 -327.5256    3.2062
 -327.4943    3.2678
      ⋮
```

These results show that the profile log likelihood is maximized between the estimated B values of 3.2678 and 3.3295, which correspond to loglikelihood values -327.4943 and -327.5178. From the earlier fit, the MLE of B is 3.27193, which is in this interval as expected.

Profile Likelihood With Restricted Parameter Values

Load the sample data. Create a probability distribution object by fitting a generalized extreme value distribution to the miles per gallon (MPG) data.

```
load carsmall
pd = fitdist(MPG,'GeneralizedExtremeValue')
```

```
pd =
  GeneralizedExtremeValueDistribution

  Generalized Extreme Value distribution
        k = -0.207765   [-0.381674, -0.0338563]
    sigma =   7.49674   [6.31755, 8.89604]
       mu =   20.6233   [18.8859, 22.3606]
```

View the parameter names for the distribution.

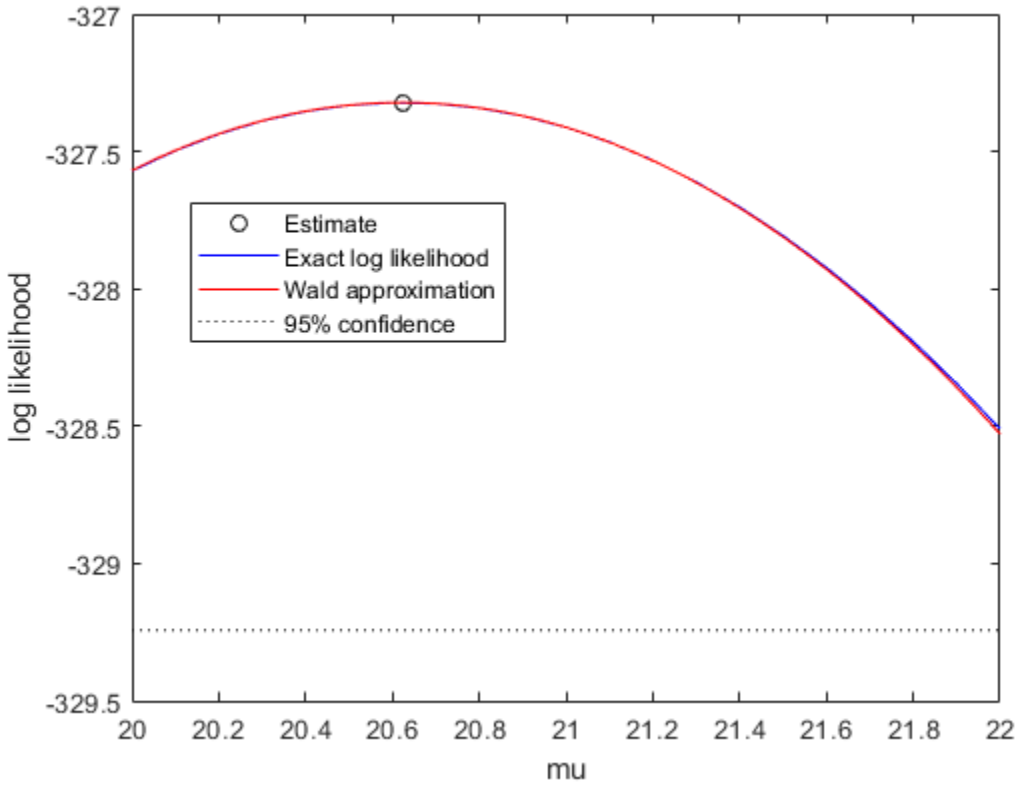
```
pd.ParameterNames
```

```
ans = 1x3 cell
    {'k'}    {'sigma'}    {'mu'}
```

For the generalized extreme value distribution, `k` is in position 1, `sigma` is in position 2, and `mu` is in position 3.

Compute the profile likelihood for `mu`, which is in position `pnum = 3`. Restrict the computation to parameter values from 20 to 22, and display the plot.

```
[ll,param,other] = proflik(pd,3,20:.1:22,'display','on');
```



The plot shows the estimated value for the parameter `mu` that maximizes the loglikelihood.

Display the loglikelihood values for the estimated values of `mu`, and the values of the other distribution parameters that maximize the corresponding loglikelihood.

```
[ll',param',other]
```

```
ans = 21×4

  -327.5706   20.0000   -0.1803    7.4087
  -327.4971   20.1000   -0.1846    7.4218
  -327.4364   20.2000   -0.1890    7.4354
  -327.3887   20.3000   -0.1934    7.4493
  -327.3538   20.4000   -0.1978    7.4636
```

```
-327.3317   20.5000   -0.2023    7.4783
-327.3223   20.6000   -0.2067    7.4932
-327.3257   20.7000   -0.2112    7.5084
-327.3418   20.8000   -0.2156    7.5240
-327.3706   20.9000   -0.2201    7.5399
     ⋮
```

The first column contains the log likelihood value that corresponds to the estimate of `mu` in the second column. The log likelihood is maximized between the parameter values 20.6000 and 20.7000, corresponding to log likelihood values -327.3223 and -327.3257. The third column contains the value of `k` that maximizes the corresponding log likelihood for `mu`. The fourth column contains the value of `sigma` that maximizes the corresponding log likelihood for `mu`.

Input Arguments

`pd` — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
`fitdist`	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

`pnum` — Parameter number

positive integer value

Parameter number for which to compute the profile likelihood, specified as a positive integer value corresponding to the position of the desired parameter in the parameter name vector. For example, a Weibull distribution has a parameter name vector `{'A','B'}`, so specify `pnum` as `2` to compute the profile likelihood for `B`.

Data Types: `single` | `double`

`setparam` — Parameter value restriction

scalar value | vector of scalar values

Parameter value restriction, specified as a scalar value or a vector of such values. If you do not specify `setparam`, `proflik` chooses the values for output vector `param` based on the default confidence interval method for the probability distribution `pd`. If the parameter can take only restricted values, and if the confidence interval violates that restriction, you can use `setparam` to specify valid values.

Example: `[3,3.5,4]`

`display` — Display toggle

`'off'` (default) | `'on'`

Display toggle, specified as either `'on'` or `'off'`. Specify `'on'` to display the profile of the exact loglikelihood overlaid on the Wald approximation of the loglikelihood. Specify `'off'` to omit the

display. The Wald approximation is based on a Taylor series expansion around the estimated parameter value, as a function of the parameter in position `pnum` or its logarithm. The intersection of the curves with the horizontal dotted line marks the endpoints of 95% confidence intervals.

Output Arguments

`ll` — Loglikelihood values

vector

Loglikelihood values, returned as a vector. The loglikelihood is the value of the likelihood with the parameter in position `pnum` set to the values in `param`, maximized over the remaining parameters.

`param` — Parameter values

vector

Parameter values corresponding to the loglikelihood values in `ll`, returned as a vector. If you specify parameter values using `setparam`, then `param` is equal to `setparam`.

`other` — Other parameter values

matrix

Other parameter values that maximize the likelihood, returned as a matrix. Each row of `other` contains the values for all parameters except the parameter in position `pnum`.

Topics

“Working with Probability Distributions” on page 5-3
“Supported Distributions” on page 5-14

Introduced in R2013a

proximity

Class: `CompactTreeBagger`

Proximity matrix for data

Syntax

```
prox = proximity(B,X)
```

Description

`prox = proximity(B,X)` computes a numeric matrix of size `Nobs`-by-`Nobs` of proximities for data `X`, where `Nobs` is the number of observations (rows) in `X`. Proximity between any two observations in the input data is defined as a fraction of trees in the ensemble `B` for which these two observations land on the same leaf. This is a symmetric matrix with ones on the diagonal and off-diagonal elements ranging from 0 to 1.

prune

Class: `ClassificationTree`

Produce sequence of classification subtrees by pruning

Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

Description

`tree1 = prune(tree)` creates a copy of the classification tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one `Name,Value` pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`tree`

A classification tree created with `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Alpha`

A numeric scalar. `prune` prunes `tree` to the specified value of the pruning cost.

`Level`

A numeric scalar from `0` (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

`Nodes`

A numeric vector with elements from `1` to `tree.NumNodes`. Any `tree` branch nodes listed in `nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

Output Arguments

`tree1`

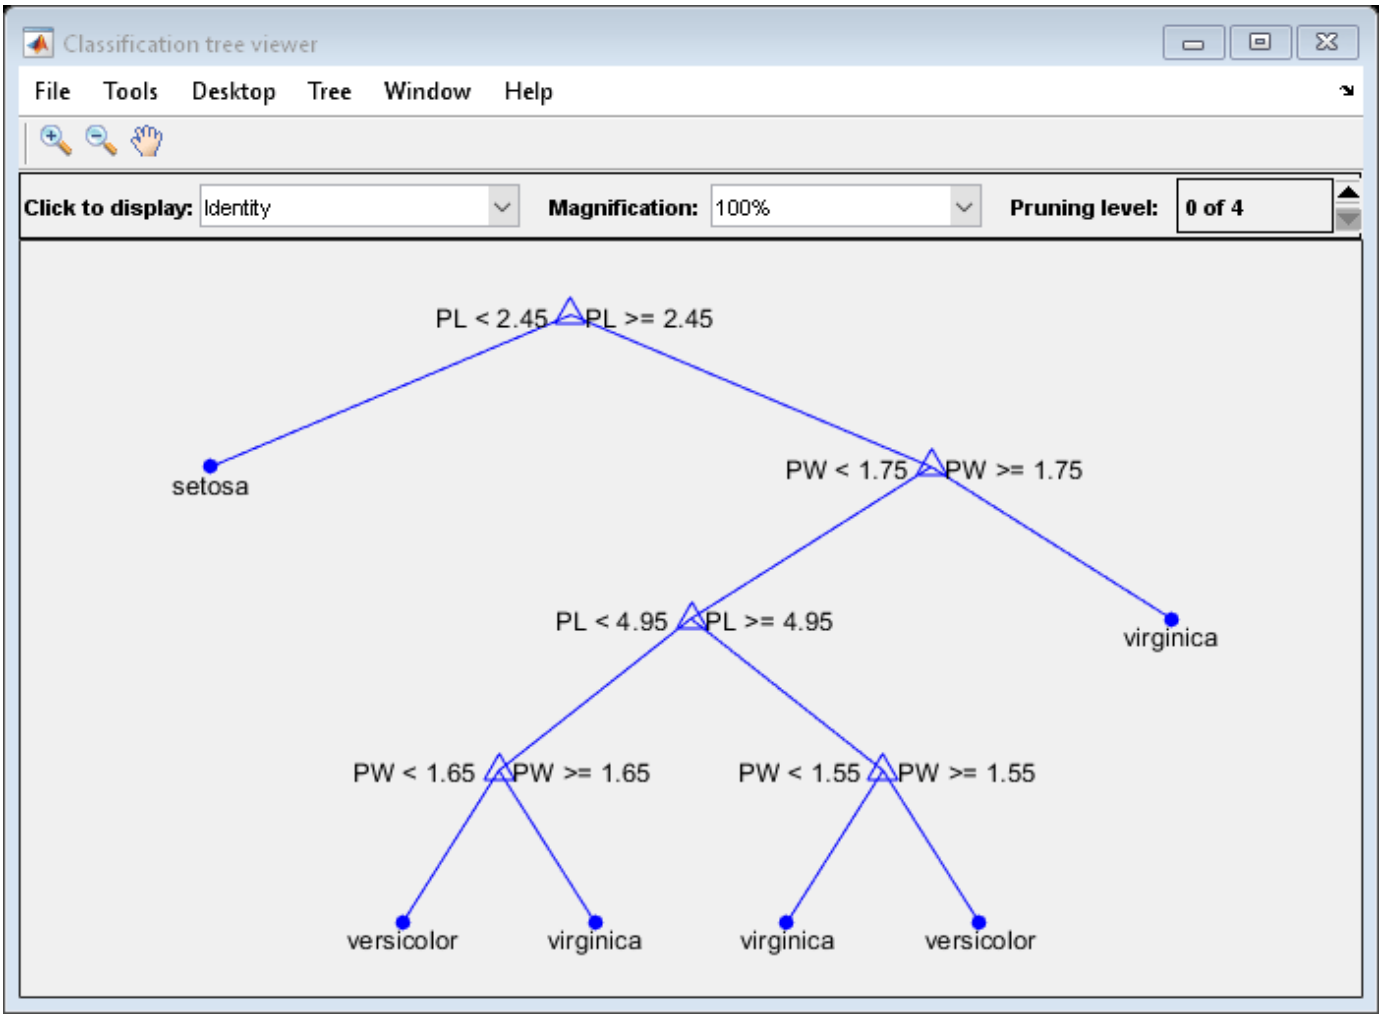
A classification tree.

Examples

Prune and Display a Classification Tree

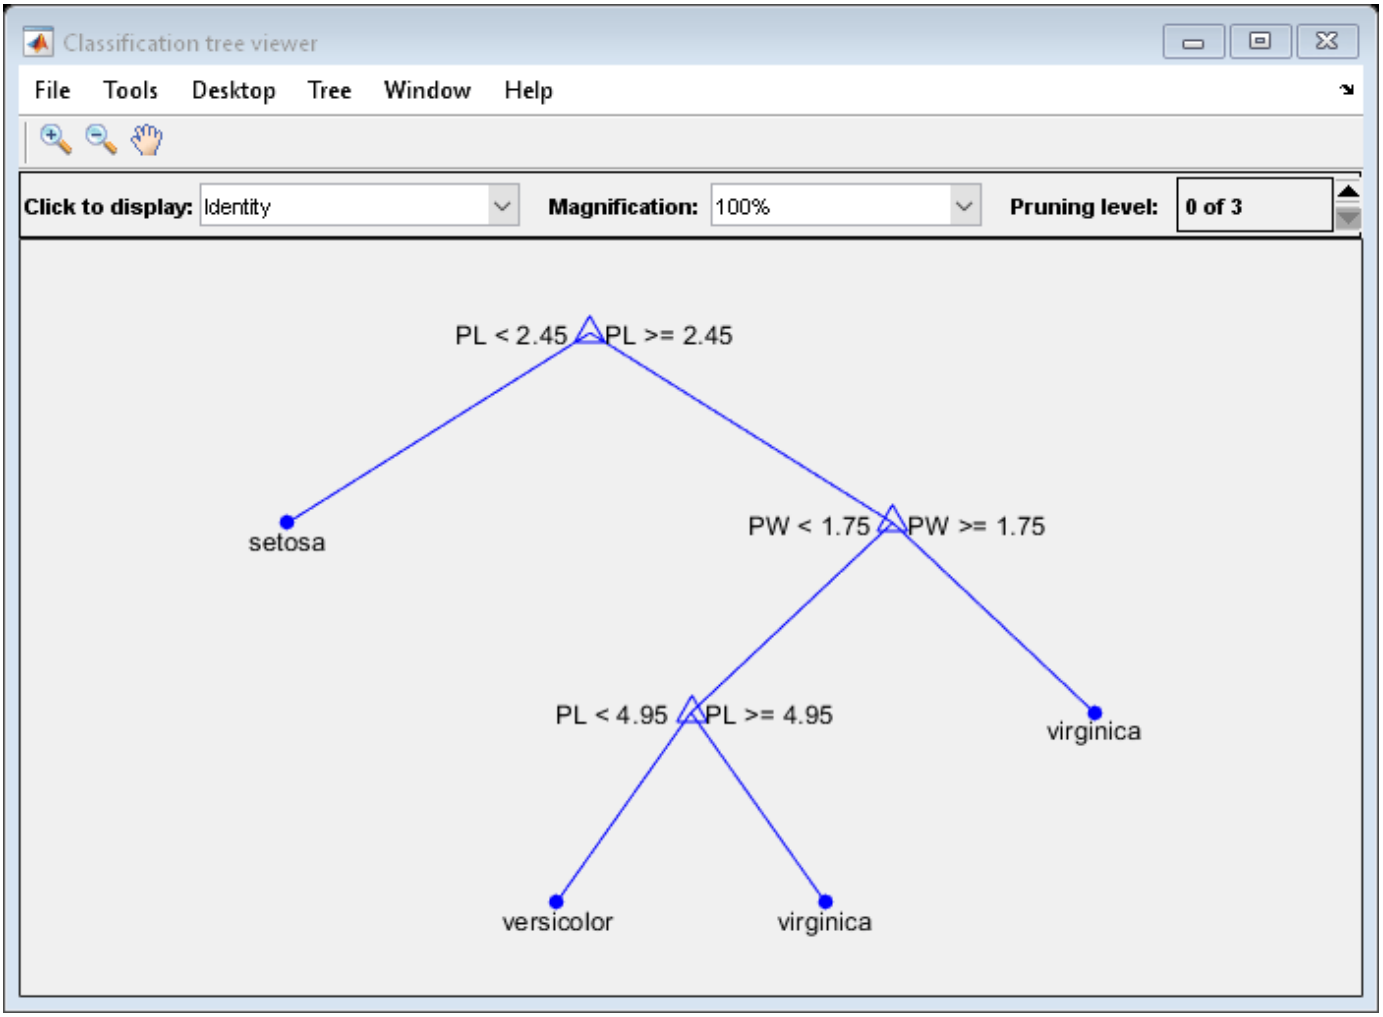
Construct and display a full classification tree for Fisher's iris data.

```
load fisheriris;
varnames = {'SL','SW','PL','PW'};
t1 = fitctree(meas,species,'MinParentSize',5,'PredictorNames',varnames);
view(t1,'Mode','graph');
```



Construct and display the next largest tree from the optimal pruning sequence.

```
t2 = prune(t1,'Level',1);
view(t2,'Mode','graph');
```



Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned `tree`, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using the `fitctree` function with pruning set `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

See Also

`fitctree`

prune

Class: `RegressionTree`

Produce sequence of regression subtrees by pruning

Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

Description

`tree1 = prune(tree)` creates a copy of the regression tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one `Name,Value` pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`tree`

A regression tree created with `fitrtree`.

Name-Value Pair Arguments

Optional comma-separated pair of `Name,Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify only one name-value pair argument.

`Alpha`

A numeric scalar from `0` (no pruning) to `1` (prune to one node). Prunes to minimize the sum of (`Alpha` times the number of leaf nodes) and a cost (mean squared error).

`Level`

A numeric scalar from `0` (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

`Nodes`

A numeric vector with elements from `1` to `tree.NumNodes`. Any `tree` branch nodes listed in `Nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

Output Arguments

tree1

A regression tree.

Examples

Prune Regression Tree

Load the `carsmall` data set. Consider `Horsepower` and `Weight` as predictor variables.

```
load carsmall;
X = [Weight Horsepower];
varNames = {'Weight' 'Horsepower'};
```

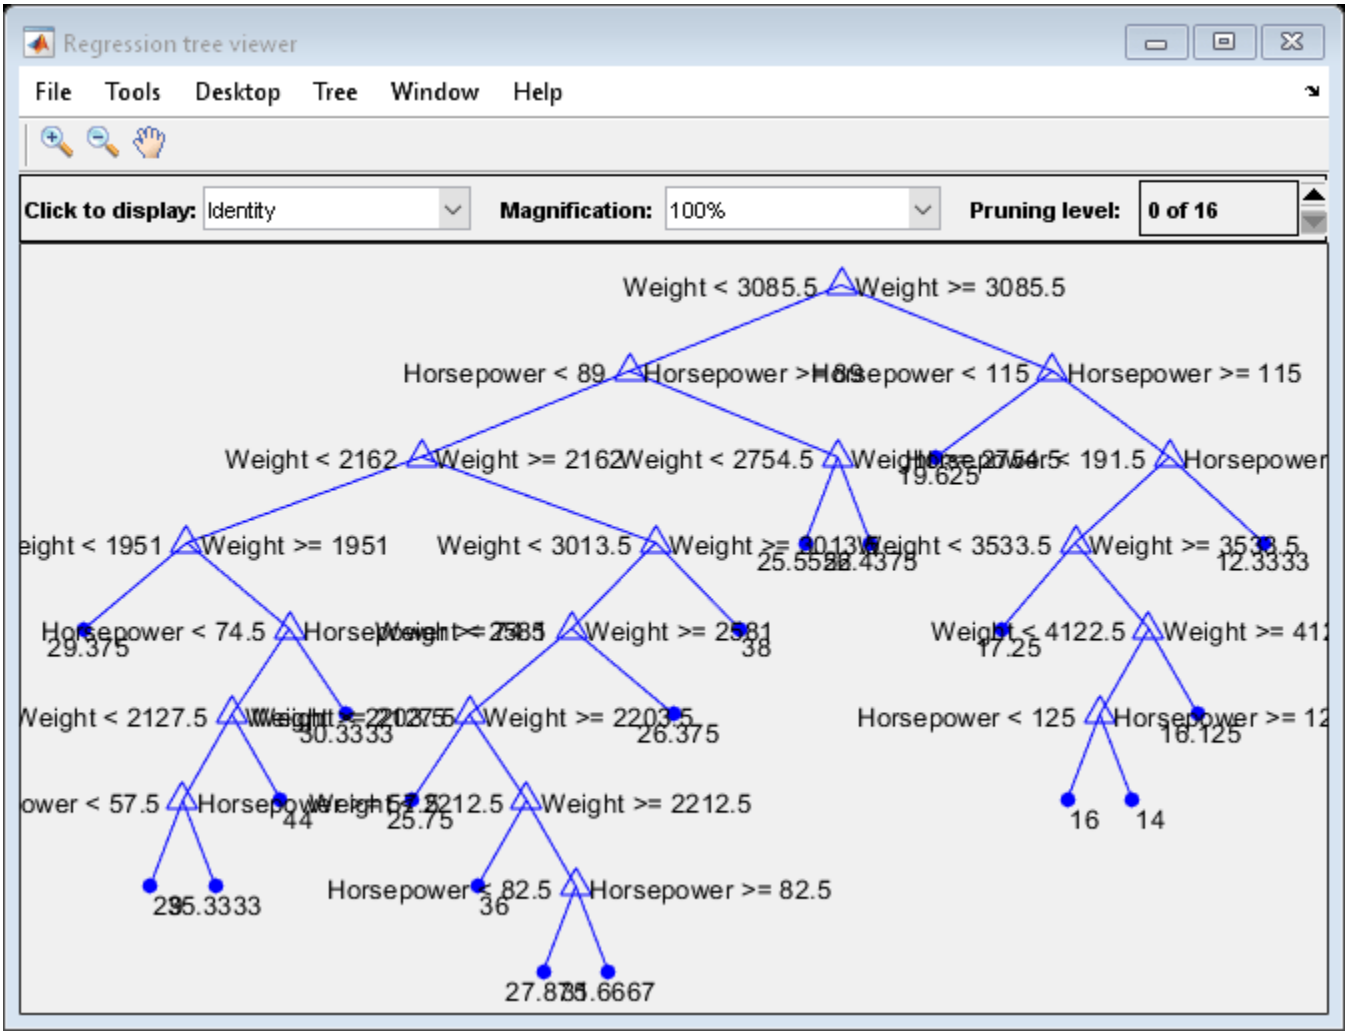
Grow a regression tree using the entire data set. View the tree.

```
Mdl = fitrtree(X,MPG,'PredictorNames',varNames)
```

```
Mdl =
  RegressionTree
             PredictorNames: {'Weight'  'Horsepower'}
               ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
          NumObservations: 94

  Properties, Methods
```

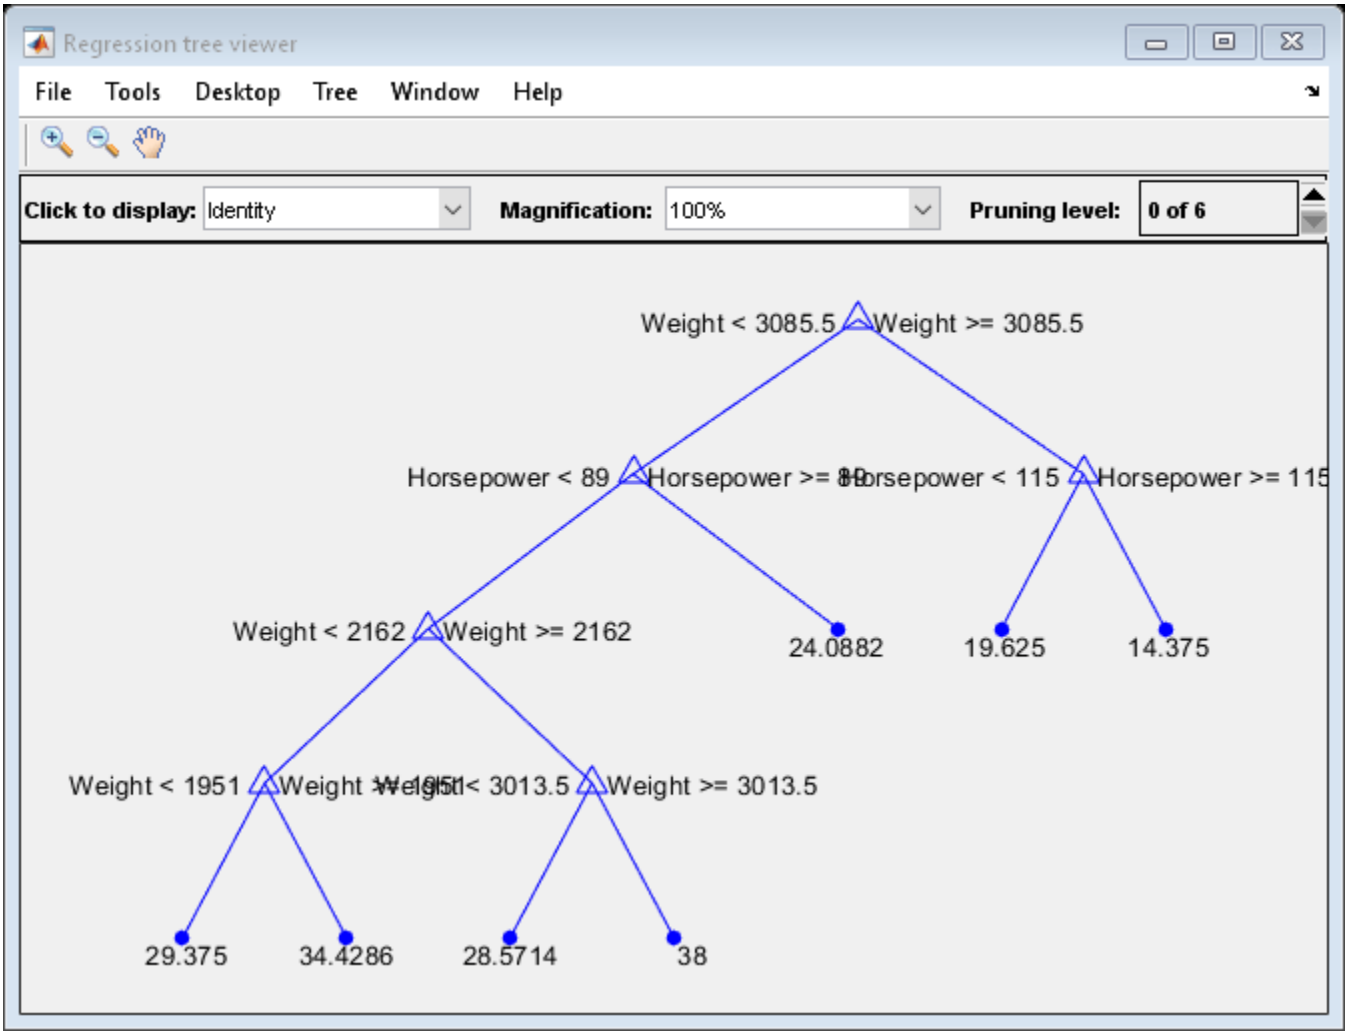
```
view(Mdl,'Mode','graph');
```



The regression tree has 16 pruning levels.

Prune the regression tree to pruning-level 10. View the pruned tree.

```
MdlPruned = prune(Mdl,'Level',10);
view(MdlPruned,'Mode','graph');
```



The pruned tree has six pruning levels.

Alternatively, you can use the pruning-level field in the Regression tree viewer to prune the tree.

Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned `tree`, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using `fitrtree` with pruning set `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

`fitrtree`

qrand

Class: `qrandstream`

Generate quasi-random points from stream

Syntax

```
x = qrand(q)
X = qrand(q,n)
```

Description

`x = qrand(q)` returns the next value `x` in the quasi-random number stream `q` of the `qrandstream` on page 33-5078 class. `x` is a 1-by-*d* vector, where *d* is the dimension of the stream. The command sets `q.State` to the index in the underlying point set of the next value to be returned.

`X = qrand(q,n)` returns the next `n` values `X` in an `n`-by-*d* matrix.

Objects `q` of the `qrandstream` class encapsulate properties of a specified quasi-random number stream. Values of the stream are not generated and stored in memory until `q` is accessed using `qrand`.

Examples

Use `qrandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
   Halton quasi-random stream in 3 dimensions
   Point set properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : none

nextIdx = q.State
nextIdx =
     1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
     5

X2 = qrand(q,4)
```

```
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
     9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
     1

X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

qrandstream

Class: `qrandstream`

Construct quasi-random number stream

Syntax

```
q = qrandstream(type,d)
q = qrandstream(type,d,prop1,val1,prop2,val2,...)
q = qrandstream(p)
```

Description

`q = qrandstream(type,d)` constructs a `d`-dimensional quasi-random number stream `q` of the `qrandstream` on page 33-5078 class, of type specified by *`type`*. *`type`* is either `'halton'` or `'sobol'`, and `q` is based on a point set from either the `haltonset` class or `sobolset` class, respectively, with default property settings.

`q = qrandstream(type,d,prop1,val1,prop2,val2,...)` specifies property name/value pairs for the point set on which the stream is based. Applicable properties depend on *`type`*.

`q = qrandstream(p)` constructs a stream based on the specified point set `p`. `p` must be a point set from either the `haltonset` class or `sobolset` class.

Examples

Construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
   Halton quasi-random stream in 3 dimensions
   Point set properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : none

nextIdx = q.State
nextIdx =
     1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
```

```
     5

X2 = qrand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
     9
```

Use `reset` to reset the stream, and then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
     1

X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

Introduced in R2008a

qqplot

Quantile-quantile plot

Syntax

```
qqplot(x)
qqplot(x,pd)

qqplot(x,y)

qqplot( ___ ,pvec)
qqplot(ax, ___ )
h = qqplot( ___ )
```

Description

`qqplot(x)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the theoretical quantile values from a normal distribution. If the distribution of `x` is normal, then the data plot appears linear.

`qqplot` plots each data point in `x` using plus sign (`'+'`) markers and draws two reference lines that represent the theoretical distribution. A solid reference line connects the first and third quartiles of the data, and a dashed reference line extends the solid line to the ends of the data.

`qqplot(x,pd)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the theoretical quantiles of the distribution specified by the probability distribution object `pd`. If the distribution of `x` is the same as the distribution specified by `pd`, then the plot appears linear.

`qqplot(x,y)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the quantiles of the sample data `y`. If the samples come from the same distribution, then the plot appears linear.

`qqplot( ___ ,pvec)` displays a quantile-quantile plot with the quantiles specified in the vector `pvec`. Specify `pvec` after any of the input argument combinations in the previous syntaxes.

`qqplot(ax, ___ )` uses the plot axes specified by the `Axes` object `ax`. The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`h = qqplot( ___ )` returns the handles (`h`) to the lines in the quantile-quantile plot.

Examples

Quantile-Quantile Plot for Normal Distribution

Use a quantile-quantile plot to determine whether gas prices in Massachusetts follow a normal distribution.

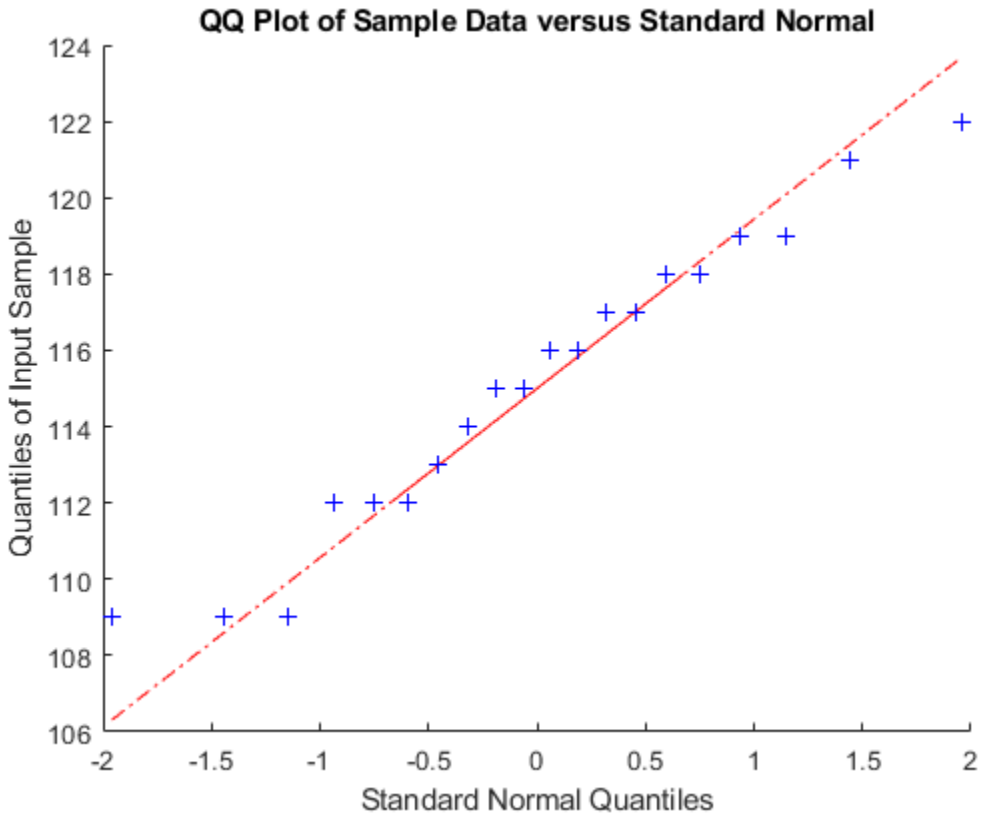
Load the sample data.

```
load gas
```

The sample data in `price1` and `price2` represent gasoline prices at 20 different gas stations in Massachusetts. The samples were collected during two different months.

Create a quantile-quantile plot to determine if the gas prices in `price1` follow a normal distribution.

```
figure
qqplot(price1)
```



The plot produces an approximately straight line, suggesting that the gas prices follow a normal distribution.

Quantile-Quantile Plot With Two Samples

Use a quantile-quantile plot to determine whether two sets of sample data come from the same distribution.

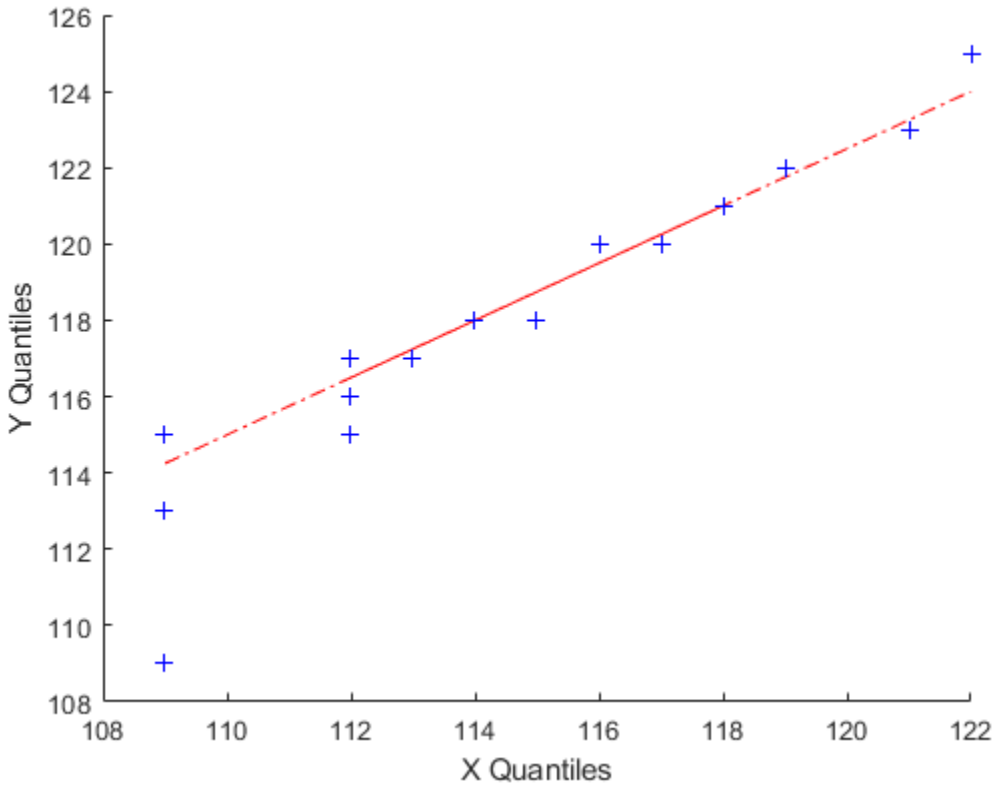
Load the sample data.

```
load gas
```

The sample data in `price1` and `price2` represent gasoline prices at 20 different gas stations in Massachusetts. The samples were collected during two different months.

Create a quantile-quantile plot using both sets of sample data, to assess whether prices at different times have the same distribution.

```
qqplot(price1,price2);
```



The plot produces an approximately straight line, suggesting that the two sets of sample data have the same distribution.

Quantile-Quantile Plot for Weibull Distribution

Use a quantile-quantile plot to determine whether sample data comes from a Weibull distribution.

Load the sample data.

```
load lightbulb
```

The first column of the data has the lifetime (in hours) of two types of light bulbs. The second column has information about the type of light bulb. 1 indicates fluorescent bulbs whereas 0 indicates the incandescent bulbs. The third column has censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Remove the censored data.

```
lightbulb = [lightbulb(lightbulb(:,3)==0,1),...
    lightbulb(lightbulb(:,3)==0,2)];
```

Create a variable for each light bulb type. Include only uncensored data.

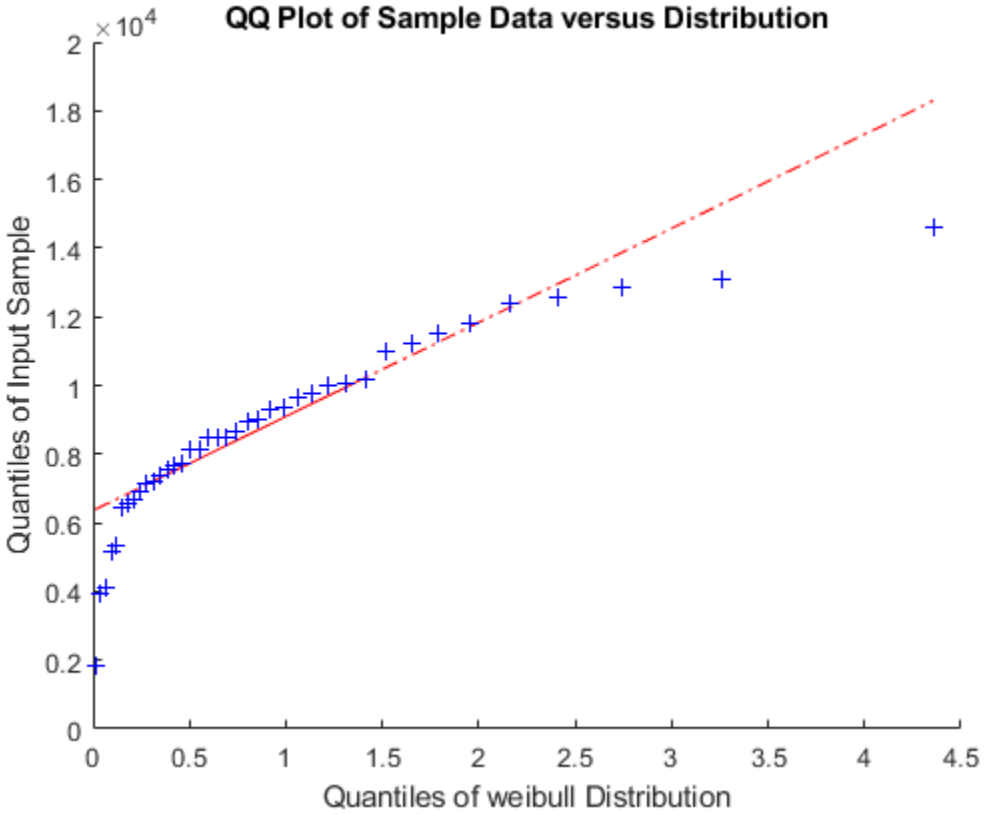
```
fluo = [lightbulb(lightbulb(:,2)==0,1)];
insc = [lightbulb(lightbulb(:,2)==1,1)];
```

Create a Weibull probability distribution object using the default parameters of `A = 1` and `B = 1`.

```
pd = makedist('Weibull');
```

Create a q-q plot to determine whether the lifetime of fluorescent bulbs has a Weibull distribution.

```
figure
qqplot(fluo,pd)
```



The plot is not a straight line, suggesting that the lifetime data for fluorescent bulbs does not follow a Weibull distribution.

Specify Axes for Quantile-Quantile Plots

Display a side-by-side pair of quantile-quantile plots using the `tiledlayout` and `nexttile` functions.

Load the `patients` data set. Separate the patient diastolic blood pressure levels into two data sets: one containing the diastolic blood pressure levels of smokers and one containing the diastolic levels of nonsmokers.

```
load patients
```

```
smokerIndices = (Smoker == 1);
nonsmokerIndices = (Smoker == 0);

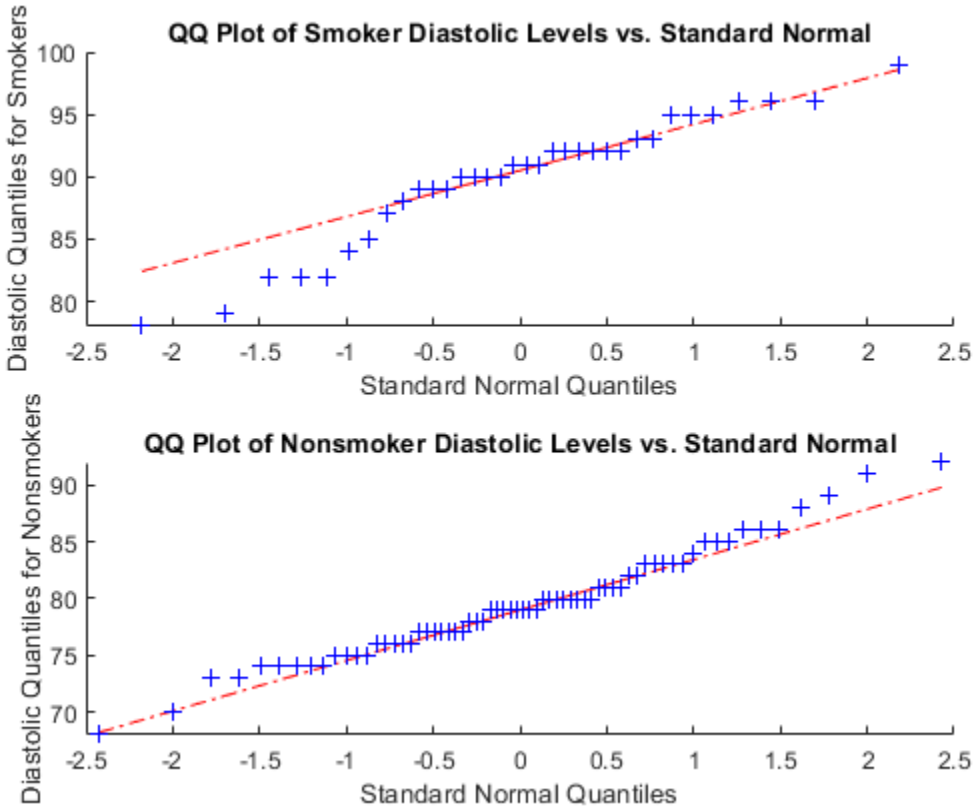
smokerDiastolic = Diastolic(smokerIndices);
nonsmokerDiastolic = Diastolic(nonsmokerIndices);
```

Create a 2-by-1 tiled chart layout using the `tiledlayout` function. Create the first set of axes `ax1` within the chart layout by calling the `nexttile` function. In the axes, display a q-q plot to determine whether the diastolic blood pressure levels of smokers come from a normal distribution. Create the second set of axes `ax2` within the tiled chart layout by calling the `nexttile` function. In the axes, display a q-q plot to determine whether the diastolic blood pressure levels of nonsmokers come from a normal distribution.

```
tiledlayout(2,1)

% Top axes
ax1 = nexttile;
qqplot(ax1,smokerDiastolic)
ylabel(ax1,'Diastolic Quantiles for Smokers')
title(ax1,'QQ Plot of Smoker Diastolic Levels vs. Standard Normal')

% Bottom axes
ax2 = nexttile;
qqplot(ax2,nonsmokerDiastolic)
ylabel(ax2,'Diastolic Quantiles for Nonsmokers')
title(ax2,'QQ Plot of Nonsmoker Diastolic Levels vs. Standard Normal')
```



The second plot more closely follows a straight line, suggesting that the sample of nonsmoker blood pressure values has an approximately normal distribution. In contrast, the first plot has points below the line to the left, suggesting a heavier tail (more outliers) than a normal distribution.

Input Arguments

x — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. If `x` is a matrix, then `qqplot` displays a separate line for each column.

`qqplot` displays the sample data using the plot symbol `'+'`. A line joining the first and third quartiles of each distribution is superimposed on the plot. The line represents a robust linear fit of the order statistics for the data in `x`. This line is extrapolated out to the minimum and maximum values in `x` to help evaluate the linearity of the data.

Data Types: `single` | `double`

y — Second set of sample data

numeric vector | numeric matrix

Second set of sample data, specified as a numeric vector or numeric matrix. `x` and `y` do not need to be the same length. However, if `x` and `y` are matrices, they must contain the same number of columns. If `x` and `y` are matrices, then `qqplot` displays a separate line for each pair of columns.

`qqplot` selects the quantiles to plot based on the size of the smaller data set.

Data Types: `single` | `double`

pd — Hypothesized probability distribution

probability distribution object

Hypothesized probability distribution, specified as a probability distribution object. `qqplot` plots the quantiles of the input data `x` versus the theoretical quartiles of the distribution specified by `pd`.

Create a probability distribution object with specified parameter values using `makedist`, or fit a probability distribution object to data using `fitdist`.

pvec — Quantiles for plot

numeric value in the range [0,100] | vector of numeric values in the range [0,100]

Quantiles for plot, specified as a numeric value, or vector of numeric values, in the range [0,100].

For a single set of sample data (`x`), `qqplot` uses the quantiles in `x`. For two sets of sample data (`x` and `y`), `qqplot` uses the quantiles in the smaller of the two data sets.

Data Types: `single` | `double`

ax — Axes for plot

`Axes` object

Axes for the plot, specified as an `Axes` object. If you do not specify `ax`, then `qqplot` creates the plot using the current axes. For more information on creating an `Axes` object, see `axes`.

Output Arguments

h — Graphics handles for line objects

vector of `Line` graphics handles

Graphics handles for line objects, returned as a vector of `Line` graphics handles. Graphics handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `x`, `qqplot` returns three handles:

- The line representing the data points. `qqplot` represents each data point in `x` using plus sign (`'+'`) markers.
- The line joining the first and third quartiles of each column of `x`, represented as a solid line.
- The extrapolation of the quartile line, extended to the minimum and maximum values of `x`, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see "Access Property Values". For information on the `Line` properties that you can set, see Primitive Line.

More About

Quantile-Quantile Plot

A *quantile-quantile plot* (also called a *q-q plot*) visually assesses whether sample data comes from a specified distribution. Alternatively, a q-q plot assesses whether two sets of sample data come from the same distribution.

A q-q plot orders the sample data values from smallest to largest, then plots these values against the expected value for the specified distribution at each quantile in the sample data. The quantile values of the input sample appear along the *y*-axis, and the theoretical values of the specified distribution at the same quantiles appear along the *x*-axis. If the resulting plot is linear, then the sample data likely comes from the specified distribution.

The q-q plot selects quantiles based on the number of values in the sample data. If the sample data contains *n* values, then the plot uses *n* quantiles. Plot the *i*th ordered value (also called the *i*th *order statistic*) against the $\frac{i-0.5}{n}$th quantile of the specified distribution.

A q-q plot can also assess whether two sets of sample data have the same distribution, even if you do not know the underlying distribution. The quantile values for the first data set appear on the *x*-axis and the corresponding quantile values for the second data set appear on the *y*-axis. Since q-q plots rely on quantiles, the number of data points in the two samples does not need to be equal. If the sample sizes are unequal, the q-q plot chooses the quantiles based on the smaller data set. If the resulting plot is linear, then the two sets of sample data likely come from the same distribution.

"Distribution Plots" on page 4-7

Introduced before R2006a

quantile

Quantiles of a data set

Syntax

```
Y = quantile(X,p)
Y = quantile(X,N)

Y = quantile( ___ ,'all')
Y = quantile( ___ ,dim)
Y = quantile( ___ ,vecdim)

Y = quantile( ___ ,'Method',method)
```

Description

`Y = quantile(X,p)` returns quantiles of the elements in data vector or array `X` for the cumulative probability or probabilities `p` in the interval [0,1].

- If `X` is a vector, then `Y` is a scalar or a vector having the same length as `p`.
- If `X` is a matrix, then `Y` is a row vector or a matrix where the number of rows of `Y` is equal to the length of `p`.
- For multidimensional arrays on page 33-5101, `quantile` operates along the first nonsingleton dimension on page 33-5101 of `X`.

`Y = quantile(X,N)` returns quantiles for `N` evenly spaced cumulative probabilities (1/(`N` + 1), 2/(`N` + 1), ..., `N`/(`N` + 1)) for integer `N`>1.

- If `X` is a vector, then `Y` is a scalar or a vector with length `N`.
- If `X` is a matrix, then `Y` is a matrix where the number of rows of `Y` is equal to `N`.
- For multidimensional arrays on page 33-5101, `quantile` operates along the first nonsingleton dimension on page 33-5101 of `X`.

`Y = quantile( ___ ,'all')` returns quantiles of all the elements of `X` for either of the first two syntaxes.

`Y = quantile( ___ ,dim)` returns quantiles along the operating dimension `dim` for either of the first two syntaxes.

`Y = quantile( ___ ,vecdim)` returns quantiles over the dimensions specified in the vector `vecdim` for either of the first two syntaxes. For example, if `X` is a matrix, then `quantile(X,0.5,[1 2])` returns the 0.5 quantile of all the elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`Y = quantile( ___ ,'Method',method)` returns either exact or approximate quantiles based on the value of `method`, using any of the input argument combinations in the previous syntaxes.

Examples

Quantiles for Given Probabilities

Calculate the quantiles of a data set for specified probabilities.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x = 1×10

    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336    0.3426    3.5784    2.7
```

Calculate the 0.3 quantile.

```
y = quantile(x,0.30)
```

```
y = -0.0574
```

Calculate the quantiles for the cumulative probabilities 0.025, 0.25, 0.5, 0.75, and 0.975.

```
y = quantile(x,[0.025 0.25 0.50 0.75 0.975])
```

```
y = 1×5

   -2.2588   -0.4336    0.4401    1.8339    3.5784
```

Quantiles for N Evenly Spaced Cumulative Probabilities

Calculate the quantiles of a data set for a given number of quantiles.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x = 1×10

    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336    0.3426    3.5784    2.7
```

Calculate four evenly spaced quantiles.

```
y = quantile(x,4)
```

```
y = 1×4

   -0.8706    0.3307    0.6999    2.3017
```

Using `y = quantile(x,[0.2,0.4,0.6,0.8])` is another way to return the four evenly spaced quantiles.

Quantiles of a Matrix for Given Probabilities

Calculate the quantiles along the columns and rows of a data matrix for specified probabilities.

Generate a 4-by-6 data matrix.

```
rng default  % For reproducibility
X = normrnd(0,1,4,6)
```

```
X = 4×6

    0.5377    0.3188    3.5784    0.7254   -0.1241    0.6715
    1.8339   -1.3077    2.7694   -0.0631    1.4897   -1.2075
   -2.2588   -0.4336   -1.3499    0.7147    1.4090    0.7172
    0.8622    0.3426    3.0349   -0.2050    1.4172    1.6302
```

Calculate the 0.3 quantile for each column of `X` (`dim` = 1).

```
y = quantile(X,0.3,1)
```

```
y = 1×6

   -0.3013   -0.6958    1.5336   -0.1056    0.9491    0.1078
```

`quantile` returns a row vector `y` when calculating one quantile for each column of a matrix. For example, `-0.3013` is the 0.3 quantile of the first column of `X` with elements (0.5377, 1.8339, -2.2588, 0.8622). Because the default value of `dim` is 1, you can return the same result with `y = quantile(X,0.3)`.

Calculate the 0.3 quantile for each row of `X` (`dim` = 2).

```
y = quantile(X,0.3,2)
```

```
y = 4×1

    0.3844
   -0.8642
   -1.0750
    0.4985
```

`quantile` returns a column vector `y` when calculating one quantile for each row of a matrix. For example `0.3844` is the 0.3 quantile of the first row of `X` with elements (0.5377, 0.3188, 3.5784, 0.7254, -0.1241, 0.6715).

Quantiles of a Matrix for Given Number of Quantiles

Calculate the *N* evenly spaced quantiles along the columns and rows of a data matrix.

Generate a 6-by-10 data matrix.

```
rng('default');  % for reproducibility
X = unidrnd(10,6,7)
```

```
X = 6×7

     9     3    10     8     7     8     7
    10     6     5    10     8     1     4
     2    10     9     7     8     3    10
    10    10     2     1     4     1     1
     7     2     5     9     7     1     5
     1    10    10    10     2     9     4
```

Calculate three evenly spaced quantiles for each column of `X` (`dim` = 1).

```
y = quantile(X,3,1)
```

```
y = 3×7

    2.0000    3.0000    5.0000    7.0000    4.0000    1.0000    4.0000
    8.0000    8.0000    7.0000    8.5000    7.0000    2.0000    4.5000
   10.0000   10.0000   10.0000   10.0000    8.0000    8.0000    7.0000
```

Each column of matrix `y` corresponds to the three evenly spaced quantiles of each column of matrix `X`. For example, the first column of `y` with elements (2, 8, 10) has the quantiles for the first column of `X` with elements (9, 10, 2, 10, 7, 1). `y = quantile(X,3)` returns the same answer because the default value of `dim` is 1.

Calculate three evenly spaced quantiles for each row of `X` (`dim` = 2).

```
y = quantile(X,3,2)
```

```
y = 6×3

    7.0000    8.0000    8.7500
    4.2500    6.0000    9.5000
    4.0000    8.0000    9.7500
    1.0000    2.0000    8.5000
    2.7500    5.0000    7.0000
    2.5000    9.0000   10.0000
```

Each row of matrix `y` corresponds to the three evenly spaced quantiles of each row of matrix `X`. For example, the first row of `y` with elements (7, 8, 8.75) has the quantiles for the first row of `X` with elements (9, 3, 10, 8, 7, 8, 7).

Quantiles of Multidimensional Array for Given Probabilities

Calculate the quantiles of a multidimensional array for specified probabilities by using the `'all'` and `vecdim` input arguments.

Create a 3-by-5-by-2 array `X`. Specify the vector of probabilities `p`.

```
X = reshape(1:30,[3 5 2])
```

```
X =
X(:,:,1) =
```

```
     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15

X(:,:,2) =

    16    19    22    25    28
    17    20    23    26    29
    18    21    24    27    30
```

```
p = [0.25 0.75];
```

Calculate the 0.25 and 0.75 quantiles of all the elements in `X`.

```
Yall = quantile(X,p,'all')
```

```
Yall = 2×1

     8
    23
```

`Yall(1)` is the 0.25 quantile of `X`, and `Yall(2)` is the 0.75 quantile of `X`.

Calculate the 0.25 and 0.75 quantiles for each page of `X` by specifying dimensions 1 and 2 as the operating dimensions.

```
Ypage = quantile(X,p,[1 2])
```

```
Ypage =
Ypage(:,:,1) =

    4.2500
   11.7500

Ypage(:,:,2) =

   19.2500
   26.7500
```

For example, `Ypage(1,1,1)` is the 0.25 quantile of the first page of `X`, and `Ypage(2,1,1)` is the 0.75 quantile of the first page of `X`.

Calculate the 0.25 and 0.75 quantiles of the elements in each `X(i,:,:)` slice by specifying dimensions 2 and 3 as the operating dimensions.

```
Yrow = quantile(X,p,[2 3])
```

```
Yrow = 3×2

     7    22
     8    23
     9    24
```

For example, `Yrow(3,1)` is the 0.25 quantile of the elements in `X(3,:,:)`, and `Yrow(3,2)` is the 0.75 quantile of the elements in `X(3,:,:)`.

Median and Quartiles for Even Number of Data Elements

Find median and quartiles of a vector, `x`, with even number of elements.

Enter the data.

```
x = [2 5 6 10 11 13]
```

```
x = 1×6

     2     5     6    10    11    13
```

Calculate the median of `x`.

```
y = quantile(x,0.50)
```

```
y = 8
```

Calculate the quartiles of `x`.

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y = 1×3

     5     8    11
```

Using `y = quantile(x,3)` is another way to compute the quartiles of `x`.

These results might be different than the textbook definitions because `quantile` uses “Linear Interpolation” on page 33-5101 to find the median and quartiles.

Median and Quartiles for Odd Number of Data Elements

Find median and quartiles of a vector, `x`, with odd number of elements.

Enter the data.

```
x = [2 4 6 8 10 12 14]
```

```
x = 1×7

     2     4     6     8    10    12    14
```

Find the median of `x`.

```
y = quantile(x,0.50)
```

```
y = 8
```

Find the quartiles of x.

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y = 1×3

    4.5000    8.0000   11.5000
```

Using `y = quantile(x,3)` is another way to compute the quartiles of x.

These results might be different than the textbook definitions because `quantile` uses “Linear Interpolation” on page 33-5101 to find the median and quartiles.

Quantiles of Tall Vector for Given Probability

Calculate exact and approximate quantiles of a tall column vector for a given probability.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)
```

Create a datastore for the `airlinesmall` data set. Treat `'NA'` values as missing data so that `datastore` replaces them with `NaN` values. Specify to work with the `ArrTime` variable.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames','ArrTime');
```

Create a tall table on top of the datastore, and extract the data from the tall table into a tall vector.

```
t = tall(ds) % Tall table
```

```
t =

  Mx1 tall table

    ArrTime
    _______

      735
     1124
     2218
     1431
      746
     1547
     1052
     1134
       :
       :
```

```
x = t{:,:}   % Tall vector
```

```
x =
```

```
  Mx1 tall double column vector

        735
       1124
       2218
       1431
        746
       1547
       1052
       1134
        :
        :
```

Calculate the exact quantile of x for `p` = 0.5. Because `X` is a tall column vector and `p` is a scalar, `quantile` returns the exact quantile value by default.

```
p = 0.5; % Cumulative probability
yExact = quantile(x,p)
```

```
yExact =

  tall double

    ?
```

Calculate the approximate quantile of x for `p` = 0.5. Specify `'Method','approximate'` to use an approximation algorithm based on “T-Digest” on page 33-5102 for computing the quantiles.

```
yApprox = quantile(x,p,'Method','approximate')
```

```
yApprox =

  MxNx... tall double array

    ?    ?    ?    ...
    ?    ?    ?    ...
    ?    ?    ?    ...
    :    :    :
    :    :    :
```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[yExact,yApprox] = gather(yExact,yApprox)
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 4: Completed in 2.1 sec
- Pass 2 of 4: Completed in 0.91 sec
- Pass 3 of 4: Completed in 1.4 sec
- Pass 4 of 4: Completed in 1.2 sec
Evaluation completed in 7.4 sec

yExact = 1522

yApprox = 1.5220e+03
```

The values of the approximate quantile and the exact quantile are the same to the four digits shown.

Quantiles of Tall Matrix Along Different Dimensions

Calculate exact and approximate quantiles of a tall matrix for specified cumulative probabilities along different dimensions.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)
```

Create a tall matrix `X` containing a subset of variables from the `airlinesmall` data set. See “Quantiles of Tall Vector for Given Probability” on page 33-5094 for details about the steps to extract data from a tall array.

```
varnames = {'ArrDelay','ArrTime','DepTime','ActualElapsedTime'}; % Subset of variables in the da
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames); % Datastore
t = tall(ds);     % Tall table
X = t{:,varnames} % Tall matrix
```

```
X =

  Mx4 tall double matrix

           8         735         642          53
           8        1124        1021          63
          21        2218        2055          83
          13        1431        1332          59
           4         746         629          77
          59        1547        1446          61
           3        1052         928          84
          11        1134         859         155
          :           :           :           :
          :           :           :           :
```

When operating along a dimension that is not 1, the `quantile` function calculates the exact quantiles only, so that it can perform the computation efficiently using a sorting-based algorithm (see “Algorithms” on page 33-5103) instead of an approximation algorithm based on “T-Digest” on page 33-5102.

