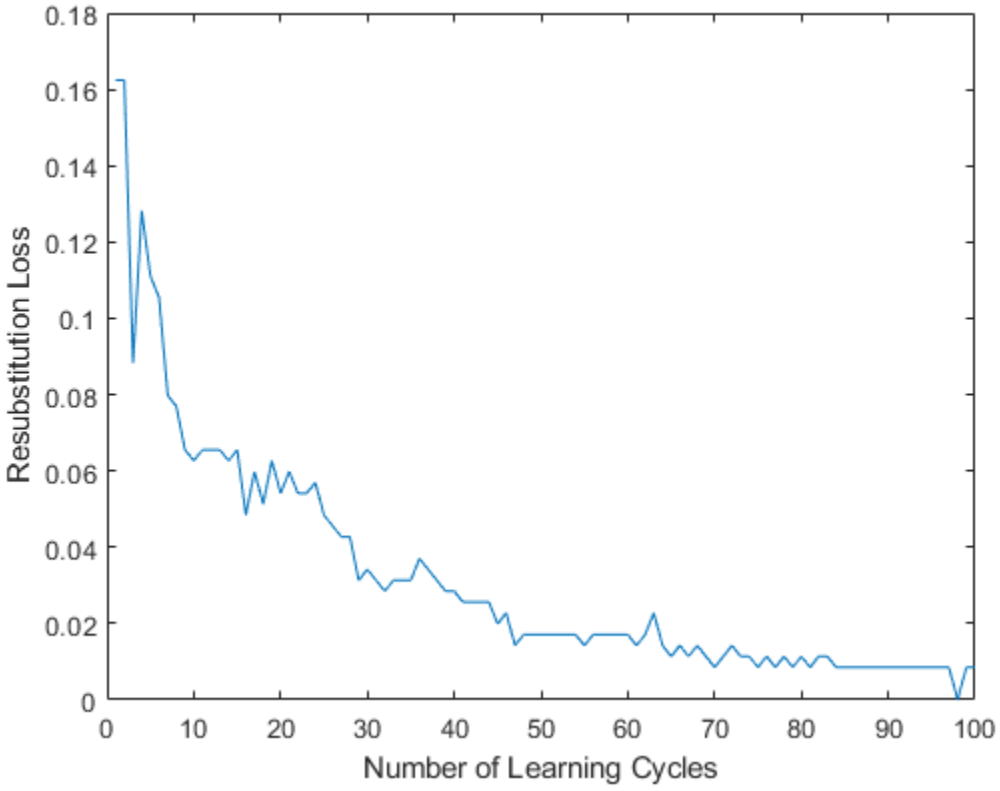
Determine the cumulative resubstitution losses (i.e., the cumulative misclassification error of the labels in the training data).

```
rsLoss = resubLoss(ClassTreeEns,'Mode','Cumulative');
```

`rsLoss` is a 100-by-1 vector, where element *k* contains the resubstitution loss after the first *k* learning cycles.

Plot the cumulative resubstitution loss over the number of learning cycles.

```
plot(rsLoss);
xlabel('Number of Learning Cycles');
ylabel('Resubstitution Loss');
```



In general, as the number of decision trees in the trained classification ensemble increases, the resubstitution loss decreases.

A decrease in resubstitution loss might indicate that the software trained the ensemble sensibly. However, you cannot infer the predictive power of the ensemble by this decrease. To measure the predictive power of an ensemble, estimate the generalization error by:

1. Randomly partitioning the data into training and cross-validation sets. Do this by specifying `'holdout',holdoutProportion` when you train the ensemble using `fitensemble`.
2. Passing the trained ensemble to `kfoldLoss`, which estimates the generalization error.

Train Regression Ensemble

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors. Then, train an ensemble using fewer predictors and compare its in-sample predictive accuracy against the first ensemble.

Load the `carsmall` data set. Store the training data in a table.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of `NaN` values.

```
t = templateTree('Surrogate','On');
```

Train the regression tree ensemble using LSBoost and 100 learning cycles.

```
Mdl1 = fitensemble(Tbl,'MPG','LSBoost',100,t);
```

`Mdl1` is a trained `RegressionEnsemble` regression ensemble. Because `MPG` is a variable in the MATLAB® Workspace, you can obtain the same result by entering

```
Mdl1 = fitensemble(Tbl,MPG,'LSBoost',100,t);
```

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
predMPG = predict(Mdl1,[4 200 150 3000])
```

```
predMPG = 22.8462
```

The average fuel economy of a car with these specifications is 21.78 mpg.

Train a new ensemble using all predictors in `Tbl` except `Displacement`.

```
formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitensemble(Tbl,formula,'LSBoost',100,t);
```

Compare the resubstitution MSEs between `Mdl1` and `Mdl2`.

```
mse1 = resubLoss(Mdl1)
```

```
mse1 = 6.4721
```

```
mse2 = resubLoss(Mdl2)
```

```
mse2 = 7.8599
```

The in-sample MSE for the ensemble that trains on all predictors is lower.

Estimate the Generalization Error of a Boosting Ensemble

Estimate the generalization error of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using AdaBoostM1, 100 learning cycles, and half of the data chosen randomly. The software validates the algorithm using the remaining half.

```
rng(2); % For reproducibility
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
    'Holdout',0.5);
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

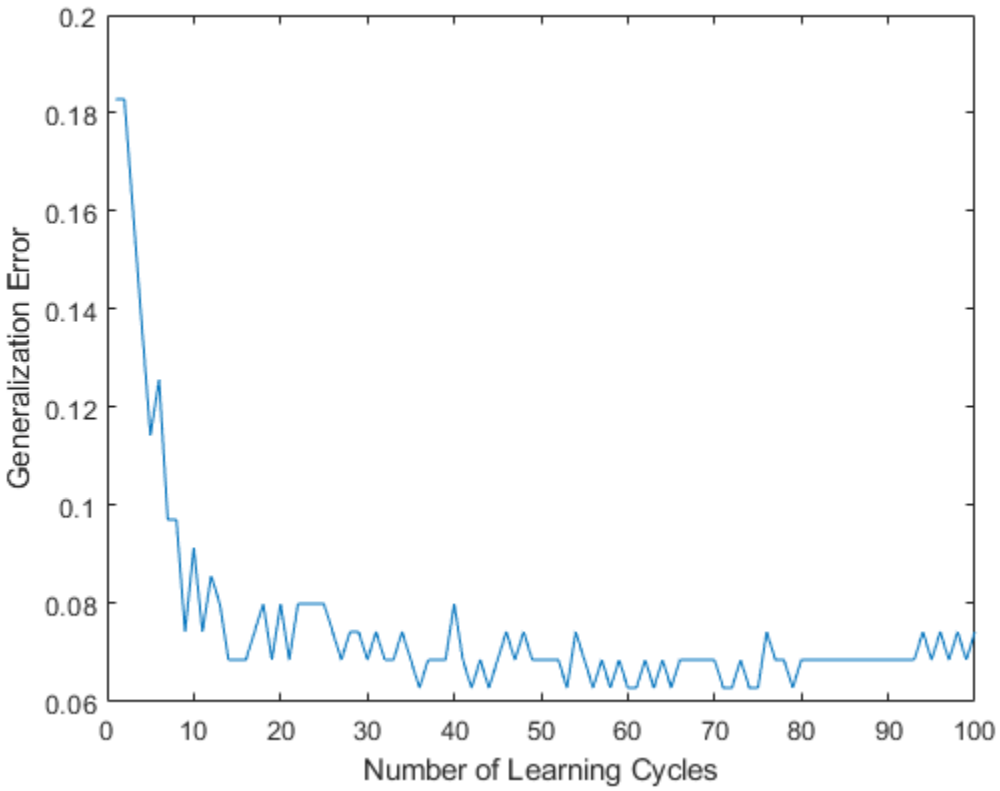
Determine the cumulative generalization error, i.e., the cumulative misclassification error of the labels in the validation data).

```
genError = kfoldLoss(ClassTreeEns,'Mode','Cumulative');
```

`genError` is a 100-by-1 vector, where element *k* contains the generalization error after the first *k* learning cycles.

Plot the generalization error over the number of learning cycles.

```
plot(genError);
xlabel('Number of Learning Cycles');
ylabel('Generalization Error');
```



The cumulative generalization error decreases to approximately 7% when 25 weak learners compose the ensemble classifier.

Find the Optimal Number of Splits and Trees for an Ensemble

You can control the depth of the trees in an ensemble of decision trees. You can also control the tree depth in an ECOC model containing decision tree binary learners using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters.

- When bagging decision trees, `fitensemble` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.
- When boosting decision trees, `fitensemble` grows stumps (a tree with one split) by default. You can grow deeper trees for better accuracy.

Load the `carsmall` data set. Specify the variables `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as predictors, and `MPG` as the response.

```
load carsmall
X = [Acceleration Displacement Horsepower Weight];
Y = MPG;
```

The default values of the tree depth controllers for boosting regression trees are:

- `1` for `MaxNumSplits`. This option grows stumps.
- `5` for `MinLeafSize`
- `10` for `MinParentSize`

To search for the optimal number of splits:

1. Train a set of ensembles. Exponentially increase the maximum number of splits for subsequent ensembles from stump to at most *n* - 1 splits, where *n* is the training sample size. Also, decrease the learning rate for each ensemble from 1 to 0.1.
2. Cross validate the ensembles.
3. Estimate the cross-validated mean-squared error (MSE) for each ensemble.
4. Compare the cross-validated MSEs. The ensemble with the lowest one performs the best, and indicates the optimal maximum number of splits, number of trees, and learning rate for the data set.

Grow and cross validate a deep regression tree and a stump. Specify to use surrogate splits because the data contains missing values. These serve as benchmarks.

```
MdlDeep = fitrtree(X,Y,'CrossVal','on','MergeLeaves','off',...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(X,Y,'MaxNumSplits',1,'CrossVal','on','Surrogate','on');
```

Train the boosting ensembles using 150 regression trees. Cross validate the ensemble using 5-fold cross validation. Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \ldots, 2^m\}$, where m is such that 2^m is no greater than n - 1, where n is the training sample size. For each variant, adjust the learning rate to each value in the set {0.1, 0.25, 0.5, 1};

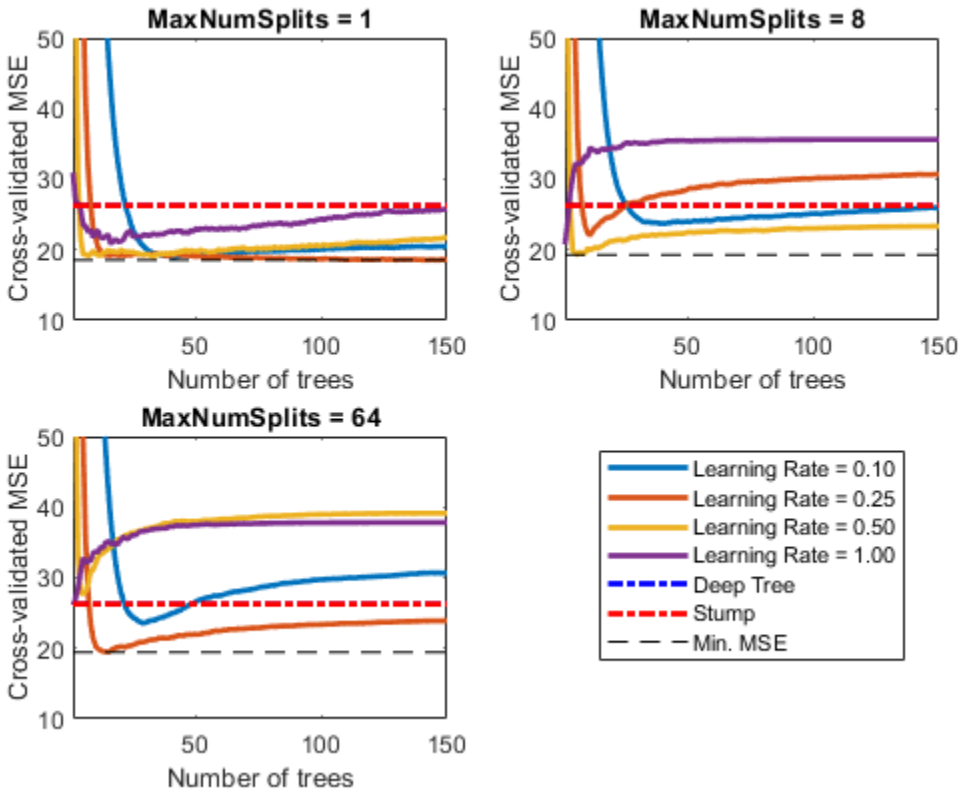
```
n = size(X,1);
m = floor(log2(n - 1));
lr = [0.1 0.25 0.5 1];
maxNumSplits = 2.^(0:m);
numTrees = 150;
Mdl = cell(numel(maxNumSplits),numel(lr));
rng(1); % For reproducibility
for k = 1:numel(lr);
    for j = 1:numel(maxNumSplits);
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitensemble(X,Y,'LSBoost',numTrees,t,...
            'Type','regression','KFold',5,'LearnRate',lr(k));
    end;
end;
```

Compute the cross-validated MSE for each ensemble.

```
kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(lr)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);
```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases for a few of the ensembles, the deep tree, and the stump. Plot the curves with respect to learning rate in the same plot, and plot separate plots for varying tree complexities. Choose a subset of tree complexity levels.

```
mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'-.b','LineWidth',2);
    plot(h.XLim,[errorStump errorStump],'-.r','LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'--k');
    h.YLim = [10 50];
    xlabel 'Number of trees';
    ylabel 'Cross-validated MSE';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;
hL = legend([cellstr(num2str(lr','Learning Rate = %0.2f'));...
        'Deep Tree';'Stump';'Min. MSE']);
hL.Position(1) = 0.6;
```



Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);

fprintf('\nMin. MSE = %0.5f',minErr)

Min. MSE = 18.42979

fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);

Optimal Parameter Values:
Num. Trees = 1

fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
    maxNumSplits(idxMNS),lr(idxLR))

MaxNumSplits = 4
Learning Rate = 1.00
```

For a different approach to optimizing this ensemble, see “Optimize a Boosted Regression Ensemble” on page 10-63.

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using `formula`.
- If `Tbl` does not contain the response variable, then specify the response data using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Note To save memory and execution time, supply `X` and `Y` instead of `Tbl`.

Data Types: `table`

`ResponseVarName` — Response variable name

name of response variable in `Tbl`

Response variable name, specified as the name of the response variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitensemble` treats all columns of `Tbl` as predictor variables.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`X` — Predictor data
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

`Y` — Response data
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each entry in `Y` is the response to or label for the observation in the corresponding row of `X` or `Tbl`. The length of `Y` and the number of rows of `X` or `Tbl` must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

- For classification, `Y` can be any of the supported data types. You can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

- For regression, `Y` must be a numeric column vector.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Method` — Ensemble aggregation method
`'AdaBoostM1'` | `'LogitBoost'` | `'GentleBoost'` | `'RUSBoost'` | `'Subspace'` | `'Bag'` | `'AdaBoostM2'` | `'LSBoost'` | ...

Ensemble aggregation method, specified as one of the method names in this list.

- For classification with two classes:
  - `'AdaBoostM1'`
  - `'LogitBoost'`
  - `'GentleBoost'`
  - `'RobustBoost'` (requires Optimization Toolbox)
  - `'LPBoost'` (requires Optimization Toolbox)
  - `'TotalBoost'` (requires Optimization Toolbox)
  - `'RUSBoost'`
  - `'Subspace'`
  - `'Bag'`
- For classification with three or more classes:
  - `'AdaBoostM2'`
  - `'LPBoost'` (requires Optimization Toolbox)
  - `'TotalBoost'` (requires Optimization Toolbox)
  - `'RUSBoost'`
  - `'Subspace'`
  - `'Bag'`
- For regression:
  - `'LSBoost'`
  - `'Bag'`

If you specify `'Method','Bag'`, then specify the problem type using the `Type` name-value pair argument, because you can specify `'Bag'` for classification and regression problems.

For details about ensemble aggregation algorithms and examples, see “Ensemble Algorithms” on page 18-39 and “Choose an Applicable Ensemble Aggregation Method” on page 18-32.

`NLearn` — Number of ensemble learning cycles
positive integer | `'AllPredictorCombinations'`

Number of ensemble learning cycles, specified as a positive integer or `'AllPredictorCombinations'`.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NLearn*numel(Learners)` learners.

- If you specify `'AllPredictorCombinations'`, then set `Method` to `'Subspace'` and specify one learner only in `Learners`. With these settings, the software trains learners for all possible combinations of predictors taken `NPredToSample` at a time. Consequently, the software trains `nchoosek(size(X,2),NPredToSample)` learners.

The software composes the ensemble using all trained learners and stores them in `Mdl.Trained`.

For more details, see “Tips” on page 33-2274.

Data Types: `single` | `double` | `char` | `string`

`Learners` — Weak learners to use in ensemble

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Settings
Discriminant analysis	`'Discriminant'`	`templateDiscriminant`	Recommended for `'Subspace'`
k nearest neighbors	`'KNN'`	`templateKNN`	For `'Subspace'` only
Decision tree	`'Tree'`	`templateTree`	All methods except `'Subspace'`

For more details, see `NLearn` and “Tips” on page 33-2274.

Example: For an ensemble composed of two types of classification trees, supply `{t1 t2}`, where `t1` and `t2` are classification tree templates.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CrossVal','on','LearnRate',0.05` specifies to implement 10-fold cross-validation and to use `0.05` as the learning rate.

General Ensemble Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitensemble` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

Specification of `'CategoricalPredictors'` is appropriate if:

- `'Learners'` specifies tree learners.
- `'Learners'` specifies *k*-nearest learners where all predictors are categorical.

Each learner identifies and treats categorical predictors in the same way as the fitting function corresponding to the learner. See `'CategoricalPredictors'` of `fitcknn` for *k*-nearest learners and `'CategoricalPredictors'` of `fitctree` for tree learners.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`NPrint` — Printout frequency
`'off'` (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of `'NPrint'` and a positive integer or `'off'`.

To track the number of *weak learners* or *folds* that `fitensemble` trained so far, specify a positive integer. That is, if you specify the positive integer *m*:

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitensemble` displays a message to the command line every time it completes training *m* weak learners.
- And a cross-validation option, then `fitensemble` displays a message to the command line every time it finishes training *m* folds.

If you specify `'off'`, then `fitensemble` does not display a message when it completes training weak learners.

Tip For fastest training of some boosted decision trees, set `NPrint` to the default value `'off'`. This tip holds when the classification `Method` is `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, or `'LogitBoost'`, or when the regression `Method` is `'LSBoost'`.

Example: `'NPrint',5`

Data Types: `single` | `double` | `char` | `string`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitensemble` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',`
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`Type` — Supervised learning type
`'classification'` | `'regression'`

Supervised learning type, specified as the comma-separated pair consisting of `'Type'` and `'classification'` or `'regression'`.

- If `Method` is `'bag'`, then the supervised learning type is ambiguous. Therefore, specify `Type` when bagging.
- Otherwise, the value of `Method` determines the supervised learning type.

Example: `'Type','classification'`

Cross-Validation Options

`CrossVal` — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.
2. Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Other Classification or Regression Options

`ClassNames` — Names of classes to use for training
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as a categorical, character, or string array; a logical or numeric vector; or a cell array of character vectors. `ClassNames` must have the same data type as the response variable in `Tbl` or `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in the response variable in `Tbl` or `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Cost` — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
  - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(`*K*`) - eye(`*K*`)`, where *K* is the number of distinct classes.

Note `fitensemble` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitensemble` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost',[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to 1/*K*, where *K* is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to `Mdl.ClassNames` or specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements such that they sum to `1`.

Value	Description
structure array	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to `1`.

`fitensemble` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `struct('ClassNames', {{'setosa','versicolor','virginica'}},'ClassProbs',1:3)`

Data Types: `char` | `string` | `double` | `single` | `struct`

`Weights` — Observation weights
numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(`*n*`,1)`, where *n* is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Sampling Options for Boosting Methods and Bagging

`FResample` — Fraction of training set to resample
`1` (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in (0,1].

To use `'FResample'`, specify `'bag'` for `Method` or set `Resample` to `'on'`.

Example: `'FResample',0.75`

Data Types: `single` | `double`

`Replace` — Flag indicating to sample with replacement
`'on'` (default) | `'off'`

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of `'Replace'` and `'off'` or `'on'`.

- For `'on'`, the software samples the training observations with replacement.
- For `'off'`, the software samples the training observations without replacement. If you set `Resample` to `'on'`, then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to `'bag'` or set `Resample` to `'on'`, `Replace` has no effect.

Example: `'Replace','off'`

`Resample` — Flag indicating to resample

`'off'` | `'on'`

Flag indicating to resample, specified as the comma-separated pair consisting of `'Resample'` and `'off'` or `'on'`.

- If `Method` is a boosting method, then:
  - `'Resample','on'` specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - `'Resample','off'`(default) specifies to reweight observations at every learning iteration.
- If `Method` is `'bag'`, then `'Resample'` must be `'on'`. The software resamples a fraction of the training observations (see `FResample`) with or without replacement (see `Replace`).

If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, and LSBoost Method Options

`LearnRate` — Learning rate for shrinkage

`1` (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of `'LearnRate'` and a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than `1`, for example, `0.1` is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate',0.1`

Data Types: `single` | `double`

RUSBoost Method Options

`LearnRate` — Learning rate for shrinkage

`1` (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of `'LearnRate'` and a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than `1`, for example, `0.1` is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate',0.1`

Data Types: `single` | `double`

`RatioToSmallest` — Sampling proportion with respect to lowest-represented class
positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of `'RatioToSmallest'` and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are K classes in the training data and the lowest-represented class has m observations in the training data.

- If you specify the positive numeric scalar s, then `fitensemble` samples $s*m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see "Algorithms" on page 33-2275.
- If you specify the numeric vector `[s1,s2,...,sK]`, then `fitensemble` samples $si*m$ observations from class i, $i = 1,...,K$. The elements of `RatioToSmallest` correspond to the order of the class names specified using `ClassNames` (see "Tips" on page 33-2274).

The default value is `ones(K,1)`, which specifies to sample m observations from each class.

Example: `'RatioToSmallest',[2,1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options

`MarginPrecision` — Margin precision to control convergence speed
`0.1` (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of `'MarginPrecision'` and a numeric scalar in the interval [0,1]. `MarginPrecision` affects the number of boosting iterations required for convergence.

Tip To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision',0.5`

Data Types: `single` | `double`

RobustBoost Method Options

`RobustErrorGoal` — Target classification error
`0.1` (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of `'RobustErrorGoal'` and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed `1`.

Tip For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal',0.05`

Data Types: `single` | `double`

`RobustMarginSigma` — Classification margin distribution spread
`0.1` (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of `'RobustMarginSigma'` and a positive numeric scalar. Before specifying `RobustMarginSigma`, consult the literature on `RobustBoost`, for example, [19].

Example: `'RobustMarginSigma',0.5`

Data Types: `single` | `double`

`RobustMaxMargin` — Maximal classification margin
`0` (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of `'RobustMaxMargin'` and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below `RobustMaxMargin`.

Example: `'RobustMaxMargin',1`

Data Types: `single` | `double`

Random Subspace Method Options

`NPredToSample` — Number of predictors to sample
`1` (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of `'NPredToSample'` and a positive integer in the interval 1,...,*p*, where *p* is the number of predictor variables (`size(X,2)` or `size(Tbl,2)`).

Data Types: `single` | `double`

Output Arguments

`Mdl` — Trained ensemble model
`ClassificationBaggedEnsemble` model object | `ClassificationEnsemble` model object | `ClassificationPartitionedEnsemble` cross-validated model object | `RegressionBaggedEnsemble` model object | `RegressionEnsemble` model object | `RegressionPartitionedEnsemble` cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Type Setting	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
`ClassificationBaggedEnsemble`	`'classification'`	No	`'Bag'`	`'on'`
`ClassificationEnsemble`	`'classification'`	No	Any ensemble-aggregation method for classification	`'off'`

Model Object	Type Setting	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
ClassificationPartitionedEnsemble	'classification'	Yes	Any classification ensemble-aggregation method	'off' or 'on'
RegressionBaggedEnsemble	'regression'	No	'Bag'	'on'
RegressionEnsemble	'regression'	No	'LSBoost'	'off'
RegressionPartitionedEnsemble	'regression'	Yes	'LSBoost' or 'Bag'	'off' or 'on'

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NLearn` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems, or `resume` for regression problems.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of `1` for `FResample`.
- In classification problems (that is, `Type` is `'classification'`):
  - If the ensemble-aggregation method (`Method`) is `'bag'` and:
    - The misclassification cost (`Cost`) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
    - The class prior probabilities (`Prior`) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

    For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using `Cost` or a less skewed prior probability vector using `Prior`.
  - Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the `ClassNames` name-value pair argument.

- To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for `ClassNames`. For example, suppose the response variable (`Y`) is a cell array of labels. This code specifies the class order in the variable `classNames`.

  ```
  Ycat = categorical(Y);
  classNames = categories(Ycat)
  ```

  `categorical` assigns `<undefined>` to unclassified observations and `categories` excludes `<undefined>` from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.
- To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to `ClassNames`. Following from the previous example, this code specifies the class order from lowest- to most-represented in `classNamesLH`.

  ```
  Ycat = categorical(Y);
  classNames = categories(Ycat);
  freq = countcats(Ycat);
  [~,idx] = sort(freq);
  classNamesLH = classNames(idx);
  ```

Algorithms

- For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-39.
- If you specify `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows stumps by default. A decision stump is one root node connected to two terminal, leaf nodes. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- `fitensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For the RUSBoost ensemble-aggregation method (`Method`), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: A and B. A have 100 observations and B have 10 observations. Also, suppose that the lowest-represented class has m observations in the training data.

  - If you set `'RatioToSmallest',2`, then $s*m = 2*10 = 20$. Consequently, `fitensemble` trains every learner using 20 observations from class A and 20 observations from class B. If you set `'RatioToSmallest',[2 2]`, then you obtain the same result.
  - If you set `'RatioToSmallest',[2,1]`, then $s1*m = 2*10 = 20$ and $s2*m = 1*10 = 10$. Consequently, `fitensemble` trains every learner using 20 observations from class A and 10 observations from class B.

- For ensembles of decision trees, and for dual-core systems and above, `fitensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Introduced in R2011a

fitnlm

Fit nonlinear regression model

Syntax

```
mdl = fitnlm(tbl,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm(___,modelfun,beta0,Name,Value)
```

Description

`mdl = fitnlm(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`.

`fitnlm` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = fitnlm(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = fitnlm(___,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name,Value` pair arguments.

Examples

Nonlinear Model from Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0)
```

```
mdl =
Nonlinear regression model:
    MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5

Estimated Coefficients:
          Estimate      SE        tStat       pValue
          ________    _______    ________    ________

    b1     -49.383     119.97    -0.41164     0.68083
    b2      376.43     567.05     0.66384     0.50719
    b3    -0.78193    0.47168     -1.6578    0.098177
    b4      422.37     776.02     0.54428     0.58656
```

```
    b5    -0.24127    0.48325    -0.49926     0.61788

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745,  Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
Nonlinear regression model:
    y ~ b1 + b2*x1^b3 + b4*x2^b5

Estimated Coefficients:
          Estimate      SE        tStat       pValue
          ________    _______    ________    ________

    b1     -49.383     119.97    -0.41164     0.68083
    b2      376.43     567.05     0.66384     0.50719
    b3    -0.78193    0.47168     -1.6578    0.098177
    b4      422.37     776.02     0.54428     0.58656
    b5    -0.24127    0.48325    -0.49926     0.61788

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745,  Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Adjust Fitting Options in Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
```

```
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = fitnlm(X,y,modelfun,beta0,'Options',opts);
```

```

```

Specify Nonlinear Regression Using Model Name Syntax

Specify a nonlinear regression model for estimation using a function handle or model syntax.

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = fitnlm(X,y,@hougen,beta0)
```

```
mdl =
Nonlinear regression model:
    y ~ hougen(b,X)

Estimated Coefficients:
          Estimate       SE       tStat     pValue
          ________    ________    ______    _______

    b1      1.2526     0.86701    1.4447    0.18654
    b2    0.062776    0.043561    1.4411    0.18753
    b3    0.040048    0.030885    1.2967    0.23089
    b4     0.11242    0.075157    1.4957    0.17309
    b5      1.1914     0.83671    1.4239     0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
```

```
R-Squared: 0.999,  Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13
```

Alternatively, you can use an expression to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = fitnlm(X,y,myfun,beta0)
```

```
mdl2 =
Nonlinear regression model:
    y ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)

Estimated Coefficients:
          Estimate       SE       tStat     pValue
          ________    ________    ______    _______

    b1      1.2526     0.86701    1.4447    0.18654
    b2    0.062776    0.043561    1.4411    0.18753
    b3    0.040048    0.030885    1.2967    0.23089
    b4     0.11242    0.075157    1.4957    0.17309
    b5      1.1914     0.83671    1.4239     0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999,  Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13
```

Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2\exp(-b_3x) + \varepsilon,$$

where b_1, b_2, and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));

rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use an expression to specify the model.

```
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';

mdl = fitnlm(x,y,modelstr,b0,'Options',opts)
```

```
mdl =
Nonlinear regression model (robust fit):
    y ~ b1 + b2*exp( - b3*x)

Estimated Coefficients:
          Estimate      SE       tStat       pValue
          ________    _______    ______    __________

    b1     1.0218     0.07202    14.188    2.1344e-25
    b2     3.6619     0.25429    14.401     7.974e-26
    b3     2.9732     0.38496    7.7232    1.0346e-11

Number of observations: 100, Error degrees of freedom: 97
Root Mean Squared Error: 0.501
R-Squared: 0.807,  Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35
```

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
 a = 1; b = 1;
 weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
Nonlinear regression model:
    y ~ hougen(b,X)

Estimated Coefficients:
          Estimate       SE       tStat     pValue
          ________    ________    ______    _______

    b1     0.83085     0.58224     1.427    0.19142
    b2     0.04095    0.029663    1.3805    0.20477
    b3    0.025063    0.019673     1.274    0.23842
    b4    0.080053    0.057812    1.3847    0.20353
    b5      1.8261       1.281    1.4256    0.19183

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.037
R-Squared: 0.998,  Adjusted R-Squared 0.998
F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11
```

Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = fitnlm(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
Nonlinear regression model:
    y ~ hougen(b,X)

Estimated Coefficients:
          Estimate       SE       tStat     pValue
          ________    ________    ______    _______

    b1      1.2526     0.86702    1.4447    0.18654
    b2    0.062776    0.043561    1.4411    0.18753
    b3    0.040048    0.030885    1.2967    0.23089
    b4     0.11242    0.075158    1.4957    0.17309
    b5      1.1914     0.83671    1.4239     0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 1.27
R-Squared: 0.999,  Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13
```

Input Arguments

`tbl` — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable must be numeric.

- If you specify `modelfun` using a formula, the model specification in the formula specifies the predictor and response variables.
- If you specify `modelfun` using a function handle, the last variable is the response variable and the others are the predictor variables, by default. You can set a different column as the response variable by using the `ResponseVar` name-value pair argument. To select a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot specify `modelfun` using a formula.

You can verify the variable names in `tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `table`

`X` — Predictor variables

matrix

Predictor variables, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

Data Types: `single` | `double`

`y` — Response variable

vector

Response variable, specified as an *n*-by-1 vector, where *n* is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double`

`modelfun` — Functional form of the model

function handle | character vector or string scalar formula in the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - `b` is a coefficient vector with the same number of elements as `beta0`.
  - `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

  `modelfun(b,x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.
- Character vector or string scalar formula in the form `'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'`, where `f` represents a scalar function of the scalar coefficient variables `b1`,...,`bj` and the scalar data variables `x1`,...,`xk`. The variable names in the formula must be valid MATLAB identifiers.

Data Types: `function_handle` | `char` | `string`

`beta0` — Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ErrorModel','combined','Exclude',2,'Options',opt` specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure `opt` to control the iterative fitting procedure.

`CoefficientNames` — Names of the model coefficients
`{'b1','b2',...,'bk'}` (default) | string array | cell array of character vectors

Names of the model coefficients, specified as a string array or cell array of character vectors.

Data Types: `string` | `cell`

`ErrorModel` — Form of the error variance model
`'constant'` (default) | `'proportional'` | `'combined'`

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f, and one or two parameters a and b

`'constant'` (default)	$y = f + ae$
`'proportional'`	$y = f + bfe$
`'combined'`	$y = f + (a + b\|f\|)e$

The only allowed error model when using `Weights` is `'constant'`.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

Example: `'ErrorModel','proportional'`

`ErrorParameters` — Initial estimates of the error model parameters
numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
`'constant'`	a	1
`'proportional'`	b	1
`'combined'`	a, b	`[1,1]`

You can only use the `'constant'` error model when using `Weights`.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

For example, if `'ErrorModel'` has the value `'combined'`, you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: `'ErrorParameters',[1,2]`

Data Types: `single` | `double`

`Exclude` — Observations to exclude
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

`Options` — Options for controlling the iterative fitting procedure
[ ] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('fitnlm')`.

Option	Meaning	Default
`DerivStep`	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.	`eps^(1/3)`
`Display`	Amount of information displayed by the fitting algorithm. • `'off'` — Displays no information. • `'final'` — Displays the final output. • `'iter'` — Displays iterative output to the Command Window.	`'off'`
`FunValCheck`	Character vector or string scalar indicating to check for invalid values, such as `NaN` or `Inf`, from the model function.	`'on'`
`MaxIter`	Maximum number of iterations allowed. Positive integer.	`200`
`RobustWgtFun`	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a `Tune` constant. See “Robust Options” on page 33-2289	`[]`
`Tune`	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 33-2289 for the default, which depends on `RobustWgtFun`.
`TolFun`	Termination tolerance for the objective function value. Positive scalar.	`1e-8`

Option	Meaning	Default
TolX	Termination tolerance for the parameters. Positive scalar.	1e-8

Data Types: struct

PredictorVars — Predictor variables
string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]

Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

ResponseVar — Response variable
last column of tbl (default) | variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable.

If you specify a model, it specifies the response variable. Otherwise, when fitting a table or dataset array, 'ResponseVar' indicates which variable fitnlm should use as the response.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'

Example: 'ResponseVar',[4]

Example: 'ResponseVar',logical([0 0 0 1 0 0])

Data Types: single | double | logical | char | string

VarNames — Names of variables
{'x1','x2',...,'xn','y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string` | `cell`

`Weights` — Observation weights
`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have *n* elements, where *n* is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by `MSE*(1/W(i))`, where MSE is the mean squared error.

Data Types: `single` | `double` | `function_handle`

Output Arguments

`mdl` — Nonlinear model
`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

More About

Robust Options

Weight Function	Equation	Default Tuning Constant
`'andrews'`	`w = (abs(r)<pi) .* sin(r) ./ r`	1.339
`'bisquare'` (default)	`w = (abs(r)<1) .* (1 - r.^2).^2`	4.685
`'cauchy'`	`w = 1 ./ (1 + r.^2)`	2.385
`'fair'`	`w = 1 ./ (1 + abs(r))`	1.400
`'huber'`	`w = 1 ./ max(1, abs(r))`	1.345
`'logistic'`	`w = tanh(r) ./ r`	1.205
`'talwar'`	`w = 1 * (abs(r)<1)`	2.795
`'welsch'`	`w = exp(-(r.^2))`	2.985
`[]`	No robust fitting	—

Algorithms

- `fitnlm` uses the same fitting algorithm as `nlinfit`.
- `fitnlm` considers `NaN` values in `tbl`, `X`, and `y` to be missing values. When fitting a model, `fitnlm` does not use observations with missing values or observations at which `modelfun` returns `NaN` values. The `ObservationInfo` property of a fitted model contains information regarding whether or not `fitnlm` uses each observation in the fit.

fitPosterior

Fit posterior probabilities for support vector machine (SVM) classifier

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)
```

Description

`ScoreSVMModel = fitPosterior(SVMModel)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. For more details, see “Algorithms” on page 33-2299.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)` additionally returns the optimal score-to-posterior-probability transformation function parameters.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify the number of folds or the holdout sample proportion.

Examples

Estimate In-Sample Posterior Probabilities of SVM Classifier

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a support vector machine (SVM) classifier. Standardize the data and specify that `'g'` is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)
```

```
ScoreSVMModel =
  ClassificationSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}
          ScoreTransform: '@(S)sigmoid(S,-9.481840e-01,-1.218721e-01)'
         NumObservations: 351
```

```
                Alpha: [90x1 double]
                 Bias: -0.1343
     KernelParameters: [1x1 struct]
                   Mu: [1x34 double]
                Sigma: [1x34 double]
       BoxConstraints: [351x1 double]
      ConvergenceInfo: [1x1 struct]
      IsSupportVector: [351x1 logical]
               Solver: 'SMO'

  Properties, Methods
```

Because the classes are inseparable, the score transformation function (`ScoreSVMModel.ScoreTransform`) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);
[~,postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2),'VariableNames',...
    {'TrueLabel','PredictedLabel','Score','PosteriorProbability'})
```

```
ans=10×4 table
    TrueLabel    PredictedLabel     Score     PosteriorProbability
    _________    ______________    _______    ____________________

      {'g'}          {'g'}          1.4861           0.82215
      {'b'}          {'b'}         -1.0002           0.30439
      {'g'}          {'g'}          1.8686           0.86917
      {'b'}          {'b'}         -2.6456          0.084197
      {'g'}          {'g'}          1.2806           0.79185
      {'b'}          {'b'}         -1.4617           0.22026
      {'g'}          {'g'}          2.1671           0.89814
      {'b'}          {'b'}         -5.7089         0.0050106
      {'g'}          {'g'}          2.4796           0.92223
      {'b'}          {'b'}         -2.7812          0.074801
```

Plot Posterior Probability Contours for Multiple Classes

Train a multiclass SVM classifier through the process of one-versus-all (OVA) classification, and then plot probability contours for each class. To implement OVA directly, see `fitcecoc`.

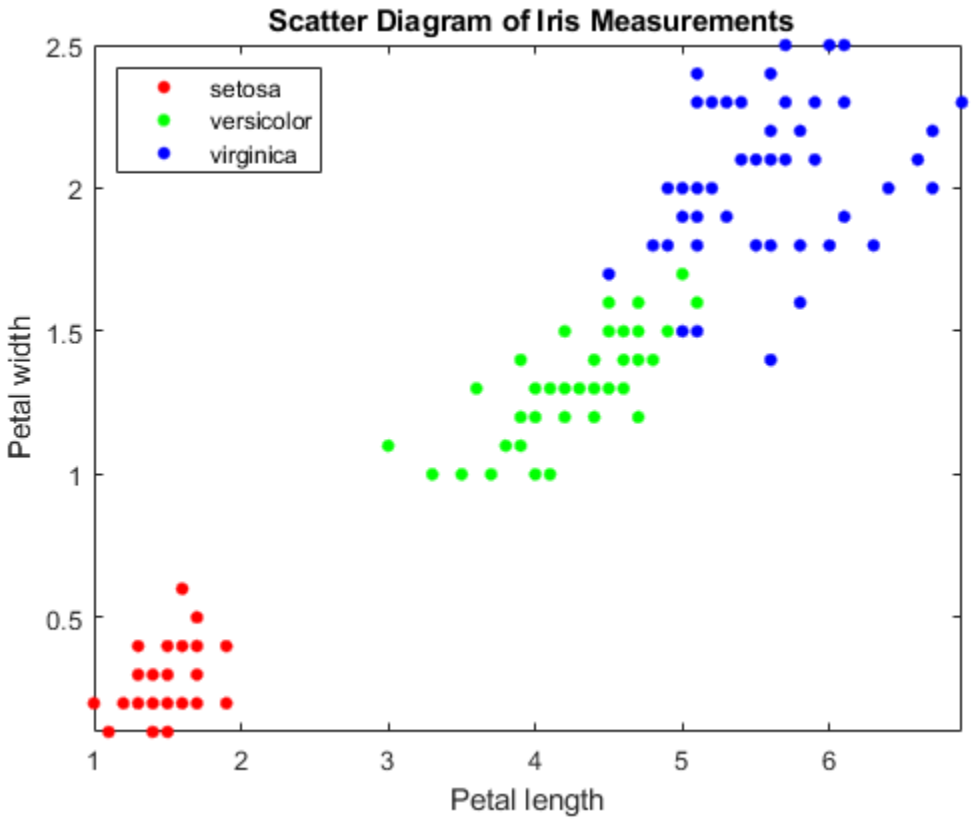
Load Fisher's iris data set. Use the petal lengths and widths as the predictor data.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
```

```
title('{\bf Scatter Diagram of Iris Measurements}');
xlabel('Petal length');
ylabel('Petal width');
legend('Location','Northwest');
axis tight
```



Train three binary SVM classifiers that separate each type of iris from the others. Assume that a radial basis function is an appropriate kernel for each, and allow the algorithm to choose a kernel scale. Define the class order.

```
classNames = {'setosa'; 'virginica'; 'versicolor'};
numClasses = size(classNames,1);
inds = cell(3,1); % Preallocation
SVMModel = cell(3,1);

rng(1); % For reproducibility
for j = 1:numClasses
    inds{j} = strcmp(Y,classNames{j});  % OVA classification
    SVMModel{j} = fitcsvm(X,inds{j},'ClassNames',[false true],...
        'Standardize',true,'KernelFunction','rbf','KernelScale','auto');
end
```

`fitcsvm` uses a heuristic procedure that involves subsampling to compute the value of the kernel scale.