Calculate the exact quantiles of `X` along the second dimension for the cumulative probabilities 0.25, 0.5, and 0.75.

```
p = [0.25 0.50 0.75]; % Vector of cumulative probabilities
Yexact = quantile(X,p,2)
```

```
Yexact =

  MxNx... tall double array

    ?    ?    ?    ...
    ?    ?    ?    ...
    ?    ?    ?    ...
    :    :    :
    :    :    :
```

When the function operates along the first dimension and `p` is a vector of cumulative probabilities, you must use the approximation algorithm based on t-digest to compute the quantiles. Using the sorting-based algorithm to find the quantiles along the first dimension of a tall array is computationally intensive.

Calculate the approximate quantiles of `X` along the first dimension for the cumulative probabilities 0.25, 0.5, and 0.75. Because the default dimension is 1, you do not need to specify a value for `dim`.

```
Yapprox = quantile(X,p,'Method','approximate')
```

```
Yapprox =

  MxNx... tall double array

    ?    ?    ?    ...
    ?    ?    ?    ...
    ?    ?    ?    ...
    :    :    :
    :    :    :
```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[Yexact,Yapprox] = gather(Yexact,Yapprox);
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 5.2 sec
Evaluation completed in 6.7 sec
```

Show the first five rows of the exact quantiles of `X` (along the second dimension) for the cumulative probabilities 0.25, 0.5, and 0.75.

```
Yexact(1:5,:)
```

```
ans = 5×3
10^3 ×

    0.0305    0.3475    0.6885
    0.0355    0.5420    1.0725
    0.0520    1.0690    2.1365
    0.0360    0.6955    1.3815
    0.0405    0.3530    0.6875
```

Each row of the matrix `Yexact` contains the three quantiles of the corresponding row in `X`. For example, `30.5`, `347.5`, and `688.5` are the 0.25, 0.5, and 0.75 quantiles, respectively, of the first row in `X`.

Show the approximate quantiles of `X` (along the first dimension) for the cumulative probabilities 0.25, 0.5, and 0.75.

```
Yapprox
```

```
Yapprox = 3×4
10^3 ×

   -0.0070    1.1149    0.9322    0.0700
         0    1.5220    1.3350    0.1020
    0.0110    1.9180    1.7400    0.1510
```

Each column of the matrix `Yapprox` corresponds to the three quantiles for each column of the matrix `X`. For example, the first column of `Yapprox` with elements (–7, 0, 11) contains the quantiles for the first column of `X`.

Quantiles of Tall Matrix for N Evenly Spaced Probabilities

Calculate exact and approximate quantiles along different dimensions of a tall matrix for `N` evenly spaced cumulative probabilities.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)
```

Create a tall matrix `X` containing a subset of variables from the `airlinesmall` data set. See “Quantiles of Tall Vector for Given Probability” on page 33-5094 for details about the steps to extract data from a tall array.

```
varnames = {'ArrDelay','ArrTime','DepTime','ActualElapsedTime'}; % Subset of variables in the da
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames); % Datastore
t = tall(ds); % Tall table
X = t{:,varnames}
```

```
X =

  Mx4 tall double matrix

           8         735         642          53
           8        1124        1021          63
          21        2218        2055          83
          13        1431        1332          59
           4         746         629          77
          59        1547        1446          61
           3        1052         928          84
          11        1134         859         155
          :           :           :           :
          :           :           :           :
```

To find evenly spaced quantiles along the first dimension, you must use the approximation algorithm based on “T-Digest” on page 33-5102. Using the sorting-based algorithm (see “Algorithms” on page 33-5103) to find quantiles along the first dimension of a tall array is computationally intensive.

Calculate three evenly spaced quantiles along the first dimension of `X`. Because the default dimension is 1, you do not need to specify a value for `dim`. Specify `'Method','approximate'` to use the approximation algorithm.

```
N = 3; % Number of quantiles
Yapprox = quantile(X,N,'Method','approximate')
```

```
Yapprox =
```

```
  MxNx... tall double array

    ?    ?    ?    ...
    ?    ?    ?    ...
    ?    ?    ?    ...
    :    :    :
    :    :    :
```

To find evenly spaced quantiles along any other dimension (`dim` is not `1`), `quantile` calculates the exact quantiles only, so that it can perform the computation efficiently by using the sorting-based algorithm.

Calculate three evenly spaced quantiles along the second dimension of `X`. Because `dim` is not 1, `quantile` returns the exact quantiles by default.

```
Yexact = quantile(X,N,2)
```

```
Yexact =

  MxNx... tall double array

    ?    ?    ?    ...
    ?    ?    ?    ...
    ?    ?    ?    ...
    :    :    :
    :    :    :
```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[Yapprox,Yexact] = gather(Yapprox,Yexact);
```

```
Evaluating tall expression using the Local MATLAB Session:
- Pass 1 of 1: Completed in 4.1 sec
Evaluation completed in 5.4 sec
```

Show the approximate quantiles of `X` (along the first dimension) for the three evenly spaced cumulative probabilities.

```
Yapprox
```

```
Yapprox = 3×4
10^3 ×

   -0.0070    1.1150    0.9322    0.0700
         0    1.5220    1.3350    0.1020
    0.0110    1.9180    1.7400    0.1510
```

Each column of the matrix `Yapprox` corresponds to the three evenly spaced quantiles for each column of the matrix `X`. For example, the first column of `Yapprox` with elements (–7, 0, 11) contains the quantiles for the first column of `X`.

Show the first five rows of the exact quantiles of `X` (along the second dimension) for the three evenly spaced cumulative probabilities.

```
Yexact(1:5,:)
```

```
ans = 5×3
10^3 ×
```

```
    0.0305    0.3475    0.6885
    0.0355    0.5420    1.0725
    0.0520    1.0690    2.1365
    0.0360    0.6955    1.3815
    0.0405    0.3530    0.6875
```

Each row of the matrix `Yexact` contains the three evenly spaced quantiles of the corresponding row in `X`. For example, `30.5`, `347.5`, and `688.5` are the 0.25, 0.5, and 0.75 quantiles, respectively, of the first row in `X`.

Input Arguments

`X` — Input data

vector | array

Input data, specified as a vector or array.

Data Types: `double` | `single`

`p` — Cumulative probabilities

scalar | vector

Cumulative probabilities for which to compute the quantiles, specified as a scalar or vector of scalars from 0 to 1.

Example: 0.3

Example: [0.25, 0.5, 0.75]

Example: (0:0.25:1)

Data Types: `double` | `single`

`N` — Number of quantiles

positive integer

Number of quantiles to compute, specified as a positive integer. `quantile` returns `N` quantiles that divide the data set into evenly distributed `N`+1 segments.

Data Types: `double` | `single`

`dim` — Dimension

positive integer

Dimension along which the quantiles of a matrix `X` are requested, specified as a positive integer. For example, for a matrix `X`, when `dim` = 1, `quantile` returns the quantile(s) of the columns of `X`; when `dim` = 2, `quantile` returns the quantile(s) of the rows of `X`. For a multidimensional array `X`, the length of the `dim`th dimension of `Y` is the same as the length of `p`.

Data Types: `single` | `double`

`vecdim` — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. In the smallest specified operating dimension (that is, dimension

`min(vecdim)`), the output `Y` has length equal to the number of quantiles requested (either `N` or `length(p)`). In each of the remaining operating dimensions, `Y` has length 1. The other dimension lengths are the same for `X` and `Y`.

For example, consider a 2-by-3-by-3 array `X` with `p = [0.2 0.4 0.6 0.8]`. In this case, `quantile(X,p,[1 2])` returns an array, where each page of the array contains the 0.2, 0.4, 0.6, and 0.8 quantiles of the elements on the corresponding page of `X`. Because 1 and 2 are the operating dimensions, with `min([1 2]) = 1` and `length(p) = 4`, the output is a 4-by-1-by-3 array.

Data Types: `single` | `double`

`method` — Method for calculating quantiles
`'exact'` (default) | `'approximate'`

Method for calculating quantiles, specified as `'exact'` or `'approximate'`. By default, `quantile` returns the exact quantiles by implementing an algorithm on page 33-5103 that uses sorting. You can specify `'method','approximate'` for `quantile` to return approximate quantiles by implementing an algorithm that uses T-Digest on page 33-5102.

Data Types: `char` | `string`

Output Arguments

`Y` — Quantiles
scalar | array

Quantiles of a data vector or array, returned as a scalar or array for one or multiple values of cumulative probabilities.

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of quantiles requested (`N` or `length(p)`). `Y(i)` contains the `p(i)` quantile.
- If `X` is an array of dimension *d*, then `Y` is an array with the length of the smallest operating dimension equal to the number of quantiles requested (`N` or `length(p)`).

More About

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if `X` is a 1-by-3-by-4 array, then `X` is a 3-D array.

Nonsingleton Dimension

A *nonsingleton dimension* of an array is a dimension whose size is not equal to 1. A *first nonsingleton dimension* of an array is the first dimension that satisfies the nonsingleton condition. For example, if `X` is a 1-by-1-by-2-by-4 array, then the third dimension is the first nonsingleton dimension of `X`.

Linear Interpolation

Linear interpolation uses linear polynomials to find $y_i = f(x_i)$, the values of the underlying function $Y = f(X)$ at the points in the vector or array x. Given the data points (x_1, y_1) and (x_2, y_2), where $y_1 = f(x_1)$ and $y_2 = f(x_2)$, linear interpolation finds $y = f(x)$ for a given x between x_1 and x_2 as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the $1.5/n$ quantile is $y_{1.5/n}$ and the $2.5/n$ quantile is $y_{2.5/n}$, then linear interpolation finds the $2.3/n$ quantile $y_{2.3/n}$ as

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)}\left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}}\right).$$

T-Digest

T-digest[2] on page 33-5104 is a probabilistic data structure that is a sparse representation of the empirical cumulative distribution function (CDF) of a data set. T-digest is useful for computing approximations of rank-based statistics (such as percentiles and quantiles) from online or distributed data in a way that allows for controllable accuracy, particularly near the tails of the data distribution.

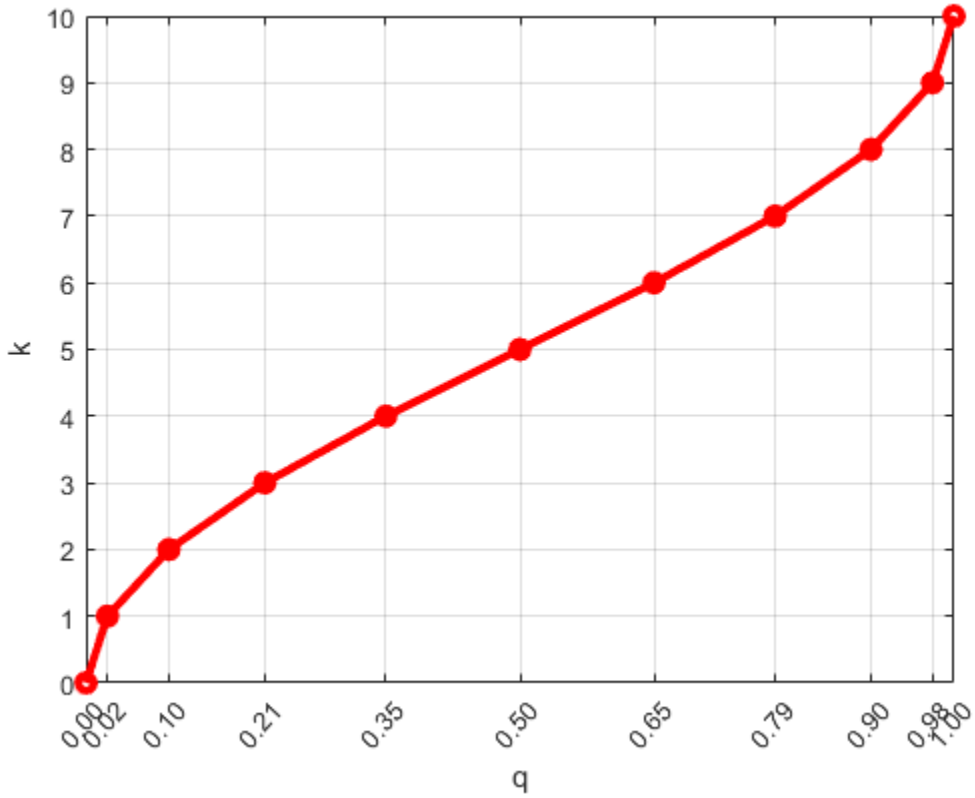
For data that is distributed in different partitions, t-digest computes quantile estimates (and percentile estimates) for each data partition separately, and then combines the estimates while maintaining a constant-memory bound and constant relative accuracy of computation ($q(1 - q)$ for the qth quantile). For these reasons, t-digest is practical for working with tall arrays.

To estimate quantiles of an array that is distributed in different partitions, first build a t-digest in each partition of the data. A t-digest clusters the data in the partition and summarizes each cluster by a centroid value and an accumulated weight that represents the number of samples contributing to the cluster. T-digest uses large clusters (widely spaced centroids) to represent areas of the CDF that are near `q = 0.5` and uses small clusters (tightly spaced centroids) to represent areas of the CDF that are near `q = 0` or `q = 1`.

T-digest controls the cluster size by using a scaling function that maps a quantile q to an index k with a compression parameter δ. That is,

$$k(q, \delta) = \delta \cdot \left(\frac{\sin^{-1}(2q - 1)}{\pi} + \frac{1}{2}\right),$$

where the mapping k is monotonic with minimum value $k(0,\delta) = 0$ and maximum value $k(1,\delta) = \delta$. The following figure shows the scaling function for $\delta = 10$.



The scaling function translates the quantile q to the scaling factor k in order to give variable size steps in q. As a result, cluster sizes are unequal (larger around the center quantiles and smaller near $q = 0$ or $q = 1$). The smaller clusters allow for better accuracy near the edges of the data.

To update a t-digest with a new observation that has a weight and location, find the cluster closest to the new observation. Then, add the weight and update the centroid of the cluster based on the weighted average, provided that the updated weight of the cluster does not exceed the size limitation.

You can combine independent t-digests from each partition of the data by taking a union of the t-digests and merging their centroids. To combine t-digests, first sort the clusters from all the independent t-digests in decreasing order of cluster weights. Then, merge neighboring clusters, when they meet the size limitation, to form a new t-digest.

Once you form a t-digest that represents the complete data set, you can estimate the end-points (or boundaries) of each cluster in the t-digest and then use interpolation between the end-points of each cluster to find accurate quantile estimates.

Algorithms

For an n-element vector `X`, `quantile` computes quantiles by using a sorting-based algorithm as follows:

1 The sorted elements in `X` are taken as the $(0.5/n)$, $(1.5/n)$, ..., $([n - 0.5]/n)$ quantiles. For example:

- For a data vector of five elements such as {6, 3, 2, 10, 1}, the sorted elements {1, 2, 3, 6, 10} respectively correspond to the 0.1, 0.3, 0.5, 0.7, 0.9 quantiles.

- For a data vector of six elements such as {6, 3, 2, 10, 8, 1}, the sorted elements {1, 2, 3, 6, 8, 10} respectively correspond to the (0.5/6), (1.5/6), (2.5/6), (3.5/6), (4.5/6), (5.5/6) quantiles.

2 `quantile` uses "Linear Interpolation" on page 33-5101 to compute quantiles for probabilities between (0.5/*n*) and ([*n* – 0.5]/*n*).

3 For the quantiles corresponding to the probabilities outside that range, `quantile` assigns the minimum or maximum values of the elements in `X`.

`quantile` treats `NaN`s as missing values and removes them.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `Y = quantile(X,p)` and `Y = quantile(X,N)` return the exact quantiles (using a sorting-based algorithm on page 33-5103) only if `X` is a tall column vector.
- `Y = quantile(__,dim)` returns the exact quantiles only when *one* of these conditions exists:
  - `X` is a tall column vector.
  - `X` is a tall array and `dim` is not `1`. For example, `quantile(X,p,2)` returns the exact quantiles along the rows of the tall array `X`.

  If `X` is a tall array and `dim` is `1`, then you must specify `'Method','approximate'` to use an approximation algorithm based on T-Digest on page 33-5102 for computing the quantiles. For example, `quantile(X,p,1,'Method','approximate')` returns the approximate quantiles along the columns of the tall array `X`.
- `Y = quantile(__,vecdim)` returns the exact quantiles only when *one* of these conditions exists:
  - `X` is a tall column vector.
  - `X` is a tall array and `vecdim` does not include `1`. For example, if `X` is a 3-by-5-by-2 array, then `quantile(X,p,[2,3])` returns the exact quantiles of the elements in each `X(i,:,:)` slice.
  - `X` is a tall array and `vecdim` includes `1` and all the nonsingleton dimensions on page 33-5101 of `X`. For example, if `X` is a 10-by-1-by-4 array, then `quantile(X,p,[1 3])` returns the exact quantiles of the elements in `X(:,1,:)`.

  If `X` is a tall array and `vecdim` includes `1` but does not include all the nonsingleton dimensions of `X`, then you must specify `'Method','approximate'` to use the approximation algorithm. For example, if `X` is a 10-by-1-by-4 array, you can use `quantile(X,p,[1 2],'Method','approximate')` to find the approximate quantiles of each page of `X`.

For more information, see “Tall Arrays”.

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `'Method'` name-value pair argument is not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).
- If the output `Y` is a vector, the orientation of `Y` differs from MATLAB when all of the following are true:
  - You do not supply `dim`.
  - `X` is a variable-size array, and not a variable-size vector, at compile time, but `X` is a vector at run time.
  - The orientation of the vector `X` does not match the orientation of the vector `p`.

  In this case, the output `Y` matches the orientation of `X`, not the orientation of `p`.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `'Method'` name-value pair argument is not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics
“Quantiles and Percentiles” on page 3-6

Introduced before R2006a

rand

Class: `qrandstream`

Generate quasi-random points from stream

Syntax

```
rand
rand(q,n)
rand(q)
rand(q,m,n)
rand(q,[m,n])
rand(q,m,n,p,...)
rand(q,[m,n,p,...])
```

Description

`rand` returns a matrix of quasi-random values and is intended to allow objects of the `qrandstream` on page 33-5078 class to be used in code that contains calls to the `rand` method of the MATLAB pseudo-random `randstream` class. Due to the multidimensional nature of quasi-random numbers, only some syntaxes of `rand` are supported by the `qrandstream` class.

`rand(q,n)` returns an `n`-by-`n` matrix only when `n` is equal to the number of dimensions. Any other value of `n` produces an error.

`rand(q)` returns a scalar only when the stream is in one dimension. Having more than one dimension in `q` produces an error.

`rand(q,m,n)` or `rand(q,[m,n])` returns an `m`-by-`n` matrix only when `n` is equal to the number of dimensions in the stream. Any other value of `n` produces an error.

`rand(q,m,n,p,...)` or `rand(q,[m,n,p,...])` produces an error unless `p` and all following dimensions sizes are equal to one.

Examples

Generate the first 256 points from a 5-D Sobol sequence:

```
q = qrandstream('sobol',5);
X = rand(q,256,5);
```

See Also

`qrand` | `qrandstream` | `rand`

quantileError

Class: `TreeBagger`

Quantile loss using bag of regression trees

Syntax

```
err = quantileError(Mdl,X)
err = quantileError(Mdl,X,ResponseVarName)
err = quantileError(Mdl,X,Y)
err = quantileError( ___ ,Name,Value)
```

Description

`err = quantileError(Mdl,X)` returns half of the mean absolute deviation (MAD) from comparing the true responses in the table `X` to the predicted medians resulting from applying the bag of regression trees `Mdl` to the observations of the predictor data in `X`.

- `Mdl` must be a `TreeBagger` model object.
- The response variable name in `X` must have the same name as the response variable in the table containing the training data.

`err = quantileError(Mdl,X,ResponseVarName)` uses the true response and predictor variables contained in the table `X`. `ResponseVarName` is the name of the response variable and `Mdl.PredictorNames` contain the names of the predictor variables.

`err = quantileError(Mdl,X,Y)` uses the predictor data in the table or matrix `X` and the response data in the vector `Y`.

`err = quantileError( ___ ,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities, the error type, or which trees to include in the quantile-regression-error estimation.

Input Arguments

`Mdl` — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`. The value of `Mdl.Method` must be `regression`.

`X` — Sample data

numeric matrix | table

Sample data used to estimate quantiles, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable. If you specify `Y`, then the number of rows in `X` must be equal to the length of `Y`.

- For a numeric matrix:
  - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl` (stored in `Mdl.PredictorNames`).
  - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types), then `quantileError` throws an error.
  - Specify `Y` for the true responses.
- For a table:
  - `quantileError` does not support multicolumn variables or cell arrays other than cell arrays of character vectors.
  - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those variables that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.).
  - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.).
  - If `X` contains the response variable:
    - If the response variable has the same name as the response variable that trained `Mdl`, then you do not have to supply the response variable name or vector of true responses. `quantileError` uses that variable for the true responses by default.
    - You can specify `ResponseVarName` or `Y` for the true responses.

Data Types: `table` | `double` | `single`

`ResponseVarName` — Response variable name
character vector | string scalar

Response variable name, specified as a character vector or string scalar. `ResponseVarName` must be the name of the response variable in the table of sample data `X`.

If the table `X` contains the response variable, and it has the same name as the response variable used to train `Mdl`, then you do not have to specify `ResponseVarName`. `quantileError` uses that variable for the true responses by default.

Data Types: `char` | `string`

`Y` — True responses
numeric vector

True responses, specified as a numeric vector. The number of rows in `X` must be equal to the length of `Y`.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Mode` — Ensemble error type

`'ensemble'` (default) | `'cumulative'` | `'individual'`

Ensemble error type, specified as the comma-separated pair consisting of `'Mode'` and a value in this table. Suppose *`tau`* is the value of `Quantile`.

Value	Description
`'cumulative'`	`err` is a `Mdl.NumTrees`-by-`numel(`*`tau`*`)` numeric matrix of cumulative quantile regression errors. `err(`*`j`*`,`*`k`*`)` is the *`tau`*`(`*`k`*`)` quantile regression error using the learners in `Mdl.Trees(1:`*`j`*`)` only.
`'ensemble'`	`err` is a 1-by-`numel(`*`tau`*`)` numeric vector of cumulative quantile regression errors for the entire ensemble. `err(`*`k`*`)` is the *`tau`*`(`*`k`*`)` ensemble quantile regression error.
`'individual'`	`err` is a `Mdl.NumTrees`-by-`numel(`*`tau`*`)` numeric matrix of quantile regression errors from individual learners. `err(`*`j`*`,`*`k`*`)` is the *`tau`*`(`*`k`*`)` quantile regression error using the learner in `Mdl.Trees(`*`j`*`)` only.

For `'cumulative'` and `'individual'`, if you include fewer trees in quantile estimation using `Trees` or `UseInstanceForTree`, then the number of rows in `err` decreases from `Mdl.NumTrees`.

Example: `'Mode','cumulative'`

`Weights` — Observation weights

`ones(size(X,1),1)` (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values with length equal to `size(X,1)`. `quantileError` uses `Weights` to compute the weighted average of the deviations when estimating the quantile regression error.

By default, `quantileError` attributes a weight of `1` to each observation, which yields an unweighted average of the deviations.

`Quantile` — Quantile probability

`0.5` (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of `'Quantile'` and a numeric vector containing values in the interval [0,1]. For each element in `Quantile`, `quantileError` returns corresponding quantile regression errors for all probabilities in `Quantile`.

Example: `'Quantile',[0 0.25 0.5 0.75 1]`

Data Types: `single` | `double`

`Trees` — Indices of trees to use in response estimation

`'all'` (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of `'Trees'` and `'all'` or a numeric vector of positive integers. Indices correspond to the cells of

`Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For `'all'`, `quantileError` uses all trees in the ensemble (that is, the indices `1:Mdl.NumTrees`).

Values other than the default can affect the number of rows in `err`.

Example: `'Trees',[1 10 Mdl.NumTrees]`

Data Types: `char` | `string` | `single` | `double`

`TreeWeights` — Weights to attribute to responses from individual trees
`ones(Mdl.NumTrees,1)` (default) | numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of `'TreeWeights'` and a numeric vector of `numel(`*`trees`*`)` nonnegative values. *`trees`* is the value of `Trees`.

If you specify `'Mode','individual'`, then `quantileError` ignores `TreeWeights`.

Data Types: `single` | `double`

`UseInstanceForTree` — Indicators specifying which trees to use to make predictions for each observation
`'all'` (default) | logical matrix

Indicators specifying which trees to use to make predictions for each observation, specified as the comma-separated pair consisting of `'UseInstanceForTree'` and an *n*-by-`Mdl.Trees` logical matrix. *n* is the number of observations (rows) in `X`. Rows of `UseInstanceForTree` correspond to observations and columns correspond to learners in `Mdl.Trees`. `'all'` indicates to use all trees for all observations when estimating the quantiles.

If `UseInstanceForTree(`*`j`*`,`*`k`*`) = true`, then `quantileError` uses the tree in `Mdl.Trees(`*`k`*`)` when it predicts the response for the observation `X(`*`j`*`,:)`.

You can estimate quantiles using the response data in `Mdl.Y` directly instead of using the predictions from the random forest by specifying a row composed entirely of `false` values. For example, to estimate the quantile for observation *`j`* using the response data, and to use the predictions from the random forest for all other observations, specify this matrix:

```
UseInstanceForTree = true(size(Mdl.X,2),Mdl.NumTrees);
UseInstanceForTree(j,:) = false(1,Mdl.NumTrees);
```

Values other than the default can affect the number of rows in `err`. Also, the value of `Trees` affects the value of `UseInstanceForTree`. Suppose that *`U`* is the value of `UseInstanceForTree`. `quantileError` ignores the columns of *`U`* corresponding to trees not being used in estimation from the specification of `Trees`. That is, `quantileError` resets the value of `'UseInstanceForTree'` to `U(:,`*`trees`*`)`, where *`trees`* is the value of `'Trees'`.

Data Types: `char` | `string` | `logical`

Output Arguments

`err` — Half of quantile regression error
numeric scalar | numeric matrix

Half of the quantile regression error on page 33-5113, returned as a numeric scalar or *T*-by-`numel(tau)` matrix. *`tau`* is the value of `Quantile`.

T depends on the values of `Mode`, `Trees`, `UseInstanceForTree`, and `Quantile`. Suppose that you specify `'Trees',trees` and you use the default value of `'UseInstanceForTree'`.

- For `'Mode','cumulative'`, `err` is a `numel(trees)`-by-`numel(tau)` numeric matrix. `err(j,k)` is the `tau(k)` cumulative quantile regression error using the learners in `Mdl.Trees(trees(1:j))`.
- For `'Mode','ensemble'`, `err` is a 1-by-`numel(tau)` numeric vector. `err(k)` is the `tau(k)` cumulative quantile regression error using the learners in `Mdl.Trees(trees)`.
- For `'Mode','individual'`, `err` is a `numel(trees)`-by-`numel(tau)` numeric matrix. `err(j,k)` is the `tau(k)` quantile regression error using the learner in `Mdl.Trees(trees(j))`.

Examples

Estimate In-Sample Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders. Consider `Cylinders` a categorical variable.

```
load carsmall
Cylinders = categorical(Cylinders);
X = table(Displacement,Weight,Cylinders,MPG);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,X,'MPG','Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression, and estimate the MAD of the entire ensemble using the predicted conditional medians.

```
err = quantileError(Mdl,X)
```

```
err = 1.2339
```

Because `X` is a table containing the response and commensurate variable names, you do not have to specify the response variable name or data. However, you can specify the response using this syntax.

```
err = quantileError(Mdl,X,'MPG')
```

```
err = 1.2339
```

Find Appropriate Ensemble Size Using Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders.

```
load carsmall
X = table(Displacement,Weight,Cylinders,MPG);
```

Randomly split the data into two sets: 75% training and 25% testing. Extract the subset indices.

```
rng(1); % For reproducibility
cvp = cvpartition(size(X,1),'Holdout',0.25);
idxTrn = training(cvp);
idxTest = test(cvp);
```

Train an ensemble of bagged regression trees using the training set. Specify 250 weak learners.

```
Mdl = TreeBagger(250,X(idxTrn,:),'MPG','Method','regression');
```

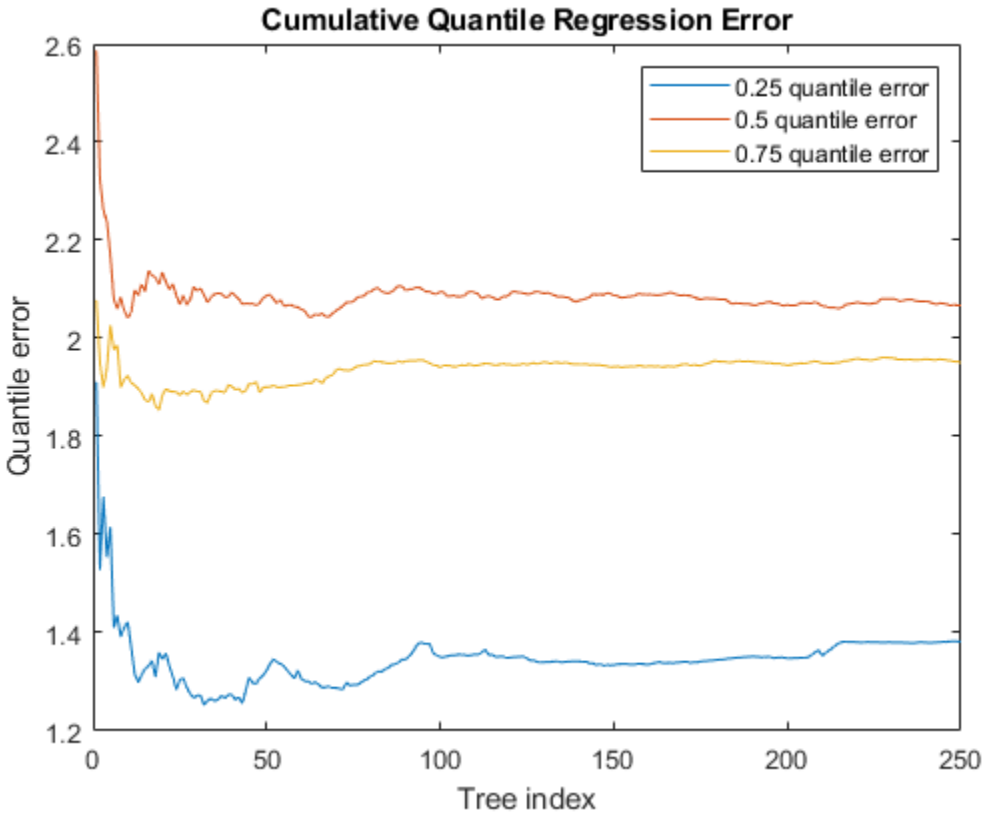
Estimate the cumulative 0.25, 0.5, and 0.75 quantile regression errors for the test set. Pass the predictor data in as a numeric matrix, and the response data in as a vector.

```
err = quantileError(Mdl,X{idxTest,1:3},MPG(idxTest),'Quantile',[0.25 0.5 0.75],...
    'Mode','cumulative');
```

`err` is a 250-by-3 matrix of cumulative quantile regression errors. Columns correspond to quantile probabilities and rows correspond to trees in the ensemble. The errors are cumulative, so they incorporate aggregated predictions from previous trees. Although, `Mdl` was trained using a table, if all predictor variables in the table are numeric, then you can supply a matrix of predictor data instead.

Plot the cumulative quantile errors on the same plot.

```
figure;
plot(err);
legend('0.25 quantile error','0.5 quantile error','0.75 quantile error');
ylabel('Quantile error');
xlabel('Tree index');
title('Cumulative Quantile Regression Error')
```



Training using about 60 trees appears to be enough for the first two quartiles, but the third quartile requires about 150 trees.

More About

Quantile Regression Error

The quantile regression error of a model given observed predictor data and responses is the weighted mean absolute deviation (MAD). If the model under-predicts the response, then deviation weights are τ, the quantile probability. If the model over-predicts, then deviation weights are 1 – τ.

That is, the τ quantile regression error is

$$L_\tau = \tau \frac{\sum_{\{j:y_j \geq \hat{y}_{\tau,j}\}} w_j(y_j - \hat{y}_{\tau,j})}{\sum_{j=1}^{n} w_j} + (1-\tau)\frac{\sum_{\{j:y_j < \hat{y}_{\tau,j}\}} w_j(\hat{y}_{\tau,j} - y_j)}{\sum_{j=1}^{n} w_j}.$$

y_j is true response j, $\hat{y}_{\tau,j}$ is the τ quantile that the model predicts, and w_j is observation weight j.

Tips

- To tune the number of trees in the ensemble, set `'Mode','cumulative'` and plot the quantile regression errors with respect to tree indices. The maximal number of required trees is the tree index where the quantile regression error appears to level off.
- To investigate the performance of a model when the training sample is small, use `oobQuantileError` instead.

`TreeBagger` | `error` | `oobQuantileError` | `quantilePredict`

Introduced in R2016b

quantilePredict

Class: `TreeBagger`

Predict response quantile using bag of regression trees

Syntax

```
YFit = quantilePredict(Mdl,X)
YFit = quantilePredict(Mdl,X,Name,Value)
[YFit,YW] = quantilePredict( ___ )
```

Description

`YFit = quantilePredict(Mdl,X)` returns a vector of medians of the predicted responses at `X`, a table or matrix of predictor data, and using the bag of regression trees `Mdl`. `Mdl` must be a `TreeBagger` model object.

`YFit = quantilePredict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities or which trees to include for quantile estimation.

`[YFit,YW] = quantilePredict( ___ )` also returns a sparse matrix of response weights on page 33-5122.

Input Arguments

`Mdl` — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`. The value of `Mdl.Method` must be `regression`.

`X` — Predictor data

numeric matrix | table

Predictor data used to estimate quantiles, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
  - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
  - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `quantilePredict` throws an error.
- For a table:

- `quantilePredict` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.
- If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those variables that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `quantilePredict` ignores them.
- If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `quantilePredict` ignores them.

Data Types: `table` | `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Quantile` — Quantile probability
`0.5` (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of `'Quantile'` and a numeric vector containing values in the interval [0,1]. For each observation (row) in `X`, `quantilePredict` returns corresponding quantiles for all probabilities in `Quantile`.

Example: `'Quantile',[0 0.25 0.5 0.75 1]`

Data Types: `single` | `double`

`Trees` — Indices of trees to use in response estimation
`'all'` (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of `'Trees'` and `'all'` or a numeric vector of positive integers. Indices correspond to the cells of `Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For `'all'`, `quantilePredict` uses the indices `1:Mdl.NumTrees`.

Example: `'Trees',[1 10 Mdl.NumTrees]`

Data Types: `char` | `string` | `single` | `double`

`TreeWeights` — Weights to attribute to responses from individual trees
numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of `'TreeWeights'` and a numeric vector of `numel(`*`trees`*`)` nonnegative values. *`trees`* is the value of the `Trees` name-value pair argument.

The default is `ones(size(`*`trees`*`))`.

Data Types: `single` | `double`

`UseInstanceForTree` — Indicators specifying which trees to use to make predictions for each observation
`'all'` (default) | logical matrix

Indicators specifying which trees to use to make predictions for each observation, specified as the comma-separated pair consisting of `'UseInstanceForTree'` and an *n*-by-`Mdl.Trees` logical matrix. *n* is the number of observations (rows) in `X`. Rows of `UseInstanceForTree` correspond to observations and columns correspond to learners in `Mdl.Trees`. `'all'` indicates to use all trees for all observations when estimating the quantiles.

If `UseInstanceForTree(j,k) = true`, then `quantilePredict` uses the tree in `Mdl.Trees(trees(k))` when it predicts the response for the observation `X(j,:)`.

You can estimate the quantile using the response data in `Mdl.Y` directly instead of using the predictions from the random forest by specifying a row composed entirely of `false` values. For example, to estimate the quantile for observation *j* using the response data, and to use the predictions from the random forest for all other observations, specify this matrix:

```
UseInstanceForTree = true(size(Mdl.X,2),Mdl.NumTrees);
UseInstanceForTree(j,:) = false(1,Mdl.NumTrees);
```

Data Types: `char` | `string` | `logical`

Output Arguments

`YFit` — Estimated quantiles
numeric matrix

Estimated quantiles, returned as an *n*-by-`numel(tau)` numeric matrix. *n* is the number of observations in `X` (`size(X,1)`) and *tau* is the value of `Quantile`. That is, `YFit(j,k)` is the estimated `100*tau(k)`% percentile of the response distribution given `X(j,:)` and using `Mdl`.

`YW` — Response weights
sparse matrix

Response weights on page 33-5122, returned as an n_{train}-by-*n* sparse matrix. n_{train} is the number of responses in the training data (`numel(Mdl.Y)`) and *n* is the number of observations in `X` (`size(X,1)`).

`quantilePredict` predicts quantiles using linear interpolation of the empirical cumulative distribution function (C.D.F.). For a particular observation, you can use its response weights to estimate quantiles using alternative methods, such as approximating the C.D.F. using kernel smoothing.

Note `quantilePredict` derives response weights by passing an observation through the trees in the ensemble. If you specify `UseInstanceForTree` and you compose row *j* entirely of `false` values, then `YW(:,j) = Mdl.W` instead, that is, the observation weights.

Examples

Predict Training Sample Medians

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression to predict the median MPG for all sorted training observations.

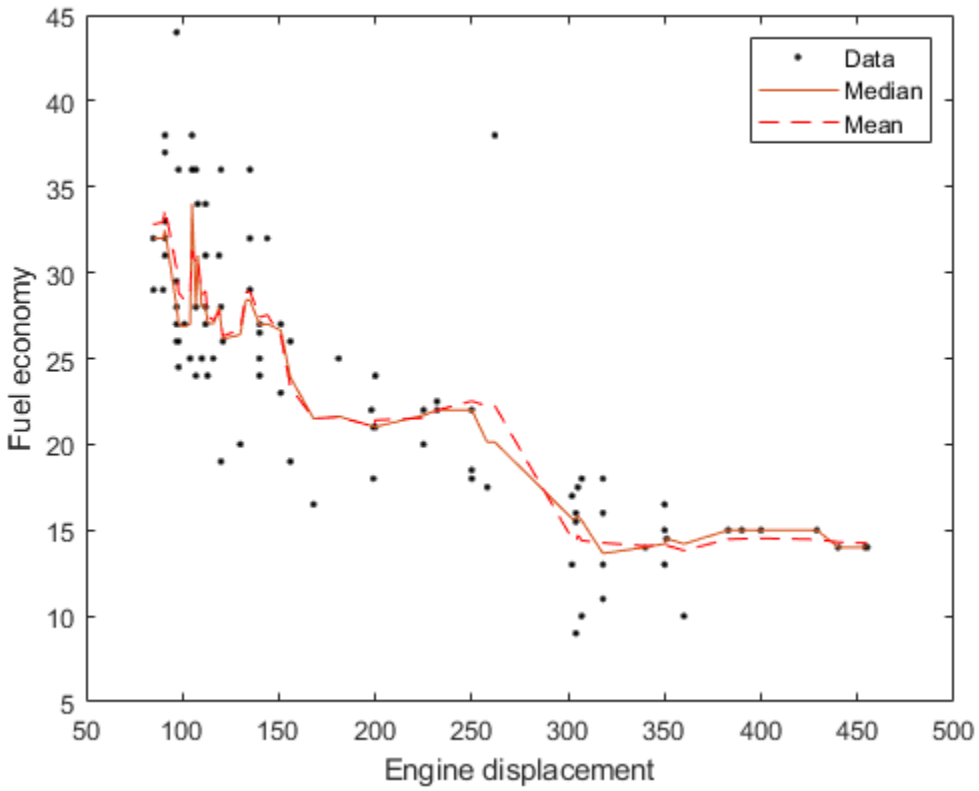
```
medianMPG = quantilePredict(Mdl,sort(Displacement));
```

`medianMPG` is an `n`-by-1 numeric vector of medians corresponding to the conditional distribution of the response given the sorted observations in `Displacement`. `n` is the number of observations in `Displacement`.

Plot the observations and the estimated medians on the same figure. Compare the median and mean responses.

```
meanMPG = predict(Mdl,sort(Displacement));

figure;
plot(Displacement,MPG,'k.');
hold on
plot(sort(Displacement),medianMPG);
plot(sort(Displacement),meanMPG,'r--');
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Median','Mean');
hold off;
```



Estimate Prediction Intervals Using Percentiles

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

Perform quantile regression to predict the 2.5% and 97.5% percentiles for ten equally-spaced engine displacements between the minimum and maximum in-sample displacement.

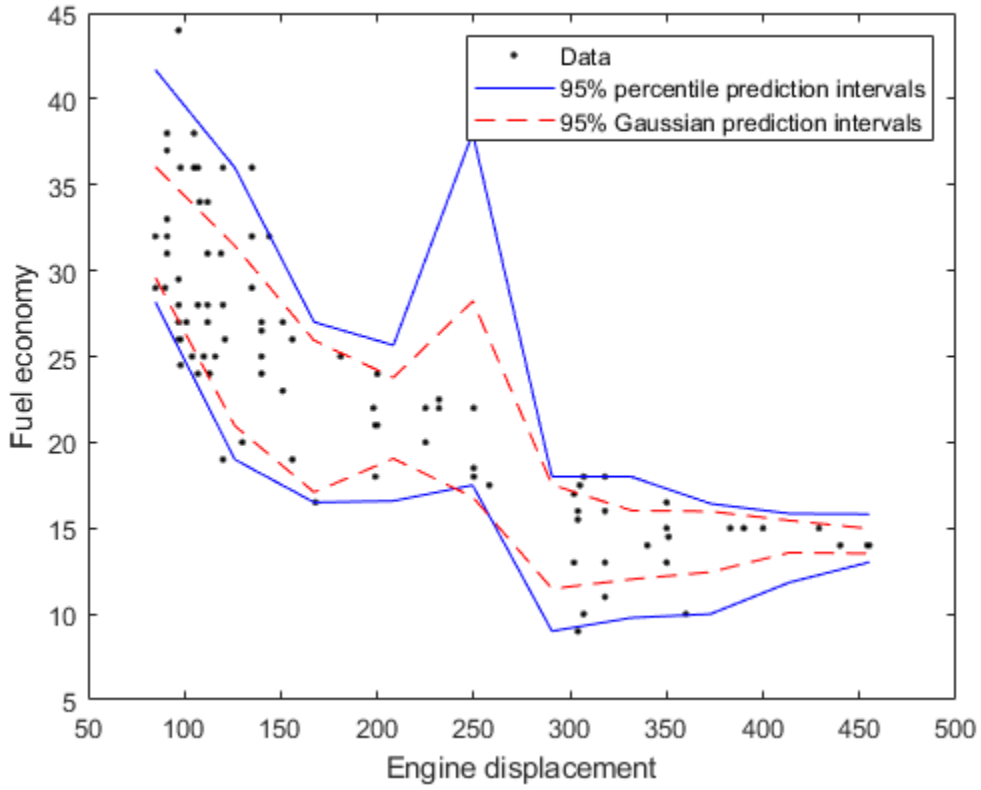
```
predX = linspace(min(Displacement),max(Displacement),10)';
quantPredInts = quantilePredict(Mdl,predX,'Quantile',[0.025,0.975]);
```

`quantPredInts` is a 10-by-2 numeric matrix of prediction intervals corresponding to the observations in `predX`. The first column contains the 2.5% percentiles and the second column contains the 97.5% percentiles.

Plot the observations and the estimated medians on the same figure. Compare the percentile prediction intervals and the 95% prediction intervals assuming the conditional distribution of `MPG` is Gaussian.

```
[meanMPG,steMeanMPG] = predict(Mdl,predX);
stndPredInts = meanMPG + [-1 1]*norminv(0.975).*steMeanMPG;

figure;
h1 = plot(Displacement,MPG,'k.');
hold on
h2 = plot(predX,quantPredInts,'b');
h3 = plot(predX,stndPredInts,'r--');
ylabel('Fuel economy');
xlabel('Engine displacement');
legend([h1,h2(1),h3(1)],{'Data','95% percentile prediction intervals',...
    '95% Gaussian prediction intervals'});
hold off;
```



Estimate Conditional Cumulative Distribution Using Quantile Regression

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

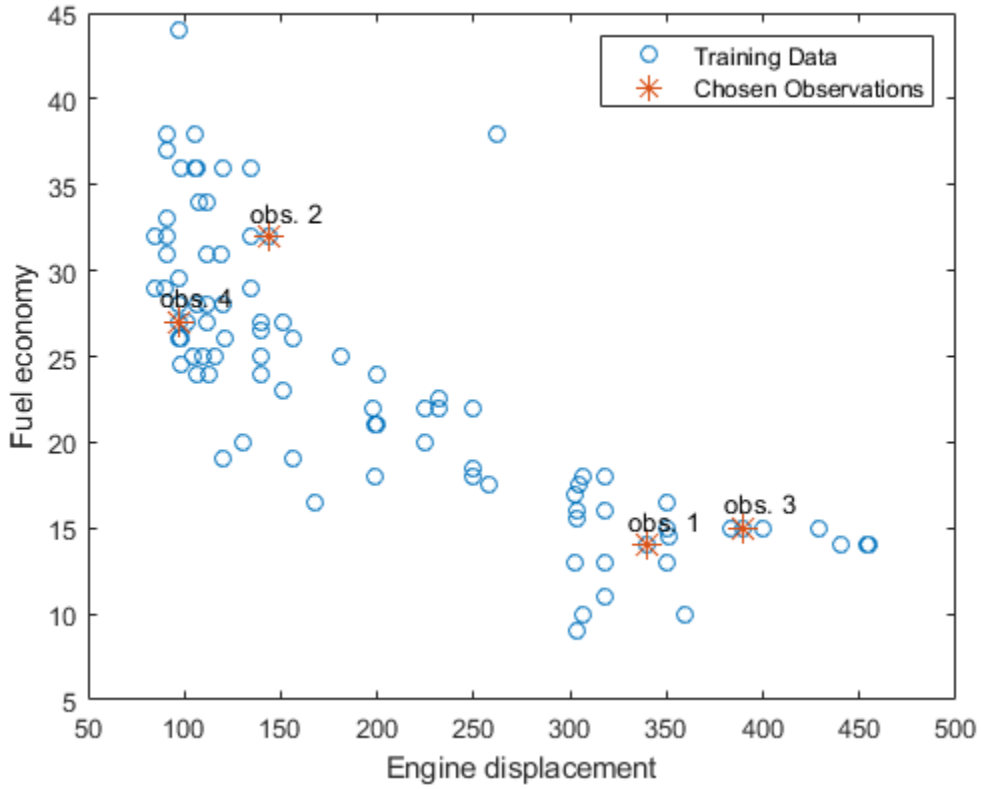
Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

Estimate the response weights for a random sample of four training observations. Plot the training sample and identify the chosen observations.

```
[predX,idx] = datasample(Mdl.X,4);
[~,YW] = quantilePredict(Mdl,predX);
n = numel(Mdl.Y);

figure;
plot(Mdl.X,Mdl.Y,'o');
hold on
plot(predX,Mdl.Y(idx),'*','MarkerSize',10);
text(predX-10,Mdl.Y(idx)+1.5,{'obs. 1' 'obs. 2' 'obs. 3' 'obs. 4'});
legend('Training Data','Chosen Observations');
xlabel('Engine displacement')
ylabel('Fuel economy')
hold off
```



`YW` is an `n`-by-4 sparse matrix containing the response weights. Columns correspond to test observations and rows correspond to responses in the training sample. Response weights are independent of the specified quantile probability.

Estimate the conditional cumulative distribution function (C.C.D.F.) of the responses by:

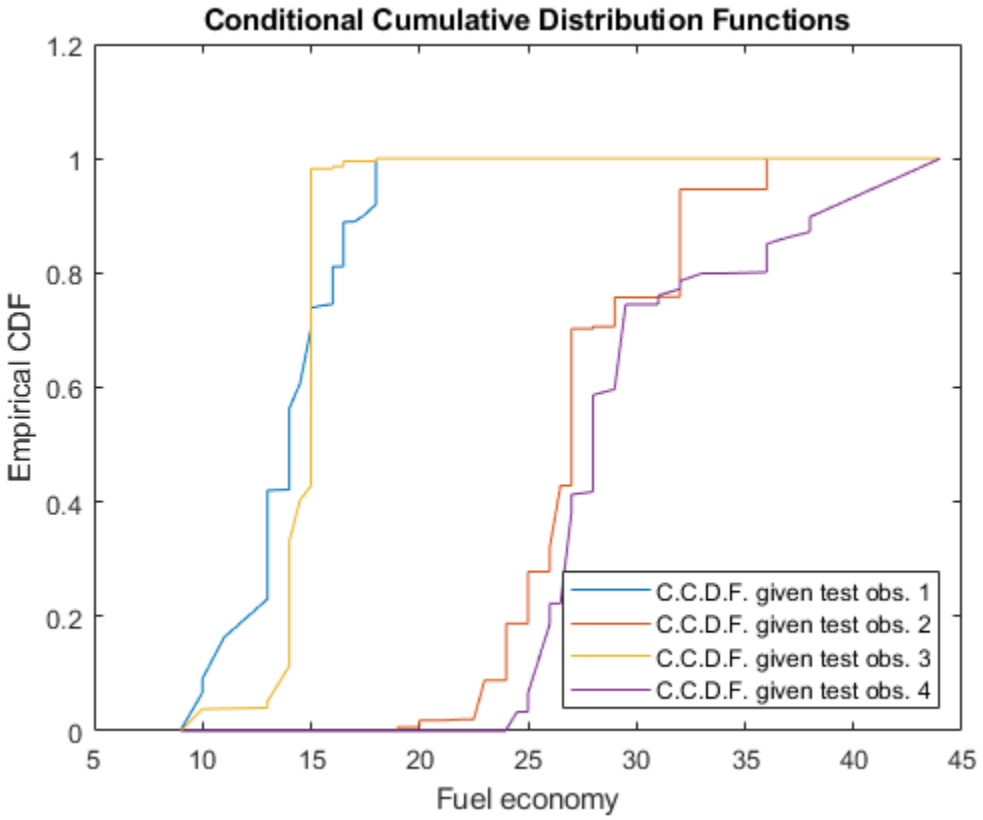
1. Sorting the responses is ascending order, and then sorting the response weights using the indices induced by sorting the responses.
2. Computing the cumulative sums over each column of the sorted response weights.

```
[sortY,sortIdx] = sort(Mdl.Y);
cpdf = full(YW(sortIdx,:));
ccdf = cumsum(cpdf);
```

`ccdf(:,j)` is the empirical C.C.D.F. of the response given test observation `j`.

Plot the four empirical C.C.D.F. in the same figure.

```
figure;
plot(sortY,ccdf);
legend('C.C.D.F. given test obs. 1','C.C.D.F. given test obs. 2',...
    'C.C.D.F. given test obs. 3','C.C.D.F. given test obs. 4',...
    'Location','SouthEast')
title('Conditional Cumulative Distribution Functions')
xlabel('Fuel economy')
ylabel('Empirical CDF')
```



More About

Response Weights

Response weights are scalars that represent the conditional distribution of the response given a value in the predictor space. The observations in the bootstrap samples and the leaves that the training and test observations share induce response weights.

Given the observation x, the response weight for observation j in the training sample using tree t in the ensemble is

$$w_{tj}(x) = \frac{I\{X_j \in S_t(x)\}}{\sum_{k=1}^{n_{\text{train}}} I\{X_k \in S_t(x)\}},$$

where:

- $I\{h\}$ is the indicator function.
- $S_t(x)$ is the leaf of tree t containing x.
- n_{train} is the number of training observations.

In other words, the response weights of a particular tree form the conditional relative frequency distribution of the response.

The response weights for the entire ensemble are averaged over the trees:

$$w_j^*(x) = \frac{1}{T}\sum_{t=1}^{T} w_{tj}(x).$$

Quantile Random Forest

Quantile random forest [2] is a quantile-regression method that uses a random forest [1] of regression trees to model the conditional distribution of a response variable, given the value of predictor variables. You can use a fitted model to estimate quantiles in the conditional distribution of the response.

Besides quantile estimation, you can use quantile regression to estimate prediction intervals or detect outliers. For example:

- To estimate 95% quantile prediction intervals, estimate the 0.025 and 0.975 quantiles.
- To detect outliers, estimate the 0.01 and 0.99 quantiles. All observations smaller than the 0.01 quantile and larger than the 0.99 quantile are outliers. All observations that are outside the interval $[L,U]$ can be considered outliers:

  $L = Q_1 - 1.5*IQR$

  and

  $U = Q_3 + 1.5*IQR,$

  where:

  - Q_1 is the 0.25 quantile.
  - Q_3 is the 0.75 quantile.
  - $IQR = Q_3 - Q_1$ (the interquartile range).

Tip

`quantilePredict` estimates the conditional distribution of the response using the training data every time you call it. To predict many quantiles efficiently, or quantiles for many observations

efficiently, you should pass X as a matrix or table of observations and specify all quantiles in a vector using the `Quantile` name-value pair argument. That is, avoid calling `quantilePredict` within a loop.

Algorithms

- `TreeBagger` grows a random forest of regression trees using the training data. Then, to implement quantile random forest on page 33-5123, `quantilePredict` predicts quantiles using the empirical conditional distribution of the response given an observation from the predictor variables. To obtain the empirical conditional distribution of the response:

  1. `quantilePredict` passes all the training observations in `Mdl.X` through all the trees in the ensemble, and stores the leaf nodes of which the training observations are members.
  2. `quantilePredict` similarly passes each observation in X through all the trees in the ensemble.
  3. For each observation in X, `quantilePredict`:

     a. Estimates the conditional distribution of the response by computing response weights on page 33-5122 for each tree.

     b. For observation k in X, aggregates the conditional distributions for the entire ensemble:

$$\widehat{F}(y|X=x_k)=\sum_{j=1}^{n}\sum_{t=1}^{T}\frac{1}{T}w_{tj}(x_k)I\{Y_j\le y\}.$$

        n is the number of training observations (`size(Y,1)`) and T is the number of trees in the ensemble (`Mdl.NumTrees`).
  4. For observation k in X, the τ quantile or, equivalently, the 100τ% percentile, is $Q_\tau(x_k)=\inf\{y:\widehat{F}(y|X=x_k)\ge\tau\}$.

- This process describes how `quantilePredict` uses all specified weights.

  1. For all training observations $j=1,\ldots,n$ and all chosen trees $t=1,\ldots,T$,

     `quantilePredict` attributes the product $v_{tj}=b_{tj}w_{j,\text{obs}}$ to training observation j (stored in `Mdl.X(j,:)` and `Mdl.Y(j)`). b_{tj} is the number of times observation j is in the bootstrap sample for tree t. $w_{j,\text{obs}}$ is the observation weight in `Mdl.W(j)`.
  2. For each chosen tree, `quantilePredict` identifies the leaves in which each training observation falls. Let $S_t(x_j)$ be the set of all observations contained in the leaf of tree t of which observation j is a member.
  3. For each chosen tree, `quantilePredict` normalizes all weights within a particular leaf to sum to 1, that is,

$$v_{tj}^{*}=\frac{v_{tj}}{\sum_{i\in S_t(x_j)}v_{ti}}.$$

  4. For each training observation and tree, `quantilePredict` incorporates tree weights ($w_{t,\text{tree}}$) specified by `TreeWeights`, that is, $w^{*}_{tj,\text{tree}}=w_{t,\text{tree}}v_{tj}^{*}$Trees not chosen for prediction have 0 weight.
  5. For all test observations $k=1,\ldots,K$ in X and all chosen trees $t=1,\ldots,T$`quantilePredict` predicts the unique leaves in which the observations fall, and then identifies all training

observations within the predicted leaves. `quantilePredict` attributes the weight u_{tj} such that

$$u_{tj} = \begin{cases} w^*_{tj,\text{tree}}; \text{ if } x_k \in S_t(x_j) \\ 0; \text{ otherwise} \end{cases}.$$

6 `quantilePredict` sums the weights over all chosen trees, that is,

$$u_j = \sum_{t=1}^{T} u_{tj}.$$

7 `quantilePredict` creates response weights by normalizing the weights so that they sum to 1, that is,

$$w^*_j = \frac{u_j}{\sum_{j=1}^{n} u_j}.$$

Topics

“Detect Outliers Using Quantile Regression” on page 18-137

Introduced in R2016b

randg

Gamma random numbers with unit scale

Syntax

```
Y = randg
Y = randg(A)
Y = randg(A,m)
Y = randg(A,m,n,p,...)
Y = randg(A,[m,n,p,...])
Y = randg(...,classname)
Y = randg(...,'like',X)
Y = randg(...,'like',classname)
```

Description

`Y = randg` returns a scalar random value chosen from a gamma distribution with unit scale and shape.

`Y = randg(A)` returns a matrix of random values chosen from gamma distributions with unit scale. `Y` is the same size as `A`, and `randg` generates each element of `Y` using a shape parameter equal to the corresponding element of `A`.

`Y = randg(A,m)` returns an `m`-by-`m` matrix of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`m` matrix or a scalar. If `A` is a scalar, `randg` uses that single shape parameter value to generate all elements of `Y`.

`Y = randg(A,m,n,p,...)` or `Y = randg(A,[m,n,p,...])` returns an `m`-by-`n`-by-`p`-by-`...` array of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`n`-by-`p`-by-`...` array or a scalar.

`Y = randg(...,classname)` returns an array of random values chosen from gamma distributions of the specified class. `classname` can be `double` or `single`.

`Y = randg(...,'like',X)` or `Y = randg(...,'like',classname)` returns an array of random values chosen from gamma distributions of the same class as `X` or `classname`, respectively. `X` is a numeric array.

`randg` produces pseudo-random numbers using the MATLAB functions `rand` and `randn`. The sequence of numbers generated is determined by the settings of the uniform random number generator that underlies `rand` and `randn`. Control that shared random number generator using `rng`. See the `rng` documentation for more information.

Note To generate gamma random numbers and specify both the scale and shape parameters, you should call `gamrnd`.

Examples

Example 1

Generate a 100-by-1 array of values drawn from a gamma distribution with shape parameter 3.

```
r = randg(3,100,1);
```

Example 2

Generate a 100-by-2 array of values drawn from gamma distributions with shape parameters 3 and 2.

```
A = [ones(100,1)*3,ones(100,1)*2];
r = randg(A,[100,2]);
```

Example 3

To create reproducible output from `randg`, reset the random number generator used by `rand` and `randn` to its default startup settings. This way `randg` produces the same random numbers as if you restarted MATLAB.

```
rng('default')
randg(3,1,5)

ans =

    6.9223    4.3369    1.0505    3.2662   11.3269
```

Example 4

Save the settings for the random number generator used by `rand` and `randn`, generate 5 values from `randg`, restore the settings, and repeat those values.

```
s = rng; % Obtain the current state of the random stream
r1 = randg(10,1,5)

r1 =

    9.4719    9.0433   15.0774   14.7763    6.3775

rng(s); % Reset the stream to the previous state
r2 = randg(10,1,5)

r2 =

    9.4719    9.0433   15.0774   14.7763    6.3775
```

`r2` contains exactly the same values as `r1`.

Example 5

Reinitialize the random number generator used by `rand` and `randn` with a seed based on the current time. `randg` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session.

```
rng('shuffle');
randg(2,1,5);
```

random

Package: prob

Random numbers

Syntax

```
R = random('name',A)
R = random('name',A,B)
R = random('name',A,B,C)
R = random('name',A,B,C,D)

R = random(pd)

R = random(___,sz1,...,szN)
R = random(___,sz)
```

Description

`R = random('name',A)` returns a random number from the one-parameter distribution family specified by `'name'` and the distribution parameter `A`.

`R = random('name',A,B)` returns a random number from the two-parameter distribution family specified by `'name'` and the distribution parameters `A` and `B`.

`R = random('name',A,B,C)` returns a random number from the three-parameter distribution family specified by `'name'` and the distribution parameters `A`, `B`, and `C`.

`R = random('name',A,B,C,D)` returns a random number from the four-parameter distribution family specified by `'name'` and the distribution parameters `A`, `B`, `C`, and `D`.

`R = random(pd)` returns a random number from the probability distribution object `pd`.

`R = random(___,sz1,...,szN)` generates an array of random numbers from the specified probability distribution using input arguments from any of the previous syntaxes, where `sz1,...,szN` indicates the size of each dimension.

`R = random(___,sz)` generates an array of random numbers from the specified probability distribution using input arguments from any of the previous syntaxes, where vector `sz` specifies `size(r)`.

Examples

Generate One Random Number

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
  NormalDistribution
```

```
  Normal distribution
       mu = 0
    sigma = 1
```

Generate one random number from the distribution.

```
rng('default') % For reproducibility
r1 = random(pd)
```

```
r1 = 0.5377
```

Alternatively, you can generate a standard normal random number by specifying its name and parameters.

```
r2 = random('Normal',0,1)
```

```
r2 = 1.8339
```

Reset Random Number Generator

Save the current state of the random number generator. Then generate a random number from the Poisson distribution with rate parameter 5.

```
s = rng;
r = random('Poisson',5)
```

```
r = 5
```

Restore the state of the random number generator to s, and then create a new random number. The value is the same as before.

```
rng(s);
r1 = random('Poisson',5)
```

```
r1 = 5
```

Clone Size from Existing Array

Create a matrix of random numbers with the same size as an existing array. Use the stable distribution with shape parameters 2 and 0, scale parameter 1, and location parameter 0.

```
A = [3 2; -2 1];
sz = size(A);
R = random('Stable',2,0,1,0,sz)
```

```
R = 2×2

    0.7604   -3.1945
    2.5935    1.2193
```

You can combine the previous two lines of code into a single line.

```
R = random('Stable',2,0,1,0,size(A))
```

```
R = 2×2

    0.4508   -0.6132
   -1.8494    0.4845
```

Generate Multiple Random Numbers

Create a Weibull probability distribution object using the default parameter values.

```
pd = makedist('Weibull')
```

```
pd =
  WeibullDistribution

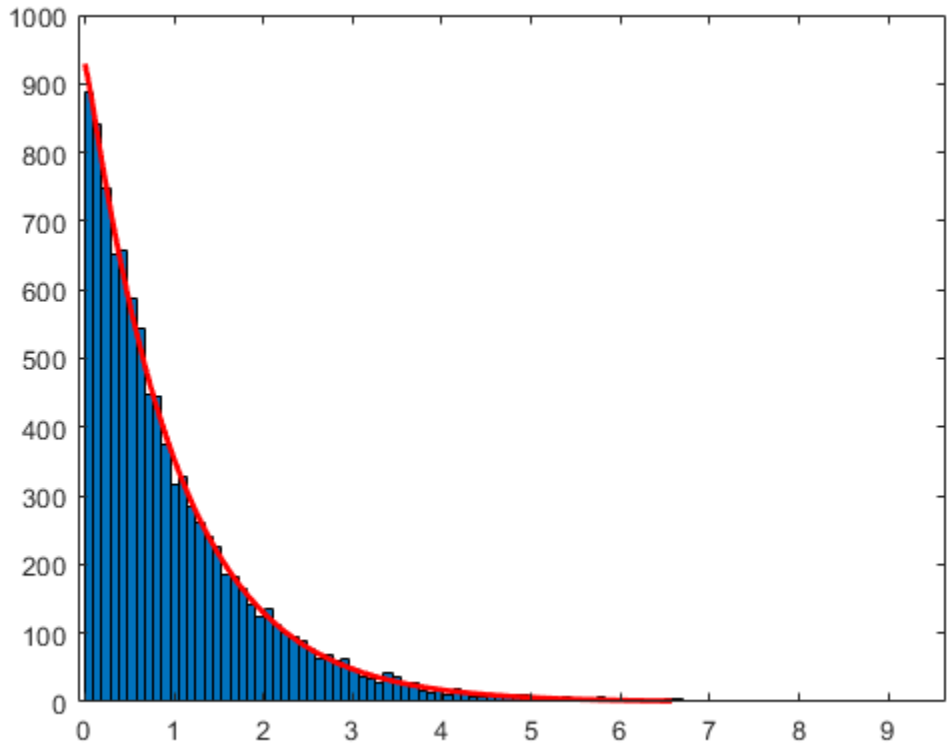
  Weibull distribution
    A = 1
    B = 1
```

Generate random numbers from the distribution.

```
rng('default')  % For reproducibility
r = random(pd,10000,1);
```

Construct a histogram using 100 bins with a Weibull distribution fit.

```
histfit(r,100,'weibull')
```



Generate Multidimensional Array of Random Numbers

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Generate a 2-by-3-by-2 array of random numbers from the distribution.

```
r = random(pd,[2,3,2])
```

```
r =
r(:,:,1) =

    0.5377   -2.2588    0.3188
    1.8339    0.8622   -1.3077
```

```
r(:,:,2) =

   -0.4336    3.5784   -1.3499
    0.3426    2.7694    3.0349
```

Input Arguments

`'name'` — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

`'name'`	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
`'Beta'`	“Beta Distribution” on page B-6	a first shape parameter	b second shape parameter	—	—
`'Binomial'`	“Binomial Distribution” on page B-10	n number of trials	p probability of success for each trial	—	—
`'BirnbaumSaunders'`	“Birnbaum-Saunders Distribution” on page B-18	β scale parameter	γ shape parameter	—	—
`'Burr'`	“Burr Type XII Distribution” on page B-19	α scale parameter	c first shape parameter	k second shape parameter	—
`'Chisquare'`	“Chi-Square Distribution” on page B-28	ν degrees of freedom	—	—	—
`'Exponential'`	“Exponential Distribution” on page B-33	μ mean	—	—	—
`'Extreme Value'`	“Extreme Value Distribution” on page B-40	μ location parameter	σ scale parameter	—	—
`'F'`	“F Distribution” on page B-45	ν_1 numerator degrees of freedom	ν_2 denominator degrees of freedom	—	—
`'Gamma'`	“Gamma Distribution” on page B-47	a shape parameter	b scale parameter	—	—
`'Generalized Extreme Value'`	“Generalized Extreme Value Distribution” on page B-55	k shape parameter	σ scale parameter	μ location parameter	—
`'Generalized Pareto'`	“Generalized Pareto Distribution” on page B-59	k tail index (shape) parameter	σ scale parameter	μ threshold (location) parameter	—
`'Geometric'`	“Geometric Distribution” on page B-63	p probability parameter	—	—	—

'name'	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'HalfNormal'	“Half-Normal Distribution” on page B-68	μ location parameter	σ scale parameter	—	—
'Hypergeometric'	“Hypergeometric Distribution” on page B-73	m size of the population	k number of items with the desired characteristic in the population	n number of samples drawn	—
'InverseGaussian'	“Inverse Gaussian Distribution” on page B-75	μ scale parameter	λ shape parameter	—	—
'Logistic'	“Logistic Distribution” on page B-85	μ mean	σ scale parameter	—	—
'LogLogistic'	“Loglogistic Distribution” on page B-86	μ mean of logarithmic values	σ scale parameter of logarithmic values	—	—
'Lognormal'	“Lognormal Distribution” on page B-88	μ mean of logarithmic values	σ standard deviation of logarithmic values	—	—
'Nakagami'	“Nakagami Distribution” on page B-108	μ shape parameter	ω scale parameter	—	—
'Negative Binomial'	“Negative Binomial Distribution” on page B-109	r number of successes	p probability of success in a single trial	—	—
'Noncentral F'	“Noncentral F Distribution” on page B-115	ν_1 numerator degrees of freedom	ν_2 denominator degrees of freedom	δ noncentrality parameter	—
'Noncentral t'	“Noncentral t Distribution” on page B-117	ν degrees of freedom	δ noncentrality parameter	—	—
'Noncentral Chi-square'	“Noncentral Chi-Square Distribution” on page B-113	ν degrees of freedom	δ noncentrality parameter	—	—
'Normal'	“Normal Distribution” on page B-119	μ mean	σ standard deviation	—	—
'Poisson'	“Poisson Distribution” on page B-131	λ mean	—	—	—
'Rayleigh'	“Rayleigh Distribution” on page B-137	b scale parameter	—	—	—
'Rician'	“Rician Distribution” on page B-139	s noncentrality parameter	σ scale parameter	—	—

'name'	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Stable'	“Stable Distribution” on page B-140	α first shape parameter	β second shape parameter	γ scale parameter	δ location parameter
'T'	“Student's t Distribution” on page B-149	ν degrees of freedom	—	—	—
'tLocationScale'	“t Location-Scale Distribution” on page B-156	μ location parameter	σ scale parameter	ν shape parameter	—
'Uniform'	“Uniform Distribution (Continuous)” on page B-163	a lower endpoint (minimum)	b upper endpoint (maximum)	—	—
'Discrete Uniform'	“Uniform Distribution (Discrete)” on page B-168	n maximum observable value	—	—	—
'Weibull'	“Weibull Distribution” on page B-170	a scale parameter	b shape parameter	—	—

Example: 'Normal'

A — First probability distribution parameter
scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, random expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

B — Second probability distribution parameter
scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, random expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

C — Third probability distribution parameter
scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, random expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

`D` — Fourth probability distribution parameter
scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the same size as the array inputs. See `'name'` for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

`pd` — Probability distribution
probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
`makedist`	Create a probability distribution object using specified parameter values.
`fitdist`	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
`paretotails`	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

`sz1,...,szN` — Size of each dimension (as separate arguments)
integer values

Size of each dimension, specified as integer values. For example, specifying `5,3,2` generates a 5-by-3-by-2 array of random numbers from the specified probability distribution.

If one or more of the input arguments `A`, `B`, `C`, and `D` are arrays, then the specified dimensions `sz1,...,szN` must match the common dimensions of `A`, `B`, `C`, and `D` after any necessary scalar expansion. The default values of `sz1,...,szN` are the common dimensions.

- If you specify a single value `sz1`, then `R` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `R` is an empty array.
- Beyond the second dimension, `random` ignores trailing dimensions with a size of 1. For example, specifying `3,1,1,1` produces a 3-by-1 vector of random numbers.

Example: `5,3,2`

Data Types: `single` | `double`

`sz` — Size of each dimension (as a row vector)
row vector of integers

Size of each dimension, specified as a row vector of integers. For example, specifying `[5 3 2]` generates a 5-by-3-by-2 array of random numbers from the specified probability distribution.

If one or more of the input arguments `A`, `B`, `C`, and `D` are arrays, then the specified dimensions `sz` must match the common dimensions of `A`, `B`, `C`, and `D` after any necessary scalar expansion. The default values of `sz` are the common dimensions.

- If you specify a single value `[sz1]`, then `R` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `R` is an empty array.
- Beyond the second dimension, `random` ignores trailing dimensions with a size of 1. For example, specifying `[3 1 1 1]` produces a 3-by-1 vector of random numbers.

Example: `[5 3 2]`

Data Types: `single` | `double`

Output Arguments

R — Random number

scalar value | array of scalar values

Random number generated from the specified probability distribution, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1,...,szN` or `sz`.

If you specify distribution parameters `A`, `B`, `C`, or `D`, then each element in `R` is the random number generated from the distribution specified by the corresponding elements in `A`, `B`, `C`, and `D`.

Alternative Functionality

- `random` is a generic function that accepts either a distribution by its name `'name'` or a probability distribution object `pd`. It is faster to use a distribution-specific function, such as `randn` and `normrnd` for the normal distribution and `binornd` for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-14.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `'name'` must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- Code generation does not support the probability distribution object (`pd`) input argument.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

random

Package:

Simulate responses with random noise for generalized linear regression model

Syntax

```
ysim = random(mdl,Xnew)
ysim = random(mdl,Xnew,Name,Value)
```

Description

`ysim = random(mdl,Xnew)` simulates responses to the predictor data in `Xnew` using the generalized linear regression model `mdl`, adding random noise.

`ysim = random(mdl,Xnew,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the number of trials for binomial distribution or the offset value used for fitting.

Examples

Simulate Response Data with Random Noise

Create a generalized linear regression model, and simulate its response with random noise to new data.

Generate sample data using Poisson random numbers with one underlying predictor `X`.

```
rng('default') % For reproducibility
X = rand(20,1);
mu = exp(1 + 2*X);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1','Distribution','poisson');
```

Create data points for prediction.

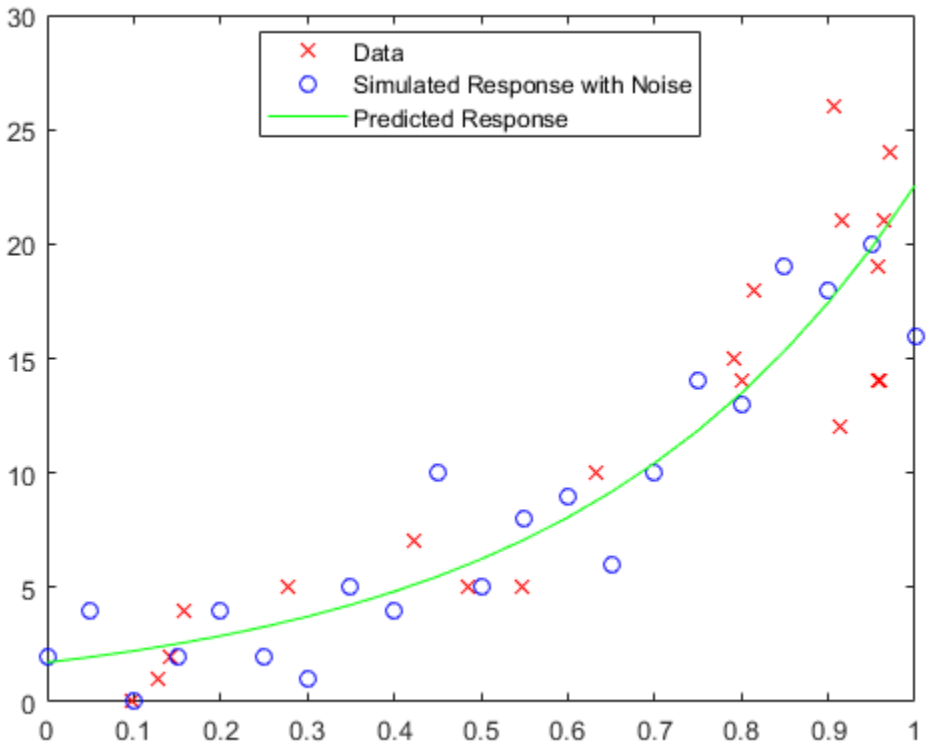
```
Xnew = (0:.05:1)';
```

Simulate responses with random noise at the data points.

```
ysim = random(mdl,Xnew);
```

Plot the simulated values and the original values.

```
plot(X,y,'rx',Xnew,ysim,'bo',Xnew,feval(mdl,Xnew),'g-')
legend('Data','Simulated Response with Noise','Predicted Response', ...
    'Location','best')
```



Generate C/C++ Code That Simulates Responses

Fit a generalized linear regression model, and then save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the fitted model. Then use `codegen` (MATLAB Coder) to generate C/C++ code. Note that generating C/C++ code requires MATLAB® Coder™.

This example briefly explains the code generation workflow for the prediction of linear regression models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9. You can also generate code using the MATLAB Coder app. For details, see “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22.

Train Model

Generate sample data of the predictor `x` and response `y` with the following distributions:

- $x \sim N(1, 0.5^2)$.
- $\beta_0 = 1$ and $\beta = -2$.
- $y \sim Binomial\left(10, \frac{exp(1 + x\beta)}{1 + exp(1 + x\beta)}\right)$.

```
rng('default') % For reproducibility
x = 1 + randn(100,1)*0.5;
beta = -2;
p = exp(1 + x*beta)./(1 + exp(1 + x*beta)); % Inverse logit
n = 10;
y = binornd(n,p,100,1);
```

Create a generalized linear regression model of binomial data. Specify a binomial sample size of 10.

```
mdl = fitglm(x,y,'y ~ x1','Distribution','Binomial','BinomialSize',n);
```

Save Model

Save the fitted generalized linear regression model to the file `GLMMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(mdl,'GLMMdl');
```

Define Entry-Point Function

In your current folder, define an entry-point function named `myrandomGLM.m` that does the following:

- Accept new predictor input and valid name-value pair arguments.
- Load the fitted generalized linear regression model in `GLMMdl.mat` by using `loadLearnerForCoder`.
- Simulate responses from the loaded GLM model.

```
function y = myrandomGLM(x,varargin) %#codegen
%MYRANDOMGLM Simulate responses using GLM model
%   MYRANDOMGLM simulates responses for the n observations in the n-by-1
%   vector x using the GLM model stored in the MAT-file GLMMdl.mat, and
%   then returns the simulations in the n-by-1 vector y.
CompactMdl = loadLearnerForCoder('GLMMdl');
narginchk(1,Inf);
y = random(CompactMdl,x,varargin{:});
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Generate Code

Generate code for the entry-point function using `codegen` (MATLAB Coder). Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and exact input array size, pass a MATLAB® expression that represents the set of values with a certain data type and array size. Use `coder.Constant` (MATLAB Coder) for the names of name-value pair arguments.

Specify the predictor data `x` and binomial parameter `n`.

```
codegen -config:mex myrandomGLM -args {x,coder.Constant('BinomialSize'),coder.Constant(n)}
```

```
Code generation successful.
```

`codegen` generates the MEX function `myrandomGLM_mex` with a platform-dependent extension.

If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof` (MATLAB Coder). For details, see “Specify Variable-Size Arguments for Code Generation” on page 32-45 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

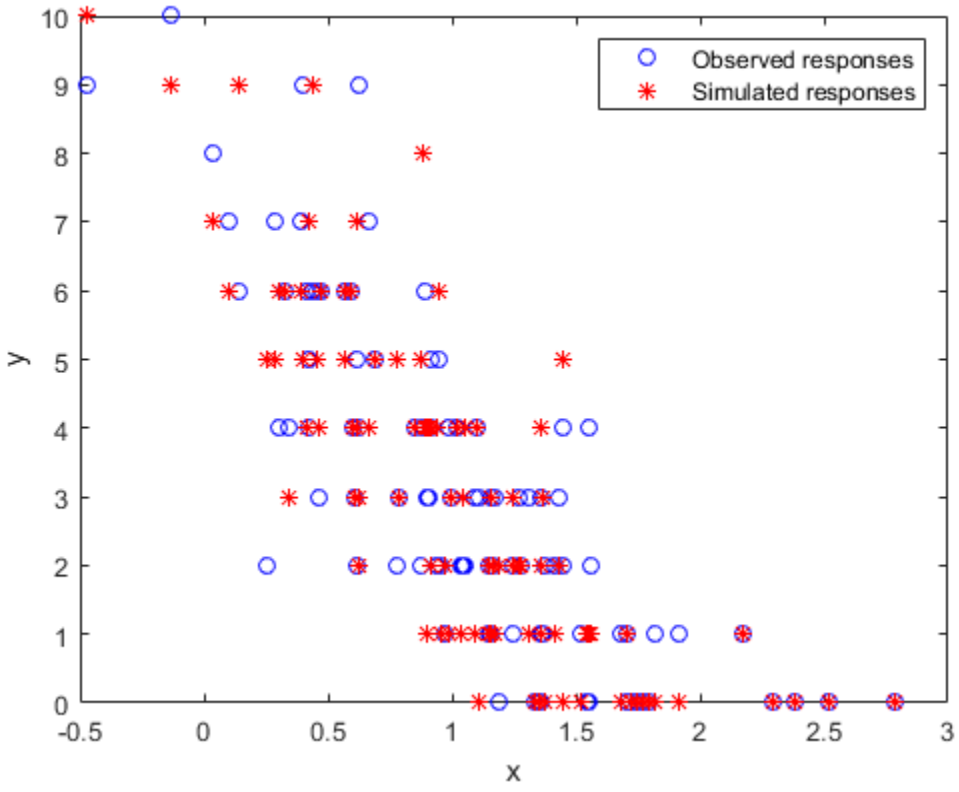
Verify Generated Code

Simulate responses using the MEX function. Specify the predictor data `x` and binomial parameter `n`.

```
ysim = myrandomGLM_mex(x,'BinomialSize',n);
```

Plot the simulated values and the data in the same figure.

```
figure
plot(x,y,'bo',x,ysim,'r*')
legend('Observed responses','Simulated responses')
xlabel('x')
ylabel('y')
```



The observed and simulated responses appear to be similarly distributed.

Input Arguments

`mdl` — Generalized linear regression model

`GeneralizedLinearModel` object | `CompactGeneralizedLinearModel` object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`, or a `CompactGeneralizedLinearModel` object created using `compact`.

`Xnew` — New predictor input values
table | dataset array | matrix

New predictor input values, specified as a table, dataset array, or matrix. Each row of `Xnew` corresponds to one observation, and each column corresponds to one variable.

- If `Xnew` is a table or dataset array, it must contain predictors that have the same predictor names as in the `PredictorNames` property of `mdl`.
- If `Xnew` is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create `mdl`. Note that `Xnew` must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating `mdl` must be numeric. To treat numerical predictors as categorical, identify the predictors using the `'CategoricalVars'` name-value pair argument when you create `mdl`.

Data Types: `single` | `double` | `table`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `ysim = random(Mdl,Xnew,'BinomialSize',50)` returns the numbers of success, perturbed by random noise, using the number of trials specified by `'BinomialSize'`.

`BinomialSize` — Number of trials for binomial distribution
1 (default) | scalar | vector

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of `'BinomialSize'` and a scalar or vector of the same length as the response. `random` expands the scalar input into a constant array of the same size as the response. The scalar input means that all observations have the same number of trials.

The meaning of the output values in `ysim` depends on the value of `'BinomialSize'`.

- If `'BinomialSize'` is 1 (default), then each value in the output `ysim` is the probability of success.
- If `'BinomialSize'` is not 1, then each value in the output `ysim` is the predicted number of successes in the trials.

Data Types: `single` | `double`

`Offset` — Offset value
`zeros(size(Xnew,1))` (default) | scalar | vector

Offset value for each row in `Xnew`, specified as the comma-separated pair consisting of `'Offset'` and a scalar or vector with the same length as the response. `random` expands the scalar input into a constant array of the same size as the response.

Note that the default value of this argument is a vector of zeros even if you specify the `'Offset'` name-value pair argument when fitting a model. If you specify `'Offset'` for fitting, the software

treats the offset as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

$$f(\mu) = \texttt{Offset} + X*b,$$

where f is the link function, μ is the mean response, and $X*b$ is the linear combination of predictors X. The `Offset` predictor has coefficient `1`.

Data Types: `single` | `double`

Output Arguments

`ysim` — Simulated response values

numeric vector

Simulated response values, returned as a numeric vector. The simulated values are the predicted response values at `Xnew` perturbed by random noise with the distribution given by the fitted model. The values in `ysim` are independent, conditional on the predictors. For binomial and Poisson fits, `random` generates `ysim` with the specified distribution and no adjustment for any estimated dispersion.

- If `'BinomialSize'` is 1 (default), then each value in the output `ysim` is the probability of success.
- If `'BinomialSize'` is not 1, then each value in the output `ysim` is the predicted number of successes in the trials.

Alternative Functionality

For predictions without random noise, use `predict` or `feval`.

- `predict` accepts a single input argument containing all predictor variables, and gives confidence intervals on its predictions.
- `feval` accepts multiple input arguments with one input for each predictor variable, which is simpler to use with a model created from a table or dataset array. The `feval` function does not support the name-value pair arguments `'Offset'` and `'BinomialSize'`. The function uses 0 as the offset value, and the output values are predicted probabilities.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `random` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `random` function. Then use `codegen` to generate code for the entry-point function.
- `random` can return a different sequence of numbers than MATLAB if either of the following is true:
  - The output is nonscalar.

- An input parameter is invalid for the distribution.

- This table contains notes about the arguments of `random`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
`mdl`	For the usage notes and limitations of the model object, see "Code Generation" on page 33-835 of the `CompactGeneralizedLinearModel` object.

`Xnew`	• `Xnew` must be a single-precision or double-precision matrix or a table containing numeric variables, categorical variables, or both.
	• The number of rows, or observations, in `Xnew` can be a variable size, but the number of columns in `Xnew` must be fixed.
	• If you want to specify `Xnew` as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:
	  • Accepts data as arrays
	  • Creates a table from the data input arguments and specifies the variable names in the table
	  • Passes the table to `predict`
	  For an example of this table workflow, see "Generate Code to Classify Data in Table" on page 32-100. For more information on using tables in code generation, see "Code Generation for Tables" (MATLAB Coder) and "Table Limitations for Code Generation" (MATLAB Coder).

Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to use the `'BinomialSize'` name-value pair argument in the generated code, include `{coder.Constant('BinomialSize'),0}` in the `-args` value of `codegen`.

For more information, see "Introduction to Code Generation" on page 32-2.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

- This function fully supports GPU arrays. For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).
- This function supports model objects fitted with GPU array input arguments.

Topics

"Predict or Simulate Responses to New Data" on page 12-23
"Generalized Linear Models" on page 12-9

Introduced in R2012a

random

Class: `GeneralizedLinearMixedModel`

Generate random responses from fitted generalized linear mixed-effects model

Syntax

```
ysim = random(glme)
ysim = random(glme,tblnew)
ysim = random( ___ ,Name,Value)
```

Description

`ysim = random(glme)` returns simulated responses, `ysim`, from the fitted generalized linear mixed-effects model `glme`, at the original design points.

`ysim = random(glme,tblnew)` returns simulated responses using new input values specified in the table or dataset array, `tblnew`.

`ysim = random( ___ ,Name,Value)` returns simulated responses using additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify observation weights, binomial sizes, or offsets for the model.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

`tblnew` — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-45, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must contain the same variables as the original table or dataset array, `tbl`, used to fit the generalized linear mixed-effects model `glme`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`BinomialSize` — Number of trials for binomial distribution

`ones(m,1)` (default) | *m*-by-1 vector of positive integer values

Number of trials for binomial distribution, specified as the comma-separated pair consisting of `'BinomialSize'` and an *m*-by-1 vector of positive integer values, where *m* is the number of rows in

`tblnew`. The `'BinomialSize'` name-value pair applies only to the binomial distribution. The value specifies the number of binomial trials when generating the random response values.

Data Types: `single` | `double`

`Offset` — Model offset
`zeros(m,1)` (default) | vector of scalar values

Model offset, specified as a vector of scalar values of length *m*, where *m* is the number of rows in `tblnew`. The offset is used as an additional predictor and has a coefficient value fixed at `1`.

`Weights` — Observation weights
m-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an *m*-by-1 vector of nonnegative scalar values, where *m* is the number of rows in `tblnew`. If the response distribution is binomial or Poisson, then `'Weights'` must be a vector of positive integers.

Data Types: `single` | `double`

Output Arguments

`ysim` — Simulated response values
m-by-1 vector

Simulated response values, returned as an *m*-by-1 vector, where *m* is the number of rows in `tblnew`. `random` creates `ysim` by first generating the random-effects vector based on its fitted prior distribution. `random` then generates `ysim` from its fitted conditional distribution given the random effects. `random` takes into account the effect of observation weights specified when fitting the model using `fitglme`, if any.

Examples

Simulate Random Responses From a GLME Model

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)

- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)','Dis
```

Use `random` to simulate a new response vector from the fitted model.

```
rng(0,'twister');  % For reproducibility
ynew = random(glme);
```

Display the first 10 rows of the simulated response vector.

```
ynew(1:10)
```

```
ans = 10×1

     3
     3
     1
     7
     5
```

```
     8
     7
     9
     5
     9
```

Simulate a new response vector using new input values. Create a new table by copying the first 10 rows of `mfr` into `tblnew`.

```
tblnew = mfr(1:10,:);
```

The first 10 rows of `mfr` include data collected from trials 1 through 5 for factories 1 and 2. Both factories used the old process for all of their trials during the experiment, so `newprocess = 0` for all 10 observations.

Change the value of `newprocess` to `1` for the observations in `tblnew`.

```
tblnew.newprocess = ones(height(tblnew),1);
```

Simulate new responses using the new input values in `tblnew`.

```
ynew2 = random(glme,tblnew)
```

```
ynew2 = 10×1

     2
     3
     5
     4
     2
     2
     2
     1
     2
     0
```

More About

Conditional Distribution Method

`random` generates random data from the fitted generalized linear mixed-effects model as follows:

- Sample $b_{sim} \sim P\left(b \middle| \widehat{\theta}, \widehat{\sigma}^2\right)$, where $P\left(b \middle| \widehat{\theta}, \widehat{\sigma}^2\right)$ is the estimated prior distribution of random effects, and $\widehat{\theta}$ is a vector of estimated covariance parameters, and $\widehat{\sigma}^2$ is the estimated dispersion parameter.
- Given b_{sim}, for $i = 1$ to m, sample $y_{sim\_i} \sim P\left(y_{new\_i} \middle| b_{sim}, \widehat{\beta}, \widehat{\theta}, \widehat{\sigma}^2\right)$, where $P\left(y_{new\_i} \middle| b_{sim}, \widehat{\beta}, \widehat{\theta}, \widehat{\sigma}^2\right)$ is the conditional distribution of the ith new response y_{new_i} given b_{sim} and the model parameters.

random

Random variate from Gaussian mixture distribution

Syntax

```
Y = random(gm)
Y = random(gm,n)
[Y,compIdx] = random( ___ )
```

Description

`Y = random(gm)` generates a 1-by-*m* random variate from the *m*-dimensional Gaussian mixture distribution `gm`.

`Y = random(gm,n)` returns `n` random variates. Each row of `Y` is a random variate generated from the *m*-dimensional Gaussian mixture distribution `gm`.

`[Y,compIdx] = random( ___ )` also returns an `n`-by-1 index vector `compIdx` for any of the input arguments in previous syntaxes. `compIdx(i)` indicates the mixture component used to generate the `i`th random variate `Y(i,:)`.

Examples

Generate Random Variates

Create a `gmdistribution` object and generate random variates.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```
mu = [1 2;-3 -5];
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =

Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:     1     2

Component 2:
Mixing proportion: 0.500000
Mean:    -3    -5
```

Generate 1000 random variates.

```
rng('default'); % For reproducibility
[Y,compIdx] = random(gm,1000);
```

`compIdx(i)` indicates the mixture component used to generate the `i`th random variate `Y(i,:)`. Count the number of random variates generated by `Component 1`.

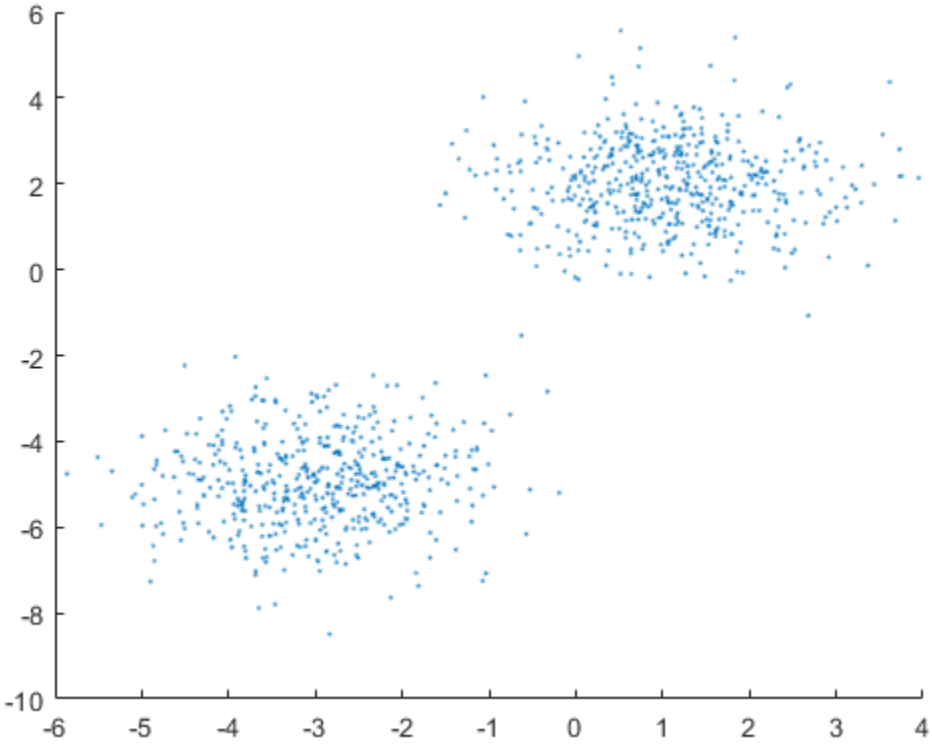
```
numIdx1 = sum(compIdx == 1)
```

```
numIdx1 = 512
```

`random` generates about half of the random variates using `Component 1` because `gm` has equal mixing proportions.

Plot the generated random variates by using `scatter`.

```
scatter(Y(:,1),Y(:,2),10,'.') % Scatter plot with points of size 10
```



Reset Random Number Generator

Reset the random number generator to generate the same random variate.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

```
p = [0.4 0.6];               % Mixing proportions
mu = [1 2;-3 -5];            % Means
sigma = cat(3,[2 .5],[1 1])  % Covariances 1-by-2-by-2 array
```

```
sigma =
sigma(:,:,1) =

    2.0000    0.5000

sigma(:,:,2) =

     1     1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object by using the `gmdistribution` function.

```
gm = gmdistribution(mu,sigma);
```

Save the current state of the random number generator, and then generate a random variate using `gm`.

```
s = rng;
r = random(gm)
```

```
r = 1×2

   -1.1661   -7.2588
```

Restore the state of the random number generator to `s`, and then generate a random variate using `gm`. The values are the same as before.

```
rng(s);
r1 = random(gm)
```

```
r1 = 1×2

   -1.1661   -7.2588
```

Input Arguments

`gm` — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

`n` — Number of random variates

1 (default) | positive integer

Number of random variates to generate, specified as a positive integer.

Data Types: `single` | `double`

Output Arguments

`Y` — Random variate

1-by-*m* numeric vector | `n`-by-*m* numeric matrix

Random variate, returned as a 1-by-*m* numeric vector or an `n`-by-*m* numeric matrix. Each row of `Y` is a random variate generated from the *m*-dimensional Gaussian mixture distribution `gm`.

`compIdx` — Component index

positive integer | *n*-by-1 numeric vector

Component index, returned as a positive integer or an `n`-by-1 index vector, where `compIdx(i)` indicates the mixture component used to generate the `i`th random variate `Y(i,:)`.

Introduced in R2007b

random

Package:

Simulate responses with random noise for linear regression model

Syntax

```
ysim = random(mdl,Xnew)
```

Description

`ysim = random(mdl,Xnew)` simulates responses to the predictor data in `Xnew` using the linear model `mdl`, adding random noise.

Examples

Simulate Response Data with Random Noise

Create a quadratic model of car mileage as a function of weight from the `carsmall` data set.

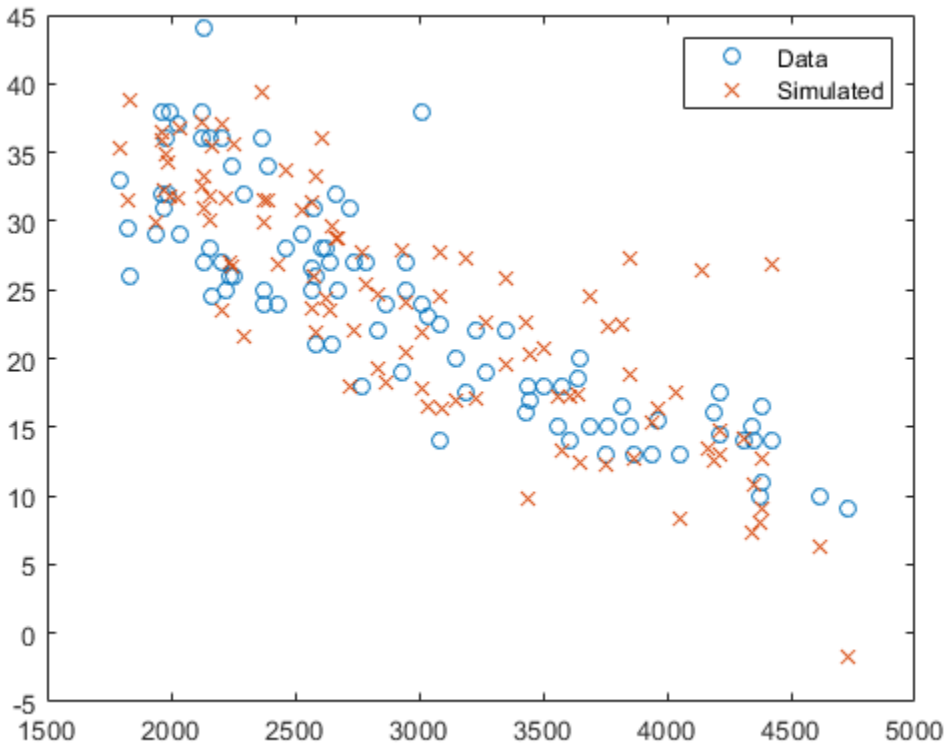
```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Create simulated responses to the data with random noise.

```
ysim = random(mdl,X);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```



Input Arguments

`mdl` — Linear regression model object

`LinearModel` object | `CompactLinearModel` object

Linear regression model object, specified as a `LinearModel` object created by using `fitlm` or `stepwiselm`, or a `CompactLinearModel` object created by using `compact`.

`Xnew` — New predictor input values

table | dataset array | matrix

New predictor input values, specified as a table, dataset array, or matrix. Each row of `Xnew` corresponds to one observation, and each column corresponds to one variable.

- If `Xnew` is a table or dataset array, it must contain predictors that have the same predictor names as in the `PredictorNames` property of `mdl`.
- If `Xnew` is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create `mdl`. Note that `Xnew` must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating `mdl` must be numeric. To treat numerical predictors as categorical, identify the predictors using the `'CategoricalVars'` name-value pair argument when you create `mdl`.

Data Types: `single` | `double` | `table`

Output Arguments

`ysim` — Simulated response values

numeric vector

Simulated response value, returned as a numeric vector. The simulated value is the predicted response values at `Xnew` perturbed by random noise. The noise is independent and normally distributed, with mean equal to zero and variance equal to the estimated error variance of the model.

Alternative Functionality

For predictions without random noise, use `predict` or `feval`. These two functions give the same predictions.

- `predict` accepts a single input argument containing all predictor variables, and gives confidence intervals on its predictions.
- `feval` accepts multiple input arguments with one input for each predictor variable.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `random` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `random` function. Then use `codegen` to generate code for the entry-point function.
- `random` can return a different sequence of numbers than MATLAB if either of the following is true:
  - The output is nonscalar.
  - An input parameter is invalid for the distribution.
- This table contains notes about the arguments of `random`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
`mdl`	• Suppose you train a linear model by using `fitlm` and specifying `'RobustOpts'` as a structure with an anonymous function handle for the `RobustWgtFun` field, use `saveLearnerForCoder` to save the model, and then use `loadLearnerForCoder` to load the model. In this case, `loadLearnerForCoder` cannot restore the Robust property into the MATLAB Workspace. However, `loadLearnerForCoder` can load the model at compile time within an entry-point function for code generation. • For the usage notes and limitations of the model object, see “Code Generation” on page 33-824 of the `CompactLinearModel` object.

Argument	Notes and Limitations

`Xnew`	• `Xnew` must be a single-precision or double-precision matrix or a table containing numeric variables, categorical variables, or both.
	• The number of rows, or observations, in `Xnew` can be a variable size, but the number of columns in `Xnew` must be fixed.
	• If you want to specify `Xnew` as a table, then your model must be trained using a table, and you must ensure that your entry-point function for prediction:
	  • Accepts data as arrays
	  • Creates a table from the data input arguments and specifies the variable names in the table
	  • Passes the table to `predict`
	  For an example of this table workflow, see "Generate Code to Classify Data in Table" on page 32-100. For more information on using tables in code generation, see "Code Generation for Tables" (MATLAB Coder) and "Table Limitations for Code Generation" (MATLAB Coder).

For more information, see "Introduction to Code Generation" on page 32-2.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

- This function fully supports GPU arrays. For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).
- This function supports model objects fitted with GPU array input arguments.

random

Class: `LinearMixedModel`

Generate random responses from fitted linear mixed-effects model

Syntax

```
ysim = random(lme)
ysim = random(lme,tblnew)
ysim = random(lme,Xnew,Znew)
ysim = random(lme,Xnew,Znew,Gnew)
```

Description

`ysim = random(lme)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the original fixed- and random-effects design points, used to fit `lme`.

`random` simulates new random-effects vector and new observation errors. So, the simulated response is

$$y_{sim} = X\widehat{\beta} + Z\widehat{b} + \varepsilon,$$

where $\widehat{\beta}$ is the estimated fixed-effects coefficients, $\widehat{b}$ is the new random effects, and ε is the new observation error.

`random` also accounts for the effect of observation weights, if you use any when fitting the model.

`ysim = random(lme,tblnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `random` if you use a table or dataset array for fitting the model `lme`.

`ysim = random(lme,Xnew,Znew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. Use the matrix format for `random` if you use design matrices for fitting the model `lme`.

`ysim = random(lme,Xnew,Znew,Gnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

`tblnew` — New input data
table | `dataset` array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-45, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

`Xnew` — New fixed-effects design matrix
n-by-*p* matrix

New fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of fixed predictor variables. Each row of `X` corresponds to one observation and each column of `X` corresponds to one variable.

Data Types: `single` | `double`

`Znew` — New random-effects design
n-by-*q* matrix | cell array of length *R*

New random-effects design, specified as an *n*-by-*q* matrix or a cell array of *R* design matrices `Z{r}`, where *r* = 1, 2, ..., *R*. If `Znew` is a cell array, then each `Z{r}` is an *n*-by-*q*(*r*) matrix, where *n* is the number of observations, and *q*(*r*) is the number of random predictor variables.

Data Types: `single` | `double` | `cell`

`Gnew` — New grouping variable or variables
vector | cell array of grouping variables of length *R*

New grouping variable or variables on page 2-45, specified as a vector or a cell array, of length *R*, of grouping variables used to fit the linear mixed-effects model, `lme`.

`random` treats all levels of each grouping variable as new levels. It draws an independent random effects vector for each level of each grouping variable.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

Output Arguments

`ysim` — Simulated response values
n-by-1 vector

Simulated response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Generate Random Responses at the Original Design Values

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five

different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Generate random response values at the original design points. Display the first five values.

```
rng(123,'twister') % For reproducibility
ysim = random(lme);
ysim(1:5)
```

```
ans = 5×1

  114.8785
  134.2018
  154.2818
  169.7554
   84.6089
```

Plot Randomly Generated vs. Observed Response Values

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed-effects for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

```
tbl = table(MPG,Weight,Model_Year);
lme = fitlme(tbl,'MPG ~ Weight + (1|Model_Year)');
```

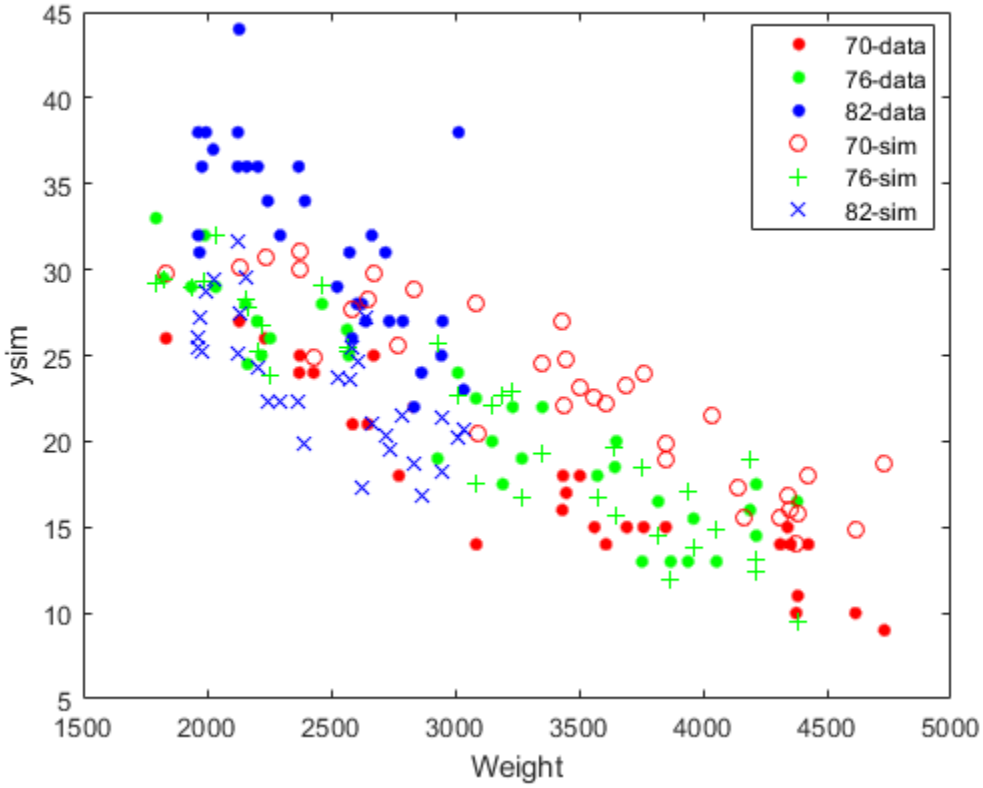
Randomly generate responses using the original data.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,tbl);
```

Plot the original and the randomly generated responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight,MPG,Model_Year)
```

```
hold on
gscatter(Weight,ysim,Model_Year,[],'o+x')
legend('70-data','76-data','82-data','70-sim','76-sim','82-sim')
hold off
```



Note that the simulated random response values for year 82 are lower than the original data for that year. This might be due to a lower simulated random effect for year 82 than the estimated random effect in the original data.

Generate Responses Using a New Dataset Array

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy';'Silty';'Silty'});
dsnew.Tomato = nominal({'Cherry';'Vine';'Plum'});
dsnew.Fertilizer = nominal([2;2;4]);
```

Generate random responses at the new points.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,dsnew)
```

```
ysim = 3×1

   99.6006
  101.9911
  161.4026
```

Generate Random Responses Using New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two

columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];
Znew = [1,13.5; 1,17; 1,21.2];
Gnew = nominal([73 77 82]);
```

Generate random responses for the data in the new design matrices.

```
rng(123,'twister') % For reproducibility
ysim = random(lme,Xnew,Znew,Gnew)
```

```
ysim = 3×1

   15.7416
   10.6085
    6.8796
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, fit the model.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'});
```

Now, recreate the new random effects design, `Znew`, and the grouping variable design, `Gnew`, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};
MY = nominal([73 77 82]);

random

Class: NonLinearModel

Simulate responses for nonlinear regression model

Syntax

```
ysim = random(mdl)
ysim = random(mdl,Xnew)
ysim = random(mdl,Xnew,'Weights',W)
```

Description

`ysim = random(mdl)` simulates responses from the fitted nonlinear model `mdl` at the original design points.

`ysim = random(mdl,Xnew)` simulates responses from the fitted nonlinear model `mdl` to the data in `Xnew`, adding random noise.

`ysim = random(mdl,Xnew,'Weights',W)` simulates responses using the observation weights, `W`.

Input Arguments

`mdl`

Nonlinear regression model, constructed by `fitnlm`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

`W`

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, the function must accept a vector of predicted response values as input, and returns a vector of real positive weights as output.

Given weights, `W`, `random` estimates the error variance at observation `i` by `MSE*(1/W(i))`, where MSE is the mean squared error.

Default: No weights

Output Arguments

`ysim`

Vector of predicted mean values at `Xnew`, perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

Examples

Simulate Responses

Create a nonlinear model of car mileage as a function of weight, and simulate the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

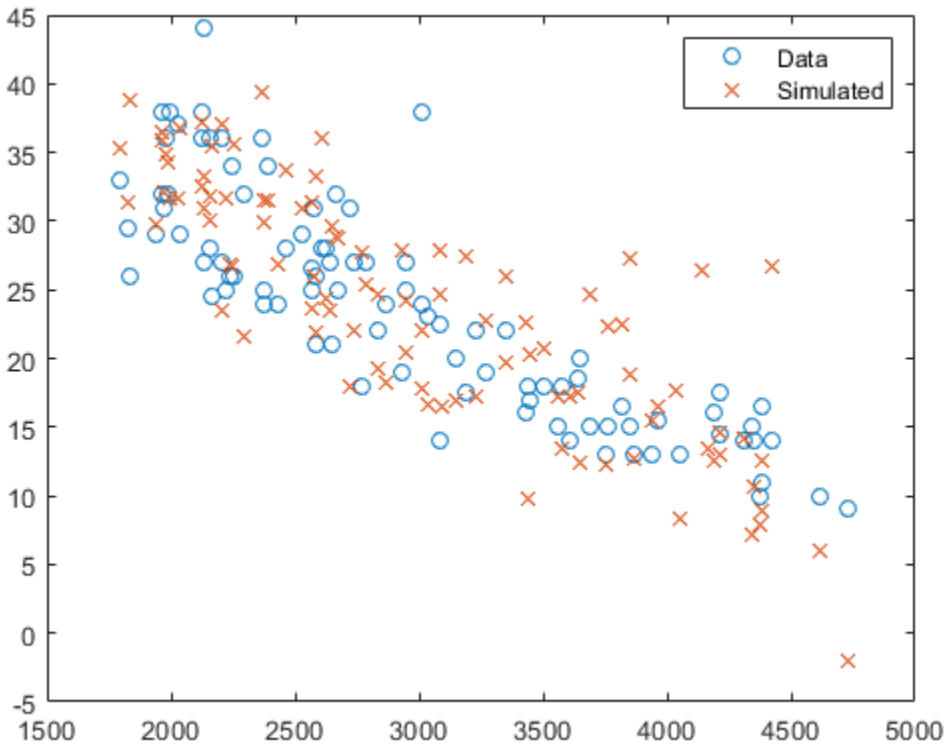
```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create simulated responses to the data.

```
Xnew = X;
ysim = random(mdl,Xnew);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```



Alternatives

For predictions without added noise, use `predict`.

random

Class: `RepeatedMeasuresModel`

Generate new random response values given predictor values

Syntax

```
ysim = random(rm,tnew)
```

Description

`ysim = random(rm,tnew)` generates random response values from the repeated measures model `rm` using the predictor variables from table `tnew`.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`tnew` — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, `rm`, specified as a table. `tnew` must contain all of the between-subject factors used to create `rm`.

Output Arguments

`ysim` — Random response values

n-by-*r* matrix

Random response values random generates, returned as an *n*-by-*r* matrix, where *n* is the number of rows in `tnew`, and *r* is the number of repeated measures in `rm`.

Examples

Randomly Generate New Response Values

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, and virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
  rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Randomly generate new response values.

```
ysim = random(rm);
```

`random` uses the predictor values in the original sample data you use to fit the repeated measures model `rm` in table `t`.

Randomly Generate Response Values Using New Data

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures *y*1 through *y*8 as responses. The table `within` includes the within-subject variables *w*1 and *w*2. This is simulated data.

Fit a repeated measures model, where the repeated measures *y*1 through *y*8 are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Define a table with new values for the predictor variables.

```
tnew = table(16,93,{'B'},{'Male'},'VariableNames',{'Age','IQ','Group','Gender'})
```

```
tnew=1×4 table
    Age    IQ    Group     Gender
    ___    __    _____    ________

    16     93    {'B'}    {'Male'}
```

Randomly generate new response values using the values in the new table `tnew`.

```
ysim = random(rm,tnew)
```

```
ysim = 1×8

   46.2252   66.8003  -40.4987   -1.9930   27.5213  -37.9809    4.8905   -3.7568
```

Algorithms

`random` computes `ysim` by creating predicted values and adding random noise values. For each row, the noise has a multivariate normal distribution with covariance the same as `rm.Covariance`.

`fitrm` | `predict`

randomEffects

Class: `GeneralizedLinearMixedModel`

Estimates of random effects and related statistics

Syntax

```
B = randomEffects(glme)
[B,BNames] = randomEffects(glme)
[B,BNames,stats] = randomEffects(glme)
[B,BNames,stats] = randomEffects(glme,Name,Value)
```

Description

`B = randomEffects(glme)` returns the estimates of the empirical Bayes predictors (EPBs) of random effects in the generalized linear mixed-effects model `glme` conditional on the estimated covariance parameters and the observed response.

`[B,BNames] = randomEffects(glme)` also returns the names of the coefficients, `BNames`. Each name corresponds to a coefficient in `B`.

`[B,BNames,stats] = randomEffects(glme)` also returns related statistics, `stats`, for the estimated EBPs of random effects in `glme`.

`[B,BNames,stats] = randomEffects(glme,Name,Value)` returns any of the above output arguments using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval level, or the method for computing the approximate degrees of freedom.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Alpha` — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α, the confidence level is 100 × (1 – α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`DFMethod` — Method for computing approximate degrees of freedom
`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

Value	Description
`'residual'`	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'none'`	The degrees of freedom is set to infinity.

Example: `'DFMethod','none'`

Output Arguments

`B` — Estimated empirical Bayes predictors for the random effects
column vector

Estimated empirical Bayes predictors (EBPs) for the random effects in the generalized linear mixed-effects model `glme`, returned as a column vector. The EBPs in `B` are approximated by the mode of the empirical posterior distribution of the random effects given the estimated covariance parameters and the observed response.

Suppose `glme` has R grouping variables g_1, g_2, ..., g_R, with levels m_1, m_2, ..., m_R, respectively. Also suppose q_1, q_2, ..., q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, ..., g_R, respectively. Then, `B` is a column vector of length $q_1*m_1 + q_2*m_2 + ... + q_R*m_R$.

`randomEffects` creates `B` by concatenating the empirical Bayes predictors of random-effects vectors corresponding to each level of each grouping variable as $[g_1\text{level}_1; g_1\text{level}_2; ...; g_1\text{level}_{m_1}; g_2\text{level}_1; g_2\text{level}_2; ...; g_2\text{level}_{m_2}; ...; g_R\text{level}_1; g_R\text{level}_2; ...; g_R\text{level}_{m_R}]'$.

`BNames` — Names of random-effects coefficients
table

Names of random-effects coefficients in `B`, returned as a table.

`stats` — Estimated empirical Bayes predictors and related statistics
table

Estimated empirical Bayes predictors (EBPs) and related statistics for the random effects in the generalized linear mixed-effects model `glme`, returned as a table. `stats` has one row for each of the random effects, and one column for each of the following statistics.

Column Name	Description
`Group`	Grouping variable associated with the random effect

Column Name	Description
`Level`	Level within the grouping variable corresponding to the random effect
`Name`	Name of the random-effect coefficient
`Estimate`	Empirical Bayes predictor (EBP) of random effect
`SEPred`	Square root of the conditional mean squared error of prediction (CMSEP) given covariance parameters and response
`tStat`	*t*-statistic for a test that the random-effects coefficient is equal to 0
`DF`	Estimated degrees of freedom for the *t*-statistic
`pValue`	*p*-value for the *t*-statistic
`Lower`	Lower limit of a 95% confidence interval for the random-effects coefficient
`Upper`	Upper limit of a 95% confidence interval for the random-effects coefficient

`randomEffects` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. An alternative interpretation of the confidence intervals is that they are approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods (`'MPL'` or `'REMPL'`), `randomEffects` computes confidence intervals and related statistics based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Compute and Plot Estimated Random Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)

- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)','Dis
```

Compute and display the names and estimated values of the empirical Bayes predictors (EBPs) for the random effects.

```
[B,BNames] = randomEffects(glme)

The first three columns of `stats` contain the group name, level, and random-effects coefficient name. Column 4 contains the estimated EBP of the random-effects coefficient. The last two columns of `stats`, `Lower` and `Upper`, contain the lower and upper bounds of the 99% confidence interval, respectively. For example, for the coefficient for `'(Intercept)'` for level `3` of `factory`, the estimated EBP is -0.26325, and the 99% confidence interval is [-0.82191,0.29541].

randomEffects

Class: `LinearMixedModel`

Estimates of random effects and related statistics

Syntax

```
B = randomEffects(lme)
[B,Bnames] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme,Name,Value)
```

Description

`B = randomEffects(lme)` returns the estimates of the best linear unbiased predictors (BLUPs) of random effects in the linear mixed-effects model `lme`.

`[B,Bnames] = randomEffects(lme)` also returns the names of the coefficients in `Bnames`. Each name corresponds to a coefficient in `B`.

`[B,Bnames,stats] = randomEffects(lme)` also returns the estimated BLUPs of random effects in the linear mixed-effects model `lme` and related statistics.

`[B,Bnames,stats] = randomEffects(lme,Name,Value)` also returns the BLUPs of random effects in the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Alpha` — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α, the confidence level is 100*(1–α)%.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`DFMethod` — Method for computing approximate degrees of freedom
`'residual'` (default) | `'satterthwaite'` | `'none'`

Method for computing approximate degrees of freedom for the *t*-statistics that test the random-effects coefficients against 0, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

`'residual'`	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
`'satterthwaite'`	Satterthwaite approximation.
`'none'`	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod','satterthwaite'`

Output Arguments

`B` — Estimated best linear unbiased predictors of random effects
column vector

Estimated best linear unbiased predictors of random effects of linear mixed-effects model `lme`, returned as a column vector.

Suppose `lme` has R grouping variables g_1, g_2, ..., g_R, with levels m_1, m_2, ..., m_R, respectively. Also suppose q_1, q_2, ..., q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, ..., g_R, respectively. Then, `B` is a column vector of length $q_1*m_1 + q_2*m_2 + ... + q_R*m_R$.

`randomEffects` creates `B` by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as $[g_1level_1; g_1level_2; ...; g_1level_{m_1}; g_2level_1; g_2level_2; ...; g_2level_{m_2}; ...; g_Rlevel_1; g_Rlevel_2; ...; g_Rlevel_{m_R}]'$.

`Bnames` — Names of random-effects coefficients
table

Names of random-effects coefficients in `B`, returned as a table.

`stats` — Estimates of random effects BLUPs and related statistics
dataset array

Estimates of random effects BLUPs and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

`Group`	Grouping variable associated with the random effect
`Level`	Level within the grouping variable corresponding to the random effect

`Name`	Name of the random-effect coefficient
`Estimate`	Best linear unbiased predictor (BLUP) of random effect
`SEPred`	Standard error of the estimate (BLUP minus random effect)
`tStat`	*t*-statistic for a test that the random effect is zero
`DF`	Estimated degrees of freedom for the *t*-statistic
`pValue`	*p*-value for the *t*-statistic
`Lower`	Lower limit of a 95% confidence interval for the random effect
`Upper`	Upper limit of a 95% confidence interval for the random effect

Examples

Display Random-Effects Estimates and Coefficient Names

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration, grouped by the model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the BLUPs of the random-effects coefficients and display the names of the corresponding random effects.

```
[B,Bnames] = randomEffects(lme)
```

```
B = 26×1

      ⋮
```

Since intercept and acceleration have potentially correlated random effects, grouped by model year of the cars, `randomEffects` creates a separate row for intercept and acceleration at each level of the grouping variable.

Compute the covariance parameters of the random effects.