Fit the optimal score-to-posterior-probability transformation function for each classifier.

```
for j = 1:numClasses
    SVMModel{j} = fitPosterior(SVMModel{j});
end
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step
```

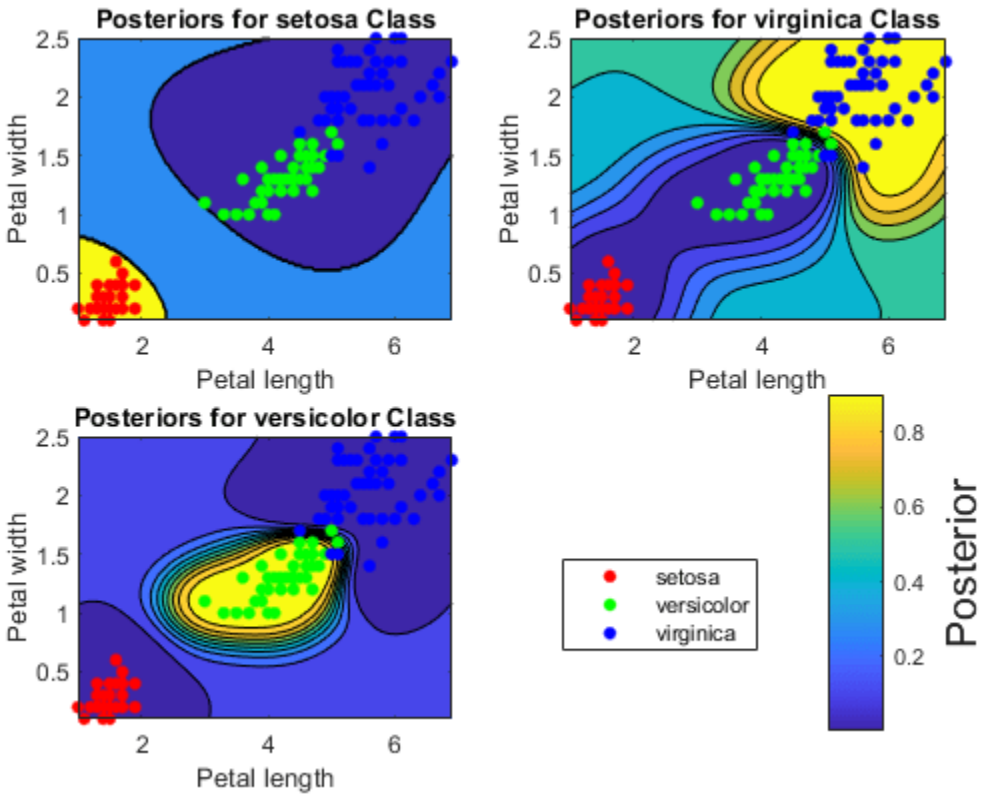
Define a grid to plot the posterior probability contours. Estimate the posterior probabilities over the grid for each classifier.

```
d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];

posterior = cell(3,1);
for j = 1:numClasses
    [~,posterior{j}] = predict(SVMModel{j},xGrid);
end
```

For each SVM classifier, plot the posterior probability contour under the scatter plot of the data.

```
figure
h = zeros(numClasses + 1,1); % Preallocation for graphics handles
for j = 1:numClasses
subplot(2,2,j)
contourf(x1Grid,x2Grid,reshape(posterior{j}(:,2),size(x1Grid,1),size(x1Grid,2)));
hold on
h(1:numClasses) = gscatter(X(:,1),X(:,2),Y);
title(sprintf('Posteriors for %s Class',classNames{j}));
xlabel('Petal length');
ylabel('Petal width');
legend off
axis tight
hold off
end
h(numClasses + 1) = colorbar('Location','EastOutside',...
    'Position',[[0.8,0.1,0.05,0.4]]);
set(get(h(numClasses + 1),'YLabel'),'String','Posterior','FontSize',16);
legend(h(1:numClasses),'Location',[0.6,0.2,0.1,0.1]);
```



Fit Optimal Posterior Probability Function Using Holdout Cross-Validation

Estimate the score-to-posterior-probability transformation function after training an SVM classifier. Use cross-validation during the estimation to reduce bias, and compare the run times for 10-fold cross-validation and holdout cross-validation.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that `'g'` is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Fit the optimal score-to-posterior-probability transformation function. Compare the run times from using 10-fold cross-validation (the default) and a 10% holdout test sample.

```
rng(1); % For reproducibility
tic;    % Start the stopwatch
SVMModel_10FCV = fitPosterior(SVMModel);
toc     % Stop the stopwatch and display the run time
```

```
Elapsed time is 1.081044 seconds.
```

```
tic;
SVMModel_HO = fitPosterior(SVMModel,'Holdout',0.10);
toc
```

```
Elapsed time is 0.269525 seconds.
```

Although both run times are short because the data set is relatively small, `SVMModel_HO` fits the score transformation function much faster than `SVMModel_10FCV`. You can specify holdout cross-validation (instead of the default 10-fold cross validation) to reduce run time for larger data sets.

Input Arguments

`SVMModel` — Full, trained SVM classifier

`ClassificationSVM` classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained with `fitcsvm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `fitPosterior(SVMModel,'KFold',5)` uses five folds in a cross-validated model.

`CVPartition` — Cross-validation partition

`[]` (default) | `cvpartition` partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

The `crossval` name-value pair argument of `fitcsvm` splits the data into subsets using `cvpartition`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'KFold',8`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross-validation to compute the transformation function, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. Use leave-one-out cross-validation by specifying `'Leaveout','on'`.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'Leaveout','on'`

Output Arguments

`ScoreSVMModel` — Trained SVM classifier
`ClassificationSVM` classifier

Trained SVM classifier, returned as a `ClassificationSVM` classifier. The trained classifier contains the estimated score-to-posterior-probability transformation function.

To estimate posterior probabilities for the training set observations, pass `ScoreSVMModel` to `resubPredict`.

To estimate posterior probabilities for new observations, pass the new observations and `ScoreSVMModel` to `predict`.

`ScoreTransform` — Optimal score-to-posterior-probability transformation function parameters
structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then `ScoreTransform` also has these fields:
  - `Slope`: The value of A in the sigmoid function on page 33-2307
  - `Intercept`: The value of B in the sigmoid function
- If the value of the `Type` field of `ScoreTransform` is `step`, then `ScoreTransform` also has these fields:
  - `PositiveClassProbability`: The value of π in the step function on page 33-2307. This value represents the probability that an observation is in the positive class or the posterior

probability that an observation is in the positive class given that its score is in the interval (`LowerBound`,`UpperBound`).

- `LowerBound`: The value $\max_{y_n = -1} s_n$ in the step function. This value represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being in the positive class equal to `0`.
- `UpperBound`: The value $\min_{y_n = +1} s_n$ in the step function. This value represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being in the positive class equal to `1`.

- If the value of the `Type` field of `ScoreTransform` is `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

  This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

More About

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \le s_j \le \min_{y_k = +1} s_k, \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases}$$

where:

- s_j is the score of observation j.
- +1 and –1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the value of the `Type` field of `ScoreTransform` is `step`, then the quantities $\max_{y_k = -1} s_k$ and $\min_{y_k = +1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

- This process describes one way to predict positive class posterior probabilities.

  1. Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
  2. Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, such as, `ScoreSVMModel`, is the same trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.
  3. Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

     If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

The software fits the appropriate score-to-posterior-probability transformation function by using the SVM classifier `SVMModel` and by conducting 10-fold cross-validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`), as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 33-2307.
- If the classes are perfectly separable, then the transformation function is the step function on page 33-2307.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 33-2428. The `fitPosterior` function is not appropriate for one-class learning.

- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to `'none'` before estimating the new one

Alternative Functionality

You can also fit the posterior probability function by using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad because it accepts a wider range of SVM classifier types.

`ClassificationSVM` | `fitSVMPosterior` | `fitcsvm` | `predict`

Introduced in R2014a

fitPosterior

Package: `classreg.learning.classif`

Fit posterior probabilities for compact support vector machine (SVM) classifier

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel,TBL,Y)
ScoreSVMModel = fitPosterior(SVMModel,X,Y)
[ScoreSVMModel,ScoreTransform] = fitPosterior( ___ )
```

Description

`ScoreSVMModel = fitPosterior(SVMModel,TBL,Y)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. For more details, see “Algorithms” on page 33-2308. If you train `SVMModel` using a table, then you must use a table as input for `fitPosterior`.

`ScoreSVMModel = fitPosterior(SVMModel,X,Y)` returns a trained SVM classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. If you train `SVMModel` using a matrix, then you must use a matrix as input for `fitPosterior`.

`[ScoreSVMModel,ScoreTransform] = fitPosterior( ___ )` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`) for any of the input argument combinations in the previous syntaxes.

Examples

Estimate Posterior Probabilities for Data with Inseparable Classes

Load the `ionosphere` data set. Reserve 20 random observations of the data, and consider this set new data.

```
load ionosphere
n = size(X,1);
rng(1);  % For reproducibility

indx = ~ismember([1:n],randsample(n,20)); % Indices for the training data
```

The classes of this data set are inseparable.

Train an SVM classifier using the training data. Standardize the data and specify that `'g'` is the positive class.

```
SVMModel = fitcsvm(X(indx,:),Y(indx),'ClassNames',{'b','g'},...
    'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as `g`. For efficiency, make a compact version of `SVMModel`, and pass it and the new data to `fitPosterior`.

```
CompactSVMModel = compact(SVMModel);
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...
    X(~indx,:),Y(~indx));

ScoreTransform = ScoreCSVMModel.ScoreTransform
```

```
ScoreTransform =
'@(S)sigmoid(S,-1.099032e+00,4.521358e-01)'
```

```
ScoreParameters
```

```
ScoreParameters = struct with fields:
         Type: 'sigmoid'
        Slope: -1.0990
    Intercept: 0.4521
```

`ScoreTransform` is the optimal score transformation function. `ScoreParameters` is a structure array with three fields: the score transformation function name (`Type`), the sigmoid slope (`Slope`), and the sigmoid intercept estimates (`Intercept`).

Alternatively, you can pass `SVMModel` and the new data to `fitSVMPosterior`, but this process is not as efficient.

Estimate the posterior probabilities that the observations in the new data are in class `g`.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
    'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans=20×3 table
    TrueLabel    PredictedLabel    PosteriorProbability

      ⋮
```

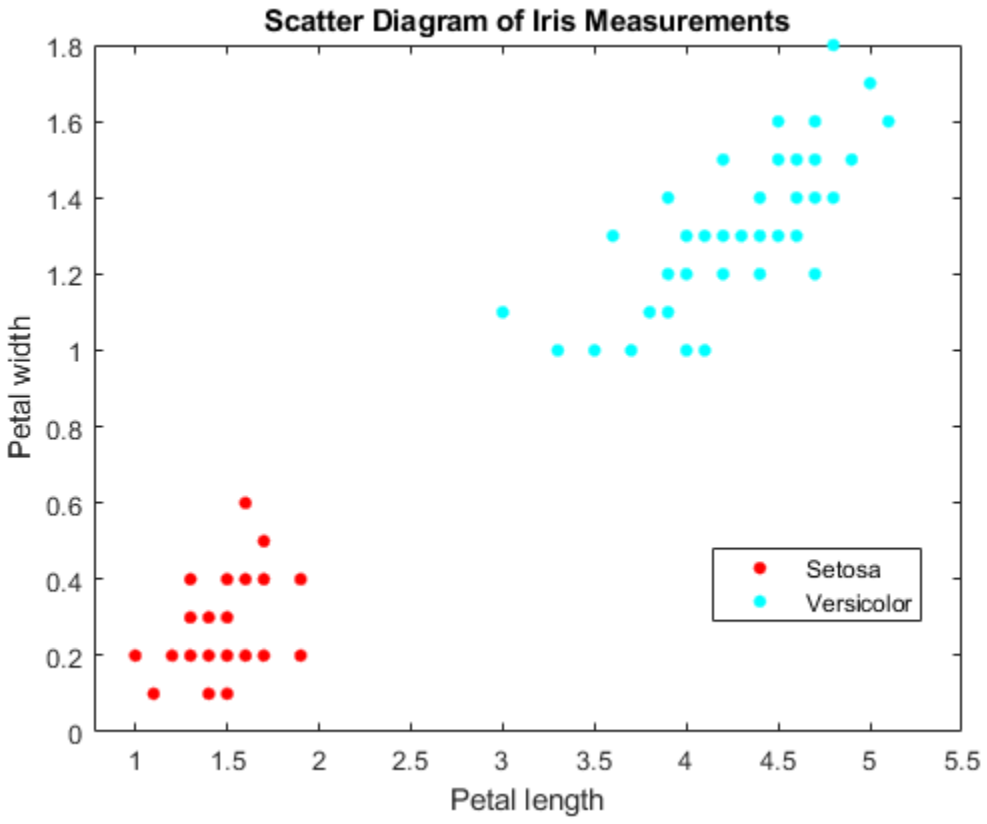
Estimate Posterior Probabilities for Data with Separable Classes

Load Fisher's iris data set. Use the petal lengths and widths as the predictor data, and remove the virginica species from the data. Reserve 10 random observations of the data, and consider this set new data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
Y = species(classKeep);

rng(1);  % For reproducibility
indx1 = 1:numel(species);
indx2 = indx1(classKeep);
indx = ~ismember(indx2,randsample(indx2,10)); % Indices for the training data

gscatter(X(indx,1),X(indx,2),Y(indx));
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa','Versicolor')
```



The classes are perfectly separable. Therefore, the score-to-posterior-probability transformation function is a step function.

Train an SVM classifier. Standardize the data and specify that `versicolor` is the positive class.

```
SVMModel = fitcsvm(X(indx,:),Y(indx),...
    'ClassNames',{'setosa','versicolor'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as `versicolor`. For efficiency, make a compact version `SVMModel`, and pass it and the new data to `fitPosterior`.

```
CompactSVMModel = compact(SVMModel);
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...
    X(~indx,:),Y(~indx));
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step
```

```
ScoreTransform = ScoreCSVMModel.ScoreTransform
```

```
ScoreTransform =
'@(S)step(S,-1.338450e+00,2.012495e+00,5.333333e-01)'
```

`fitPosterior` displays a warning whenever the classes are separable, and stores the step function in `ScoreSVMModel.ScoreTransform`.

Display the score function type and its estimated values.

```
ScoreParameters
```

```
ScoreParameters = struct with fields:
                      Type: 'step'
                LowerBound: -1.3385
                UpperBound: 2.0125
    PositiveClassProbability: 0.5333
```

`ScoreParameters` is a structure array with four fields:

- Score transformation function type (`Type`)
- Score corresponding to the negative class boundary (`LowerBound`)
- Score corresponding to the positive class boundary (`UpperBound`)
- Positive class probability (`PositiveClassProbability`)

Alternatively, you can pass `SVMModel` and the new data to `fitSVMPosterior`, but this process is not as efficient.

Estimate the posterior probabilities that the observations in the new data are versicolor irises.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
    'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans=10×3 table
      TrueLabel       PredictedLabel    PosteriorProbability
    ______________    ______________    ____________________

    {'setosa'    }    {'setosa'    }             0
    {'setosa'    }    {'setosa'    }             0
```

```
    {'setosa'    }    {'setosa'    }            0
    {'setosa'    }    {'setosa'    }            0
    {'setosa'    }    {'setosa'    }            0
    {'setosa'    }    {'setosa'    }            0
    {'setosa'    }    {'setosa'    }            0
    {'setosa'    }    {'setosa'    }            0
    {'versicolor'}    {'versicolor'}            1
    {'versicolor'}    {'versicolor'}            1
```

Because the classes are separable, the step function transforms the positive-class score to:

- `0` if the score is less than `ScoreParameters.LowerBound`
- `1` if the score is greater than `ScoreParameters.UpperBound`
- `ScoreParameters.PositiveClassProbability` if the score is in the interval [`ScoreParameters.LowerBound` , `ScoreParameters.LowerBound`]

Input Arguments

`SVMModel` — Trained, compact SVM classifier

`CompactClassificationSVM` classifier

Trained, compact SVM classifier, specified as a `CompactClassificationSVM` model returned by `compact`.

`TBL` — Sample data

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. `TBL` must contain all of the predictors used to train `SVMModel`. Optionally, `TBL` can contain an additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable used to train `SVMModel`, then you do not need to specify `Y`. If `TBL` does not include the response variable, then the length of `Y` must be equal to the number of rows in `TBL`.

If the sample data used to train `SVMModel` is a `table`, then you must specify the input data for `fitPosterior` as a table.

If you set `'Standardize',true` in `fitcsvm` when training `SVMModel`, then the software fits the transformation function parameter estimates using standardized data.

Data Types: `table`

`X` — Predictor data

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows in X must be equal.

If you set 'Standardize',true in fitcsvm when training SVMModel, then the software fits the transformation function parameter estimates using standardized data.

Data Types: double | single

Y — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.

If Y is a character array, then each element must correspond to one class label.

The length of Y and the number of rows in X must be equal.

Data Types: categorical | char | string | logical | single | double | cell

Output Arguments

ScoreSVMModel — Trained, compact SVM classifier
CompactClassificationSVM classifier

Trained, compact SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a CompactClassificationSVM classifier.

To estimate posterior probabilities for new observations, pass ScoreSVMModel and the new observations to predict.

ScoreTransform — Optimal score-to-posterior-probability transformation function parameters
structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If the value of the Type field of ScoreTransform is sigmoid, then ScoreTransform also has these fields:
  - Slope: The value of A in the sigmoid function on page 33-2307
  - Intercept: The value of B in the sigmoid function
- If the value of the Type field of ScoreTransform is step, then ScoreTransform also has these fields:
  - PositiveClassProbability: The value of π in the step function on page 33-2307. This value represents the probability that an observation is in the positive class or the posterior probability that an observation is in the positive class given that its score is in the interval (LowerBound,UpperBound).
  - LowerBound: The value $\max_{y_n = -1} s_n$ in the step function. This value represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class PositiveClassProbability. Any observation with

a score less than `LowerBound` has the posterior probability of being in the positive class equal to `0`.

- `UpperBound`: The value $\min_{y_n = +1} s_n$ in the step function. This value represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being in the positive class equal to `1`.

- If the value of the `Type` field of `ScoreTransform` is `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

  This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

More About

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \le s_j \le \min_{y_k = +1} s_k, \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases}$$

where:

- s_j is the score of observation j.
- +1 and –1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the value of the `Type` field of `ScoreTransform` is `step`, then the quantities $\max_{y_k = -1} s_k$ and $\min_{y_k = +1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

- This process describes one way to predict positive class posterior probabilities.

  1. Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
  2. Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, such as, `ScoreSVMModel`, is the same trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.
  3. Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

     If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

The software fits the appropriate score-to-posterior-probability transformation function by using the SVM classifier `SVMModel` and by conducting 10-fold cross-validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`), as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 33-2307.
- If the classes are perfectly separable, then the transformation function is the step function on page 33-2307.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 33-2428. The `fitPosterior` function is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to `'none'` before estimating the new one

Alternative Functionality

You can also fit the optimal score-to-posterior-probability function by using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad because it accepts a wider range of SVM classifier types.

Introduced in R2014a

fitrensemble

Fit ensemble of learners for regression

Syntax

```
Mdl = fitrensemble(Tbl,ResponseVarName)
Mdl = fitrensemble(Tbl,formula)
Mdl = fitrensemble(Tbl,Y)

Mdl = fitrensemble(X,Y)

Mdl = fitrensemble( ___ ,Name,Value)
```

Description

`Mdl = fitrensemble(Tbl,ResponseVarName)` returns the trained regression ensemble model object (`Mdl`) that contains the results of boosting 100 regression trees using LSBoost and the predictor and response data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`.

`Mdl = fitrensemble(Tbl,formula)` applies `formula` to fit the model to the predictor and response data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. For example, `'Y~X1+X2+X3'` fits the response variable `Tbl.Y` as a function of the predictor variables `Tbl.X1`, `Tbl.X2`, and `Tbl.X3`.

`Mdl = fitrensemble(Tbl,Y)` treats all variables in the table `Tbl` as predictor variables. `Y` is the vector of responses that is not in `Tbl`.

`Mdl = fitrensemble(X,Y)` uses the predictor data in the matrix `X` and response data in the vector `Y`.

`Mdl = fitrensemble( ___ ,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments and any of the input arguments in the previous syntaxes. For example, you can specify the number of learning cycles, the ensemble aggregation method, or to implement 10-fold cross-validation.

Examples

Train Regression Ensemble

Create a regression ensemble that predicts the fuel economy of a car given the number of cylinders, volume displaced by the cylinders, horsepower, and weight. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the `carsmall` data set. Store the variables to be used in training in a table.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

Train a regression ensemble.

```
Mdl1 = fitrensemble(Tbl,'MPG');
```

`Mdl1` is a `RegressionEnsemble` model. Some notable characteristics of `Mdl1` are:

- The ensemble aggregation algorithm is `'LSBoost'`.
- Because the ensemble aggregation method is a boosting algorithm, regression trees that allow a maximum of 10 splits compose the ensemble.
- One hundred trees compose the ensemble.

Because `MPG` is a variable in the MATLAB® Workspace, you can obtain the same result by entering

```
Mdl1 = fitrensemble(Tbl,MPG);
```

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
pMPG = predict(Mdl1,[4 200 150 3000])
```

```
pMPG = 25.6467
```

Train a new ensemble using all predictors in `Tbl` except `Displacement`.

```
formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitrensemble(Tbl,formula);
```

Compare the resubstitution MSEs between `Mdl1` and `Mdl2`.

```
mse1 = resubLoss(Mdl1)
```

```
mse1 = 0.3096
```

```
mse2 = resubLoss(Mdl2)
```

```
mse2 = 0.5861
```

The in-sample MSE for the ensemble that trains on all predictors is lower.

Speed Up Training by Binning Numeric Predictor Values

Train an ensemble of boosted regression trees by using `fitrensemble`. Reduce training time by specifying the `'NumBins'` name-value pair argument to bin numeric predictors. After training, you can reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

Generate a sample data set.

```
rng('default') % For reproducibility
N = 1e6;
X1 = randi([-1,5],[N,1]);
X2 = randi([5,10],[N,1]);
X3 = randi([0,5],[N,1]);
X4 = randi([1,10],[N,1]);
X = [X1 X2 X3 X4];
y = X1 + X2 + X3 + X4 + normrnd(0,1,[N,1]);
```

Train an ensemble of boosted regression trees using least-squares boosting (`LSBoost`, the default value). Time the function for comparison purposes.

```
tic
Mdl1 = fitrensemble(X,y);
toc
```

```
Elapsed time is 78.662954 seconds.
```

Speed up training by using the `'NumBins'` name-value pair argument. If you specify the `'NumBins'` value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. The software does not bin categorical predictors.

```
tic
Mdl2 = fitrensemble(X,y,'NumBins',50);
toc
```

```
Elapsed time is 43.353208 seconds.
```

The process is about two times faster when you use binned data instead of the original data. Note that the elapsed time can vary depending on your operating system.

Compare the regression errors by resubstitution.

```
rsLoss = resubLoss(Mdl1)
```

```
rsLoss = 1.0134
```

```
rsLoss2 = resubLoss(Mdl2)
```

```
rsLoss2 = 1.0133
```

In this example, binning predictor values reduces training time without a significant loss of accuracy. In general, when you have a large data set like the one in this example, using the binning option speeds up training but causes a potential decrease in accuracy. If you want to reduce training time further, specify a smaller number of bins.

Reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

```
X = Mdl2.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl2.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are `0` for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

Estimate Generalization Error of Boosting Ensemble

Estimate the generalization error of an ensemble of boosted regression trees.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
```

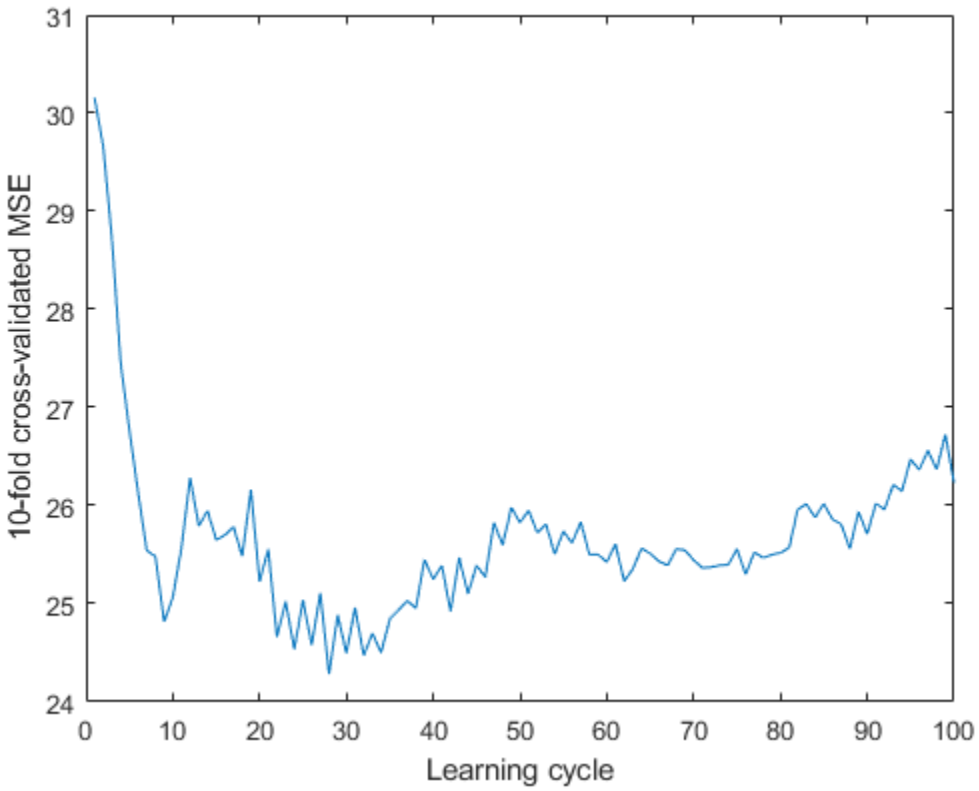
Cross-validate an ensemble of regression trees using 10-fold cross-validation. Using a decision tree template, specify that each tree should be a split once only.

```
rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitrensemble(X,MPG,'Learners',t,'CrossVal','on');
```

`Mdl` is a `RegressionPartitionedEnsemble` model.

Plot the cumulative, 10-fold cross-validated, mean-squared error (MSE). Display the estimated generalization error of the ensemble.

```
kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold cross-validated MSE');
xlabel('Learning cycle');
```



```
estGenError = kflc(end)
```

```
estGenError = 26.2356
```

`kfoldLoss` returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves an MSE of around 23.5 after accumulating about 30 weak learners.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-validation. However, it is good practice to tune hyperparameters such as the maximum number of decision splits per tree and the number of learning cycles..

Optimize Regression Ensemble

This example shows how to optimize hyperparameters automatically using `fitrensemble`. The example uses the `carsmall` data.

Load the data.

```
load carsmall
```

You can find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

```
Mdl = fitrensemble([Horsepower,Weight],MPG,'OptimizeHyperparameters','auto')
```

In this example, for reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function. Also, for reproducibility of random forest algorithm, specify the `'Reproducible'` name-value pair argument as `true` for tree learners.

```
rng('default')
t = templateTree('Reproducible',true);
Mdl = fitrensemble([Horsepower,Weight],MPG,'OptimizeHyperparameters','auto','Learners',t, ...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-p
```

  Properties, Methods
```

The optimization searched over the methods for regression (`Bag` and `LSBoost`), over `NumLearningCycles`, over the `LearnRate` for `LSBoost`, and over the tree learner `MinLeafSize`. The output is the ensemble regression with the minimum estimated cross-validation loss.

Optimize Regression Ensemble Using Cross-Validation

One way to create an ensemble of boosted regression trees that has satisfactory predictive performance is to tune the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles as well.

This example manually finds optimal parameters by using the cross-validation option (the `'KFold'` name-value pair argument) and the `kfoldLoss` function. Alternatively, you can use the `'OptimizeHyperparameters'` name-value pair argument to optimize hyperparameters automatically. See “Optimize Regression Ensemble” on page 33-2314.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

The default values of the tree depth controllers for boosting regression trees are:

- `10` for `MaxNumSplits`.
- `5` for `MinLeafSize`
- `10` for `MinParentSize`

To search for the optimal tree-complexity level:

1. Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most n - 1 splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.

2. Estimate the cross-validated mean-squared error (MSE) for each ensemble.
3. For tree-complexity level j, $j = 1 \ldots J$, compare the cumulative, cross-validated MSE of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
4. Choose the curve that achieves the minimal MSE, and note the corresponding learning cycle and learning rate.

Cross-validate a deep regression tree and a stump. Because the data contain missing values, use surrogate splits. These regression trees serve as benchmarks.

```
rng(1) % For reproducibility
MdlDeep = fitrtree(Tbl,'MPG','CrossVal','on','MergeLeaves','off', ...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(Tbl,'MPG','MaxNumSplits',1,'CrossVal','on', ...
    'Surrogate','on');
```

Cross-validate an ensemble of 150 boosted regression trees using 5-fold cross-validation. Using a tree template:

- Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \ldots, 2^m\}$. m is such that 2^m is no greater than n - 1.
- Turn on surrogate splits.

For each variant, adjust the learning rate using each value in the set {0.1, 0.25, 0.5, 1}.

```
n = size(Tbl,1);
m = floor(log2(n - 1));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 2.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);

for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitrensemble(Tbl,'MPG','NumLearningCycles',numTrees, ...
            'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end
end
```

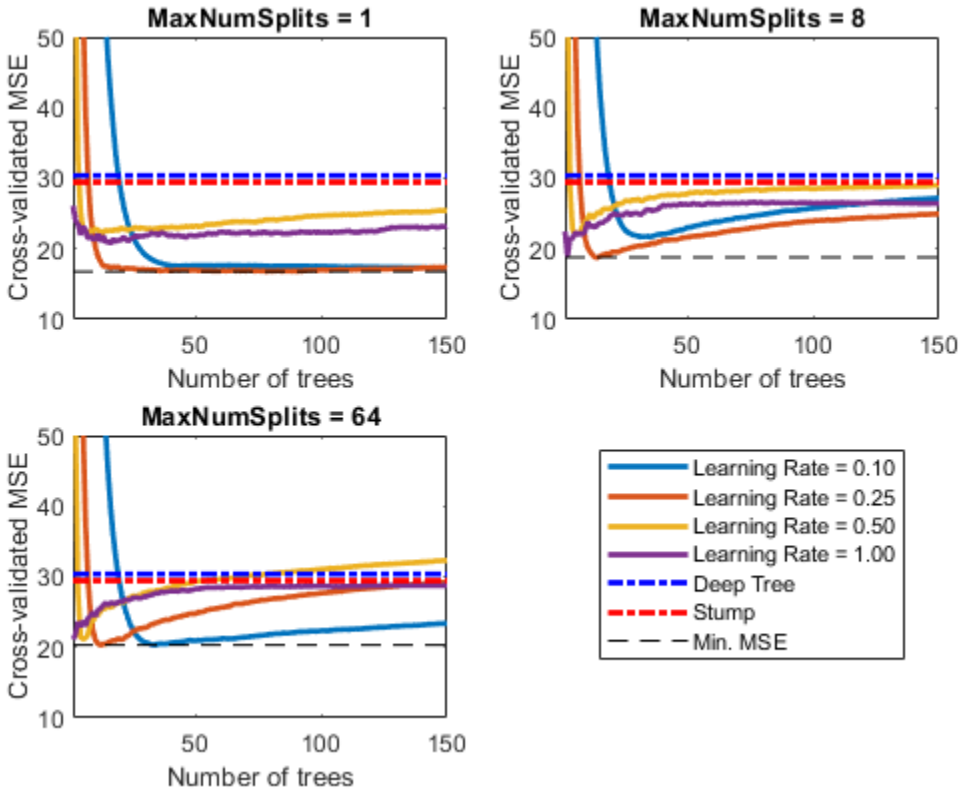
Estimate the cumulative, cross-validated MSE of each ensemble.

```
kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);
```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```
mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
```

```
for k = 1:3
    subplot(2,2,k)
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2)
    axis tight
    hold on
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'-.b','LineWidth',2)
    plot(h.XLim,[errorStump errorStump],'-.r','LineWidth',2)
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'--k')
    h.YLim = [10 50];
    xlabel('Number of trees')
    ylabel('Cross-validated MSE')
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
    hold off
end
hL = legend([cellstr(num2str(learnRate','Learning Rate = %0.2f')); ...
        'Deep Tree';'Stump';'Min. MSE']);
hL.Position(1) = 0.6;
```



Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);
fprintf('\nMin. MSE = %0.5f',minErr)
```

```
Min. MSE = 16.77593

fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);

Optimal Parameter Values:
Num. Trees = 78

fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
    maxNumSplits(idxMNS),learnRate(idxLR))

MaxNumSplits = 1
Learning Rate = 0.25
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```
tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS),'Surrogate','on');
MdlFinal = fitrensemble(Tbl,'MPG','NumLearningCycles',idxNumTrees, ...
    'Learners',tFinal,'LearnRate',learnRate(idxLR))

MdlFinal =
  RegressionEnsemble

  Properties, Methods
```

`MdlFinal` is a `RegressionEnsemble`. To predict the fuel economy of a car given its number of cylinders, volume displaced by the cylinders, horsepower, and weight, you can pass the predictor data and `MdlFinal` to `predict`.

Instead of searching optimal values manually by using the cross-validation option (`'KFold'`) and the `kfoldLoss` function, you can use the `'OptimizeHyperparameters'` name-value pair argument. When you specify `'OptimizeHyperparameters'`, the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using `'OptimizeHyperparameters'` can be different from those obtained using manual search.

```
t = templateTree('Surrogate','on');
mdl = fitrensemble(Tbl,'MPG','Learners',t, ...
    'OptimizeHyperparameters',{'NumLearningCycles','LearnRate','MaxNumSplits'})

```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using `formula`.
- If `Tbl` does not contain the response variable, then specify the response data using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Note To save memory and execution time, supply `X` and `Y` instead of `Tbl`.

Data Types: `table`

`ResponseVarName` — Response variable name

name of response variable in `Tbl`

Response variable name, specified as the name of the response variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitrensemble` treats all columns of `Tbl` as predictor variables.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables

character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

X — Predictor data
numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Y — Response
numeric vector

Response, specified as a numeric vector. Each element in `Y` is the response to the observation in the corresponding row of `X` or `Tbl`. The length of `Y` and the number of rows of `X` or `Tbl` must be equal.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'NumLearningCycles',500,'Method','Bag','Learners',templateTree(),'CrossVal','on'` cross-validates an ensemble of 500 bagged regression trees using 10-fold cross-validation.

General Ensemble Options

`Method` — Ensemble aggregation method

`'LSBoost'` (default) | `'Bag'`

Ensemble aggregation method, specified as the comma-separated pair consisting of `'Method'` and `'LSBoost'` or `'Bag'`.

Value	Method	Notes
`'LSBoost'`	Least-squares boosting (LSBoost)	You can specify the learning rate for shrinkage by using the `'LearnRate'` name-value pair argument.
`'Bag'`	Bootstrap aggregation (bagging, for example, random forest[2])	`fitrensemble` uses bagging with random predictor selections at each split (random forest) by default. To use bagging without the random selections, use tree learners whose `'NumVariablesToSample'` value is `'all'`.

For details about ensemble aggregation algorithms and examples, see “Algorithms” on page 33-2337, “Ensemble Algorithms” on page 18-39, and “Choose an Applicable Ensemble Aggregation Method” on page 18-32.

Example: `'Method','Bag'`

`NumLearningCycles` — Number of ensemble learning cycles

`100` (default) | positive integer

Number of ensemble learning cycles, specified as the comma-separated pair consisting of `'NumLearningCycles'` and a positive integer. At every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NumLearningCycles*numel(Learners)` learners.

The software composes the ensemble using all trained learners and stores them in `Mdl.Trained`.

For more details, see “Tips” on page 33-2337.

Example: `'NumLearningCycles',500`

Data Types: `single` | `double`

`Learners` — Weak learners to use in ensemble

`'tree'` (default) | tree template object | cell vector of tree template objects

Weak learners to use in the ensemble, specified as the comma-separated pair consisting of `'Learners'` and `'tree'`, a tree template object, or a cell vector of tree template objects.

- `'tree'` (default) — `fitrensemble` uses default regression tree learners, which is the same as using `templateTree()`. The default values of `templateTree()` depend on the value of `'Method'`.

- For bagged decision trees, the maximum number of decision splits (`'MaxNumSplits'`) is `n–1`, where `n` is the number of observations. The number of predictors to select at random for each split (`'NumVariablesToSample'`) is one third of the number of predictors. Therefore, `fitrensemble` grows deep decision trees. You can grow shallower trees to reduce model complexity or computation time.
- For boosted decision trees, `'MaxNumSplits'` is 10 and `'NumVariablesToSample'` is `'all'`. Therefore, `fitrensemble` grows shallow decision trees. You can grow deeper trees for better accuracy.

See `templateTree` for the default settings of a weak learner.

- Tree template object — `fitrensemble` uses the tree template object created by `templateTree`. Use the name-value pair arguments of `templateTree` to specify settings of the tree learners.
- Cell vector of *m* tree template objects — `fitrensemble` grows *m* regression trees per learning cycle (see `NumLearningCycles`). For example, for an ensemble composed of two types of regression trees, supply `{t1 t2}`, where `t1` and `t2` are regression tree template objects returned by `templateTree`.

To obtain reproducible results, you must specify the `'Reproducible'` name-value pair argument of `templateTree` as `true` if `'NumVariablesToSample'` is not `'all'`.

For details on the number of learners to train, see `NumLearningCycles` and “Tips” on page 33-2337.

Example: `'Learners',templateTree('MaxNumSplits',5)`

`NPrint` — Printout frequency
`'off'` (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of `'NPrint'` and a positive integer or `'off'`.

To track the number of *weak learners* or *folds* that `fitrensemble` trained so far, specify a positive integer. That is, if you specify the positive integer *m*:

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitrensemble` displays a message to the command line every time it completes training *m* weak learners.
- And a cross-validation option, then `fitrensemble` displays a message to the command line every time it finishes training *m* folds.

If you specify `'off'`, then `fitrensemble` does not display a message when it completes training weak learners.

Tip For fastest training of some boosted decision trees, set `NPrint` to the default value `'off'`. This tip holds when the classification `Method` is `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, or `'LogitBoost'`, or when the regression `Method` is `'LSBoost'`.

Example: `'NPrint',5`

Data Types: `single` | `double` | `char` | `string`

`NumBins` — Number of bins for numeric predictors
`[]` (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

- If the `'NumBins'` value is empty (default), then `fitrensemble` does not bin any predictors.
- If you specify the `'NumBins'` value as a positive integer scalar (`numBins`), then `fitrensemble` bins every numeric predictor into at most `numBins` equiprobable bins, and then grows trees on the bin indices instead of the original data.
  - The number of bins can be less than `numBins` if a predictor has fewer than `numBins` unique values.
  - `fitrensemble` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but might cause a potential decrease in accuracy. You can try `'NumBins',50` first, and then change the value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single` | `double`

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitrensemble` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrensemble` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitrensemble` assumes that all

predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitrensemble` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',`
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ResponseTransform` — Response transformation
`'none'` (default) | function handle

Response transformation, specified as either `'none'` or a function handle. The default is `'none'`, which means `@(y)y`, or no transformation. For a MATLAB function or a function you define, use its function handle for the response transformation. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as `'ResponseTransform',myfunction`.

Data Types: `char` | `string` | `function_handle`

Parallel Options

`Options` — Options for computing in parallel and setting random numbers

structure

Options for computing in parallel and setting random numbers, specified as a structure. Create the `Options` structure with `statset`.

Note You need Parallel Computing Toolbox to compute in parallel.

This table lists the option fields and their values.

Field Name	Value	Default
`UseParallel`	Set this value to `true` to compute in parallel. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.	`false`
`UseSubstreams`	Set this value to `true` to run computations in parallel in a reproducible manner. To compute reproducibly, set `Streams` to a type that allows substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Also, use a tree template with the `'Reproducible'` name-value argument set to `true`. See “Reproducibility in Parallel Statistical Computations” on page 31-13.	`false`
`Streams`	Specify this value as a `RandStream` object or cell array of such objects. Use a single object except when the `UseParallel` value is `true` and the `UseSubstreams` value is `false`. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify `Streams`, then `fitrensemble` uses the default stream or streams.

For an example using reproducible parallel training, see “Train Classification Ensemble in Parallel” on page 18-109.

For dual-core systems and above, `fitrensemble` parallelizes training using Intel Threading Building Blocks (TBB). Therefore, specifying the `UseParallel` option as `true` might not provide a significant speedup on a single computer. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Cross-Validation Options

`CrossVal` — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: `'Crossval','on'`

`CVPartition` — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.
2. Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Other Regression Options

`Weights` — Observation weights

numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes the values of `Weights` to sum to 1.

By default, `Weights` is `ones(n,1)`, where *n* is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Sampling Options

`FResample` — Fraction of training set to resample
1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in (0,1].

To use `'FResample'`, specify `'bag'` for `Method` or set `Resample` to `'on'`.

Example: `'FResample',0.75`

Data Types: `single` | `double`

`Replace` — Flag indicating to sample with replacement
`'on'` (default) | `'off'`

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of `'Replace'` and `'off'` or `'on'`.

- For `'on'`, the software samples the training observations with replacement.
- For `'off'`, the software samples the training observations without replacement. If you set `Resample` to `'on'`, then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to `'bag'` or set `Resample` to `'on'`, `Replace` has no effect.

Example: `'Replace','off'`

`Resample` — Flag indicating to resample
`'off'` | `'on'`

Flag indicating to resample, specified as the comma-separated pair consisting of `'Resample'` and `'off'` or `'on'`.

- If `Method` is a boosting method, then:
  - `'Resample','on'` specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - `'Resample','off'`(default) specifies to reweight observations at every learning iteration.
- If `Method` is `'bag'`, then `'Resample'` must be `'on'`. The software resamples a fraction of the training observations (see `FResample`) with or without replacement (see `Replace`).