```
[~,~,stats] = covarianceParameters(lme)
```

```
stats=2×1 cell array

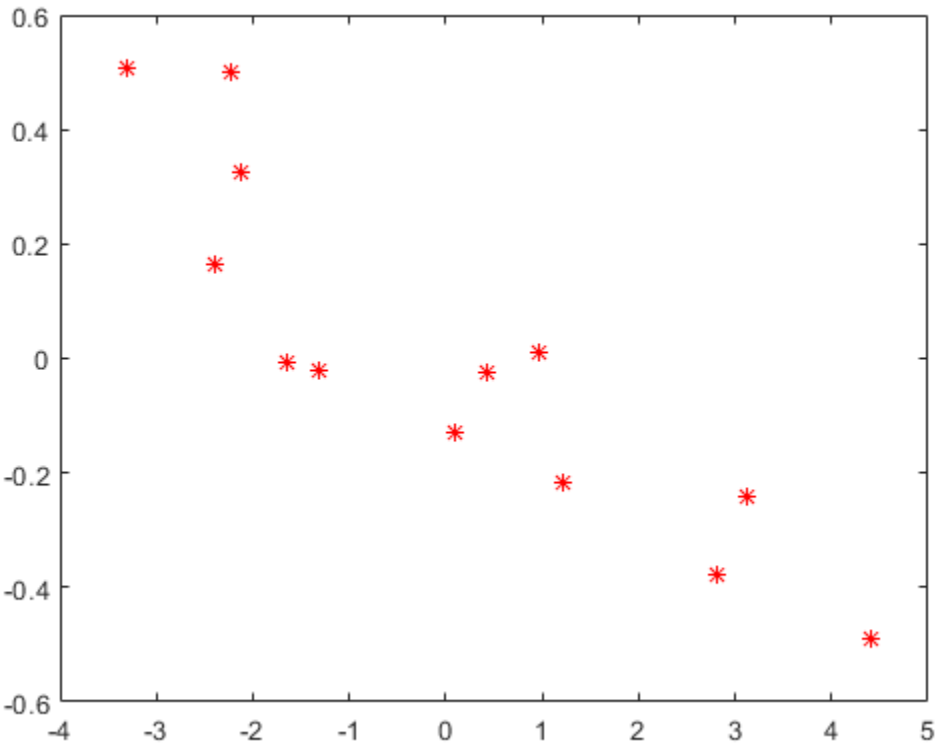
     0.33789      0.1825     0.62558
```

The correlation value suggests that random effects seem negatively correlated. Plot the random effects for intercept versus acceleration to confirm this.

```
plot(B(1:2:end),B(2:2:end),'r*')
```



Compute Random-Effects Estimates and Related Statistics

Load the sample data.

```
load('fertilizer.mat');
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Compute the BLUPs and related statistics for random effects.

```
[~,~,stats] = randomEffects(lme)
```

```
stats =

```

The first three rows contain the random-effects estimates and the statistics for the three levels, `Loamy`, `Sandy`, and `Silty` of the grouping variable `Soil`. The corresponding *p*-values 0.66918, 0.51825, and 0.82593 indicate that these random-effects are not significantly different from 0. The following 15 rows include the BLUPS of random-effects estimates for the intercept, grouped by the variable Tomato nested in Soil, i.e. interaction of `Tomato` and `Soil`.

Compute Confidence Intervals with Specified Options

Load the sample data.

```
load shift
```

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is a significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method.

```
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for random effects using the residuals option to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = randomEffects(lme,'Alpha',0.01)
```

```
stats =
    Random effect coefficients: DFMethod = 'Residual', Alpha = 0.01

    Group               Level        Name                    Estimate    SEPred
    {'Operator'}        {'1'}        {'(Intercept)'}         0.57753     0.90378

    0.63902    6.4253      0.5449      -2.684     3.839
     1.3009    6.4253     0.23799     -2.0858    4.4372
    -2.4027    6.4253    0.050386      -5.433      1.09
     2.6174    6.4253    0.037302    -0.89598     5.627
    -2.1546    6.4253    0.071626     -5.2087    1.3142
```

The Satterthwaite method usually produces smaller values for the degrees of freedom (`DF`), which results in larger p-values (`pValue`) and larger confidence intervals (`Lower` and `Upper`) for the random-effects estimates.

randsample

Random sample

Syntax

```
y = randsample(n,k)
y = randsample(population,k)
y = randsample( ___ ,replacement)
y = randsample(n,k,true,w)
y = randsample(population,k,true,w)
y = randsample(s, ___ )
```

Description

`y = randsample(n,k)` returns `k` values sampled uniformly at random, without replacement, from the integers `1` to `n`.

`y = randsample(population,k)` returns a vector of `k` values sampled uniformly at random, without replacement, from the values in the vector `population`.

`y = randsample( ___ ,replacement)` returns a sample taken with replacement if `replacement` is `true`, or without replacement if `replacement` is `false`. Specify `replacement` following any of the input argument combinations in the previous syntaxes.

`y = randsample(n,k,true,w)` uses a vector of non-negative weights, `w`, whose length is `n`, to determine the probability that an integer `i` is selected as an entry for `y`.

`y = randsample(population,k,true,w)` uses a vector of nonnegative weights, `w`, of the same length as the vector `population`, to determine the probability that a value `population(i)` is selected as an entry for `y`.

`y = randsample(s, ___ )` uses the stream `s` for random number generation. The option `s` can precede any of the input arguments in the previous syntaxes. `s` is a member of the `RandStream` class.

Examples

Sample Unique Value from Range

Draw a single value from the integers `1` through `10`.

```
n = 10;
x = randsample(n,1)
```

```
x = 9
```

Sample from Population Vector

Create the random seed for reproducibility of the results.

```
s = RandStream('mlfg6331_64');
```

Draw a single value from the vector `[10:20]`.

```
population = 10:20;
y = randsample(s,population,1)
```

```
y = 17
```

Generate Random Sequence for Specified Probabilities

Create the random number stream for reproducibility.

```
s = RandStream('mlfg6331_64');
```

Choose 48 characters randomly and with replacement from the sequence `ACGT`, according to the specified probabilities.

```
R = randsample(s,'ACGT',48,true,[0.15 0.35 0.35 0.15])
```

```
R =
'GGCGGCGCAAGGCGCCGGACCTGGCTGCACGCCGTTCCCTGCTACTCG'
```

Set Random Number Stream

Create the random number stream for reproducibility.

```
s = RandStream('mlfg6331_64');
```

Draw five values with replacement from the integers `1:10`.

```
y = randsample(s,10,5,true)
```

```
y = 5×1

     7
     8
     5
     7
     8
```

Input Arguments

n — Upper limit of range

positive integer

Upper limit of the range (`1` to `n`) from which to sample, specified as a positive integer. By default, `randsample` samples uniformly at random, without replacement, from the values in the range `1` to `n`.

Data Types: `single` | `double`

`population` — Input data
vector

Input data from which to sample, specified as a vector. By default, `randsample` samples uniformly at random, without replacement, from the values in `population`. The orientation of `y` (row or column) is the same as that of `population`.

If `population` is a numeric vector containing only nonnegative integer values, and `population` can have the length 1, then use `y = population(randsample(length(population),k))` instead of `y = randsample(population,k)`.

Example: `y = randsample([50:100],20)` returns a vector of `20` values sampled uniformly at random, without replacement, from the `population` vector consisting of integers from `50` to `100`.

Data Types: `single` | `double` | `logical` | `char` | `string` | `categorical`

`k` — Number of samples
positive integer

Number of samples, specified as a positive integer.

Example: `randsample(20,10)` returns a vector of `10` values sampled uniformly at random, without replacement, from the integers `1` to `20`.

Data Types: `single` | `double`

`replacement` — Indicator for sampling with replacement
false (default) | true

Indicator for sampling with replacement, specified as either `false` or `true`.

Example: `randsample(10,2,true)` returns two values with replacement from the integers `1` to `10`.

Data Types: `logical`

`w` — Sampling weights
`ones(n,1)` (default) | vector of nonnegative scalar values

Sampling weights, specified as a vector of nonnegative scalar values. The length of `w` must be equal to the range of integers to sample or the length of `population`. The vector `w` must have at least one positive value. If `w` contains negative values or `NaN` values, `randsample` displays an error message. The `randsample` function samples with probability proportional to `w(i)/sum(w)`. Usually, `w` is a vector of probabilities. The `randsample` function supports specifying weights only for sampling with replacement.

Example: `[0.1 0.5 0.35 0.46]`

Data Types: `single` | `double`

`s` — Random number stream
MATLAB default random number stream (default) | `RandStream`

Random number stream, specified as the MATLAB default random number stream or `RandStream`. For details, see “Creating and Controlling a Random Number Stream”.

Example: `s = RandStream('mlfg6331_64')` creates a random number stream that uses the multiplicative lagged Fibonacci generator algorithm.

Output Arguments

y — Sample

vector | scalar

Sample, returned as a vector or scalar.

- If `k = 1`, then `y` is a scalar.
- If `k > 1`, then `y` is a *k*-by-1 vector.

Tips

To sample data randomly, with or without replacement, use `datasample`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- When you sample without replacement, the order of the output values might not match the order in MATLAB.
- Code generation does not support the random number stream input argument `s`.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`RandStream` | `datasample` | `rand` | `randperm`

Introduced before R2006a

randtool

Interactive random number generation

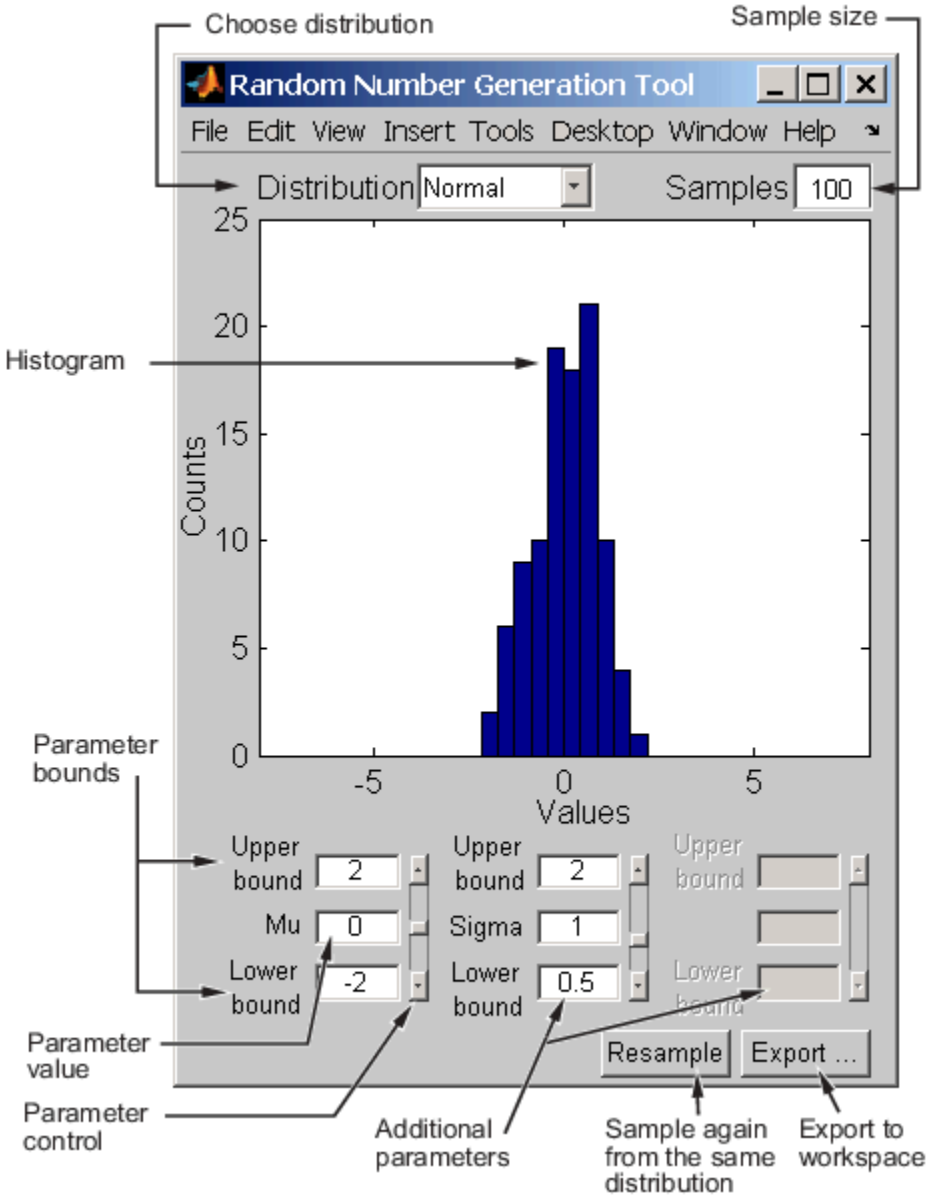
Syntax

```
randtool
```

Description

`randtool` opens the Random Number Generation Tool.

The Random Number Generation Tool is a graphical user interface that generates random samples from specified probability distributions and displays the samples as histograms. Use the tool to explore the effects of changing parameters and sample size on the distributions.



Start by selecting a distribution, then enter the desired sample size.

You can also

- Use the controls at the bottom of the window to set parameter values for the distribution and to change their upper and lower bounds.
- Draw another sample from the same distribution, with the same size and parameters.
- Export the current sample to your workspace. A dialog box enables you to provide a name for the sample.

`randttool` does not provide printing functionality in MATLAB Online.

Introduced before R2006a

range

Range of values

Syntax

```
y = range(X)
y = range(X,'all')
y = range(X,dim)
y = range(X,vecdim)
```

Description

`y = range(X)` returns the difference between the maximum and minimum values of sample data in `X`.

- If `X` is a vector, then `range(X)` is the range of the values in `X`.
- If `X` is a matrix, then `range(X)` is a row vector containing the range of each column in `X`.
- If `X` is a multidimensional array, then `range` operates along the first nonsingleton dimension of `X`, treating the values as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. If `X` is an empty array with first dimension 0, then `range(X)` returns an empty array with the same size as `X`.

`y = range(X,'all')` returns the range of all elements in `X`.

`y = range(X,dim)` returns the range along the operating dimension `dim` of `X`. For example, if `X` is a matrix, then `range(X,2)` is a column vector containing the range value of each row.

`y = range(X,vecdim)` returns the range over the dimensions specified in the vector `vecdim`. For example, if `X` is a matrix, then `range(X,[1 2])` is the range of all elements in `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Range of Standard Normal Random Numbers

Generate five large samples of standard normal random numbers.

```
rng('default') % For reproducibility
rv = normrnd(0,1,1000,5);
```

Find the range values of the samples.

```
near6 = range(rv)
```

```
near6 = 1×5

    6.8104    6.6420    6.9578    6.0860    6.8165
```

The range value is approximately 6 for each sample.

Range of Exam Scores

Find the range of exam scores over the course of five exams.

Load the `examgrades` data set.

```
load examgrades
```

Find the range of all exam scores.

```
y = range(grades,'all')
```

```
y = 46
```

Range of Exam Scores by Student

Find the range of exam scores for each student over the course of five exams.

Load the `examgrades` data set.

```
load examgrades
```

Find the range of exam scores for the first 10 students. For example, the difference between the eighth student's best and worst exam scores is 7 points.

```
X = grades(1:10,:);
y = range(X,2)
```

```
y = 10×1

    12
    13
    10
    12
     8
    16
    14
     7
    12
    10
```

Range Along Vector Dimension

Find the range of a multidimensional array over multiple dimensions.

Create a 3-by-5-by-2 array of normal random numbers with mean `mu = 2` and standard deviation `sigma = 7`.

```
rng('default') % For reproducibility
mu = 2;
```

```
sigma = 7;
X = normrnd(mu,sigma,[3 5 2])

X =
X(:,:,1) =

    5.7637    8.0352   -1.0351   21.3861    7.0778
   14.8372    4.2314    4.3984   -7.4492    1.5586
  -13.8119   -7.1538   27.0488   23.2445    7.0032

X(:,:,2) =

    0.5652   11.8632   -6.4524    5.4223   -0.1241
    1.1310   11.9203    7.0207    9.2429    4.0571
   12.4279    6.7005   13.4116    7.0882   -3.5110
```

Find the range of each page of `X` by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = range(X,[1 2])

ypage =
ypage(:,:,1) =

   40.8607

ypage(:,:,2) =

   19.8641
```

For example, `ypage(1,1,2)` is the range of all the elements in `X(:,:,2)`.

Find the range of the elements in each `X(i,:,:)` slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = range(X,[2 3])

yrow = 3×1

   27.8385
   22.2864
   40.8607
```

For example, `yrow(3)` is the range of all the elements in `X(3,:,:)`.

Input Arguments

X — Data sample

scalar | vector | matrix | multidimensional array

Data sample, specified as a scalar, vector, matrix, or multidimensional array.

- If `X` is a scalar, then `range(X)` is 0.
- If `X` is a 0-by-0 empty array, then `range(X)` is also an empty array.

Data Types: `single` | `double` | `logical` | `datetime` | `duration`

`dim` — Dimension to operate along
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y,dim)` is 1, while the sizes of all other dimensions remain the same unless `size(X,dim)` is 0. If `size(X,dim)` is 0, then `range(X,dim)` returns an empty array of the same size as `X`.

Consider a two-dimensional data sample `X`:

- If `dim` is equal to 1, then `range(X,1)` returns a row vector containing the range for each column.
- If `dim` is equal to 2, then `range(X,2)` returns a column vector containing the range for each row.

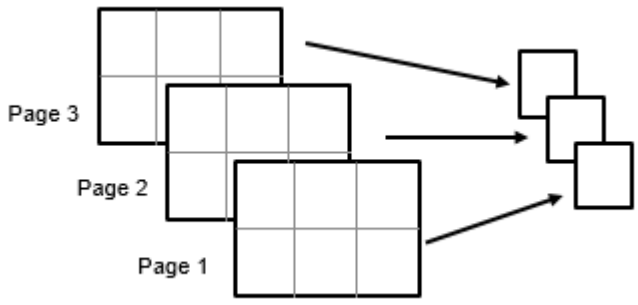
If `dim` is greater than `ndims(X)`, `range` returns an array of zeros with the same dimensions and missing values as `X`.

Data Types: `single` | `double`

`vecdim` — Vector of dimensions
positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `range(X,[1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the range of the elements on the corresponding page of `X`.



Data Types: `single` | `double`

Output Arguments

`y` — Difference between maximum and minimum values
scalar | vector | matrix | multidimensional array

Difference between the maximum and minimum values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- `range` treats `NaN`s as missing values and ignores them.
- `range` provides an easily calculated estimate of the spread of a sample. Avoid using `range` with data that has outliers because they have an undue influence on this statistic.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also

`iqr` | `mad` | `std`

Introduced before R2006a

rangesearch

Find all neighbors within specified distance using searcher object

Syntax

```
Idx = rangesearch(Mdl,Y,r)
Idx = rangesearch(Mdl,Y,r,Name,Value)
[Idx,D] = rangesearch( ___ )
```

Description

`Idx = rangesearch(Mdl,Y,r)` searches for all neighbors (i.e., points, rows, or observations) in `Mdl.X` within radius `r` of each point (i.e., row or observation) in the query data `Y` using an exhaustive search or a *K*d-tree. `rangesearch` returns `Idx`, which is a column vector of the indices of `Mdl.X` within `r` units.

`Idx = rangesearch(Mdl,Y,r,Name,Value)` returns the indices of the observation in `Mdl.X` within radius `r` of each observation in `Y` with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to use a different distance metric than is stored in `Mdl.Distance` or a different distance metric parameter than is stored in `Mdl.DistParameter`.

`[Idx,D] = rangesearch( ___ )` additionally returns the matrix `D` using any of the input arguments in the previous syntaxes. `D` contains the distances between the observations in `Mdl.X` within radius `r` of each observation in `Y`. By default, the function arranges the columns of `D` in ascending order by closeness, with respect to the distance metric.

Examples

Search for Neighbors Within a Radius Using *K*d-tree and Exhaustive Search

`rangesearch` accepts `ExhaustiveSearcher` or `KDTreeSearcher` model objects to search the training data for the nearest neighbors to the query data. An `ExhaustiveSearcher` model invokes the exhaustive searcher algorithm, and a `KDTreeSearcher` model defines a *K*d-tree, which `rangesearch` uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data. Focus on the petal dimensions.

```
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),3:4); % Training data
Y = meas(idx,3:4);                % Query data
```

Grow a default two-dimensional *K*d-tree.

```
MdlKDT = KDTreeSearcher(X)
```

```
MdlKDT =
  KDTreeSearcher with properties:

      BucketSize: 50
        Distance: 'euclidean'
    DistParameter: []
                X: [145x2 double]
```

`MdlKDT` is a `KDTreeSearcher` model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbor searcher.

```
MdlES = ExhaustiveSearcher(X)
```

```
MdlES =
  ExhaustiveSearcher with properties:

        Distance: 'euclidean'
    DistParameter: []
                X: [145x2 double]
```

`MdlES` is an `ExhaustiveSearcher` model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a *K*d-tree or prepare an exhaustive nearest neighbor searcher using `createns`.

Search training data for the nearest neighbor indices that correspond to each query observation that are within a 0.5 cm radius. Conduct both types of searches and use the default settings.

```
r = 0.15; % Search radius
IdxKDT = rangesearch(MdlKDT,Y,r);
IdxES = rangesearch(MdlES,Y,r);
[IdxKDT IdxES]
```

```
ans=5×2 cell array
    {1x27 double}    {1x27 double}
    {[       13]}    {[       13]}
    {1x27 double}    {1x27 double}
    {[    64 66]}    {[    64 66]}
    {1x0  double}    {1x0  double}
```

`IdxKDT` and `IdxES` are cell arrays of vectors corresponding to the indices of `X` that are within 0.15 cm of the observations in `Y`. Each row of the index matrices corresponds to a query observation.

Compare the results between the methods.

```
cellfun(@isequal,IdxKDT,IdxES)
```

```
ans = 5x1 logical array

   1
   1
   1
   1
```

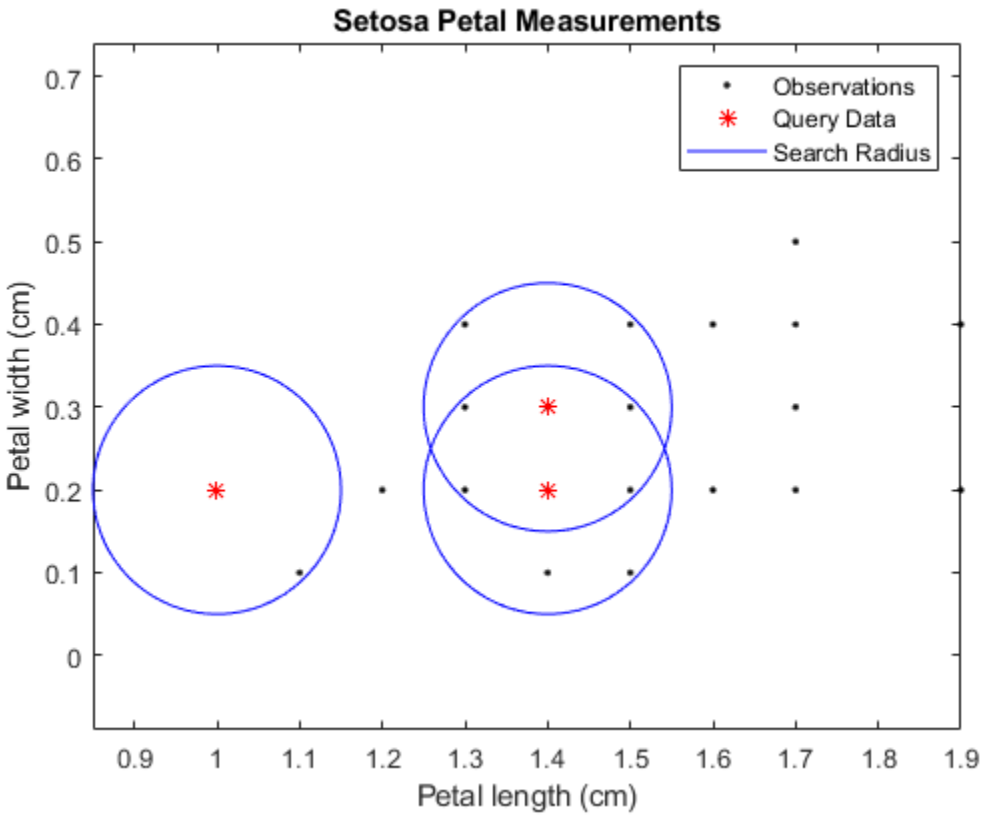
```
1
```

In this case, the results are the same.

Plot the results for the setosa irises.

```
setosaIdx = strcmp(species(~ismember(1:n,idx)),'setosa');
XSetosa = X(setosaIdx,:);
ySetosaIdx = strcmp(species(idx),'setosa');
YSetosa = Y(ySetosaIdx,:);

figure;
plot(XSetosa(:,1),XSetosa(:,2),'.k');
hold on;
plot(YSetosa(:,1),YSetosa(:,2),'*r');
for j = 1:sum(ySetosaIdx)
    c = YSetosa(j,:);
    circleFun = @(x1,x2)r^2 - (x1 - c(1)).^2 - (x2 - c(2)).^2;
    fimplicit(circleFun,[c(1) + [-1 1]*r, c(2) + [-1 1]*r],'b-')
end
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
title 'Setosa Petal Measurements';
legend('Observations','Query Data','Search Radius');
axis equal
hold off
```



Search for Neighbors Within a Radius Using the Mahalanobis Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare a default exhaustive nearest neighbor searcher.

```
Mdl = ExhaustiveSearcher(X)
```

```
Mdl =
  ExhaustiveSearcher with properties:

         Distance: 'euclidean'
    DistParameter: []
                X: [145x4 double]
```

`Mdl` is an `ExhaustiveSearcher` model.

Find the indices of the training data (`X`) that are within 0.15 cm of each point in the query data (`Y`). Specify that the distances are with respect to the Mahalanobis metric.

```
r = 1;
Idx = rangesearch(Mdl,Y,r,'Distance','mahalanobis')
```

```
Idx=5×1 cell array
    {[26 38 7 17 47 4 27 46 25 10 39 20 21 2 33]}
    {[                              6 21 25 4 19]}
    {[                           1 34 33 22 24 2]}
    {[                                       84]}
    {[                                       69]}
```

```
Idx{3}
```

```
ans = 1×6

     1    34    33    22    24     2
```

Each cell of `Idx` corresponds to a query data observation and contains in `X` a vector of indices of the neighbors within 0.15cm of the query data. `rangesearch` arranges the indices in ascending order by distance. For example, using the Mahalanobis distance, the second nearest neighbor of `Y(3,:)` is `X(34,:)`.

Compute Distances of Neighbors Within a Radius

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4);                      % For reproducibility
n = size(meas,1);            % Sample size
qIdx = randsample(n,5);      % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional *K*d-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors.

```
Mdl = KDTreeSearcher(X);
```

`Mdl` is a `KDTreeSearcher` model. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (`X`) that are within 0.5 cm from each point in the query data (`Y`).

```
r = 0.5;
[Idx,D] = rangesearch(Mdl,Y,r);
```

`Idx` and `D` are five-element cell arrays of vectors. The vector values in `Idx` are the indices in `X`. The `X` indices represent the observations that are within 0.5 cm of the query data, `Y`. `D` contains the distances that correspond to the observations.

Display the results for query observation 3.

```
Idx{3}
```

```
ans = 1×2

   127   122
```

```
D{3}
```

```
ans = 1×2

    0.2646    0.4359
```

The closest observation to `Y(3,:)` is `X(127,:)`, which is `0.2646` cm away. The next closest is `X(122,:)`, which is `0.4359` cm away. All other observations are greater than `0.5` cm away from `Y(5,:)`.

Input Arguments

`Mdl` — Nearest neighbor searcher

`ExhaustiveSearcher` model object | `KDTreeSearcher` model object

Nearest neighbor searcher, specified as an `ExhaustiveSearcher` or `KDTreeSearcher` model object, respectively.

If `Mdl` is an `ExhaustiveSearcher` model, then `rangesearch` searches for nearest neighbors using an exhaustive search. Otherwise, `rangesearch` uses the grown *K*d-tree to search for nearest neighbors.

Y — Query data

numeric matrix

Query data, specified as a numeric matrix.

`Y` is an *m*-by-*K* matrix. Rows of `Y` correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). `Y` must have the same number of columns as the training data stored in `Mdl.X`.

Data Types: `single` | `double`

r — Search radius

nonnegative scalar

Search radius around each point in the query data, specified as a nonnegative scalar.

`rangesearch` finds all observations in `Mdl.X` that are within distance `r` of each observation in `Y`. The property `Mdl.Distance` stores the distance.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Distance','minkowski','P',3` specifies to find all observations in `Mdl.X` within distance `r` of each observation in `Y`, using the Minkowski distance metric with exponent `3`.

For Both Nearest Neighbor Searchers

Distance — Distance metric

`Mdl.Distance` (default) | `'cityblock'` | `'euclidean'` | `'mahalanobis'` | `'minkowski'` | `'seuclidean'` | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of `'Distance'` and a character vector, string scalar, or function handle.

For both types of nearest neighbor searchers, `rangesearch` supports these distance metrics.

Value	Description
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'cityblock'`	City block distance.
`'euclidean'`	Euclidean distance.

Value	Description
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.

If Mdl is an ExhaustiveSearcher model object, then rangesearch also supports these distance metrics.

Value	Description
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as row vectors).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in Mdl.X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from Mdl.X. To specify another scaling, use the 'Scale' name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

If Mdl is an ExhaustiveSearcher model object, then you can also specify a function handle for a custom distance metric by using @ (for example, @distfun). The custom distance function must:

- Have the form function D2 = distfun(ZI,ZJ).
- Take as arguments:
  - A 1-by-*K* vector ZI containing a single row from Mdl.X or Y, where *K* is the number of columns of Mdl.X.
  - An *m*-by-*K* matrix ZJ containing multiple rows of Mdl.X or Y, where *m* is a positive integer.
- Return an *m*-by-1 vector of distances D2, where D2(*j*) is the distance between the observations ZI and ZJ(*j*,:).

For more details, see “Distance Metrics” on page 18-12.

Example: 'Distance','minkowski'

P — Exponent for Minkowski distance metric
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. This argument is valid only if `'Distance'` is `'minkowski'`.

Example: `'P',3`

Data Types: `single` | `double`

`SortIndices` — Flag to sort returned indices according to distance
`true` (`1`) (default) | `false` (`0`)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of `'SortIndices'` and either `true` (`1`) or `false` (`0`).

For faster performance when `Y` contains many observations that have many nearest points, you can set `SortIndices` to `false`. In this case, `rangesearch` returns the indices of the nearest points in no particular order. When `SortIndices` is `true`, the function arranges the indices of the nearest points in ascending order by distance.

Example: `'SortIndices',false`

Data Types: `logical`

For Exhaustive Nearest Neighbor Searchers

`Cov` — Covariance matrix for Mahalanobis distance metric
`cov(Mdl.X,'omitrows')` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix. `Cov` is a K-by-K matrix, where K is the number of columns of `Mdl.X`. If you specify `Cov` and do not specify `'Distance','mahalanobis'`, then `rangesearch` returns an error message.

Example: `'Cov',eye(3)`

Data Types: `single` | `double`

`Scale` — Scale parameter value for standardized Euclidean distance metric
`std(Mdl.X,'omitnan')` (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of `'Scale'` and a nonnegative numeric vector. `Scale` has length K, where K is the number of columns of `Mdl.X`.

The software scales each difference between the training and query data using the corresponding element of `Scale`. If you specify `Scale` and do not specify `'Distance','seuclidean'`, then `rangesearch` returns an error message.

Example: `'Scale',quantile(Mdl.X,0.75) - quantile(Mdl.X,0.25)`

Data Types: `single` | `double`

Note If you specify `'Distance'`, `'Cov'`, `'P'`, or `'Scale'`, then `Mdl.Distance` and `Mdl.DistParameter` do not change value.

Output Arguments

`Idx` — Training data indices of nearest neighbors

cell array of numeric vectors

Training data indices of nearest neighbors, returned as a cell array of numeric vectors.

`Idx` is an *m*-by-`1` cell array such that cell `j` (`Idx{j}`) contains an m_j-dimensional vector of indices of the observations in `Mdl.X` that are within `r` units to the query observation `Y(j,:)`. If `SortIndices` is `true`, then `rangesearch` arranges the elements of the vectors in ascending order by distance.

`D` — Distances of nearest neighbors to the query data

cell array of numeric vectors

Distances of the neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

`D` is an *m*-by-`1` cell array such that cell `j` (`D{j}`) contains an m_j-dimensional vector of the distances that the observations in `Mdl.X` are from the query observation `Y(j,:)`. All elements of the vector are less than `r`. If `SortIndices` is `true`, then `rangesearch` arranges the elements of the vectors in ascending order.

Tips

`knnsearch` finds the *k* (positive integer) points in `Mdl.X` that are *k*-nearest for each `Y` point. In contrast, `rangesearch` finds all the points in `Mdl.X` that are within distance `r` (positive scalar) of each `Y` point.

Alternative Functionality

`rangesearch` is an object function that requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object, query data, and a distance. Under equivalent conditions, `rangesearch` returns the same results as `rangesearch` when you specify the name-value pair argument `'NSMethod','exhaustive'` or `'NSMethod','kdtree'`, respectively.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This table contains notes about the arguments of `rangesearch`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
`Mdl`	There are two ways to use `Mdl` in code generation. For an example, see “Code Generation for Nearest Neighbor Searcher” on page 32-19. • Use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen` to generate code for the `rangesearch` function. Save a trained model by using `saveLearnerForCoder`. Define an entry-point function that loads the saved model by using `loadLearnerForCoder` and calls the `rangesearch` function. Then use `codegen` to generate code for the entry-point function. • Include `coder.Constant(Mdl)` in the `-args` value of `codegen`. If `Mdl` is a `KDTreeSearcher` object, and the code generation build type is a MEX function, then `codegen` generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, `codegen` generates code using `parfor`. • MEX function for the *k*d-tree search algorithm — `codegen` generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb. If you generate the MEX function to test the generated code of the `parfor` version, you can disable the usage of Intel TBB. Set the `ExtrinsicCalls` property of the MEX configuration object to `false`. For details, see `coder.MexCodeConfig`. • MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of `rangesearch` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see `https://www.mathworks.com/support/compilers/current_release/`. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.
`'Distance'`	• Cannot be a custom distance function. • Must be a compile-time constant; its value cannot change in the generated code.
`'SortIndices'`	Not supported. The output arguments are always sorted.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include `{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0}` in the `-args` value of `codegen`.

Argument	Notes and Limitations
`Idx`	• The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision. • Starting in R2020a, `rangesearch` returns integer-type (`int32`) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information, see “Introduction to Code Generation” on page 32-2 and “Code Generation for Nearest Neighbor Searcher” on page 32-19.

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-14
“Distance Metrics” on page 18-12

Introduced in R2011b

rangesearch

Find all neighbors within specified distance using input data

Syntax

```
Idx = rangesearch(X,Y,r)
[Idx,D] = rangesearch(X,Y,r)
[Idx,D] = rangesearch(X,Y,r,Name,Value)
```

Description

`Idx = rangesearch(X,Y,r)` finds all the `X` points that are within distance `r` of the `Y` points. The rows of `X` and `Y` correspond to observations, and the columns correspond to variables.

`[Idx,D] = rangesearch(X,Y,r)` also returns the distances between the `Y` points and the `X` points that are within a distance of `r`.

`[Idx,D] = rangesearch(X,Y,r,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the nearest neighbor search method and the distance metric used in the search.

Examples

Find All Points Within Specified Distance

Find the `X` points that are within a Euclidean distance `1.5` of each `Y` point. Both `X` and `Y` are samples of five-dimensional normally distributed variables.

```
rng('default') % For reproducibility
X = randn(100,5);
Y = randn(10,5);
[Idx,D] = rangesearch(X,Y,1.5)
```

```
Idx=10×1 cell array
    {[             25 62 33 99 87 92 16]}
    {[                               92 25]}
    {[ 93 42 31 73 60 28 78 83 48 89 85]}
    {[                               92 41]}
    {[44 7 28 78 75 42 69 31 1 26 83 93]}
    {[       15 31 89 41 27 17 29 60 34]}
    {[                                  89]}
    {1x0 double                            }
    {1x0 double                            }
    {1x0 double                            }

D=10×1 cell array
    {[              0.9546 1.0987 1.2730 1.3981 1.4140 1.4249 1.4822]}
    {[                                                 1.4203 1.4558]}
    {1x11 double                                                      }
    {[                                                 1.1244 1.4672]}
```

```
    {1x12 double                                                          }
    {[1.2824 1.2843 1.3342 1.3469 1.4154 1.4237 1.4625 1.4626 1.4744]}
    {[                                                                1.1739]}
    {1x0  double                                                          }
    {1x0  double                                                          }
    {1x0  double                                                          }
```

In this case, the last three `Y` points are more than `1.5` distance away from any `X` point. `X(89,:)` is `1.1739` distance away from `Y(7,:)`, and no other `X` point is within distance `1.5` of `Y(7,:)`. `X` contains `12` points within distance `1.5` of `Y(5,:)`.

Find Nearest Points in Clustered Data

Generate 5000 random points from each of three distinct multivariate normal distributions. Shift the means of the distributions so that the randomly generated points are likely to form three separate clusters.

```
rng('default')  % For reproducibility
N = 5000;
dist = 10;
X = [mvnrnd([0 0],eye(2),N);
     mvnrnd(dist*[1 1],eye(2),N);
     mvnrnd(dist*[-1 -1],eye(2),N)];
```

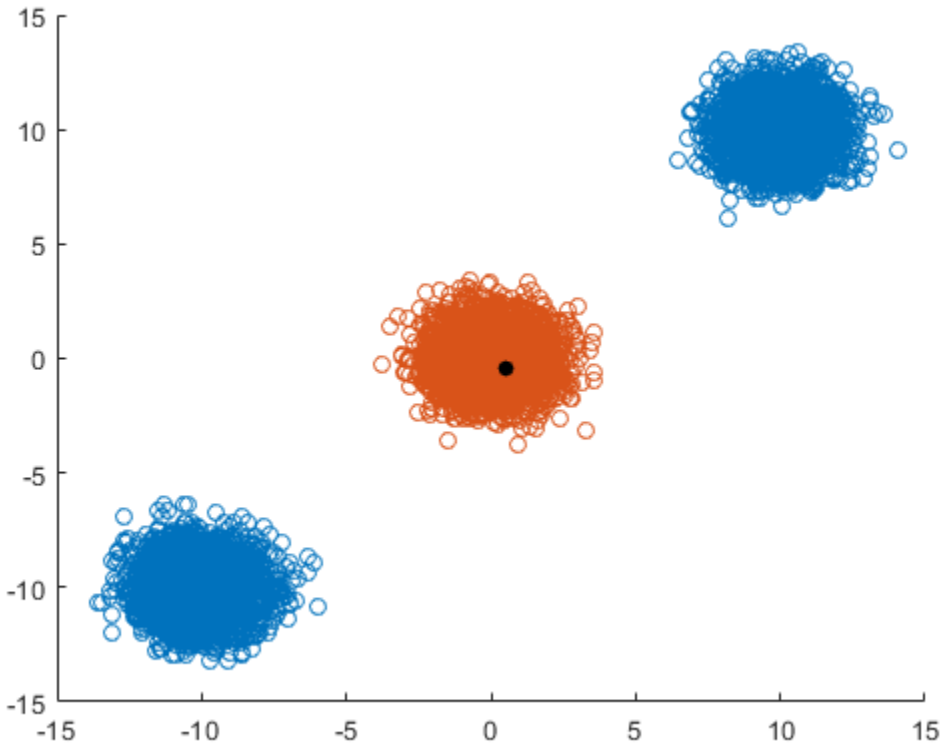
For each point in `X`, find the points in `X` that are within a radius `dist` away from the point. For faster computation, specify to keep the indices of the nearest neighbors unsorted. Select the first point in `X`, and find its nearest neighbors.

```
Idx = rangesearch(X,X,dist,'SortIndices',false);
x = X(1,:);
nearestPoints = X(Idx{1},:);
```

Find the values in `X` that are not the nearest neighbors of `x`. Display those points in one color and the nearest neighbors of `x` in a different color. Label the point `x` with a black, filled circle.

```
nonNearestIdx = true(size(X,1),1);
nonNearestIdx(Idx{1}) = false;

scatter(X(nonNearestIdx,1),X(nonNearestIdx,2))
hold on
scatter(nearestPoints(:,1),nearestPoints(:,2))
scatter(x(1),x(2),'black','filled')
hold off
```



Find Nearest Points Using Custom Distance Function

Find the patients in the `patients` data set that are within a certain age and weight range of the patients in `Y`.

Load the `patients` data set. The `Age` values are in years, and the `Weight` values are in pounds.

```
load patients
X = [Age Weight];
Y = [20 162; 30 169; 40 168];   % New patients
```

Create a custom distance function `distfun` that determines the distance between patients in terms of age and weight. For example, according to `distfun`, two patients that are one year apart in age and have the same weight are one distance unit apart. Similarly, two patients that have the same age and are five pounds apart in weight are also one distance unit apart.

```
type distfun.m % Display contents of distfun.m file
```

```
function D2 = distfun(ZI,ZJ)
ageDifference = abs(ZI(1)-ZJ(:,1));
weightDifference = abs(ZI(2)-ZJ(:,2));
D2 = ageDifference + 0.2*weightDifference;
end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the function file `distfun.m`.

Find the patients in `X` that are within the distance `2` of the patients in `Y`.

```
[Idx,D] = rangesearch(X,Y,2,'Distance',@distfun)
```

```
Idx=3×1 cell array
    {1x0 double}
    {1x0 double}
    {[      41]}

D=3×1 cell array
    {1x0 double}
    {1x0 double}
    {[  1.8000]}
```

The third patient in `Y` is the only one to have a patient in `X` within a distance of `2`.

Display the `Age` and `Weight` values for the nearest patient in `X` to the patient with age `40` and weight `168`.

```
X(Idx{3},:)
```

```
ans = 1×2

    39   164
```

Input Arguments

`X` — Input data

numeric matrix

Input data, specified as an *mx*-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal the number of columns in `Y`.

Data Types: `single` | `double`

`Y` — Query points

numeric matrix

Query points, specified as an *my*-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal the number of columns in `X`.

Data Types: `single` | `double`

`r` — Search radius

nonnegative scalar

Search radius around each query point, specified as a nonnegative scalar. `rangesearch` finds all `X` points (rows) that are within distance `r` of each `Y` point. The meaning of distance depends on the `'Distance'` name-value pair argument.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `rangesearch(X,Y,1.4,'Distance','seuclidean','Scale',iqr(X))` specifies to find all the observations in `X` within distance `1.4` of each observation in `Y`, using a standardized Euclidean distance scaled by the interquartile range of `X`.

`NSMethod` — Nearest neighbor search method

`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and one of these values.

Value	Description
`'kdtree'`	Create and use a *K*d-tree to find nearest neighbors. `'kdtree'` is valid only when the distance metric is one of these options: • `'chebychev'` • `'cityblock'` • `'euclidean'` • `'minkowski'`
`'exhaustive'`	Use the exhaustive search algorithm. The software computes the distances from all `X` points to each `Y` point to find nearest neighbors.

`'kdtree'` is the default value when the number of columns in `X` is less than or equal to `10`, `X` is not sparse, and the distance metric is one of the valid `'kdtree'` metrics. Otherwise, the default value is `'exhaustive'`.

Example: `'NSMethod','exhaustive'`

`Distance` — Distance metric

`'euclidean'` (default) | `'seuclidean'` | `'mahalanobis'` | `'cityblock'` | `'minkowski'` | `'chebychev'` | function handle | ...

Distance metric that `rangesearch` uses, specified as the comma-separated pair consisting of `'Distance'` and one of the values in this table.

Value	Description
`'euclidean'`	Euclidean distance.
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between a row in `X` and a query point is scaled by dividing by the corresponding element of the standard deviation computed from `X`, `std(X,'omitnan')`. To specify another scaling, use the `'Scale'` name-value pair argument.

Value	Description
`'mahalanobis'`	Mahalanobis distance, computed using a positive definite covariance matrix `C`. The default value of `C` is the sample covariance matrix of `X`, as computed by `cov(X,'omitrows')`. To specify a different value for `C`, use the `'Cov'` name-value pair argument.
`'cityblock'`	City block distance.
`'minkowski'`	Minkowski distance. The default exponent is `2`. To specify a different exponent, use the `'P'` name-value pair argument.
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'cosine'`	One minus the cosine of the included angle between observations (treated as vectors).
`'correlation'`	One minus the sample linear correlation between observations (treated as sequences of values).
`'hamming'`	Hamming distance, the percentage of coordinates that differ.
`'jaccard'`	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

`@`*`distfun`*	Custom distance function handle. A distance function has the form
	`function D2 = distfun(ZI,ZJ)`
	`% calculation of distance`
	`...`
	where
	• `ZI` is a 1-by-*n* vector containing one row of `X` or `Y`.
	• `ZJ` is an *m*-by-*n* matrix containing multiple rows of `X` or `Y`.
	• `D2` is an *m*-by-1 vector of distances, and `D2(j)` is the distance between the observations `ZI` and `ZJ(j,:)`.

For more information, see “Distance Metrics” on page 18-12.

Example: `'Distance','minkowski'`

P — Exponent for Minkowski distance metric
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. This argument is valid only if `'Distance'` is `'minkowski'`.

Example: `'P',4`

Data Types: `single` | `double`

Cov — Covariance matrix for Mahalanobis distance metric
`cov(X,'omitrows')` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix. This argument is valid only when `'Distance'` is `'mahalanobis'`.

Example: `'Cov',eye(4)`

Data Types: `single` | `double`

`Scale` — Scale parameter value for standardized Euclidean distance metric
`std(X,'omitnan')` (default) | nonnegative vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of `'Scale'` and a nonnegative vector. `Scale` has length equal to the number of columns in `X`. Each coordinate difference between a row in `X` and a query point is scaled by the corresponding element of `Scale`. This argument is valid only when `'Distance'` is `'seuclidean'`.

Example: `'Scale',iqr(X)`

Data Types: `single` | `double`

`BucketSize` — Maximum number of data points in leaf node of *K*d-tree
`50` (default) | positive integer scalar

Maximum number of data points in the leaf node of the *K*d-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer scalar. This argument is valid only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',20`

Data Types: `single` | `double`

`SortIndices` — Flag to sort returned indices according to distance
`true` (`1`) (default) | `false` (`0`)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of `'SortIndices'` and either `true` (`1`) or `false` (`0`).

For faster performance when `Y` contains many observations that have many nearest points in `X`, you can set `SortIndices` to `false`. In this case, `rangesearch` returns the indices of the nearest points in no particular order. When `SortIndices` is `true`, the function arranges the indices of the nearest points in ascending order by distance.

Example: `'SortIndices',false`

Data Types: `logical`

Output Arguments

`Idx` — Indices of nearest points
cell array of numeric vectors

Indices of nearest points, returned as a cell array of numeric vectors.

`Idx` is an *my*-by-`1` cell array, where *my* is the number of rows in `Y`. The vector `Idx{j}` contains the indices of points (rows) in `X` whose distances to `Y(j,:)` are not greater than `r`. If `SortIndices` is `true`, then `rangesearch` arranges the indices in ascending order by distance.

`D` — Distances of nearest points to query points
cell array of numeric vectors

Distances of the nearest points to the query points, returned as a cell array of numeric vectors.

`D` is an *my*-by-`1` cell array, where *my* is the number of rows in `Y`. `D{j}` contains the distance values between `Y(j,:)` and the points (rows) in `X(Idx{j},:)`. If `SortIndices` is `true`, then `rangesearch` arranges the distances in ascending order.

Tips

- For a fixed positive real value `r`, `rangesearch` finds all the `X` points that are within a distance `r` of each `Y` point. To find the *k* points in `X` that are nearest to each `Y` point, for a fixed positive integer *k*, use `knnsearch`.
- `rangesearch` does not save a search object. To create a search object, use `createns`.

Algorithms

- For an overview of the *k*d-tree algorithm, see “k-Nearest Neighbor Search Using a Kd-Tree” on page 18-15.
- The exhaustive search algorithm finds the distance from each point in `X` to each point in `Y`.

Alternative Functionality

If you set the `rangesearch` function `'NSMethod'` name-value pair argument to the appropriate value (`'exhaustive'` for an exhaustive search algorithm or `'kdtree'` for a *K*d-tree algorithm), then the search results are equivalent to the results obtained by conducting a distance search using the `rangesearch` object function. Unlike the `rangesearch` function, the `rangesearch` object function requires an `ExhaustiveSearcher` or `KDTreeSearcher` model object.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- If `X` is a tall array, then `Y` cannot be a tall array. Similarly, if `Y` is a tall array, then `X` cannot be a tall array.

For more information, see “Tall Arrays”.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, the default value of the `'NSMethod'` name-value pair argument is `'exhaustive'` when the number of columns in `X` is greater than 7.
- The value of the `'Distance'` name-value pair argument must be a compile-time constant and cannot be a custom distance function.
- The `'SortIndices'` name-value pair argument is not supported. The output arguments are always sorted.
- Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include

`{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0}` in the `-args` value of `codegen`.

- The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
- When `rangesearch` uses the *k*d-tree search algorithm, and the code generation build type is a MEX function, `codegen` generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, `codegen` generates code using `parfor`.
  - MEX function for the *k*d-tree search algorithm — `codegen` generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

    If you generate the MEX function to test the generated code of the `parfor` version, you can disable the usage of Intel TBB. Set the `ExtrinsicCalls` property of the MEX configuration object to `false`. For details, see `coder.MexCodeConfig`.
  - MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of `rangesearch` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see `https://www.mathworks.com/support/compilers/current_release/`. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.
- Starting in R2020a, `rangesearch` returns integer-type (`int32`) indices, rather than double-precision indices, in generated standalone C/C++ code. Therefore, the function allows for strict single-precision support when you use single-precision inputs. For MEX code generation, the function still returns double-precision indices to match the MATLAB behavior.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-14
“Distance Metrics” on page 18-12

Introduced in R2011b

ranksum

Wilcoxon rank sum test

Syntax

```
p = ranksum(x,y)
[p,h] = ranksum(x,y)
[p,h,stats] = ranksum(x,y)
[___] = ranksum(x,y,Name,Value)
```

Description

`p = ranksum(x,y)` returns the *p*-value of a two-sided Wilcoxon rank sum test on page 33-5220. `ranksum` tests the null hypothesis that data in `x` and `y` are samples from continuous distributions with equal medians, against the alternative that they are not. The test assumes that the two samples are independent. `x` and `y` can have different lengths.

This test is equivalent to a Mann-Whitney U-test.

`[p,h] = ranksum(x,y)` also returns a logical value indicating the test decision. The result `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level.

`[p,h,stats] = ranksum(x,y)` also returns the structure `stats` with information about the test statistic.

`[___] = ranksum(x,y,Name,Value)` returns any of the output arguments in the previous syntaxes, for a rank sum test with additional options specified by one or more `Name,Value` pair arguments.

Examples

Test for Equal Median of Two Populations

Test the hypothesis of equal medians for two independent unequal-sized samples.

Generate sample data.

```
rng('default') % for reproducibility
x = unifrnd(0,1,10,1);
y = unifrnd(0.25,1.25,15,1);
```

These samples come from populations with identical distributions except for a shift of 0.25 in the location.

Test the equality of medians of `x` and `y`.

```
p = ranksum(x,y)
```

```
p = 0.0375
```

The *p*-value of 0.0375 indicates that `ranksum` rejects the null hypothesis of equal medians at the default 5% significance level.

Statistics of the Test for Two Population Medians

Obtain the statistics of the test for the equality of two population medians.

Load the sample data.

```
load mileage
```

Test if the mileage per gallon is the same for the first and second type of cars.

```
[p,h,stats] = ranksum(mileage(:,1),mileage(:,2))
```

```
p = 0.0043
```

```
h = logical
   1
```

```
stats = struct with fields:
    ranksum: 21.5000
```

Both the *p*-value, 0.043, and `h = 1` indicate the rejection of the null hypothesis of equal medians at the default 5% significance level. Because the sample sizes are small (six each), `ranksum` calculates the *p*-value using the exact method. The structure `stats` includes only the value of the rank sum test statistic.

Increase in the Median

Test the hypothesis of an increase in the population median.

Load the sample data.

```
load('weather.mat');
```

The weather data shows the daily high temperatures taken in the same month in two consecutive years.

Perform a left-sided test to assess the increase in the median at the 1% significance level.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...
'tail','left')
```

```
p = 0.1271
```

```
h = logical
   0
```

```
stats = struct with fields:
       zval: -1.1403
```

```
    ranksum: 837.5000
```

Both the *p*-value of 0.1271 and `h = 0` indicate that there is not enough evidence to reject the null hypothesis and conclude that there is a positive shift in the median of observed high temperatures in the same month from year 1 to year 2 at the 1% significance level. Notice that `ranksum` uses the approximate method to calculate the *p*-value due to the large sample sizes.

Use the exact method to calculate the *p*-value.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...
'tail','left','method','exact')
```

```
p = 0.1273
```

```
h = logical
   0
```

```
stats = struct with fields:
    ranksum: 837.5000
```

The results of the approximate and exact methods are consistent with each other.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. The length of `y` does not have to be the same as the length of `x`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'alpha',0.01,'method','approximate','tail','right'` specifies a right-tailed rank sum test with 1% significance level, which returns the approximate p-value.

alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. The significance level of `h` is 100 * `alpha`%.

Example: `'alpha',0.01`

Data Types: `double` | `single`

`method` — Computation method of the *p*-value
`'exact'` | `'approximate'`

Computation method of the *p*-value, `p`, specified as the comma-separated pair consisting of `'method'` and one of the following:

`'exact'`	Exact computation of the *p*-value, `p`.
`'approximate'`	Normal approximation while computing the *p*-value, `p`.

When `'method'` is unspecified, the default is:

- `'exact'` if $\min(n_x,n_y) < 10$ and $n_x + n_y < 20$
- `'approximate'` otherwise

n_x and n_y are the sizes of the samples in `x` and `y`, respectively.

Example: `'method','exact'`

`tail` — Type of test
`'both'` (default) | `'right'` | `'left'`

Type of test, specified as the comma-separated pair consisting of `'tail'` and one of the following:

`'both'`	Two-sided hypothesis test, where the alternative hypothesis states that `x` and `y` have different medians. Default test type if `'tail'` is not specified.
`'right'`	Right-tailed hypothesis test, where the alternative hypothesis states that the median of `x` is greater than the median of `y`.
`'left'`	Left-tailed hypothesis test, where the alternative hypothesis states that the median of `x` is less than the median of `y`.

Example: `'tail','left'`

Output Arguments

`p` — *p*-value of the test
nonnegative scalar

p-value of the test, returned as a positive scalar from 0 to 1. `p` is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `ranksum` computes the two-sided *p*-value by doubling the most significant one-sided value.

`h` — Result of the hypothesis test
1 | 0

Result of the hypothesis test, returned as a logical value.

- If `h` = 1, this indicates rejection of the null hypothesis at the 100 * `alpha`% significance level.
- If `h` = 0, this indicates a failure to reject the null hypothesis at the 100 * `alpha`% significance level.

`stats` — Test statistics
structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `ranksum` : Value of the rank sum test statistic
- `zval`: Value of the z-statistic on page 33-5220 (computed when `'method'` is `'approximate'`)

More About

Wilcoxon Rank Sum Test

The Wilcoxon rank sum test is a nonparametric test for two populations when samples are independent. If `X` and `Y` are independent samples with different sample sizes, the test statistic which `ranksum` returns is the rank sum of the first sample.

The Wilcoxon rank sum test is equivalent to the Mann-Whitney U-test. The Mann-Whitney U-test is a nonparametric test for equality of population medians of two independent samples `X` and `Y`.

The Mann-Whitney U-test statistic, U, is the number of times a y precedes an x in an ordered arrangement of the elements in the two independent samples `X` and `Y`. It is related to the Wilcoxon rank sum statistic in the following way: If `X` is a sample of size n_X, then

$$U = W - \frac{n_X(n_X + 1)}{2}.$$

z-Statistic

For large samples, `ranksum` uses a z-statistic to compute the approximate p-value of the test.

If `X` and `Y` are two independent samples of size n_X and n_Y, where $n_X < n_Y$ the z-statistic is

$$z = \frac{W - E(W)}{\sqrt{V(W)}} = \frac{W - \left[\frac{n_X n_Y + n_X(n_X + 1)}{2}\right] - 0.5 * sign(W - E(W))}{\sqrt{\frac{n_X n_Y (n_X + n_Y + 1) - tiescor}{12}}},$$

with continuity correction and tie adjustment. Here *tiescor* is given by

$$tiescor = \frac{2 * tieadj}{(n_X + n_Y)(n_X + n_Y - 1)},$$

where `ranksum` uses `[ranks,tieadj] = tiedrank(x,y)` to obtain tie adjustments. The standard normal distribution gives the p-value for this z-statistic.

Algorithms

`ranksum` treats `NaN`s in `x` and `y` as missing values and ignores them.

For a two-sided test of medians with unequal sample sizes, the test statistic that `ranksum` returns is the rank sum of the first sample.

Introduced before R2006a

ranova

Class: `RepeatedMeasuresModel`

Repeated measures analysis of variance

Syntax

```
ranovatbl = ranova(rm)
ranovatbl = ranova(rm,'WithinModel',WM)
[ranovatbl,A,C,D] = ranova( ___ )
```

Description

`ranovatbl = ranova(rm)` returns the results of repeated measures analysis of variance for a repeated measures model `rm` in table `ranovatbl`.

`ranovatbl = ranova(rm,'WithinModel',WM)` returns the results of repeated measures analysis of variance using the responses specified by the within-subject model `WM`.

`[ranovatbl,A,C,D] = ranova( ___ )` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form `A*B*C = D`, where `D` is zero.

Input Arguments

`rm` — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

`WM` — Model specifying responses

`'separatemeans'` (default) | *r*-by-*nc* contrast matrix | character vector or string scalar that defines a model specification

Model specifying the responses, specified as one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `C` — *r*-by-*nc* contrast matrix specifying the *nc* contrasts among the *r* repeated measures. If *Y* represents a matrix of repeated measures, `ranova` tests the hypothesis that the means of *Y***C* are zero.
- A character vector or string scalar that defines a model specification in the within-subject factors. You can define the model based on the rules for the `terms` in the `modelspec` argument of `fitrm`. Also see “Model Specification for Repeated Measures Models” on page 9-54.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: `'WithinModel','w1+w2+w2*w3'`

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`ranovatbl` — Results of repeated measures anova

table

Results of repeated measures anova, returned as a `table`.

`ranovatbl` includes a term representing all differences across the within-subjects factors. This term has either the name of the within-subjects factor if specified while fitting the model, or the name `Time` if the name of the within-subjects factor is not specified while fitting the model or there are more than one within-subjects factors. `ranovatbl` also includes all interactions between the terms in the within-subject model and all between-subject model terms. It contains the following columns.

Column Name	Definition
`SumSq`	Sum of squares.
`DF`	Degrees of freedom.
`MeanSq`	Mean squared error.
`F`	*F*-statistic.
`pValue`	*p*-value for the corresponding *F*-statistic. A small *p*-value indicates significant term effect.
`pValueGG`	*p*-value with Greenhouse-Geisser adjustment.
`pValueHF`	*p*-value with Huynh-Feldt adjustment.
`pValueLB`	*p*-value with Lower bound adjustment.

The last three *p*-values are the adjusted *p*-values for use when the compound symmetry assumption is not satisfied. For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 9-55. The `mauchy` method tests for sphericity (hence, compound symmetry) and `epsilon` method returns the epsilon adjustment values.

`A` — Specification based on between-subjects model

matrix | cell array

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of `B` (within time hypothesis). If `ranovatbl` contains multiple hypothesis tests, `A` might be a cell array.

Data Types: `single` | `double` | `cell`

`C` — Specification based on within-subjects model

matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of `B` (between time hypotheses). If `ranovatbl` contains multiple hypothesis tests, `C` might be a cell array.

Data Types: `single` | `double` | `cell`

`D` — Hypothesis value

0

Hypothesis value, returned as 0.

Examples

Repeated Measures Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl=3×8 table
                              SumSq     DF      MeanSq       F          pValue          pValueGG
                              ______    ___    ________    ______    ____________    ____________

    (Intercept):Measurements    1656.3     3      552.09    6873.3              0    9.4491e-279
    species:Measurements        282.47     6      47.078     586.1    1.4271e-206    4.9313e-150
    Error(Measurements)         35.423   441    0.080324
```

There are four measurements, three types of species, and 150 observations. So, degrees of freedom for measurements is (4–1) = 3, for species-measurements interaction it is (4–1)*(3–1) = 6, and for error it is (150–3)*(4–1) = 441. `ranova` computes the last three *p*-values using Greenhouse-Geisser, Huynh-Feldt, and Lower bound corrections, respectively. You can check the compound symmetry (sphericity) assumption using the `mauchly` method, and display the epsilon corrections using the `epsilon` method.