If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

LSBoost Method Options

`LearnRate` — Learning rate for shrinkage
1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of `'LearnRate'` and a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than `1`, for example, `0.1` is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate',0.1`

Data Types: `single` | `double`

Hyperparameter Optimization Options

`OptimizeHyperparameters` — Parameters to optimize
`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Method','NumLearningCycles','LearnRate'}` along with the default parameters for the specified `Learners`:
  - `Learners = 'tree'` (default) — `{'MinLeafSize'}`

  Note For hyperparameter optimization, `Learners` must be a single argument, not a string array or cell array.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitrensemble` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitrensemble` are:

- `Method` — Eligible methods are `'Bag'` or `'LSBoost'`.
- `NumLearningCycles` — `fitrensemble` searches among positive integers, by default log-scaled with range `[10,500]`.
- `LearnRate` — `fitrensemble` searches among positive reals, by default log-scaled with range `[1e-3,1]`.
- `MinLeafSize` — `fitrensemble` searches among integers log-scaled in the range `[1,max(2,floor(NumObservations/2))]`.
- `MaxNumSplits` — `fitrensemble` searches among integers log-scaled in the range `[1,max(2,NumObservations-1)]`.
- `NumVariablesToSample` — `fitrensemble` searches among integers in the range `[1,max(2,NumPredictors)]`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrensemble',[Horsepower,Weight],MPG,'Tree');
params(4).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Regression Ensemble” on page 33-2314.

Example: `'OptimizeHyperparameters',{'Method','NumLearningCycles','LearnRate','MinLeafSize','MaxNumSplits'}`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`

Field Name	Values	Default
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`

Field Name	Values	Default
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see "Parallel Bayesian Optimization" on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained regression ensemble model

`RegressionBaggedEnsemble` model object | `RegressionEnsemble` model object | `RegressionPartitionedEnsemble` cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Specify Any Cross-Validation Options?	`Method` Setting	`Resample` Setting
`RegressionBaggedEnsemble`	No	`'Bag'`	`'on'`

Model Object	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
`RegressionEnsemble`	No	`'LSBoost'`	`'off'`
`RegressionPartitionedEnsemble`	Yes	`'LSBoost'` or `'Bag'`	`'off'` or `'on'`

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NumLearningCycles` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume`.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of `1` for `FResample`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-39.
- If you specify `'Method','LSBoost'`, then the software grows shallow decision trees by default. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- For dual-core systems and above, `fitrensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

`fitrensemble` supports parallel training using the `'Options'` name-value argument. Create options using `statset`, such as `options = statset('UseParallel',true)`. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016b

fitrsvm

Fit a support vector machine regression model

Syntax

```
Mdl = fitrsvm(Tbl,ResponseVarName)
Mdl = fitrsvm(Tbl,formula)
Mdl = fitrsvm(Tbl,Y)

Mdl = fitrsvm(X,Y)

Mdl = fitrsvm( ___ ,Name,Value)
```

Description

`fitrsvm` trains or cross-validates a support vector machine (SVM) regression model on a low- through moderate-dimensional predictor data set. `fitrsvm` supports mapping the predictor data using kernel functions, and supports SMO, ISDA, or $L1$ soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM regression model on a high-dimensional data set, that is, data sets that include many predictor variables, use `fitrlinear` instead.

To train an SVM model for binary classification, see `fitcsvm` for low- through moderate-dimensional predictor data sets, or `fitclinear` for high-dimensional data sets.

`Mdl = fitrsvm(Tbl,ResponseVarName)` returns a full, trained support vector machine (SVM) regression model `Mdl` trained using the predictors values in the table `Tbl` and the response values in `Tbl.ResponseVarName`.

`Mdl = fitrsvm(Tbl,formula)` returns a full SVM regression model trained using the predictors values in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitrsvm(Tbl,Y)` returns a full, trained SVM regression model trained using the predictors values in the table `Tbl` and the response values in the vector `Y`.

`Mdl = fitrsvm(X,Y)` returns a full, trained SVM regression model trained using the predictors values in the matrix `X` and the response values in the vector `Y`.

`Mdl = fitrsvm( ___ ,Name,Value)` returns an SVM regression model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the kernel function or train a cross-validated model.

Examples

Train Linear Support Vector Machine Regression Model

Train a support vector machine (SVM) regression model using sample data stored in matrices.

Load the `carsmall` data set.

```
load carsmall
rng 'default'  % For reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a default SVM regression model.

```
Mdl = fitrsvm(X,Y)
```

```
Mdl =
  RegressionSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
                    Alpha: [75x1 double]
                     Bias: 57.3800
          KernelParameters: [1x1 struct]
           NumObservations: 93
            BoxConstraints: [93x1 double]
           ConvergenceInfo: [1x1 struct]
           IsSupportVector: [93x1 logical]
                   Solver: 'SMO'

  Properties, Methods
```

`Mdl` is a trained `RegressionSVM` model.

Check the model for convergence.

```
Mdl.ConvergenceInfo.Converged
```

```
ans = logical
   0
```

`0` indicates that the model did not converge.

Retrain the model using standardized data.

```
MdlStd = fitrsvm(X,Y,'Standardize',true)
```

```
MdlStd =
  RegressionSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
                    Alpha: [77x1 double]
                     Bias: 22.9131
          KernelParameters: [1x1 struct]
                       Mu: [109.3441 2.9625e+03]
                    Sigma: [45.3545 805.9668]
           NumObservations: 93
```

```
          BoxConstraints: [93x1 double]
         ConvergenceInfo: [1x1 struct]
         IsSupportVector: [93x1 logical]
                  Solver: 'SMO'

  Properties, Methods
```

Check the model for convergence.

```
MdlStd.ConvergenceInfo.Converged
```

```
ans = logical
   1
```

1 indicates that the model did converge.

Compute the resubstitution (in-sample) mean-squared error for the new model.

```
lStd = resubLoss(MdlStd)
```

```
lStd = 17.0256
```

Train Support Vector Machine Regression Model

Train a support vector machine regression model using the abalone data from the UCI Machine Learning Repository.

Download the data and save it in your current folder with the name `'abalone.csv'`.

```
url = 'https://archive.ics.uci.edu/ml/machine-learning-databases/abalone/abalone.data';
websave('abalone.csv',url);
```

Read the data into a table. Specify the variable names.

```
varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight';...
    'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};
Tbl = readtable('abalone.csv','Filetype','text','ReadVariableNames',false);
Tbl.Properties.VariableNames = varnames;
```

The sample data contains 4177 observations. All the predictor variables are continuous except for `Sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings (stored in `Rings`) on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
rng default  % For reproducibility
Mdl = fitrsvm(Tbl,'Rings','KernelFunction','gaussian','KernelScale','auto',...
    'Standardize',true)
```

```
Mdl =
```

```
  RegressionSVM
           PredictorNames: {1×8 cell}
             ResponseName: 'Rings'
    CategoricalPredictors: 1
        ResponseTransform: 'none'
                    Alpha: [3635×1 double]
                     Bias: 10.8144
          KernelParameters: [1×1 struct]
                       Mu: [1×10 double]
                    Sigma: [1×10 double]
           NumObservations: 4177
            BoxConstraints: [4177×1 double]
           ConvergenceInfo: [1×1 struct]
           IsSupportVector: [4177×1 logical]
                    Solver: 'SMO'
```

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and displays a property list.

Display the properties of `Mdl` using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

```
conv = Mdl.ConvergenceInfo.Converged
iter = Mdl.NumIterations
```

```
conv =

  logical

   1

iter =

        2759
```

The returned results indicate that the model converged after 2759 iterations.

Cross-Validate SVM Regression Model

Load the `carsmall` data set.

```
load carsmall
rng 'default'  % For reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Horsepower Weight];
Y = MPG;
```

Cross-validate two SVM regression models using 5-fold cross-validation. For both models, specify to standardize the predictors. For one of the models, specify to train using the default linear kernel, and the Gaussian kernel for the other model.

```
MdlLin = fitrsvm(X,Y,'Standardize',true,'KFold',5)
```

```
MdlLin =
  RegressionPartitionedSVM
    CrossValidatedModel: 'SVM'
         PredictorNames: {'x1'  'x2'}
           ResponseName: 'Y'
        NumObservations: 94
                  KFold: 5
              Partition: [1x1 cvpartition]
      ResponseTransform: 'none'

  Properties, Methods
```

```
MdlGau = fitrsvm(X,Y,'Standardize',true,'KFold',5,'KernelFunction','gaussian')
```

```
MdlGau =
  RegressionPartitionedSVM
    CrossValidatedModel: 'SVM'
         PredictorNames: {'x1'  'x2'}
           ResponseName: 'Y'
        NumObservations: 94
                  KFold: 5
              Partition: [1x1 cvpartition]
      ResponseTransform: 'none'

  Properties, Methods
```

```
MdlLin.Trained
```

```
ans=5×1 cell array
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
```

`MdlLin` and `MdlGau` are `RegressionPartitionedSVM` cross-validated models. The `Trained` property of each model is a 5-by-1 cell array of `CompactRegressionSVM` models. The models in the cell store the results of training on 4 folds of observations, and leaving one fold of observations out.

Compare the generalization error of the models. In this case, the generalization error is the out-of-sample mean-squared error.

```
mseLin = kfoldLoss(MdlLin)
```

```
mseLin = 17.4417
```

```
mseGau = kfoldLoss(MdlGau)
```

```
mseGau = 16.7333
```

The SVM regression model using the Gaussian kernel performs better than the one using the linear kernel.

Create a model suitable for making predictions by passing the entire data set to `fitrsvm`, and specify all name-value pair arguments that yielded the better-performing model. However, do not specify any cross-validation options.

```
MdlGau = fitrsvm(X,Y,'Standardize',true,'KernelFunction','gaussian');
```

To predict the MPG of a set of cars, pass `Mdl` and a table containing the horsepower and weight measurements of the cars to `predict`.

Optimize SVM Regression

This example shows how to optimize hyperparameters automatically using `fitrsvm`. The example uses the `carsmall` data.

Load the `carsmall` data set.

```
load carsmall
```

Specify `Horsepower` and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Horsepower Weight];
Y = MPG;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
rng default
Mdl = fitrsvm(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

```

  Properties, Methods
```

The optimization searched over `BoxConstraint`, `KernelScale`, and `Epsilon`. The output is the regression with the minimum estimated cross-validation loss.

Input Arguments

`Tbl` — Predictor data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

If a row of `Tbl` or an element of `Y` contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the names of the predictors in the order of their appearance in `Tbl`, use the `PredictorNames` name-value pair argument.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Response data
numeric vector

Response data, specified as an *n*-by-1 numeric vector. The length of `Y` and the number of rows of `Tbl` or `X` must be equal.

If a row of `Tbl` or `X`, or an element of `Y`, contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the response variable name, use the `ResponseName` name-value pair argument.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data to which the SVM regression model is fit, specified as an *n*-by-*p* numeric matrix. *n* is the number of observations and *p* is the number of predictor variables.

The length of `Y` and the number of rows of `X` must be equal.

If a row of `X` or an element of `Y` contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'KernelFunction','gaussian','Standardize',true,'CrossVal','on'` trains a 10-fold cross-validated SVM regression model using a Gaussian kernel and standardized training data.

Support Vector Machine Options

BoxConstraint — Box constraint

positive scalar value

Box constraint for the alpha coefficients, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar value.

The absolute value of the `Alpha` coefficients cannot exceed the value of `BoxConstraint`.

The default `BoxConstraint` value for the `'gaussian'` or `'rbf'` kernel function is `iqr(Y)/1.349`, where `iqr(Y)` is the interquartile range of response variable `Y`. For all other kernels, the default `BoxConstraint` value is 1.

Example: `BoxConstraint,10`

Data Types: `single` | `double`

KernelFunction — Kernel function

`'linear'` (default) | `'gaussian'` | `'rbf'` | `'polynomial'` | function name

Kernel function used to compute the Gram matrix on page 33-1862, specified as the comma-separated pair consisting of `'KernelFunction'` and a value in this table.

Value	Description	Formula
`'gaussian'` or `'rbf'`	Gaussian or Radial Basis Function (RBF) kernel	$G(x_j, x_k) = \exp\left(-\|x_j - x_k\|^2\right)$
`'linear'`	Linear kernel	$G(x_j, x_k) = x_j' x_k$
`'polynomial'`	Polynomial kernel. Use `'PolynomialOrder',q` to specify a polynomial kernel of order q.	$G(x_j, x_k) = (1 + x_j' x_k)^q$

You can set your own kernel function, for example, `kernel`, by setting `'KernelFunction','kernel'`. `kernel` must have the following form:

```
function G = kernel(U,V)
```

where:

- `U` is an m-by-p matrix.
- `V` is an n-by-p matrix.
- `G` is an m-by-n Gram matrix of the rows of `U` and `V`.

And `kernel.m` must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function `'mysigmoid'` rather than `'sigmoid'`.

Example: `'KernelFunction','gaussian'`

Data Types: `char` | `string`

`KernelScale` — Kernel scale parameter

1 (default) | `'auto'` | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar. The software divides all elements of the predictor matrix `X` by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify `'auto'`, then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using `rng` before training.
- If you specify `KernelScale` and your own kernel function, for example, `'KernelFunction','kernel'`, then the software throws an error. You must apply scaling within `kernel`.

Example: `'KernelScale','auto'`

Data Types: `double` | `single` | `char` | `string`

`PolynomialOrder` — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer.

If you set 'PolynomialOrder' and KernelFunction is not 'polynomial', then the software throws an error.

Example: 'PolynomialOrder',2

Data Types: double | single

KernelOffset — Kernel offset parameter
nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds KernelOffset to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (that is, you set 'Solver','SMO')
- 0.1 if the solver is ISDA (that is, you set 'Solver','ISDA')

Example: 'KernelOffset',0

Data Types: double | single

Epsilon — Half the width of epsilon-insensitive band
iqr(Y)/13.49 (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and a nonnegative scalar value.

The default Epsilon value is iqr(Y)/13.49, which is an estimate of a tenth of the standard deviation using the interquartile range of the response variable Y. If iqr(Y) is equal to zero, then the default Epsilon value is 0.1.

Example: 'Epsilon',0.3

Data Types: single | double

Standardize — Flag to standardize predictor data
false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize',true:

- The software centers and scales each column of the predictor data (X) by the weighted column mean and standard deviation, respectively (for details on weighted standardizing, see “Algorithms” on page 33-1865). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the model using the standardized predictor matrix, but stores the unstandardized data in the model property X.

Example: 'Standardize',true

Data Types: logical

`Solver` — Optimization routine

`'ISDA'` | `'L1QP'` | `'SMO'`

Optimization routine, specified as the comma-separated pair consisting of `'Solver'` and a value in this table.

Value	Description
`'ISDA'`	Iterative Single Data Algorithm (see [30])
`'L1QP'`	Uses `quadprog` to implement $L1$ soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
`'SMO'`	Sequential Minimal Optimization (see [17])

The defaults are:

- `'ISDA'` if you set `'OutlierFraction'` to a positive value
- `'SMO'` otherwise

Example: `'Solver','ISDA'`

`Alpha` — Initial estimates of alpha coefficients

numeric vector

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of `'Alpha'` and a numeric vector. The length of `Alpha` must be equal to the number of rows of `X`.

- Each element of `Alpha` corresponds to an observation in `X`.
- `Alpha` cannot contain any `NaN`s.
- If you specify `Alpha` and any one of the cross-validation name-value pair arguments (`'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`), then the software returns an error.

If `Y` contains any missing values, then remove all rows of `Y`, `X`, and `Alpha` that correspond to the missing values. That is, enter:

```
idx = ~isnan(Y);
Y = Y(idx);
X = X(idx,:);
alpha = alpha(idx);
```

Then, pass `Y`, `X`, and `alpha` as the response, predictors, and initial alpha estimates, respectively.

The default is `zeros(size(Y,1))`.

Example: `'Alpha',0.1*ones(size(X,1),1)`

Data Types: `single` | `double`

`CacheSize` — Cache size

`1000` (default) | `'maximal'` | positive scalar

Cache size, specified as the comma-separated pair consisting of `'CacheSize'` and `'maximal'` or a positive scalar.

If `CacheSize` is `'maximal'`, then the software reserves enough memory to hold the entire *n*-by-*n* Gram matrix on page 33-1862.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of memory for training the model.

Example: `'CacheSize','maximal'`

Data Types: `double` | `single` | `char` | `string`

`ClipAlphas` — Flag to clip alpha coefficients
`true` (default) | `false`

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of `'ClipAlphas'` and either `true` or `false`.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is C_j, $j = 1,...,n$, where n is the training sample size.

Value	Description
`true`	At each iteration, if α_j is near 0 or near C_j, then MATLAB sets α_j to 0 or to C_j, respectively.
`false`	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the `Alpha` property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: `'ClipAlphas',false`

Data Types: `logical`

`NumPrint` — Number of iterations between optimization diagnostic message output
`1000` (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you specify `'Verbose',1` and `'NumPrint',numprint`, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: `'NumPrint',500`

Data Types: `double` | `single`

`OutlierFraction` — Expected proportion of outliers in training data
0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in training data, specified as the comma-separated pair consisting of `'OutlierFraction'` and a numeric scalar in the interval [0,1). `fitrsvm` removes observations with large gradients, ensuring that `fitrsvm` removes the fraction of observations specified by `OutlierFraction` by the time convergence is reached. This name-value pair is only valid when `'Solver'` is `'ISDA'`.

Example: `'OutlierFraction',0.1`

Data Types: `single` | `double`

`RemoveDuplicates` — Flag to replace duplicate observations with single observations
`false` (default) | `true`

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of `'RemoveDuplicates'` and `true` or `false`.

If `RemoveDuplicates` is `true`, then `fitrsvm` replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see `Weights`).

Tip If your data set contains many duplicate observations, then specifying `'RemoveDuplicates',true` can decrease convergence time considerably.

Data Types: `logical`

`Verbose` — Verbosity level
`0` (default) | `1` | `2`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0`, `1`, or `2`. The value of `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software does not display or save convergence information.
`1`	The software displays diagnostic messages and saves convergence criteria every `numprint` iterations, where `numprint` is the value of the name-value pair argument `'NumPrint'`.
`2`	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: `'Verbose',1`

Data Types: `double` | `single`

Other Regression Options

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitrsvm` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrsvm` assumes that a variable is categorical if it is a logical vector, categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitrsvm` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

For the identified categorical predictors, `fitrsvm` creates dummy variables using two different schemes, depending on whether a categorical variable is unordered or ordered. For an unordered categorical variable, `fitrsvm` creates one dummy variable for each level of the categorical variable. For an ordered categorical variable, `fitrsvm` creates one less dummy variable than the number of categories. For details, see “Automatic Creation of Dummy Variables” on page 2-49.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`PredictorNames` — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.

- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitrsvm` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ResponseTransform` — Response transformation
`'none'` (default) | function handle

Response transformation, specified as either `'none'` or a function handle. The default is `'none'`, which means `@(y)y`, or no transformation. For a MATLAB function or a function you define, use its function handle for the response transformation. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as `'ResponseTransform',myfunction`.

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | vector of numeric values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of numeric values. The size of `Weights` must equal the number of rows in `X`. `fitrsvm` normalizes the values of `Weights` to sum to 1.

Data Types: `single` | `double`

Cross-Validation Options

`CrossVal` — Cross-validation flag
`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, you can cross-validate the model later using the `crossval` method.

Example: `'CrossVal','on'`

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software completes these steps:

1. Randomly select and reserve `p*100`% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

1. Randomly partition the data into `k` sets.
2. For each set, reserve the set as validation data, and train the model using the other `k` – 1 sets.
3. Store the `k` compact, trained models in a `k`-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as `'on'` or `'off'`. If you specify `'Leaveout','on'`, then for each of the *n* observations (where *n* is the number of observations, excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

1. Reserve the one observation as validation data, and train the model using the other *n* – 1 observations.
2. Store the *n* compact, trained models in an *n*-by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can specify only one of these four name-value arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Convergence Controls

`DeltaGradientTolerance` — Tolerance for gradient difference

0 (default) | nonnegative scalar

Tolerance for gradient difference between upper and lower violators obtained by SMO or ISDA, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

Example: `'DeltaGradientTolerance',1e-4`

Data Types: `single` | `double`

`GapTolerance` — Feasibility gap tolerance

`1e-3` (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of `'GapTolerance'` and a nonnegative scalar.

If `GapTolerance` is `0`, then `fitrsvm` does not use this parameter to check convergence.

Example: `'GapTolerance',1e-4`

Data Types: `single` | `double`

`IterationLimit` — Maximal number of numerical optimization iterations

`1e6` (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: `'IterationLimit',1e8`

Data Types: `double` | `single`

KKTTolerance — Tolerance for KKT violation
0 | nonnegative scalar value

Tolerance for Karush-Kuhn-Tucker (KKT) violation, specified as the comma-separated pair consisting of `'KKTTolerance'` and a nonnegative scalar value.

This name-value pair applies only if `'Solver'` is `'SMO'` or `'ISDA'`.

If `KKTTolerance` is `0`, then `fitrsvm` does not use this parameter to check convergence.

Example: `'KKTTolerance',1e-4`

Data Types: `single` | `double`

ShrinkagePeriod — Number of iterations between reductions of active set
`0` (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of `'ShrinkagePeriod'` and a nonnegative integer.

If you set `'ShrinkagePeriod',0`, then the software does not shrink the active set.

Example: `'ShrinkagePeriod',1000`

Data Types: `double` | `single`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize
`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'BoxConstraint','KernelScale','Epsilon'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitrsvm` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitrsvm` are:

- `BoxConstraint` — `fitrsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.

- `KernelScale` — `fitrsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `Epsilon` — `fitrsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e2]*iqr(Y)/1.349`.
- `KernelFunction` — `fitrsvm` searches among `'gaussian'`, `'linear'`, and `'polynomial'`.
- `PolynomialOrder` — `fitrsvm` searches among integers in the range `[2,4]`.
- `Standardize` — `fitrsvm` searches among `'true'` and `'false'`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrsvm',[Horsepower,Weight],MPG);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize SVM Regression” on page 33-2344.

Example: `'OptimizeHyperparameters','auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`

Field Name	Values	Default
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`

Field Name	Values	Default
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see "Parallel Bayesian Optimization" on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`Mdl` — Trained SVM regression model

`RegressionSVM` model | `RegressionPartitionedSVM` cross-validated model

Trained SVM regression model, returned as a `RegressionSVM` model or `RegressionPartitionedSVM` cross-validated model.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `RegressionPartitionedSVM` cross-validated model. Otherwise, `Mdl` is a `RegressionSVM` model.

Limitations

`fitrsvm` supports low- through moderate-dimensional data sets. For high-dimensional data set, use `fitrlinear` instead.

Tips

- Unless your data set is large, always try to standardize the predictors (see `Standardize`). Standardization makes predictors insensitive to the scales on which they are measured.
- It is good practice to cross-validate using the `KFold` name-value pair argument. The cross-validation results determine how well the SVM model generalizes.
- Sparsity in support vectors is a desirable property of an SVM model. To decrease the number of support vectors, set the `BoxConstraint` name-value pair argument to a large value. This action also increases the training time.
- For optimal training time, set `CacheSize` as high as the memory limit on your computer allows.
- If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active-set using the name-value pair argument `'ShrinkagePeriod'`. It is good practice to use `'ShrinkagePeriod',1000`.
- Duplicate observations that are far from the regression line do not affect convergence. However, just a few duplicate observations that occur near the regression line can slow down convergence considerably. To speed up convergence, specify `'RemoveDuplicates',true` if:

  - Your data set contains many duplicate observations.
  - You suspect that a few duplicate observations can fall near the regression line.

  However, to maintain the original data set during training, `fitrsvm` must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify `true` for data sets containing few duplicates, then `fitrsvm` consumes close to double the memory of the original data.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- For the mathematical formulation of linear and nonlinear SVM regression problems and the solver algorithms, see “Understanding Support Vector Machine Regression” on page 25-2.
- `NaN`, `<undefined>`, empty character vector (`''`), empty string (`""`), and `<missing>` values indicate missing data values. `fitrsvm` removes entire rows of data corresponding to a missing response. When normalizing weights, `fitrsvm` ignores any weight corresponding to an observation with at least one missing predictor. Consequently, observation box constraints might not equal `BoxConstraint`.
- `fitrsvm` removes observations that have zero weight.
- If you set `'Standardize',true` and `'Weights'`, then `fitrsvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `fitrsvm` standardizes predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

- $\mu_j^* = \frac{1}{\sum_k w_k} \sum_k w_k x_{jk}$.
- x_{jk} is observation k (row) of predictor j (column).
- $\left(\sigma_j^*\right)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k \left(x_{jk} - \mu_j^*\right)^2$.
- $v_1 = \sum_j w_j$.
- $v_2 = \sum_j \left(w_j\right)^2$.

- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.
  - The `PredictorNames` property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `PredictorNames` is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.
  - The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.
  - Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.
  - The `SupportVectors` property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then `SupportVectors` is an m-by-5 matrix.
  - The `X` property stores the training data as originally input. It does not include the dummy variables. When the input is a table, `X` contains only the columns used as predictors.
- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
  - For a variable having k ordered levels, the software creates k – 1 dummy variables. The jth dummy variable is -1 for levels up to j, and +1 for levels j + 1 through k.
  - The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value +1. The software stores k – 1 additional predictor names for the dummy variables, including the names of levels 2, 3, ..., k.
- All solvers implement $L1$ soft-margin minimization.
- Let `p` be the proportion of outliers that you expect in the training data. If you set `'OutlierFraction',p`, then the software implements robust learning. In other words, the software attempts to remove 100`p`% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Understanding Support Vector Machine Regression” on page 25-2

Introduced in R2015b

fitrtree

Fit binary decision tree for regression

Syntax

```
tree = fitrtree(Tbl,ResponseVarName)
tree = fitrtree(Tbl,formula)
tree = fitrtree(Tbl,Y)

tree = fitrtree(X,Y)

tree = fitrtree(___,Name,Value)
```

Description

`tree = fitrtree(Tbl,ResponseVarName)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and the output (response) contained in `Tbl.ResponseVarName`. The returned `tree` is a binary tree where each branching node is split based on the values of a column of `Tbl`.

`tree = fitrtree(Tbl,formula)` returns a regression tree based on the input variables contained in the table `Tbl`. The input `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `tree`.

`tree = fitrtree(Tbl,Y)` returns a regression tree based on the input variables contained in the table `Tbl` and the output in vector `Y`.

`tree = fitrtree(X,Y)` returns a regression tree based on the input variables `X` and the output `Y`. The returned `tree` is a binary tree where each branching node is split based on the values of a column of `X`.

`tree = fitrtree(___,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify observation weights or train a cross-validated model.

Examples

Construct Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree using the sample data. The response variable is miles per gallon, MPG.

```
tree = fitrtree([Weight, Cylinders],MPG,...
                'CategoricalPredictors',2,'MinParentSize',20,...
                'PredictorNames',{'W','C'})
```

```
tree =
  RegressionTree
```

```
          PredictorNames: {'W'  'C'}
            ResponseName: 'Y'
    CategoricalPredictors: 2
        ResponseTransform: 'none'
          NumObservations: 94

  Properties, Methods
```

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
MPG4Kpred = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
MPG4Kpred = 3×1

   19.2778
   19.2778
   14.3889
```

Control Regression Tree Depth

`fitrtree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time. To control the depth of trees, use the `'MaxNumSplits'`, `'MinLeafSize'`, or `'MinParentSize'` name-value pair arguments.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

The default values of the tree-depth controllers for growing regression trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

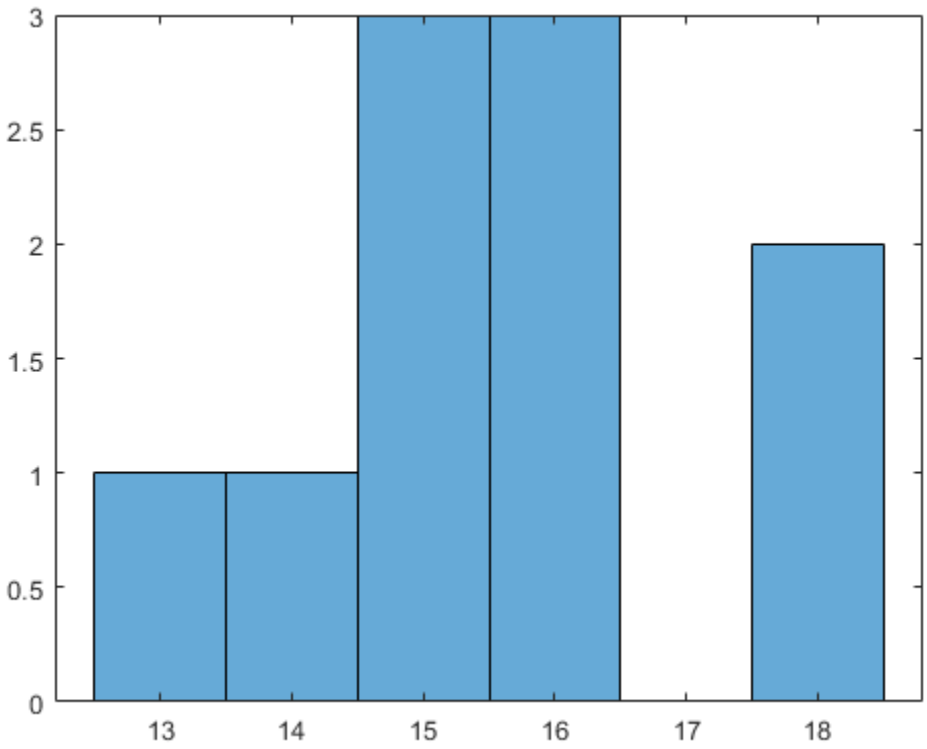
Train a regression tree using the default values for tree-depth control. Cross-validate the model using 10-fold cross-validation.

```
rng(1); % For reproducibility
MdlDefault = fitrtree(X,MPG,'CrossVal','on');
```

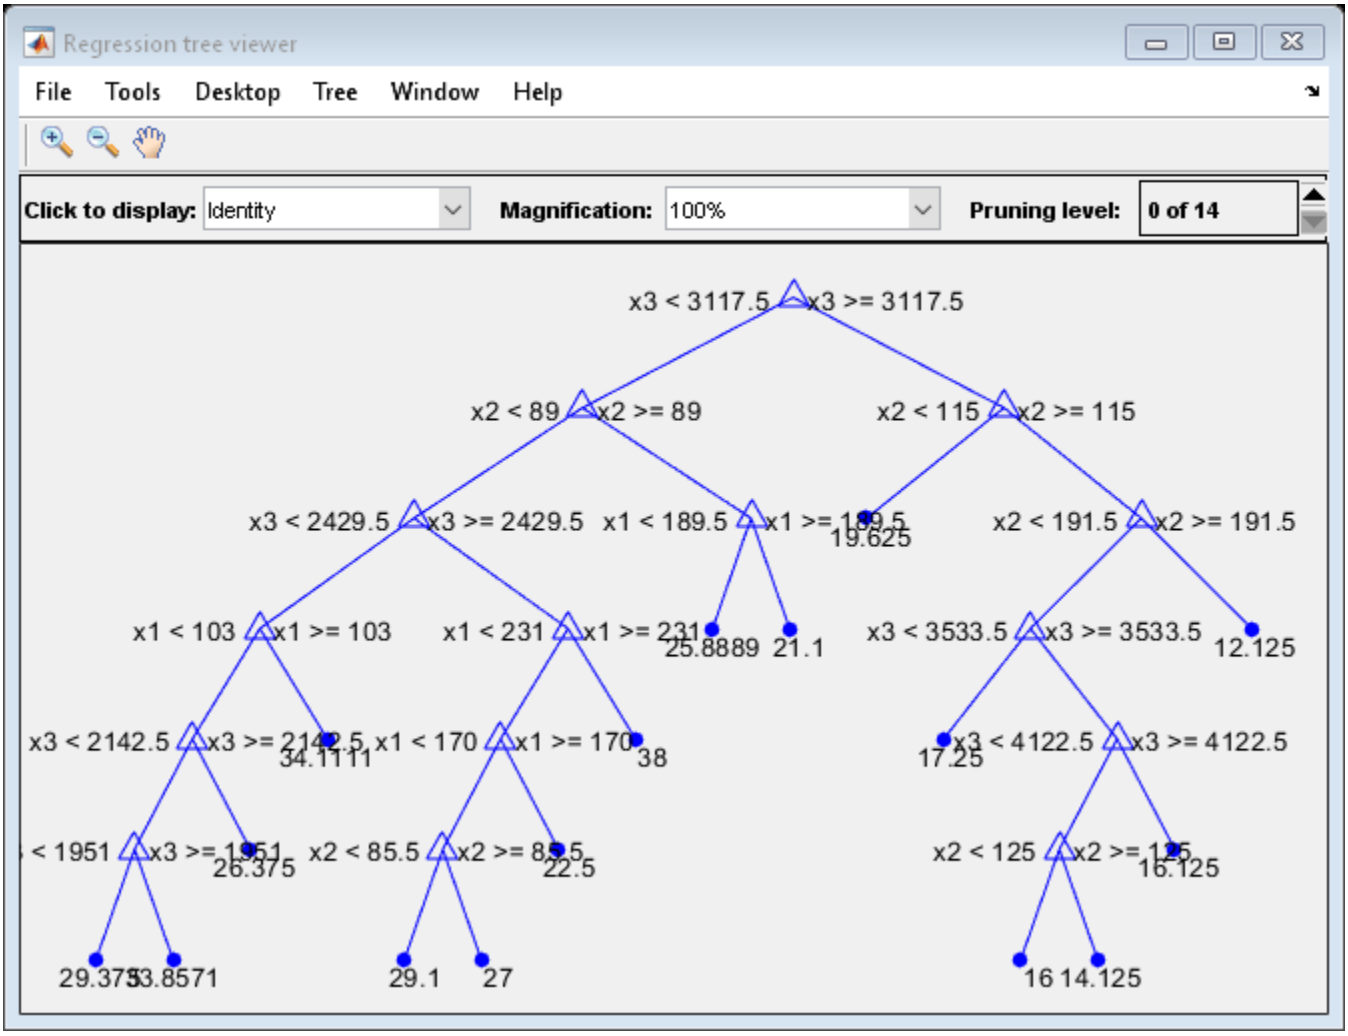
Draw a histogram of the number of imposed splits on the trees. The number of imposed splits is one less than the number of leaves. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
```



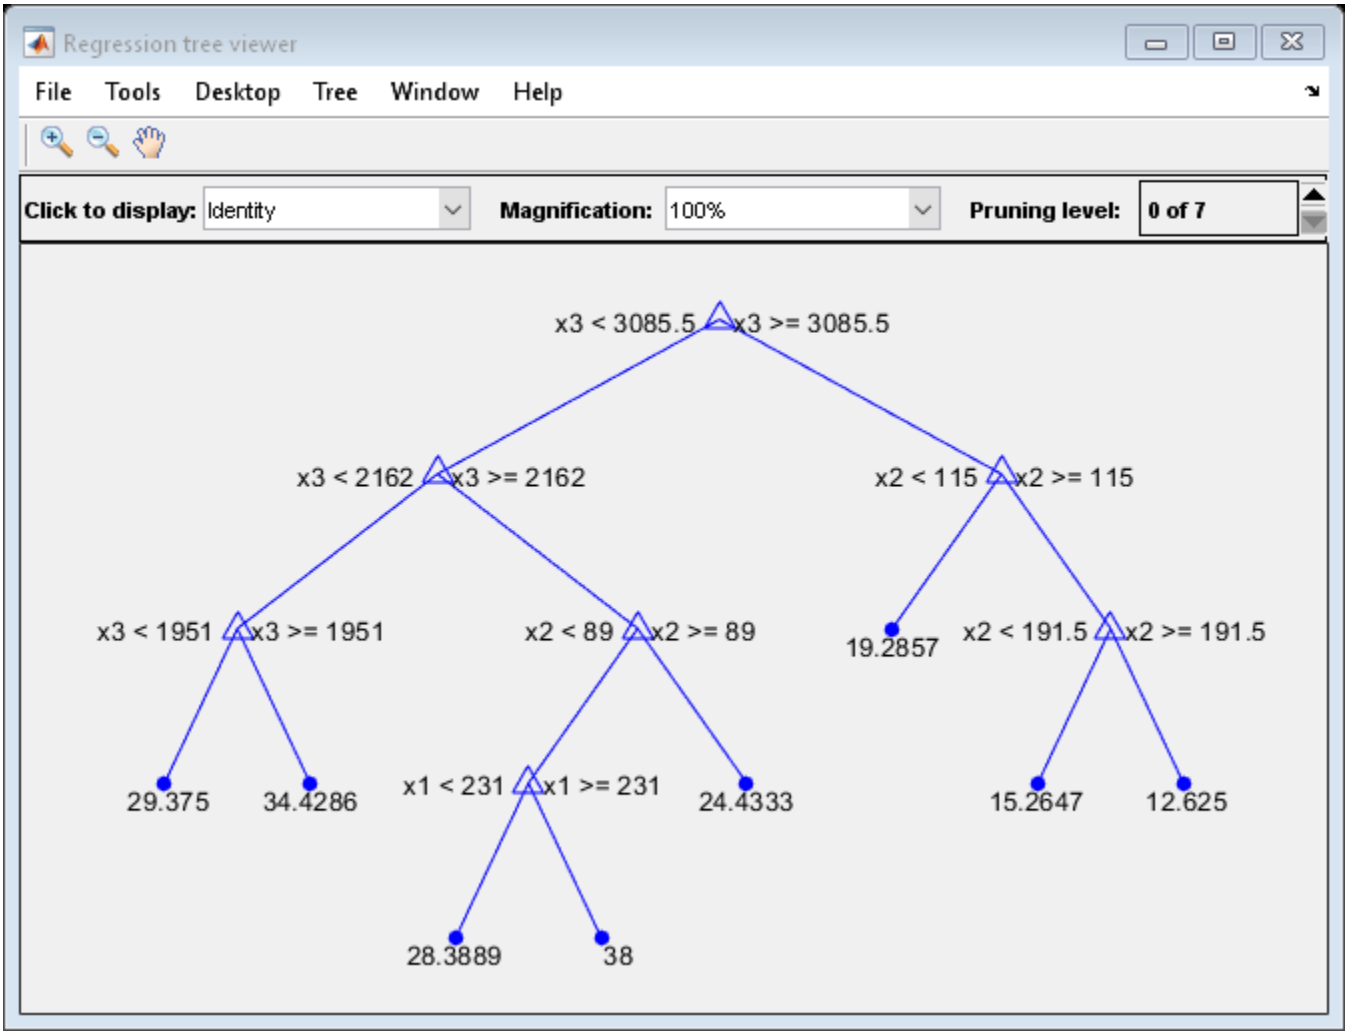
```
view(MdlDefault.Trained{1},'Mode','graph')
```



The average number of splits is between 14 and 15.

Suppose that you want a regression tree that is not as complex (deep) as the ones trained using the default number of splits. Train another regression tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default regression tree. Cross-validate the model using 10-fold cross-validation.

```
Mdl7 = fitrtree(X,MPG,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```



Compare the cross-validation mean squared errors (MSEs) of the models.

```
mseDefault = kfoldLoss(MdlDefault)
```

```
mseDefault = 25.7383
```

```
mse7 = kfoldLoss(Mdl7)
```

```
mse7 = 26.5748
```

`Mdl7` is much less complex and performs only slightly worse than `MdlDefault`.

Optimize Regression Tree

Optimize hyperparameters automatically using `fitrtree`.

Load the `carsmall` data set.

```
load carsmall
```

Use `Weight` and `Horsepower` as predictors for `MPG`. Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
X = [Weight,Horsepower];
Y = MPG;
rng default
Mdl = fitrtree(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

```

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```
numMfg = 28
```

```
numModelYear = numel(categories(Model_Year))
```

```
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

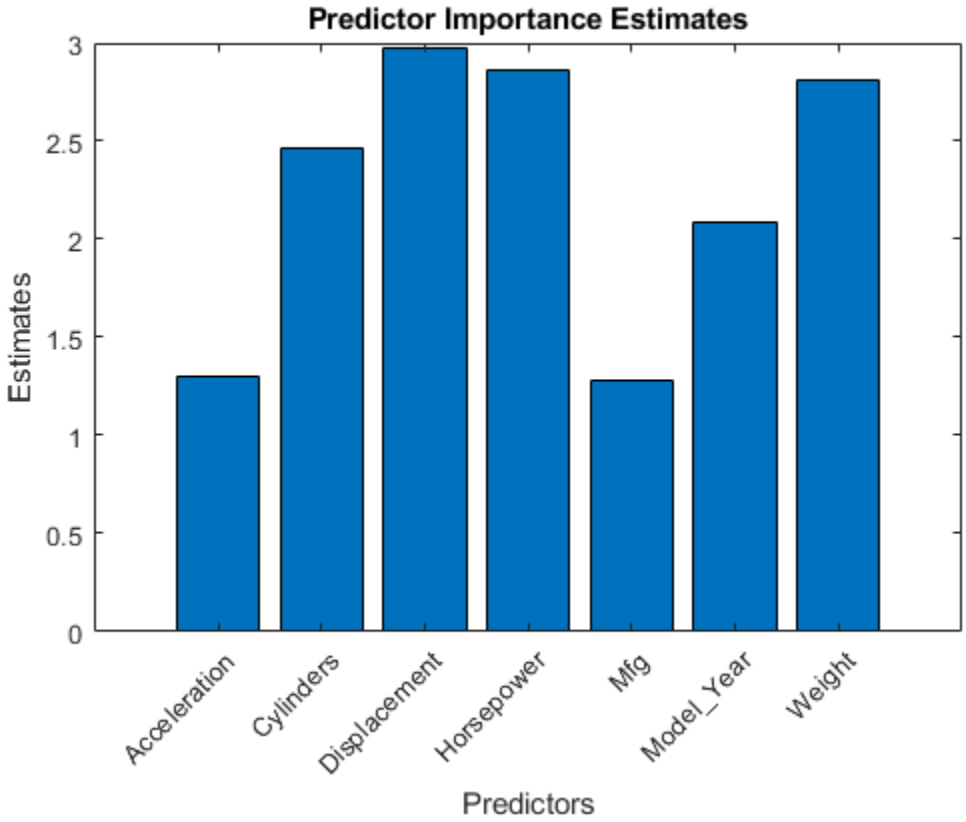
Train a regression tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.

```
Mdl = fitrtree(X,'MPG','PredictorSelection','curvature','Surrogate','on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```



In this case, `Displacement` is the most important predictor, followed by `Horsepower`.

Control Maximum Tree Depth on Tall Array

`fitrtree` grows deep decision trees by default. Build a shallower tree that requires fewer passes through a tall array. Use the `'MaxDepth'` name-value pair argument to control the maximum tree depth.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Convert the in-memory arrays `X` and `MPG` to tall arrays.