Longitudinal Data

Load the sample data.

```
load('longitudinalData.mat');
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual,

and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M']';
```

Store the data in a proper table array format to do repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl=3×8 table
                       SumSq     DF    MeanSq       F         pValue       pValueGG      pValueH
                       ______    __    ______    _______    __________    __________    _______

    (Intercept):Time    881.7     4    220.43     37.539    3.0348e-15    4.7325e-09    2.4439e-
    Gender:Time         17.65     4    4.4125    0.75146      0.56126        0.4877      0.501
    Error(Time)         328.83    56    5.872
```

There are 5 time points, 2 genders, and 16 observations. So, the degrees of freedom for time is (5–1) = 4, for gender-time interaction it is (5–1)*(2–1) = 4, and for error it is (16–2)*(5–1) = 56. The small *p*-value of 2.6198e–05 indicates that there is a significant effect of time on blood pressure. The *p* -value of 0.40063 indicates that there is no significant gender-time interaction.

Specify the Within-Subjects Model

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables age, IQ, group, gender, and eight repeated measures `y1` through `y8` as responses. The table within includes the within-subject variables `w1` and `w2`. This is simulated data. Hypothetically, the response can be results of a memory test. The within-subject variable `w1` can be the type of exercise the subject does before the test and `w2` can be the different points in the day the subject takes the memory test. So, one subject does two different type of exercises A and B before taking the test and takes the test at four different times on different days. For each subject, the measurements are taken under these conditions:

Exercise to perform before the test: A B A B A B A B

Test time: 1 1 2 2 3 3 4 4

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',within);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl=7×8 table
                        SumSq     DF     MeanSq       F        pValue      pValueGG    pValueHF
                        ______    ___    ______    _______    _________    ________    ________

    (Intercept):Time     6645.2     7    949.31     2.2689     0.031674    0.071235     0.05625
    Age:Time             5824.3     7    832.05     1.9887     0.059978     0.10651     0.09012
    IQ:Time              5188.3     7    741.18     1.7715     0.096749     0.14492      0.1289
    Group:Time            15800    14    1128.6     2.6975    0.0014425    0.011884    0.006434
    Gender:Time          4455.8     7    636.55     1.5214      0.16381     0.20533      0.1925
    Group:Gender:Time    4247.3    14    303.38    0.72511      0.74677       0.663      0.6918
    Error(Time)           64433   154    418.39
```

Specify the model for the within-subject factors. Also display the matrices used in the hypothesis test.

```
[ranovatbl,A,C,D] = ranova(rm,'WithinModel','w1+w2')
```

```
ranovatbl=21×8 table
                      SumSq     DF    MeanSq       F        pValue      pValueGG     pValueHF

Algorithms

`ranova` computes the regular *p*-value (in the `pValue` column of the `rmanova` table) using the *F*-statistic cumulative distribution function:

p-value = 1 – fcdf(F,v_1,v_2).

When the compound symmetry assumption is not satisfied, `ranova` uses a correction factor epsilon, ε, to compute the corrected *p*-values as follows:

p-value_corrected = 1 – fcdf(F,ε*v_1,ε*v_2).

The `mauchly` method tests for sphericity (hence, compound symmetry) and `epsilon` method returns the epsilon adjustment values.

raylcdf

Rayleigh cumulative distribution function

Syntax

```
p = raylcdf(x,b)
p = raylcdf(x,b,'upper')
```

Description

`p = raylcdf(x,b)` returns the Rayleigh cdf at each value in `x` using the corresponding scale parameter, `b`. `x` and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x` or `b` is expanded to a constant array with the same dimensions as the other input.

`p = raylcdf(x,b,'upper')` returns the complement of the Rayleigh cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Rayleigh cdf is

$$y = F(x|b) = \int_0^x \frac{t}{b^2} e\left(\frac{-t^2}{2b^2}\right) dt$$

Examples

Compute and Plot Rayleigh Distribution cdf

Compute the cdf of a Rayleigh distribution with parameter `B = 1`.

```
x = 0:0.1:3;
p = raylcdf(x,1);
```

Plot the cdf.

```
figure;
plot(x,p)
```

raylfit

Rayleigh parameter estimates

Syntax

```
raylfit(data,alpha)
[phat,pci] = raylfit(data,alpha)
```

Description

`raylfit(data,alpha)` returns the maximum likelihood estimates of the parameter of the Rayleigh distribution given the data in the vector `data`.

`[phat,pci] = raylfit(data,alpha)` returns the maximum likelihood estimate and 100(1 - `alpha`)% confidence interval given the data. The default value of the optional parameter `alpha` is 0.05, corresponding to 95% confidence intervals.

raylinv

Rayleigh inverse cumulative distribution function

Syntax

```
X = raylinv(P,B)
```

Description

`X = raylinv(P,B)` returns the inverse of the Rayleigh cumulative distribution function using the corresponding scale parameter, `B` at the corresponding probabilities in `P`. `P` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `P` or `B` is expanded to a constant array with the same dimensions as the other input.

Examples

```
x = raylinv(0.9,1)
x =
  2.1460
```

raylpdf

Rayleigh probability density function

Syntax

```
Y = raylpdf(X,B)
```

Description

`Y = raylpdf(X,B)` computes the Rayleigh pdf at each of the values in `X` using the corresponding scale parameter, `B`. `X` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X` or `B` is expanded to a constant array with the same dimensions as the other input.

The Rayleigh pdf is

$$y = f(x \mid b) = \frac{x}{b^2} e\left(\frac{-x^2}{2b^2}\right)$$

Examples

Compute and Plot Rayleigh Distribution pdf

Compute the pdf of a Rayleigh distribution with parameter `B = 0.5`.

```
x = [0:0.01:2];
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;
plot(x,p)
```

raylrnd

Rayleigh random numbers

Syntax

```
R = raylrnd(B)
R = raylrnd(B,v)
R = raylrnd(B,m,n)
```

Description

`R = raylrnd(B)` returns a matrix of random numbers chosen from the Rayleigh distribution with scale parameter, `B`. `B` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `B`.

`R = raylrnd(B,v)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter `B`, where `v` is a row vector. If `v` is a 1-by-2 vector, `R` is a matrix with `v(1)` rows and `v(2)` columns. If `v` is 1-by-n, `R` is an n-dimensional array.

`R = raylrnd(B,m,n)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter `B`, where scalars `m` and `n` are the row and column dimensions of `R`.

Examples

```
r = raylrnd(1:5)
r =
  1.7986  0.8795  3.3473  8.9159  3.5182
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

raylstat

Rayleigh mean and variance

Syntax

```
[M,V] = raylstat(B)
```

Description

`[M,V] = raylstat(B)` returns the mean of and variance for the Rayleigh distribution with scale parameter `B`.

The mean of the Rayleigh distribution with parameter b is $b\sqrt{\pi/2}$and the variance is

$$\frac{4-\pi}{2}b^2$$

Examples

```
[mn,v] = raylstat(1)
mn =
  1.2533
v =
  0.4292
```

Extended Capabilities

rcoplot

Residual case order plot

Syntax

```
rcoplot(r,rint)
```

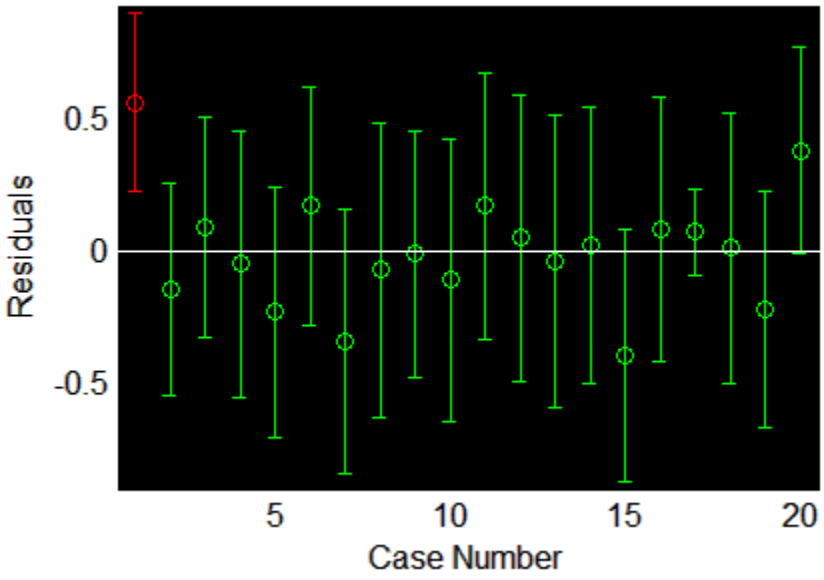
Description

`rcoplot(r,rint)` displays an error bar plot of the confidence intervals on the residuals from a regression. The residuals appear in the plot in case order. Inputs `r` and `rint` are outputs from the `regress` function.

Examples

The following plots residuals and prediction intervals from a regression of a linearly additive model to the data in `moore.mat`:

```
load moore
X = [ones(size(moore,1),1) moore(:,1:5)];
y = moore(:,6);
alpha = 0.05;
[betahat,Ibeta,res,Ires,stats] = regress(y,X,alpha);
rcoplot(res,Ires)
```



The interval around the first residual, shown in red, does not contain zero. This indicates that the residual is larger than expected in 95% of new observations, and suggests the data point is an outlier.

`regress`

Introduced before R2006a

ReconstructionICA

Feature extraction by reconstruction ICA

Description

`ReconstructionICA` applies reconstruction independent component analysis (RICA) to learn a transformation that maps input predictors to new predictors.

Creation

Create a `ReconstructionICA` object by using the `rica` function.

Properties

`FitInfo` — Fitting history
structure

This property is read-only.

Fitting history, returned as a structure with two fields:

- `Iteration` — Iteration numbers from 0 through the final iteration.
- `Objective` — Objective function value at each corresponding iteration. Iteration 0 corresponds to the initial values, before any fitting.

Data Types: `struct`

`InitialTransformWeights` — Initial feature transformation weights
`p`-by-`q` matrix

This property is read-only.

Initial feature transformation weights, returned as a `p`-by-`q` matrix, where `p` is the number of predictors passed in `X` and `q` is the number of features that you want. These weights are the initial weights passed to the creation function. The data type is single when the training data `X` is single.

Data Types: `single` | `double`

`ModelParameters` — Parameters for training model
structure

This property is read-only.

Parameters for training the model, returned as a structure. The structure contains a subset of the fields that correspond to the `rica` name-value pairs that were in effect during model creation:

- `IterationLimit`
- `VerbosityLevel`

- `Lambda`
- `Standardize`
- `ContrastFcn`
- `GradientTolerance`
- `StepTolerance`

For details, see the `rica` `Name,Value` on page 33-5704 pairs.

Data Types: `struct`

`Mu` — Predictor means when standardizing
`p`-by-1 vector

This property is read-only.

Predictor means when standardizing, returned as a `p`-by-`1` vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor means in the training data. The data type is single when the training data `X` is single.

Data Types: `single` | `double`

`NonGaussianityIndicator` — Non-Gaussianity of sources
length-`q` vector of ±1

This property is read-only.

Non-Gaussianity of sources, returned as a length-`q` vector of ±1.

- `NonGaussianityIndicator(k) = 1` means `rica` models the `k`th source as sub-Gaussian.
- `NonGaussianityIndicator(k) = -1` means `rica` models the `k`th source as super-Gaussian, with a sharp peak at 0.

Data Types: `double`

`NumLearnedFeatures` — Number of output features
positive integer

This property is read-only.

Number of output features, returned as a positive integer. This value is the `q` argument passed to the creation function, which is the requested number of features to learn.

Data Types: `double`

`NumPredictors` — Number of input predictors
positive integer

This property is read-only.

Number of input predictors, returned as a positive integer. This value is the number of predictors passed in `X` to the creation function.

Data Types: `double`

`Sigma` — Predictor standard deviations when standardizing
`p`-by-1 vector

This property is read-only.

Predictor standard deviations when standardizing, returned as a p-by-1 vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor standard deviations in the training data. The data type is single when the training data X is single.

Data Types: `single` | `double`

`TransformWeights` — Feature transformation weights
p-by-q matrix

This property is read-only.

Feature transformation weights, returned as a p-by-q matrix, where p is the number of predictors passed in X and q is the number of features that you want. The data type is single when the training data X is single.

Data Types: `single` | `double`

Object Functions

transform Transform predictors into extracted features

Examples

Create Reconstruction ICA Object

Create a `ReconstructionICA` object by using the `rica` function.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1×2

        5000         363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
q = 100;
Mdl = rica(data.X,q,'IterationLimit',100)
```

```
Warning: Solver LBFGS was not able to converge to a solution.

Mdl =
  ReconstructionICA
           ModelParameters: [1x1 struct]
             NumPredictors: 363
         NumLearnedFeatures: 100
                        Mu: []
```

```
                    Sigma: []
                  FitInfo: [1x1 struct]
          TransformWeights: [363x100 double]
    InitialTransformWeights: []
    NonGaussianityIndicator: [100x1 double]

  Properties, Methods
```

`rica` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Introduced in R2017a

refcurve

Add reference curve to plot

Syntax

```
refcurve(p)
refcurve
refcurve(ax,p)
hcurve = refcurve(...)
```

Description

`refcurve(p)` adds a polynomial reference curve with coefficients `p` to the current axes. If `p` is a vector with `n+1` elements, the curve is:

```
y = p(1)*x^n + p(2)*x^(n-1) + ... + p(n)*x + p(n+1)
```

`refcurve` with no input arguments adds a line along the *x* axis.

`refcurve(ax,p)` uses the plot axes specified in `ax`, an `Axes` object. For more information, see `axes`.

`hcurve = refcurve(...)` returns the handle `hcurve` to the curve using any of the input argument combinations in the previous syntaxes.

Examples

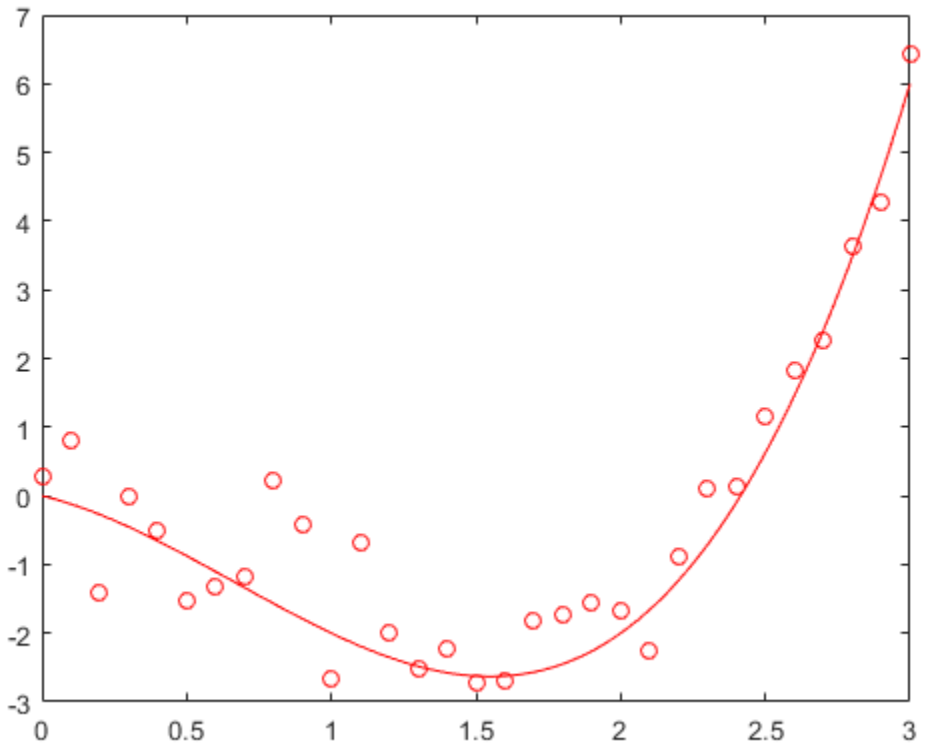
Add Population and Fitted Mean Functions

Generate data with a polynomial trend.

```
p = [1 -2 -1 0];
t = 0:0.1:3;
rng default  % For reproducibility
y = polyval(p,t) + 0.5*randn(size(t));
```

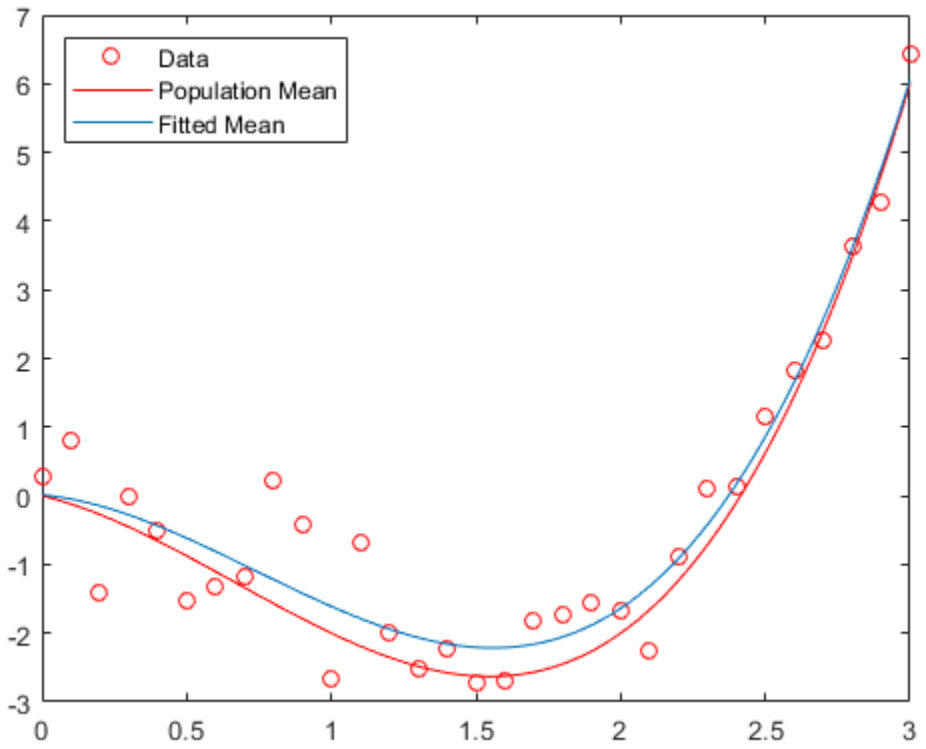
Plot data and add the population mean function using `refcurve` .

```
plot(t,y,'ro')
h = refcurve(p);
h.Color = 'r';
```



Also add the fitted mean function.

```
q = polyfit(t,y,3);
refcurve(q)
legend('Data','Population Mean','Fitted Mean',...
       'Location','NW')
```



Plot Trajectories of a Batted Baseball Using `refcurve`

Introduce the relevant physical constants.

```
M = 0.145;      % Mass (kg)
R = 0.0366;     % Radius (m)
A = pi*R^2;     % Area (m^2)
rho = 1.2;      % Density of air (kg/m^3)
C = 0.5;        % Drag coefficient
D = rho*C*A/2;  % Drag proportional to the square of the speed
g = 9.8;        % Acceleration due to gravity (m/s^2)
```

Simulate the trajectory with drag proportional to the square of the speed, assuming constant acceleration in each time interval.

```
dt = 1e-2;      % Simulation time interval (s)
r0 = [0 1];     % Initial position (m)
s0 = 50;        % Initial speed (m/s)
alpha0 = 35;    % Initial angle (deg)
v0 = s0*[cosd(alpha0) sind(alpha0)]; % Initial velocity (m/s)

r = r0;
v = v0;
trajectory = r0;
while r(2) > 0
```

```
    a = [0 -g] - (D/M)*norm(v)*v;
    v = v + a*dt;
    r = r + v*dt + (1/2)*a*(dt^2);
    trajectory = [trajectory;r];
end
```

Plot `trajectory` and use `refcurve` to add the drag-free parabolic trajectory (found analytically) to the plot of trajectory.

```
figure
plot(trajectory(:,1),trajectory(:,2),'m','LineWidth',2)
xlim([0,250])
h = refcurve([-g/(2*v0(1)^2),...
    (g*r0(1)/v0(1)^2) + (v0(2)/v0(1)),...
    (-g*r0(1)^2/(2*v0(1)^2)) - (v0(2)*r0(1)/v0(1)) + r0(2)]);
h.Color = 'c';
h.LineWidth = 2;
axis equal
ylim([0,50])
grid on
xlabel('Distance (m)')
ylabel('Height (m)')
title('{\bf Baseball Trajectories}')
legend('With Drag','Without Drag')
```

Introduced before R2006a

refit

Class: `GeneralizedLinearMixedModel`

Refit generalized linear mixed-effects model

Syntax

```
glmenew = refit(glme,ynew)
```

Description

`glmenew = refit(glme,ynew)` returns a refitted generalized linear mixed-effects model, `glmenew`, based on the input model `glme`, using a new response vector, `ynew`.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

`ynew` — New response vector

n-by-1 vector of scalar values

New response vector, specified as an *n*-by-1 vector of scalar values, where *n* is the number of observations used to fit `glme`.

For an observation i with prior weights w_i^p and binomial size n_i (when applicable), the response values y_i contained in `ynew` can have the following values.

Distribution	Permitted Values	Notes
`Binomial`	$\left\{0, \frac{1}{w_i^p n_i}, \frac{2}{w_i^p n_i}, \ldots, 1\right\}$	w_i^p and n_i are integer values > 0
`Poisson`	$\left\{0, \frac{1}{w_i^p}, \frac{2}{w_i^p}, \cdots, 1\right\}$	w_i^p is an integer value > 0
`Gamma`	$(0,\infty)$	$w_i^p \geq 0$
`InverseGaussian`	$(0,\infty)$	$w_i^p \geq 0$
`Normal`	$(-\infty,\infty)$	$w_i^p \geq 0$

You can access the prior weights property w_i^p using dot notation.

```
glme.ObservationInfo.Weights
```

Data Types: `single` | `double`

Output Arguments

`glmenew` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, returned as a `GeneralizedLinearMixedModel` object. `glmenew` is an updated version of the generalized linear mixed-effects model `glme`, refit to the values in the response vector `ynew`.

For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Examples

Refit Model to New Response Vector

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- $defects_{ij}$ is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- $newprocess_{ij}$, $time\_dev_{ij}$, and $temp\_dev_{ij}$ are the measurements for each variable that correspond to factory i during batch j. For example, $newprocess_{ij}$ indicates whether the batch produced by factory i during batch j used the new process.
- $supplier\_C_{ij}$ and $supplier\_B_{ij}$ are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)','Dis
```

Use `random` to simulate a new response vector from the fitted model.

```
rng(0,'twister');  % For reproducibility
ynew = random(glme);
```

Refit the model using the new response vector.

```
glme = refit(glme,ynew)
```

```
glme =

refit

Class: `FeatureSelectionNCAClassification`

Refit neighborhood component analysis (NCA) model for classification

Syntax

```
mdlrefit = refit(mdl,Name,Value)
```

Description

`mdlrefit = refit(mdl,Name,Value)` refits the model `mdl`, with modified parameters specified by one or more `Name,Value` pair arguments.

Input Arguments

`mdl` — Neighborhood component analysis model for classification

`FeatureSelectionNCAClassification` object

Neighborhood component analysis model or classification, specified as a `FeatureSelectionNCAClassification` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Fitting Options

`FitMethod` — Method for fitting the model

`mdl.FitMethod` (default) | `'exact'` | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following.

- `'exact'` — Performs fitting using all of the data.
- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscnca`.
- `'average'` — The function divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: `'FitMethod','none'`

`Lambda` — Regularization parameter

`mdl.Lambda` (default) | non-negative scalar value

Regularization parameter, specified as the comma-separated pair consisting of `'Lambda'` and a non-negative scalar value.

For *n* observations, the best `Lambda` value that minimizes the generalization error of the NCA model is expected to be a multiple of 1/*n*

Example: `'Lambda',0.01`

Data Types: `double` | `single`

`Solver` — Solver type
`mdl.Solver` (default) | `'lbfgs'` | `'sgd'` | `'minibatch-lbfgs'`

Solver type for estimating feature weights, specified as the comma-separated pair consisting of `'Solver'` and one of the following.

- `'lbfgs'` — Limited memory BFGS (Broyden-Fletcher-Goldfarb-Shanno) algorithm (LBFGS algorithm)
- `'sgd'` — Stochastic gradient descent
- `'minibatch-lbfgs'` — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Example: `'solver','minibatch-lbfgs'`

`InitialFeatureWeights` — Initial feature weights
`mdl.InitialFeatureWeights` (default) | *p*-by-1 vector of real positive scalar values

Initial feature weights, specified as the comma-separated pair consisting of `'InitialFeatureWeights'` and a *p*-by-1 vector of real positive scalar values.

Data Types: `double` | `single`

`Verbose` — Indicator for verbosity level
`mdl.Verbose` (default) | 0 | 1 | >1

Indicator for verbosity level for the convergence summary display, specified as the comma-separated pair consisting of `'Verbose'` and one of the following.

- 0 — No convergence summary
- 1 — Convergence summary including iteration number, norm of the gradient, and objective function value.
- >1 — More convergence information depending on the fitting algorithm

  When using solver `'minibatch-lbfgs'` and verbosity level >1, the convergence information includes iteration log from intermediate minibatch LBFGS fits.

Example: `'Verbose',2`

Data Types: `double` | `single`

LBFGS or Mini-Batch LBFGS Options

`GradientTolerance` — Relative convergence tolerance
`mdl.GradientTolerance` (default) | positive real scalar value

Relative convergence tolerance on the gradient norm for solver `lbfgs`, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive real scalar value.

Example: `'GradientTolerance',0.00001`

Data Types: `double` | `single`

SGD or Mini-Batch LBFGS Options

`InitialLearningRate` — Initial learning rate for solver `sgd`

`mdl.InitialLearningRate` (default) | positive real scalar value

Initial learning rate for solver `sgd`, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive scalar value.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

Example: `'InitialLearningRate',0.8`

Data Types: `double` | `single`

`PassLimit` — Maximum number of passes for solver `'sgd'`

`mdl.PassLimit` (default) | positive integer value

Maximum number of passes for solver `'sgd'` (stochastic gradient descent), specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer. Every pass processes `size(mdl.X,1)` observations.

Example: `'PassLimit',10`

Data Types: `double` | `single`

SGD or LBFGS or Mini-Batch LBFGS Options

`IterationLimit` — Maximum number of iterations

`mdl.IterationLimit` (default) | positive integer value

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit',250`

Data Types: `double` | `single`

Output Arguments

`mdlrefit` — Neighborhood component analysis model for classification

`FeatureSelectionNCAClassification` object

Neighborhood component analysis model for classification, returned as a `FeatureSelectionNCAClassification` object. You can either save the results as a new model or update the existing model as `mdl = refit(mdl,Name,Value)`.

Examples

Refit NCA Model for Classification with Modified Settings

Generate checkerboard data using the `generateCheckerBoardData.m` function.

```
rng(2016,'twister'); % For reproducibility
pps = 1375;
```

```
[X,y] = generateCheckerBoardData(pps);
X = X + 2;
```

Plot the data.

```
figure
plot(X(y==1,1),X(y==1,2),'rx')
hold on
plot(X(y==-1,1),X(y==-1,2),'bx')

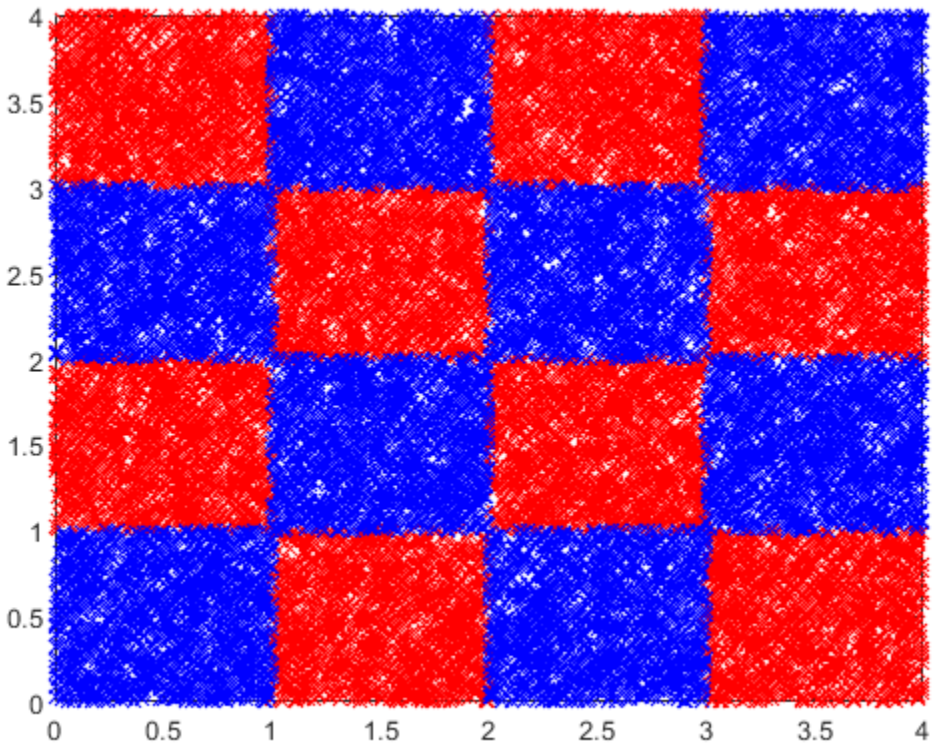
[n,p] = size(X)
```

```
n =

       22000

p =

     2
```



Add irrelevant predictors to the data.

```
Q = 98;
Xrnd = unifrnd(0,4,n,Q);
Xobs = [X,Xrnd];
```

This piece of code creates 98 additional predictors, all uniformly distributed between 0 and 4.

Partition the data into training and test sets. To create stratified partitions, so that each partition has similar proportion of classes, use `y` instead of `length(y)` as the partitioning criteria.

```
cvp = cvpartition(y,'holdout',2000);
```

`cvpartition` randomly chooses 2000 of the observations to add to the test set and the rest of the data to add to the training set. Create the training and validation sets using the assignments stored in the `cvpartition` object `cvp` .

```
Xtrain = Xobs(cvp.training(1),:);
ytrain = y(cvp.training(1),:);

Xval = Xobs(cvp.test(1),:);
yval = y(cvp.test(1),:);
```

Compute the misclassification error without feature selection.

```
nca = fscnca(Xtrain,ytrain,'FitMethod','none','Standardize',true, ...
    'Solver','lbfgs');
loss_nofs = loss(nca,Xval,yval)
```

```
loss_nofs =

    0.5165
```

`'FitMethod','none'` option uses the default weights (all 1s), which means all features are equally important.

This time, perform feature selection using neighborhood component analysis for classification, with $\lambda = 1/n$.

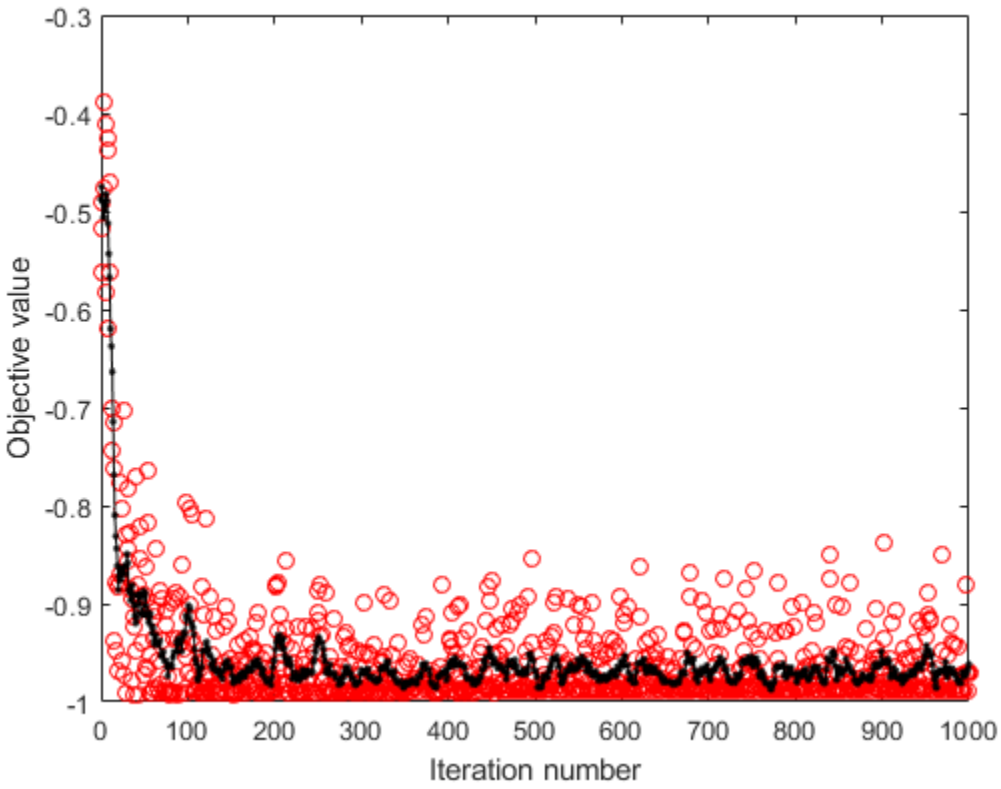
```
w0 = rand(100,1);
n = length(ytrain)
lambda = 1/n;
nca = refit(nca,'InitialFeatureWeights',w0,'FitMethod','exact', ...
       'Lambda',lambda,'solver','sgd');
```

```
n =

       20000
```

Plot the objective function value versus the iteration number.

```
figure()
plot(nca.FitInfo.Iteration,nca.FitInfo.Objective,'ro')
hold on
plot(nca.FitInfo.Iteration,movmean(nca.FitInfo.Objective,10),'k.-')
xlabel('Iteration number')
ylabel('Objective value')
```



Compute the misclassification error with feature selection.

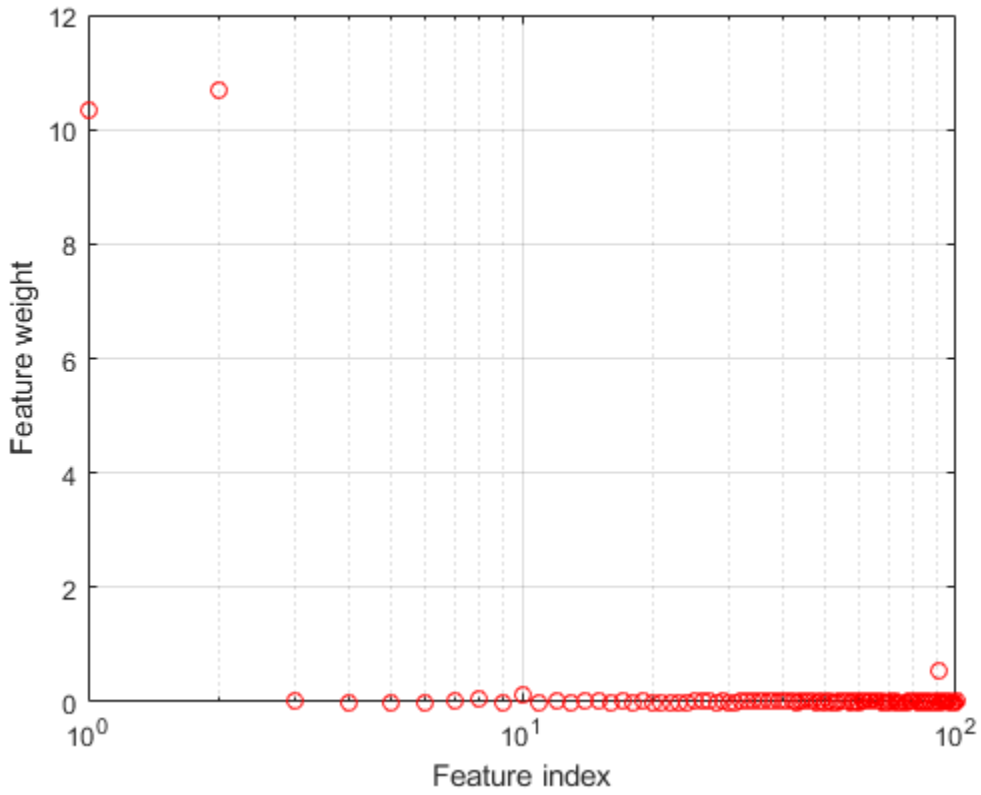
```
loss_withfs = loss(nca,Xval,yval)
```

```
loss_withfs =

    0.0115
```

Plot the selected features.

```
figure
semilogx(nca.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```



Select features using the feature weights and a relative threshold.

```
tol = 0.15;
selidx = find(nca.FeatureWeights > tol*max(1,max(nca.FeatureWeights)))
```

```
selidx =

     1
     2
```

Feature selection improves the results and `fscnca` detects the correct two features as relevant.

Introduced in R2016b

refit

Class: `FeatureSelectionNCARegression`

Refit neighborhood component analysis (NCA) model for regression

Syntax

```
mdlrefit = refit(mdl,Name,Value)
```

Description

`mdlrefit = refit(mdl,Name,Value)` refits the model `mdl`, with modified parameters specified by one or more `Name,Value` pair arguments.

Input Arguments

`mdl` — Neighborhood component analysis model for regression

`FeatureSelectionNCARegression` object

Neighborhood component analysis model or classification, specified as a `FeatureSelectionNCARegression` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Fitting Options

`FitMethod` — Method for fitting the model

`mdl.FitMethod` (default) | `'exact'` | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following.

- `'exact'` — Performs fitting using all of the data.
- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fsrnca`.
- `'average'` — The function divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: `'FitMethod','none'`

`Lambda` — Regularization parameter

`mdl.Lambda` (default) | non-negative scalar value

Regularization parameter, specified as the comma-separated pair consisting of `'Lambda'` and a non-negative scalar value.

For *n* observations, the best `Lambda` value that minimizes the generalization error of the NCA model is expected to be a multiple of 1/*n*

Example: `'Lambda',0.01`

Data Types: `double` | `single`

`Solver` — Solver type
`mdl.Solver` (default) | `'lbfgs'` | `'sgd'` | `'minibatch-lbfgs'`

Solver type for estimating feature weights, specified as the comma-separated pair consisting of `'Solver'` and one of the following.

- `'lbfgs'` — Limited memory BFGS (Broyden-Fletcher-Goldfarb-Shanno) algorithm (LBFGS algorithm)
- `'sgd'` — Stochastic gradient descent
- `'minibatch-lbfgs'` — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Example: `'solver','minibatch-lbfgs'`

`InitialFeatureWeights` — Initial feature weights
`mdl.InitialFeatureWeights` (default) | *p*-by-1 vector of real positive scalar values

Initial feature weights, specified as the comma-separated pair consisting of `'InitialFeatureWeights'` and a *p*-by-1 vector of real positive scalar values.

Data Types: `double` | `single`

`Verbose` — Indicator for verbosity level
`mdl.Verbose` (default) | 0 | 1 | >1

Indicator for verbosity level for the convergence summary display, specified as the comma-separated pair consisting of `'Verbose'` and one of the following.

- 0 — No convergence summary
- 1 — Convergence summary including iteration number, norm of the gradient, and objective function value.
- >1 — More convergence information depending on the fitting algorithm

  When using solver `'minibatch-lbfgs'` and verbosity level >1, the convergence information includes iteration log from intermediate minibatch LBFGS fits.

Example: `'Verbose',2`

Data Types: `double` | `single`

LBFGS or Mini-Batch LBFGS Options

`GradientTolerance` — Relative convergence tolerance
`mdl.GradientTolerance` (default) | positive real scalar value

Relative convergence tolerance on the gradient norm for solver `lbfgs`, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive real scalar value.

Example: `'GradientTolerance',0.00001`

Data Types: `double` | `single`

SGD or Mini-Batch LBFGS Options

`InitialLearningRate` — Initial learning rate for solver `sgd`
`mdl.InitialLearningRate` (default) | positive real scalar value

Initial learning rate for solver `sgd`, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive scalar value.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

Example: `'InitialLearningRate',0.8`

Data Types: `double` | `single`

`PassLimit` — Maximum number of passes for solver `'sgd'`
`mdl.PassLimit` (default) | positive integer value

Maximum number of passes for solver `'sgd'` (stochastic gradient descent), specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer. Every pass processes `size(mdl.X,1)` observations.

Example: `'PassLimit',10`

Data Types: `double` | `single`

SGD or LBFGS or Mini-Batch LBFGS Options

`IterationLimit` — Maximum number of iterations
`mdl.IterationLimit` (default) | positive integer value

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit',250`

Data Types: `double` | `single`

Output Arguments

`mdlrefit` — Neighborhood component analysis model for regression
`FeatureSelectionNCARegression` object

Neighborhood component analysis model or classification, returned as a `FeatureSelectionNCARegression` object. You can either save the results as a new model or update the existing model as `mdl = refit(mdl,Name,Value)`.

Examples

Refit NCA Model for Regression with Modified Settings

Load the sample data.

```
load('robotarm.mat')
```

The `robotarm` (pumadyn32nm) dataset is created using a robot arm simulator with 7168 training and 1024 test observations with 32 features [1], [2]. This is a preprocessed version of the original data set. Data are preprocessed by subtracting off a linear regression fit followed by normalization of all features to unit variance.

Compute the generalization error without feature selection.

```
nca = fsrnca(Xtrain,ytrain,'FitMethod','none','Standardize',1);
L = loss(nca,Xtest,ytest)
```

```
L = 0.9017
```

Now, refit the model and compute the prediction loss with feature selection, with $\lambda = 0$ (no regularization term) and compare to the previous loss value, to determine feature selection seems necessary for this problem. For the settings that you do not change, `refit` uses the settings of the initial model `nca`. For example, it uses the feature weights found in `nca` as the initial feature weights.

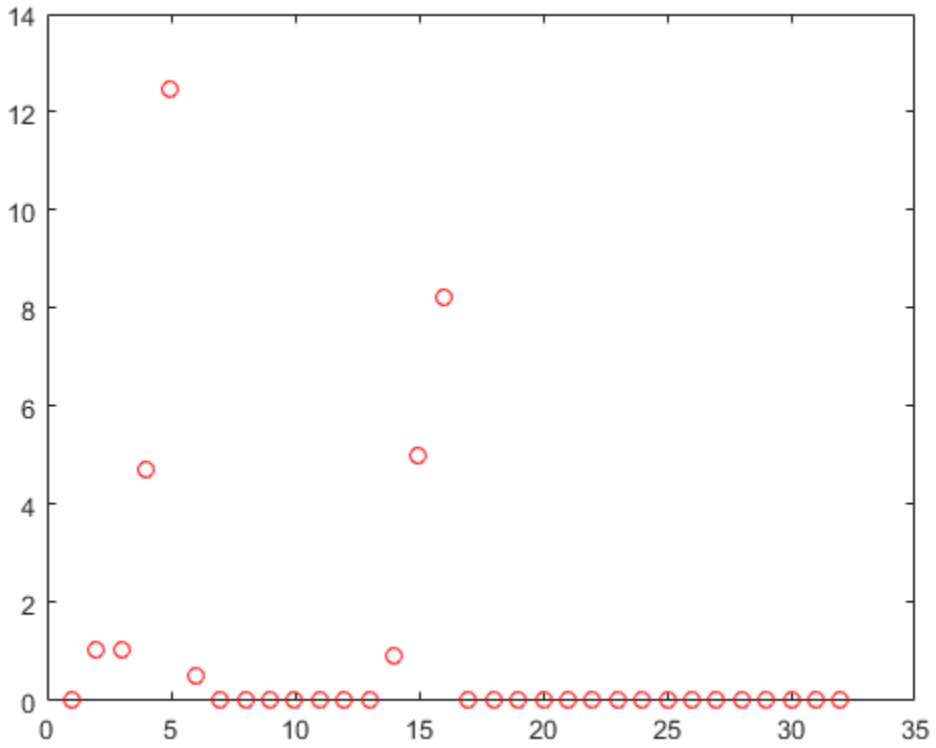
```
nca2 = refit(nca,'FitMethod','exact','Lambda',0);
L2 = loss(nca2,Xtest,ytest)
```

```
L2 = 0.1088
```

The decrease in the loss suggests that feature selection is necessary.

Plot the feature weights.

```
figure()
plot(nca2.FeatureWeights,'ro')
```



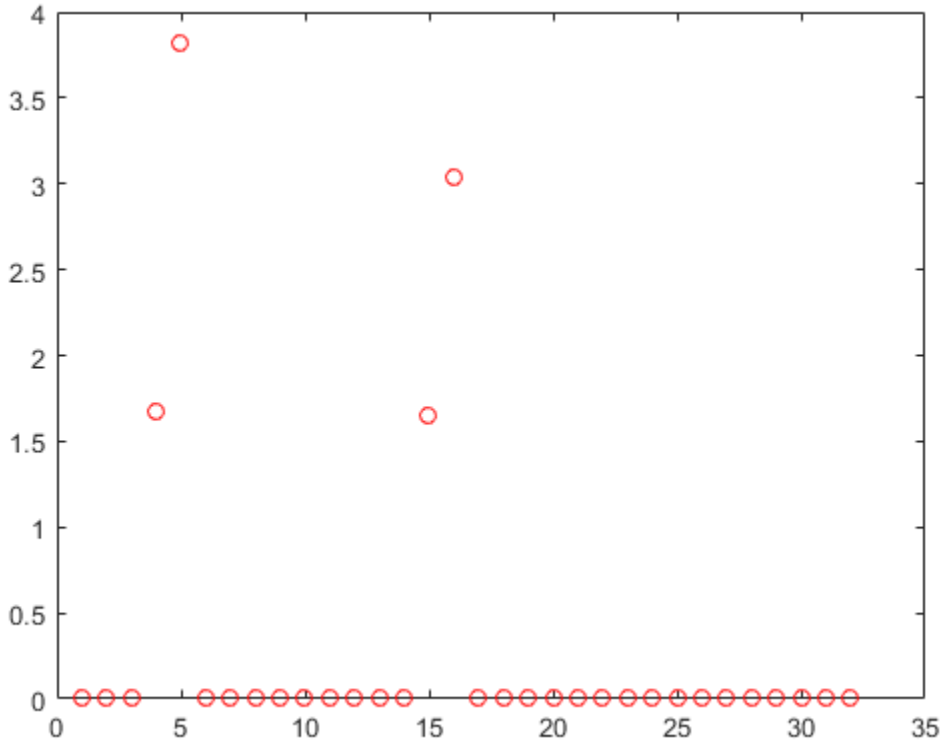
Tuning the regularization parameter usually improves the results. Suppose that, after tuning λ using cross-validation as in "Tune Regularization Parameter in NCA for Regression" on page 33-2503, the best λ value found is 0.0035. Refit the `nca` model using this λ value and stochastic gradient descent as the solver. Compute the prediction loss.

```
nca3 = refit(nca2,'FitMethod','exact','Lambda',0.0035,...
          'Solver','sgd');
L3 = loss(nca3,Xtest,ytest)
```

```
L3 = 0.0573
```

Plot the feature weights.

```
figure()
plot(nca3.FeatureWeights,'ro')
```



After tuning the regularization parameter, the loss decreased even more and the software identified four of the features as relevant.

Introduced in R2016b

reduceDimensions

Reduce dimensions of Sobol point set

Syntax

```
pr = reduceDimensions(p,d)
```

Description

`pr = reduceDimensions(p,d)` reduces the Sobol quasirandom point set `p` to the first `d` dimensions. `d` must be less than or equal to the number of dimensions in `p`.

The reduced point set `pr` is a `sobolset` object.

Examples

Reduce Dimensions of Sobol Point Set

Generate a seven-dimensional Sobol point set and scramble the points.

```
p = sobolset(7);
ps = scramble(p,'MatousekAffineOwen')
```

```
ps =
Sobol point set in 7 dimensions (9007199254740992 points)

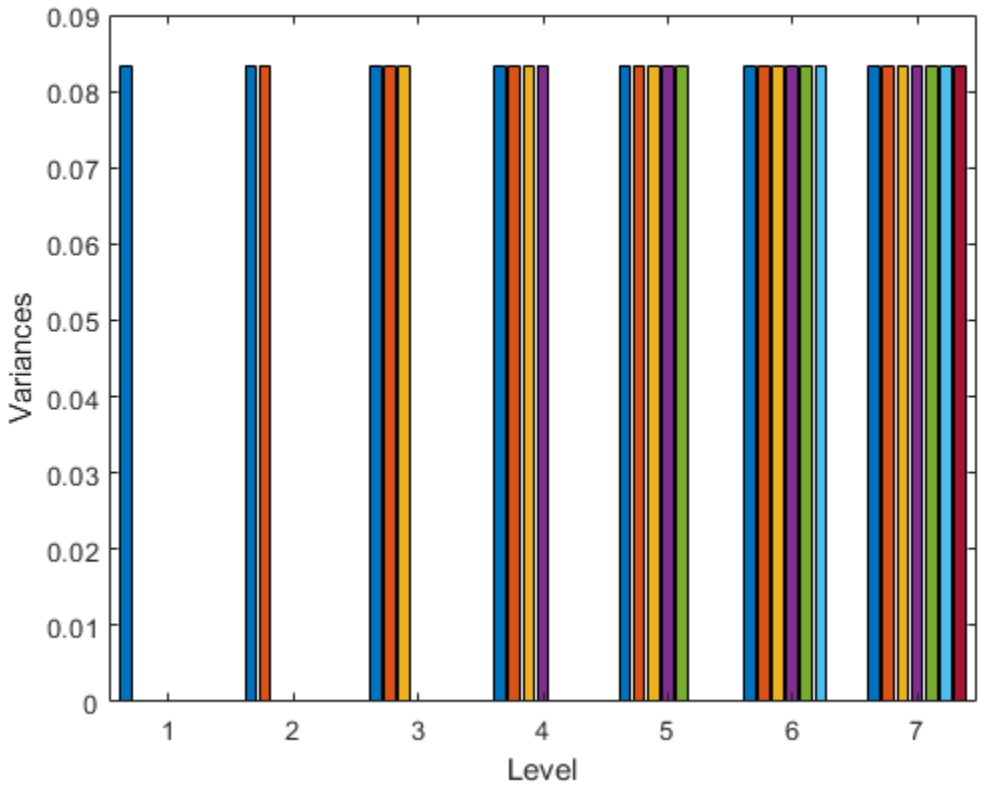
Properties:
              Skip : 0
              Leap : 0
    ScrambleMethod : MatousekAffineOwen
        PointOrder : standard
```

Split the first 7168 points in `ps` into seven levels of 1024 points each. Reduce the first 1024 points to be one-dimensional, the second 1024 points to be two-dimensional, and so on. For each level, compute the variance of the point values in each dimension.

```
variance = NaN(7);
for level = 1:7
    pr = reduceDimensions(ps,level);
    pr.Skip = (level-1)*1024;
    pts = pr(1:1024,:);
    variance(level,1:level) = var(pts);
end
```

Plot the variances. The dark blue bars show the variance of the points in the first dimension, the dark orange bars show the variance of the points in the second dimension, and so on.

```
bar(variance)
xlabel('Level')
ylabel('Variances')
```



Input Arguments

p — Sobol point set

`sobolset` object

Sobol point set, specified as a `sobolset` object.

d — Number of dimensions to retain

positive integer scalar

Number of dimensions to retain from the point set `p`, specified as a positive integer scalar between 1 and the number of dimensions in `p`. The function always retains the first `d` dimensions of `p`.

Data Types: `single` | `double`

`net` | `scramble` | `sobolset`

Introduced in R2019a

refline

Add reference line to plot

Syntax

```
refline(m,b)
refline(coeffs)
refline
refline(ax, ___ )
hline = refline( ___ )
```

Description

`refline(m,b)` adds a reference line with slope `m` and intercept `b` to the current axes.

`refline(coeffs)` adds the line defined by the elements of the vector `coeffs` to the figure.

`refline` with no input arguments is equivalent to `lsline`.

`refline(ax, ___ )` adds a reference line to the plot in the axis specified by `ax`, using any of the input arguments in the previous syntaxes.

`hline = refline( ___ )` returns the reference line object `hline` using any of the input arguments in the previous syntaxes. Use `hline` to modify properties of a specific reference line after you create it. For a list of properties, see Line Properties.

Examples

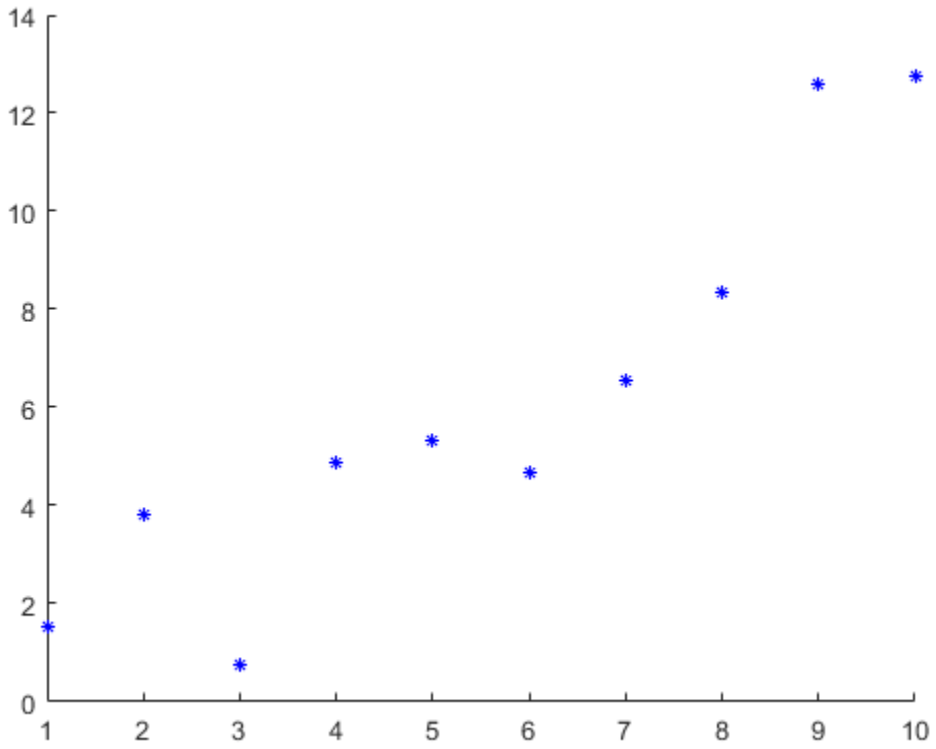
Add Reference Line at the Mean

Generate sample data for an independent variable `x` and a dependent variable `y` .

```
x = 1:10;
y = x + randn(1,10);
```

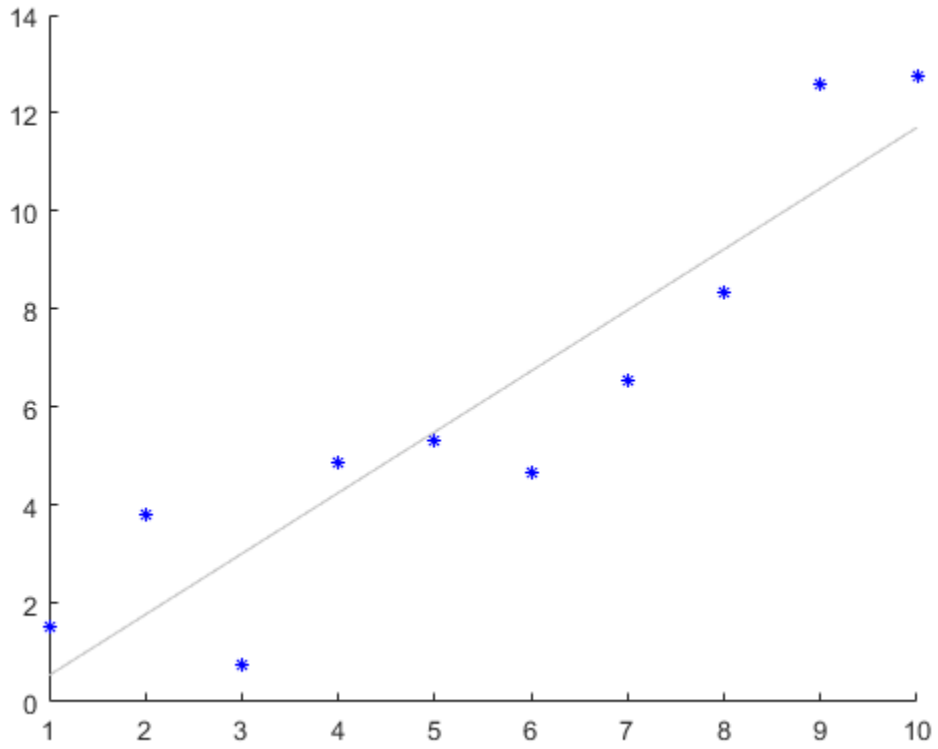
Create a scatter plot of `x` and `y` .

```
scatter(x,y,25,'b','*')
```



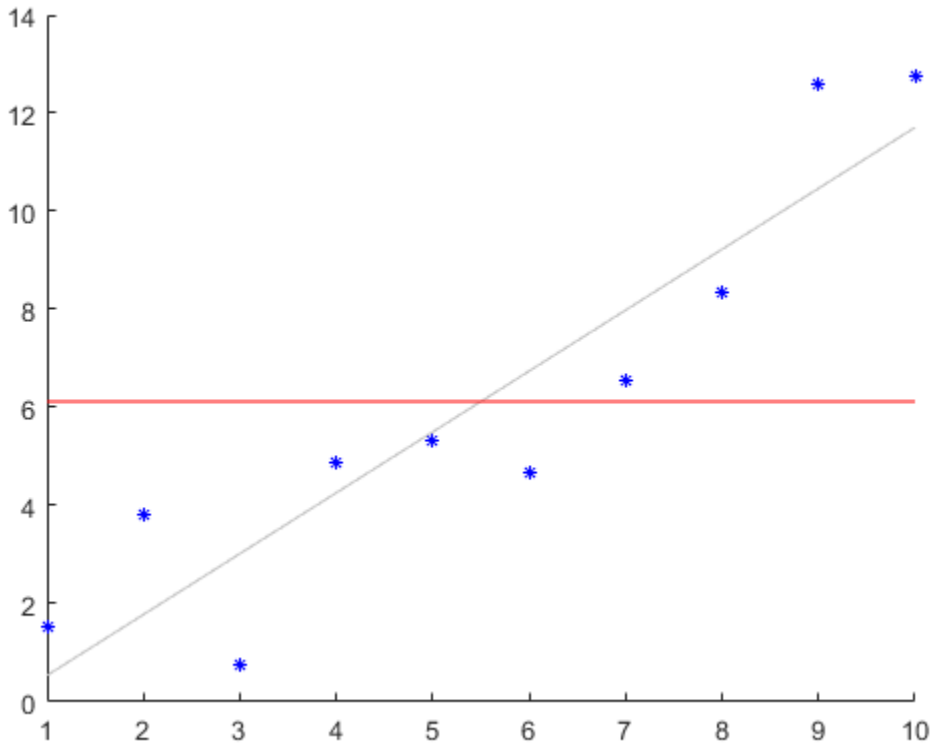
Superimpose a least-squares line on the scatter plot.

```
refline
```



Add a reference line at the mean of the scatter plot.

```
mu = mean(y);
hline = refline([0 mu]);
hline.Color = 'r';
```



The red line is the reference line at the mean of the data.