```
tx = tall(X);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
ty = tall(MPG);
```

Grow a regression tree using all observations. Allow the tree to grow to the maximum possible depth.

For reproducibility, set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs”.

```
rng('default')
tallrng('default')
Mdl = fitrtree(tx,ty);
```

- Pass 7 of 7: Completed in 1.6 sec
Evaluation completed in 7 sec
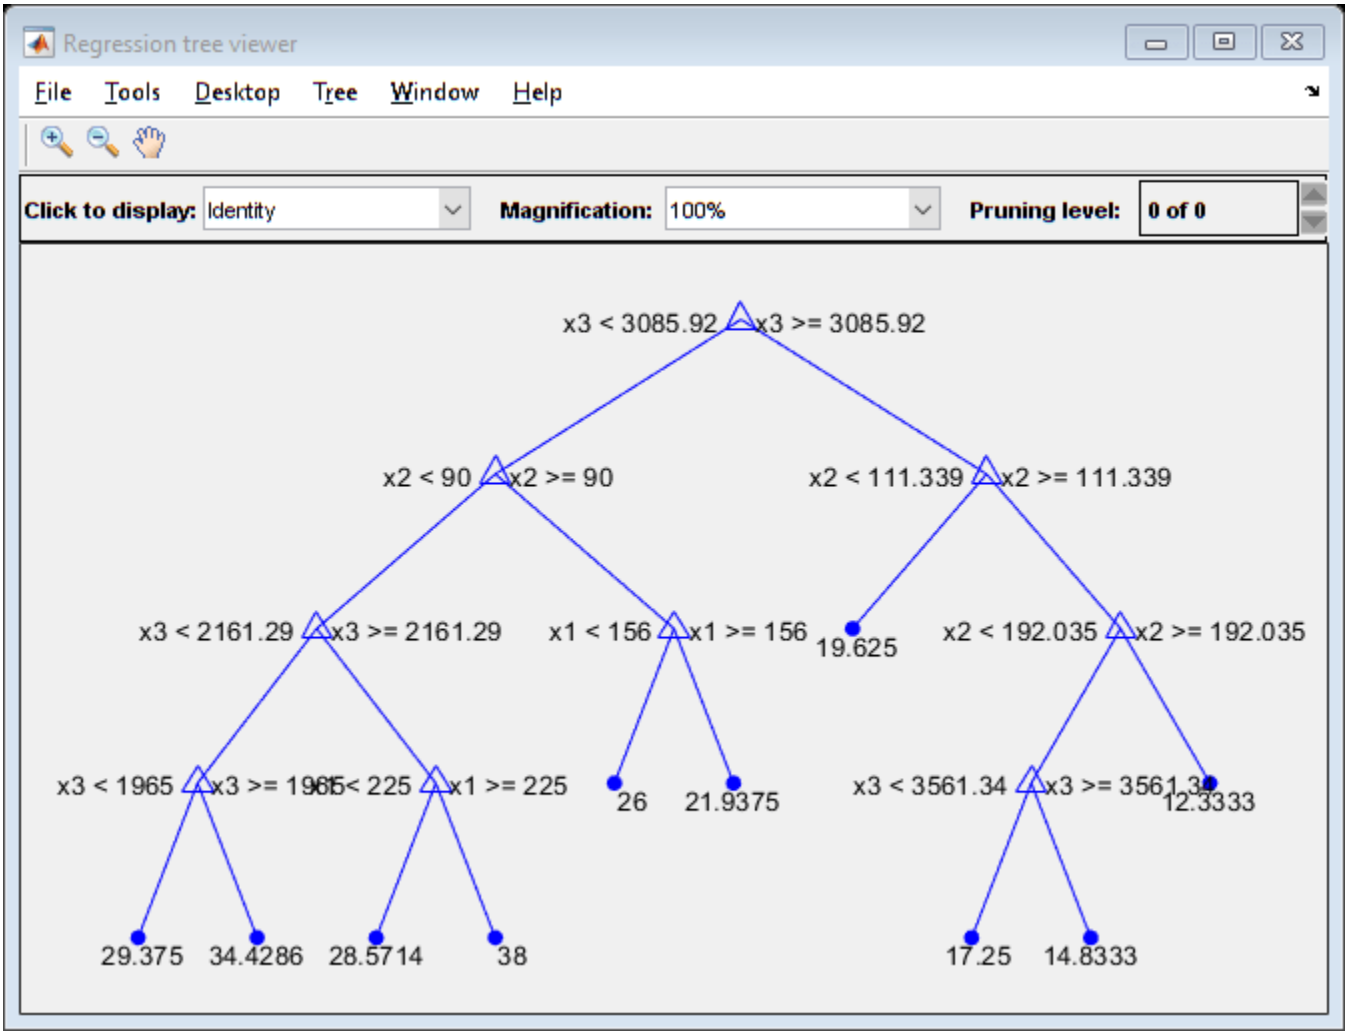
```

View the trained tree `Mdl2`.

```
view(Mdl2,'Mode','graph')
```



Estimate the in-sample mean squared error.

```
MSE_Mdl2 = gather(loss(Mdl2,tx,ty))
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 0.73 sec
Evaluation completed in 1 sec

MSE_Mdl2 = 9.3903
```

`Mdl2` is a less complex tree with a depth of 4 and an in-sample mean squared error that is higher than the mean squared error of `Mdl`.

Optimize Regression Tree on Tall Array

Optimize hyperparameters of a regression tree automatically using a tall array. The sample data set is the `carsmall` data set. This example converts the data set to a tall array and uses it to run the optimization procedure.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. If you want to run the example using the local MATLAB session when you have Parallel Computing Toolbox, you can change the global execution environment by using the `mapreducer` function.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Convert the in-memory arrays `X` and `MPG` to tall arrays.

```
tx = tall(X);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
ty = tall(MPG);
```

Optimize hyperparameters automatically using the `'OptimizeHyperparameters'` name-value pair argument. Find the optimal `'MinLeafSize'` value that minimizes holdout cross-validation loss. (Specifying `'auto'` uses `'MinLeafSize'`.) For reproducibility, use the `'expected-improvement-plus'` acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs”.

```
rng('default')
tallrng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrtree(tx,ty,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('Holdout',0.3,...
    'AcquisitionFunctionName','expected-improvement-plus'))
```

Input Arguments

`Tbl` — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

`ResponseVarName` — Response variable name
name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~x1+x2+x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Response data
numeric column vector

Response data, specified as a numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

The software considers `NaN` values in `Y` to be missing values. `fitrtree` does not use observations with missing values for `Y` in the fit.

Data Types: `single` | `double`

`X` — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each column of `X` represents one variable, and each row represents one observation.

`fitrtree` considers `NaN` values in `X` as missing values. `fitrtree` does not use observations with all missing values for `X` in the fit. `fitrtree` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'CrossVal','on','MinParentSize',30` specifies a cross-validated regression tree with a minimum of 30 observations per branch node.

Model Parameters

`CategoricalPredictors` — Categorical predictors list
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fitrtree` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in `PredictorNames`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in `PredictorNames`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrtree` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fitrtree` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`MaxDepth` — Maximum tree depth
positive integer

Maximum tree depth, specified as the comma-separated pair consisting of `'MaxDepth'` and a positive integer. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of `fitrtree` takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

Note This option applies only when you use `fitrtree` on tall arrays. See Tall Arrays on page 33-2416 for more information.

`MergeLeaves` — Leaf merge flag
`'on'` (default) | `'off'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and `'on'` or `'off'`.

If `MergeLeaves` is `'on'`, then `fitrtree`:

- Merges leaves that originate from the same parent node and yield a sum of risk values greater than or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the regression tree

Otherwise, `fitrtree` does not merge leaves.

Example: `'MergeLeaves','off'`

`MinParentSize` — Minimum number of branch node observations
`10` (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParentSize'` and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitrtree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

Example: `'MinParentSize',8`

Data Types: `single` | `double`

`NumBins` — Number of bins for numeric predictors
`[]`(empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

- If the `'NumBins'` value is empty (default), then `fitrtree` does not bin any predictors.
- If you specify the `'NumBins'` value as a positive integer scalar (`numBins`), then `fitrtree` bins every numeric predictor into at most `numBins` equiprobable bins, and then grows trees on the bin indices instead of the original data.

- The number of bins can be less than `numBins` if a predictor has fewer than `numBins` unique values.
- `fitrtree` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but might cause a potential decrease in accuracy. You can try `'NumBins',50` first, and then change the value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single` | `double`

`PredictorNames` — Predictor variable names
string array of unique names | cell array of unique character vectors

Predictor variable names, specified as a string array of unique names or cell array of unique character vectors. The functionality of `PredictorNames` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `PredictorNames` to assign names to the predictor variables in `X`.
  - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
  - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `PredictorNames` to choose which predictor variables to use in training. That is, `fitrtree` uses only the predictor variables in `PredictorNames` and the response variable during training.
  - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
  - By default, `PredictorNames` contains the names of all predictor variables.
  - A good practice is to specify the predictors for training using either `'PredictorNames'` or `formula`, but not both.

Example: `'PredictorNames',`
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

`PredictorSelection` — Algorithm used to select the best split predictor
`'allsplits'` (default) | `'curvature'` | `'interaction-curvature'`

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of `'PredictorSelection'` and a value in this table.

Value	Description
`'allsplits'`	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].

Value	Description
`'curvature'`	Curvature test on page 33-2411 — Selects the split predictor that minimizes the *p*-value of chi-square tests of independence between each predictor and the response [2]. Training speed is similar to standard CART.
`'interaction-curvature'`	Interaction test on page 33-2412 — Chooses the split predictor that minimizes the *p*-value of chi-square tests of independence between each predictor and the response (that is, conducts curvature tests), and that minimizes the *p*-value of a chi-square test of independence between each pair of predictors and response [2]. Training speed can be slower than standard CART.

For `'curvature'` and `'interaction-curvature'`, if all tests yield *p*-values greater than 0.05, then `fitrtree` stops splitting nodes.

Tip

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. Consider specifying the curvature or interaction test if any of the following are true:
  - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
  - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `predictorImportance` and “Introduction to Feature Selection” on page 15-49.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test .
- Prediction speed is unaffected by the value of `'PredictorSelection'`.

For details on how `fitrtree` selects split predictors, see “Node Splitting Rules” on page 33-2413 and “Choose Split Predictor Selection Technique” on page 19-14.

Example: `'PredictorSelection','curvature'`

`Prune` — Flag to estimate optimal sequence of pruned subtrees
`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then `fitrtree` grows the regression tree and estimates the optimal sequence of pruned subtrees, but does not prune the regression tree. Otherwise, `fitrtree` grows the regression tree without estimating the optimal sequence of pruned subtrees.

To prune a trained regression tree, pass the regression tree to `prune`.

Example: `'Prune','off'`

`PruneCriterion` — Pruning criterion
`'mse'` (default)

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and `'mse'`.

`QuadraticErrorTolerance` — Quadratic error tolerance
`1e-6` (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of `'QuadraticErrorTolerance'` and a positive scalar value. The function stops splitting nodes when the weighted mean squared error per node drops below `QuadraticErrorTolerance*ε`, where `ε` is the weighted mean squared error of all n responses computed before growing the decision tree.

$$\varepsilon = \sum_{i=1}^{n} w_i (y_i - \bar{y})^2 .$$

w_i is the weight of observation i, given that the weights of all the observations sum to one ($\sum_{i=1}^{n} w_i = 1$), and

$$\bar{y} = \sum_{i=1}^{n} w_i y_i$$

is the weighted average of all the responses.

For more details on node splitting, see Node Splitting Rules on page 33-2413.

Example: `'QuadraticErrorTolerance',1e-4`

`Reproducible` — Flag to enforce reproducibility
`false` (logical `0`) (default) | `true` (logical `1`)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of `'Reproducible'` and either `false` or `true`.

If `'NumVariablesToSample'` is not `'all'`, then the software selects predictors at random for each split. To reproduce the random selections, you must specify `'Reproducible',true` and set the seed of the random number generator by using `rng`. Note that setting `'Reproducible'` to `true` can slow down training.

Example: `'Reproducible',true`

Data Types: `logical`

`ResponseName` — Response variable name
`'Y'` (default) | character vector | string scalar

Response variable name, specified as a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

`ResponseTransform` — Response transformation
`'none'` (default) | function handle

Response transformation, specified as either `'none'` or a function handle. The default is `'none'`, which means `@(y)y`, or no transformation. For a MATLAB function or a function you define, use its function handle for the response transformation. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as `'ResponseTransform',myfunction`.

Data Types: `char` | `string` | `function_handle`

`SplitCriterion` — Split criterion
`'MSE'` (default)

Split criterion, specified as the comma-separated pair consisting of `'SplitCriterion'` and `'MSE'`, meaning mean squared error.

Example: `'SplitCriterion','MSE'`

`Surrogate` — Surrogate decision splits flag
`'off'` (default) | `'on'` | `'all'` | positive integer

Surrogate decision splits flag, specified as the comma-separated pair consisting of `'Surrogate'` and `'on'`, `'off'`, `'all'`, or a positive integer.

- When `'on'`, `fitrtree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer, `fitrtree` finds at most the specified number of surrogate splits at each branch node.
- When set to `'all'`, `fitrtree` finds all surrogate splits at each branch node. The `'all'` setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: `'Surrogate','on'`

Data Types: `single` | `double` | `char` | `string`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values or the name of a variable in `Tbl`. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

`fitrtree` normalizes the values of `Weights` to sum to 1.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation

`CrossVal` — Cross-validation flag
`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If `'on'`, `fitrtree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments. You can only use one of these four options (`'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`) at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

Example: `'CrossVal','on'`

`CVPartition` — Partition for cross-validation tree
`cvpartition` object

Partition for cross-validated tree, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`.

If you use `'CVPartition'`, you cannot use any of the `'KFold'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

`Holdout` — Fraction of data for holdout validation
`0` (default) | scalar value in the range `[0,1]`

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range `[0,1]`. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use `'Holdout'`, you cannot use any of the `'CVPartition'`, `'KFold'`, or `'Leaveout'` name-value pair arguments.

Example: `'Holdout',0.1`

Data Types: `single` | `double`

`KFold` — Number of folds
`10` (default) | positive integer greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1.

If you use `'KFold'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

Example: `'KFold',8`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and either `'on'` or `'off'`. Use leave-one-out cross-validation by setting to `'on'`.

If you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

Hyperparameters

`MaxNumSplits` — Maximal number of decision splits
`size(X,1) - 1` (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of `'MaxNumSplits'` and a positive integer. `fitrtree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see “Tree Depth Control” on page 33-2415.

Example: `'MaxNumSplits',5`

Data Types: `single` | `double`

`MinLeafSize` — Minimum number of leaf node observations
`1` (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of `'MinLeafSize'` and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitrtree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

Example: `'MinLeafSize',3`

Data Types: `single` | `double`

`NumVariablesToSample` — Number of predictors to select at random for each split
`'all'` (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. Alternatively, you can specify `'all'` to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify `'NumVariablesToSample'` as `'all'`. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

Example: `'NumVariablesToSample',3`

Data Types: `char` | `string` | `single` | `double`

Hyperparameter Optimization

`OptimizeHyperparameters` — Parameters to optimize
`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'MinLeafSize'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitrtree` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitrtree` are:

- `MaxNumSplits` — `fitrtree` searches among integers, by default log-scaled in the range `[1,max(2,NumObservations-1)]`.
- `MinLeafSize` — `fitrtree` searches among integers, by default log-scaled in the range `[1,max(2,floor(NumObservations/2))]`.
- `NumVariablesToSample` — `fitrtree` does not optimize over this hyperparameter. If you pass `NumVariablesToSample` as a parameter name, `fitrtree` simply uses the full number of predictors. However, `fitrensemble` does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrtree',[Horsepower,Weight],MPG);
params(1).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is log(1 + cross-validation loss) for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Regression Tree” on page 33-2369.

Example: `'auto'`

`HyperparameterOptimizationOptions` — Options for optimization
structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
`Optimizer`	• `'bayesopt'` — Use Bayesian optimization. Internally, this setting calls `bayesopt`. • `'gridsearch'` — Use grid search with `NumGridDivisions` values per dimension. • `'randomsearch'` — Search at random among `MaxObjectiveEvaluations` points. `'gridsearch'` searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command `sortrows(Mdl.HyperparameterOptimizationResults)`.	`'bayesopt'`
`AcquisitionFunctionName`	• `'expected-improvement-per-second-plus'` • `'expected-improvement'` • `'expected-improvement-plus'` • `'expected-improvement-per-second'` • `'lower-confidence-bound'` • `'probability-of-improvement'` Acquisition functions whose names include `per-second` do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include `plus` modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-3.	`'expected-improvement-per-second-plus'`
`MaxObjectiveEvaluations`	Maximum number of objective function evaluations.	`30` for `'bayesopt'` or `'randomsearch'`, and the entire grid for `'gridsearch'`
`MaxTime`	Time limit, specified as a positive real. The time limit is in seconds, as measured by `tic` and `toc`. Run time can exceed `MaxTime` because `MaxTime` does not interrupt function evaluations.	`Inf`
`NumGridDivisions`	For `'gridsearch'`, the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	`10`

Field Name	Values	Default
`ShowPlots`	Logical value indicating whether to show plots. If `true`, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if `Optimizer` is `'bayesopt'`, then `ShowPlots` also plots a model of the objective function against the parameters.	`true`
`SaveIntermediateResults`	Logical value indicating whether to save results when `Optimizer` is `'bayesopt'`. If `true`, this field overwrites a workspace variable named `'BayesoptResults'` at each iteration. The variable is a `BayesianOptimization` object.	`false`
`Verbose`	Display to the command line. • `0` — No iterative display • `1` — Iterative display • `2` — Iterative display with extra information For details, see the `bayesopt` `Verbose` name-value pair argument.	`1`
`UseParallel`	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. Due to the nonreproducibility of parallel timing, parallel Bayesian optimization does not necessarily yield reproducible results. For details, see “Parallel Bayesian Optimization” on page 10-7.	`false`
`Repartition`	Logical value indicating whether to repartition the cross-validation at every iteration. If `false`, the optimizer uses a single partition for the optimization. `true` usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, `true` requires at least twice as many function evaluations.	`false`
Use no more than one of the following three field names.		
`CVPartition`	A `cvpartition` object, as created by `cvpartition`.	`'Kfold',5` if you do not specify any cross-validation field
`Holdout`	A scalar in the range `(0,1)` representing the holdout fraction.	
`Kfold`	An integer greater than 1.	

Example: `'HyperparameterOptimizationOptions',struct('MaxObjectiveEvaluations',60)`

Data Types: `struct`

Output Arguments

`tree` — Regression tree

regression tree object

Regression tree, returned as a regression tree object. Using the `'Crossval'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

More About

Curvature Test

The curvature test is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable x and y is conducted using this process.

1. If x is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
2. For each level in the partitioned predictor $j = 1...J$ and class in the response $k = 1,...,K$, compute the weighted proportion of observations in class k

   $$\widehat{\pi}_{jk} = \sum_{i=1}^{n} I\{y_i = k\} w_i .$$

   w_i is the weight of observation i, $\sum w_i = 1$, I is the indicator function, and n is the sample size. If all observations have the same weight, then $\widehat{\pi}_{jk} = \frac{n_{jk}}{n}$, where n_{jk} is the number of observations in level j of the predictor that are in class k.
3. Compute the test statistic

   $$t = n \sum_{k=1}^{K} \sum_{j=1}^{J} \frac{\left(\widehat{\pi}_{jk} - \widehat{\pi}_{j+}\widehat{\pi}_{+k}\right)^2}{\widehat{\pi}_{j+}\widehat{\pi}_{+k}}$$

   $\widehat{\pi}_{j+} = \sum_{k} \widehat{\pi}_{jk}$, that is, the marginal probability of observing the predictor at level j. $\widehat{\pi}_{+k} = \sum_{j} \widehat{\pi}_{jk}$, that is the marginal probability of observing class k. If n is large enough, then t is distributed as a χ^2 with $(K - 1)(J - 1)$ degrees of freedom.
4. If the p-value for the test is less than 0.05, then reject the null hypothesis that there is no association between x and y.

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant *p*-values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

For more details on how the curvature test applies to growing regression trees, see "Node Splitting Rules" on page 33-2413 and [3].

Interaction Test

The interaction test is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables x_1 and x_2 with respect to y is conducted using this process.

1. If x_1 or x_2 is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
2. Create the nominal variable z with $J = J_1J_2$ levels that assigns an index to observation i according to which levels of x_1 and x_2 it belongs. Remove any levels of z that do not correspond to any observations.
3. Conduct a curvature test on page 33-2411 between z and y.

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see "Curvature Test" on page 33-2411, "Node Splitting Rules" on page 33-2413 and [2].

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 33-1928 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k, respectively, and $j \neq k$. At node t, the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - \left(1 - P_{L_jL_k} - P_{R_jR_k}\right)}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t, such that $x_j < u$. The subscript L stands for the left child of node t.
- P_R is the proportion of observations in node t, such that $x_j \geq u$. The subscript R stands for the right child of node t.
- $P_{L_jL_k}$ is the proportion of observations at node t, such that $x_j < u$ and $x_k < v$.

- $P_{R_jR_k}$ is the proportion of observations at node t, such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in (–∞,1]. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 33-2412.

Tip

- By default, `Prune` is `'on'`. However, this specification does not prune the regression tree. To prune a trained regression tree, pass the regression tree to `prune`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

Node Splitting Rules

`fitrtree` uses these processes to determine how to split node t.

- For standard CART (that is, if `PredictorSelection` is `'allpairs'`) and for all predictors x_i, $i = 1,\ldots,p$:

  1. `fitrtree` computes the weighted mean squared error (MSE) of the responses in node t using

     $$\varepsilon_t = \sum_{j \in T} w_j \left(y_j - \bar{y}_t\right)^2 .$$

     w_j is the weight of observation j, and T is the set of all observation indices in node t. If you do not specify `Weights`, then $w_j = 1/n$, where n is the sample size.

  2. `fitrtree` estimates the probability that an observation is in node t using

     $$P(T) = \sum_{j \in T} w_j .$$

  3. `fitrtree` sorts x_i in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. `fitrtree` records any indices corresponding to missing values in the set T_U, which is the unsplit set.
  4. `fitrtree` determines the best way to split node t using x_i by maximizing the reduction in MSE (ΔI) over all splitting candidates. That is, for all splitting candidates in x_i:

a `fitrtree` splits the observations in node t into left and right child nodes (t_L and t_R, respectively).

b `fitrtree` computes ΔI. Suppose that for a particular splitting candidate, t_L and t_R contain observation indices in the sets T_L and T_R, respectively.

- If x_i does not contain any missing values, then the reduction in MSE for the current splitting candidate is

$$\Delta I = P(T)\varepsilon_t - P(T_L)\varepsilon_{t_L} - P(T_R)\varepsilon_{t_R}.$$

- If x_i contains missing values, then, assuming that the observations are missing at random, the reduction in MSE is

$$\Delta I_U = P(T - T_U)\varepsilon_t - P(T_L)\varepsilon_{t_L} - P(T_R)\varepsilon_{t_R}.$$

  $T - T_U$ is the set of all observation indices in node t that are not missing.

- If you use surrogate decision splits on page 33-2413, then:

  i `fitrtree` computes the predictive measures of association on page 33-2412 between the decision split $x_j < u$ and all possible decision splits $x_k < v, j \neq k$.

  ii `fitrtree` sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.

  iii `fitrtree` decides the child node assignments for observations with a missing value for x_i using the surrogate split. If the surrogate predictor also contains a missing value, then `fitrtree` uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for `fitrtree` to split two different observations at node t using two different surrogate splits. For example, suppose the predictors x_1 and x_2 are the best and second best surrogates, respectively, for the predictor x_i, $i \notin \{1,2\}$, at node t. If observation m of predictor x_i is missing (i.e., x_{mi} is missing), but x_{m1} is not missing, then x_1 is the surrogate predictor for observation x_{mi}. If observations $x_{(m+1),i}$ and $x(m+1),1$ are missing, but $x_{(m+1),2}$ is not missing, then x_2 is the surrogate predictor for observation $m+1$.

  iv `fitrtree` uses the appropriate MSE reduction formula. That is, if `fitrtree` fails to assign all missing observations in node t to children nodes using surrogate splits, then the MSE reduction is ΔI_U. Otherwise, `fitrtree` uses ΔI for the MSE reduction.

c `fitrtree` chooses the candidate that yields the largest MSE reduction.

`fitrtree` splits the predictor variable at the cut point that maximizes the MSE reduction.

- For the curvature test (that is, if `PredictorSelection` is `'curvature'`):

1 `fitrtree` computes the residuals $r_{ti} = y_{ti} - \bar{y}_t$ for all observations in node t.

$\bar{y}_t = \frac{1}{\sum_i w_i}\sum_i w_i y_{ti}$, which is the weighted average of the responses in node t. The weights are the observation weights in `Weights`.

2 `fitrtree` assigns observations to one of two bins according to the sign of the corresponding residuals. Let z_t be a nominal variable that contains the bin assignments for the observations in node t.

3. `fitrtree` conducts curvature tests on page 33-2411 between each predictor and z_t. For regression trees, $K = 2$.
   - If all p-values are at least 0.05, then `fitrtree` does not split node t.
   - If there is a minimal p-value, then `fitrtree` chooses the corresponding predictor to split node t.
   - If more than one p-value is zero due to underflow, then `fitrtree` applies standard CART to the corresponding predictors to choose the split predictor.
4. If `fitrtree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

- For the interaction test (that is, if `PredictorSelection` is `'interaction-curvature'`):
  1. For observations in node t, `fitrtree` conducts curvature tests on page 33-2411 between each predictor and the response and interaction tests on page 33-2412 between each pair of predictors and the response.
     - If all p-values are at least 0.05, then `fitrtree` does not split node t.
     - If there is a minimal p-value and it is the result of a curvature test, then `fitrtree` chooses the corresponding predictor to split node t.
     - If there is a minimal p-value and it is the result of an interaction test, then `fitrtree` chooses the split predictor using standard CART on the corresponding pair of predictors.
     - If more than one p-value is zero due to underflow, then `fitrtree` applies standard CART to the corresponding predictors to choose the split predictor.
  2. If `fitrtree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

Tree Depth Control

- If `MergeLeaves` is `'on'` and `PruneCriterion` is `'mse'` (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using MSE. This specification amounts to merging leaves coming from the same parent node whose MSE is at most the sum of the MSE of its two leaves.
- To accommodate `MaxNumSplits`, `fitrtree` splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitrtree` follows this procedure:
  1. Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
  2. Sort the branch nodes by their impurity gains.
  3. Unsplit the number of least successful branches.
  4. Return the decision tree grown so far.

  This procedure produces maximally balanced trees.
- The software splits branch nodes layer by layer until at least one of these events occurs:
  - There are `MaxNumSplits` branch nodes.
  - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
  - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.

- The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
- For values `'curvature'` or `'interaction-curvature'` of `PredictorSelection`, all tests yield *p*-values greater than 0.05.

`MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set `'MaxNumSplits'`, splitting might stop due to the value of `MinParentSize`, before `MaxNumSplits` splits occur.

Parallelization

For dual-core systems and above, `fitrtree` parallelizes training decision trees using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
  - `tree = fitrtree(Tbl,Y)`
  - `tree = fitrtree(X,Y)`
  - `tree = fitrtree(___,Name,Value)`
  - `[tree,FitInfo,HyperparameterOptimizationResults] = fitrtree(___,Name,Value)` — `fitrtree` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the `'OptimizeHyperparameters'` name-value pair argument.

  `tree` is a `CompactRegressionTree` object; therefore, it does not include the data used in training the regression tree.
- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.
- The `HyperparameterOptimizationResults` output argument is a `BayesianOptimization` object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

`'HyperparameterOptimizationResults'` is nonempty when the `'OptimizeHyperparameters'` name-value pair argument is nonempty at the time you create the model. The values in `'HyperparameterOptimizationResults'` depend on the value you specify for the `'HyperparameterOptimizationOptions'` name-value pair argument when you create the model.

- If you specify `'bayesopt'` (default), then `HyperparameterOptimizationResults` is an object of class `BayesianOptimization`.
- If you specify `'gridsearch'` or `'randomsearch'`, then `HyperparameterOptimizationResults` is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).

- Supported name-value pair arguments are:
  - `'CategoricalPredictors'`
  - `'HyperparameterOptimizationOptions'` — For cross-validation, tall optimization supports only `'Holdout'` validation. By default, the software selects and reserves 20% of the data as holdout validation data, and trains the model using the rest of the data. You can specify a different value for the holdout fraction by using this argument. For example, specify `'HyperparameterOptimizationOptions',struct('Holdout',0.3)` to reserve 30% of the data as validation data.
  - `'MaxNumSplits'` — For tall optimization, `fitrtree` searches among integers, log-scaled (by default) in the range `[1,max(2,min(10000,NumObservations−1))]`.
  - `'MergeLeaves'`
  - `'MinLeafSize'` — For tall optimization, `fitrtree` searches among integers, log-scaled (by default) in the range `[1,max(2,floor(NumObservations/2))]`.
  - `'MinParentSize'`
  - `'NumVariablesToSample'` — For tall optimization, `fitrtree` searches among integers in the range `[1,max(2,NumPredictors)]`.
  - `'OptimizeHyperparameters'`
  - `'PredictorNames'`
  - `'QuadraticErrorTolerance'`
  - `'ResponseName'`
  - `'ResponseTransform'`
  - `'SplitCriterion'`
  - `'Weights'`
- This additional name-value pair argument is specific to tall arrays:
  - `'MaxDepth'` — A positive integer specifying the maximum depth of the output tree. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of `fitrtree` takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

For more information, see “Tall Arrays”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptimizationOptions', struct('UseParallel',true)` name-value argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-7.

For general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014a

fitSVMPosterior

Fit posterior probabilities

Syntax

```
ScoreSVMModel = fitSVMPosterior(SVMModel)

ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,ResponseVarName)
ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,Y)

ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)

ScoreSVMModel = fitSVMPosterior(___,Name,Value)

[ScoreSVMModel,ScoreTransform] = fitSVMPosterior(___)
```

Description

`ScoreSVMModel = fitSVMPosterior(SVMModel)` returns `ScoreSVMModel`, which is a trained, support vector machine (SVM) classifier containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`). The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 33-2427.
- If the classes are perfectly separable, the transformation function is the step function on page 33-2427.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 33-2428. `fitSVMPosterior` is not appropriate for one-class learning.
- If `SVMModel` is a `ClassificationSVM` classifier, then the software estimates the optimal transformation function by 10-fold cross validation as outlined in [1]. Otherwise, `SVMModel` must be a `ClassificationPartitionedModel` classifier. `SVMModel` specifies the cross-validation method.
- The software stores the optimal transformation function in `ScoreSVMModel.ScoreTransform`.

`ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,ResponseVarName)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data in the table `TBL` and class labels `TBL.ResponseVarName`.

`ScoreSVMModel = fitSVMPosterior(SVMModel,TBL,Y)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data in the table `TBL` and class labels `Y`.

`ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data `X` and class labels `Y`.

`ScoreSVMModel = fitSVMPosterior(___,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments provided `SVMModel` is a `ClassificationSVM` classifier. For example, you can specify the number of folds to use in *k*-fold cross validation.

`[ScoreSVMModel,ScoreTransform] = fitSVMPosterior(___)` additionally returns the transformation function parameters (`ScoreTransform`) using any of the input arguments in the previous syntaxes.

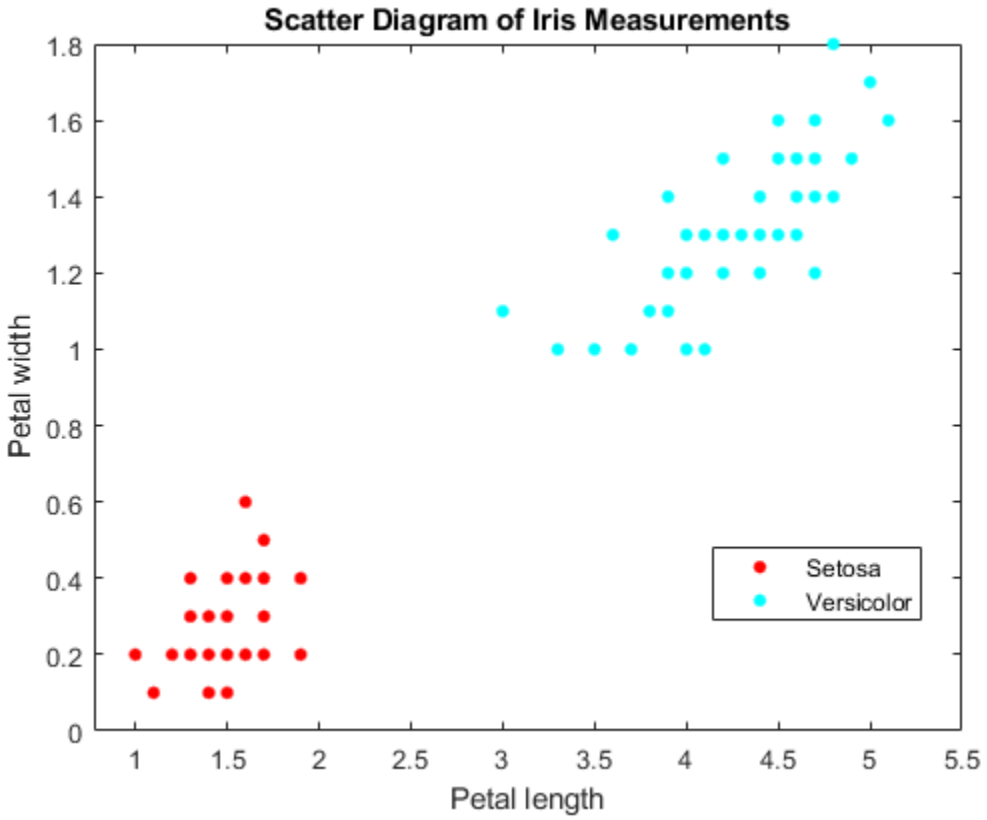
Examples

Fit the Score-to-Posterior Probability Function for Separable Classes

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
y = species(classKeep);

gscatter(X(:,1),X(:,2),y);
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa','Versicolor')
```



The classes are perfectly separable. Therefore, the score transformation function is a step function.

Train an SVM classifier using the data. Cross validate the classifier using 10-fold cross validation (the default).

```
rng(1);
CVSVMModel = fitcsvm(X,y,'CrossVal','on');
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` SVM classifier.

Estimate the step function that transforms scores to posterior probabilities.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step
```

`fitSVMPosterior` does the following:

- Uses the data that the software stored in `CVSVMModel` to fit the transformation function
- Warns whenever the classes are separable
- Stores the step function in `ScoreCSVMModel.ScoreTransform`

Display the score function type and its parameter values.

```
ScoreParameters
```

```
ScoreParameters = struct with fields:
                     Type: 'step'
```

```
                LowerBound: -0.8431
                UpperBound: 0.6897
    PositiveClassProbability: 0.5000
```

`ScoreParameters` is a structure array with four fields:

- The score transformation function type (`Type`)
- The score corresponding to the negative class boundary (`LowerBound`)
- The score corresponding to the positive class boundary (`UpperBound`)
- The positive class probability (`PositiveClassProbability`)

Since the classes are separable, the step function transforms the score to either `0` or `1`, which is the posterior probability that an observation is a versicolor iris.

Fit the Score-to-Posterior Probability Function for Inseparable Classes

Load the `ionosphere` data set.

```
load ionosphere
```

The classes of this data set are not separable.

Train an SVM classifier. Cross validate using 10-fold cross validation (the default). It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true,...
    'CrossVal','on');
ScoreTransform = CVSVMModel.ScoreTransform
```

```
ScoreTransform =
'none'
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` SVM classifier. The positive class is `'g'`. The `ScoreTransform` property is `none`.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as `'g'`.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
ScoreTransform = ScoreCVSVMModel.ScoreTransform
```

```
ScoreTransform =
'@(S)sigmoid(S,-9.481989e-01,-1.218252e-01)'
```

```
ScoreParameters
```

```
ScoreParameters = struct with fields:
         Type: 'sigmoid'
        Slope: -0.9482
    Intercept: -0.1218
```

`ScoreTransform` is the optimal score transform function. `ScoreParameters` contains the score transformation function, slope estimate, and the intercept estimate.

You can estimate test-sample, posterior probabilities by passing `ScoreCVSVMModel` to `kfoldPredict`.

Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as `'g'`.

```
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

`ScoreSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

```
ans=10×2 table
    ObservationIndex    PosteriorProbability

Input Arguments

SVMModel — Trained SVM classifier

`ClassificationSVM` classifier | `CompactClassificationSVM` classifier | `ClassificationPartitionedModel` classifier

Trained SVM classifier, specified as a `ClassificationSVM`, `CompactClassificationSVM`, or `ClassificationPartitionedModel` classifier.

If `SVMModel` is a `ClassificationSVM` classifier, then you can set optional name-value pair arguments.

If `SVMModel` is a `CompactClassificationSVM` classifier, then you must input predictor data `X` and class labels `Y`.

TBL — Sample data

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional columns for the response variable and observation weights. `TBL` must contain all of the predictors used to train `SVMModel`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `SVMModel` using sample data contained in a table, then the input data for `fitSVMPosterior` must also be in a table.

If you set `'Standardize',true` in `fitcsvm` when training `SVMModel`, then the software standardizes the columns of the predictor data using the corresponding means in `SVMModel.Mu` and the standard deviations in `SVMModel.Sigma`.

Data Types: `table`

X — Predictor data

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of `Y` and the number of rows in `X` must be equal.

If you set `'Standardize',true` in `fitcsvm` when training `SVMModel`, then the software fits the transformation function parameter estimates using standardized data.

Data Types: `double` | `single`

`ResponseVarName` — Response variable name
name of variable in `TBL`

Response variable name, specified as the name of a variable in `TBL`. If `TBL` contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify `ResponseVarName` as `'Response'`. Otherwise, the software treats all columns of `TBL`, including `TBL.Response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

`Y` — Class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.

If `Y` is a character array, then each element must correspond to one class label.

The length of `Y` and the number of rows in `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KFold',8` performs 8-fold cross validation when `SVMModel` is a `ClassificationSVM` classifier.

`CVPartition` — Cross-validation partition
`[]` (default) | `cvpartition` partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

The `crossval` name-value pair argument of `fitcsvm` splits the data into subsets using `cvpartition`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

`Holdout` — Fraction of data for holdout validation
scalar value in the range (0,1)

Fraction of the data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

`KFold` — Number of folds
`10` (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'KFold',8`

Data Types: `single` | `double`

`Leaveout` — Leave-one-out cross-validation flag
`'off'` (default) | `'on'`

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross-validation to compute the transformation function, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. Use leave-one-out cross-validation by specifying `'Leaveout','on'`.

You can use only one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Example: `'Leaveout','on'`

Output Arguments

`ScoreSVMModel` — Trained SVM classifier
`ClassificationSVM` classifier | `CompactClassificationSVM` classifier | `ClassificationPartitionedModel` classifier

Trained SVM classifier containing the estimated score transformation function, returned as a `ClassificationSVM`, `CompactClassificationSVM`, or `ClassificationPartitionedModel` classifier.

The `ScoreSVMModel` classifier type is the same as the `SVMModel` classifier type.

To estimate posterior probabilities, pass `ScoreSVMModel` and predictor data to `predict`. If you set `'Standardize',true` in `fitcsvm` to train `SVMModel`, then `predict` standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

`ScoreTransform` — Optimal score-to-posterior-probability transformation function parameters
structure array

Optimal score-to-posterior-probability transformation function parameters, specified as a structure array. If field `Type` is:

- `sigmoid`, then `ScoreTransform` has these fields:
  - `Slope` — The value of A in the sigmoid function on page 33-2427
  - `Intercept` — The value of `B` in the sigmoid function
- `step`, then `ScoreTransform` has these fields:
  - `PositiveClassProbability`: the value of π in the step function on page 33-2427. π represents:
    - The probability that an observation is in the positive class.
    - The posterior probability that a score is in the interval (`LowerBound`,`UpperBound`).
  - `LowerBound`: the value $\max_{y_n = -1} s_n$ in the step function. It represents the lower bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability` to scores. Any observation with a score less than `LowerBound` has posterior probability of being the positive class `0`.
  - `UpperBound`: the value $\min_{y_n = +1} s_n$ in the step function. It represents the upper bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has posterior probability of being the positive class `1`.
- `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

  This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

More About

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \le s_j \le \min_{y_k = +1} s_k, \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases}$$

where:

- s_j is the score of observation j.
- +1 and –1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the value of the `Type` field of `ScoreTransform` is `step`, then the quantities $\max_{y_k = -1} s_k$ and $\min_{y_k = +1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

- This process describes one way to predict positive class posterior probabilities.

  1. Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
  2. Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, such as, `ScoreSVMModel`, is the same trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.
  3. Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

     If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to `'none'` before estimating the new one

Introduced in R2014a

fitted

Class: `GeneralizedLinearMixedModel`

Fitted responses from generalized linear mixed-effects model

Syntax

```
mufit = fitted(glme)
mufit = fitted(glme,Name,Value)
```

Description

`mufit = fitted(glme)` returns the fitted conditional response of the generalized linear mixed-effects model `glme`.

`mufit = fitted(glme,Name,Value)` returns the fitted response with additional options specified by one or more name-value pair arguments. For example, you can specify to compute the marginal fitted response.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Conditional` — Indicator for conditional response

`true` (default) | `false`

Indicator for conditional response, specified as the comma-separated pair consisting of `'Conditional'` and one of the following.

Value	Description
`true`	Contributions from both fixed effects and random effects (conditional)
`false`	Contribution from only fixed effects (marginal)

To obtain fitted marginal response values, `fitted` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects *b* set equal to 0. For more information, see “Conditional and Marginal Response” on page 33-2433

Example: `'Conditional',false`

Output Arguments

`mufit` — Fitted response values

n-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Plot Observed Versus Fitted Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

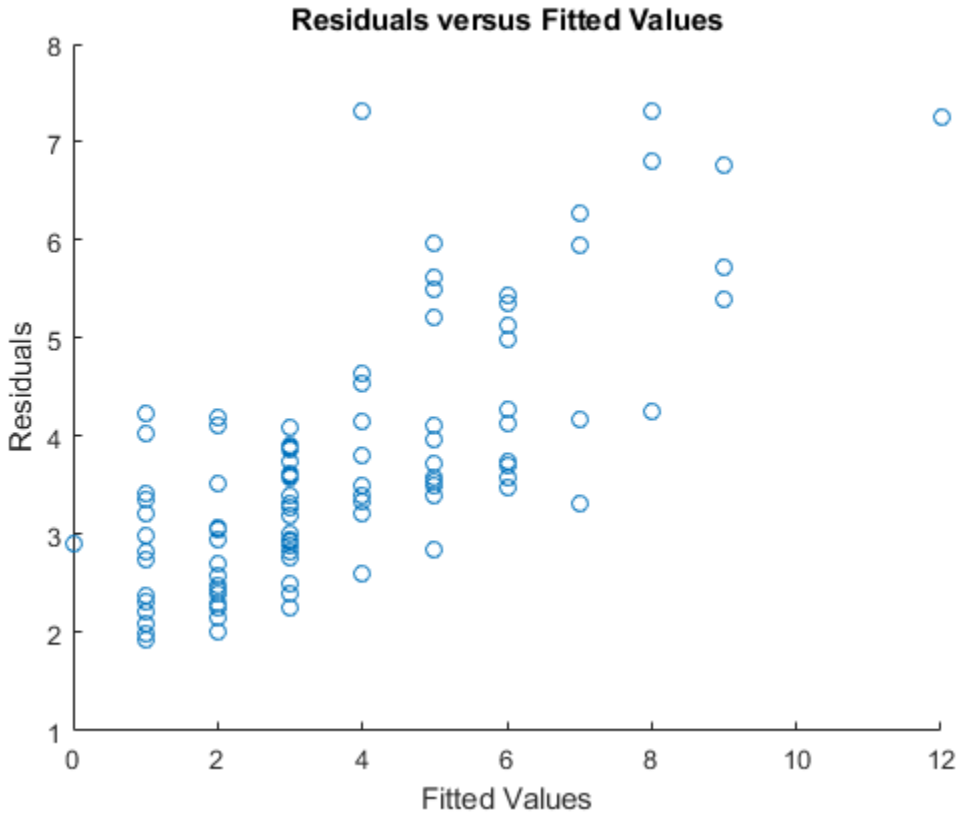
```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ..
    'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Generate the fitted conditional mean values for the model.

```
mufit = fitted(glme);
```

Create a scatterplot of the observed values versus fitted values.

```
figure
scatter(mfr.defects,mufit)
title('Residuals versus Fitted Values')
xlabel('Fitted Values')
ylabel('Residuals')
```



More About

Conditional and Marginal Response

A *conditional response* includes contributions from both fixed- and random-effects predictors. A *marginal response* includes contribution from only fixed effects.

Suppose the generalized linear mixed-effects model `glme` has an *n*-by-*p* fixed-effects design matrix `X` and an *n*-by-*q* random-effects design matrix `Z`. Also, suppose the estimated *p*-by-1 fixed-effects vector is $\widehat{\beta}$, and the *q*-by-1 empirical Bayes predictor vector of random effects is $\widehat{b}$.

The fitted conditional response corresponds to the `'Conditional',true` name-value pair argument, and is defined as

$$\widehat{\mu}_{cond} = g^{-1}(\widehat{\eta}_{ME}),$$

where $\widehat{\eta}_{ME}$ is the linear predictor including the fixed- and random-effects of the generalized linear mixed-effects model

$$\widehat{\eta}_{ME} = X\widehat{\beta} + Z\widehat{b} + \delta .$$

The fitted marginal response corresponds to the `'Conditional',false` name-value pair argument, and is defined as

$$\widehat{\mu}_{mar} = g^{-1}(\widehat{\eta}_{FE}),$$

where $\widehat{\eta}_{FE}$ is the linear predictor including only the fixed-effects portion of the generalized linear mixed-effects model

$$\widehat{\eta}_{FE} = X\widehat{\beta} + \delta \ .$$

`GeneralizedLinearMixedModel` | `designMatrix` | `fitglme` | `residuals` | `response`

fitted

Class: `LinearMixedModel`

Fitted responses from a linear mixed-effects model

Syntax

```
yfit = fitted(lme)
yfit = fitted(lme,Name,Value)
```

Description

`yfit = fitted(lme)` returns the fitted conditional response on page 33-2440 from the linear mixed-effects model `lme`.

`yfit = fitted(lme,Name,Value)` returns the fitted response from the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify if you want to compute the fitted marginal response on page 33-2440.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Conditional` — Indicator for conditional response

`true` (default) | false

Indicator for conditional response, specified as the comma-separated pair consisting of `'Conditional'` and either of the following.

`true`	Contribution from both fixed effects and random effects (conditional)
`false`	Contribution from only fixed effects (marginal)

Example: `'Conditional',false`

Data Types: `logical`

Output Arguments

yfit — Fitted response values

n-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Compute Fitted Conditional and Marginal Responses

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate','IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

Region is a categorical variable. You can specify the contrasts for categorical variables using the `DummyVarCoding` name-value pair argument when fitting the model. When you do not specify the contrasts, `fitlme` uses the `'reference'` contrast by default. Because the model has an intercept, `fitlme` takes the first region, `NE`, as the reference and creates eight dummy variables representing the other eight regions. For example, $I[\text{MidAtl}]$ is the dummy variable representing the region `MidAtl`. For details, see “Dummy Variables” on page 2-48.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SAtl}]_i + \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \ldots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j, $j = 0, 1, \ldots, 8$, are the fixed-effects coefficients, with β_0 being the coefficient for region `NE`. b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i. The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')
```

```
lme =
Linear mixed-effects model fit by ML
```

```
Model information:

     0.0022936     -0.26276    -0.057514

Random effects covariance parameters (95% CIs):
Group: Date (52 Levels)
    Name1                  Name2                  Type           Estimate
    {'(Intercept)'}        {'(Intercept)'}        {'std'}        0.6443

    Lower     Upper
    0.5297    0.78368

Group: Error
    Name               Estimate    Lower      Upper
    {'Res Std'}        0.26627     0.24878    0.285
```

The *p*-values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b, do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{\text{WNCentral, 10/9/2005}} &= \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
```

```
y_hat = 1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for β_0 and `beta(4)` corresponds to the estimate for β_3. You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans = 1.2884
```

The estimated marginal response for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}^{(\text{marginal})}_{\text{WNCentral, 10/9/2005}} &= \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] \\ &= 1.2233 + 0.23687 \\ &= 1.46017.\end{aligned}$$

Compute the fitted marginal response.

```
F = fitted(lme,'Conditional',false);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans = 1.4602
```

Plot Residuals vs. Fitted Values

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

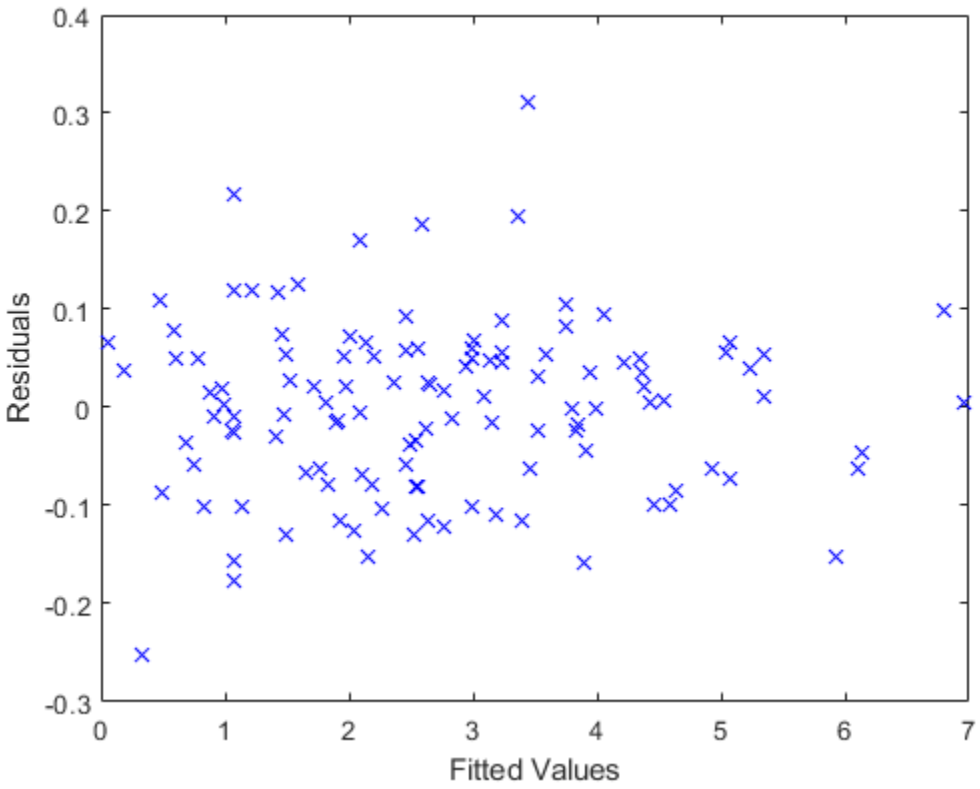
```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);
R = residuals(lme);
```

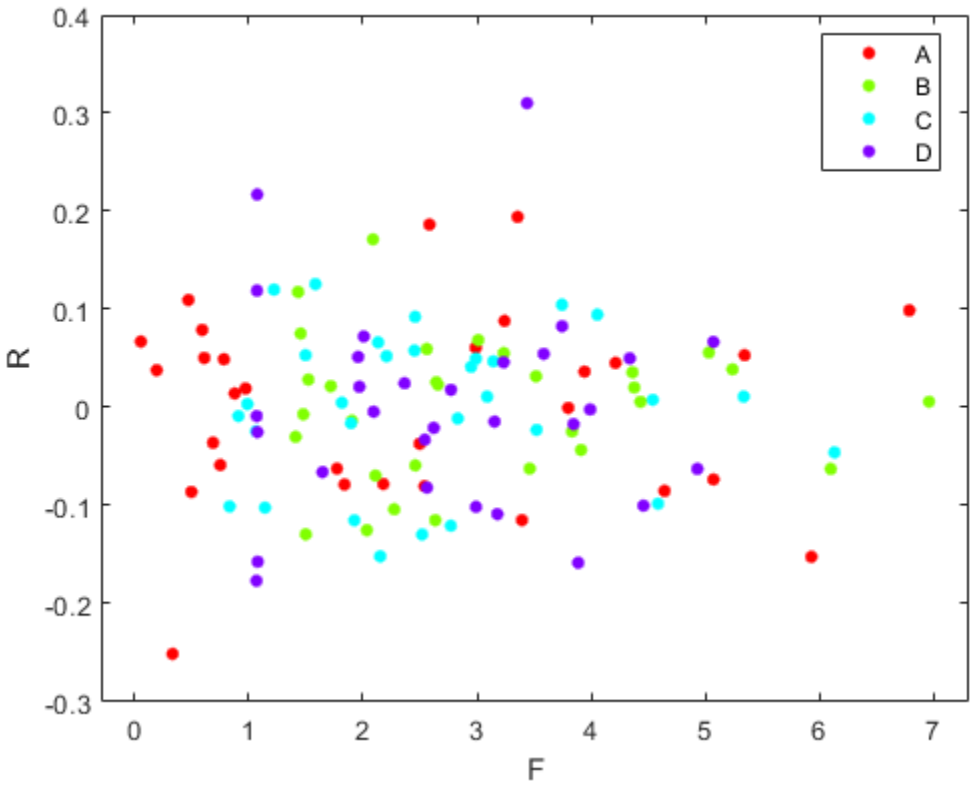
Plot the residuals versus the fitted values.

```
plot(F,R,'bx')
xlabel('Fitted Values')
ylabel('Residuals')
```



Now, plot the residuals versus the fitted values, grouped by program.

```
figure()
gscatter(F,R,Program)
```



More About

Fitted Conditional and Marginal Response

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model, `lme`, has an n-by-p fixed-effects design matrix X and an n-by-q random-effects design matrix Z. Also, suppose the p-by-1 estimated fixed-effects vector is $\widehat{\beta}$, and the q-by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is $\widehat{b}$. The fitted conditional response is

$$\widehat{y}_{Cond} = X\widehat{\beta} + Z\widehat{b},$$

and the fitted marginal response is

$$\widehat{y}_{Mar} = X\widehat{\beta},$$

`LinearMixedModel` | `residuals` | `response`

fixedEffects

Class: `GeneralizedLinearMixedModel`

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(glme)
[beta,betanames] = fixedEffects(glme)
[beta,betanames,stats] = fixedEffects(glme)
[___] = fixedEffects(glme,Name,Value)
```

Description

`beta = fixedEffects(glme)` returns the estimated fixed-effects coefficients, `beta`, of the generalized linear mixed-effects model `glme`.

`[beta,betanames] = fixedEffects(glme)` also returns the names of estimated fixed-effects coefficients in `betanames`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betanames,stats] = fixedEffects(glme)` also returns a table of statistics, `stats`, related to the estimated fixed-effects coefficients of `glme`.

`[___] = fixedEffects(glme,Name,Value)` returns any of the output arguments in previous syntaxes using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level, or the method for computing the approximate degrees of freedom for the *t*-statistic.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Alpha` — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α, the confidence level is 100 × (1 – α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`DFMethod` — Method for computing approximate degrees of freedom
`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

Value	Description
`'residual'`	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'none'`	The degrees of freedom is set to infinity.

Example: `'DFMethod','none'`

Output Arguments

`beta` — Estimated fixed-effects coefficients
vector

Estimated fixed-effects coefficients of the fitted generalized linear mixed-effects model `glme`, returned as a vector.

`betanames` — Names of fixed-effects coefficients
table

Names of fixed-effects coefficients in `beta`, returned as a table.

`stats` — Fixed-effects estimates and related statistics
dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Column Name	Description
`Name`	Name of the fixed-effects coefficient
`Estimate`	Estimated coefficient value
`SE`	Standard error of the estimate
`tStat`	*t*-statistic for a test that the coefficient is 0
`DF`	Estimated degrees of freedom for the *t*-statistic
`pValue`	*p*-value for the *t*-statistic
`Lower`	Lower limit of a 95% confidence interval for the fixed-effects coefficient
`Upper`	Upper limit of a 95% confidence interval for the fixed-effects coefficient

When fitting a model using `fitglme` and one of the maximum likelihood fit methods (`'Laplace'` or `'ApproximateLaplace'`), if you specify the `'CovarianceMethod'` name-value pair argument as

`'conditional'`, then `SE` does not account for the uncertainty in estimating the covariance parameters. To account for this uncertainty, specify `'CovarianceMethod'` as `'JointHessian'`.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods (`'MPL'` or `'REMPL'`), `fixedEffects` bases the fixed effects estimates and related statistics on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Estimate Fixed-Effects Coefficients

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)', ..
    'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Compute and display the estimated fixed-effects coefficient values and related statistics.

```
[beta,betanames,stats] = fixedEffects(glme);
stats
```

```
stats =
    Fixed effect coefficients: DFMethod = 'residual', Alpha = 0.05

    Name                    Estimate     SE          tStat       DF    pValue
    {'(Intercept)'}            1.4689     0.15988      9.1875    94    9.8194e-15
    {'newprocess' }          -0.36766     0.17755     -2.0708    94      0.041122
    {'time_dev'   }          -0.094521    0.82849    -0.11409    94       0.90941
    {'temp_dev'   }          -0.28317      0.9617    -0.29444    94       0.76907
    {'supplier_C' }          -0.071868    0.078024     -0.9211    94       0.35936
    {'supplier_B' }           0.071072     0.07739     0.91836    94       0.36078

    Lower        Upper
       1.1515       1.7864
    -0.72019    -0.015134
     -1.7395       1.5505
     -2.1926       1.6263
    -0.22679     0.083051
    -0.082588      0.22473
```

The returned results indicate, for example, that the estimated coefficient for `temp_dev` is –0.28317. Its large *p*-value, 0.76907, indicates that it is not a statistically significant predictor at the 5% significance level. Additionally, the confidence interval boundaries `Lower` and `Upper` indicate that the 95% confidence interval for the coefficient for `temp_dev` is [-2.1926 , 1.6263]. This interval contains 0, which supports the conclusion that `temp_dev` is not statistically significant at the 5% significance level.

fixedEffects

Class: `LinearMixedModel`

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(lme)
[beta,betanames] = fixedEffects(lme)
[beta,betanames,stats] = fixedEffects(lme)
[beta,betanames,stats] = fixedEffects(lme,Name,Value)
```

Description

`beta = fixedEffects(lme)` returns the estimated fixed-effects coefficients, `beta`, of the linear mixed-effects model `lme`.

`[beta,betanames] = fixedEffects(lme)` also returns the names of estimated fixed-effects coefficients in `betanames`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betanames,stats] = fixedEffects(lme)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics in `stats`.

`[beta,betanames,stats] = fixedEffects(lme,Name,Value)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Alpha` — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α, the confidence level is 100*(1–α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`DFMethod` — Method for computing approximate degrees of freedom
`'residual'` (default) | `'satterthwaite'` | `'none'`

Method for computing approximate degrees of freedom for the *t*-statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'residual'`	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'satterthwaite'`	Satterthwaite approximation.
`'none'`	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod','satterthwaite'`

Output Arguments

`beta` — Fixed-effects coefficients estimates
vector

Fixed-effects coefficients estimates of the fitted linear mixed-effects model `lme`, returned as a vector.

`betanames` — Names of fixed-effects coefficients
table

Names of fixed-effects coefficients in `beta`, returned as a table.

`stats` — Fixed-effects estimates and related statistics
dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

`Name`	Name of the fixed effect coefficient
`Estimate`	Estimated coefficient value
`SE`	Standard error of the estimate
`tStat`	*t*-statistic for a test that the coefficient is zero
`DF`	Estimated degrees of freedom for the *t*-statistic
`pValue`	*p*-value for the *t*-statistic
`Lower`	Lower limit of a 95% confidence interval for the fixed-effect coefficient
`Upper`	Upper limit of a 95% confidence interval for the fixed-effect coefficient

Examples

Display Fixed-Effects Coefficient Estimates and Names

Load the sample data.

```
load('weight.mat');
```

The data set `weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

```
[beta,betanames] = fixedEffects(lme)
```

```
beta = 9×1

    0.6610
    0.0032
    0.3608

    0.1132
    0.1732
    0.0388
    0.0305
    0.0331

betanames=9×1 table
           Name
    ________________

    {'(Intercept)'   }
    {'InitialWeight' }
    {'Program_B'     }
    {'Program_C'     }
    {'Program_D'     }
    {'Week'          }
    {'Program_B:Week'}
    {'Program_C:Week'}
    {'Program_D:Week'}
```

Compute Coefficient Estimates and Related Statistics

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficients estimates and related statistics.

```
[~,~,stats] = fixedEffects(lme)
```

```
stats =
    Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.05

    Name                    Estimate    SE           tStat      DF
    {'(Intercept)' }          50.133       2.2652     22.132    389
    {'Acceleration'}        -0.58327      0.13394    -4.3545    389
    {'Horsepower'  }        -0.16954    0.0072609     -23.35    389

    pValue        Lower       Upper
    7.7727e-71      45.679      54.586
    1.7075e-05    -0.84661    -0.31992
     5.188e-76    -0.18382    -0.15527
```

The small *p*-values (under `pValue`) indicate that all fixed-effects coefficients are significant.

Compute Confidence Intervals with Specified Options

Load the sample data.

```
load('shift.mat');
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

`Shift` and `Operator` are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = fixedEffects(lme,'alpha',0.01)
```

```
stats =
    Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.01

    Name                    Estimate    SE         tStat       DF    pValue
    {'(Intercept)'  }        3.1196     0.88681      3.5178    12    0.0042407
    {'Shift_Morning'}       -0.3868     0.48344    -0.80009    12      0.43921
    {'Shift_Night'  }        1.9856     0.48344      4.1072    12    0.0014535

    Lower      Upper
    0.41081    5.8284
    -1.8635    1.0899
     0.5089    3.4623
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = fixedEffects(lme,'DFMethod','satterthwaite','alpha',0.01)
```

```
stats =
    Fixed effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01

    Name                    Estimate    SE         tStat       DF       pValue
    {'(Intercept)'  }        3.1196     0.88681      3.5178    6.123    0.01214
    {'Shift_Morning'}       -0.3868     0.48344    -0.80009       10    0.44225
    {'Shift_Night'  }        1.9856     0.48344      4.1072       10    0.00212

    Lower       Upper
    -0.14122    6.3804
      -1.919    1.1454
     0.45343    3.5178
```

The Satterthwaite approximation usually produces smaller `DF` values than the residual method. That is why it produces larger *p*-values (`pValue`) and larger confidence intervals (see `Lower` and `Upper`).

fpdf

F probability density function

Syntax

```
Y = fpdf(X,V1,V2)
```

Description

`Y = fpdf(X,V1,V2)` computes the *F* pdf at each of the values in `X` using the corresponding numerator degrees of freedom `V1` and denominator degrees of freedom `V2`. `X`, `V1`, and `V2` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. `V1` and `V2` parameters must contain real positive values, and the values in `X` must lie on the interval `[0 Inf]`.

The probability density function for the *F* distribution is

$$y = f(x \mid \nu_1, \nu_2) = \frac{\Gamma\left[\frac{(\nu_1 + \nu_2)}{2}\right]}{\Gamma\left(\frac{\nu_1}{2}\right)\Gamma\left(\frac{\nu_2}{2}\right)}\left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_1}{2}} \frac{x^{\frac{\nu_1 - 2}{2}}}{\left[1 + \left(\frac{\nu_1}{\nu_2}\right)x\right]^{\frac{\nu_1 + \nu_2}{2}}}$$

Examples

```
y = fpdf(1:6,2,2)
y =
  0.2500  0.1111  0.0625  0.0400  0.0278  0.0204

z = fpdf(3,5:10,5:10)
z =
  0.0689  0.0659  0.0620  0.0577  0.0532  0.0487
```

fracfact

Fractional factorial design

Syntax

```
X = fracfact(gen)
[X,conf] = fracfact(gen)
[X,conf] = fracfact(gen,Name,Value)
```

Description

`X = fracfact(gen)` creates the two-level fractional factorial design defined by the generator `gen`.

`[X,conf] = fracfact(gen)` returns a cell array of character vectors containing the confounding pattern for the design.

`[X,conf] = fracfact(gen,Name,Value)` creates a fractional factorial designs with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`gen`

Either a string array or cell array of character vectors where each element contains one “word,” or a character array or string scalar consisting of “words” separated by spaces. “Words” consist of case-sensitive letters or groups of letters, where `'a'` represents value `1`, `'b'` represents value `2`, ..., `'A'` represents value `27`, ..., `'Z'` represents value `52`.

Each word defines how the corresponding factor’s levels are defined as products of generators from a `2^K` full-factorial design. `K` is the number of letters of the alphabet in `gen`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`FactorNames`

String array or cell array specifying the name for each factor.

Default: `{'X1','X2',...}`

`MaxInt`

Positive integer setting the maximum level of interaction to include in the confounding output.

Default: 2

Output Arguments

X

The two-level fractional factorial design. X is a matrix of size N-by-P, where

- N = 2^K, where K is the number of letters of the alphabet in gen.
- P is the number of words in gen.

Because X is a two-level design, the components of X are ±1. For the meaning of X, see “Fractional Factorial Designs” on page 28-5.

conf

Cell array of character vectors containing the confounding pattern for the design.

Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:

```
x = fracfact('a b c abc')

x =
    -1    -1    -1    -1
    -1    -1     1     1
    -1     1    -1     1
    -1     1     1    -1
     1    -1    -1     1
     1    -1     1    -1
     1     1    -1    -1
     1     1     1     1
```

Find generators for a six-factor design that uses four factors and achieves resolution IV using fracfactgen. Use the result to specify the design:

```
generators = fracfactgen('a b c d e f',4, ... % 4 factors
    4) % resolution 4

generators =
    'a'
    'b'
    'c'
    'd'
    'bcd'
    'acd'

x = fracfact(generators)

x =
    -1    -1    -1    -1    -1    -1
    -1    -1    -1     1     1     1
    -1    -1     1    -1     1     1
    -1    -1     1     1    -1    -1
    -1     1    -1    -1     1    -1
    -1     1    -1     1    -1     1
```

```
    -1     1     1    -1    -1     1
    -1     1     1     1     1    -1
     1    -1    -1    -1    -1     1
     1    -1    -1     1     1    -1
     1    -1     1    -1     1    -1
     1    -1     1     1    -1     1
     1     1    -1    -1     1     1
     1     1    -1     1    -1    -1
     1     1     1    -1    -1    -1
     1     1     1     1     1     1
```

fracfactgen

Fractional factorial design generators

Syntax

```
generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)
```

Description

`generators = fracfactgen(terms)` uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by `terms`. `terms` is a character vector or string scalar consisting of words formed from the `52` case-sensitive letters `a`-`Z`, separated by spaces. Use `'a'-'z'` for the first 26 factors, and, if necessary, `'A'-'Z'` for the remaining factors. For example, `terms = 'a b c ab ac'`. Single-letter words indicate main effects to be estimated; multiple-letter words indicate interactions. Alternatively, `terms` is an *m*-by-*n* matrix of `0`s and `1`s where *m* is the number of model terms to be estimated and *n* is the number of factors. For example, if `terms` contains rows `[0 1 0 0]` and `[1 0 0 1]`, then the factor `b` and the interaction between factors `a` and `d` are included in the model. `generators` is a cell array of character vectors with one generator per cell. Pass `generators` to `fracfact` to produce the fractional-factorial design and corresponding confounding pattern.

`generators = fracfactgen(terms,k)` returns generators for a two-level fractional-factorial design with 2^k-runs, if possible. If `k` is `[]`, `fracfactgen` finds the smallest design.

`generators = fracfactgen(terms,k,R)` finds a design with resolution `R`, if possible. The default resolution is `3`.

A design of resolution *R* is one in which no *n*-factor interaction is confounded with any other effect containing less than *R* – *n* factors. Thus a resolution III design does not confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If `fracfactgen` is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model. If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

`generators = fracfactgen(terms,k,R,basic)` also accepts a vector `basic` specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in `terms`.

Examples

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require $2^4 = 16$ runs. The `fracfactgen` function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only $2^3 = 8$ runs:

```
generators = fracfactgen('a b c d',3,4)
generators =
    'a'
    'b'
    'c'
    'abc'
```

The more economical design and the corresponding confounding pattern are returned by `fracfact`:

```
[dfF,confounding] = fracfact(generators)
dfF =
    -1    -1    -1    -1
    -1    -1     1     1
    -1     1    -1     1
    -1     1     1    -1
     1    -1    -1     1
     1    -1     1    -1
     1     1    -1    -1
     1     1     1     1
confounding =
    'Term'     'Generator'    'Confounding'
    'X1'       'a'            'X1'
    'X2'       'b'            'X2'
    'X3'       'c'            'X3'
    'X4'       'abc'          'X4'
    'X1*X2'    'ab'           'X1*X2 + X3*X4'
    'X1*X3'    'ac'           'X1*X3 + X2*X4'
    'X1*X4'    'bc'           'X1*X4 + X2*X3'
    'X2*X3'    'bc'           'X1*X4 + X2*X3'
    'X2*X4'    'ac'           'X1*X3 + X2*X4'
    'X3*X4'    'ab'           'X1*X2 + X3*X4'
```

The confounding pattern shows, for example, that the two-way interaction between `X1` and `X2` is confounded by the two-way interaction between `X3` and `X4`.

Introduced in R2006a

friedman

Friedman’s test

Syntax

```
p = friedman(x,reps)
p = friedman(x,reps,displayopt)
[p,tbl] = friedman( ___ )
[p,tbl,stats] = friedman( ___ )
```

Description

`p = friedman(x,reps)` returns the *p*-value for the nonparametric Friedman's test to compare column effects in a two-way layout. `friedman` tests the null hypothesis that the column effects are all the same against the alternative that they are not all the same.

`p = friedman(x,reps,displayopt)` enables the ANOVA table display when `displayopt` is `'on'` (default) and suppresses the display when `displayopt` is `'off'`.

`[p,tbl] = friedman( ___ )` returns the ANOVA table (including column and row labels) in cell array `tbl`.

`[p,tbl,stats] = friedman( ___ )` also returns a structure `stats` that you can use to perform a follow-up multiple comparison test.

Examples

Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.

```
load popcorn
popcorn
```

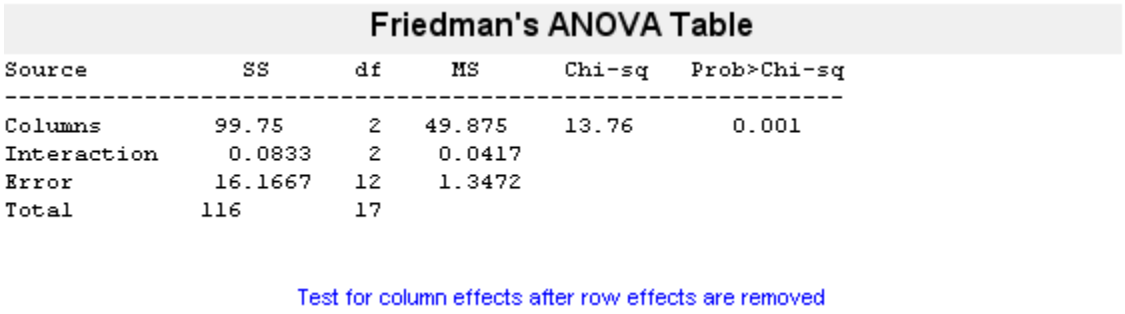
```
popcorn = 6×3

    5.5000    4.5000    3.5000
    5.5000    4.5000    4.0000
    6.0000    4.0000    3.0000
    6.5000    5.0000    4.0000
    7.0000    5.5000    5.0000
    7.0000    5.0000    4.5000
```

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

```
p = friedman(popcorn,3)
```



```
p = 0.0010
```

The small value of `p = 0.001` indicates the popcorn brand affects the yield of popcorn.

Input Arguments

x — Sample data

matrix

Sample data for the hypothesis test, specified as a matrix. The columns of `x` represent changes in a factor A. The rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input reps indicates the number of replicates in each “cell,” which must be constant.

Data Types: `single` | `double`

reps — Number of replicates

1 (default) | positive integer value

Number of replicates for each combination of groups, specified as a positive integer value. For example, the following data has two replicates (`reps = 2`) for each group combination of row factor A and column factor B.

$$\begin{matrix} B=1 & B=2 \end{matrix}$$
$$\begin{bmatrix} x_{111} & x_{121} \\ x_{112} & x_{122} \\ x_{211} & x_{221} \\ x_{212} & x_{222} \\ x_{311} & x_{321} \\ x_{312} & x_{322} \end{bmatrix} \begin{matrix} \} A=1 \\ \} A=2 \\ \} A=3 \end{matrix}$$

Data Types: `single` | `double`

displayopt — ANOVA table display option

`'off'` (default) | `'on'`

ANOVA table display option, specified as `'off'` or `'on'`.

If `displayopt` is `'on'`, then `friedman` displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if reps is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the *p* value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting `Copy Text` from the **Edit** menu.

Output Arguments

`p` — *p*-value

scalar value in the range `[0,1]`

p-value of the test, returned as a scalar value in the range `[0,1]`. `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

`tbl` — ANOVA table

cell array

ANOVA table, including column and row labels, returned as a cell array. The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the *p* value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting `Copy Text` from the **Edit** menu.

`stats` — Test data

structure

Test data, returned as a structure. `friedman` evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. However, sometimes it is preferable to

perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying `stats` as the input value.

More About

Friedman's Test

Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman's test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of `X` represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input `reps` indicates the number of replicates in each "cell," which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (`reps=2`). The subscripts indicate row, column, and replicate, respectively.

$$\begin{bmatrix} x_{111} & x_{121} & x_{131} \\ x_{112} & x_{122} & x_{132} \\ x_{211} & x_{221} & x_{231} \\ x_{212} & x_{222} & x_{232} \end{bmatrix}$$

Friedman's test assumes a model of the form

$$x_{ijk} = \mu + \alpha_i + \beta_j + \varepsilon_{ijk}$$

where μ is an overall location parameter, α_i represents the column effect, β_j represents the row effect, and ε_{ijk} represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The `p` that `friedman` returns is the p value for the null hypothesis that $\alpha_i = 0$. If the p value is near zero, this casts doubt on the null hypothesis. A sufficiently small p value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical p value to determine whether a result is "statistically significant" is left to the researcher. It is common to declare a result significant if the p value is less than 0.05 or 0.01.

Friedman's test makes the following assumptions about the data in `X`:

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

Introduced before R2006a

frnd

F random numbers

Syntax

```
R = frnd(V1,V2)
R = frnd(V1,V2,m,n,...)
R = frnd(V1,V2,[m,n,...])
```

Description

`R = frnd(V1,V2)` generates random numbers from the *F* distribution with numerator degrees of freedom `V1` and denominator degrees of freedom `V2`. `V1` and `V2` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `V1` or `V2` is expanded to a constant array with the same dimensions as the other input. `V1` and `V2` parameters must contain real positive values.

`R = frnd(V1,V2,m,n,...)` or `R = frnd(V1,V2,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the *F* distribution with parameters `V1` and `V2`. `V1` and `V2` can each be scalars or arrays of the same size as `R`.

Examples

```
n1 = frnd(1:6,1:6)
n1 =
  0.0022  0.3121  3.0528  0.3189  0.2715  0.9539

n2 = frnd(2,2,[2 3])
n2 =
  0.3186  0.9727  3.0268
  0.2052 148.5816  0.2191

n3 = frnd([1 2 3;4 5 6],1,2,3)
n3 =
  0.6233  0.2322  31.5458
  2.5848  0.2121  4.4955
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

fscchi2

Univariate feature ranking for classification using chi-square tests

Syntax

```
idx = fscchi2(Tbl,ResponseVarName)
idx = fscchi2(Tbl,formula)
idx = fscchi2(Tbl,Y)

idx = fscchi2(X,Y)

idx = fscchi2(___,Name,Value)
[idx,scores] = fscchi2(___)
```

Description

`idx = fscchi2(Tbl,ResponseVarName)` ranks features (predictors) using chi-square tests on page 33-2471. The table `Tbl` contains predictor variables and a response variable, and `ResponseVarName` is the name of the response variable in `Tbl`. The function returns `idx`, which contains the indices of predictors ordered by predictor importance, meaning `idx(1)` is the index of the most important predictor. You can use `idx` to select important predictors for classification problems.

`idx = fscchi2(Tbl,formula)` specifies a response variable and predictor variables to consider among the variables in `Tbl` by using `formula`.

`idx = fscchi2(Tbl,Y)` ranks predictors in `Tbl` using the response variable `Y`.

`idx = fscchi2(X,Y)` ranks predictors in `X` using the response variable `Y`.

`idx = fscchi2(___,Name,Value)` specifies additional options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntaxes. For example, you can specify prior probabilities and observation weights.

`[idx,scores] = fscchi2(___)` also returns the predictor scores `scores`. A large score value indicates that the corresponding predictor is important.

Examples

Rank Predictors in Matrix

Rank predictors in a numeric matrix and create a bar plot of predictor importance scores.

Load the sample data.

```
load ionosphere
```

`ionosphere` contains predictor variables (`X`) and a response variable (`Y`).

Rank the predictors using chi-square tests.

```
[idx,scores] = fscchi2(X,Y);
```

The values in `scores` are the negative logs of the *p*-values. If a *p*-value is smaller than `eps(0)`, then the corresponding score value is `Inf`. Before creating a bar plot, determine whether `scores` includes `Inf` values.

```
find(isinf(scores))
```

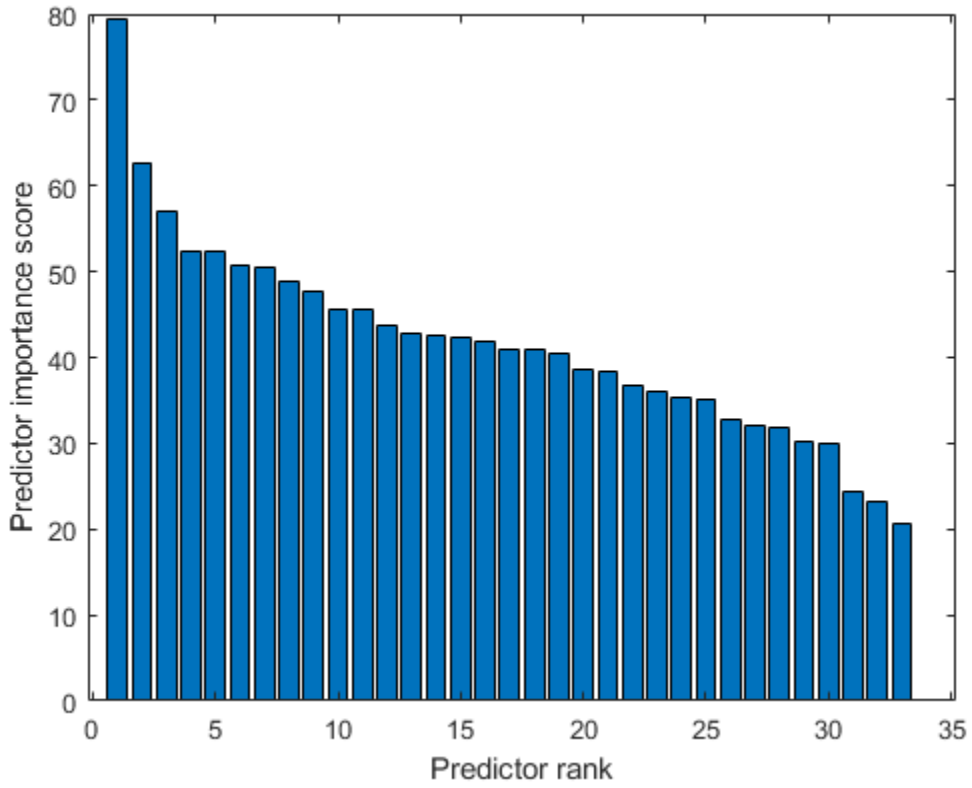
```
ans =

  1x0 empty double row vector
```

`scores` does not include `Inf` values. If `scores` includes `Inf` values, you can replace `Inf` by a large numeric number before creating a bar plot for visualization purposes. For details, see “Rank Predictors in Table” on page 33-2465.

Create a bar plot of the predictor importance scores.

```
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
```



Select the top five most important predictors. Find the columns of these predictors in X.

```
idx(1:5)
```

```
ans = 1×5
```

```
     5     7     3     8     6
```

The fifth column of X is the most important predictor of Y.

Rank Predictors in Table

Rank predictors in a table and create a bar plot of predictor importance scores.

If your data is in a table and `fscchi2` ranks a subset of the variables in the table, then the function indexes the variables using only the subset. Therefore, a good practice is to move the predictors that you do not want to rank to the end of the table. Move the response variable and observation weight vector as well. Then, the indexes of the output arguments are consistent with the indexes of the table.