Specify Axes for Least-Squares and Reference Lines

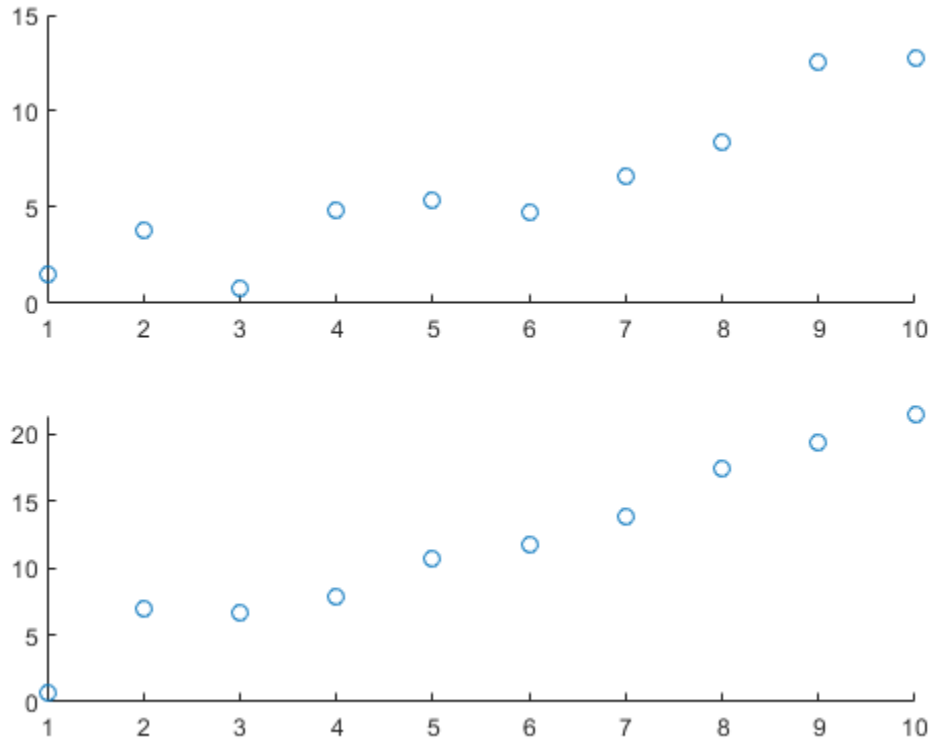
Define the x-variable and two different y-variables to use for the plots.

```
rng default  % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);

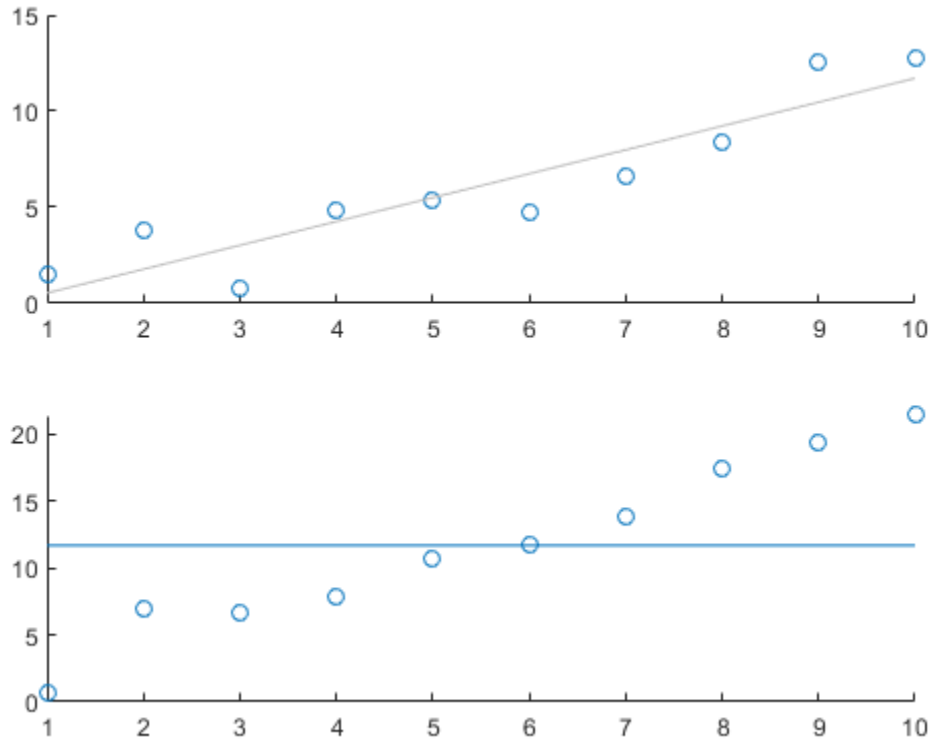
scatter(ax1,x,y1)
scatter(ax2,x,y2)
```



Superimpose a least-squares line on the top plot, and a reference line at the mean of the `y2` values in the bottom plot.

```
lsline(ax1) % This is equivalent to refline(ax1)

mu = mean(y2);
refline(ax2,[0 mu])
```



Input Arguments

`m` — Slope of reference line

numeric scalar

Slope of the reference line, specified as a numeric scalar. The function uses `m` to define the line

```
y = m*x + b.
```

Example: `refline(-1,1)`

Data Types: `single` | `double`

`b` — Intercept of reference line

numeric scalar

Intercept of the reference line, specified as a numeric scalar. The function uses `b` to define the line

```
y = m*x + b.
```

Example: `refline(2,-10)`

Data Types: `single` | `double`

`coeffs` — Linear coefficients

length-two numeric vector

Linear coefficients, specified as a length-two numeric vector. `coeffs` contains the coefficients of a line defined as

```
y = coeffs(1)*x + coeffs(2).
```

Example: `refline([-1,2])`

Data Types: `single` | `double`

`ax` — Target axes
`gca` (default) | `axes` object

Target axes, specified as an `axes` object. If you do not specify the axes and if the current axes are Cartesian axes, then the `refline` function uses the current axes.

Output Arguments

`hline` — One or more reference line objects
scalar | vector

One or more reference line objects, returned as a scalar or a vector. These objects are unique identifiers, which you can use to query and modify properties of a specific reference line. For a list of properties, see Chart Line.

`gline` | `lsline` | `refcurve`

Introduced before R2006a

regress

Multiple linear regression

Syntax

```
b = regress(y,X)
[b,bint] = regress(y,X)
[b,bint,r] = regress(y,X)
[b,bint,r,rint] = regress(y,X)
[b,bint,r,rint,stats] = regress(y,X)
[___] = regress(y,X,alpha)
```

Description

`b = regress(y,X)` returns a vector `b` of coefficient estimates for a multiple linear regression of the responses in vector `y` on the predictors in matrix `X`. To compute coefficient estimates for a model with a constant term (intercept), include a column of ones in the matrix `X`.

`[b,bint] = regress(y,X)` also returns a matrix `bint` of 95% confidence intervals for the coefficient estimates.

`[b,bint,r] = regress(y,X)` also returns an additional vector `r` of residuals.

`[b,bint,r,rint] = regress(y,X)` also returns a matrix `rint` of intervals that can be used to diagnose outliers.

`[b,bint,r,rint,stats] = regress(y,X)` also returns a vector `stats` that contains the R^2 statistic, the F-statistic and its p-value, and an estimate of the error variance. The matrix `X` must include a column of ones for the software to compute the model statistics correctly.

`[___] = regress(y,X,alpha)` uses a `100*(1-alpha)`% confidence level to compute `bint` and `rint`. Specify any of the output argument combinations in the previous syntaxes.

Examples

Estimate Multiple Linear Regression Coefficients

Load the `carsmall` data set. Identify weight and horsepower as predictors and mileage as the response.

```
load carsmall
x1 = Weight;
x2 = Horsepower;    % Contains NaN data
y = MPG;
```

Compute the regression coefficients for a linear model with an interaction term.

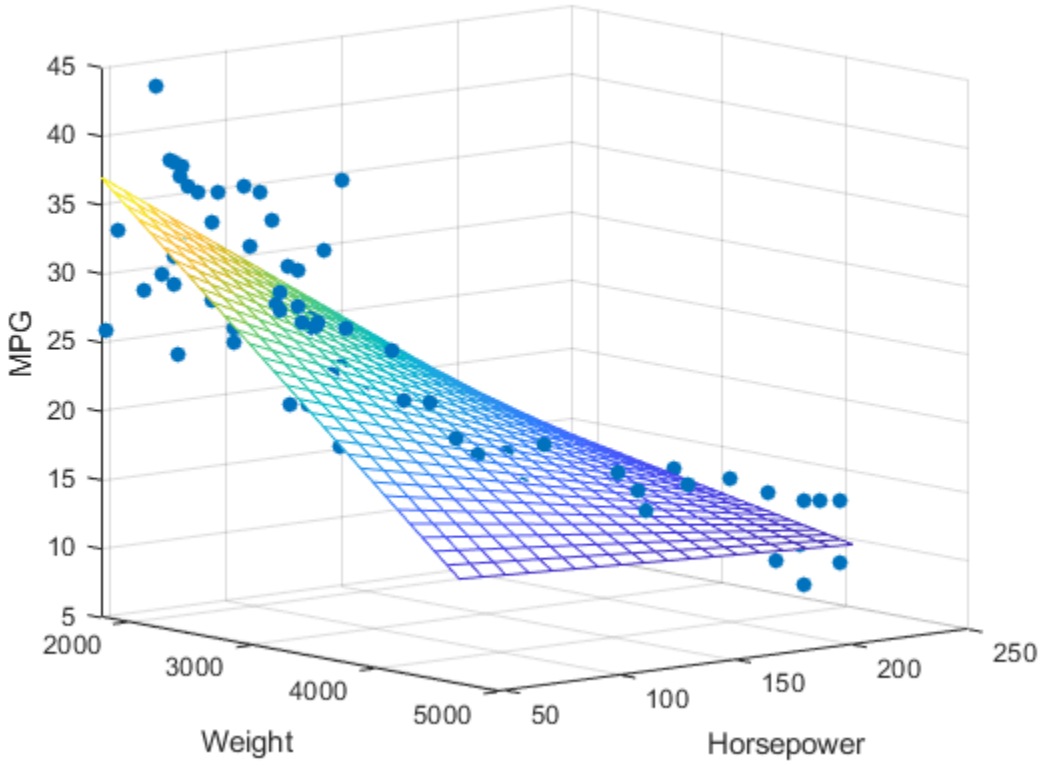
```
X = [ones(size(x1)) x1 x2 x1.*x2];
b = regress(y,X)    % Removes NaN data
```

```
b = 4×1

   60.7104
   -0.0102
   -0.1882
    0.0000
```

Plot the data and the model.

```
scatter3(x1,x2,y,'filled')
hold on
x1fit = min(x1):100:max(x1);
x2fit = min(x2):10:max(x2);
[X1FIT,X2FIT] = meshgrid(x1fit,x2fit);
YFIT = b(1) + b(2)*X1FIT + b(3)*X2FIT + b(4)*X1FIT.*X2FIT;
mesh(X1FIT,X2FIT,YFIT)
xlabel('Weight')
ylabel('Horsepower')
zlabel('MPG')
view(50,10)
hold off
```



Diagnose Outliers Using Residuals

Load the `examgrades` data set.

```
load examgrades
```

Use the last exam scores as response data and the first two exam scores as predictor data.

```
y = grades(:,5);
X = [ones(size(grades(:,1))) grades(:,1:2)];
```

Perform multiple linear regression with alpha = 0.01.

```
[~,~,r,rint] = regress(y,X,0.01);
```

Diagnose outliers by finding the residual intervals `rint` that do not contain 0.

```
contain0 = (rint(:,1)<0 & rint(:,2)>0);
idx = find(contain0==false)
```

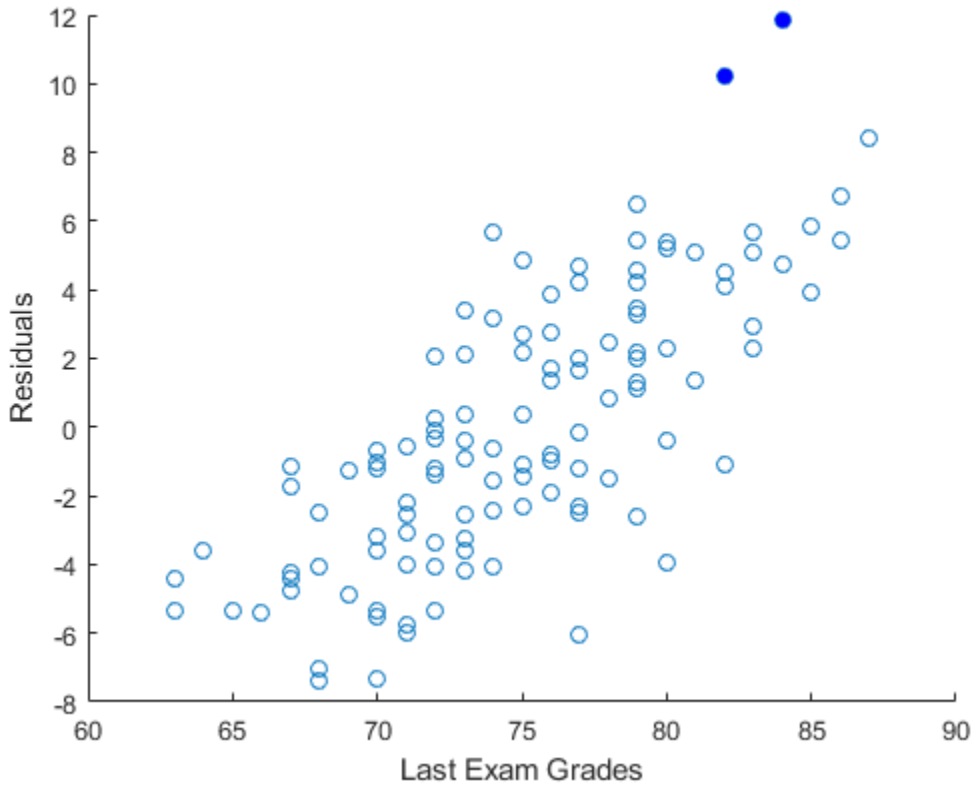
```
idx = 2×1

    53
    54
```

Observations 53 and 54 are possible outliers.

Create a scatter plot of the residuals. Fill in the points corresponding to the outliers.

```
hold on
scatter(y,r)
scatter(y(idx),r(idx),'b','filled')
xlabel("Last Exam Grades")
ylabel("Residuals")
hold off
```



Determine Significance of Linear Regression Relationship

Load the `hald` data set. Use `heat` as the response variable and `ingredients` as the predictor data.

```
load hald
y = heat;
X1 = ingredients;
x1 = ones(size(X1,1),1);
X = [x1 X1];    % Includes column of ones
```

Perform multiple linear regression and generate model statistics.

```
[~,~,~,~,stats] = regress(y,X)
```

```
stats = 1×4

    0.9824  111.4792    0.0000    5.9830
```

Because the R^2 value of `0.9824` is close to 1, and the p-value of `0.0000` is less than the default significance level of 0.05, a significant linear regression relationship exists between the response `y` and the predictor variables in `X`.

Input Arguments

y — Response data

numeric vector

Response data, specified as an *n*-by-1 numeric vector. Rows of `y` correspond to different observations. `y` must have the same number of rows as `X`.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix. Rows of `X` correspond to observations, and columns correspond to predictor variables. `X` must have the same number of rows as `y`.

Data Types: `single` | `double`

alpha — Significance level

`0.05` (default) | positive scalar

Significance level, specified as a positive scalar. `alpha` must be between 0 and 1.

Data Types: `single` | `double`

Output Arguments

b — Coefficient estimates for multiple linear regression

numeric vector

Coefficient estimates for multiple linear regression, returned as a numeric vector. `b` is a *p*-by-1 vector, where *p* is the number of predictors in `X`. If the columns of `X` are linearly dependent, `regress` sets the maximum number of elements of `b` to zero.

Data Types: `double`

bint — Lower and upper confidence bounds for coefficient estimates

numeric matrix

Lower and upper confidence bounds for coefficient estimates, returned as a numeric matrix. `bint` is a *p*-by-2 matrix, where *p* is the number of predictors in `X`. The first column of `bint` contains lower confidence bounds for each of the coefficient estimates; the second column contains upper confidence bounds. If the columns of `X` are linearly dependent, `regress` returns zeros in elements of `bint` corresponding to the zero elements of `b`.

Data Types: `double`

r — Residuals

numeric vector

Residuals, returned as a numeric vector. `r` is an *n*-by-1 vector, where *n* is the number of observations, or rows, in `X`.

Data Types: `single` | `double`

rint — Intervals to diagnose outliers

numeric matrix

Intervals to diagnose outliers, returned as a numeric matrix. `rint` is an *n*-by-2 matrix, where *n* is the number of observations, or rows, in `X`. If the interval `rint(i,:)` for observation `i` does not contain zero, the corresponding residual is larger than expected in `100*(1-alpha)`% of new observations, suggesting an outlier. For more information, see “Algorithms” on page 33-5281.

Data Types: `single` | `double`

`stats` — Model statistics
numeric vector

Model statistics, returned as a numeric vector including the R^2 statistic, the F-statistic and its p-value, and an estimate of the error variance.

- `X` must include a column of ones so that the model contains a constant term. The F-statistic and its p-value are computed under this assumption and are not correct for models without a constant.
- The F-statistic is the test statistic of the F-test on the regression model. The F-test looks for a significant linear regression relationship between the response variable and the predictor variables.
- The R^2 statistic can be negative for models without a constant, indicating that the model is not appropriate for the data.

Data Types: `single` | `double`

Tips

- `regress` treats `NaN` values in `X` or `y` as missing values. `regress` omits observations with missing values from the regression fit.

Algorithms

Residual Intervals

In a linear model, observed values of `y` and their residuals are random variables. Residuals have normal distributions with zero mean but with different variances at different values of the predictors. To put residuals on a comparable scale, `regress` “Studentizes” the residuals. That is, `regress` divides the residuals by an estimate of their standard deviation that is independent of their value. Studentized residuals have t-distributions with known degrees of freedom. The intervals returned in `rint` are shifts of the `100*(1-alpha)`% confidence intervals of these t-distributions, centered at the residuals.

Alternative Functionality

`regress` is useful when you simply need the output arguments of the function and when you want to repeat fitting a model multiple times in a loop. If you need to investigate a fitted regression model further, create a linear regression model object `LinearModel` by using `fitlm` or `stepwiselm`. A `LinearModel` object provides more features than `regress`.

- Use the properties of `LinearModel` to investigate a fitted linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data.
- Use the object functions of `LinearModel` to predict responses and to modify, evaluate, and visualize the linear regression model.

- Unlike `regress`, the `fitlm` function does not require a column of ones in the input data. A model created by `fitlm` always includes an intercept term unless you specify not to include it by using the `'Intercept'` name-value pair argument.
- You can find the information in the output of `regress` using the properties and object functions of `LinearModel`.

Output of regress	Equivalent Values in LinearModel
`b`	See the `Estimate` column of the `Coefficients` property.
`bint`	Use the `coefCI` function.
`r`	See the `Raw` column of the `Residuals` property.
`rint`	Not supported. Instead, use studentized residuals (`Residuals` property) and observation diagnostics (`Diagnostics` property) to find outliers.
`stats`	See the model display in the Command Window. You can find the statistics in the model properties (`MSE` and `Rsquared`) and by using the `anova` function.

Introduced before R2006a

RegressionBaggedEnsemble

Package: `classreg.learning.regr`
Superclasses: `RegressionEnsemble`

Regression ensemble grown by resampling

Description

`RegressionBaggedEnsemble` combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a bagged regression ensemble object using `fitrensemble`. Set the name-value pair argument `'Method'` of `fitrensemble` to `'Bag'` to use bootstrap aggregation (bagging, for example, random forest).

Properties

`BinEdges`

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
```

```
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`CombineWeights`

A character vector describing how the ensemble combines learner predictions.

`ExpandedPredictorNames`

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

`FitInfo`

A numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

`FitInfoDescription`

Character vector describing the meaning of the `FitInfo` array.

`FResample`

A numeric scalar between `0` and `1`. `FResample` is the fraction of training data `fitrensemble` resampled at random for every weak learner when constructing the ensemble.

`HyperparameterOptimizationResults`

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

`LearnerNames`

Cell array of character vectors with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{'Tree'}`.

Method

A character vector with the name of the algorithm `fitrensemble` used for training the ensemble.

ModelParameters

Parameters used in training `ens`.

NumObservations

Numeric scalar containing the number of observations in the training data.

NumTrained

Number of trained learners in the ensemble, a positive scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

ReasonForTermination

A character vector describing the reason `fitrensemble` stopped adding weak learners to the ensemble.

Regularization

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

Replace

Boolean flag indicating if training data for weak learners in this ensemble were sampled with replacement. `Replace` is `true` for sampling with replacement, `false` otherwise.

ResponseName

A character vector with the name of the response variable `Y`.

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. `'none'` means no transformation; equivalently, `'none'` means `@(x)x`.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

`UseObsForLearner`

A logical matrix of size `N`-by-`NumTrained`, where `N` is the number of rows (observations) in the training data `X`, and `NumTrained` is the number of trained weak learners. `UseObsForLearner(I,J)` is `true` if observation `I` was used for training learner `J`, and is `false` otherwise.

`W`

The scaled `weights`, a vector with length `n`, the number of rows in `X`. The sum of the elements of `W` is `1`.

`X`

The matrix or table of predictor values that trained the ensemble. Each column of `X` represents one variable, and each row represents one observation.

`Y`

The numeric column vector with the same number of rows as `X` that trained the ensemble. Each entry in `Y` is the response to the data in the corresponding row of `X`.

Object Functions

compact	Create compact regression ensemble
crossval	Cross validate ensemble
cvshrink	Cross validate shrinking (pruning) ensemble
lime	Local interpretable model-agnostic explanations (LIME)
loss	Regression error
oobLoss	Out-of-bag regression error
oobPermutedPredictorImportance	Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of regression trees
oobPredict	Predict out-of-bag response of ensemble
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Predict responses using ensemble of regression models
predictorImportance	Estimates of predictor importance for regression ensemble
regularize	Find weights to minimize resubstitution error plus penalty term
removeLearners	Remove members of compact regression ensemble
resubLoss	Regression error by resubstitution
resubPredict	Predict response of ensemble by resubstitution
resume	Resume training ensemble
shapley	Shapley values
shrink	Prune ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Train Bagged Ensemble of Regression Trees

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (`MPG`) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a bagged ensemble of 100 regression trees using all measurements.

```
Mdl = fitrensemble(X,Y,'Method','bag')
```

```
Mdl =
  RegressionBaggedEnsemble
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
          NumObservations: 94
                NumTrained: 100
                    Method: 'Bag'
             LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: []
       FitInfoDescription: 'None'
           Regularization: []
                 FResample: 1
                   Replace: 1
          UseObsForLearner: [94x100 logical]

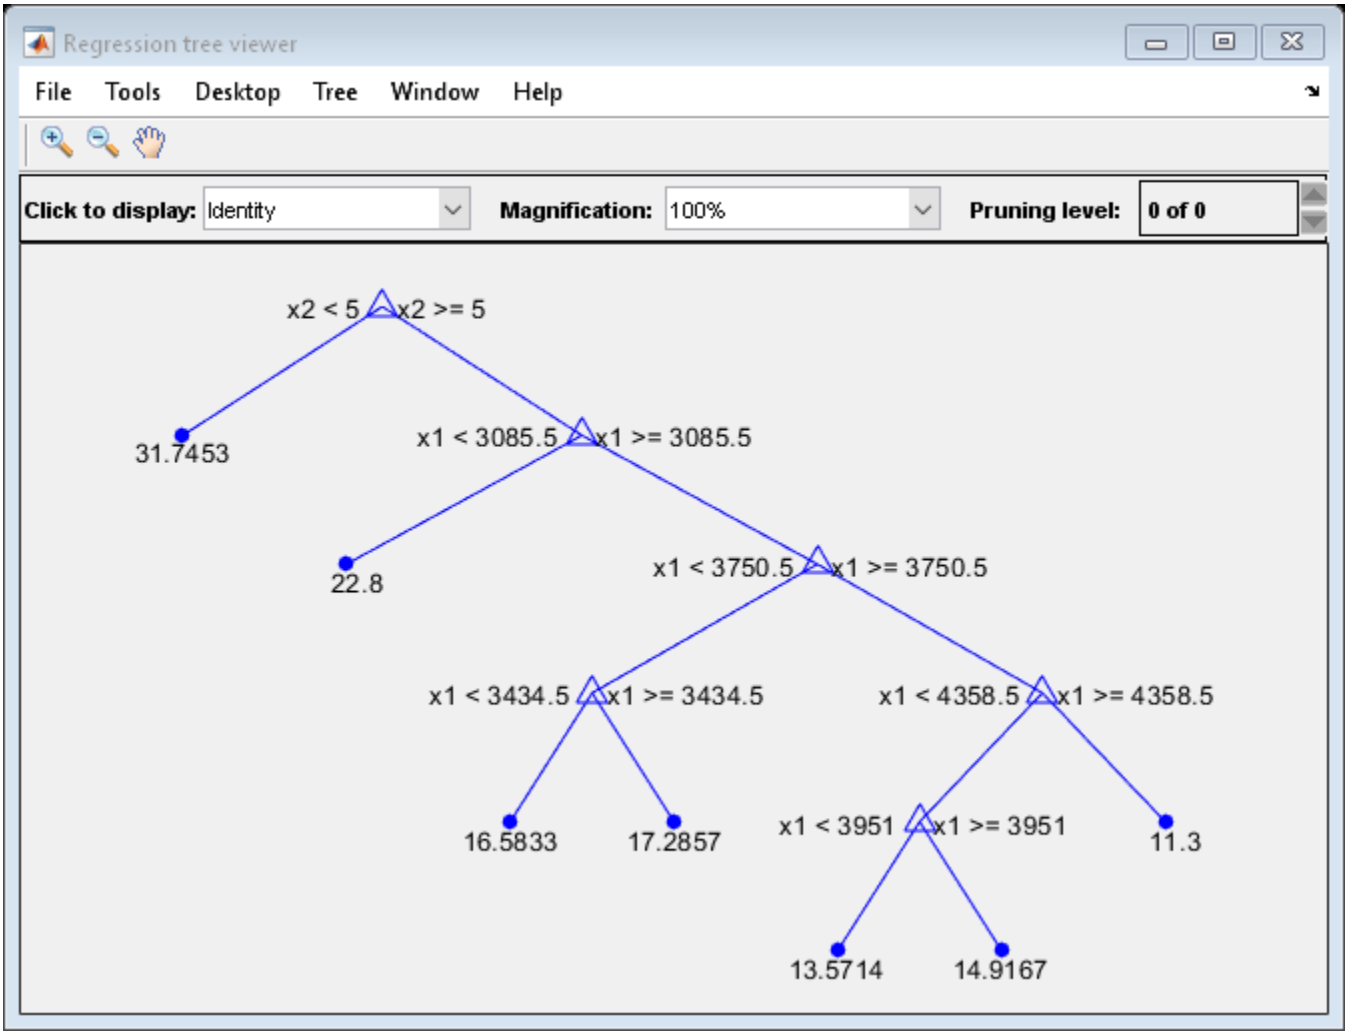
  Properties, Methods
```

`Mdl` is a `RegressionBaggedEnsemble` model object.

`Mdl.Trained` is the property that stores a 100-by-1 cell vector of the trained, compact regression trees (`CompactRegressionTree` model objects) that compose the ensemble.

Plot a graph of the first trained regression tree.

```
view(Mdl.Trained{1},'Mode','graph')
```



By default, `fitrensemble` grows deep trees for bags of trees.

Estimate the in-sample mean-squared error (MSE).

```
L = resubLoss(Mdl)
```

```
L = 12.4048
```

Tip

For a bagged ensemble of regression trees, the `Trained` property of `ens` stores a cell vector of `ens.NumTrained` `CompactRegressionTree` model objects. For a textual or graphical display of tree *`t`* in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- To integrate the prediction of an ensemble into Simulink, you can use the RegressionEnsemble Predict block in the Statistics and Machine Learning Toolbox library or a MATLAB Function block with the `predict` function.
- When you train an ensemble by using `fitrensemble`, code generation limitations for regression trees also apply to ensembles of regression trees. For more details, see "Code Generation" on page 33-868 of the `CompactRegressionTree` class.

For more information, see "Introduction to Code Generation" on page 32-2.

RegressionEnsemble

Package: `classreg.learning.regr`
Superclasses: `CompactRegressionEnsemble`

Ensemble regression

Description

`RegressionEnsemble` combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a regression ensemble object using `fitrensemble`.

Properties

`BinEdges`

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`CombineWeights`

A character vector describing how the ensemble combines learner predictions.

`ExpandedPredictorNames`

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

`FitInfo`

A numeric array of fit information. The `FitInfoDescription` property describes the content of this array.

`FitInfoDescription`

Character vector describing the meaning of the `FitInfo` array.

`LearnerNames`

Cell array of character vectors with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{'Tree'}`.

`HyperparameterOptimizationResults`

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

`Method`

A character vector with the name of the algorithm `fitrensemble` used for training the ensemble.

`ModelParameters`

Parameters used in training `ens`.

NumObservations

Numeric scalar containing the number of observations in the training data.

NumTrained

Number of trained learners in the ensemble, a positive scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

ReasonForTermination

A character vector describing the reason `fitrensemble` stopped adding weak learners to the ensemble.

Regularization

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

ResponseName

A character vector with the name of the response variable `Y`.

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. `'none'` means no transformation; equivalently, `'none'` means `@(x)x`.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

W

The scaled `weights`, a vector with length `n`, the number of rows in `X`. The sum of the elements of `W` is `1`.

X

The matrix or table of predictor values that trained the ensemble. Each column of `X` represents one variable, and each row represents one observation.

Y

The numeric column vector with the same number of rows as X that trained the ensemble. Each entry in Y is the response to the data in the corresponding row of X.

Object Functions

compact	Create compact regression ensemble
crossval	Cross validate ensemble
cvshrink	Cross validate shrinking (pruning) ensemble
lime	Local interpretable model-agnostic explanations (LIME)
loss	Regression error
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Predict responses using ensemble of regression models
predictorImportance	Estimates of predictor importance for regression ensemble
regularize	Find weights to minimize resubstitution error plus penalty term
removeLearners	Remove members of compact regression ensemble
resubLoss	Regression error by resubstitution
resubPredict	Predict response of ensemble by resubstitution

shrink	Prune ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Train Boosted Regression Ensemble

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (`MPG`) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a boosted ensemble of 100 regression trees using the `LSBoost` method. Specify that `Cylinders` is a categorical variable.

```
Mdl = fitrensemble(X,Y,'Method','LSBoost',...
    'PredictorNames',{'W','C'},'CategoricalPredictors',2)
```

```
Mdl =
  RegressionEnsemble
            PredictorNames: {'W'  'C'}
              ResponseName: 'Y'
    CategoricalPredictors: 2
        ResponseTransform: 'none'
          NumObservations: 94
```

```
               NumTrained: 100
                   Method: 'LSBoost'
              LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: [100x1 double]
       FitInfoDescription: {2x1 cell}
           Regularization: []

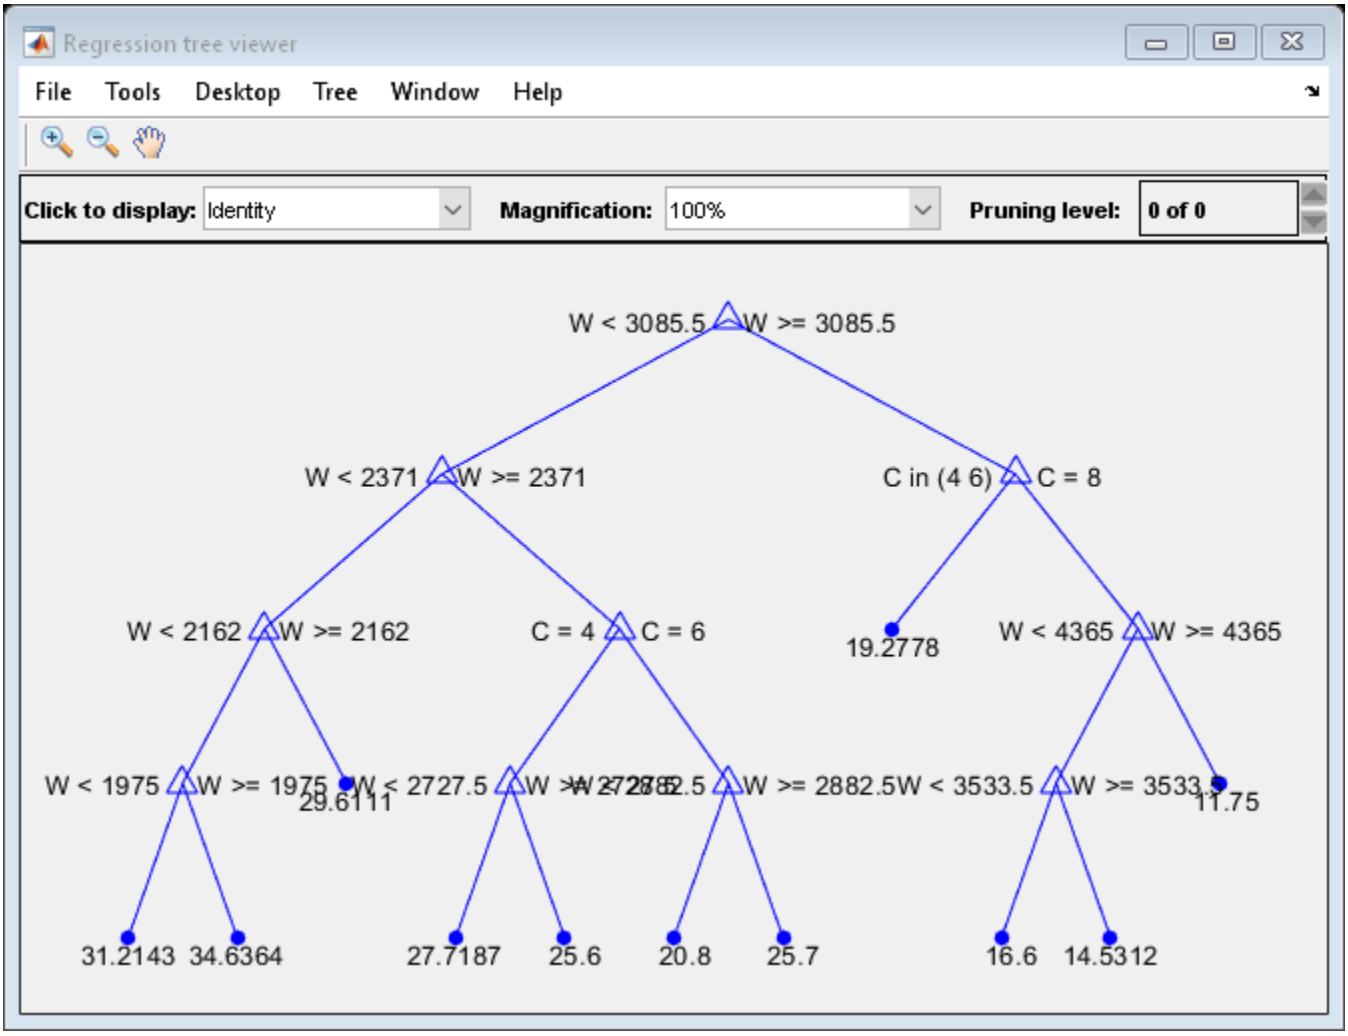
  Properties, Methods
```

`Mdl` is a `RegressionEnsemble` model object that contains the training data, among other things.

`Mdl.Trained` is the property that stores a 100-by-1 cell vector of the trained regression trees (`CompactRegressionTree` model objects) that compose the ensemble.

Plot a graph of the first trained regression tree.

```
view(Mdl.Trained{1},'Mode','graph')
```



By default, `fitrensemble` grows shallow trees for boosted ensembles of trees.

Predict the fuel economy of 4,000 pound cars with 4, 6, and 8 cylinders.

```
XNew = [4000*ones(3,1) [4; 6; 8]];
mpgNew = predict(Mdl,XNew)
```

```
mpgNew = 3×1

   19.5926
   18.6388
   15.4810
```

Tip

For an ensemble of regression trees, the `Trained` property contains a cell vector of `ens.NumTrained` `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(ens.Trained{t})
```

RegressionEnsemble Predict

Predict responses using ensemble of decision trees for regression
Library: Statistics and Machine Learning Toolbox / Regression

Description

The RegressionEnsemble Predict block predicts responses using an ensemble of decision trees (`RegressionEnsemble`, `RegressionBaggedEnsemble`, or `CompactRegressionEnsemble`).

Import a trained regression object into the block by specifying the name of a workspace variable that contains the object. The input port **x** receives an observation (predictor data), and the output port **yfit** returns a predicted response for the observation.

Ports

Input

x — Predictor data

row vector | column vector

Predictor data, specified as a column vector or row vector of one observation.

Dependencies

- The variables in **x** must have the same order as the predictor variables that trained the model specified by **`Select trained machine learning model`**.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

yfit — Predicted response

scalar

Predicted response, returned as a scalar.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main

Select trained machine learning model — Regression ensemble model

`ensMdl` (default) | `RegressionEnsemble` object | `RegressionBaggedEnsemble` object | `CompactRegressionEnsemble` object

Specify the name of a workspace variable that contains a `RegressionEnsemble` object, `RegressionBaggedEnsemble` object, or `CompactRegressionEnsemble` object.

When you train the model by using `fitrensemble`, the following restrictions apply:

- The predictor data cannot include categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
- The value of the `'ResponseTransform'` name-value argument must be `'none'` (default).
- You cannot use surrogate splits for tree weak learners, that is, the value of the `'Surrogate'` name-value argument must be `'off'` (default) when you define tree weak learners by using the `templateTree` function.

Programmatic Use

Block Parameter: `TrainedLearner`
Type: workspace variable
Values: `RegressionEnsemble` object | `RegressionBaggedEnsemble` object | `CompactRegressionEnsemble` object
Default: `'ensMdl'`

Data Types

Fixed-Point Operational Parameters

`Integer rounding mode` — Rounding mode for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action
`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of –128.
Clear this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors" (Simulink).	Overflows wrap to the appropriate value that the data type can represent.	The maximum value that the `int8` (signed 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8` is –126.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data type
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data type you specify for the block. For more information, see "Use Lock Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Data Type

`Output data type` — Data type of yfit output
`Inherit: auto` (default) | `double` | `single` | `half` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the data type for the **yfit** output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select `Inherit: auto`, the block uses a rule that inherits a data type.

For more information about data types, see “Control Signal Data Types” (Simulink).

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: auto'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'boolean'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: auto'`

`Output minimum` — Minimum value of yfit output for range checking
`[]` (default) | scalar

Lower value of the **yfit** output range that Simulink checks.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Output minimum** parameter does not saturate or clip the actual **yfit** signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

`Output maximum` — Maximum value of yfit output for range checking

`[]` (default) | scalar

Upper value of the **yfit** output range that Simulink checks.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Output maximum** parameter does not saturate or clip the actual **yfit** signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

`Weak learner data type` — Data type of weak learner outputs

`Inherit: auto` (default) | `double` | `single` | `half` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the data type for the outputs from weak learners. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select `Inherit: auto`, the block uses a rule that inherits a data type.

For more information about data types, see “Control Signal Data Types” (Simulink).

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Programmatic Use

Block Parameter: `WeakLearnerDataTypeStr`
Type: character vector
Values: `'Inherit: auto'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'boolean'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: auto'`

`Weak learner minimum` — Minimum value of weak learner outputs for range checking

`[]` (default) | scalar

Lower value of the weak learner output range that Simulink checks.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Weak learner minimum** parameter does not saturate or clip the actual weak learner output signals.

Programmatic Use

Block Parameter: `WeakLearnerOutMin`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

`Weak learner maximum` — Maximum value of weak learner outputs for range checking

`[]` (default) | scalar

Upper value of the weak learner output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Weak learner maximum** parameter does not saturate or clip the actual weak learner output signals.

Programmatic Use

Block Parameter: `WeakLearnerOutMax`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `half` | `integer` | `single`
Direct Feedthrough	`yes`
Multidimensional Signals	`no`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

Alternative Functionality

You can use a MATLAB Function block with the `predict` object function of an ensemble of decision trees (`RegressionEnsemble`, `RegressionBaggedEnsemble`, or `CompactRegressionEnsemble`). For an example, see “Predict Class Labels Using MATLAB Function Block” on page 32-40.

When deciding whether to use the RegressionEnsemble Predict block in the Statistics and Machine Learning Toolbox library or a MATLAB Function block with the `predict` function, consider the following:

- If you use the Statistics and Machine Learning Toolbox library block, you can use the **Fixed-Point Tool** to convert a floating-point model to fixed point.
- Support for variable-size arrays must be enabled for a MATLAB Function block with the `predict` function.
- If you use a MATLAB Function block, you can use MATLAB functions for preprocessing or post-processing before or after predictions in the same MATLAB Function block.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

RegressionGAM

Generalized additive model (GAM) for regression

Description

A `RegressionGAM` object is a generalized additive model on page 33-5314 (GAM) object for regression. It is an interpretable model that explains a response variable using a sum of univariate and bivariate shape functions.

You can predict responses for new observations by using the `predict` function, and plot the effect of each shape function on the prediction (response value) for an observation by using the `plotLocalEffects` function. For the full list of object functions for `RegressionGAM`, see “Object Functions” on page 33-5308.

Creation

Create a `RegressionGAM` object by using `fitrgam`. You can specify both linear terms and interaction terms for predictors to include univariate shape functions (predictor trees) and bivariate shape functions (interaction trees) in a trained model, respectively.

You can update a trained model by using `resume` or `addInteractions`.

- The `resume` function resumes training for the existing terms in a model.
- The `addInteractions` function adds interaction terms to a model that contains only linear terms.

Properties

GAM Properties

`BinEdges` — Bin edges for numeric predictors
cell array of numeric vectors | `[ ]`

This property is read-only.

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
```

```
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

Data Types: `cell`

`Interactions` — Interaction term indices
two-column matrix of positive integers | `[]`

This property is read-only.

Interaction term indices, specified as a `t`-by-2 matrix of positive integers, where `t` is the number of interaction terms in the model. Each row of the matrix represents one interaction term and contains the column indexes of the predictor data `X` for the interaction term. If the model does not include an interaction term, then this property is empty (`[]`).

The software adds interaction terms to the model in the order of importance based on the *p*-values. Use this property to check the order of the interaction terms added to the model.

Data Types: `double`

`Intercept` — Intercept term of model
numeric scalar

This property is read-only.

Intercept (constant) term of the model, which is the sum of the intercept terms in the predictor trees and interaction trees, specified as a numeric scalar.

Data Types: `single` | `double`

`ModelParameters` — Parameters used to train model
model parameter object

This property is read-only.

Parameters used to train the model, specified as a model parameter object. `ModelParameters` contains parameter values such as those for the name-value arguments used to train the model. `ModelParameters` does not contain estimated parameters.

Access the fields of `ModelParameters` by using dot notation. For example, access the maximum number of decision splits per interaction tree by using `Mdl.ModelParameters.MaxNumSplitsPerInteraction`.

`PairDetectionBinEdges` — Bin edges for interaction term detection
cell array of numeric vectors

This property is read-only.

Bin edges for interaction term detection for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

To speed up the interaction term detection process, the software bins numeric predictors into at most 8 equiprobable bins. The number of bins can be less than 8 if a predictor has fewer than 8 unique values.

Data Types: `cell`

`ReasonForTermination` — Reason training stops
structure

This property is read-only.

Reason training the model stops, specified as a structure with two fields, `PredictorTrees` and `InteractionTrees`.

Use this property to check if the model contains the specified number of trees for each linear term (`'NumTreesPerPredictor'`) and for each interaction term (`'NumTreesPerInteraction'`). If the `fitrgam` function terminates training before adding the specified number of trees, this property contains the reason for the termination.

Data Types: `struct`

Other Regression Properties

`CategoricalPredictors` — Categorical predictor indices
vector of positive integers | `[]`

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `double`

`ExpandedPredictorNames` — Expanded predictor names
cell array of character vectors

This property is read-only.

Expanded predictor names, specified as a cell array of character vectors.

`ExpandedPredictorNames` is the same as `PredictorNames` for a generalized additive model.

Data Types: `cell`

`NumObservations` — Number of observations
numeric scalar

This property is read-only.

Number of observations in the training data stored in `X` and `Y`, specified as a numeric scalar.

Data Types: `double`

`PredictorNames` — Predictor variable names
cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Data Types: `cell`

`ResponseName` — Response variable name
character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

`ResponseTransform` — Response transformation function
`'none'` | function handle

Response transformation function, specified as `'none'` or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @`*`function`*, where *`function`* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

`RowsUsed` — Rows used in fitting
`[]` | logical vector

This property is read-only.

Rows of the original training data used in fitting the `RegressionGAM` model, specified as a logical vector. This property is empty if all rows are used.

Data Types: `logical`

`W` — Observation weights
numeric vector

This property is read-only.

Observation weights used to train the model, specified as an *n*-by-1 numeric vector. *n* is the number of observations (`NumObservations`).

The software normalizes the observation weights specified in the `'Weights'` name-value argument so that the elements of `W` sum up to 1.

Data Types: `double`

`X` — Predictors
numeric matrix | table

This property is read-only.

Predictors used to train the model, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

Data Types: `single` | `double` | `table`

`Y` — Response
numeric vector

This property is read-only.

Response, specified as a numeric vector.

Each row of `Y` represents the observed response of the corresponding row of `X`.

Data Types: `single` | `double`

Object Functions

Create `CompactRegressionGAM`

compact	Reduce size of machine learning model

Create `RegressionPartitionedGAM`

crossval	Cross-validate machine learning model

Update GAM

addInteractions	Add interaction terms to univariate generalized additive model (GAM)
resume	Resume training of generalized additive model (GAM)

Interpret Prediction

lime	Local interpretable model-agnostic explanations (LIME)
partialDependence	Compute partial dependence
plotLocalEffects	Plot local effects of terms in generalized additive model (GAM)
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
shapley	Shapley values

Assess Predictive Performance on New Observations

predict	Predict responses using generalized additive model (GAM)
loss	Regression loss for generalized additive model (GAM)

Assess Predictive Performance on Training Data

resubPredict	Predict responses for training data using trained regression model
resubLoss	Resubstitution regression loss

Examples

Train Generalized Additive Model

Train a univariate GAM, which contains linear terms for predictors. Then, interpret the prediction for a specified data instance by using the `plotLocalEffects` function.

Load the data set `NYCHousing2015`.

```
load NYCHousing2015
```

The data set includes 10 variables with information on the sales of properties in New York City in 2015. This example uses these variables to analyze the sale prices (`SALEPRICE`).

Preprocess the data set. Remove outliers, convert the `datetime` array (`SALEDATE`) to the month numbers, and move the response variable (`SALEPRICE`) to the last column.

```
idx = isoutlier(NYCHousing2015.SALEPRICE);
NYCHousing2015(idx,:) = [];
NYCHousing2015.SALEDATE = month(NYCHousing2015.SALEDATE);
NYCHousing2015 = movevars(NYCHousing2015,'SALEPRICE','After','SALEDATE');
```

Display the first three rows of the table.

```
head(NYCHousing2015,3)
```

```
ans=3×10 table
    BOROUGH    NEIGHBORHOOD       BUILDINGCLASSCATEGORY        RESIDENTIALUNITS    COMMERCIALUNI
    _______    ____________    ___________________________    ________________    _____________

       2       {'BATHGATE'}    {'01  ONE FAMILY DWELLINGS'}          1                   0
       2       {'BATHGATE'}    {'01  ONE FAMILY DWELLINGS'}          1                   0
       2       {'BATHGATE'}    {'01  ONE FAMILY DWELLINGS'}          1                   1
```

Train a univariate GAM for the sale prices. Specify the variables for `BOROUGH`, `NEIGHBORHOOD`, `BUILDINGCLASSCATEGORY`, and `SALEDATE` as categorical predictors.

```
Mdl = fitrgam(NYCHousing2015,'SALEPRICE','CategoricalPredictors',[1 2 3 9])
```

```
Mdl =
  RegressionGAM
             PredictorNames: {1x9 cell}
               ResponseName: 'SALEPRICE'
    CategoricalPredictors: [1 2 3 9]
        ResponseTransform: 'none'
                Intercept: 3.7518e+05
```

```
          NumObservations: 83517

  Properties, Methods
```

`Mdl` is a `RegressionGAM` model object. The model display shows a partial list of the model properties. To view the full list of properties, double-click the variable name `Mdl` in the Workspace. The Variables editor opens for `Mdl`. Alternatively, you can display the properties in the Command Window by using dot notation. For example, display the estimated intercept (constant) term of `Mdl`.

```
Mdl.Intercept
```

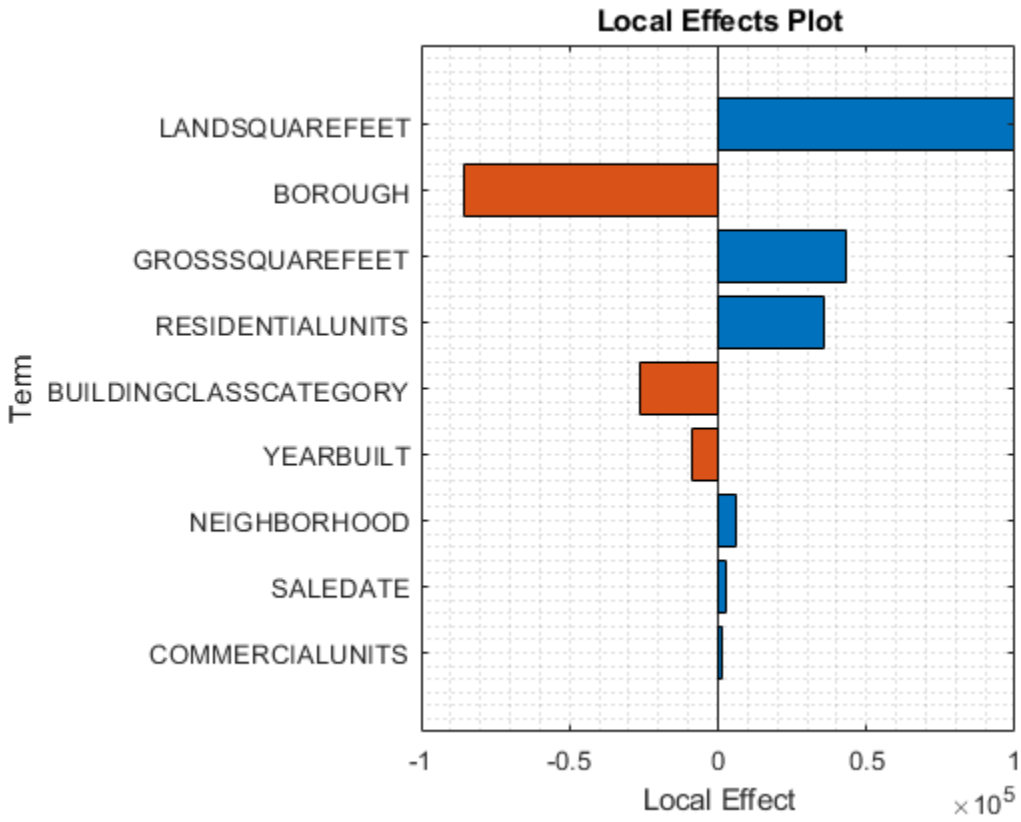
```
ans = 3.7518e+05
```

Predict the sale price for the first observation of the training data, and plot the local effects of the terms in `Mdl` on the prediction.

```
yFit = predict(Mdl,NYCHousing2015(1,:))
```

```
yFit = 4.4421e+05
```

```
plotLocalEffects(Mdl,NYCHousing2015(1,:))
```



The `predict` function predicts the sale price for the first observation as `4.4421e5`. The `plotLocalEffects` function creates a horizontal bar graph that shows the local effects of the terms in `Mdl` on the prediction. Each local effect value shows the contribution of each term to the predicted sale price.

Train GAM with Interaction Terms

Train a generalized additive model that contains linear and interaction terms for predictors in three different ways:

- Specify the interaction terms using the `formula` input argument.
- Specify the `'Interactions'` name-value argument.
- Build a model with linear terms first and add interaction terms to the model by using the `addInteractions` function.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table that contains the predictor variables (`Acceleration`, `Displacement`, `Horsepower`, and `Weight`) and the response variable (`MPG`).

```
tbl = table(Acceleration,Displacement,Horsepower,Weight,MPG);
```

Specify `formula`

Train a GAM that contains the four linear terms (`Acceleration`, `Displacement`, `Horsepower`, and `Weight`) and two interaction terms (`Acceleration*Displacement` and `Displacement*Horsepower`). Specify the terms using a formula in the form `'Y ~ terms'`.

```
Mdl1 = fitrgam(tbl,'MPG ~ Acceleration + Displacement + Horsepower + Weight + Acceleration:Displa
```

The function adds interaction terms to the model in the order of importance. You can use the `Interactions` property to check the interaction terms in the model and the order in which `fitrgam` adds them to the model. Display the `Interactions` property.

```
Mdl1.Interactions
```

```
ans = 2×2

     2     3
     1     2
```

Each row of `Interactions` represents one interaction term and contains the column indexes of the predictor variables for the interaction term.

Specify `'Interactions'`

Pass the training data (`tbl`) and the name of the response variable in `tbl` to `fitrgam`, so that the function includes the linear terms for all the other variables as predictors. Specify the `'Interactions'` name-value argument using a logical matrix to include the two interaction terms, `x1*x2` and `x2*x3`.

```
Mdl2 = fitrgam(tbl,'MPG','Interactions',logical([1 1 0 0; 0 1 1 0]));
Mdl2.Interactions
```

```
ans = 2×2
```

```
     2     3
     1     2
```

You can also specify `'Interactions'` as the number of interaction terms or as `'all'` to include all available interaction terms. Among the specified interaction terms, `fitrgam` identifies those whose *p*-values are not greater than the `'MaxPValue'` value and adds them to the model. The default `'MaxPValue'` is 1 so that the function adds all specified interaction terms to the model.

Specify `'Interactions','all'` and set the `'MaxPValue'` name-value argument to 0.05.

```
Mdl3 = fitrgam(tbl,'MPG','Interactions','all','MaxPValue',0.05);
```

```
Warning: Model does not include interaction terms because all interaction terms have p-values gre
```

```
Mdl3.Interactions
```

```
ans =

  0x2 empty double matrix
```

`Mdl3` includes no interaction terms, which implies one of the following: all interaction terms have *p*-values greater than 0.05, or adding the interaction terms does not improve the model fit.

Use `addInteractions` Function

Train a univariate GAM that contains linear terms for predictors, and then add interaction terms to the trained model by using the `addInteractions` function. Specify the second input argument of `addInteractions` in the same way you specify the `'Interactions'` name-value argument of `fitrgam`. You can specify the list of interaction terms using a logical matrix, the number of interaction terms, or `'all'`.

Specify the number of interaction terms as 3 to add the three most important interaction terms to the trained model.

```
Mdl4 = fitrgam(tbl,'MPG');
UpdatedMdl4 = addInteractions(Mdl4,3);
UpdatedMdl4.Interactions
```

```
ans = 3×2

     2     3
     1     2
     3     4
```

`Mdl4` is a univariate GAM, and `UpdatedMdl4` is an updated GAM that contains all the terms in `Mdl4` and three additional interaction terms.

Resume Training Interaction Trees in GAM

Train a regression GAM that contains both linear and interaction terms. Specify to train the interaction terms for a small number of iterations. After training the interaction terms for more iterations, compare the resubstitution loss.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Specify `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Acceleration,Displacement,Horsepower,Weight];
Y = MPG;
```

Train a GAM that includes all available linear and interaction terms in `X`. Specify the number of trees per interaction term as 2. `fitrgam` iterates the boosting algorithm 300 times (default) for linear terms, and iterates the algorithm the specified number of iterations for interaction terms. For each boosting iteration, the function adds one tree per linear term or one tree per interaction term. Specify `'Verbose'` as 1 to display diagnostic messages at every 10 iterations.

```
Mdl = fitrgam(X,Y,'Interactions','all','NumTreesPerInteraction',2,'Verbose',1);
```

```

```

To check whether `fitrgam` trains the specified number of trees, display the `ReasonForTermination` property of the trained model and view the displayed messages.

```
Mdl.ReasonForTermination
```

```
ans = struct with fields:
      PredictorTrees: 'Terminated after training the requested number of trees.'
    InteractionTrees: 'Terminated after training the requested number of trees.'
```

Compute the regression loss for the training data.

```
resubLoss(Mdl)
```

```
ans = 3.8277
```

Resume training the model for another 100 iterations. Because `Mdl` contains both linear and interaction terms, the `resume` function resumes training for the interaction terms and adds more trees for them (interaction trees).

```
UpdatedMdl = resume(Mdl,100);
```

```

```

```
UpdatedMdl.ReasonForTermination
```

```
ans = struct with fields:
      PredictorTrees: 'Terminated after training the requested number of trees.'
    InteractionTrees: 'Unable to improve the model fit.'
```

`resume` terminates training when adding more trees does not improve the deviance of the model fit.

Compute the regression loss using the updated model.

```
resubLoss(UpdatedMdl)
```

```
ans = 0.0944
```

The regression loss decreases after `resume` updates the model with more iterations.

More About

Generalized Additive Model (GAM) for Regression

A generalized additive model (GAM) is an interpretable model that explains a response variable using a sum of univariate and bivariate shape functions of predictors.

`fitrgam` uses a boosted tree as a shape function for each predictor and, optionally, each pair of predictors; therefore, the function can capture a nonlinear relation between a predictor and the response variable. Because contributions of individual shape functions to the prediction (response value) are well separated, the model is easy to interpret.

The standard GAM uses a univariate shape function for each predictor.

$$y \sim N\left(\mu, \sigma^2\right)$$
$$g(\mu) = \mu = c + f_1(x_1) + f_2(x_2) + \cdots + f_p(x_p),$$

where y is a response variable that follows the normal distribution with mean μ and standard deviation σ. $g(\mu)$ is an identity link function, and c is an intercept (constant) term. $f_i(x_i)$ is a univariate shape function for the ith predictor, which is a boosted tree for a linear term for the predictor (predictor tree).

You can include interactions between predictors in a model by adding bivariate shape functions of important interaction terms to the model.

$$\mu = c + f_1(x_1) + f_2(x_2) + \cdots + f_p(x_p) + \sum_{i,\, j \in \{1, 2, \cdots, p\}} f_{ij}(x_i x_j),$$

where $f_{ij}(x_i x_j)$ is a bivariate shape function for the ith and jth predictors, which is a boosted tree for an interaction term for the predictors (interaction tree).

`fitrgam` finds important interaction terms based on the p-values of F-tests. For details, see “Interaction Term Detection” on page 33-2135.

Topics

“Train Generalized Additive Model for Regression” on page 12-91

Introduced in R2021a

RegressionGP class

Superclasses: `CompactRegressionGP`

Gaussian process regression model class

Description

`RegressionGP` is a Gaussian process regression (GPR) model. You can train a GPR model, using `fitrgp`. Using the trained model, you can

- Predict responses for training data using `resubPredict` or new predictor data using `predict`. You can also compute the prediction intervals.
- Compute the regression loss for training data using `resubLoss` or new data using `loss`.

Construction

Create a `RegressionGP` object by using `fitrgp`.

Properties

Fitting

`FitMethod` — Method used to estimate the parameters

`'none'` | `'exact'` | `'sd'` | `'sr'` | `'fic'`

Method used to estimate the basis function coefficients, β; noise standard deviation, σ; and kernel parameters, θ, of the GPR model, stored as a character vector. It can be one of the following.

Fit Method	Description
`'none'`	No estimation. `fitrgp` uses the initial parameter values as the parameter values.
`'exact'`	Exact Gaussian process regression.
`'sd'`	Subset of data points approximation.
`'sr'`	Subset of regressors approximation.
`'fic'`	Fully independent conditional approximation.

`BasisFunction` — Explicit basis function

`'none'` | `'constant'` | `'linear'` | `'pureQuadratic'` | function handle

Explicit basis function used in the GPR model, stored as a character vector or a function handle. It can be one of the following. If n is the number of observations, the basis function adds the term $\boldsymbol{H}*\boldsymbol{\beta}$ to the model, where $\boldsymbol{H}$ is the basis matrix and $\boldsymbol{\beta}$ is a p-by-1 vector of basis coefficients.

Explicit Basis	Basis Matrix
`'none'`	Empty matrix.

Explicit Basis	Basis Matrix
`'constant'`	$H = 1$ (n-by-1 vector of 1s, where n is the number of observations)
`'linear'`	$H = [1, X]$
`'pureQuadratic'`	$H = [1, X, X_2]$, where $X_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \cdots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \cdots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \cdots & x_{nd}^2 \end{bmatrix}$.
Function handle	Function handle, `hfcn`, that `fitrgp` calls as: $H = hfcn(X)$, where X is an n-by-d matrix of predictors and H is an n-by-p matrix of basis functions.

Data Types: `char` | `function_handle`

`Beta` — Estimated coefficients
vector

Estimated coefficients for the explicit basis functions, stored as a vector. You can define the explicit basis function by using the `BasisFunction` name-value pair argument in `fitrgp`.

Data Types: `double`

`Sigma` — Estimated noise standard deviation
scalar value

Estimated noise standard deviation of the GPR model, stored as a scalar value.

Data Types: `double`

`CategoricalPredictors` — Indices of categorical predictors
vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

`HyperparameterOptimizationResults` — Cross-validation optimization of hyperparameters
`BayesianOptimization` object | table

This property is read-only.

Cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property is nonempty if the

`'OptimizeHyperparameters'` name-value pair argument is nonempty when you create the model. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure when you create the model.

Value of `Optimizer` Field	Value of `HyperparameterOptimizationResults`
`'bayesopt'` (default)	Object of class `BayesianOptimization`
`'gridsearch'` or `'randomsearch'`	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

`LogLikelihood` — Maximized marginal log likelihood
scalar value | `[]`

Maximized marginal log likelihood of the GPR model, stored as a scalar value if the `FitMethod` is different from `'none'`. If `FitMethod` is `'none'`, then `LogLikelihood` is empty.

If `FitMethod` is `'sd'`, `'sr'`, or `'fic'`, then `LogLikelihood` is the maximized approximation of the marginal log likelihood of the GPR model.

Data Types: `double`

`ModelParameters` — Parameters used for training
`GPParams` object

Parameters used for training the GPR model, stored as a `GPParams` object.

Kernel Function

`KernelFunction` — Form of the covariance function
`'squaredExponential'` | `'matern32'` | `'matern52'` | `'ardsquaredexponential'` | `'ardmatern32'` | `'ardmatern52'` | function handle

Form of the covariance function used in the GPR model, stored as a character vector containing the name of the built-in covariance function or a function handle. It can be one of the following.

Function	Description
`'squaredexponential'`	Squared exponential kernel.
`'matern32'`	Matern kernel with parameter 3/2.
`'matern52'`	Matern kernel with parameter 5/2.
`'ardsquaredexponential'`	Squared exponential kernel with a separate length scale per predictor.
`'ardmatern32'`	Matern kernel with parameter 3/2 and a separate length scale per predictor.
`'ardmatern52'`	Matern kernel with parameter 5/2 and a separate length scale per predictor.

Function	Description
Function handle	A function handle that `fitrgp` can call like this: `Kmn = kfcn(Xm,Xn,theta)` where `Xm` is an *m*-by-*d* matrix, `Xn` is an *n*-by-*d* matrix and `Kmn` is an *m*-by-*n* matrix of kernel products such that `Kmn`(*i*,*j*) is the kernel product between `Xm`(*i*,:) and `Xn`(*j*,:). `theta` is the *r*-by-1 unconstrained parameter vector for `kfcn`.

Data Types: `char` | `function_handle`

`KernelInformation` — Information about the parameters of the kernel function

structure

Information about the parameters of the kernel function used in the GPR model, stored as a structure with the following fields.

Field Name	Description
`Name`	Name of the kernel function
`KernelParameters`	Vector of the estimated kernel parameters
`KernelParameterNames`	Names associated with the elements of `KernelParameters`.

Data Types: `struct`

Prediction

`PredictMethod` — Method used to make predictions

`'exact'` | `'bcd'` | `'sd'` | `'sr'` | `'fic'`

Method that `predict` uses to make predictions from the GPR model, stored as a character vector. It can be one of the following.

`PredictMethod`	Description
`'exact'`	Exact Gaussian process regression
`'bcd'`	Block Coordinate Descent
`'sd'`	Subset of Data points approximation
`'sr'`	Subset of Regressors approximation
`'fic'`	Fully Independent Conditional approximation

`Alpha` — Weights

numeric vector

Weights used to make predictions from the trained GPR model, stored as a numeric vector. `predict` computes the predictions for a new predictor matrix `Xnew` by using the product

$$K(X_{new}, A) * \alpha \ .$$

$K(X_{new}, A)$ is the matrix of kernel products between X_{new} and active set vector $\boldsymbol{A}$ and α is a vector of weights.

Data Types: `double`

`BCDInformation` — Information on BCD-based computation of `Alpha`
structure | `[]`

Information on block coordinate descent (BCD)-based computation of `Alpha` when `PredictMethod` is `'bcd'`, stored as a structure containing the following fields.

Field Name	Description
`Gradient`	*n*-by-1 vector containing the gradient of the BCD objective function at convergence.
`Objective`	Scalar containing the BCD objective function at convergence.
`SelectionCounts`	*n*-by-1 integer vector indicating the number of times each point was selected into a block during BCD.

`Alpha` property contains the `Alpha` vector computed from BCD.

If `PredictMethod` is not `'bcd'`, then `BCDInformation` is empty.

Data Types: `struct`

`ResponseTransform` — Transformation applied to predicted response
`'none'` (default)

Transformation applied to the predicted response, stored as a character vector describing how the response values predicted by the model are transformed. In `RegressionGP`, `ResponseTransform` is `'none'` by default, and `RegressionGP` does not use `ResponseTransform` when making predictions.

Active Set Selection

`ActiveSetVectors` — Subset of training data
matrix

Subset of training data used to make predictions from the GPR model, stored as a matrix.

`predict` computes the predictions for a new predictor matrix `Xnew` by using the product

$$K(X_{new}, A) * \alpha \ .$$

$K(X_{new}, A)$ is the matrix of kernel products between X_{new} and active set vector $\boldsymbol{A}$ and α is a vector of weights.

`ActiveSetVectors` is equal to the training data `X` for exact GPR fitting and a subset of the training data `X` for sparse GPR methods. When there are categorical predictors in the model, `ActiveSetVectors` contains dummy variables for the corresponding predictors.

Data Types: `double`

`ActiveSetHistory` — History of active set selection and parameter estimation
structure

History of interleaved active set selection and parameter estimation on page 33-5323 for `FitMethod` equal to `'sd'`, `'sr'`, or `'fic'`, stored as a structure with the following fields.

Field Name	Description
`ParameterVector`	Cell array containing the parameter vectors: basis function coefficients, β, kernel function parameters θ, and noise standard deviation σ.
`ActiveSetIndices`	Cell array containing the active set indices.
`Loglikelihood`	Vector containing the maximized log likelihoods.
`CriterionProfile`	Cell array containing the active set selection criterion values as the active set grows from size 0 to its final size.

Data Types: `struct`

`ActiveSetMethod` — Method used to select the active set
`'sgma'` | `'entropy'` | `'likelihood'` | `'random'`

Method used to select the active set for sparse methods (`'sd'`,`'sr'`, or `'fic'`), stored as a character vector. It can be one of the following.

`ActiveSetMethod`	Description
`'sgma'`	Sparse greedy matrix approximation
`'entropy'`	Differential entropy-based selection
`'likelihood'`	Subset of regressors log likelihood-based selection
`'random'`	Random selection

The selected active set is used in parameter estimation or prediction, depending on the choice of `FitMethod` and `PredictMethod` in `fitrgp`.

`ActiveSetSize` — Size of the active set
integer value

Size of the active set for sparse methods (`'sd'`,`'sr'`, or `'fic'`), stored as an integer value.

Data Types: `double`

`IsActiveSetVector` — Indicators for selected active set
logical vector

Indicators for selected active set for making predictions from the trained GPR model, stored as a logical vector. These indicators mark the subset of training data that `fitrgp` selects as the active set. For example, if `X` is the original training data, then `ActiveSetVectors = X(IsActiveSetVector,:)`.

Data Types: `logical`

Training Data

`NumObservations` — Number of observations in training data
scalar value

Number of observations in training data, stored as a scalar value.

Data Types: `double`

X — Training data
n-by-*d* table | *n*-by-*d* matrix

Training data, stored as an *n*-by-*d* table or matrix, where *n* is the number of observations and *d* is the number of predictor variables (columns) in the training data. If the GPR model is trained on a table, then `X` is a table. Otherwise, `X` is a matrix.

Data Types: `double` | `table`

Y — Observed response values
n-by-1 vector

Observed response values used to train the GPR model, stored as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `double`

`PredictorNames` — Names of predictors
cell array of character vectors

Names of predictors used in the GPR model, stored as a cell array of character vectors. Each name (cell) corresponds to a column in `X`.

Data Types: `cell`

`ExpandedPredictorNames` — Names of expanded predictors
cell array of character vectors

Names of expanded predictors for the GPR model, stored as a cell array of character vectors. Each name (cell) corresponds to a column in `ActiveSetVectors`.

If the model uses dummy variables for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

`ResponseName` — Name of the response variable
character vector

Name of the response variable in the GPR model, stored as a character vector.

Data Types: `char`

`PredictorLocation` — Means of predictors
1-by-*d* vector | `[]`

Means of predictors used for training the GPR model if the training data is standardized, stored as a 1-by-*d* vector. If the training data is not standardized, `PredictorLocation` is empty.

If `PredictorLocation` is not empty, then the `predict` method centers the predictor values by subtracting the respective element of `PredictorLocation` from every column of `X`.

If there are categorical predictors, then `PredictorLocation` includes a 0 for each dummy variable corresponding to those predictors. The dummy variables are not centered or scaled.

Data Types: `double`

`PredictorScale` — Standard deviations of predictors
1-by-*d* vector | `[ ]`

Standard deviations of predictors used for training the GPR model if the training data is standardized, stored as a 1-by-*d* vector. If the training data is not standardized, `PredictorScale` is empty.

If `PredictorScale` is not empty, the `predict` method scales the predictors by dividing every column of `X` by the respective element of `PredictorScale` (after centering using `PredictorLocation`).

If there are categorical predictors, then `PredictorLocation` includes a 1 for each dummy variable corresponding to those predictors. The dummy variables are not centered or scaled.

Data Types: `double`

`RowsUsed` — Indicators for rows used in training
logical vector | `[ ]`

Indicators for rows used in training the GPR model, stored as a logical vector. If all rows are used in training the model, then `RowsUsed` is empty.

Data Types: `logical`

Object Functions

compact	Create compact Gaussian process regression model
crossval	Cross-validate Gaussian process regression model
lime	Local interpretable model-agnostic explanations (LIME)
loss	Regression error for Gaussian process regression model
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
postFitStatistics	Compute post-fit statistics for the exact Gaussian process regression model
predict	Predict response of Gaussian process regression model
resubLoss	Resubstitution loss for a trained Gaussian process regression model
resubPredict	Resubstitution prediction from a trained Gaussian process regression model
shapley	Shapley values

More About

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (`FitMethod` equal to `'sd'`, `'sr'`, or `'fic'`), if you do not provide the active set, `fitrgp` selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector $\eta_0 = [\beta_0,\sigma_0,\theta_0]$ to select an active set A_1. It maximizes the GPR marginal log likelihood or its approximation using η_0 as the initial values and A_1 to compute the new parameter estimates η_1. Next, it computes the new log likelihood L_1 using η_1 and A_1.

In the second iteration, the software selects the active set A_2 using the parameter values in η_1. Then, using η_1 as the initial values and A_2, it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values η_2. Then using η_2 and A_2, computes the new log likelihood value L_2.

The following table summarizes the iterations and what is computed at each iteration.

Iteration Number	Active Set	Parameter Vector	Log Likelihood
1	A_1	η_1	L_1
2	A_2	η_2	L_2
3	A_3	η_3	L_3
…	…	…	…

The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the `NumActiveSetRepeats` name-value pair argument.

Tips

- You can access the properties of this class using dot notation. For example, `KernelInformation` is a structure holding the kernel parameters and their names. Hence, to access the kernel function parameters of the trained model `gprMdl`, use `gprMdl.KernelInformation.KernelParameters`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.

For more information, see “Introduction to Code Generation” on page 32-2.

Introduced in R2015b

RegressionLinear class

Linear regression model for high-dimensional data

Description

`RegressionLinear` is a trained linear model object for regression; the linear model is a support vector machine regression (SVM) or linear regression model. `fitrlinear` fits a `RegressionLinear` model by minimizing the objective function using techniques that reduce computation time for high-dimensional data sets (e.g., stochastic gradient descent). The regression loss plus the regularization term compose the objective function.

Unlike other regression models, and for economical memory usage, `RegressionLinear` model objects do not store the training data. However, they do store, for example, the estimated linear model coefficients, estimated coefficients, and the regularization strength.

You can use trained `RegressionLinear` models to predict responses for new data. For details, see `predict`.

Construction

Create a `RegressionLinear` object by using `fitrlinear`.

Properties

Linear Regression Properties

`Epsilon` — Half of width of epsilon-insensitive band

nonnegative scalar

Half of the width of the epsilon-insensitive-band, specified as a nonnegative scalar.

If `Learner` is not `'svm'`, then `Epsilon` is an empty array (`[]`).

Data Types: `single` | `double`

`Lambda` — Regularization term strength

nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as a nonnegative scalar or vector of nonnegative values.

Data Types: `double` | `single`

`Learner` — Linear regression model type

`'leastsquares'` | `'svm'`

Linear regression model type, specified as `'leastsquares'` or `'svm'`.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.

- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Loss function	FittedLoss Value
'leastsquares'	Linear regression through ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	'mse'
'svm'	Support vector machine regression	Epsilon insensitive: $\ell[y, f(x)] = \max[0, \lvert y - f(x)\rvert - \varepsilon]$	'epsiloninsensitive'

Beta — Linear coefficient estimates
numeric vector

Linear coefficient estimates, specified as a numeric vector with length equal to the number of predictors.

Data Types: double

Bias — Estimated bias term
numeric scalar

Estimated bias term or model intercept, specified as a numeric scalar.

Data Types: double

FittedLoss — Loss function used to fit the linear model
'epsiloninsensitive' | 'mse'

Loss function used to fit the model, specified as 'epsiloninsensitive' or 'mse'.

Value	Algorithm	Loss function	Learner Value
'epsiloninsensitive'	Support vector machine regression	Epsilon insensitive: $\ell[y, f(x)] = \max[0, \lvert y - f(x)\rvert - \varepsilon]$	'svm'
'mse'	Linear regression through ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	'leastsquares'

Regularization — Complexity penalty type
'lasso (L1)' | 'ridge (L2)'

Complexity penalty type, specified as 'lasso (L1)' or 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see FittedLoss) and a regularization value from this table.

Value	Description
`'lasso (L1)'`	Lasso (L_1) penalty: $\lambda \sum_{j=1}^{p} \left|\beta_j\right|$
`'ridge (L2)'`	Ridge (L_2) penalty: $\frac{\lambda}{2} \sum_{j=1}^{p} \beta_j^2$

λ specifies the regularization term strength (see `Lambda`).

The software excludes the bias term (β_0) from the regularization penalty.

Other Regression Properties

`CategoricalPredictors` — Categorical predictor indices

vector of positive integers | `[]`

Categorical predictor indices, specified as a vector of positive integers. Assuming that the predictor data contains observations in rows, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

`ModelParameters` — Parameters used for training model

structure

Parameters used for training the `RegressionLinear` model, specified as a structure.

Access fields of `ModelParameters` using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: `struct`

`PredictorNames` — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data, specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of variables in the training data `X` or `Tbl` used as predictor variables.

Data Types: `cell`

`ExpandedPredictorNames` — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

`ResponseName` — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

`ResponseTransform` — Response transformation function
`'none'` | function handle

Response transformation function, specified as `'none'` or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where `function` accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Object Functions

incrementalLearner	Convert linear regression model to incremental learner
lime	Local interpretable model-agnostic explanations (LIME)
loss	Regression loss for linear regression models
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Predict response of linear regression model
selectModels	Select fitted regularized linear regression models
shapley	Shapley values
update	Update model parameters for code generation

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = x_1, \ldots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. By default, `fitrlinear` uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
[Mdl,FitInfo] = fitrlinear(X,Y)
```

```
Mdl =
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x1 double]
                 Bias: -0.0056
               Lambda: 1.0000e-04
              Learner: 'svm'

  Properties, Methods

FitInfo = struct with fields:
                    Lambda: 1.0000e-04
                 Objective: 0.2725
                 PassLimit: 10
                 NumPasses: 10
                BatchLimit: []
             NumIterations: 100000
              GradientNorm: NaN
         GradientTolerance: 0
       RelativeChangeInBeta: 0.4907
             BetaTolerance: 1.0000e-04
             DeltaGradient: 1.5816
    DeltaGradientTolerance: 0
           TerminationCode: 0
         TerminationStatus: {'Iteration limit exceeded.'}
                     Alpha: [10000x1 double]
                   History: []
                   FitTime: 0.1318
                    Solver: {'dual'}
```

`Mdl` is a `RegressionLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample mean-squared error. Or, you can pass `Mdl` and new predictor data to `predict` to predict responses for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. In this case, `fitrlinear` reached the maximum number of iterations. Because training time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as LBFGS.

Predict Responses Using Linear Regression Model

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = \{x_1, \ldots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Hold out 5% of the data.

```
rng(1); % For reproducibility
cvp = cvpartition(n,'Holdout',0.05)
```

```
cvp =
Hold-out cross validation partition
   NumObservations: 10000
       NumTestSets: 1
         TrainSize: 9500
          TestSize: 500
```

`cvp` is a `CVPartition` object that defines the random partition of n data into training and test sets.

Train a linear regression model using the training set. For faster training time, orient the predictor data matrix so that the observations are in columns.

```
idxTrain = training(cvp); % Extract training set indices
X = X';
Mdl = fitrlinear(X(:,idxTrain),Y(idxTrain),'ObservationsIn','columns');
```

Predict observations and the mean squared error (MSE) for the hold out sample.

```
idxTest = test(cvp); % Extract test set indices
yHat = predict(Mdl,X(:,idxTest),'ObservationsIn','columns');
L = loss(Mdl,X(:,idxTest),Y(idxTest),'ObservationsIn','columns')
```

```
L = 0.1851
```

The hold-out sample MSE is 0.1852.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train a linear regression model by using `fitrlinear`, the following restrictions apply.
  - If the predictor data input argument value is a matrix, it must be a full, numeric matrix. Code generation does not support sparse data.

- You can specify only one regularization strength, either `'auto'` or a nonnegative scalar for the `'Lambda'` name-value pair argument.
- The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function.
- Code generation with a coder configurer does not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). You cannot use the `'CategoricalPredictors'` name-value argument. To include categorical predictors in a model, preprocess them by using `dummyvar` before fitting the model.

For more information, see “Introduction to Code Generation” on page 32-2.

RegressionLinearCoderConfigurer

Coder configurer for linear regression model with high-dimensional data

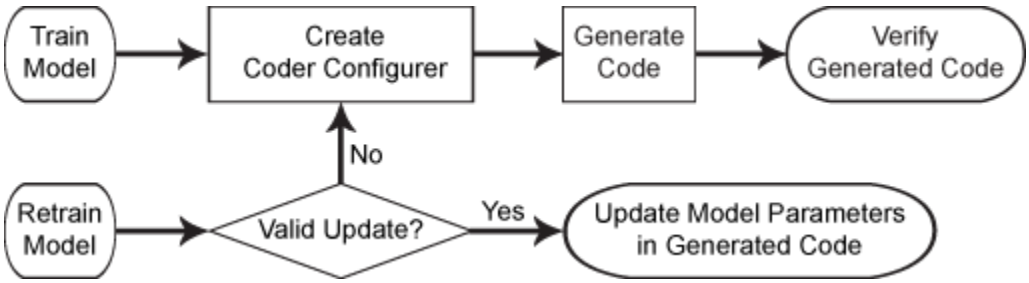
Description

A `RegressionLinearCoderConfigurer` object is a coder configurer of a linear regression model (`RegressionLinear`) with high-dimensional data.

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes for linear model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the linear regression model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the linear model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.



For the code generation usage notes and limitations of a linear regression model, see the Code Generation sections of `RegressionLinear`, `predict`, and `update`.

Creation

After training a linear regression model by using `fitrlinear`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of the `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

`LearnerCoderInput` object

Coder attributes of the predictor data to pass to the generated C/C++ code for the `predict` function of the linear regression model, specified as a `LearnerCoderInput` on page 33-5343 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
  - If the `Value` attribute of the `ObservationsIn` property for the `RegressionLinearCoderConfigurer` is `'rows'`, then this `SizeVector` value is `[n p]`, where `n` corresponds to the number of observations and `p` corresponds to the number of predictors.
  - If the `Value` attribute of the `ObservationsIn` property for the `RegressionLinearCoderConfigurer` is `'columns'`, then this `SizeVector` value is `[p n]`.

  To switch the elements of `SizeVector` (for example, to change `[n p]` to `[p n]`), modify the `Value` attribute of the `ObservationsIn` property for the `RegressionLinearCoderConfigurer` accordingly. You cannot modify the `SizeVector` value directly.
- `VariableDimensions` — The default value is `[0 0]`, which indicates that the array size is fixed as specified in `SizeVector`.

  You can set this value to `[1 0]` if the `SizeVector` value is `[n p]` or to `[0 1]` if it is `[p n]`, which indicates that the array has variable-size rows and fixed-size columns. For example, `[1 0]` specifies that the first value of `SizeVector` (`n`) is the upper bound for the number of rows, and the second value of `SizeVector` (`p`) is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations (in rows) of three predictor variables (in columns), specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of

observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

`ObservationsIn` — Coder attributes of predictor data observation dimension
`EnumeratedInput` object

Coder attributes of the predictor data observation dimension (`'ObservationsIn'` name-value pair argument of `predict`), specified as an `EnumeratedInput` on page 33-5343 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the `'ObservationsIn'` name-value pair argument determines the default values of the `EnumeratedInput` coder attributes:

- `Value` — The default value is the predictor data observation dimension you use when creating the coder configurer, specified as `'rows'` or `'columns'`. If you do not specify `'ObservationsIn'` when creating the coder configurer, the default value is `'rows'`.
- `SelectedOption` — This value is always `'Built-in'`. This attribute is read-only.
- `BuiltInOptions` — Cell array of `'rows'` and `'columns'`. This attribute is read-only.
- `IsConstant` — This value must be `true`.
- `Tunability` — The default value is `false` if you specify `'ObservationsIn','rows'` when creating the coder configurer, and `true` if you specify `'ObservationsIn','columns'`. If you set `Tunability` to `false`, the software sets `Value` to `'rows'`. If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

`NumOutputs` — Number of outputs in `predict`
1 (default)

Number of output arguments to return from the generated C/C++ code for the `predict` function of the linear regression model, specified as 1. `predict` returns `YHat` (predicted responses) in the generated C/C++ code.

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of a linear regression model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

`update` Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 33-5343 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

`Beta` — Coder attributes of linear predictor coefficients
`LearnerCoderInput` object

Coder attributes of the linear predictor coefficients (`Beta` of a linear regression model), specified as a `LearnerCoderInput` on page 33-5343 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[p 1]`, where `p` is the number of predictors in `Mdl`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

`Bias` — Coder attributes of bias term
`LearnerCoderInput` object

Coder attributes of the bias term (`Bias` of a linear regression model), specified as a `LearnerCoderInput` on page 33-5343 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[1 1]`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

Other Configurer Options

`OutputFileName` — File name of generated C/C++ code
`'RegressionLinearModel'` (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `RegressionLinearCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

`Verbose` — Verbosity level
`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
`true` (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
`false` (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

`CodeGenerationArguments` — `codegen` arguments
cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

`PredictInputs` — List of tunable input arguments of `predict`
cell array

This property is read-only.

List of tunable input arguments of the entry-point function `predict.m` for code generation, specified as a cell array. The cell array contains another cell array that includes `coder.PrimitiveType` objects and `coder.Constant` objects.

If you modify the coder attributes of `predict` arguments on page 33-5332, then the software updates the corresponding objects accordingly. If you specify the `Tunability` attribute as `false`, then the software removes the corresponding objects from the `PredictInputs` list.

The cell array in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

`UpdateInputs` — List of tunable input arguments of `update`
cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (`update` Arguments on page 33-5334 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

generateCode	Generate C/C++ code using coder configurer
generateFiles	Generate MATLAB files for code generation using coder configurer
validatedUpdateInputs	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Simulate 10,000 observations from the model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = x_1, \ldots, x_{1000}$ is a 10,000-by-1000 numeric matrix with standard normal elements.
- e is a random normal error with mean 0 and standard deviation 0.3.

```
rng('default') % For reproducibility
n = 10000;
p = 1000;
X = randn(n,p);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model using the simulated data. Pass the transposed predictor matrix `Xnew` to `fitrlinear`, and use the `'ObservationsIn'` name-value pair argument to specify that the columns of `Xnew` correspond to observations.

```
Xnew = X';
Mdl = fitrlinear(Xnew,Y,'ObservationsIn','columns');
```

`Mdl` is a `RegressionLinear` object.

Create a coder configurer for the `RegressionLinear` model by using `learnerCoderConfigurer`. Specify the predictor data `Xnew`, and use the `'ObservationsIn'` name-value pair argument to specify the observation dimension of `Xnew`. The `learnerCoderConfigurer` function uses these input arguments to configure the coder attributes of the corresponding input arguments of `predict`.

```
configurer = learnerCoderConfigurer(Mdl,Xnew,'ObservationsIn','columns')
```

```
configurer =
  RegressionLinearCoderConfigurer with properties:

   Update Inputs:
              Beta: [1x1 LearnerCoderInput]
              Bias: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]
    ObservationsIn: [1x1 EnumeratedInput]

   Code Generation Parameters:
        NumOutputs: 1
    OutputFileName: 'RegressionLinearModel'

  Properties, Methods
```

`configurer` is a `RegressionLinearCoderConfigurer` object, which is a coder configurer of a `RegressionLinear` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the linear regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionLinearModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionLinearModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionLinearModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:17
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:17
initialize('update',varargin{:});
end
```

```
type initialize.m
```

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:17
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionLinearModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Beta
        %                       Bias
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X, ObservationsIn
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end
```

Update Parameters of Linear Regression Model in Generated Code

Train a linear regression model using a partial data set, and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the linear regression model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the entire data set, and update parameters in the generated code without regenerating the code.

Train Model

Simulate 10,000 observations from the model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = x_1, \ldots, x_{1000}$ is a 10,000-by-1000 numeric matrix with standard normal elements.
- e is a random normal error with mean 0 and standard deviation 0.3.

```
rng('default') % For reproducibility
n = 10000;
p = 1000;
X = randn(n,p);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model using the first 500 observations. Transpose the predictor data, and use the `'ObservationsIn'` name-value pair argument to specify that the columns of `XTrain` correspond to observations.

```
XTrain = X(1:500,:)';
YTrain = Y(1:500);
Mdl = fitrlinear(XTrain,YTrain,'ObservationsIn','columns');
```

`Mdl` is a `RegressionLinear` object.

Create Coder Configurer

Create a coder configurer for the `RegressionLinear` model by using `learnerCoderConfigurer`. Specify the predictor data `XTrain`, and use the `'ObservationsIn'` name-value pair argument to specify the observation dimension of `XTrain`. The `learnerCoderConfigurer` function uses these input arguments to configure the coder attributes of the corresponding input arguments of `predict`.

```
configurer = learnerCoderConfigurer(Mdl,XTrain,'ObservationsIn','columns');
```

`configurer` is a `RegressionLinearCoderConfigurer` object, which is a coder configurer of a `RegressionLinear` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the linear regression model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of the predictor data that you want to pass to the generated code.

Specify the coder attributes of the `X` property of `configurer` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The

`SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [1000 Inf];
configurer.X.VariableDimensions
```

```
ans = 1x2 logical array

   0   1
```

The size of the first dimension is the number of predictor variables. This value must be fixed for a machine learning model. Because the predictor data contains 1000 predictors, the value of the `SizeVector` attribute must be 1000 and the value of the `VariableDimensions` attribute must be `0`.

The size of the second dimension is the number of observations. Setting the value of the `SizeVector` attribute to `Inf` causes the software to change the value of the `VariableDimensions` attribute to `1`. In other words, the upper bound of the size is `Inf` and the size is variable, meaning that the predictor data can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The order of the dimensions in `SizeVector` and `VariableDimensions` depends on the coder attributes of `ObservationsIn`.

```
configurer.ObservationsIn
```

```
ans =
  EnumeratedInput with properties:

             Value: 'columns'
    SelectedOption: 'Built-in'
    BuiltInOptions: {'rows'  'columns'}
        IsConstant: 1
        Tunability: 1
```

When the `Value` attribute of the `ObservationsIn` property is `'columns'`, the first dimension of the `SizeVector` and `VariableDimensions` attributes of `X` corresponds to the number of predictors, and the second dimension corresponds to the number of observations. When the `Value` attribute of `ObservationsIn` is `'rows'`, the order of the dimensions is switched.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the linear regression model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionLinearModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionLinearModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionLinearModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
YHat = predict(Mdl,XTrain,'ObservationsIn','columns');
YHat_mex = RegressionLinearModel('predict',XTrain,'ObservationsIn','columns');
```

Compare `YHat` and `YHat_mex`.

```
max(abs(YHat-YHat_mex))
```

```
ans = 0
```

In general, `YHat_mex` might include round-off differences compared to `YHat`. In this case, the comparison confirms that `YHat` and `YHat_mex` are equal.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrlinear(X',Y,'ObservationsIn','columns');
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionLinearModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
YHat = predict(retrainedMdl,X','ObservationsIn','columns');
YHat_mex = RegressionLinearModel('predict',X','ObservationsIn','columns');
max(abs(YHat-YHat_mex))
```

```
ans = 0
```

The comparison confirms that `YHat` and `YHat_mex` are equal.

More About

`LearnerCoderInput` Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
`SizeVector`	Array size if the corresponding `VariableDimensions` value is `false`. Upper bound of the array size if the corresponding `VariableDimensions` value is `true`. To allow an unbounded array, specify the bound as `Inf`.
`VariableDimensions`	Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as `true` (logical 1) or `false` (logical 0): • A value of `true` (logical 1) means that the corresponding dimension has a variable size. • A value of `false` (logical 0) means that the corresponding dimension has a fixed size.
`DataType`	Data type of the array
`Tunability`	Indicator specifying whether or not `predict` or `update` includes the argument as an input in the generated code, specified as `true` (logical 1) or `false` (logical 0). If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the data type of the bias term `Bias` of the coder configurer `configurer`:

```
configurer.Bias.DataType = 'single';
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

`EnumeratedInput` Object

A coder configurer uses an `EnumeratedInput` object to specify the coder attributes of `predict` input arguments that have a finite set of available values.

An `EnumeratedInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description

`Value`	Value of the `predict` argument in the generated code, specified as a character vector or a `LearnerCoderInput` on page 33-5343 object.
	• Character vector in `BuiltInOptions` — You can specify one of the `BuiltInOptions` using either the option name or its index value. For example, to choose the first option, specify `Value` as either the first character vector in `BuiltInOptions` or `1`.
	• Character vector designating a custom function name — To use a custom option, define a custom function on the MATLAB search path, and specify `Value` as the name of the custom function.
	• `LearnerCoderInput` on page 33-5343 object — If you set `IsConstant` to `false` (logical 0), then the software changes `Value` to a `LearnerCoderInput` on page 33-5343 object with the following read-only coder attribute values. These values indicate that the input in the generated code is a variable-size, tunable character vector that is one of the available values in `BuiltInOptions`.
	  • `SizeVector` — `[1 c]`, indicating the upper bound of the array size, where `c` is the length of the longest available character vector in `Option`
	  • `VariableDimensions` — `[0 1]`, indicating that the array is a variable-size vector
	  • `DataType` — `'char'`
	  • `Tunability` — 1
	The default value of `Value` is consistent with the default value of the corresponding `predict` argument, which is one of the character vectors in `BuiltInOptions`.

`SelectedOption`	Status of the selected option, specified as `'Built-in'`, `'Custom'`, or `'NonConstant'`. The software sets `SelectedOption` according to `Value`: • `'Built-in'`(default) — When `Value` is one of the character vectors in `BuiltInOptions` • `'Custom'` — When `Value` is a character vector that is not in `BuiltInOptions` • `'NonConstant'` — When `Value` is a `LearnerCoderInput` on page 33-5343 object This attribute is read-only.
`BuiltInOptions`	List of available character vectors for the corresponding `predict` argument, specified as a cell array. This attribute is read-only.

Attribute Name	Description
`IsConstant`	Indicator specifying whether or not the array value is a compile-time constant (`coder.Constant`) in the generated code, specified as `true` (logical 1, default) or `false` (logical 0). If you set this value to `false`, then the software changes `Value` to a `LearnerCoderInput` on page 33-5343 object.
`Tunability`	Indicator specifying whether or not `predict` includes the argument as an input in the generated code, specified as `true` (logical 1) or `false` (logical 0, default). If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of `ObservationsIn` of the coder configurer `configurer`:

```
configurer.ObservationsIn.Value = 'columns';
```

RegressionNeuralNetwork

Neural network model for regression

Description

A `RegressionNeuralNetwork` object is a trained, feedforward, and fully connected neural network for regression. The first fully connected layer of the neural network has a connection from the network input (predictor data `X`), and each subsequent layer has a connection from the previous layer. Each fully connected layer multiplies the input by a weight matrix (`LayerWeights`) and then adds a bias vector (`LayerBiases`). An activation function follows each fully connected layer, excluding the last (`Activations` and `OutputLayerActivation`). The final fully connected layer produces the network's output, namely predicted response values. For more information, see “Neural Network Structure” on page 33-2239.

Creation

Create a `RegressionNeuralNetwork` object by using `fitrnet`.

Properties

Neural Network Properties

`LayerSizes` — Sizes of fully connected layers
positive integer vector

This property is read-only.

Sizes of the fully connected layers in the neural network model, returned as a positive integer vector. The *i*th element of `LayerSizes` is the number of outputs in the *i*th fully connected layer of the neural network model.

`LayerSizes` does not include the size of the final fully connected layer. This layer always has one output.

Data Types: `single` | `double`

`LayerWeights` — Learned layer weights
cell array

This property is read-only.

Learned layer weights for fully connected layers, returned as a cell array. The *i*th entry in the cell array corresponds to the layer weights for the *i*th fully connected layer. For example, `Mdl.LayerWeights{1}` returns the weights for the first fully connected layer of the model `Mdl`.

`LayerWeights` includes the weights for the final fully connected layer.

Data Types: `cell`

`LayerBiases` — Learned layer biases

cell array

This property is read-only.

Learned layer biases for fully connected layers, returned as a cell array. The *i*th entry in the cell array corresponds to the layer biases for the *i*th fully connected layer. For example, `Mdl.LayerBiases{1}` returns the biases for the first fully connected layer of the model `Mdl`.

`LayerBiases` includes the biases for the final fully connected layer.

Data Types: `cell`

`Activations` — Activation functions for fully connected layers

`'relu'` | `'tanh'` | `'sigmoid'` | `'none'` | cell array of character vectors

This property is read-only.

Activation functions for the fully connected layers of the neural network model, returned as a character vector or cell array of character vectors with values from this table.

Value	Description
`'relu'`	Rectified linear unit (ReLU) function — Performs a threshold operation on each element of the input, where any value less than zero is set to zero, that is, $$f(x) = \begin{cases} x, & x \geq 0 \\ 0, & x < 0 \end{cases}$$
`'tanh'`	Hyperbolic tangent (tanh) function — Applies the `tanh` function to each input element
`'sigmoid'`	Sigmoid function — Performs the following operation on each input element: $$f(x) = \frac{1}{1 + e^{-x}}$$
`'none'`	Identity function — Returns each input element without performing any transformation, that is, $f(x) = x$

- If `Activations` contains only one activation function, then it is the activation function for every fully connected layer of the neural network model, excluding the final fully connected layer, which does not have an activation function (`OutputLayerActivation`).
- If `Activations` is an array of activation functions, then the *i*th element is the activation function for the *i*th layer of the neural network model.

Data Types: `char` | `cell`

`OutputLayerActivation` — Activation function for final fully connected layer

`'none'`

This property is read-only.

Activation function for final fully connected layer, returned as `'none'`.

`ModelParameters` — Parameter values used to train model

`NeuralNetworkParams` object

This property is read-only.

Parameter values used to train the `RegressionNeuralNetwork` model, returned as a `NeuralNetworkParams` object. `ModelParameters` contains parameter values such as the name-value arguments used to train the regression neural network model.

Access the properties of `ModelParameters` by using dot notation. For example, access the function used to initialize the fully connected layer weights of a model `Mdl` by using `Mdl.ModelParameters.LayerWeightsInitializer`.

Convergence Control Properties

`ConvergenceInfo` — Convergence information

structure array

This property is read-only.

Convergence information, returned as a structure array.

Field	Description
`Iterations`	Number of training iterations used to train the neural network model
`TrainingLoss`	Training mean squared error (MSE) for the returned model, or `resubLoss(Mdl)` for model `Mdl`
`Gradient`	Gradient of the loss function with respect to the weights and biases at the iteration corresponding to the returned model
`Step`	Step size at the iteration corresponding to the returned model
`Time`	Total time spent across all iterations (in seconds)
`ValidationLoss`	Validation MSE for the returned model
`ValidationChecks`	Maximum number of times in a row that the validation loss was greater than or equal to the minimum validation loss
`ConvergenceCriterion`	Criterion for convergence
`History`	See `TrainingHistory`

Data Types: `struct`

`TrainingHistory` — Training history

table

This property is read-only.

Training history, returned as a table.

Column	Description
`Iteration`	Training iteration
`TrainingLoss`	Training mean squared error (MSE) for the model at this iteration
`Gradient`	Gradient of the loss function with respect to the weights and biases at this iteration
`Step`	Step size at this iteration
`Time`	Time spent during this iteration (in seconds)
`ValidationLoss`	Validation MSE for the model at this iteration
`ValidationChecks`	Running total of times that the validation loss is greater than or equal to the minimum validation loss

Data Types: `table`

`Solver` — Solver used to train neural network model
`'LBFGS'`

This property is read-only.

Solver used to train the neural network model, returned as `'LBFGS'`. To create a `RegressionNeuralNetwork` model, `fitrnet` uses a limited-memory Broyden-Flecter-Goldfarb-Shanno quasi-Newton algorithm (LBFGS) as its loss function minimization technique, where the software minimizes the mean squared error (MSE).

Predictor Properties

`PredictorNames` — Predictor variable names
cell array of character vectors

This property is read-only.

Predictor variable names, returned as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Data Types: `cell`

`CategoricalPredictors` — Categorical predictor indices
vector of positive integers | `[]`

This property is read-only.

Categorical predictor indices, returned as a vector of positive integers. Assuming that the predictor data contains observations in rows, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `double`

`ExpandedPredictorNames` — Expanded predictor names
cell array of character vectors

This property is read-only.

Expanded predictor names, returned as a cell array of character vectors. If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

`X` — Unstandardized predictors
numeric matrix | table

This property is read-only.

Unstandardized predictors used to train the neural network model, returned as a numeric matrix or table. `X` retains its original orientation, with observations in rows or columns depending on the value of the `ObservationsIn` name-value argument in the call to `fitrnet`.

Data Types: `single` | `double` | `table`

Response Properties

`ResponseName` — Response variable name
character vector

This property is read-only.

Response variable name, returned as a character vector.

Data Types: `char`

`Y` — Response values
numeric vector

This property is read-only.

Response values used to train the model, returned as a numeric vector. Each row of `Y` represents the response value of the corresponding observation in `X`.

Data Types: `single` | `double`

`ResponseTransform` — Response transformation function
`'none'`

This property is read-only.

Response transformation function, returned as `'none'`. The software does not transform the raw response values.

Other Data Properties

`NumObservations` — Number of observations
positive numeric scalar

This property is read-only.

Number of observations in the training data stored in `X` and `Y`, returned as a positive numeric scalar.

Data Types: `double`

RowsUsed — Rows used in fitting

[] | logical vector

This property is read-only.

Rows of the original training data used in fitting the model, returned as a logical vector. This property is empty if all rows are used.

Data Types: `logical`

W — Observation weights

numeric vector

This property is read-only.

Observation weights used to train the model, returned as an *n*-by-1 numeric vector. *n* is the number of observations (`NumObservations`).

The software normalizes the observation weights specified in the `Weights` name-value argument so that the elements of `W` sum up to 1.

Data Types: `single` | `double`

Object Functions

compact	Reduce size of machine learning model
crossval	Cross-validate machine learning model
loss	Loss for regression neural network
resubLoss	Resubstitution regression loss
resubPredict	Predict responses for training data using trained regression model
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Predict responses using regression neural network

Examples

Train Neural Network Regression Model

Train a neural network regression model, and assess the performance of the model on a test set.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s. Create a table containing the predictor variables `Acceleration`, `Displacement`, and so on, as well as the response variable `MPG`.

```
load carbig
cars = table(Acceleration,Displacement,Horsepower, ...
    Model_Year,Origin,Weight,MPG);
```

Partition the data into training and test sets. Use approximately 80% of the observations to train a neural network model, and 20% of the observations to test the performance of the trained model on new data. Use `cvpartition` to partition the data.

```
rng("default") % For reproducibility of the data partition
c = cvpartition(length(MPG),"Holdout",0.20);
```

```
trainingIdx = training(c); % Training set indices
carsTrain = cars(trainingIdx,:);
testIdx = test(c); % Test set indices
carsTest = cars(testIdx,:);
```

Train a neural network regression model by passing the `carsTrain` training data to the `fitrnet` function. For better results, specify to standardize the predictor data.

```
Mdl = fitrnet(carsTrain,"MPG","Standardize",true)
```

```
Mdl =
  RegressionNeuralNetwork
           PredictorNames: {'Acceleration'  'Displacement'  'Horsepower'  'Model_Year'  'Origin'
             ResponseName: 'MPG'
    CategoricalPredictors: 5
        ResponseTransform: 'none'
          NumObservations: 314
               LayerSizes: 10
              Activations: 'relu'
    OutputLayerActivation: 'linear'
                   Solver: 'LBFGS'
         ConvergenceInfo: [1×1 struct]
         TrainingHistory: [1000×7 table]

  Properties, Methods
```

`Mdl` is a trained `RegressionNeuralNetwork` model. You can use dot notation to access the properties of `Mdl`. For example, you can specify `Mdl.TrainingHistory` to get more information about the training history of the neural network model.

Evaluate the performance of the regression model on the test set by computing the test mean squared error (MSE). Smaller MSE values indicate better performance.

```
testMSE = loss(Mdl,carsTest,"MPG")
```

```
testMSE = 16.6154
```

Specify Neural Network Regression Model Architecture

Specify the structure of the neural network regression model, including the size of the fully connected layers.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s. Create a matrix `X` containing the predictor variables `Acceleration`, `Cylinders`, and so on. Store the response variable `MPG` in the variable `Y`.

```
load carbig
X = [Acceleration Cylinders Displacement Weight];
Y = MPG;
```

Partition the data into training data (`XTrain` and `YTrain`) and test data (`XTest` and `YTest`). Reserve approximately 20% of the observations for testing, and use the rest of the observations for training.

```
rng("default") % For reproducibility of the partition
c = cvpartition(length(Y),"Holdout",0.20);
trainingIdx = training(c); % Indices for the training set
XTrain = X(trainingIdx,:);
YTrain = Y(trainingIdx);
testIdx = test(c); % Indices for the test set
XTest = X(testIdx,:);
YTest = Y(testIdx);
```

Train a neural network regression model. Specify to standardize the predictor data, and to have 30 outputs in the first fully connected layer and 10 outputs in the second fully connected layer. By default, both layers use a rectified linear unit (ReLU) activation function. You can change the activation functions for the fully connected layers by using the `Activations` name-value argument.

```
Mdl = fitrnet(XTrain,YTrain,"Standardize",true, ...
    "LayerSizes",[30 10])
```

```
Mdl =
  RegressionNeuralNetwork
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
          NumObservations: 318
              LayerSizes: [30 10]
             Activations: 'relu'
    OutputLayerActivation: 'linear'
                  Solver: 'LBFGS'
          ConvergenceInfo: [1×1 struct]
          TrainingHistory: [1000×7 table]

  Properties, Methods
```

Access the weights and biases for the fully connected layers of the trained model by using the `LayerWeights` and `LayerBiases` properties of `Mdl`. The first two elements of each property correspond to the values for the first two fully connected layers, and the third element corresponds to the values for the final fully connected layer for regression. For example, display the weights and biases for the first fully connected layer.

```
Mdl.LayerWeights{1}
```

```
ans = 30×4

   -1.0617    0.1287    0.0797    0.4648
   -0.6497   -1.4565   -2.6026    2.6962
   -0.6420    0.2744   -0.0234   -0.0252
   -1.9727   -0.4665   -0.5833    0.9371
   -0.4373    0.1607    0.3930    0.7859
    0.5091   -0.0032   -0.6503   -1.6694
    0.0123   -0.2624   -2.2928   -1.0965
   -0.1386    1.2747    0.4085    0.5395
   -0.1755    1.5641   -3.1896   -1.1336
    0.4401    0.4942    1.8957   -1.1617
      ⋮
```

```
Mdl.LayerBiases{1}
```

```
ans = 30×1

   -1.3086
   -1.6205
   -0.7815
    1.5382
   -0.5256
    1.2394
   -2.3078
   -1.0709
   -1.8898
    1.9443
      ⋮
```

The final fully connected layer has one output. The number of layer outputs corresponds to the first dimension of the layer weights and layer biases.

```
size(Mdl.LayerWeights{end})
```

```
ans = 1×2

     1    10
```

```
size(Mdl.LayerBiases{end})
```

```
ans = 1×2

     1     1
```

To estimate the performance of the trained model, compute the test set mean squared error (MSE) for `Mdl`. Smaller MSE values indicate better performance.

```
testMSE = loss(Mdl,XTest,YTest)
```

```
testMSE = 17.2022
```

Compare the predicted test set response values to the true response values. Plot the predicted miles per gallon (MPG) along the vertical axis and the true MPG along the horizontal axis. Points on the reference line indicate correct predictions. A good model produces predictions that are scattered near the line.

```
testPredictions = predict(Mdl,XTest);
plot(YTest,testPredictions,".")
hold on
plot(YTest,YTest)
hold off
xlabel("True MPG")
ylabel("Predicted MPG")
```

Introduced in R2021a

RegressionPartitionedEnsemble

Package: `classreg.learning.partition`
Superclasses: `RegressionPartitionedModel`

Cross-validated regression ensemble

Description

`RegressionPartitionedEnsemble` is a set of regression ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more "kfold" methods: `kfoldfun`, `kfoldLoss`, or `kfoldPredict`. Every "kfold" method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on `X` and `Y` with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on `X` and `Y` with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

Construction

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. For syntax details, see the `crossval` method reference page.

`cvens = fitrensemble(X,Y,Name,Value)` creates a cross-validated ensemble when `Name` is one of `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. For syntax details, see the `fitrensemble` function reference page.

Input Arguments

`ens`

A regression ensemble constructed with `fitrensemble`.

Properties

`BinEdges`

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`CrossValidatedModel`

Name of the cross-validated model, a character vector.

`Kfold`

Number of folds used in a cross-validated tree, a positive integer.

`ModelParameters`

Object holding parameters of `tree`.

`NumObservations`

Numeric scalar containing the number of observations in the training data.

`NumTrainedPerFold`

Vector of `Kfold` elements. Each entry contains the number of trained learners in this cross-validation fold.

`Partition`

The partition of class `cvpartition` used in creating the cross-validated ensemble.

`PredictorNames`

A cell array of names for the predictor variables, in the order in which they appear in `X`.

ResponseName

Name of the response variable `Y`, a character vector.

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. `'none'` means no transformation; equivalently, `'none'` means `@(x)x`.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trainable

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.

Trained

Cell array of compact ensembles trained on cross-validation folds.

W

The scaled `weights`, a vector with length `n`, the number of rows in `X`.

X

A matrix or table of predictor values. Each column of `X` represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

Object Functions

kfoldLoss	Loss for cross-validated partitioned regression model
kfoldPredict	Predict responses for observations in cross-validated regression model
kfoldfun	Cross-validate function for regression
resume	Resume training ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Construct Partitioned Regression Ensemble

Construct a partitioned regression ensemble, and examine the cross-validation losses for the folds.

Load the `carsmall` data set.

```
load carsmall;
```

Create a subset of variables.

```
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
```

Construct the ensemble model.

```
rens = fitrensemble(XX,YY);
```

Create a cross-validated ensemble from `rens`.

```
rng(10,'twister') % For reproducibility
cvrens = crossval(rens);
```

Examine the cross-validation losses.

```
L = kfoldLoss(cvrens,'mode','individual')
```

```
L = 10×1

   21.4489
   48.4388
   28.2560
   17.5354
   29.9441
   49.5254
   51.2372
   31.0152
   31.6388
    8.9607
```

L is a vector containing the cross-validation loss for each trained learner in the ensemble.

RegressionPartitionedGAM

Cross-validated generalized additive model (GAM) for regression

Description

`RegressionPartitionedGAM` is a set of generalized additive models trained on cross-validated folds. Estimate the quality of the cross-validated regression by using one or more *kfold* functions: `kfoldPredict`, `kfoldLoss`, and `kfoldfun`.

Every *kfold* object function uses models trained on training-fold (in-fold) observations to predict the response for validation-fold (out-of-fold) observations. For example, suppose you cross-validate using five folds. The software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (roughly 4/5 of the data), and the validation fold contains the other group (roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

1. The software trains the first model (stored in `CVMdl.Trained{1}`) by using the observations in the last four groups, and reserves the observations in the first group for validation.
2. The software trains the second model (stored in `CVMdl.Trained{2}`) by using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
3. The software proceeds in a similar manner for the third, fourth, and fifth models.

If you validate by using `kfoldPredict`, the software computes predictions for the observations in group *i* by using the *i*th model. In short, the software estimates a response for every observation by using the model trained without that observation.

Creation

You can create a `RegressionPartitionedGAM` model in two ways:

- Create a cross-validated model from a GAM object `RegressionGAM` by using the `crossval` object function.
- Create a cross-validated model by using the `fitrgam` function and specifying one of the name-value arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Properties

Cross-Validation Properties

`CrossValidatedModel` — Cross-validated model name
`'GAM'`

This property is read-only.

Cross-validated model name, specified as `'GAM'`.

`KFold` — Number of cross-validated folds
positive integer

This property is read-only.

Number of cross-validated folds, specified as a positive integer.

Data Types: `double`

`ModelParameters` — Cross-validation parameter values
object

This property is read-only.

Cross-validation parameter values, specified as an object. The parameter values correspond to the values of the name-value arguments used to cross-validate the generalized additive model. `ModelParameters` does not contain estimated parameters.

You can access the properties of `ModelParameters` using dot notation.

`Partition` — Data partition
`cvpartition` model

This property is read-only.

Data partition indicating how the software splits the data into cross-validation folds, specified as a `cvpartition` model.

`Trained` — Compact models trained on cross-validation folds
cell array of `CompactRegressionGAM` models

This property is read-only.

Compact models trained on cross-validation folds, specified as a cell array of `CompactRegressionGAM` model objects. `Trained` has k cells, where k is the number of folds.

Data Types: `cell`

Other Regression Properties

`CategoricalPredictors` — Categorical predictor indices
vector of positive integers | `[]`

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `double`

`NumObservations` — Number of observations
numeric scalar

This property is read-only.

Number of observations in the training data stored in `X` and `Y`, specified as a numeric scalar.

Data Types: `double`

`PredictorNames` — Predictor variable names
cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the training data.

Data Types: `cell`

`ResponseName` — Response variable name
character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

`ResponseTransform` — Response transformation function
`'none'` | function handle

Response transformation function, specified as `'none'` or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @`*`function`*, where *`function`* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

`W` — Observation weights
numeric vector

This property is read-only.

Observation weights used to train the model, specified as an *n*-by-1 numeric vector. *n* is the number of observations (`NumObservations`).

The software normalizes the observation weights specified in the `'Weights'` name-value argument so that the elements of `W` sum up to 1.

Data Types: `double`

`X` — Predictors
numeric matrix | table

This property is read-only.

Predictors used to cross-validate the model, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

Data Types: `single` | `double` | `table`

`Y` — Response
numeric vector

This property is read-only.

Response used to cross-validate the model, specified as a numeric vector.

Each row of `Y` represents the observed response of the corresponding row of `X`.

Data Types: `single` | `double`

Object Functions

kfoldPredict	Predict responses for observations in cross-validated regression model
kfoldLoss	Loss for cross-validated partitioned regression model
kfoldfun	Cross-validate function for regression

Examples

Create Cross-Validated GAM Using `fitrgam`

Train a cross-validated GAM with 10 folds, which is the default cross-validation option, by using `fitrgam`. Then, use `kfoldPredict` to predict responses for validation-fold observations using a model trained on training-fold observations.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table that contains the predictor variables (`Acceleration`, `Displacement`, `Horsepower`, and `Weight`) and the response variable (`MPG`).

```
tbl = table(Acceleration,Displacement,Horsepower,Weight,MPG);
```

Create a cross-validated GAM by using the default cross-validation option. Specify the `'CrossVal'` name-value argument as `'on'`.

```
rng('default') % For reproducibility
CVMdl = fitrgam(tbl,'MPG','CrossVal','on')
```

```
CVMdl =
  RegressionPartitionedGAM
    CrossValidatedModel: 'GAM'
         PredictorNames: {1x4 cell}
           ResponseName: 'MPG'
        NumObservations: 398
                  KFold: 10
              Partition: [1x1 cvpartition]
      NumTrainedPerFold: [1x1 struct]
      ResponseTransform: 'none'

  Properties, Methods
```

The `fitrgam` function creates a `RegressionPartitionedGAM` model object `CVMdl` with 10 folds. During cross-validation, the software completes these steps:

1. Randomly partition the data into 10 sets.
2. For each set, reserve the set as validation data, and train the model using the other 9 sets.
3. Store the 10 compact, trained models a in a 10-by-1 cell vector in the `Trained` property of the cross-validated model object `RegressionPartitionedGAM`.

You can override the default cross-validation setting by using the `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'` name-value argument.

Predict responses for the observations in `tbl` by using `kfoldPredict`. The function predicts responses for every observation using the model trained without that observation.

```
yHat = kfoldPredict(CVMdl);
```

`yHat` is a numeric vector. Display the first five predicted responses.

```
yHat(1:5)
```

```
ans = 5×1

   19.4848
   15.7203
   15.5742
   15.3185
   17.8223
```

Compute the regression loss (mean squared error).

```
L = kfoldLoss(CVMdl)
```

```
L = 17.7248
```

`kfoldLoss` returns the average mean squared error over 10 folds.

Create Cross-Validated Regression GAM Using `crossval`

Train a regression generalized additive model (GAM) by using `fitrgam`, and create a cross-validated GAM by using `crossval` and the holdout option. Then, use `kfoldPredict` to predict responses for validation-fold observations using a model trained on training-fold observations.

Load the `patients` data set.

```
load patients
```

Create a table that contains the predictor variables (`Age`, `Diastolic`, `Smoker`, `Weight`, `Gender`, `SelfAssessedHealthStatus`) and the response variable (`Systolic`).

```
tbl = table(Age,Diastolic,Smoker,Weight,Gender,SelfAssessedHealthStatus,Systolic);
```

Train a GAM that contains linear terms for predictors.

```
Mdl = fitrgam(tbl,'Systolic');
```

`Mdl` is a `RegressionGAM` model object.

Cross-validate the model by specifying a 30% holdout sample.

```
rng('default') % For reproducibility
CVMdl = crossval(Mdl,'Holdout',0.3)
```

```
CVMdl =
  RegressionPartitionedGAM
      CrossValidatedModel: 'GAM'
           PredictorNames: {1x6 cell}
    CategoricalPredictors: [3 5 6]
             ResponseName: 'Systolic'
          NumObservations: 100
                    KFold: 1
                Partition: [1x1 cvpartition]
        NumTrainedPerFold: [1x1 struct]
        ResponseTransform: 'none'

  Properties, Methods
```

The `crossval` function creates a `RegressionPartitionedGAM` model object `CVMdl` with the holdout option. During cross-validation, the software completes these steps:

1. Randomly select and reserve 30% of the data as validation data, and train the model using the rest of the data.
2. Store the compact, trained model in the `Trained` property of the cross-validated model object `RegressionPartitionedGAM`.

You can choose a different cross-validation setting by using the `'CrossVal'`, `'CVPartition'`, `'KFold'`, or `'Leaveout'` name-value argument.

Predict responses for the validation-fold observations by using `kfoldPredict`. The function predicts responses for the validation-fold observations by using the model trained on the training-fold observations. The function assigns `NaN` to the training-fold observations.

```
yFit = kfoldPredict(CVMdl);
```

Find the validation-fold observation indexes, and create a table containing the observation index, observed response values, and predicted response values. Display the first eight rows of the table.

```
idx = find(~isnan(yFit));
t = table(idx,tbl.Systolic(idx),yFit(idx), ...
    'VariableNames',{'Obseraction Index','Observed Value','Predicted Value'});
head(t)
```

```
ans=8×3 table
    Obseraction Index    Observed Value    Predicted Value
    _________________    ______________    _______________

            1                124              130.22
            6                121              124.38
            7                130              125.26
           12                115              117.05
           20                125              121.82
           22                123              116.99
           23                114                 107
```

```
           24                128              122.52
```

Compute the regression error (mean squared error) for the validation-fold observations.

```
L = kfoldLoss(CVMdl)
```

```
L = 43.8715
```

Find Optimal Number of Trees for GAM Using kfoldLoss

Train a cross-validated generalized additive model (GAM) with 10 folds. Then, use `kfoldLoss` to compute the cumulative cross-validation regression loss (mean squared errors). Use the errors to determine the optimal number of trees per predictor (linear term for predictor) and the optimal number of trees per interaction term.

Alternatively, you can find optimal values of `fitrgam` name-value arguments by using the `bayesopt` function. For an example, see “Optimize Cross-Validated GAM Using bayesopt” on page 33-2120.

Load the `patients` data set.

```
load patients
```

Create a table that contains the predictor variables (`Age`, `Diastolic`, `Smoker`, `Weight`, `Gender`, and `SelfAssessedHealthStatus`) and the response variable (`Systolic`).

```
tbl = table(Age,Diastolic,Smoker,Weight,Gender,SelfAssessedHealthStatus,Systolic);
```

Create a cross-validated GAM by using the default cross-validation option. Specify the `'CrossVal'` name-value argument as `'on'`. Also, specify to include 5 interaction terms.