Load the census1994 data set.

```
load census1994
```

The table `adultdata` in `census1994` contains demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. Display the first three rows of the table.

```
head(adultdata,3)
```

```
ans=3×15 table
    age       workClass          fnlwgt      education    education_num      marital_status
    ___    _________________    __________    _________    _____________    ____________________

    39     State-gov                77516    Bachelors          13         Never-married
    50     Self-emp-not-inc         83311    Bachelors          13         Married-civ-spouse
    38     Private             2.1565e+05    HS-grad             9         Divorced
```

In the table `adultdata`, the third column `fnlwgt` is the weight of the samples, and the last column `salary` is the response variable. Move `fnlwgt` to the left of `salary` by using the `movevars` function.

```
adultdata = movevars(adultdata,'fnlwgt','before','salary');
head(adultdata,3)
```

```
ans=3×15 table
    age       workClass          education    education_num      marital_status          occupation
    ___    _________________    _________    _____________    ____________________    _____________

    39     State-gov            Bachelors          13         Never-married          Adm-clerical
    50     Self-emp-not-inc     Bachelors          13         Married-civ-spouse     Exec-managerial
    38     Private              HS-grad             9         Divorced               Handlers-clean
```

Rank the predictors in `adultdata`. Specify the column `salary` as a response variable, and specify the column `fnlwgt` as observation weights.

```
[idx,scores] = fscchi2(adultdata,'salary','Weights','fnlwgt');
```

The values in `scores` are the negative logs of the *p*-values. If a *p*-value is smaller than `eps(0)`, then the corresponding score value is `Inf`. Before creating a bar plot, determine whether `scores` includes `Inf` values.

```
idxInf = find(isinf(scores))
```

```
idxInf = 1×8

     1     3     4     5     6     7    10    12
```

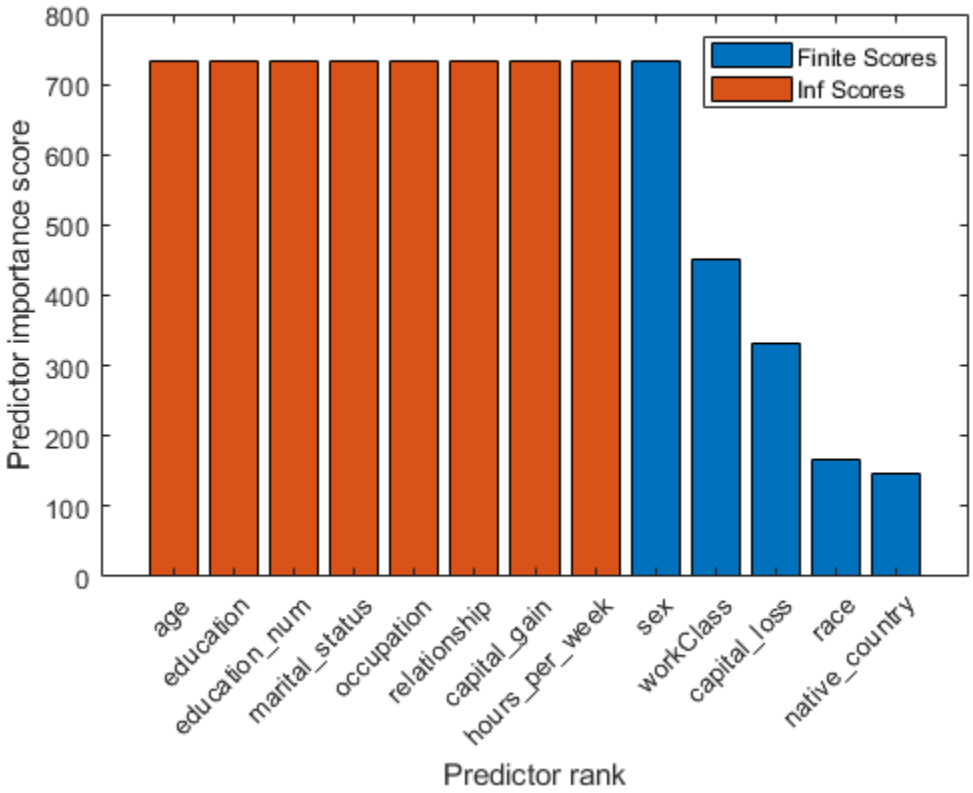
`scores` includes eight `Inf` values.

Create a bar plot of predictor importance scores. Use the predictor names for the *x*-axis tick labels.

```
figure
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
xticklabels(strrep(adultdata.Properties.VariableNames(idx),'_','\_'))
xtickangle(45)
```

The `bar` function does not plot any bars for the `Inf` values. For the `Inf` values, plot bars that have the same length as the largest finite score.

```
hold on
bar(scores(idx(length(idxInf)+1))*ones(length(idxInf),1))
legend('Finite Scores','Inf Scores')
hold off
```



The bar graph displays finite scores and Inf scores using different colors.

Input Arguments

`Tbl` — Sample data

table

Sample data, specified as a table. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain additional columns for a response variable and observation weights.

A response variable can be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element of the response variable must correspond to one row of the array.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`. If `Tbl` also contains the observation weights, then you can specify the weights by using `Weights`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify the subset of variables by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The response variable and `Tbl` must have the same number of rows.

If `fscchi2` uses a subset of variables in `Tbl` as predictors, then the function indexes the predictors using only the subset. The values in the `'CategoricalPredictors'` name-value pair argument and the output argument `idx` do not count the predictors that the function does not rank.

`fscchi2` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Tbl` for a response variable to be missing values. `fscchi2` does not use observations with missing values for a response variable.

Data Types: `table`

`ResponseVarName` — Response variable name

character vector or string scalar containing name of variable in `Tbl`

Response variable name, specified as a character vector or string scalar containing the name of a variable in `Tbl`.

For example, if a response variable is the column `Y` of `Tbl` (`Tbl.Y`), then specify `ResponseVarName` as `'Y'`.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables

character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y ~ x1 + x2 + x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors, use a formula. If you specify a formula, then `fscchi2` does not rank any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

Y — Response variable
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response variable, specified as a numeric, categorical, or logical vector, a character or string array, or a cell array of character vectors. Each row of `Y` represents the labels of the corresponding row of `X`.

`fscchi2` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Y` to be missing values. `fscchi2` does not use observations with missing values for `Y`.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

X — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NumBins',20,'UseMissing',true` sets the number of bins as 20 and specifies to use missing values in predictors for ranking.

`CategoricalPredictors` — List of categorical predictors
vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

List of categorical predictors, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fscchi2` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.

Value	Description
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the names in `Tbl`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the names in `Tbl`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fscchi2` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fscchi2` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for ranking

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of the classes to use for ranking, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y` or the response variable in `Tbl`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `'ClassNames'` to:

- Specify the order of the `Prior` dimensions that corresponds to the class order.
- Select a subset of classes for ranking. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To rank predictors using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `'ClassNames'` is the set of all distinct class names in `Y` or the response variable in `Tbl`. The default `'ClassNames'` value has mathematical ordering if the response variable is ordinal. Otherwise, the default value has alphabetical ordering.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`NumBins` — Number of bins for binning continuous predictors

10 (default) | positive integer scalar

Number of bins for binning continuous predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

Example: `'NumBins',50`

Data Types: `single` | `double`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as one of the following:

- Character vector or string scalar.
  - `'empirical'` determines class probabilities from class frequencies in the response variable in `Y` or `Tbl`. If you pass observation weights, `fscchi2` uses the weights to compute the class probabilities.
  - `'uniform'` sets all class probabilities to be equal.
- Vector (one scalar value for each class). To specify the class order for the corresponding elements of `'Prior'`, set the `'ClassNames'` name-value argument.
- Structure `S` with two fields.
  - `S.ClassNames` contains the class names as a variable of the same type as the response variable in `Y` or `Tbl`.
  - `S.ClassProbs` contains a vector of corresponding probabilities.

`fscchi2` normalizes the weights in each class (`'Weights'`) to add up to the value of the prior probability of the respective class.

Example: `'Prior','uniform'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`UseMissing` — Indicator for whether to use or discard missing values in predictors
`false` (default) | `true`

Indicator for whether to use or discard missing values in predictors, specified as the comma-separated pair consisting of `'UseMissing'` and either `true` to use or `false` to discard missing values in predictors for ranking.

`fscchi2` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values to be missing values.

If you specify `'UseMissing',true`, then `fscchi2` uses missing values for ranking. For a categorical variable, `fscchi2` treats missing values as an extra category. For a continuous variable, `fscchi2` places `NaN` values in a separate bin for binning.

If you specify `'UseMissing',false`, then `fscchi2` does not use missing values for ranking. Because `fscchi2` computes importance scores individually for each predictor, the function does not discard an entire row when values in the row are partially missing. For each variable, `fscchi2` uses all values that are not missing.

Example: `'UseMissing',true`

Data Types: `logical`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values or the name of a variable in `Tbl`. The function weights the observations in each row of `X`

or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weight vector is the column `W` of `Tbl` (`Tbl.W`), then specify `'Weights','W'`.

`fscchi2` normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`idx` — Indices of predictors ordered by predictor importance

numeric vector

Indices of predictors in `X` or `Tbl` ordered by predictor importance, returned as a 1-by-*r* numeric vector, where *r* is the number of ranked predictors.

If `fscchi2` uses a subset of variables in `Tbl` as predictors, then the function indexes the predictors using only the subset. For example, suppose `Tbl` includes 10 columns and you specify the last five columns of `Tbl` as the predictor variables by using `formula`. If `idx(3)` is `5`, then the third most important predictor is the 10th column in `Tbl`, which is the fifth predictor in the subset.

`scores` — Predictor scores

numeric vector

Predictor scores, returned as a 1-by-*r* numeric vector, where *r* is the number of ranked predictors.

A large score value indicates that the corresponding predictor is important.

- If you use `X` to specify the predictors or use all the variables in `Tbl` as predictors, then the values in `scores` have the same order as the predictors in `X` or `Tbl`.
- If you specify a subset of variables in `Tbl` as predictors, then the values in `scores` have the same order as the subset.

For example, suppose `Tbl` includes 10 columns and you specify the last five columns of `Tbl` as the predictor variables by using `formula`. Then, `score(3)` contains the score value of the 8th column in `Tbl`, which is the third predictor in the subset.

Algorithms

Univariate Feature Ranking Using Chi-Square Tests

- `fscchi2` examines whether each predictor variable is independent of a response variable by using individual chi-square tests. A small *p*-value of the test statistic indicates that the corresponding predictor variable is dependent on the response variable, and, therefore is an important feature.
- The output `scores` is –log(*p*). Therefore, a large score value indicates that the corresponding predictor is important. If a *p*-value is smaller than `eps(0)`, then the output is `Inf`.

- `fscchi2` examines a continuous variable after binning, or discretizing, the variable. You can specify the number of bins using the `'NumBins'` name-value pair argument.

Topics

“Introduction to Feature Selection” on page 15-49

Introduced in R2020a

fscmrmr

Rank features for classification using minimum redundancy maximum relevance (MRMR) algorithm

Syntax

```
idx = fscmrmr(Tbl,ResponseVarName)
idx = fscmrmr(Tbl,formula)
idx = fscmrmr(Tbl,Y)

idx = fscmrmr(X,Y)

idx = fscmrmr( ___ ,Name,Value)
[idx,scores] = fscmrmr( ___ )
```

Description

`idx = fscmrmr(Tbl,ResponseVarName)` ranks features (predictors) using the MRMR algorithm on page 33-2482. The table `Tbl` contains predictor variables and a response variable, and `ResponseVarName` is the name of the response variable in `Tbl`. The function returns `idx`, which contains the indices of predictors ordered by predictor importance. You can use `idx` to select important predictors for classification problems.

`idx = fscmrmr(Tbl,formula)` specifies a response variable and predictor variables to consider among the variables in `Tbl` by using `formula`.

`idx = fscmrmr(Tbl,Y)` ranks predictors in `Tbl` using the response variable `Y`.

`idx = fscmrmr(X,Y)` ranks predictors in `X` using the response variable `Y`.

`idx = fscmrmr( ___ ,Name,Value)` specifies additional options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntaxes. For example, you can specify prior probabilities and observation weights.

`[idx,scores] = fscmrmr( ___ )` also returns the predictor scores `scores`. A large score value indicates that the corresponding predictor is important.

Examples

Rank Predictors by Importance

Load the sample data.

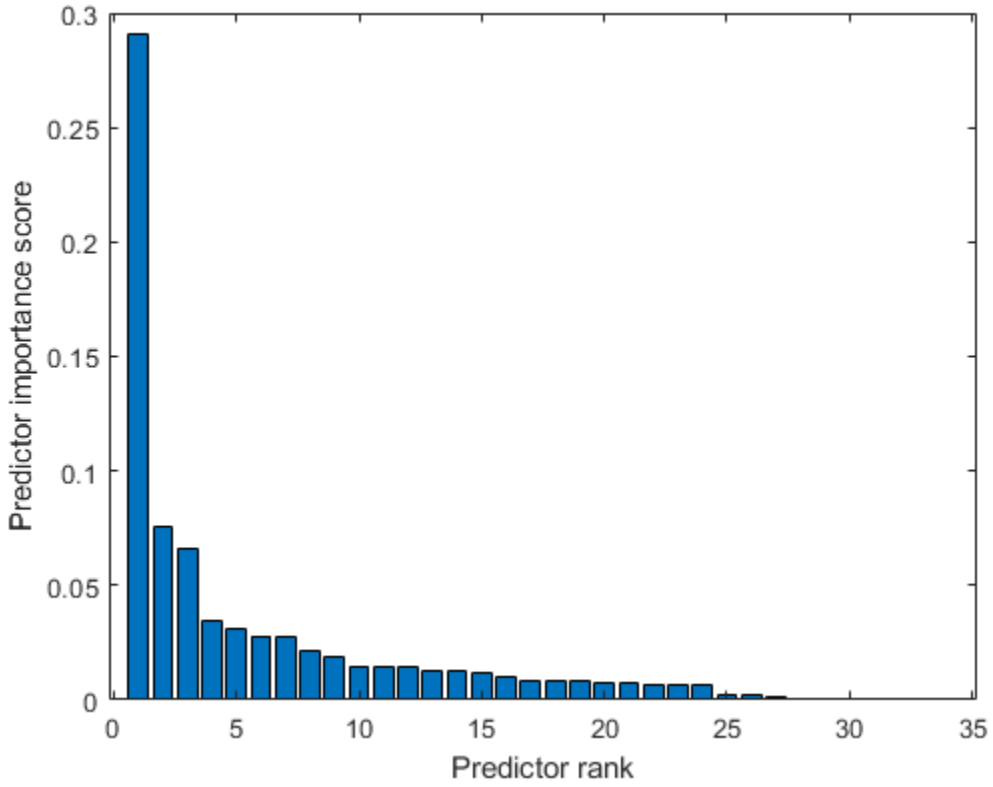
```
load ionosphere
```

Rank the predictors based on importance.

```
[idx,scores] = fscmrmr(X,Y);
```

Create a bar plot of the predictor importance scores.

```
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
```



The drop in score between the first and second most important predictors is large, while the drops after the sixth predictor are relatively small. A drop in the importance score represents the confidence of feature selection. Therefore, the large drop implies that the software is confident of selecting the most important predictor. The small drops indicate that the difference in predictor importance are not significant.

Select the top five most important predictors. Find the columns of these predictors in X.

```
idx(1:5)
```

```
ans = 1×5

     5     4     1     7    24
```

The fifth column of X is the most important predictor of Y.

Select Features and Compare Accuracies of Two Classification Models

Find important predictors by using `fscmrmr`. Then compare the accuracies of the full classification model (which uses all the predictors) and a reduced model that uses the five most important predictors by using `testckfold`.

Load the census1994 data set.

```
load census1994
```

The table `adultdata` in `census1994` contains demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. Display the first three rows of the table.

```
head(adultdata,3)
```

```
ans=3×15 table
    age       workClass          fnlwgt      education    education_num      marital_status
    ___    _________________    __________    _________    _____________    ____________________

    39     State-gov                77516    Bachelors         13          Never-married
    50     Self-emp-not-inc         83311    Bachelors         13          Married-civ-spouse
    38     Private              2.1565e+05    HS-grad            9          Divorced
```

The output arguments of `fscmrmr` include only the variables ranked by the function. Before passing a table to the function, move the variables that you do not want to rank, including the response variable and weight, to the end of the table so that the order of the output arguments is consistent with the order of the table.

In the table `adultdata`, the third column `fnlwgt` is the weight of the samples, and the last column `salary` is the response variable. Move `fnlwgt` to the left of `salary` by using the `movevars` function.

```
adultdata = movevars(adultdata,'fnlwgt','before','salary');
head(adultdata,3)
```

```
ans=3×15 table
    age       workClass          education    education_num      marital_status          occupation
    ___    _________________    _________    _____________    ____________________    _____________

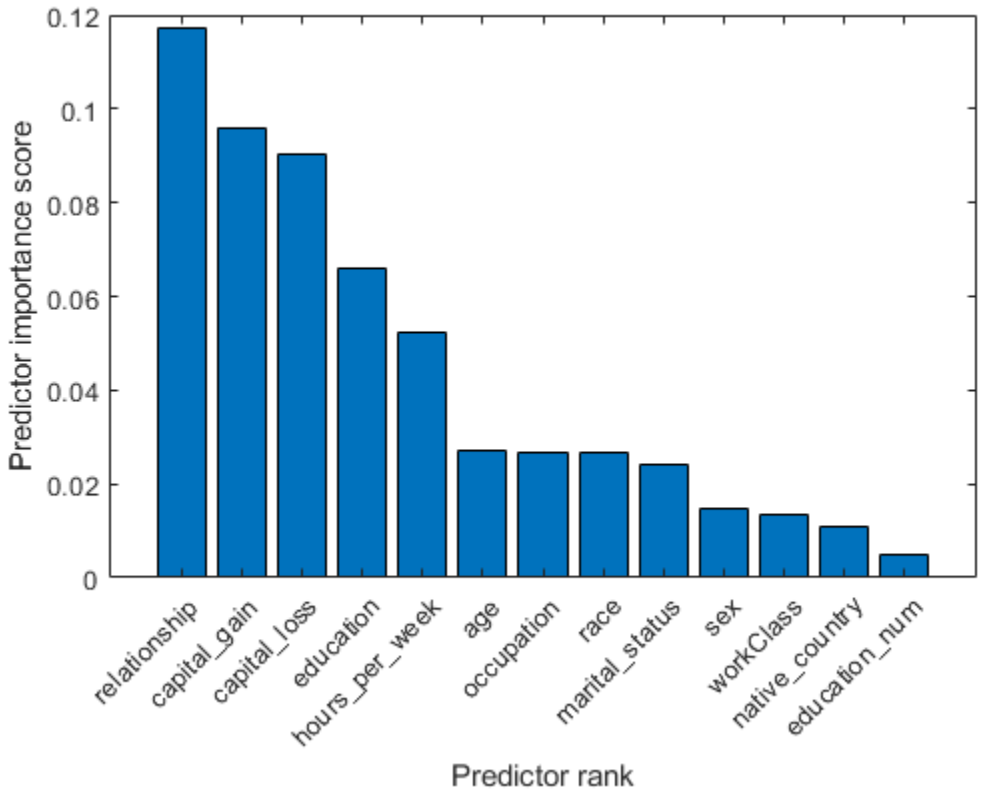
    39     State-gov            Bachelors         13          Never-married          Adm-clerical
    50     Self-emp-not-inc     Bachelors         13          Married-civ-spouse     Exec-managerial
    38     Private              HS-grad            9          Divorced               Handlers-cleaners
```

Rank the predictors in `adultdata`. Specify the column `salary` as the response variable.

```
[idx,scores] = fscmrmr(adultdata,'salary','Weights','fnlwgt');
```

Create a bar plot of predictor importance scores. Use the predictor names for the *x*-axis tick labels.

```
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
xticklabels(strrep(adultdata.Properties.VariableNames(idx),'_','\_'))
xtickangle(45)
```



The five most important predictors are `relationship`, `capital_loss`, `capital_gain`, `education`, and `hours_per_week`.

Compare the accuracy of a classification tree trained with all predictors to the accuracy of one trained with the five most important predictors.

Create a classification tree template using the default options.

```
C = templateTree;
```

Define the table `tbl1` to contain all predictors and the table `tbl2` to contain the five most important predictors.

```
tbl1 = adultdata(:,adultdata.Properties.VariableNames(idx(1:13)));
tbl2 = adultdata(:,adultdata.Properties.VariableNames(idx(1:5)));
```

Pass the classification tree template and the two tables to the `testckfold` function. The function compares the accuracies of the two models by repeated cross-validation. Specify `'Alternative','greater'` to test the null hypothesis that the model with all predictors is, at most, as accurate as the model with the five predictors. The `'greater'` option is available when `'Test'` is `'5x2t'` (5-by-2 paired *t* test) or `'10x10t'` (10-by-10 repeated cross-validation *t* test).

```
[h,p] = testckfold(C,C,tbl1,tbl2,adultdata.salary,'Weights',adultdata.fnlwgt,'Alternative','grea
```

```
h = logical
   0
```

```
p = 0.9969
```

`h` equals 0 and the *p*-value is almost 1, indicating failure to reject the null hypothesis. Using the model with the five predictors does not result in loss of accuracy compared to the model with all the predictors.

Now train a classification tree using the selected predictors.

```
mdl = fitctree(adultdata,'salary ~ relationship + capital_loss + capital_gain + education +  hou
    'Weights',adultdata.fnlwgt)
```

```
mdl =
  ClassificationTree
           PredictorNames: {1x5 cell}
             ResponseName: 'salary'
    CategoricalPredictors: [1 2]
               ClassNames: [<=50K    >50K]
           ScoreTransform: 'none'
          NumObservations: 32561

  Properties, Methods
```

Input Arguments

`Tbl` — Sample data

table

Sample data, specified as a table. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain additional columns for a response variable and observation weights.

A response variable can be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element of the response variable must correspond to one row of the array.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`. If `Tbl` also contains the observation weights, then you can specify the weights by using `Weights`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify the subset of variables by using `formula`.
- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The response variable and `Tbl` must have the same number of rows.

If `fscmrmr` uses a subset of variables in `Tbl` as predictors, then the function indexes the predictors using only the subset. The values in the `'CategoricalPredictors'` name-value pair argument and the output argument `idx` do not count the predictors that the function does not rank.

`fscmrmr` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Tbl` for a response variable to be missing values. `fscmrmr` does not use observations with missing values for a response variable.

Data Types: `table`

`ResponseVarName` — Response variable name
character vector or string scalar containing name of variable in `Tbl`

Response variable name, specified as a character vector or string scalar containing the name of a variable in `Tbl`.

For example, if a response variable is the column `Y` of `Tbl` (`Tbl.Y`), then specify `ResponseVarName` as `'Y'`.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y ~ x1 + x2 + x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors, use a formula. If you specify a formula, then `fscmrmr` does not rank any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Response variable
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response variable, specified as a numeric, categorical, or logical vector, a character or string array, or a cell array of character vectors. Each row of `Y` represents the labels of the corresponding row of `X`.

`fscmrmr` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Y` to be missing values. `fscmrmr` does not use observations with missing values for `Y`.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`X` — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CategoricalPredictors',[1 2],'Verbose',2` specifies the first two predictor variables as categorical variables and specifies the verbosity level as 2.

`CategoricalPredictors` — List of categorical predictors

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

List of categorical predictors, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fscmrmr` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the names in `Tbl`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the names in `Tbl`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fscmrmr` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fscmrmr` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`ClassNames` — Names of classes to use for ranking

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of the classes to use for ranking, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell

array of character vectors. `ClassNames` must have the same data type as `Y` or the response variable in `Tbl`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `'ClassNames'` to:

- Specify the order of the `Prior` dimensions that corresponds to the class order.
- Select a subset of classes for ranking. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To rank predictors using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `'ClassNames'` is the set of all distinct class names in `Y` or the response variable in `Tbl`. The default `'ClassNames'` value has mathematical ordering if the response variable is ordinal. Otherwise, the default value has alphabetical ordering.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

`Prior` — Prior probabilities
`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as one of the following:

- Character vector or string scalar.
  - `'empirical'` determines class probabilities from class frequencies in the response variable in `Y` or `Tbl`. If you pass observation weights, `fscmrmr` uses the weights to compute the class probabilities.
  - `'uniform'` sets all class probabilities to be equal.
- Vector (one scalar value for each class). To specify the class order for the corresponding elements of `'Prior'`, set the `'ClassNames'` name-value argument.
- Structure `S` with two fields.
  - `S.ClassNames` contains the class names as a variable of the same type as the response variable in `Y` or `Tbl`.
  - `S.ClassProbs` contains a vector of corresponding probabilities.

`fscmrmr` normalizes the weights in each class (`'Weights'`) to add up to the value of the prior probability of the respective class.

Example: `'Prior','uniform'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`UseMissing` — Indicator for whether to use or discard missing values in predictors
`false` (default) | `true`

Indicator for whether to use or discard missing values in predictors, specified as the comma-separated pair consisting of `'UseMissing'` and either `true` to use or `false` to discard missing values in predictors for ranking.

`fscmrmr` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values to be missing values.

If you specify `'UseMissing',true`, then `fscmrmr` uses missing values for ranking. For a categorical variable, `fscmrmr` treats missing values as an extra category. For a continuous variable, `fscmrmr` places `NaN` values in a separate bin for binning.

If you specify `'UseMissing',false`, then `fscmrmr` does not use missing values for ranking. Because `fscmrmr` computes mutual information for each pair of variables, the function does not discard an entire row when values in the row are partially missing. `fscmrmr` uses all pair values that do not include missing values.

Example: `'UseMissing',true`

Data Types: `logical`

`Verbose` — Verbosity level
`0` (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. The value of `Verbose` controls the amount of diagnostic information that the software displays in the Command Window.

- 0 — `fscmrmr` does not display any diagnostic information.
- 1 — `fscmrmr` displays the elapsed times for computing “Mutual Information” on page 33-2482 and ranking predictors.
- ≥ 2 — `fscmrmr` displays the elapsed times and more messages related to computing mutual information. The amount of information increases as you increase the `'Verbose'` value.

Example: `'Verbose',1`

Data Types: `single` | `double`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values or the name of a variable in `Tbl`. The function weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weight vector is the column `W` of `Tbl` (`Tbl.W`), then specify `'Weights','W'`.

`fscmrmr` normalizes the weights in each class to add up to the value of the prior probability of the respective class.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`idx` — Indices of predictors ordered by predictor importance
numeric vector

Indices of predictors in `X` or `Tbl` ordered by predictor importance, returned as a 1-by-*r* numeric vector, where *r* is the number of ranked predictors.

If `fscmrmr` uses a subset of variables in `Tbl` as predictors, then the function indexes the predictors using only the subset. For example, suppose `Tbl` includes 10 columns and you specify the last five columns of `Tbl` as the predictor variables by using `formula`. If `idx(3)` is `5`, then the third most important predictor is the 10th column in `Tbl`, which is the fifth predictor in the subset.

`scores` — Predictor scores
numeric vector

Predictor scores, returned as a 1-by-*r* numeric vector, where *r* is the number of ranked predictors.

A large score value indicates that the corresponding predictor is important. Also, a drop in the feature importance score represents the confidence of feature selection. For example, if the software is confident of selecting a feature *x*, then the score value of the next most important feature is much smaller than the score value of *x*.

- If you use `X` to specify the predictors or use all the variables in `Tbl` as predictors, then the values in `scores` have the same order as the predictors in `X` or `Tbl`.
- If you specify a subset of variables in `Tbl` as predictors, then the values in `scores` have the same order as the subset.

For example, suppose `Tbl` includes 10 columns and you specify the last five columns of `Tbl` as the predictor variables by using `formula`. Then, `score(3)` contains the score value of the 8th column in `Tbl`, which is the third predictor in the subset.

More About

Mutual Information

The mutual information between two variables measures how much uncertainty of one variable can be reduced by knowing the other variable.

The mutual information I of the discrete random variables X and Z is defined as

$$I(X,Z) = \sum_{i,j} P\left(X = x_i, Z = z_j\right) \log \frac{P\left(X = x_i, Z = z_j\right)}{P(X = x_i) P\left(Z = z_j\right)}.$$

If X and Z are independent, then I equals 0. If X and Z are the same random variable, then I equals the entropy of X.

The `fscmrmr` function uses this definition to compute the mutual information values for both categorical (discrete) and continuous variables. `fscmrmr` discretizes a continuous variable into 256 bins or the number of unique values in the variable if it is less than 256. The function finds optimal bivariate bins for each pair of variables using the adaptive algorithm [2].

Algorithms

Minimum Redundancy Maximum Relevance (MRMR) Algorithm

The MRMR algorithm[1] finds an optimal set of features that is mutually and maximally dissimilar and can represent the response variable effectively. The algorithm minimizes the redundancy of a feature set and maximizing the relevance of a feature set to the response variable. The algorithm quantifies the redundancy and relevance using the mutual information of variables—pairwise mutual

information of features and mutual information of a feature and the response. You can use this algorithm for classification problems.

The goal of the MRMR algorithm is to find an optimal set S of features that maximizes V_S, the relevance of S with respect to a response variable y, and minimizes W_S, the redundancy of S, where V_S and W_S are defined with mutual information on page 33-2482 I:

$$V_S = \frac{1}{|S|}\sum_{x \in S} I(x, y),$$

$$W_S = \frac{1}{|S|^2}\sum_{x, z \in S} I(x, z)\,.$$

$|S|$ is the number of features in S.

Finding an optimal set S requires considering all $2^{|\Omega|}$ combinations, where Ω is the entire feature set. Instead, the MRMR algorithm ranks features through the forward addition scheme, which requires $O(|\Omega|\cdot|S|)$ computations, by using the mutual information quotient (MIQ) value.

$$\mathrm{MIQ}_x = \frac{V_x}{W_x},$$

where V_x and W_x are the relevance and redundancy of a feature, respectively:

$$V_x = I(x, y),$$

$$W_x = \frac{1}{|S|}\sum_{z \in S} I(x, z)\,.$$

The `fscmrmr` function ranks all features in Ω and returns `idx` (the indices of features ordered by feature importance) using the MRMR algorithm. Therefore, the computation cost becomes $O(|\Omega|^2)$. The function quantifies the importance of a feature using a heuristic algorithm and returns `score`. A large score value indicates that the corresponding predictor is important. Also, a drop in the feature importance score represents the confidence of feature selection. For example, if the software is confident of selecting a feature x, then the score value of the next most important feature is much smaller than the score value of x. You can use the outputs to find an optimal set S for a given number of features.

`fscmrmr` ranks features as follows:

1. Select the feature with the largest relevance, $\max_{x \in \Omega} V_x$. Add the selected feature to an empty set S.
2. Find the features with nonzero relevance and zero redundancy in the complement of S, S^c.
   - If S^c does not include a feature with nonzero relevance and zero redundancy, go to step 4.
   - Otherwise, select the feature with the largest relevance, $\max_{x \in S^C,\, W_X = 0} V_x$. Add the selected feature to the set S.
3. Repeat Step 2 until the redundancy is not zero for all features in S^c.
4. Select the feature that has the largest MIQ value with nonzero relevance and nonzero redundancy in S^c, and add the selected feature to the set S.

$$\max_{x \in S^c} \mathrm{MIQ}_x = \max_{x \in S^c} \frac{I(x, y)}{\frac{1}{|S|}\sum_{z \in S} I(x, z)}\,.$$

5 Repeat Step 4 until the relevance is zero for all features in S^c.

6 Add the features with zero relevance to S in random order.

The software can skip any step if it cannot find a feature that satisfies the conditions described in the step.

Compatibility Considerations

Specify `'UseMissing',true` to use missing values in predictors for ranking

Behavior changed in R2020a

Starting in R2020a, you can specify whether to use or discard missing values in predictors for ranking by using the `'UseMissing'` name-value pair argument. The default value of `'UseMissing'` is `false` because most classification training functions in Statistics and Machine Learning Toolbox do not use missing values for training.

In R2019b, `fscmrmr` used missing values in predictors by default. To update your code, specify `'UseMissing',true`.

Topics

“Introduction to Feature Selection” on page 15-49
“Sequential Feature Selection” on page 15-61

Introduced in R2019b

fscnca

Feature selection using neighborhood component analysis for classification

Syntax

```
mdl = fscnca(X,Y)
mdl = fscnca(X,Y,Name,Value)
```

Description

`mdl = fscnca(X,Y)` performs feature selection for classification using the predictors in `X` and responses in `Y`.

`fscnca` learns the feature weights by using a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

`mdl = fscnca(X,Y,Name,Value)` performs feature selection for classification with additional options specified by one or more name-value pair arguments.

Examples

Detect Relevant Features in Data Using NCA for Classification

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

```
rng(0,'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = -ones(N,1);
y(X(:,3).*X(:,9)./X(:,15) < 0.4) = 1;
```

Fit the neighborhood component analysis model for classification.

```
mdl = fscnca(X,y,'Solver','sgd','Verbose',1);
```

```

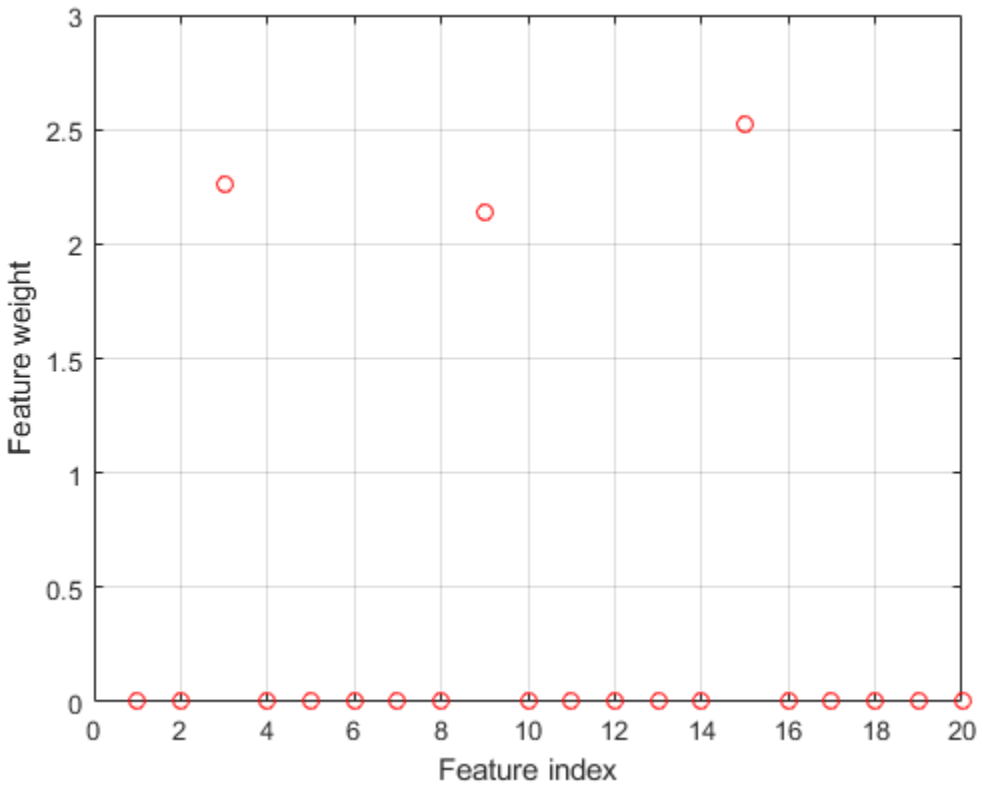
Relative two norm of the final step = 6.588e-02, TolX = 1.000e-06
EXIT: Iteration or pass limit reached.
```

Plot the selected features. The weights of the irrelevant features should be close to zero.

```
figure()
plot(mdl.FeatureWeights,'ro')
grid on
xlabel('Feature index')
ylabel('Feature weight')
```



`fscnca` correctly detects the relevant features.

Identify Relevant Features for Classification

Load sample data

```
load ovariancancer;
whos
```

```
  Name        Size                Bytes  Class     Attributes

  grp       216x1                 25056  cell
  obs       216x4000            3456000  single
```

This example uses the high-resolution ovarian cancer data set that was generated using the WCX2 protein array. After some preprocessing steps, the data set has two variables: `obs` and `grp`. The `obs` variable consists 216 observations with 4000 features. Each element in `grp` defines the group to which the corresponding row of `obs` belongs.

Divide data into training and test sets

Use `cvpartition` to divide data into a training set of size 160 and a test set of size 56. Both the training set and the test set have roughly the same group proportions as in `grp`.

```
rng(1); % For reproducibility
cvp = cvpartition(grp,'holdout',56)

cvp =
Hold-out cross validation partition
   NumObservations: 216
       NumTestSets: 1
         TrainSize: 160
          TestSize: 56

Xtrain = obs(cvp.training,:);
ytrain = grp(cvp.training,:);
Xtest  = obs(cvp.test,:);
ytest  = grp(cvp.test,:);
```

Determine if feature selection is necessary

Compute generalization error without fitting.

```
nca = fscnca(Xtrain,ytrain,'FitMethod','none');
L = loss(nca,Xtest,ytest)

L = 0.0893
```

This option computes the generalization error of the neighborhood component analysis (NCA) feature selection model using the initial feature weights (in this case the default feature weights) provided in `fscnca`.

Fit NCA without regularization parameter (Lambda = 0)

```
nca = fscnca(Xtrain,ytrain,'FitMethod','exact','Lambda',0,...
      'Solver','sgd','Standardize',true);
L = loss(nca,Xtest,ytest)

L = 0.0714
```

The improvement on the loss value suggests that feature selection is a good idea. Tuning the λ value usually improves the results.

Tune the regularization parameter for NCA using five-fold cross-validation

Tuning λ means finding the λ value that produces the minimum classification loss. To tune λ using cross-validation:

1. Partition the training data into five folds and extract the number of validation (test) sets. For each fold, `cvpartition` assigns four-fifths of the data as a training set, and one-fifth of the data as a test set.

```
cvp = cvpartition(ytrain,'kfold',5);
numvalidsets = cvp.NumTestSets;
```

Assign λ values and create an array to store the loss function values.

```
n = length(ytrain);
lambdavals = linspace(0,20,20)/n;
lossvals = zeros(length(lambdavals),numvalidsets);
```

2. Train the NCA model for each λ value, using the training set in each fold.

3. Compute the classification loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this process for all λ values.

```
for i = 1:length(lambdavals)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fscnca(X,y,'FitMethod','exact', ...
             'Solver','sgd','Lambda',lambdavals(i), ...
             'IterationLimit',30,'GradientTolerance',1e-4, ...
             'Standardize',true);

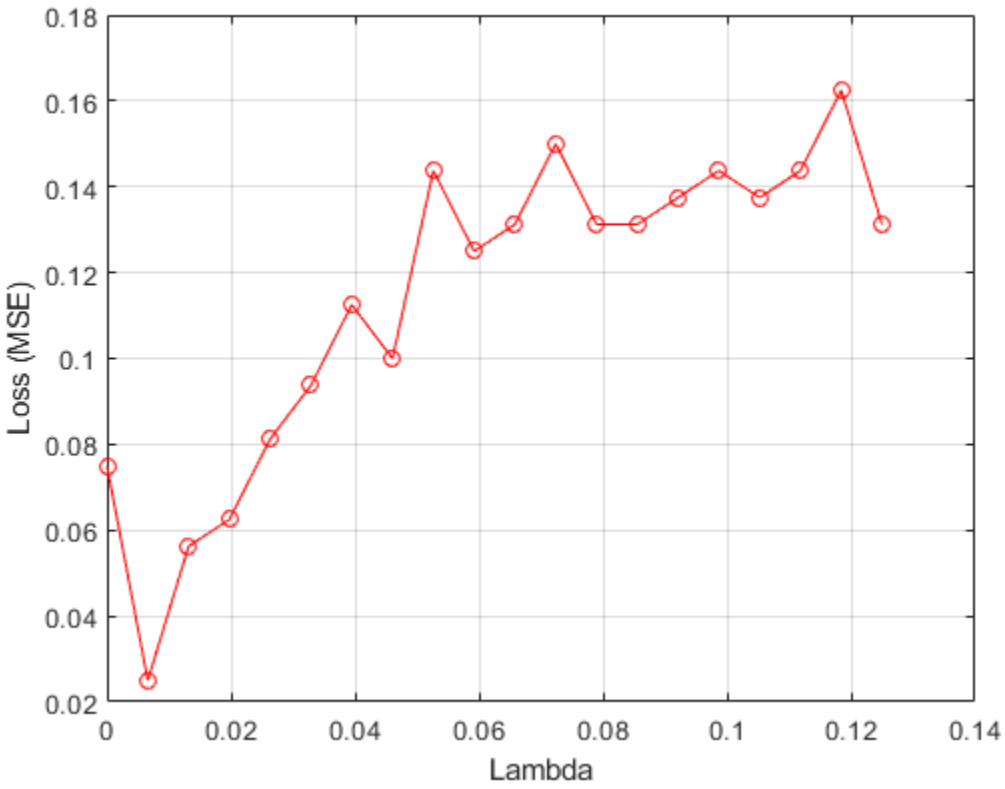
        lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','classiferror');
    end
end
```

Compute the average loss obtained from the folds for each λ value.

```
meanloss = mean(lossvals,2);
```

Plot the average loss values versus the λ values.

```
figure()
plot(lambdavals,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```



Find the best lambda value that corresponds to the minimum average loss.

```
[~,idx] = min(meanloss) % Find the index
```

```
idx = 2
```

```
bestlambda = lambdavals(idx) % Find the best lambda value
```

```
bestlambda = 0.0066
```

```
bestloss = meanloss(idx)
```

```
bestloss = 0.0250
```

Fit the nca model on all data using best λ and plot the feature weights

Use the solver lbfgs and standardize the predictor values.

```
nca = fscnca(Xtrain,ytrain,'FitMethod','exact','Solver','sgd',...
    'Lambda',bestlambda,'Standardize',true,'Verbose',1);
```

```

Input Arguments

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: `single` | `double`

Y — Class labels

categorical vector | logical vector | numeric vector | string array | cell array of character vectors of length *n* | character matrix with *n* rows

Class labels, specified as a categorical vector, logical vector, numeric vector, string array, cell array of character vectors of length *n*, or character matrix with *n* rows, where *n* is the number of observations. Element *i* or row *i* of `Y` is the class label corresponding to row *i* of `X` (observation *i*).

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Solver','sgd','Weights',W,'Lambda',0.0003` specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector `W`, and sets the regularization parameter at 0.0003.

Fitting Options

`FitMethod` — Method for fitting the model

`'exact'` (default) | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following:

- `'exact'` — Performs fitting using all of the data.
- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to fscnca.

- `'average'` — Divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: `'FitMethod','none'`

`NumPartitions` — Number of partitions
`max(2,min(10,n))` (default) | integer between 2 and *n*

Number of partitions to split the data for using with `'FitMethod','average'` option, specified as the comma-separated pair consisting of `'NumPartitions'` and an integer value between 2 and *n*, where *n* is the number of observations.

Example: `'NumPartitions',15`

Data Types: `double` | `single`

`Lambda` — Regularization parameter
1/*n* (default) | nonnegative scalar

Regularization parameter to prevent overfitting, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

As the number of observations *n* increases, the chance of overfitting decreases and the required amount of regularization also decreases. See “Identify Relevant Features for Classification” on page 33-2487 and “Tune Regularization Parameter to Detect Features Using NCA for Classification” on page 15-210 to learn how to tune the regularization parameter.

Example: `'Lambda',0.002`

Data Types: `double` | `single`

`LengthScale` — Width of the kernel
1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of `'LengthScale'` and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in `X` are of very different magnitudes, then consider standardizing the predictor values using `'Standardize',true` and setting `'LengthScale',1`.

Example: `'LengthScale',1.5`

Data Types: `double` | `single`

`InitialFeatureWeights` — Initial feature weights
`ones(p,1)` (default) | *p*-by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of `'InitialFeatureWeights'` and a *p*-by-1 vector of real positive scalars, where *p* is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1 generally works well, but in some cases, random initialization using `rand(p,1)` can give better quality solutions.

Data Types: `double` | `single`

`Weights` — Observation weights
n-by-1 vector of 1s (default) | *n*-by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of `'ObservationWeights'` and an *n*-by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: `double` | `single`

`Prior` — Prior probabilities for each class
`'empirical'` (default) | `'uniform'` | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following:

- `'empirical'` — `fscnca` obtains the prior class probabilities from class frequencies.
- `'uniform'` — `fscnca` sets all class probabilities equal.
- Structure with two fields:
  - `ClassProbs` — Vector of class probabilities. If these are numeric values with a total greater than 1, `fsnca` normalizes them to add up to 1.
  - `ClassNames` — Class names corresponding to the class probabilities in `ClassProbs`.

Example: `'Prior','uniform'`

`Standardize` — Indicator for standardizing predictor data
`false` (default) | `true`

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and either `false` or `true`. For more information, see “Impact of Standardization” on page 15-102.

Example: `'Standardize',true`

Data Types: `logical`

`Verbose` — Verbosity level indicator
0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of `'Verbose'` and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- > 1 — More convergence information, depending on the fitting algorithm

  When using `'minibatch-lbfgs'` solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: `'Verbose',1`

Data Types: `double` | `single`

`Solver` — Solver type
`'lbfgs'` | `'sgd'` | `'minibatch-lbfgs'`

Solver type for estimating feature weights, specified as the comma-separated pair consisting of `'Solver'` and one of the following:

- `'lbfgs'` — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- `'sgd'` — Stochastic gradient descent (SGD) algorithm
- `'minibatch-lbfgs'` — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is `'lbfgs'` for $n \le 1000$, and `'sgd'` for $n > 1000$.

Example: `'solver','minibatch-lbfgs'`

`LossFunction` — Loss function
`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFunction'` and one of the following.

- `'classiferror'` — Misclassification error

  $$l(y_i, y_j) = \begin{cases} 1 & \text{if } y_i \neq y_j, \\ 0 & \text{otherwise.} \end{cases}$$

- `@lossfun` — Custom loss function handle. A loss function has this form.

  ```
  function L = lossfun(Yu,Yv)
  % calculation of loss
  ...
  ```

  `Yu` is a u-by-1 vector and `Yv` is a v-by-1 vector. `L` is a u-by-v matrix of loss values such that `L(i,j)` is the loss value for `Yu(i)` and `Yv(j)`.

The objective function for minimization includes the loss function $l(y_i,y_j)$ as follows:

$$f(w) = \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1, j \neq i}^{n} p_{ij} l(y_i, y_j) + \lambda \sum_{r=1}^{p} w_r^2,$$

where w is the feature weight vector, n is the number of observations, and p is the number of predictor variables. p_{ij} is the probability that x_j is the reference point for x_i. For details, see “NCA Feature Selection for Classification” on page 15-99.

Example: `'LossFunction',@lossfun`

`CacheSize` — Memory size
`1000MB` (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of `'CacheSize'` and an integer.

Example: `'CacheSize',1500MB`

Data Types: `double` | `single`

LBFGS Options

`HessianHistorySize` — Size of history buffer for Hessian approximation
`15` (default) | positive integer

Size of history buffer for Hessian approximation for the `'lbfgs'` solver, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. At each iteration the function uses the most recent `HessianHistorySize` iterations to build an approximation to the inverse Hessian.

Example: `'HessianHistorySize',20`

Data Types: `double` | `single`

`InitialStepSize` — Initial step size
`'auto'` (default) | positive real scalar

Initial step size for the `'lbfgs'` solver, specified as the comma-separated pair consisting of `'InitialStepSize'` and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: `double` | `single`

`LineSearchMethod` — Line search method
`'weakwolfe'` (default) | `'strongwolfe'` | `'backtracking'`

Line search method, specified as the comma-separated pair consisting of `'LineSearchMethod'` and one of the following:

- `'weakwolfe'` — Weak Wolfe line search
- `'strongwolfe'` — Strong Wolfe line search
- `'backtracking'` — Backtracking line search

Example: `'LineSearchMethod','backtracking'`

`MaxLineSearchIterations` — Maximum number of line search iterations
`20` (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of `'MaxLineSearchIterations'` and a positive integer.

Example: `'MaxLineSearchIterations',25`

Data Types: `double` | `single`

`GradientTolerance` — Relative convergence tolerance
`1e-6` (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver `lbfgs`, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive real scalar.

Example: `'GradientTolerance',0.000002`

Data Types: `double` | `single`

SGD Options

`InitialLearningRate` — Initial learning rate for `'sgd'` solver
`'auto'` (default) | positive real scalar

Initial learning rate for the `'sgd'` solver, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive real scalar.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

The default `'auto'` means that the initial learning rate is determined using experiments on small subsets of data. Use the `NumTuningIterations` name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the `TuningSubsetSize` name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type `'minibatch-lbfgs'`, you can set `'InitialLearningRate'` to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the `Iteration` versus the `Objective` values saved in the `mdl.FitInfo` property.

You can use the `refit` method with `'InitialFeatureWeights'` equal to `mdl.FeatureWeights` to start from the current solution and run additional iterations

Example: `'InitialLearningRate',0.9`

Data Types: `double` | `single`

`MiniBatchSize` — Number of observations to use in each batch for the `'sgd'` solver
min(10,*n*) (default) | positive integer value from 1 to *n*

Number of observations to use in each batch for the `'sgd'` solver, specified as the comma-separated pair consisting of `'MiniBatchSize'` and a positive integer from 1 to *n*.

Example: `'MiniBatchSize',25`

Data Types: `double` | `single`

`PassLimit` — Maximum number of passes for solver `'sgd'`
5 (default) | positive integer

Maximum number of passes through all *n* observations for solver `'sgd'`, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer. Each pass through all of the data is called an epoch.

Example: `'PassLimit',10`

Data Types: `double` | `single`

`NumPrint` — Frequency of batches for displaying convergence summary
10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the `'sgd'` solver , specified as the comma-separated pair consisting of `'NumPrint'` and a positive integer. This argument applies when

the `'Verbose'` value is greater than 0. `NumPrint` mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: `'NumPrint',5`

Data Types: `double` | `single`

`NumTuningIterations` — Number of tuning iterations
20 (default) | positive integer

Number of tuning iterations for the `'sgd'` solver, specified as the comma-separated pair consisting of `'NumTuningIterations'` and a positive integer. This option is valid only for `'InitialLearningRate','auto'`.

Example: `'NumTuningIterations',15`

Data Types: `double` | `single`

`TuningSubsetSize` — Number of observations to use for tuning initial learning rate
min(100,*n*) (default) | positive integer value from 1 to *n*

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of `'TuningSubsetSize'` and a positive integer value from 1 to *n*. This option is valid only for `'InitialLearningRate','auto'`.

Example: `'TuningSubsetSize',25`

Data Types: `double` | `single`

SGD or LBFGS Options

`IterationLimit` — Maximum number of iterations
positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into *k* mini-batches, then every epoch is equivalent to *k* iterations.

Example: `'IterationLimit',250`

Data Types: `double` | `single`

`StepTolerance` — Convergence tolerance on the step size
1e-6 (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of `'StepTolerance'` and a positive real scalar. The `'lbfgs'` solver uses an absolute step tolerance, and the `'sgd'` solver uses a relative step tolerance.

Example: `'StepTolerance',0.000005`

Data Types: `double` | `single`

Mini-Batch LBFGS Options

`MiniBatchLBFGSIterations` — Maximum number of iterations per mini-batch LBFGS step
10 (default) | positive integer

Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of `'MiniBatchLBFGSIterations'` and a positive integer.

Example: `'MiniBatchLBFGSIterations',15`

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: `double` | `single`

Output Arguments

`mdl` — Neighborhood component analysis model for classification

`FeatureSelectionNCAClassification` object

Neighborhood component analysis model for classification, returned as a `FeatureSelectionNCAClassification` object.

Introduced in R2016b

fsrnca

Feature selection using neighborhood component analysis for regression

Syntax

```
mdl = fsrnca(X,Y)
mdl = fsrnca(X,Y,Name,Value)
```

Description

`mdl = fsrnca(X,Y)` performs feature selection for regression using the predictors in `X` and responses in `Y`.

`fsrnca` learns the feature weights by a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

`mdl = fsrnca(X,Y,Name,Value)` performs feature selection for regression with additional options specified by one or more name-value pair arguments.

Examples

Detect Relevant Features in Data Using NCA for Regression

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

```
rng(0,'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = 1 + X(:,3)*5 + sin(X(:,9)./X(:,15) + 0.25*randn(N,1));
```

Fit the neighborhood component analysis model for regression.

```
mdl = fsrnca(X,y,'Verbose',1,'Lambda',0.5/N);
```

```
 o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

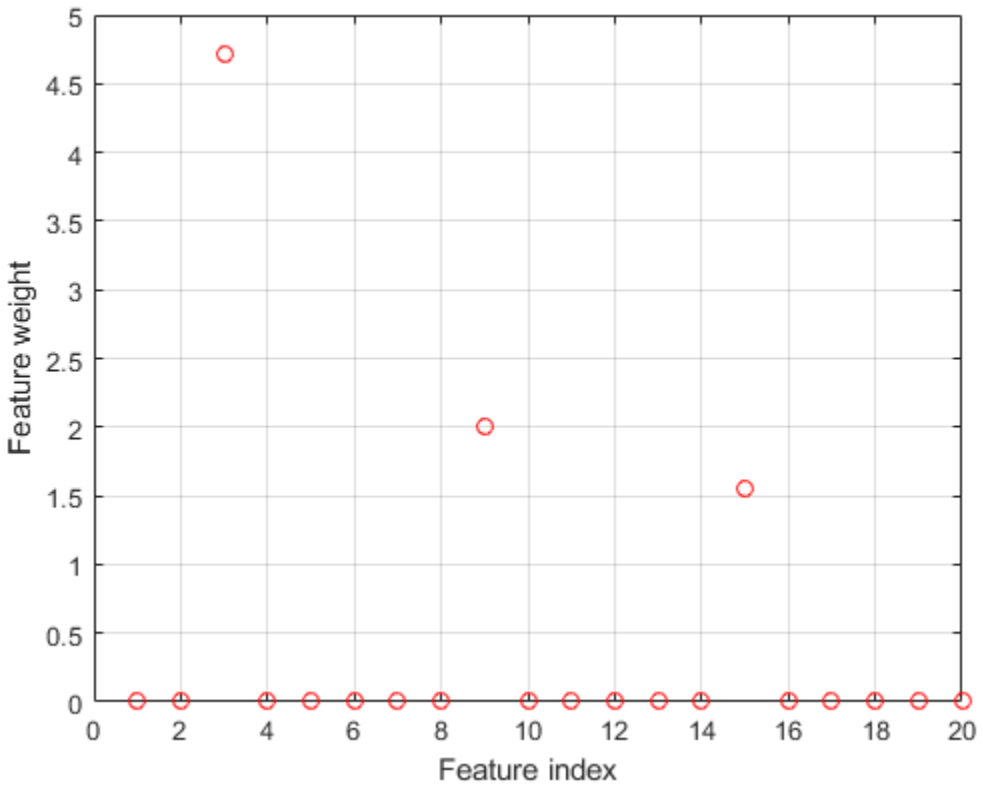
         Infinity norm of the final gradient = 2.596e-07
             Two norm of the final step     = 1.111e-04, TolX   = 1.000e-06
Relative infinity norm of the final gradient = 2.596e-07, TolFun = 1.000e-06
EXIT: Local minimum found.
```

Plot the selected features. The weights of the irrelevant features should be close to zero.

```
figure()
plot(mdl.FeatureWeights,'ro')
grid on
xlabel('Feature index')
ylabel('Feature weight')
```



`fsrnca` correctly detects the relevant predictors for this response.

Tune Regularization Parameter in NCA for Regression

Load the sample data.

```
load robotarm.mat
```

The `robotarm` (pumadyn32nm) dataset is created using a robot arm simulator with 7168 training observations and 1024 test observations with 32 features [1][2]. This is a preprocessed version of the original data set. The data are preprocessed by subtracting off a linear regression fit, followed by normalization of all features to unit variance.

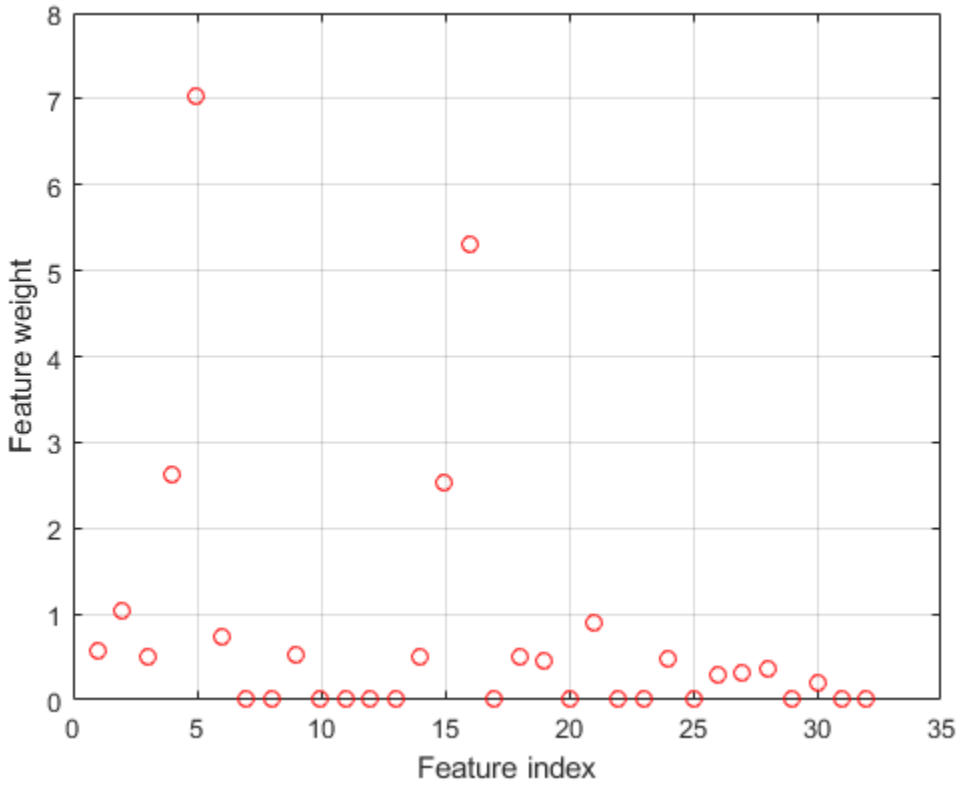
Perform neighborhood component analysis (NCA) feature selection for regression with the default λ (regularization parameter) value.

```
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...
    'Solver','lbfgs');
```

Plot the selected values.

```
figure
plot(nca.FeatureWeights,'ro')
xlabel('Feature index')
```

```
ylabel('Feature weight')
grid on
```



More than half of the feature weights are nonzero. Compute the loss using the test set as a measure of the performance by using the selected features.

```
L = loss(nca,Xtest,ytest)
```

```
L = 0.0837
```

Try improving the performance. Tune the regularization parameter λ for feature selection using five-fold cross-validation. Tuning λ means finding the λ value that produces the minimum regression loss. To tune λ using cross-validation:

1. Partition the data into five folds. For each fold, `cvpartition` assigns 4/5th of the data as a training set, and 1/5th of the data as a test set.

```
rng(1) % For reproducibility
n = length(ytrain);
cvp = cvpartition(length(ytrain),'kfold',5);
numvalidsets = cvp.NumTestSets;
```

Assign the λ values for the search. Multiplying response values by a constant increases the loss function term by a factor of the constant. Therefore, including the `std(ytrain)` factor in the λ values balances the default loss function (`'mad'`, mean absolute deviation) term and the regularization term in the objective function. In this example, the `std(ytrain)` factor is one because the loaded sample data is a preprocessed version of the original data set.

```
lambdavals = linspace(0,50,20)*std(ytrain)/n;
```

Create an array to store the loss values.

```
lossvals = zeros(length(lambdavals),numvalidsets);
```

2. Train the NCA model for each λ value, using the training set in each fold.

3. Compute the regression loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this for each λ value and each fold.

```
for i = 1:length(lambdavals)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fsrnca(X,y,'FitMethod','exact', ...
             'Solver','minibatch-lbfgs','Lambda',lambdavals(i), ...
             'GradientTolerance',1e-4,'IterationLimit',30);

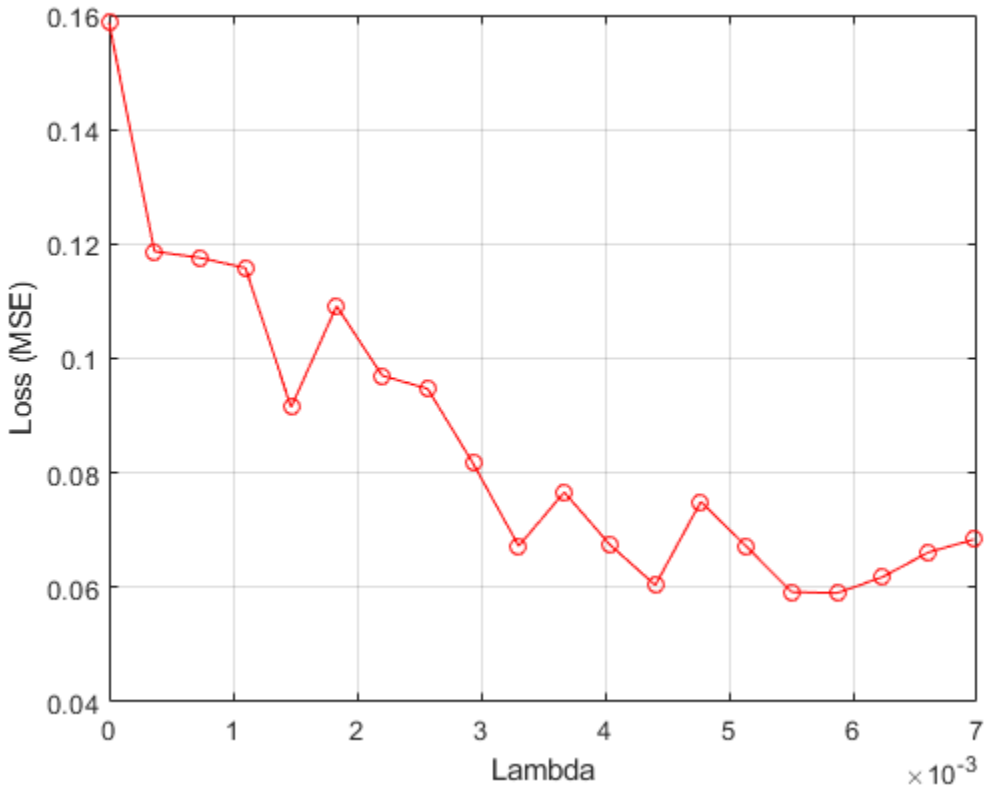
        lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','mse');
    end
end
```

Compute the average loss obtained from the folds for each λ value.

```
meanloss = mean(lossvals,2);
```

Plot the mean loss versus the λ values.

```
figure
plot(lambdavals,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```



Find the λ value that gives the minimum loss value.

```
[~,idx] = min(meanloss)
```

```
idx = 17
```

```
bestlambda = lambdavals(idx)
```

```
bestlambda = 0.0059
```

```
bestloss = meanloss(idx)
```

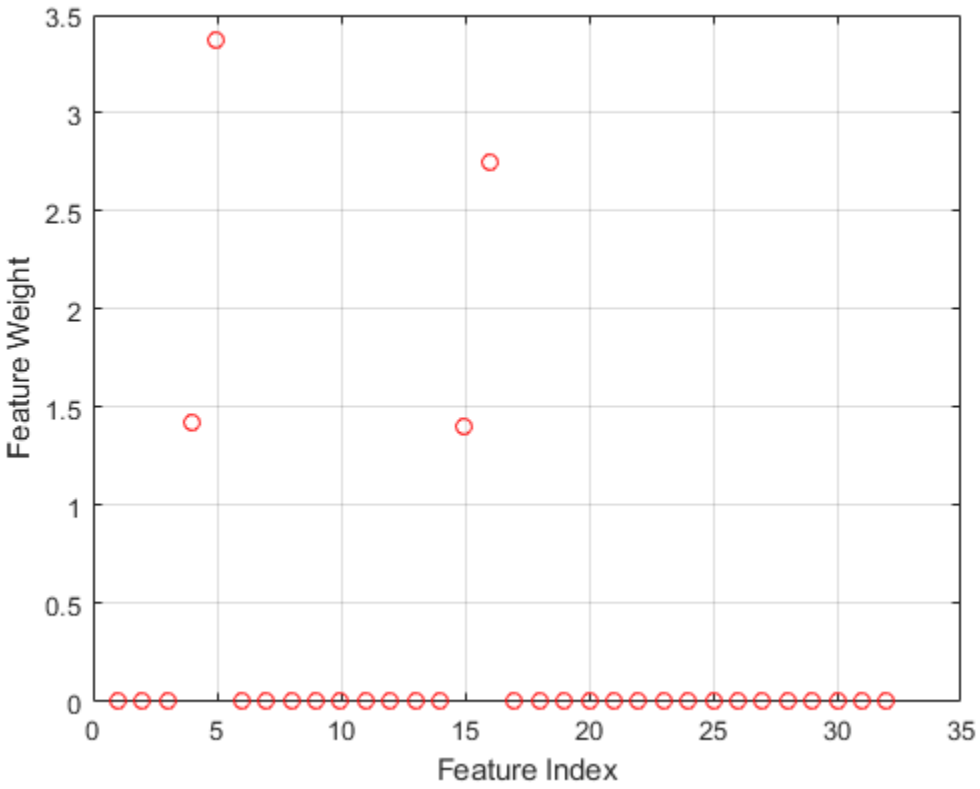
```
bestloss = 0.0590
```

Fit the NCA feature selection model for regression using the best λ value.

```
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...
    'Solver','lbfgs','Lambda',bestlambda);
```

Plot the selected features.

```
figure
plot(nca.FeatureWeights,'ro')
xlabel('Feature Index')
ylabel('Feature Weight')
grid on
```



Most of the feature weights are zero. `fsrnca` identifies the four most relevant features.

Compute the loss for the test set.

```
L = loss(nca,Xtest,ytest)
```

```
L = 0.0571
```

Tuning the regularization parameter, λ, eliminated more of the irrelevant features and improved the performance.

Compare NCA and ARD Feature Selection

This example uses the Abalone data [3][4] from the UCI Machine Learning Repository [5]. Download the data and save it in your current folder with the name `'abalone.data'`.

Store the data into a table. Display the first seven rows.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height', ...
    'WWeight','SWeight','VWeight','ShWeight','NoShellRings'};
tbl(1:7,:)
```

```
ans=7×9 table
     Sex      Length     Diameter     Height     WWeight     SWeight     VWeight     ShWeight     NoShel
```

```
_____    ______    ________    ______    _______    _______    _______    ________    _____

{'M'}    0.455      0.365      0.095      0.514      0.2245      0.101       0.15        15
{'M'}     0.35      0.265       0.09     0.2255      0.0995     0.0485       0.07         7
{'F'}     0.53       0.42      0.135      0.677      0.2565     0.1415       0.21         9

{'I'}     0.33      0.255       0.08      0.205      0.0895     0.0395      0.055         7
{'I'}    0.425        0.3      0.095     0.3515       0.141     0.0775       0.12         8
{'F'}     0.53      0.415       0.15     0.7775       0.237     0.1415       0.33        20
```

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, the number of shell rings, shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Prepare the predictor and response variables for `fsrnca`. The last column of `tbl` contains the number of shell rings, which is the response variable. The first predictor variable, sex, is categorical. You must create dummy variables.

```
y = table2array(tbl(:,end));
X(:,1:3) = dummyvar(categorical(tbl.Sex));
X = [X,table2array(tbl(:,2:end-1))];
```

Use four-fold cross-validation to tune the regularization parameter in the NCA model. First partition the data into four folds.

```
rng('default') % For reproducibility
n = length(y);
cvp = cvpartition(n,'kfold',4);
numtestsets = cvp.NumTestSets;
```

`cvpartition` divides the data into four partitions (folds). In each fold, about three-fourths of the data is assigned as a training set and one-fourth is assigned as a test set.

Generate a variety of λ (regularization parameter) values for fitting the model to determine the best λ value. Create a vector to collect the loss values from each fit.

```
lambdavals = linspace(0,25,20)*std(y)/n;
lossvals = zeros(length(lambdavals),numtestsets);
```

The rows of `lossvals` corresponds to the λ values and the columns correspond to the folds.

Fit the NCA model for regression using `fsrnca` to the data from each fold using each λ value. Compute the loss for each model using the test data from each fold.

```
for i = 1:length(lambdavals)
   for k = 1:numtestsets
       Xtrain = X(cvp.training(k),:);
       ytrain = y(cvp.training(k),:);
       Xtest = X(cvp.test(k),:);
       ytest = y(cvp.test(k),:);

       nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...
                 'Solver','lbfgs','Lambda',lambdavals(i),'Standardize',true);

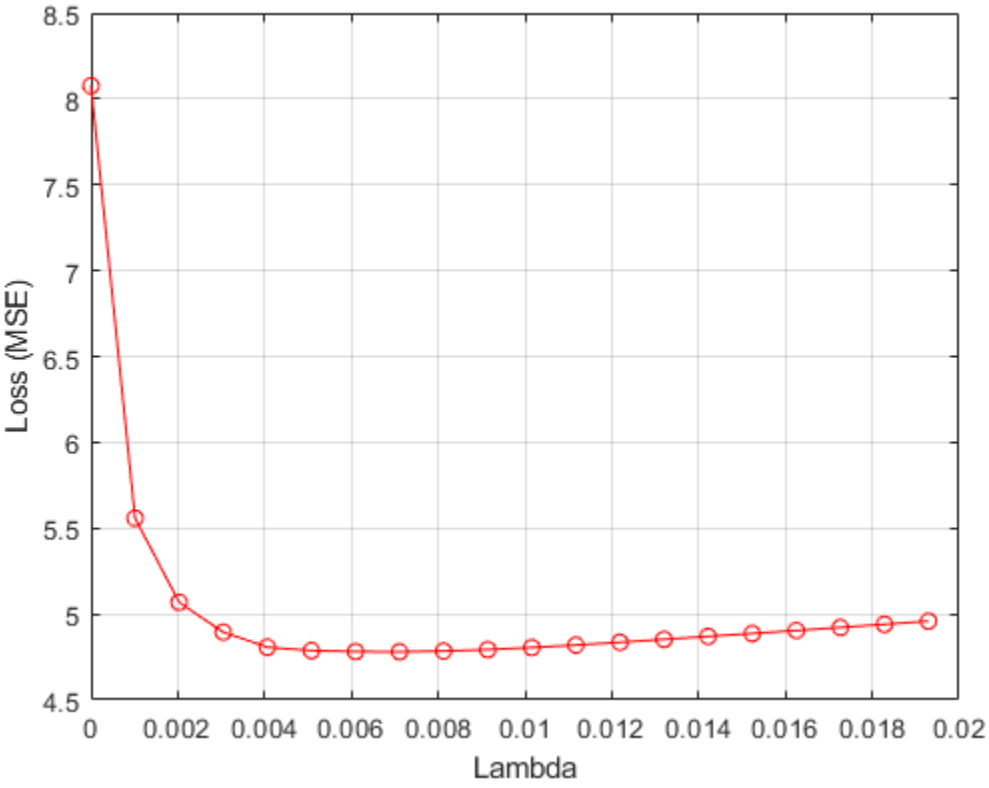
       lossvals(i,k) = loss(nca,Xtest,ytest,'LossFunction','mse');
    end
end
```

Compute the average loss for the folds, that is, compute the mean in the second dimension of `lossvals`.

```
meanloss = mean(lossvals,2);
```

Plot the λ values versus the mean loss from the four folds.

```
figure
plot(lambdavals,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```



Find the λ value that minimizes the mean loss.

```
[~,idx] = min(meanloss);
bestlambda = lambdavals(idx)
```

```
bestlambda = 0.0071
```

Compute the best loss value.

```
bestloss = meanloss(idx)
```

```
bestloss = 4.7799
```

Fit the NCA model on all of the data using the best λ value.

```
nca = fsrnca(X,y,'FitMethod','exact','Solver','lbfgs', ...
    'Verbose',1,'Lambda',bestlambda,'Standardize',true);
```

```
 o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

  Properties, Methods
```

Compute the regression loss on the training data (resubstitution loss) for the trained model.

```
L = resubLoss(gprMdl)
```

```
L = 4.0306
```

The smallest cross-validated loss using `fsrnca` is comparable to the loss obtained using a GPR model with an ARD kernel.

Input Arguments

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: `single` | `double`

Y — Response values

numeric real vector of length *n*

Response values, specified as a numeric real vector of length *n*, where *n* is the number of observations.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Solver','sgd','Weights',W,'Lambda',0.0003` specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector `W`, and sets the regularization parameter at 0.0003.

Fitting Options

FitMethod — Method for fitting the model

`'exact'` (default) | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following:

- `'exact'` — Performs fitting using all of the data.
- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to fsrnca.
- `'average'` — Divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: `'FitMethod','none'`

`NumPartitions` — Number of partitions
`max(2,min(10,n))` (default) | integer between 2 and *n*

Number of partitions to split the data for using with `'FitMethod','average'` option, specified as the comma-separated pair consisting of `'NumPartitions'` and an integer value between 2 and *n*, where *n* is the number of observations.

Example: `'NumPartitions',15`

Data Types: `double` | `single`

`Lambda` — Regularization parameter
1/*n* (default) | nonnegative scalar

Regularization parameter to prevent overfitting, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

As the number of observations *n* increases, the chance of overfitting decreases and the required amount of regularization also decreases. See “Tune Regularization Parameter in NCA for Regression” on page 33-2503 to learn how to tune the regularization parameter.

Example: `'Lambda',0.002`

Data Types: `double` | `single`

`LengthScale` — Width of the kernel
1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of `'LengthScale'` and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in `X` are of very different magnitudes, then consider standardizing the predictor values using `'Standardize',true` and setting `'LengthScale',1`.

Example: `'LengthScale',1.5`

Data Types: `double` | `single`

`InitialFeatureWeights` — Initial feature weights
`ones(p,1)` (default) | *p*-by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of `'InitialFeatureWeights'` and a *p*-by-1 vector of real positive scalars, where *p* is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1

generally works well, but in some cases, random initialization using `rand(p,1)` can give better quality solutions.

Data Types: `double` | `single`

`Weights` — Observation weights
n-by-1 vector of 1s (default) | *n*-by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of `'ObservationWeights'` and an *n*-by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: `double` | `single`

`Standardize` — Indicator for standardizing predictor data
`false` (default) | `true`

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and either `false` or `true`. For more information, see “Impact of Standardization” on page 15-102.

Example: `'Standardize',true`

Data Types: `logical`

`Verbose` — Verbosity level indicator
0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of `'Verbose'` and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- > 1 — More convergence information, depending on the fitting algorithm

  When using `'minibatch-lbfgs'` solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: `'Verbose',1`

Data Types: `double` | `single`

`Solver` — Solver type
`'lbfgs'` | `'sgd'` | `'minibatch-lbfgs'`

Solver type for estimating feature weights, specified as the comma-separated pair consisting of `'Solver'` and one of the following:

- `'lbfgs'` — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- `'sgd'` — Stochastic gradient descent (SGD) algorithm
- `'minibatch-lbfgs'` — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is `'lbfgs'` for $n \le 1000$, and `'sgd'` for $n > 1000$.

Example: `'solver','minibatch-lbfgs'`

`LossFunction` — Loss function

`'mad'` (default) | `'mse'` | `'epsiloninsensitive'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFunction'` and one of the following:

- `'mad'` — Mean absolute deviation

  $$l(y_i, y_j) = |y_i - y_j|.$$

- `'mse'` — Mean squared error

  $$l(y_i, y_j) = (y_i - y_j)^2.$$

- `'epsiloninsensitive'` — ε-insensitive loss function

  $$l(y_i, y_j) = \max(0, |y_i - y_j| - \epsilon).$$

  This loss function is more robust to outliers than mean squared error or mean absolute deviation.

- `@lossfun` — Custom loss function handle. A loss function has this form.

  ```
  function L = lossfun(Yu,Yv)
  % calculation of loss
  ...
  ```

  `Yu` is a *u*-by-1 vector and `Yv` is a *v*-by-1 vector. `L` is a *u*-by-*v* matrix of loss values such that `L(i,j)` is the loss value for `Yu(i)` and `Yv(j)`.

The objective function for minimization includes the loss function $l(y_i,y_j)$ as follows:

$$f(w) = \frac{1}{n}\sum_{i=1}^{n}\sum_{j=1, j\neq i}^{n} p_{ij} l(y_i, y_j) + \lambda \sum_{r=1}^{p} w_r^2,$$

where w is the feature weight vector, n is the number of observations, and p is the number of predictor variables. p_{ij} is the probability that x_j is the reference point for x_i. For details, see “NCA Feature Selection for Regression” on page 15-101.

Example: `'LossFunction',@lossfun`

`Epsilon` — Epsilon value

`iqr(Y)/13.49` (default) | nonnegative real scalar

Epsilon value for the `'LossFunction','epsiloninsensitive'` option, specified as the comma-separated pair consisting of `'LossFunction'` and a nonnegative real scalar. The default value is an estimate of the sample standard deviation using the interquartile range of the response variable.

Example: `'Epsilon',0.1`

Data Types: `double` | `single`

`CacheSize` — Memory size

`1000MB` (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of `'CacheSize'` and an integer.

Example: `'CacheSize',1500MB`

Data Types: `double` | `single`

LBFGS Options

`HessianHistorySize` — Size of history buffer for Hessian approximation
`15` (default) | positive integer

Size of history buffer for Hessian approximation for the `'lbfgs'` solver, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. At each iteration the function uses the most recent `HessianHistorySize` iterations to build an approximation to the inverse Hessian.

Example: `'HessianHistorySize',20`

Data Types: `double` | `single`

`InitialStepSize` — Initial step size
`'auto'` (default) | positive real scalar

Initial step size for the `'lbfgs'` solver, specified as the comma-separated pair consisting of `'InitialStepSize'` and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: `double` | `single`

`LineSearchMethod` — Line search method
`'weakwolfe'` (default) | `'strongwolfe'` | `'backtracking'`

Line search method, specified as the comma-separated pair consisting of `'LineSearchMethod'` and one of the following:

- `'weakwolfe'` — Weak Wolfe line search
- `'strongwolfe'` — Strong Wolfe line search
- `'backtracking'` — Backtracking line search

Example: `'LineSearchMethod','backtracking'`

`MaxLineSearchIterations` — Maximum number of line search iterations
`20` (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of `'MaxLineSearchIterations'` and a positive integer.

Example: `'MaxLineSearchIterations',25`

Data Types: `double` | `single`

`GradientTolerance` — Relative convergence tolerance
`1e-6` (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver `lbfgs`, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive real scalar.

Example: `'GradientTolerance',0.000002`

Data Types: `double` | `single`

SGD Options

`InitialLearningRate` — Initial learning rate for `'sgd'` solver
`'auto'` (default) | positive real scalar

Initial learning rate for the `'sgd'` solver, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive real scalar.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

The default `'auto'` means that the initial learning rate is determined using experiments on small subsets of data. Use the `NumTuningIterations` name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the `TuningSubsetSize` name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type `'minibatch-lbfgs'`, you can set `'InitialLearningRate'` to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the `Iteration` versus the `Objective` values saved in the `mdl.FitInfo` property.

You can use the `refit` method with `'InitialFeatureWeights'` equal to `mdl.FeatureWeights` to start from the current solution and run additional iterations

Example: `'InitialLearningRate',0.9`

Data Types: `double` | `single`

`MiniBatchSize` — Number of observations to use in each batch for the `'sgd'` solver
min(10,*n*) (default) | positive integer value from 1 to *n*

Number of observations to use in each batch for the `'sgd'` solver, specified as the comma-separated pair consisting of `'MiniBatchSize'` and a positive integer from 1 to *n*.

Example: `'MiniBatchSize',25`

Data Types: `double` | `single`

`PassLimit` — Maximum number of passes for solver `'sgd'`
5 (default) | positive integer

Maximum number of passes through all *n* observations for solver `'sgd'`, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer. Each pass through all of the data is called an epoch.

Example: `'PassLimit',10`

Data Types: `double` | `single`

`NumPrint` — Frequency of batches for displaying convergence summary
10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the `'sgd'` solver , specified as the comma-separated pair consisting of `'NumPrint'` and a positive integer. This argument applies when

the 'Verbose' value is greater than 0. NumPrint mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint',5

Data Types: double | single

NumTuningIterations — Number of tuning iterations
20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate','auto'.

Example: 'NumTuningIterations',15

Data Types: double | single

TuningSubsetSize — Number of observations to use for tuning initial learning rate
min(100,*n*) (default) | positive integer value from 1 to *n*

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of 'TuningSubsetSize' and a positive integer value from 1 to *n*. This option is valid only for 'InitialLearningRate','auto'.

Example: 'TuningSubsetSize',25

Data Types: double | single

SGD or LBFGS Options

IterationLimit — Maximum number of iterations
positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into *k* mini-batches, then every epoch is equivalent to *k* iterations.

Example: 'IterationLimit',250

Data Types: double | single

StepTolerance — Convergence tolerance on the step size
1e-6 (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive real scalar. The 'lbfgs' solver uses an absolute step tolerance, and the 'sgd' solver uses a relative step tolerance.

Example: 'StepTolerance',0.000005

Data Types: double | single

Mini-batch LBFGS Options

MiniBatchLBFGSIterations — Maximum number of iterations per mini-batch LBFGS step
10 (default) | positive integer

Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of `'MiniBatchLBFGSIterations'` and a positive integer.

Example: `'MiniBatchLBFGSIterations',15`

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: `double` | `single`

Output Arguments

`mdl` — Neighborhood component analysis model for regression

`FeatureSelectionNCARegression` object

Neighborhood component analysis model for regression, returned as a `FeatureSelectionNCARegression` object.

Introduced in R2016b

fsrftest

Univariate feature ranking for regression using *F*-tests

Syntax

```
idx = fsrftest(Tbl,ResponseVarName)
idx = fsrftest(Tbl,formula)
idx = fsrftest(Tbl,Y)

idx = fsrftest(X,Y)

idx = fsrftest(___,Name,Value)
[idx,scores] = fsrftest(___)
```

Description

`idx = fsrftest(Tbl,ResponseVarName)` ranks features (predictors) using *F*-tests on page 33-2528. The table `Tbl` contains predictor variables and a response variable, and `ResponseVarName` is the name of the response variable in `Tbl`. The function returns `idx`, which contains the indices of predictors ordered by predictor importance, meaning `idx(1)` is the index of the most important predictor. You can use `idx` to select important predictors for regression problems.

`idx = fsrftest(Tbl,formula)` specifies a response variable and predictor variables to consider among the variables in `Tbl` by using `formula`.

`idx = fsrftest(Tbl,Y)` ranks predictors in `Tbl` using the response variable `Y`.

`idx = fsrftest(X,Y)` ranks predictors in `X` using the response variable `Y`.

`idx = fsrftest(___,Name,Value)` specifies additional options using one or more name-value pair arguments in addition to any of the input argument combinations in the previous syntaxes. For example, you can specify categorical predictors and observation weights.

`[idx,scores] = fsrftest(___)` also returns the predictor scores `scores`. A large score value indicates that the corresponding predictor is important.

Examples

Rank Predictors in Matrix

Rank predictors in a numeric matrix and create a bar plot of predictor importance scores.

Load the sample data.

```
load robotarm.mat
```

The `robotarm` data set contains 7168 training observations (`Xtrain` and `ytrain`) and 1024 test observations (`Xtest` and `ytest`) with 32 features [1][2].

Rank the predictors using the training observations.

```
[idx,scores] = fsrftest(Xtrain,ytrain);
```

The values in `scores` are the negative logs of the *p*-values. If a *p*-value is smaller than `eps(0)`, then the corresponding score value is `Inf`. Before creating a bar plot, determine whether `scores` includes `Inf` values.

```
find(isinf(scores))
```

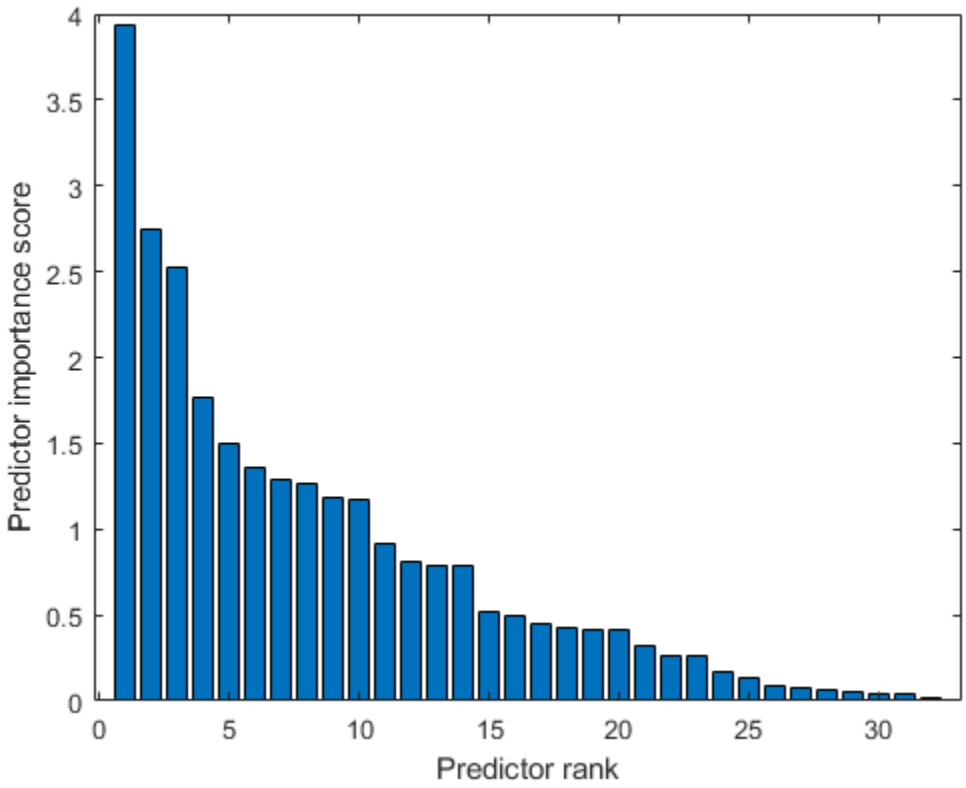
```
ans =

  1x0 empty double row vector
```

`scores` does not include `Inf` values. If `scores` includes `Inf` values, you can replace `Inf` by a large numeric number before creating a bar plot for visualization purposes. For details, see “Rank Predictors in Table” on page 33-2522.

Create a bar plot of the predictor importance scores.

```
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
```



Select the top five most important predictors. Find the columns of these predictors in `Xtrain`.

```
idx(1:5)
```

```
ans = 1×5
```

```
    30    24    10     4     5
```

The 30th column of `Xtrain` is the most important predictor of `ytrain`.

Rank Predictors in Table

Rank predictors in a table and create a bar plot of predictor importance scores.

If your data is in a table and `fsrftest` ranks a subset of the variables in the table, then the function indexes the variables using only the subset. Therefore, a good practice is to move the predictors that you do not want to rank to the end of the table. Move the response variable and observation weight vector as well. Then, the indexes of the output arguments are consistent with the indexes of the table. You can move variables in a table using the `movevars` function.

This example uses the Abalone data [3][4] from the UCI Machine Learning Repository [5]. Download the data and save it in your current folder with the name `'abalone.data'`.

Store the data in a table.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
tbl.Properties.VariableNames = {'Sex','Length','Diameter','Height', ...
    'WWeight','SWeight','VWeight','ShWeight','NoShellRings'};
```

Preview the first few rows of the table.

```
head(tbl)
```

```
ans=8×9 table
     Sex     Length    Diameter    Height    WWeight    SWeight    VWeight    ShWeight    NoShell
    _____    ______    ________    ______    _______    _______    _______    ________    _______

    {'M'}    0.455      0.365      0.095      0.514     0.2245      0.101       0.15          15
    {'M'}     0.35      0.265       0.09     0.2255     0.0995     0.0485       0.07           7
    {'F'}     0.53       0.42      0.135      0.677     0.2565     0.1415       0.21           9
    {'M'}     0.44      0.365      0.125      0.516     0.2155      0.114      0.155          10
    {'I'}     0.33      0.255       0.08      0.205     0.0895     0.0395      0.055           7
    {'I'}    0.425        0.3      0.095     0.3515      0.141     0.0775       0.12           8
    {'F'}     0.53      0.415       0.15     0.7775      0.237     0.1415       0.33          20
    {'F'}    0.545      0.425      0.125      0.768      0.294     0.1495       0.26          16
```

The last variable in the table is a response variable.

Rank the predictors in `tbl`. Specify the last column `NoShellRings` as a response variable.

```
[idx,scores] = fsrftest(tbl,'NoShellRings')
```

```
idx = 1×8

     3     4     5     7     8     2     6     1

scores = 1×8
```

```
  447.6891  736.9619       Inf       Inf       Inf  604.6692       Inf       Inf
```

The values in `scores` are the negative logs of the *p*-values. If a *p*-value is smaller than `eps(0)`, then the corresponding score value is `Inf`. Before creating a bar plot, determine whether `scores` includes `Inf` values.

```
idxInf = find(isinf(scores))
```

```
idxInf = 1×5

     3     4     5     7     8
```

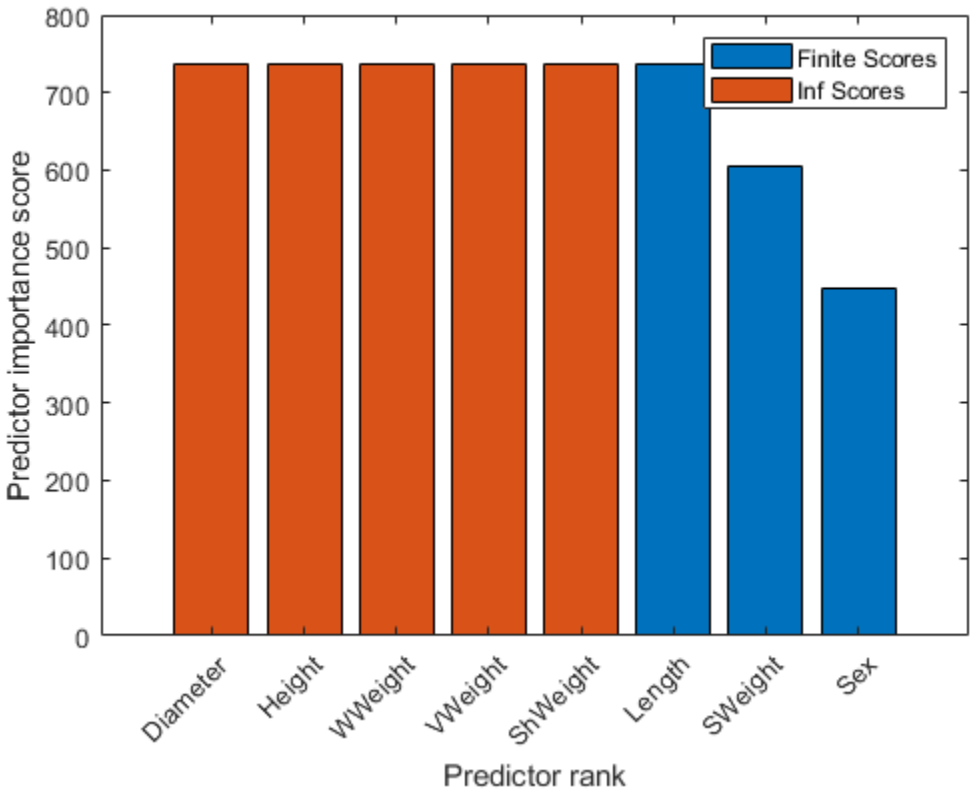
`scores` includes five `Inf` values.

Create a bar plot of predictor importance scores. Use the predictor names for the *x*-axis tick labels.

```
bar(scores(idx))
xlabel('Predictor rank')
ylabel('Predictor importance score')
xticklabels(strrep(tbl.Properties.VariableNames(idx),'_','\_'))
xtickangle(45)
```

The `bar` function does not plot any bars for the `Inf` values. For the `Inf` values, plot bars that have the same length as the largest finite score.

```
hold on
bar(scores(idx(length(idxInf)+1))*ones(length(idxInf),1))
legend('Finite Scores','Inf Scores')
hold off
```



The bar graph displays finite scores and Inf scores using different colors.

Input Arguments

`Tbl` — Sample data

table

Sample data, specified as a table. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain additional columns for a response variable and observation weights.

A response variable can be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element of the response variable must correspond to one row of the array.

- If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`. If `Tbl` also contains the observation weights, then you can specify the weights by using `Weights`.
- If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify the subset of variables by using `formula`.

- If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The response variable and `Tbl` must have the same number of rows.

If `fsrftest` uses a subset of variables in `Tbl` as predictors, then the function indexes the predictors using only the subset. The values in the `'CategoricalPredictors'` name-value pair argument and the output argument `idx` do not count the predictors that the function does not rank.

`fsrftest` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Tbl` for a response variable to be missing values. `fsrftest` does not use observations with missing values for a response variable.

Data Types: `table`

`ResponseVarName` — Response variable name
character vector or string scalar containing name of variable in `Tbl`

Response variable name, specified as a character vector or string scalar containing the name of a variable in `Tbl`.

For example, if a response variable is the column `Y` of `Tbl` (`Tbl.Y`), then specify `ResponseVarName` as `'Y'`.

Data Types: `char` | `string`

`formula` — Explanatory model of response variable and subset of predictor variables
character vector | string scalar

Explanatory model of the response variable and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y ~ x1 + x2 + x3'`. In this form, `Y` represents the response variable, and `x1`, `x2`, and `x3` represent the predictor variables.

To specify a subset of variables in `Tbl` as predictors, use a formula. If you specify a formula, then `fsrftest` does not rank any variables in `Tbl` that do not appear in `formula`.

The variable names in the formula must be both variable names in `Tbl` (`Tbl.Properties.VariableNames`) and valid MATLAB identifiers. You can verify the variable names in `Tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Data Types: `char` | `string`

`Y` — Response variable
numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response variable, specified as a numeric, categorical, or logical vector, a character or string array, or a cell array of character vectors. Each row of `Y` represents the labels of the corresponding row of `X`.

`fsrftest` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Y` to be missing values. `fsrftest` does not use observations with missing values for `Y`.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`X` — Predictor data
numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NumBins',20,'UseMissing',true` sets the number of bins as 20 and specifies to use missing values in predictors for ranking.

`CategoricalPredictors` — List of categorical predictors

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

List of categorical predictors, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `fsrftest` uses a subset of input variables as predictors, then the function indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the names in `Tbl`. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the names in `Tbl`.
`'all'`	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fsrftest` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix (`X`), `fsrftest` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`NumBins` — Number of bins for binning continuous predictors

10 (default) | positive integer scalar

Number of bins for binning continuous predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

Example: `'NumBins',50`

Data Types: `single` | `double`

`UseMissing` — Indicator for whether to use or discard missing values in predictors
`false` (default) | `true`

Indicator for whether to use or discard missing values in predictors, specified as the comma-separated pair consisting of `'UseMissing'` and either `true` to use or `false` to discard missing values in predictors for ranking.

`fsrftest` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values to be missing values.

If you specify `'UseMissing',true`, then `fsrftest` uses missing values for ranking. For a categorical variable, `fsrftest` treats missing values as an extra category. For a continuous variable, `fsrftest` places `NaN` values in a separate bin for binning.

If you specify `'UseMissing',false`, then `fsrftest` does not use missing values for ranking. Because `fsrftest` computes importance scores individually for each predictor, the function does not discard an entire row when values in the row are partially missing. For each variable, `fsrftest` uses all values that are not missing.

Example: `'UseMissing',true`

Data Types: `logical`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values or the name of a variable in `Tbl`. The function weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weight vector is the column `W` of `Tbl` (`Tbl.W`), then specify `'Weights','W'`.

`fsrftest` normalizes the weights to add up to one.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`idx` — Indices of predictors ordered by predictor importance
numeric vector

Indices of predictors in `X` or `Tbl` ordered by predictor importance, returned as a 1-by-*r* numeric vector, where *r* is the number of ranked predictors.

If `fsrftest` uses a subset of variables in `Tbl` as predictors, then the function indexes the predictors using only the subset. For example, suppose `Tbl` includes 10 columns and you specify the last five

columns of `Tbl` as the predictor variables by using `formula`. If `idx(3)` is `5`, then the third most important predictor is the 10th column in `Tbl`, which is the fifth predictor in the subset.

`scores` — Predictor scores
numeric vector

Predictor scores, returned as a 1-by-*r* numeric vector, where *r* is the number of ranked predictors.

A large score value indicates that the corresponding predictor is important.

- If you use `X` to specify the predictors or use all the variables in `Tbl` as predictors, then the values in `scores` have the same order as the predictors in `X` or `Tbl`.
- If you specify a subset of variables in `Tbl` as predictors, then the values in `scores` have the same order as the subset.

For example, suppose `Tbl` includes 10 columns and you specify the last five columns of `Tbl` as the predictor variables by using `formula`. Then, `score(3)` contains the score value of the 8th column in `Tbl`, which is the third predictor in the subset.

Algorithms

Univariate Feature Ranking Using *F*-Tests

- `fsrftest` examines the importance of each predictor individually using an *F*-test. Each *F*-test tests the hypothesis that the response values grouped by predictor variable values are drawn from populations with the same mean against the alternative hypothesis that the population means are not all the same. A small *p*-value of the test statistic indicates that the corresponding predictor is important.
- The output `scores` is –log(*p*). Therefore, a large score value indicates that the corresponding predictor is important. If a *p*-value is smaller than `eps(0)`, then the output is `Inf`.
- `fsrftest` examines a continuous variable after binning, or discretizing, the variable. You can specify the number of bins using the `'NumBins'` name-value pair argument.

Topics

“Introduction to Feature Selection” on page 15-49

Introduced in R2020a

fstat

F mean and variance

Syntax

```
[M,V] = fstat(V1,V2)
```

Description

`[M,V] = fstat(V1,V2)` returns the mean of and variance for the *F* distribution with numerator degrees of freedom `V1` and denominator degrees of freedom `V2`. `V1` and `V2` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `V1` or `V2` is expanded to a constant arrays with the same dimensions as the other input. `V1` and `V2` parameters must contain real positive values.

The mean of the *F* distribution for values of ν_2 greater than 2 is

$$\frac{\nu_2}{\nu_2 - 2}$$

The variance of the *F* distribution for values of ν_2 greater than 4 is

$$\frac{2\nu_2^2(\nu_1 + \nu_2 - 2)}{\nu_1(\nu_2 - 2)^2(\nu_2 - 4)}$$

The mean of the *F* distribution is undefined if ν_2 is less than 3. The variance is undefined for ν_2 less than 5.

Examples

`fstat` returns `NaN` when the mean and variance are undefined.

```
[m,v] = fstat(1:5,1:5)
m =
    NaN  NaN  3.0000  2.0000  1.6667
v =
    NaN  NaN  NaN  NaN  8.8889
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

fsulaplacian

Rank features for unsupervised learning using Laplacian scores

Syntax

```
idx = fsulaplacian(X)
idx = fsulaplacian(X,Name,Value)
[idx,scores] = fsulaplacian( ___ )
```

Description

`idx = fsulaplacian(X)` ranks features (variables) in `X` using the Laplacian scores on page 33-2538. The function returns `idx`, which contains the indices of features ordered by feature importance. You can use `idx` to select important features for unsupervised learning.

`idx = fsulaplacian(X,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify `'NumNeighbors',10` to create a similarity graph on page 33-2537 using 10 nearest neighbors.

`[idx,scores] = fsulaplacian( ___ )` also returns the feature scores `scores`, using any of the input argument combinations in the previous syntaxes. A large score value indicates that the corresponding feature is important.

Examples

Rank Features by Importance

Load the sample data.

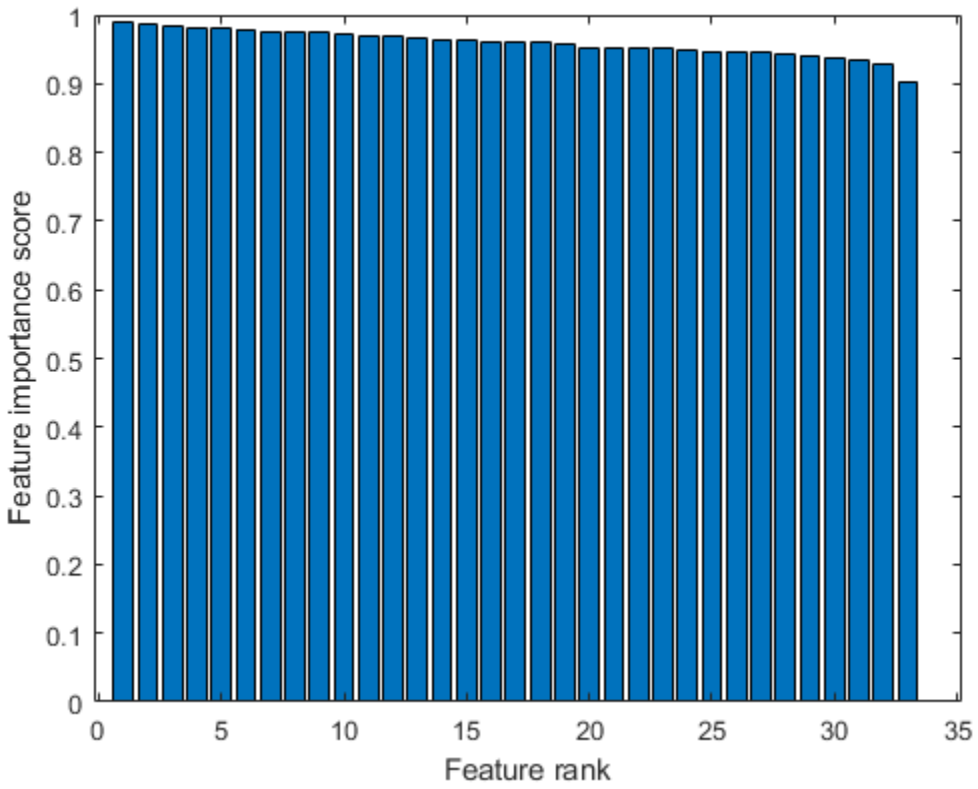
```
load ionosphere
```

Rank the features based on importance.

```
[idx,scores] = fsulaplacian(X);
```

Create a bar plot of the feature importance scores.

```
bar(scores(idx))
xlabel('Feature rank')
ylabel('Feature importance score')
```



Select the top five most important features. Find the columns of these features in X.

```
idx(1:5)
```

```
ans = 1×5

    15    13    17    21    19
```

The 15th column of X is the most important feature.

Rank Features Using Specified Similarity Matrix

Compute a similarity matrix from Fisher's iris data set and rank the features using the similarity matrix.

Load Fisher's iris data set.

```
load fisheriris
```

Find the distance between each pair of observations in `meas` by using the `pdist` and `squareform` functions with the default Euclidean distance metric.

```
D = pdist(meas);
Z = squareform(D);
```

Construct the similarity matrix and confirm that it is symmetric.

```
S = exp(-Z.^2);
issymmetric(S)
```

```
ans = logical
   1
```

Rank the features.

```
idx = fsulaplacian(meas,'Similarity',S)
```

```
idx = 1×4

     3     4     1     2
```

Ranking using the similarity matrix `S` is the same as ranking by specifying `'NumNeighbors'` as `size(meas,1)`.

```
idx2 = fsulaplacian(meas,'NumNeighbors',size(meas,1))
```

```
idx2 = 1×4

     3     4     1     2
```

Input Arguments

X — Input data

numeric matrix

Input data, specified as an *n*-by-*p* numeric matrix. The rows of `X` correspond to observations (or points), and the columns correspond to features.

The software treats `NaN`s in `X` as missing data and ignores any row of `X` containing at least one `NaN`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NumNeighbors',10,'KernelScale','auto'` specifies the number of nearest neighbors as 10 and the kernel scale factor as `'auto'`.

Similarity — Similarity matrix

`[]` (empty matrix) (default) | symmetric matrix

Similarity matrix, specified as the comma-separated pair consisting of `'Similarity'` and an *n*-by-*n* symmetric matrix, where *n* is the number of observations. The similarity matrix (or adjacency matrix) represents the input data by modeling local neighborhood relationships among the data points. The values in a similarity matrix represent the edges (or connections) between nodes (data points) that

are connected in a similarity graph on page 33-2537. For more information, see “Similarity Matrix” on page 33-2538.

If you specify the `'Similarity'` value, then you cannot specify any other name-value pair argument. If you do not specify the `'Similarity'` value, then the software computes a similarity matrix using the options specified by the other name-value pair arguments.

Data Types: `single` | `double`

`Distance` — Distance metric
character vector | string scalar | function handle

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a character vector, string scalar, or function handle, as described in this table.

Value	Description
`'euclidean'`	Euclidean distance (default)
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation computed from `X`. Use the `Scale` name-value pair argument to specify a different scaling factor.
`'mahalanobis'`	Mahalanobis distance using the sample covariance of `X`, `C = cov(X,'omitrows')`. Use the `Cov` name-value pair argument to specify a different covariance matrix.
`'cityblock'`	City block distance
`'minkowski'`	Minkowski distance. The default exponent is 2. Use the `P` name-value pair argument to specify a different exponent, where `P` is a positive scalar value.
`'chebychev'`	Chebychev distance (maximum coordinate difference)
`'cosine'`	One minus the cosine of the included angle between observations (treated as vectors)
`'correlation'`	One minus the sample correlation between observations (treated as sequences of values)
`'hamming'`	Hamming distance, which is the percentage of coordinates that differ
`'jaccard'`	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)

Value	Description

`@distfun`	Custom distance function handle. A distance function has the form
	`function D2 = distfun(ZI,ZJ)`
	`% calculation of distance`
	`...`
	where
	• `ZI` is a `1`-by-`n` vector containing a single observation.
	• `ZJ` is an `m2`-by-`n` matrix containing multiple observations. `distfun` must accept a matrix `ZJ` with an arbitrary number of observations.
	• `D2` is an `m2`-by-`1` vector of distances, and `D2(k)` is the distance between observations `ZI` and `ZJ(k,:)`.
	If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.

For more information, see “Distance Metrics” on page 18-12.

When you use the `'seuclidean'`, `'minkowski'`, or `'mahalanobis'` distance metric, you can specify the additional name-value pair argument `'Scale'`, `'P'`, or `'Cov'`, respectively, to control the distance metrics.

Example: `'Distance','minkowski','P',3` specifies to use the Minkowski distance metric with an exponent of 3.

P — Exponent for Minkowski distance metric
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar.

This argument is valid only if `'Distance'` is `'minkowski'`.

Example: `'P',3`

Data Types: `single` | `double`

Cov — Covariance matrix for Mahalanobis distance metric
`cov(X,'omitrows')` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix.

This argument is valid only if `'Distance'` is `'mahalanobis'`.

Example: `'Cov',eye(4)`

Data Types: `single` | `double`

Scale — Scaling factors for standardized Euclidean distance metric
`std(X,'omitnan')` (default) | numeric vector of nonnegative values

Scaling factors for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of `'Scale'` and a numeric vector of nonnegative values.

`Scale` has length *p* (the number of columns in `X`), because each dimension (column) of `X` has a corresponding value in `Scale`. For each dimension of `X`, `fsulaplacian` uses the corresponding value in `Scale` to standardize the difference between observations.

This argument is valid only if `'Distance'` is `'seuclidean'`.

Data Types: `single` | `double`

`NumNeighbors` — Number of nearest neighbors
`log(size(X,1))` (default) | positive integer

Number of nearest neighbors used to construct the similarity graph, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer.

Example: `'NumNeighbors',10`

Data Types: `single` | `double`

`KernelScale` — Scale factor
`1` (default) | `'auto'` | positive scalar

Scale factor for the kernel, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar. The software uses the scale factor to transform distances to similarity measures. For more information, see “Similarity Graph” on page 33-2537.

- The `'auto'` option is supported only for the `'euclidean'` and `'seuclidean'` distance metrics.
- If you specify `'auto'`, then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. To reproduce results, set a random number seed using `rng` before calling `fsulaplacian`.

Example: `'KernelScale','auto'`

Output Arguments

`idx` — Indices of features ordered by feature importance
numeric vector

Indices of the features in `X` ordered by feature importance, returned as a numeric vector. For example, if `idx(3)` is `5`, then the third most important feature is the fifth column in `X`.

`scores` — Feature scores
numeric vector

Feature scores, returned as a numeric vector. A large score value in `scores` indicates that the corresponding feature is important. The values in `scores` have the same order as the features in `X`.

More About

Similarity Graph

A similarity graph models the local neighborhood relationships between data points in `X` as an undirected graph. The nodes in the graph represent data points, and the edges, which are directionless, represent the connections between the data points.

If the pairwise distance $Dist_{i,j}$ between any two nodes i and j is positive (or larger than a certain threshold), then the similarity graph connects the two nodes using an edge [2]. The edge between the two nodes is weighted by the pairwise similarity $S_{i,j}$, where $S_{i,j} = \exp\left(-\left(\frac{Dist_{i,j}}{\sigma}\right)^2\right)$, for a specified kernel scale σ value.

`fsulaplacian` constructs a similarity graph using the nearest neighbor method. The function connects points in `X` that are nearest neighbors. Use `'NumNeighbors'` to specify the number of nearest neighbors.

Similarity Matrix

A similarity matrix is a matrix representation of a similarity graph on page 33-2537. The n-by-n matrix $S = (S_{i,j})_{i,j = 1,\ldots,n}$ contains pairwise similarity values between connected nodes in the similarity graph. The similarity matrix of a graph is also called an adjacency matrix.

The similarity matrix is symmetric because the edges of the similarity graph are directionless. A value of $S_{i,j} = 0$ means that nodes i and j of the similarity graph are not connected.

Degree Matrix

A degree matrix D_g is an n-by-n diagonal matrix obtained by summing the rows of the similarity matrix on page 33-2538 S. That is, the ith diagonal element of D_g is $D_g(i,i) = \sum_{j=1}^{n} S_{i,j}$.

Laplacian Matrix

A Laplacian matrix, which is one way of representing a similarity graph on page 33-2537, is defined as the difference between the degree matrix on page 33-2538 D_g and the similarity matrix on page 33-2538 S.

$$L = D_g - S.$$

Algorithms

Laplacian Score

The `fsulaplacian` function ranks features using Laplacian scores[1] obtained from a nearest neighbor similarity graph on page 33-2537.

`fsulaplacian` computes the values in `scores` as follows:

1. For each data point in `X`, define a local neighborhood using the nearest neighbor method, and find pairwise distances $Dist_{i,j}$ for all points i and j in the neighborhood.
2. Convert the distances to the similarity matrix on page 33-2538 S using the kernel transformation $S_{i,j} = \exp\left(-\left(\frac{Dist_{i,j}}{\sigma}\right)^2\right)$, where σ is the scale factor for the kernel as specified by the `'KernelScale'` name-value pair argument.
3. Center each feature by removing its mean.

$$\tilde{x}_r = x_r - \frac{x_r^T D_g \mathbf{1}}{\mathbf{1}^T D_g \mathbf{1}}\mathbf{1},$$

where x_r is the rth feature, D_g is the degree matrix on page 33-2538, and $\mathbf{1}^T = [1, \cdots, 1]^T$.

4 Compute the score s_r for each feature.

$$s_r = \frac{\tilde{x}_r^T S \tilde{x}_r}{\tilde{x}_r^T D_g \tilde{x}_r}.$$

Note that [1] defines the Laplacian score as

$$L_r = \frac{\tilde{x}_r^T L \tilde{x}_r}{\tilde{x}_r^T D_g \tilde{x}_r} = 1 - \frac{\tilde{x}_r^T S \tilde{x}_r}{\tilde{x}_r^T D_g \tilde{x}_r},$$

where L is the Laplacian matrix on page 33-2538, defined as the difference between D_g and S. The `fsulaplacian` function uses only the second term of this equation for the score value of `scores` so that a large score value indicates an important feature.

Selecting features using the Laplacian score is consistent with minimizing the value

$$\frac{\sum_{i,j} (x_{ir} - x_{jr})^2 S_{i,j}}{Var(x_r)},$$

where x_{ir} represents the ith observation of the rth feature. Minimizing this value implies that the algorithm prefers features with large variance. Also, the algorithm assumes that two data points of an important feature are close if and only if the similarity graph has an edge between the two data points.

“Introduction to Feature Selection” on page 15-49

Introduced in R2019b

fsurfht

Interactive contour plot

Syntax

```
fsurfht(fun,xlims,ylims)
fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)
```

Description

`fsurfht(fun,xlims,ylims)` is an interactive contour plot of the function specified by the text variable `fun`. The *x*-axis limits are specified by `xlims` in the form `[xmin xmax]`, and the *y*-axis limits are specified by `ylims` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current *x* value and *y* value. You can drag these reference lines and watch the calculated *z*-values (at the top of the plot) update simultaneously. Alternatively, you can type the *x* value and *y* value into editable text fields on the *x*-axis and *y*-axis.

Examples

Plot the Gaussian likelihood function for the `gas.mat` data.

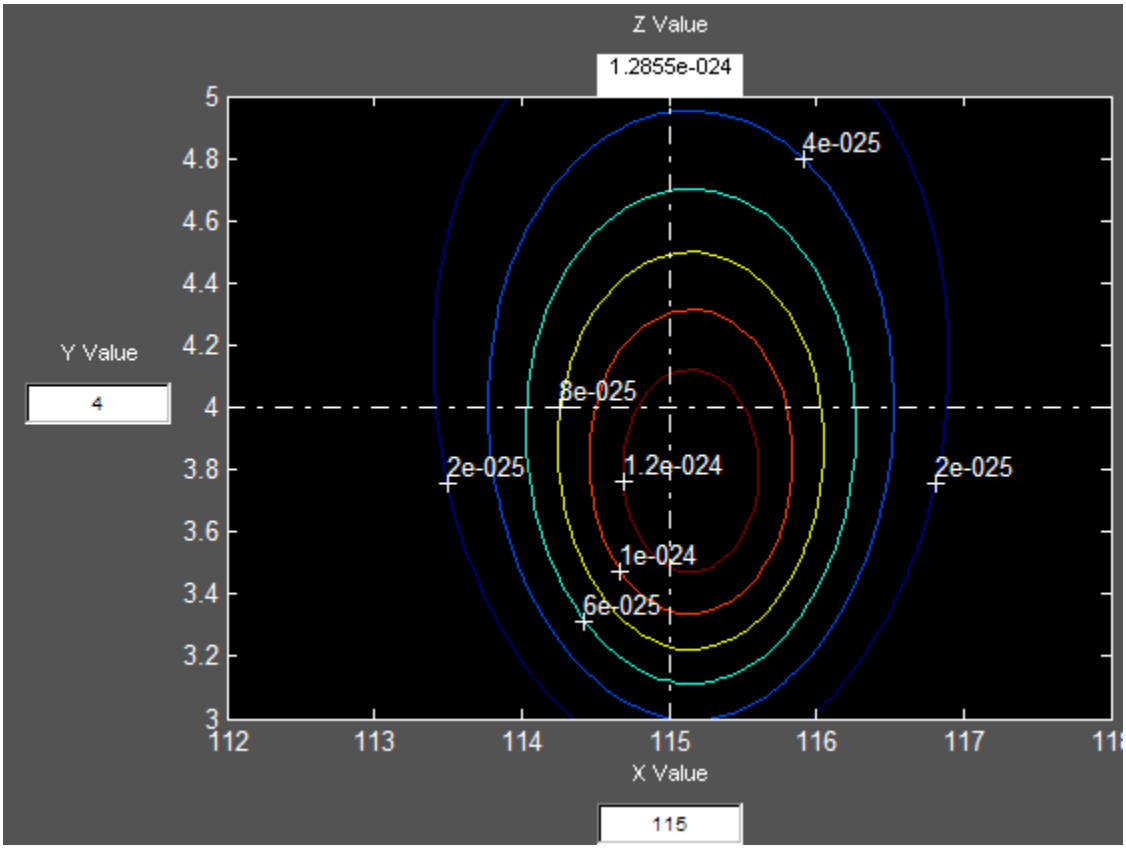
```
load gas
```

Create a function containing the following commands, and name it `gauslike.m`.

```
function z = gauslike(mu,sigma,p1)
n = length(p1);
z = ones(size(mu));
for i = 1:n
z = z .* (normpdf(p1(i),mu,sigma));
end
```

The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters μ and σ as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

```
fsurfht('gauslike',[112 118],[3 5],price1)
```



The sample mean is the *x* value at the maximum, but the sample standard deviation is *not* the *y* value at the maximum.

```
mumax = mean(price1)
mumax =
 115.1500
sigmamax = std(price1)*sqrt(19/20)
sigmamax =
  3.7719
```

Introduced before R2006a

fullfact

Full factorial design

Syntax

```
dFF = fullfact(levels)
```

Description

`dFF = fullfact(levels)` gives factor settings `dFF` for a full factorial design with *n* factors, where the number of levels for each factor is given by the vector `levels` of length *n*. `dFF` is *m*-by-*n*, where *m* is the number of treatments in the full-factorial design. Each row of `dFF` corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

Examples

The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

```
dFF = fullfact([2 4])
dFF =
   1   1
   2   1
   1   2
   2   2
   1   3
   2   3
   1   4
   2   4
```

`ff2n`

Introduced before R2006a

gagerr

Gage repeatability and reproducibility study

Syntax

```
gagerr(y,{part,operator})
gagerr(y,GROUP)
gagerr(y,part)
gagerr(...,param1,val1,param2,val2,...)
[TABLE, stats] = gagerr(...)
```

Description

`gagerr(y,{part,operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, string arrays, or cell arrays of character vectors. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 x standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If NDC > 5, the measurement system is capable.
- If NDC < 2, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:

- If PRR < 10%, the measurement system is capable.
- If PRR > 30%, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

`gagerr(y,GROUP)` performs a gage R&R study on measurements in `y` with `part` and `operator` represented in `GROUP`. `GROUP` is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in `GROUP` should be the same as the number of elements in `y`.

`gagerr(y,part)` performs a gage R&R study on measurements in `y` without operator information. The assumption is that all variability is contributed by `part`.

`gagerr(...,param1,val1,param2,val2,...)` performs a gage R&R study using one or more of the following parameter name/value pairs:

- `'spec'` — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

  To determine the capability of a measurement system using PTR, use the following guidelines:

  - If PTR < 0.1, the measurement system is capable.
  - If PTR > 0.3, the measurement system is not capable.
  - Otherwise, the measurement system may be acceptable.
- `'printtable'` — A value `'on'` or `'off'` that indicates whether the tabular output should be printed in the command window or not. The default value is `'on'`.
- `'printgraph'` — A value `'on'` or `'off'` that indicates whether the bar graph should be plotted or not. The default value is `'on'`.
- `'randomoperator'` — A logical value, `true` or `false`, that indicates whether the effect of `operator` is random or not. The default value is `true`.
- `'model'` — The model to use, specified by one of:

  - `'linear'` — Main effects only (default)
  - `'interaction'` — Main effects plus two-factor interactions
  - `'nested'` — Nest `operator` in `part`

  The default value is `'linear'`.

`[TABLE, stats] = gagerr(...)` returns a 6-by-5 matrix `TABLE` and a structure `stats`. The columns of `TABLE`, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of `TABLE`, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. `stats` is a structure containing summary statistics for the performance of the measurement system. The fields of `stats` are:

- `ndc` — Number of distinct categories
- `prr` — Percentage of gage R&R of total variations
- `ptr` — Precision-to-tolerance ratio. The value is `NaN` if the parameter `'spec'` is not given.

Examples

Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, `y` , operators do on the parts.

```
rng(1234,'twister')              % for reproducibility
y = randn(100,1);                % measurements
part = ceil(3*rand(100,1));      % parts
operator = ceil(4*rand(100,1));  % operators
```

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

```
gagerr(y,{part, operator},'randomoperator',true)
```

```
  Columns 1 through 4

    {'Source'           }    {'Variance'}    {'% Variance'}    {'sigma' }
    {'Gage R&R'         }    {[  0.9715]}    {[   99.2653]}    {[0.9857]}

“Grouping Variables” on page 2-45

Introduced in R2006b

gamcdf

Gamma cumulative distribution function

Syntax

```
p = gamcdf(x,a)
p = gamcdf(x,a,b)

[p,pLo,pUp] = gamcdf(x,a,b,pCov)
[p,pLo,pUp] = gamcdf(x,a,b,pCov,alpha)

___ = gamcdf( ___ ,'upper')
```

Description

`p = gamcdf(x,a)` returns the cumulative distribution function (cdf) of the standard gamma distribution with the shape parameters in `a`, evaluated at the values in `x`.

`p = gamcdf(x,a,b)` returns the cdf of the gamma distribution with the shape parameters in `a` and scale parameters in `b`, evaluated at the values in `x`.

`[p,pLo,pUp] = gamcdf(x,a,b,pCov)` also returns the 95% confidence interval [`pLo`,`pUp`] of `p` when `a` and `b` are estimates. `pCov` is the covariance matrix of the estimated parameters.

`[p,pLo,pUp] = gamcdf(x,a,b,pCov,alpha)` specifies the confidence level for the confidence interval [`pLo` `pUp`] to be `100(1–alpha)`%.

`___ = gamcdf( ___ ,'upper')` returns the complement of the cdf, evaluated at the values in `x`, using an algorithm that more accurately computes the extreme upper-tail probabilities than subtracting the lower tail value from 1. `'upper'` can follow any of the input argument combinations in the previous syntaxes.

Examples

Compute Gamma Distribution cdf

Compute the cdf of the mean of the gamma distribution, which is equal to the product of the parameters *ab*.

```
a = 1:6;
b = 5:10;
prob = gamcdf(a.*b,a,b)
```

```
prob = 1×6

    0.6321    0.5940    0.5768    0.5665    0.5595    0.5543
```

As `ab` increases, the distribution becomes more symmetric, and the mean approaches the median.

Confidence Interval of Gamma cdf Value

Find a confidence interval estimating the probability that an observation is in the interval `[0 10]` using gamma distributed data.

Generate a sample of `1000` gamma distributed random numbers with shape `2` and scale `5`.

```
x = gamrnd(2,5,1000,1);
```

Compute estimates for the parameters.

```
[params,~] = gamfit(x)
```

```
params = 1×2

    2.1089    4.8147
```

Store the parameters as `ahat` and `bhat`.

```
ahat = params(1);
bhat = params(2);
```

Find the covariance of the parameter estimates.

```
[~,nCov] = gamlike(params,x)
```

```
nCov = 2×2

    0.0077   -0.0176
   -0.0176    0.0512
```

Create a confidence interval estimating the probability that an observation is in the interval `[0 10]`.

```
[prob,pLo,pUp] = gamcdf(10,ahat,bhat,nCov)
```

```
prob = 0.5830

pLo = 0.5587

pUp = 0.6069
```

Complementary cdf (Tail Distribution)

Determine the probability that an observation from the gamma distribution with shape parameter 2 and scale parameter 3 will is in the interval `[150 Inf]`.

```
p1 = 1 - gamcdf(150,2,3)
```

```
p1 = 0
```

`gamcdf(150, 2, 3)` is nearly `1`, so `p1` becomes `0`. Specify `'upper'` so that `gamcdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = gamcdf(150,2,3,'upper')
```

```
p2 = 9.8366e-21
```

Input Arguments

x — Values at which to evaluate cdf

nonnegative scalar value | array of nonnegative scalar values

Values at which to evaluate the cdf, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If you specify `pCov` to compute the confidence interval `[pLo,pUp]`, then `x` must be a scalar value.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gamcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[3 4 7 9]`

Data Types: `single` | `double`

a — Shape parameter

positive scalar value | array of positive scalar values

Shape of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gamcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `a` and `b`, evaluated at the corresponding element in `x`.

Example: `[1 2 3 5]`

Data Types: `single` | `double`

b — Scale parameter

1 (default) | positive scalar value | array of positive scalar values

Scale of the gamma distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `a` and `b` using arrays.

If one or more of the input arguments `x`, `a`, and `b` are arrays, then the array sizes must be the same. In this case, `gamcdf` expands each scalar input into a constant array of the same size as the array

inputs. Each element in p is the cdf value of the distribution specified by the corresponding elements in a and b, evaluated at the corresponding element in x.

Example: [1 1 2 2]

Data Types: single | double

pCov — Covariance of estimates
2-by-2 numeric matrix

Covariance of the estimates a and b, specified as a 2-by-2 matrix.

If you specify pCov to compute the confidence interval [pLo,pUp], then x, a, and b must be scalar values.

You can estimate a and b by using gamfit or mle, and estimate the covariance of a and b by using gamlike. For an example, see “Confidence Interval of Gamma cdf Value” on page 33-2548.

Data Types: single | double

alpha — Significance level
0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is 100(1–alpha)%, where alpha is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: single | double

Output Arguments

p — cdf values
scalar value | array of scalar values

cdf values evaluated at the values in x, returned as a scalar value or an array of scalar values. p is the same size as x, a, and b after any necessary scalar expansion. Each element in p is the cdf value of the distribution specified by the corresponding elements in a and b, evaluated at the corresponding element in x.

pLo — Lower confidence bound for p
scalar value | array of scalar values

Lower confidence bound for p, returned as a scalar value or an array of scalar values. pLo has the same size as p.

pUp — Upper confidence bound for p
scalar value | array of scalar values

Upper confidence bound for p, returned as a scalar value or an array of scalar values. pUp has the same size as p.

More About

Gamma cdf

The gamma distribution is a two-parameter family of curves. The parameters a and b are shape and scale, respectively.

The gamma cdf is

$$p = F(x \mid a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{\frac{-t}{b}} dt .$$

The result p is the probability that a single observation from a gamma distribution with parameters a and b falls in the interval $[0,x]$.

The gamma cdf is related to the incomplete gamma function `gammainc` by

$$f(x \mid a, b) = \text{gammainc}\left(\frac{x}{b}, a\right).$$

The standard gamma distribution occurs when $b = 1$, which coincides with the incomplete gamma function precisely.

For more information, see “Gamma Distribution” on page B-47.

Alternative Functionality

- `gamcdf` is a function specific to the gamma distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, create a `GammaDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `gamcdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Gamma Distribution” on page B-47

Introduced before R2006a

gamfit

Gamma parameter estimates

Syntax

```
phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)
```

Description

`phat = gamfit(data)` returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector `data`.