```
rng('default') % For reproducibility
CVMdl = fitrgam(tbl,'Systolic','CrossVal','on','Interactions',5);
```

If you specify `'Mode'` as `'cumulative'` for `kfoldLoss`, then the function returns cumulative errors, which are the average errors across all folds obtained using the same number of trees for each fold. Display the number of trees for each fold.

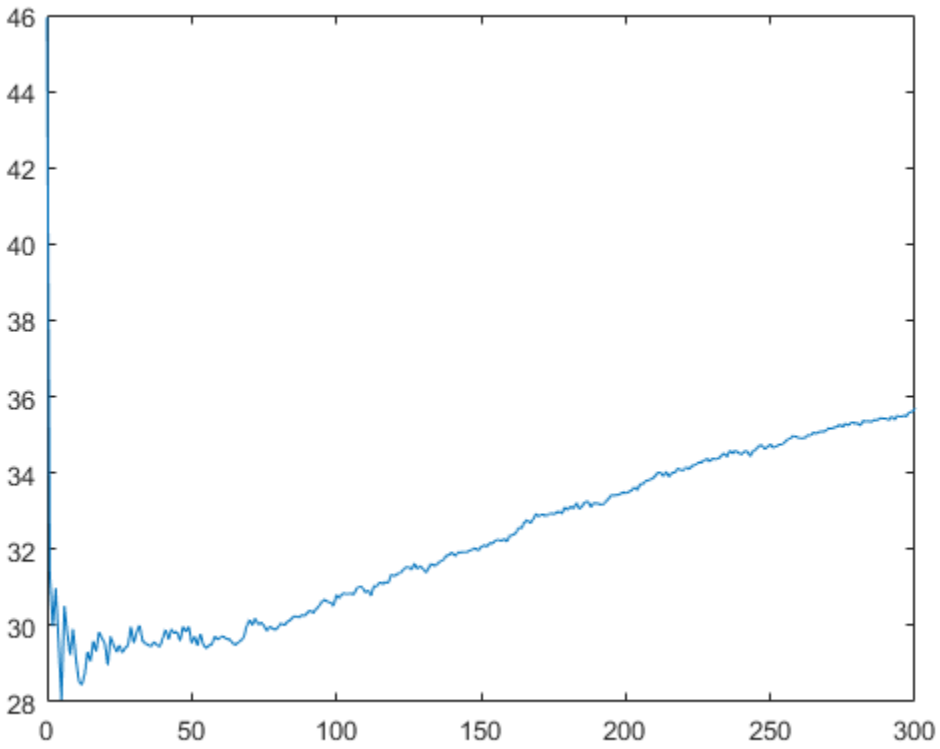
```
CVMdl.NumTrainedPerFold
```

```
ans = struct with fields:
      PredictorTrees: [300 300 300 300 300 300 300 300 300 300]
    InteractionTrees: [76 100 100 100 100 42 100 100 59 100]
```

`kfoldLoss` can compute cumulative errors using up to 300 predictor trees and 42 interaction trees.

Plot the cumulative, 10-fold cross-validated, mean squared errors. Specify `'IncludeInteractions'` as `false` to exclude interaction terms from the computation.

```
L_noInteractions = kfoldLoss(CVMdl,'Mode','cumulative','IncludeInteractions',false);
figure
plot(0:min(CVMdl.NumTrainedPerFold.PredictorTrees),L_noInteractions)
```



The first element of `L_noInteractions` is the average error over all folds obtained using only the intercept (constant) term. The (`J`+1)th element of `L_noInteractions` is the average error obtained using the intercept term and the first `J` predictor trees per linear term. Plotting the cumulative loss allows you to monitor how the error changes as the number of predictor trees in the GAM increases.

Find the minimum error and the number of predictor trees used to achieve the minimum error.

```
[M,I] = min(L_noInteractions)
```

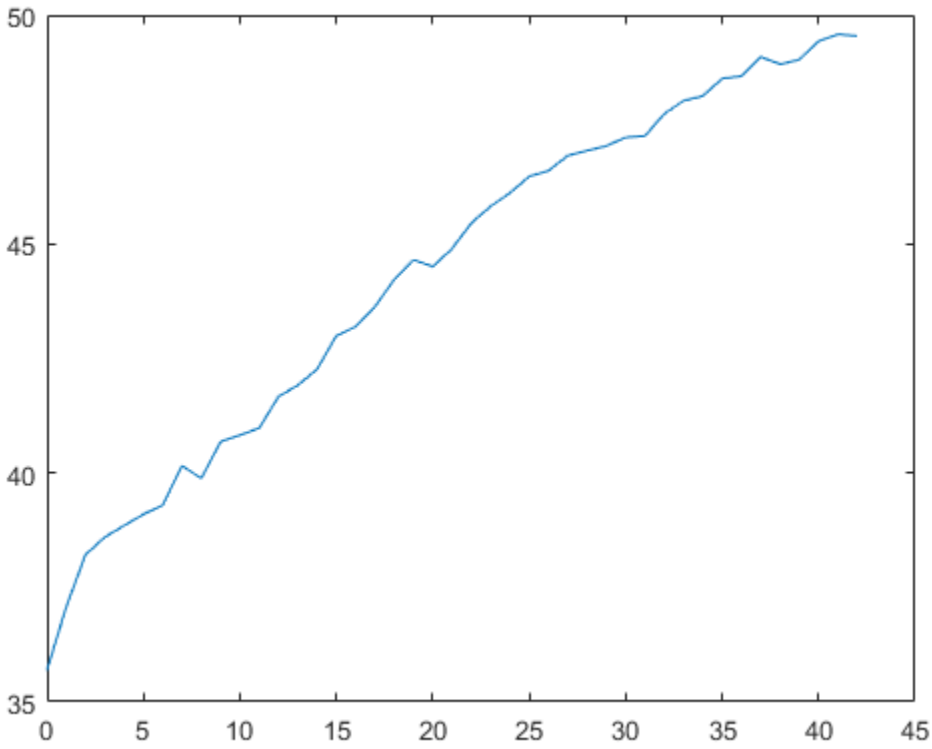
```
M = 28.0506
```

```
I = 6
```

The GAM achieves the minimum error when it includes 5 predictor trees.

Compute the cumulative mean squared error using both linear terms and interaction terms.

```
L = kfoldLoss(CVMdl,'Mode','cumulative');
figure
plot(0:min(CVMdl.NumTrainedPerFold.InteractionTrees),L)
```



The first element of `L` is the average error over all folds obtained using the intercept (constant) term and all predictor trees per linear term. The `(J+1)`th element of `L` is the average error obtained using the intercept term, all predictor trees per linear term, and the first `J` interaction trees per interaction term. The plot shows that the error increases when interaction terms are added.

If you are satisfied with the error when the number of predictor trees is 5, you can create a predictive model by training the univariate GAM again and specifying `'NumTreesPerPredictor',5` without cross-validation.

RegressionPartitionedLinear

Package: `classreg.learning.partition`
Superclasses: `RegressionPartitionedModel`

Cross-validated linear regression model for high-dimensional data

Description

`RegressionPartitionedLinear` is a set of linear regression models trained on cross-validated folds. To obtain a cross-validated, linear regression model, use `fitrlinear` and specify one of the cross-validation options. You can estimate the predictive quality of the model, or how well the linear regression model generalizes, using one or more of these "kfold" methods: `kfoldPredict` and `kfoldLoss`.

Every "kfold" method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

1. The software trains the first model (stored in `CVMdl.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
2. The software trains the second model (stored in `CVMdl.Trained{2}`) using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.
3. The software proceeds in a similar fashion for the third through fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note Unlike other cross-validated, regression models, `RegressionPartitionedLinear` model objects do not store the predictor data set.

Construction

`CVMdl = fitrlinear(X,Y,Name,Value)` creates a cross-validated, linear regression model when `Name` is either `'CrossVal'`, `'CVPartition'`, `'Holdout'`, or `'KFold'`. For more details, see `fitrlinear`.

Properties

Cross-Validation Properties

`CrossValidatedModel` — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, `'Linear'` specifies a cross-validated linear model for binary classification or regression.

Data Types: `char`

`KFold` — Number of cross-validated folds
positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: `double`

`ModelParameters` — Cross-validation parameter values
object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the linear model, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation.

`NumObservations` — Number of observations
positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: `double`

`Partition` — Data partition
`cvpartition` model

Data partition indicating how the software splits the data into cross-validation folds, specified as a `cvpartition` model.

`Trained` — Linear regression models trained on cross-validation folds
cell array of `RegressionLinear` model objects

Linear regression models trained on cross-validation folds, specified as a cell array of `RegressionLinear` models. `Trained` has k cells, where k is the number of folds.

Data Types: `cell`

`W` — Observation weights
numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. `W` has `NumObservations` elements.

The software normalizes the weights used for training so that `sum(W,'omitnan')` is `1`.

Data Types: `single` | `double`

`Y` — Observed responses
numeric vector

Observed responses used to cross-validate the model, specified as a numeric vector containing `NumObservations` elements.

Each row of `Y` represents the observed response of the corresponding observation in the predictor data.

Data Types: `single` | `double`

Other Regression Properties

`CategoricalPredictors` — Categorical predictor indices

vector of positive integers | `[]`

Categorical predictor indices, specified as a vector of positive integers. Assuming that the predictor data contains observations in rows, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

`PredictorNames` — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data, specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of variables in the training data `X` or `Tbl` used as predictor variables.

Data Types: `cell`

`ResponseName` — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

`ResponseTransform` — Response transformation function

`'none'` | function handle

Response transformation function, specified as `'none'` or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @`*`function`*, where *`function`* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Methods

kfoldLoss	Regression loss for observations not used in training
kfoldPredict	Predict responses for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Create Cross-Validated Linear Regression Model

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = \{x_1, \ldots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns');
```

`CVMdl` is a `RegressionPartitionedLinear` cross-validated model. Because `fitrlinear` implements 10-fold cross-validation by default, `CVMdl.Trained` contains a cell vector of ten `RegressionLinear` models. Each cell contains a linear regression model trained on nine folds, and then tested on the remaining fold.

Predict responses for out-of-fold observations and estimate the generalization error by passing `CVMdl` to `kfoldPredict` and `kfoldLoss`, respectively.

```
oofYHat = kfoldPredict(CVMdl);
ge = kfoldLoss(CVMdl)
```

```
ge = 0.1748
```

The estimated, generalization, mean squared error is 0.1748.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = \{x_1, \ldots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.

- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1}.

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpaRSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');

numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

`CVMdl` is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, `CVMdl` contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 = 
  RegressionLinear
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x15 double]
                 Bias: [1x15 double]
               Lambda: [1x15 double]
              Learner: 'leastsquares'

  Properties, Methods
```

`Mdl1` is a `RegressionLinear` model object. `fitrlinear` constructed `Mdl1` by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 15 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

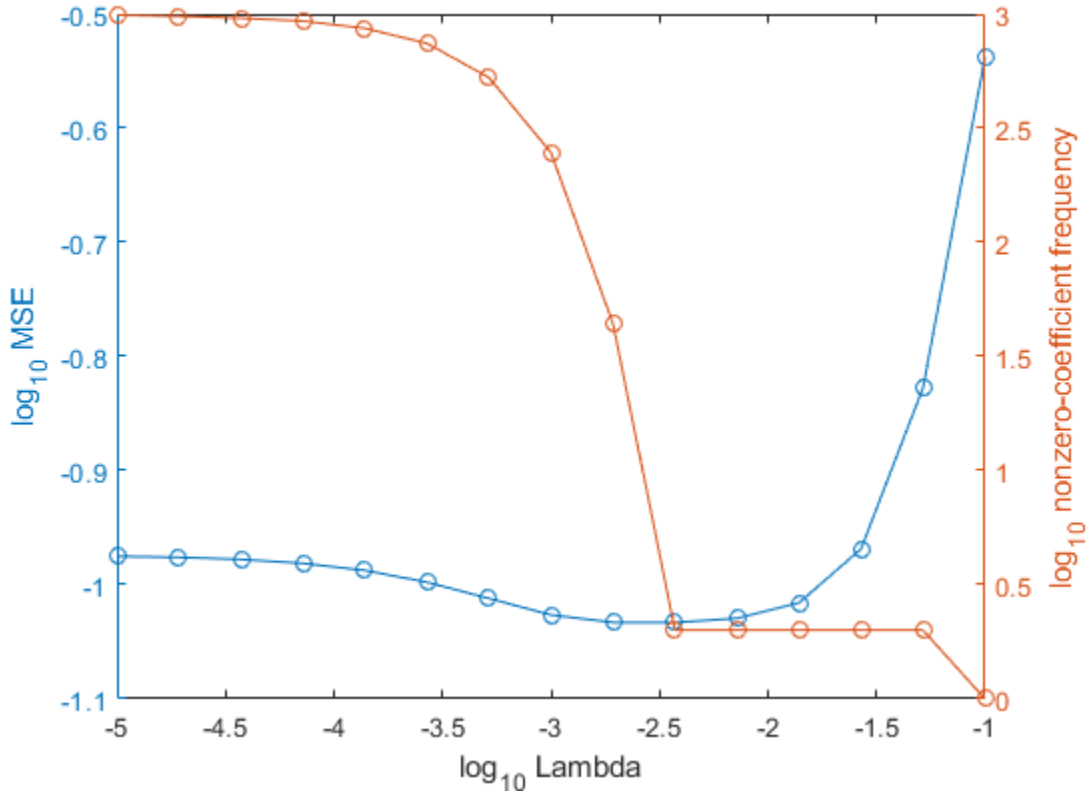
```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```



Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, `Lambda(10)`).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =
  RegressionLinear
```

```
         ResponseName: 'Y'
    ResponseTransform: 'none'
                 Beta: [1000x1 double]
                 Bias: -0.0050
               Lambda: 0.0037
              Learner: 'leastsquares'

  Properties, Methods
```

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2×1

   100
   200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1

    1.0051
    1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Introduced in R2016a

RegressionPartitionedModel

Package: `classreg.learning.partition`

Cross-validated regression model

Description

`RegressionPartitionedModel` is a set of regression models trained on cross-validated folds. Estimate the quality of regression by cross validation using one or more "kfold" methods: `kfoldPredict`, `kfoldLoss`, and `kfoldfun`. Every "kfold" method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on `X` and `Y` with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on `X` and `Y` with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

Construction

`CVMdl = crossval(Mdl)` creates a cross-validated regression model from a regression model (`Mdl`).

Alternatively:

- `CVNetMdl = fitrnet(X,Y,Name,Value)`
- `CVTreeMdl = fitrtree(X,Y,Name,Value)`

create a cross-validated model when `Name` is either `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. For syntax details, see `fitrnet` and `fitrtree`.

Input Arguments

`Mdl`

A regression model, specified as one of the following:

- A neural network regression model trained using `fitrnet`
- A regression tree trained using `fitrtree`

Properties

`BinEdges`

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. Assuming that the predictor data contains observations in rows, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`CrossValidatedModel`

Name of the cross-validated model, a character vector.

`Kfold`

Number of folds used in the cross-validated model, a positive integer.

`ModelParameters`

Object holding parameters of `Mdl`.

`NumObservations`

Number of observations in the training data stored in `X` and `Y`, specified as a numeric scalar.

`Partition`

The partition of class `cvpartition` used in the cross-validated model.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X.

ResponseName

Name of the response variable Y, a character vector.

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default character vector `'none'` means `@(x)x`, or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
CVMdl.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

W

The scaled `weights`, a vector with length `n`, the number of observations in X.

X

A matrix or table of predictor values.

Y

A numeric column vector. Each entry in Y is the response value of the corresponding observation in X.

Object Functions

kfoldLoss	Loss for cross-validated partitioned regression model
kfoldPredict	Predict responses for observations in cross-validated regression model
kfoldfun	Cross-validate function for regression

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Evaluate Cross-Validation Error

Load the sample data. Create a variable X containing the `Horsepower` and `Weight` data.

```
load carsmall
X = [Horsepower Weight];
```

Construct a regression tree using the sample data.

```
cvtree = fitrtree(X,MPG,'crossval','on');
```

Evaluate the cross-validation error of the `carsmall` data using `Horsepower` and `Weight` as predictor variables for mileage (`MPG`).

```
L = kfoldLoss(cvtree)
```

```
L = 25.5338
```

RegressionPartitionedSVM

Package: `classreg.learning.partition`
Superclasses: `RegressionPartitionedModel`

Cross-validated support vector machine regression model

Description

`RegressionPartitionedSVM` is a set of support vector machine (SVM) regression models trained on cross-validated folds.

Construction

`CVMdl = crossval(mdl)` returns a cross-validated (partitioned) support vector machine regression model, `CVMdl`, from a trained SVM regression model, `mdl`.

`CVMdl = crossval(mdl,Name,Value)` returns a cross-validated model with additional options specified by one or more `Name,Value` pair arguments. `Name` can also be a property name on page 33-5380 and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`mdl` — Full, trained SVM regression model

`RegressionSVM` model

Full, trained SVM regression model, specified as a `RegressionSVM` model returned by `fitrsvm`.

Properties

`CategoricalPredictors` — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

`CrossValidatedModel` — Name of the cross-validated model

character vector

Name of the cross-validated model, stored as a character vector.

Data Types: `char`

`KFold` — Number of cross-validation folds

positive integer value

Number of cross-validation folds, stored as a positive integer value.

Data Types: `single` | `double`

`ModelParameters` — Cross-validation parameters
object

Cross-validation parameters, stored as an object.

`NumObservations` — Number of observations
positive integer value

Number of observations in the training data, stored as a positive integer value.

Data Types: `single` | `double`

`Partition` — Data partition for cross-validation
`cvpartition` object

Data partition for cross-validation, stored as a `cvpartition` object.

`PredictorNames` — Predictor names
cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order in which they appear in `X`. `PredictorNames` has a length equal to the number of columns in `X`.

Data Types: `cell`

`ResponseName` — Response variable name
character vector

Response variable name, stored as a character vector.

Data Types: `char`

`ResponseTransform` — Response transformation function
`'none'` | function handle

Response transformation function, specified as `'none'` or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @`*`function`*, where *`function`* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

`Trained` — Trained, compact regression models
cell array of `CompactRegressionSVM` models

Trained, compact regression models, stored as a cell array of `CompactRegressionSVM` models.

Data Types: `cell`

`W` — Observation weights
vector of numeric values

Observation weights used to train the model, stored as a numeric vector containing `NumObservation` number of elements. `fitrsvm` normalizes the weights used for training so that they sum to 1.

Data Types: `single` | `double`

`X` — Predictor values
matrix of numeric values | table of numeric values

Predictor values used to train the model, stored as a matrix of numeric values if the model is trained on a matrix, or a table if the model is trained on a table. `X` has size *n*-by-*p*, where *n* is the number of rows and *p* is the number of predictor variables or columns in the training data.

Data Types: `single` | `double` | `table`

`Y` — Observed responses
numeric vector

Observed responses used to cross-validate the model, specified as a numeric vector containing `NumObservations` elements.

Each row of `Y` represents the observed classification of the corresponding row of `X`.

Data Types: `single` | `double`

Object Functions

kfoldLoss	Loss for cross-validated partitioned regression model
kfoldPredict	Predict responses for observations in cross-validated regression model
kfoldfun	Cross-validate function for regression

Examples

Train Cross-Validated SVM Regression Model Using `crossval`

This example shows how to train a cross-validated SVM regression model using `crossval`.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default  % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

```
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale',2.2,'Standardize',true);
```

`mdl` is a trained `RegressionSVM` regression model.

Cross validate the model using 10-fold cross validation.

```
CVMdl = crossval(mdl)

CVMdl =

  classreg.learning.partition.RegressionPartitionedSVM
      CrossValidatedModel: 'SVM'
           PredictorNames: {1x8 cell}
    CategoricalPredictors: 1
             ResponseName: 'Var9'
          NumObservations: 4177
                    KFold: 10
                Partition: [1x1 cvpartition]
        ResponseTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `RegressionPartitionedSVM` cross-validated regression model. The software:

1. Randomly partitions the data into ten equally-sized sets.

2. Trains an SVM regression model on nine of the ten sets.

3. Repeats steps 1 and 2 $k = 10$ times. It leaves out one of the partitions each time, and trains on the other nine partitions.

4. Combines generalization statistics for each fold.

Display the first of the 10 trained models.

```
FirstModel = CVMdl.Trained{1}

FirstModel =

  classreg.learning.regr.CompactRegressionSVM
       PredictorNames: {1x8 cell}
         ResponseName: 'Var9'
    ResponseTransform: 'none'
                Alpha: [3553x1 double]
                 Bias: 11.0623
     KernelParameters: [1x1 struct]
                   Mu: [0 0 0 0.5242 0.4080 0.1393 0.8300 0.3599 0.1811 0.2392]
                Sigma: [1 1 1 0.1205 0.0995 0.0392 0.4907 0.2217 0.1103 0.1392]
        SupportVectors: [3553x10 double]

  Properties, Methods
```

`FirstModel` is the first of the 10 trained `CompactRegressionSVM` models.

Specify Cross-Validation Holdout Proportion for SVM Regression

This example shows how to specify a holdout proportion for training a cross-validated SVM regression model.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default  % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

```
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale',2.2,'Standardize',true);
```

`mdl` is a trained `RegressionSVM` regression model.

Cross validate the regression model by specifying a 10% holdout sample.

```
CVMdl = crossval(mdl,'Holdout',0.1)
```

```
CVMdl =

  classreg.learning.partition.RegressionPartitionedSVM
      CrossValidatedModel: 'SVM'
           PredictorNames: {1x8 cell}
    CategoricalPredictors: 1
             ResponseName: 'Var9'
          NumObservations: 4177
                    KFold: 1
                Partition: [1x1 cvpartition]
       ResponseTransform: 'none'

  Properties, Methods
```

`CVMdl` is a `RegressionPartitionedSVM` model object.

Extract and display the trained, compact SVM regression model from `CVMdl`.

```
CVMdl.Trained{1}
```

```
TrainedModel =

  classreg.learning.regr.CompactRegressionSVM
       PredictorNames: {1x8 cell}
         ResponseName: 'Var9'
    ResponseTransform: 'none'
                Alpha: [3530x1 double]
                 Bias: 11.2646
     KernelParameters: [1x1 struct]
                   Mu: [0 0 0 0.5244 0.4080 0.1393 0.8282 0.3595 0.1805 0.2386]
                Sigma: [1 1 1 0.1198 0.0989 0.0388 0.4891 0.2218 0.1093 0.1390]
       SupportVectors: [3530x10 double]

  Properties, Methods
```

`TrainedModel` is a `CompactRegressionSVM` regression model that was trained using 90% of the data.

Alternatives

You can create a `RegressionPartitionedSVM` model using the following techniques:

- Use the training function `fitrsvm` and specify one of the `'CrossVal'`, `'Holdout'`, `'KFold'`, or `'Leaveout'` name-value pairs.
- Train a model using `fitrsvm`, then cross validate the model using the `crossval` method.
- Create a cross validation partition using `cvpartition`, then pass the resulting partition object to `fitrsvm` during training using the `'CVPartition'` name-value pair.

`RegressionSVM` | `crossval` | `cvpartition` | `fitrsvm`

Introduced in R2015b

RegressionSVM class

Superclasses: `CompactRegressionSVM`

Support vector machine regression model

Description

`RegressionSVM` is a support vector machine (SVM) regression model. Train a `RegressionSVM` model using `fitrsvm` and the sample data.

`RegressionSVM` models store data, parameter values, support vectors, and algorithmic implementation information. You can use these models to:

- Estimate resubstitution predictions. For details, see `resubPredict`.
- Predict values for new data. For details, see `predict`.
- Compute resubstitution loss. For details, see `resubLoss`.
- Compute the mean square error or epsilon-insensitive loss. For details, see `loss`.

Construction

Create a `RegressionSVM` object by using `fitrsvm`.

Properties

`Alpha` — Dual problem coefficients

vector of numeric values

Dual problem coefficients, specified as a vector of numeric values. `Alpha` contains *m* elements, where *m* is the number of support vectors in the trained SVM regression model. The dual problem introduces two Lagrange multipliers for each support vector. The values of `Alpha` are the differences between the two estimated Lagrange multipliers for the support vectors. For more details, see “Understanding Support Vector Machine Regression” on page 25-2.

If you specified to remove duplicates using `RemoveDuplicates`, then, for a particular set of duplicate observations that are support vectors, `Alpha` contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one observation from the set of duplicates and a coefficient of `0` to all other duplicate observations in the set.

Data Types: `single` | `double`

`Beta` — Primal linear problem coefficients

vector of numeric values | `'[]'`

Primal linear problem coefficients, stored as a numeric vector of length *p*, where *p* is the number of predictors in the SVM regression model.

The values in `Beta` are the linear coefficients for the primal optimization problem.

If the model is obtained using a kernel function other than `'linear'`, this property is empty (`'[]'`).

The `predict` method computes predicted response values for the model as `YFIT = (X/S)×Beta + Bias`, where `S` is the value of the kernel scale stored in the `KernelParameters.Scale` property.

Data Types: `single` | `double`

`Bias` — Bias term

scalar value

Bias term in the SVM regression model, stored as a scalar value.

Data Types: `single` | `double`

`BoxConstraints` — Box constraints for dual problem coefficients

vector of numeric values

Box constraints for dual problem alpha coefficients, stored as a numeric vector containing *n* elements, where *n* is the number of observations in `X` (`Mdl.NumObservations`).

The absolute value of the dual coefficient `Alpha` for observation *i* cannot exceed `BoxConstraints(i)`.

If you specify removing duplicates using `'RemoveDuplicates'`, then for a given set of duplicate observations, MATLAB sums the box constraints, and then attributes the sum to one observation and box constraints of `0` to all other observations in the set.

Data Types: `single` | `double`

`CacheInfo` — Caching information

structure

Caching information, stored as a structure with the following fields.

Field	Description
`'Size'`	Positive scalar value indicating the cache size (in MB) that the software reserves to store entries of the Gram matrix. Set the cache size by using the `'CacheSize'` name-value pair argument in `fitrsvm`.
`'Algorithm'`	Character vector containing the name of the algorithm used to remove entries from the cache when its capacity is exceeded. Currently, the only available caching algorithm is `'Queue'`. You cannot set the caching algorithm.

Data Types: `struct`

`CategoricalPredictors` — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

`ConvergenceInfo` — Convergence information
structure

Convergence information, stored as a structure with the following fields.

Field	Description
`Converged`	Logical flag indicating whether the algorithm converged. A value of `1` indicates convergence.
`ReasonForConvergence`	Character vector indicating the criterion the software used to detect convergence.
`Gap`	Scalar feasibility gap between the dual and primal objective functions.
`GapTolerance`	Scalar tolerance for the feasibility gap. You can set this tolerance using the `'GapTolerance'` name-value pair argument in `fitrsvm`.
`DeltaGradient`	Scalar gradient difference between upper and lower violators.
`DeltaGradientTolerance`	Scalar tolerance for the gradient difference. You can set this tolerance using the `DeltaGradientTolerance` name-value pair argument in `fitrsvm`.
`LargestKKTViolation`	Maximal scalar Karush-Kuhn-Tucker (KKT) violation value.
`KKTTolerance`	Scalar tolerance for the largest KKT violation. You can set this tolerance using the `'KKTTolerance'` name-value pair argument in `fitrsvm`.
`History`	Structure containing convergence information recorded at periodic intervals during the model training process. This structure contains the following fields: • `NumIterations` — Array of iteration indices at which the software recorded convergence criteria. • `Gap` — `Gap` values at these iterations. • `DeltaGradient` — `DeltaGradient` values at these iterations. • `LargestKKTViolation` — `LargestKKTViolation` values at these iterations. • `NumSupportVectors` — Number of support vectors at these iterations. • `Objective` — `Objective` values at these iterations.
`Objective`	Numeric value of the dual objective.

Data Types: `struct`

`Epsilon` — Half the width of the epsilon-insensitive band
nonnegative scalar value

Half the width of the epsilon-insensitive band, stored as a nonnegative scalar value.

Data Types: `single` | `double`

`ExpandedPredictorNames` — Expanded predictor names
cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: `cell`

`Gradient` — Gradient values in training data
vector of numeric values

Gradient values in training data, stored as a numeric vector containing 2*n* elements, where *n* is the number of observations in the training data.

Element *i* of `Gradient` contains the gradient value for the `Alpha` coefficient that corresponds to the upper boundary of the epsilon-insensitive band at observation *i* at the end of the optimization.

Element *i* + *NumObservations* of `Gradient` contains the gradient value for the `Alpha` coefficient that corresponds to the lower boundary of the epsilon-insensitive band at observation *i* at the end of the optimization.

Data Types: `single` | `double`

`HyperparameterOptimizationResults` — Cross-validation optimization of hyperparameters
`BayesianOptimization` object | table

This property is read-only.

Cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property is nonempty if the `'OptimizeHyperparameters'` name-value pair argument is nonempty when you create the model. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure when you create the model.

Value of `Optimizer` Field	**Value of `HyperparameterOptimizationResults`**
`'bayesopt'` (default)	Object of class `BayesianOptimization`
`'gridsearch'` or `'randomsearch'`	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

`IsSupportVector` — Flag indicating whether observation is support vector
logical vector

Flag indicating whether an observation is a support vector, stored as an *n*-by-1 logical vector. *n* is the number of observations in `X` (see `NumObservations`). A value of `1` indicates that the corresponding observation in the training data is a support vector.

If you specify removing duplicates using `RemoveDuplicates`, then for a given set of duplicate observations that are support vectors, `IsSupportVector` flags only one as a support vector.

Data Types: `logical`

`KernelParameters` — Kernel function parameters
structure

Kernel function parameters, stored as a structure with the following fields.

Field	Description
`Function`	Kernel function name (a character vector).
`Scale`	Numeric scale factor used to divide predictor values.

You can specify values for `KernelParameters.Function` and `KernelParameters.Scale` by using the `KernelFunction` and `KernelScale` name-value pair arguments in `fitrsvm`, respectively.

Data Types: `struct`

`ModelParameters` — Parameter values
model parameter object

Parameter values used to train the SVM regression model, stored as a model parameter object. Access the properties of `ModelParameters` using dot notation. For example, access the value of `Epsilon` used to train the model as `Mdl.ModelParameters.Epsilon`.

`Mu` — Predictor means
vector of numeric values | `'[]'`

Predictor means, stored as a vector of numeric values.

If the predictors are standardized, then `Mu` is a numeric vector of length *p*, where *p* is the number of predictors used to train the model. In this case, the `predict` method centers predictor matrix `X` by subtracting the corresponding element of `Mu` from each column.

If the predictors are not standardized, then `Mu` is empty (`'[]'`).

If the data contains categorical predictors, then `Mu` includes elements for the dummy variables for those predictors. The corresponding entries in `Mu` are 0 because dummy variables are not centered or scaled.

Data Types: `single` | `double`

`NumIterations` — Number of iterations required for convergence
positive integer value

Number of iterations required for the optimization routine to reach convergence, stored as a positive integer value.

To set a limit on the number of iterations, use the `'IterationLimit'` name-value pair argument of `fitrsvm`.

Data Types: `single` | `double`

`NumObservations` — Number of observations
positive integer value

Number of observations in the training data, stored as a positive integer value.

Data Types: `single` | `double`

`PredictorNames` — Predictor names
cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order they appear in `X`. `PredictorNames` has a length equal to the number of columns in `X`.

Data Types: `cell`

`OutlierFraction` — Expected fraction of outliers
scalar value in the range [0,1]

Expected fraction of outliers in the training set, stored as a scalar value in the range [0,1]. You can specify the expected fraction of outliers using the `'OutlierFraction'` name-value pair argument in `fitrsvm`.

Data Types: `double`

`ResponseName` — Response variable name
character vector

Response variable name, stored as a character vector.

Data Types: `char`

`ResponseTransform` — Response transformation function
`'none'` | function handle

Response transformation function, specified as `'none'` or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @`*`function`*, where *`function`* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

`ShrinkagePeriod` — Number of iterations between reductions of active set
nonnegative integer value

Number of iterations between reductions of the active set during optimization, stored as a nonnegative integer value.

You can set the shrinkage period by using the `'ShrinkagePeriod'` name-value pair argument in `fitrsvm`.

Data Types: `single` | `double`

`Sigma` — Predictor standard deviations
vector of numeric values | `'[]'`

Predictor standard deviations, stored as a vector of numeric values.

If the predictors are standardized, then `Sigma` is a numeric vector of length *p*, where *p* is the number of predictors used to train the model. In this case, the `predict` method scales the predictor matrix `X` by dividing each column by the corresponding element of `Sigma`, after centering each element using `Mu`.

If the predictors are not standardized, then `Sigma` is empty (`'[]'`).

If the data contains categorical predictors, `Sigma` includes elements for the dummy variables for those predictors. The corresponding entries in `Sigma` are 1, because dummy variables are not centered or scaled.

Data Types: `single` | `double`

`Solver` — Name of solver algorithm
character vector

Name of the solver algorithm used to solve the optimization problem, stored as a value in this table.

Value	Description
`'SMO'`	Sequential Minimal Optimization
`'ISDA'`	Iterative Single Data Algorithm
`'L1QP'`	L1 soft-margin minimization by quadratic programming (requires an Optimization Toolbox license).

`SupportVectors` — Support vectors
matrix of numeric values

Support vectors, stored as an *m*-by-*p* matrix of numeric values. *m* is the number of support vectors (`sum(Mdl.IsSupportVector)`), and *p* is the number of predictors in `X`.

If you specified to remove duplicates using `RemoveDuplicates`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

`W` — Observation weights
vector of numeric values

Observation weights used to train the model, stored as a numeric vector containing `NumObservation` number of elements. `fitrsvm` normalizes the weights used for training so that they sum to 1.

Data Types: `single` | `double`

`X` — Predictor values
matrix of numeric values | table of numeric values

Predictor values used to train the model, stored as a matrix of numeric values if the model is trained on a matrix, or a table if the model is trained on a table. `X` has size *n*-by-*p*, where *n* is the number of rows and *p* is the number of predictor variables or columns in the training data.

Data Types: `single` | `double` | `table`

Y — Observed response values
vector of numeric values

Observed response values, stored as a numeric vector containing `NumObservations` number of elements.

Data Types: `single` | `double`

Object Functions

compact	Compact support vector machine regression model
crossval	Cross-validated support vector machine regression model
discardSupportVectors	Discard support vectors
incrementalLearner	Convert support vector machine (SVM) regression model to incremental learner
lime	Local interpretable model-agnostic explanations (LIME)
loss	Regression error for support vector machine regression model
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Predict responses using support vector machine regression model
resubLoss	Resubstitution loss for support vector machine regression model
resubPredict	Predict resubstitution response of support vector machine regression model
resume	Resume training support vector machine regression model
shapley	Shapley values

Examples

Train Linear Support Vector Machine Regression Model

This example shows how to train a linear support vector machine (SVM) regression model using sample data stored in matrices.

Load the `carsmall` data set.

```
load carsmall
rng default  % for reproducibility
```

Specify `Horsepower` and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model.

```
Mdl = fitrsvm(X,Y)
```

```
Mdl =
  RegressionSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
                    Alpha: [75x1 double]
                     Bias: 57.3800
         KernelParameters: [1x1 struct]
          NumObservations: 93
           BoxConstraints: [93x1 double]
          ConvergenceInfo: [1x1 struct]
          IsSupportVector: [93x1 logical]
                   Solver: 'SMO'

  Properties, Methods
```

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and a list of its properties.

Check the model for convergence.

```
Mdl.ConvergenceInfo.Converged
```

```
ans = logical
   0
```

`0` indicates that the model did not converge.

```
MdlStd = fitrsvm(X,Y,'Standardize',true)
```

```
MdlStd =
  RegressionSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
                    Alpha: [77x1 double]
                     Bias: 22.9131
         KernelParameters: [1x1 struct]
                       Mu: [109.3441 2.9625e+03]
                    Sigma: [45.3545 805.9668]
          NumObservations: 93
           BoxConstraints: [93x1 double]
          ConvergenceInfo: [1x1 struct]
          IsSupportVector: [93x1 logical]
                   Solver: 'SMO'

  Properties, Methods
```

Check the model for convergence.

```
MdlStd.ConvergenceInfo.Converged
```

```
ans = logical
   1
```

`1` indicates that the model did converge.

Compute the resubstitution mean squared error for the new model.

```
lStd = resubLoss(MdlStd)
```

```
lStd = 17.0256
```

Train Support Vector Machine Regression Model

Train a support vector machine regression model using the abalone data from the UCI Machine Learning Repository.

Download the data and save it in your current folder with the name `'abalone.csv'`.

```
url = 'https://archive.ics.uci.edu/ml/machine-learning-databases/abalone/abalone.data';
websave('abalone.csv',url);
```

Read the data into a table. Specify the variable names.

```
varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight';...
    'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};
Tbl = readtable('abalone.csv','Filetype','text','ReadVariableNames',false);
Tbl.Properties.VariableNames = varnames;
```

The sample data contains 4177 observations. All the predictor variables are continuous except for `Sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings (stored in `Rings`) on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
rng default  % For reproducibility
Mdl = fitrsvm(Tbl,'Rings','KernelFunction','gaussian','KernelScale','auto',...
    'Standardize',true)
```

```
Mdl =

  RegressionSVM
           PredictorNames: {1×8 cell}
             ResponseName: 'Rings'
    CategoricalPredictors: 1
        ResponseTransform: 'none'
                    Alpha: [3635×1 double]
                     Bias: 10.8144
         KernelParameters: [1×1 struct]
                       Mu: [1×10 double]
                    Sigma: [1×10 double]
          NumObservations: 4177
```

```
          BoxConstraints: [4177×1 double]
         ConvergenceInfo: [1×1 struct]
         IsSupportVector: [4177×1 logical]
                  Solver: 'SMO'
```

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and displays a property list.

Display the properties of `Mdl` using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

```
conv = Mdl.ConvergenceInfo.Converged
iter = Mdl.NumIterations
```

```
conv =

  logical

   1

iter =

        2759
```

The returned results indicate that the model converged after 2759 iterations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- To integrate the prediction of an SVM regression model into Simulink, you can use the RegressionSVM Predict block in the Statistics and Machine Learning Toolbox library or a MATLAB Function block with the `predict` function.
- When you train an SVM regression model by using `fitrsvm`, the following restrictions apply.
  - The value of the `'ResponseTransform'` name-value pair argument must be `'none'` (default).
  - For fixed-point code generation, the value of the `'KernelFunction'` name-value pair argument must be `'gaussian'`, `'linear'`, or `'polynomial'`.
  - Fixed-point code generation and code generation with a coder configurer do not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). You cannot use the `'CategoricalPredictors'` name-value argument. To include categorical predictors in a model, preprocess them by using `dummyvar` before fitting the model.

RegressionSVMCoderConfigurer

Coder configurer for support vector machine (SVM) regression model

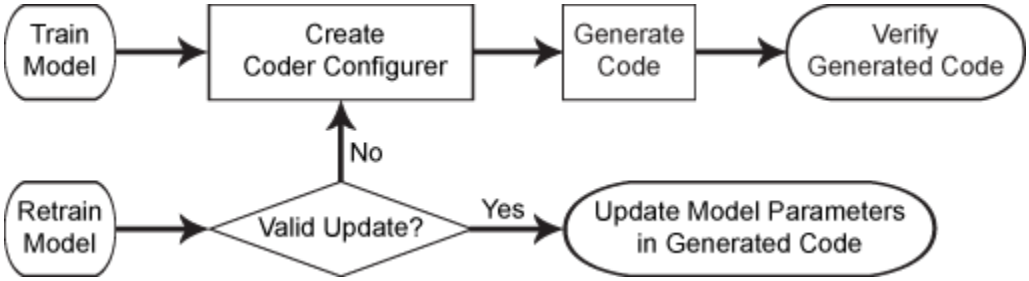
Description

A `RegressionSVMCoderConfigurer` object is a coder configurer of an SVM regression model (`RegressionSVM` or `CompactRegressionSVM`).

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes for SVM model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the SVM regression model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the SVM model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.



For the code generation usage notes and limitations of an SVM regression model, see the Code Generation sections of `CompactRegressionSVM`, `predict`, and `update`.

Creation

After training an SVM regression model by using `fitrsvm`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

`LearnerCoderInput` object

Coder attributes of predictor data to pass to the generated C/C++ code for the `predict` function of the SVM regression model, specified as a `LearnerCoderInput` on page 33-5409 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations of three predictor variables, specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

NumOutputs — Number of outputs in predict

1 (default)

Number of output arguments to return from the generated C/C++ code for the `predict` function of the SVM regression model, specified as 1. `predict` returns `yfit` (predicted responses) in the generated C/C++ code.

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the

`predict` and `update` functions of an SVM regression model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `single` | `double`

`update` Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 33-5409 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

`Alpha` — Coder attributes of dual problem coefficients

`LearnerCoderInput` object

Coder attributes of the dual problem coefficients (`Alpha` of an SVM regression model), specified as a `LearnerCoderInput` on page 33-5409 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[s,1]`, where `s` is the number of support vectors in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function and discard support vectors by using `discardSupportVectors`, this value must be `false`. Otherwise, this value must be `true`.

`Beta` — Coder attributes of primal linear problem coefficients

`LearnerCoderInput` object

Coder attributes of the primal linear problem coefficients (`Beta` of an SVM regression model), specified as a `LearnerCoderInput` on page 33-5409 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[p 1]`, where `p` is the number of predictors in `Mdl`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function and discard support vectors by using `discardSupportVectors`, this value must be `true`. Otherwise, this value must be `false`.

`Bias` — Coder attributes of bias term

`LearnerCoderInput` object

Coder attributes of the bias term (`Bias` of an SVM regression model), specified as a `LearnerCoderInput` on page 33-5409 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[1 1]`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

`Mu` — Coder attributes of predictor means

`LearnerCoderInput` object

Coder attributes of the predictor means (`Mu` of an SVM regression model), specified as a `LearnerCoderInput` on page 33-5409 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — If you train `Mdl` using standardized predictor data by specifying `'Standardize',true`, this value must be `[1,p]`, where `p` is the number of predictors in `Mdl`. Otherwise, this value must be `[0,0]`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train `Mdl` using standardized predictor data by specifying `'Standardize',true`, the default value is `true`. Otherwise, this value must be `false`.

`Scale` — Coder attributes of kernel scale parameter

`LearnerCoderInput` object

Coder attributes of the kernel scale parameter (`KernelParameters.Scale` of an SVM regression model), specified as a `LearnerCoderInput` on page 33-5409 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be `[1 1]`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — The default value is `true`.

`Sigma` — Coder attributes of predictor standard deviations
`LearnerCoderInput` object

Coder attributes of the predictor standard deviations (`Sigma` of an SVM regression model), specified as a `LearnerCoderInput` on page 33-5409 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — If you train `Mdl` using standardized predictor data by specifying `'Standardize',true`, this value must be `[1,p]`, where `p` is the number of predictors in `Mdl`. Otherwise, this value must be `[0,0]`.
- `VariableDimensions` — This value must be `[0 0]`, indicating that the array size is fixed as specified in `SizeVector`.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train `Mdl` using standardized predictor data by specifying `'Standardize',true`, the default value is `true`. Otherwise, this value must be `false`.

`SupportVectors` — Coder attributes of support vectors
`LearnerCoderInput` object

Coder attributes of the support vectors (`SupportVectors` of an SVM regression model), specified as a `LearnerCoderInput` on page 33-5409 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[s,p]`, where `s` is the number of support vectors, and `p` is the number of predictors in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function and discard support vectors by using `discardSupportVectors`, this value must be `false`. Otherwise, this value must be `true`.

Other Configurer Options

`OutputFileName` — File name of generated C/C++ code
`'RegressionSVMModel'` (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `RegressionSVMCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

`Verbose` — Verbosity level

`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
`true` (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
`false` (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

`CodeGenerationArguments` — `codegen` arguments

cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

`PredictInputs` — Input argument of `predict`
cell array of a `coder.PrimitiveType` object

This property is read-only.

Input argument of the entry-point function `predict.m` for code generation, specified as a cell array of a `coder.PrimitiveType` object. The `coder.PrimitiveType` object includes the coder attributes of the predictor data stored in the `X` property.

If you modify the coder attributes of the predictor data, then the software updates the `coder.PrimitiveType` object accordingly.

The `coder.PrimitiveType` object in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

`UpdateInputs` — List of tunable input arguments of `update`
cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (`update` Arguments on page 33-5400 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

generateCode	Generate C/C++ code using coder configurer
generateFiles	Generate MATLAB files for code generation using coder configurer

validatedUpdateInputs Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carsmall` data set and train a support vector machine (SVM) regression model.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

`Mdl` is a `RegressionSVM` object.

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)
```

```
configurer =
  RegressionSVMCoderConfigurer with properties:

   Update Inputs:
             Alpha: [1x1 LearnerCoderInput]
    SupportVectors: [1x1 LearnerCoderInput]
             Scale: [1x1 LearnerCoderInput]
              Bias: [1x1 LearnerCoderInput]

   Predict Inputs:
                 X: [1x1 LearnerCoderInput]

   Code Generation Parameters:
        NumOutputs: 1
    OutputFileName: 'RegressionSVMModel'

  Properties, Methods
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
initialize('update',varargin{:});
end
```

```
type initialize.m
```

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:01
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                       SupportVectors
        %                       Scale
        %                       Bias
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
```

```
end
end
```

Update Parameters of SVM Regression Model in Generated Code

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `carsmall` data set and train an SVM regression model using the first 50 observations.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `RegressionSVM` object.

Create Coder Configurer

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:));
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM regression model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM regression model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 2];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains two predictors, so the value of the `SizeVector` attribute must be two and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 2];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
```

```
configurer.SupportVectors.VariableDimensions = [true false];
```

```
VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.
```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'
Code generation successful.
```

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `RegressionSVMModel` for the two entry-point functions in the `codegen\mex\RegressionSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
yfit = predict(Mdl,X);
yfit_mex = RegressionSVMModel('predict',X);
```

`yfit_mex` might include round-off differences compared with `yfit`. In this case, compare `yfit` and `yfit_mex`, allowing a small tolerance.

```
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =

  0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance `1e–6`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
yfit = predict(retrainedMdl,X);
yfit_mex = RegressionSVMModel('predict',X);
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =

  0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance `1e-6`.

More About

`LearnerCoderInput` Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
`SizeVector`	Array size if the corresponding `VariableDimensions` value is `false`. Upper bound of the array size if the corresponding `VariableDimensions` value is `true`. To allow an unbounded array, specify the bound as `Inf`.

Attribute Name	Description
`VariableDimensions`	Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as `true` (logical 1) or `false` (logical 0): • A value of `true` (logical 1) means that the corresponding dimension has a variable size. • A value of `false` (logical 0) means that the corresponding dimension has a fixed size.
`DataType`	Data type of the array
`Tunability`	Indicator specifying whether or not `predict` or `update` includes the argument as an input in the generated code, specified as `true` (logical 1) or `false` (logical 0). If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the coefficients `Alpha` of the coder configurer `configurer` as follows:

```
configurer.Alpha.SizeVector = [100 1];
configurer.Alpha.VariableDimensions = [1 0];
configurer.Alpha.DataType = 'double';
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

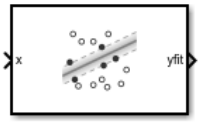
RegressionSVM Predict

Predict responses using support vector machine (SVM) regression model
Library: Statistics and Machine Learning Toolbox / Regression



Description

The RegressionSVM Predict block predicts responses using an SVM regression object (`RegressionSVM` or `CompactRegressionSVM`).

Import a trained SVM regression object into the block by specifying the name of a workspace variable that contains the object. The input port **x** receives an observation (predictor data), and the output port **yfit** returns a predicted response for the observation.

Ports

Input

x — Predictor data

row vector | column vector

Predictor data, specified as a column vector or row vector of one observation.

Dependencies

- The variables in **x** must have the same order as the predictor variables that trained the SVM model specified by **`Select trained machine learning model`**.
- If you set `'Standardize',true` in `fitrsvm` when training the SVM model, then the RegressionSVM Predict block standardizes the values of **x** using the means and standard deviations in the `Mu` and `Sigma` properties (respectively) of the SVM model.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

yfit — Predicted response

scalar

Predicted response, returned as a scalar.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main

`Select trained machine learning model` — SVM regression model

`svmMdl` (default) | `RegressionSVM` object | `CompactRegressionSVM` object

Specify the name of a workspace variable that contains a `RegressionSVM` object or `CompactRegressionSVM` object.

When you train the SVM model by using `fitrsvm`, the following restrictions apply:

- The predictor data cannot include categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
- The value of the `'ResponseTransform'` name-value argument must be `'none'` (default).
- The value of the `'KernelFunction'` name-value argument must be `'gaussian'`, `'linear'` (default), or `'polynomial'`.

Programmatic Use

Block Parameter: `TrainedLearner`
Type: workspace variable
Values: `RegressionSVM` object | `CompactRegressionSVM` object
Default: `'svmMdl'`

Data Types

Fixed-Point Operational Parameters

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of –128.
Clear this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors" (Simulink).	Overflows wrap to the appropriate value that the data type can represent.	The maximum value that the `int8` (signed 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8` is –126.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data type
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data type you specify for the block. For more information, see "Use Lock Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Data Type

`Output data type` — Data type of yfit output
`Inherit: auto` (default) | `double` | `single` | `half` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the data type for the **yfit** output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select `Inherit: auto`, the block uses a rule that inherits a data type.

For more information about data types, see “Control Signal Data Types” (Simulink).

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: auto'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'boolean'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: auto'`

`Output minimum` — Minimum value of yfit output for range checking
`[]` (default) | scalar

Lower value of the **yfit** output range that Simulink checks.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Output minimum** parameter does not saturate or clip the actual **yfit** signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

`Output maximum` — Maximum value of yfit output for range checking

`[]` (default) | scalar

Upper value of the **yfit** output range that Simulink checks.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Output maximum** parameter does not saturate or clip the actual **yfit** signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

`Kernel data type` — Kernel computation data type

`double` (default) | `single` | `half` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `int64` | `uint64` | `uint32` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the data type of a parameter for kernel computation. The type can be specified directly or expressed as a data type object such as `Simulink.NumericType`.

The **Kernel data type** parameter specifies the data type of a different parameter depending on the type of kernel function of the specified SVM model. You specify the `'KernelFunction'` name-value argument when training the SVM model.

`'KernelFunction'` value	Data Type
`'gaussian'` or `'rbf'`	**Kernel data type** specifies the data type of the squared distance $D^2 = \|x - s\|^2$ for the Gaussian kernel $G(x,s) = \exp\left(-D^2\right)$, where x is the predictor data for an observation and s is a support vector.
`'linear'`	**Kernel data type** specifies the data type for the output of the linear kernel function $G(x,s) = xs'$, where x is the predictor data for an observation and s is a support vector.

'KernelFunction' value	Data Type
'polynomial'	**Kernel data type** specifies the data type for the output of the polynomial kernel function $G(x,s) = (1 + xs')^p$, where x is the predictor data for an observation, s is a support vector, and p is a polynomial kernel function order.

For more information about data types, see “Control Signal Data Types” (Simulink).

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Programmatic Use
Block Parameter: `KernelDataTypeStr`
Type: character vector
Values: `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'uint64'` | `'int64'` | `'boolean'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'double'`

`Kernel minimum` — Minimum kernel computation value for range checking

`[ ]` (default) | scalar

Lower value of the kernel computation internal variable range that Simulink checks.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Kernel minimum** parameter does not saturate or clip the actual kernel computation value signal.

Programmatic Use
Block Parameter: `KernelOutMin`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

`Kernel maximum` — Maximum kernel computation value for range checking

`[ ]` (default) | scalar

Upper value of the kernel computation internal variable range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Kernel maximum** parameter does not saturate or clip the actual kernel computation value signal.

Programmatic Use

Block Parameter: `KernelOutMax`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `half` | `integer` | `single`
Direct Feedthrough	`yes`
Multidimensional Signals	`no`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

Tips

- If you are using a linear SVM model and it has many support vectors, then prediction can be slow. To efficiently predict responses based on a linear SVM model, remove the support vectors from the `RegressionSVM` or `CompactRegressionSVM` object by using `discardSupportVectors`.

Alternative Functionality

You can use a MATLAB Function block with the `predict` object function of an SVM regression object (`RegressionSVM` or `CompactRegressionSVM`). For an example, see “Predict Class Labels Using MATLAB Function Block” on page 32-40.

When deciding whether to use the RegressionSVM Predict block in the Statistics and Machine Learning Toolbox library or a MATLAB Function block with the `predict` function, consider the following:

- If you use the Statistics and Machine Learning Toolbox library block, you can use the **Fixed-Point Tool** to convert a floating-point model to fixed point.
- Support for variable-size arrays must be enabled for a MATLAB Function block with the `predict` function.
- If you use a MATLAB Function block, you can use MATLAB functions for preprocessing or post-processing before or after predictions in the same MATLAB Function block.

Compatibility Considerations

Specify Kernel data type as a data type name or data type object

Behavior changed in R2021a

Starting in R2021a, the **Kernel data type** parameter does not support inherited options. You can specify **Kernel data type** as a supported data type name or data type object.

Introduced in R2020b

RegressionTree class

Superclasses: `CompactRegressionTree`

Regression tree

Description

A decision tree with binary splits for regression. An object of class `RegressionTree` can predict responses for new data with the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

Construction

Create a `RegressionTree` object by using `fitrtree`.

Properties

`BinEdges`

Bin edges for numeric predictors, specified as a cell array of *p* numeric vectors, where *p* is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

`CategoricalPredictors`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

`CategoricalSplits`

An *n*-by-2 cell array, where `n` is the number of categorical splits in `tree`. Each row in `CategoricalSplits` gives left and right values for a categorical split. For each branch node with categorical split `j` based on a categorical predictor variable `z`, the left child is chosen if `z` is in `CategoricalSplits(j,1)` and the right child is chosen if `z` is in `CategoricalSplits(j,2)`. The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running `cuttype` and selecting `'categorical'` cuts from top to bottom.

`Children`

An *n*-by-2 array containing the numbers of the child nodes for each node in `tree`, where *n* is the number of nodes. Leaf nodes have child node `0`.

`CutCategories`

An *n*-by-2 cell array of the categories used at branches in `tree`, where *n* is the number of nodes. For each branch node `i` based on a categorical predictor variable `x`, the left child is chosen if `x` is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if `x` is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for `'continuous'` cuts, and `CutCategories` contains the set of categories.

`CutPoint`

An *n*-element vector of the values used as cut points in `tree`, where *n* is the number of nodes. For each branch node `i` based on a continuous predictor variable `x`, the left child is chosen if `x<CutPoint(i)` and the right child is chosen if `x>=CutPoint(i)`. `CutPoint` is `NaN` for branch nodes based on categorical predictors and for leaf nodes.

`CutType`

An *n*-element cell array indicating the type of cut at each node in `tree`, where *n* is the number of nodes. For each node `i`, `CutType{i}` is:

- `'continuous'` — If the cut is defined in the form `x < v` for a variable `x` and cut point `v`.
- `'categorical'` — If the cut is defined by whether a variable `x` takes a value in a set of categories.
- `''` — If `i` is a leaf node.

`CutPoint` contains the cut points for `'continuous'` cuts, and `CutCategories` contains the set of categories.

CutPredictor

An *n*-element cell array of the names of the variables used for branching in each node in `tree`, where *n* is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for `'continuous'` cuts, and `CutCategories` contains the set of categories.

CutPredictorIndex

An *n*-element array of numeric indices for the variables used for branching in each node in `tree`, where *n* is the number of nodes. For more information, see `CutPredictor`.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

IsBranchNode

An *n*-element logical vector `ib` that is `true` for each branch node and `false` for each leaf node of `tree`.

ModelParameters

Object holding parameters of `tree`.

NumObservations

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data `X` when there are missing values in `X` or response `Y`.

NodeError

An *n*-element vector `e` of the errors of the nodes in `tree`, where *n* is the number of nodes. `e(i)` is the mean squared error for node `i`.

NodeMean

An *n*-element numeric array with mean values in each node of `tree`, where *n* is the number of nodes in the tree. Every element in `NodeMean` is the average of the true `Y` values over all observations in the node.

NodeProbability

An *n*-element vector `p` of the probabilities of the nodes in `tree`, where *n* is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node.

NodeRisk

An *n*-element vector of the risk of the nodes in the tree, where *n* is the number of nodes. The risk for each node is the node error weighted by the node probability.

NodeSize

An *n*-element vector `sizes` of the sizes of the nodes in `tree`, where *n* is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes `n` in `tree`.

Parent

An *n*-element vector `p` containing the number of the parent node for each node in `tree`, where *n* is the number of nodes. The parent of the root node is `0`.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to *M*, then `PruneAlpha` has *M* + 1 elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An *n*-element numeric vector with the pruning levels in each node of `tree`, where *n* is the number of nodes. The pruning levels range from 0 (no pruning) to *M*, where *M* is the distance between the deepest leaf and the root node.

ResponseName

A character vector that specifies the name of the response variable (`Y`).

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle must accept a matrix of response values and return a matrix of the same size. The default `'none'` means `@(x)x`, or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
tree.ResponseTransform = @function
```

RowsUsed

An *n*-element logical vector indicating which rows of the original predictor data (`X`) were used in fitting. If the software uses all rows of `X`, then `RowsUsed` is an empty array (`[]`).

SurrogateCutCategories

An *n*-element cell array of the categories used for surrogate splits in `tree`, where *n* is the number of nodes in `tree`. For each node `k`, `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An *n*-element cell array of the numeric cut assignments used for surrogate splits in `tree`, where *n* is the number of nodes in `tree`. For each node `k`, `SurrogateCutFlip{k}` is a numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either –1 or +1. For every surrogate split with a numeric cut C based on a continuous predictor variable Z, the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is +1, or if $Z \geq C$ and the cut assignment for this surrogate split is –1. Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is +1, or if $Z < C$ and the cut assignment for this surrogate split is –1. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An *n*-element cell array of the numeric values used for surrogate splits in `tree`, where *n* is the number of nodes in `tree`. For each node `k`, `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either `NaN` for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z, the left child is chosen if $Z<C$ and `SurrogateCutFlip` for this surrogate split is +1, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is –1. Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is +1, or if $Z < C$ and

SurrogateCutFlip for this surrogate split is –1. The order of the surrogate split variables at each node is matched to the order of variables returned by SurrCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutPoint contains an empty cell.

SurrogateCutType

An *n*-element cell array indicating types of surrogate splits at each node in tree, where *n* is the number of nodes in tree. For each node k, SurrogateCutType{k} is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutType contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form Z < V for a variable Z and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An *n*-element cell array of the names of the variables used for surrogate splits in each node in tree, where *n* is the number of nodes in tree. Every element of SurrogateCutPredictor is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogateCutPredictor contains an empty cell.

SurrogatePredictorAssociation

An *n*-element cell array of the predictive measures of association for surrogate splits in tree, where *n* is the number of nodes in tree. For each node k, SurrogatePredictorAssociation{k} is a numeric vector. The length of SurrogatePredictorAssociation{k} is equal to the number of surrogate predictors found at this node. Every element of SurrogatePredictorAssociation{k} gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in SurrogateCutPredictor. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrogatePredictorAssociation contains an empty cell.

W

The scaled weights, a vector with length n, the number of rows in X.

X

A matrix or table of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as X. Each entry in Y is the response to the data in the corresponding row of X.

Object Functions

compact	Compact regression tree

crossval	Cross-validated decision tree
cvloss	Regression error by cross validation
lime	Local interpretable model-agnostic explanations (LIME)
loss	Regression error
partialDependence	Compute partial dependence
plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Predict responses using regression tree
predictorImportance	Estimates of predictor importance for regression tree
prune	Produce sequence of regression subtrees by pruning
resubLoss	Regression error by resubstitution
resubPredict	Predict resubstitution response of tree
shapley	Shapley values
surrogateAssociation	Mean predictive measure of association for surrogate splits in regression tree
view	View regression tree

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects.

Examples

Construct Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree using the sample data. The response variable is miles per gallon, MPG.

```
tree = fitrtree([Weight, Cylinders],MPG,...
                'CategoricalPredictors',2,'MinParentSize',20,...
                'PredictorNames',{'W','C'})
```

```
tree =
  RegressionTree
           PredictorNames: {'W'  'C'}
             ResponseName: 'Y'
    CategoricalPredictors: 2
        ResponseTransform: 'none'
          NumObservations: 94

  Properties, Methods
```

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
MPG4Kpred = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
MPG4Kpred = 3×1

   19.2778
```

```
19.2778
14.3889
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- To integrate the prediction of a regression tree model into Simulink, you can use the RegressionTree Predict block in the Statistics and Machine Learning Toolbox library or a MATLAB Function block with the `predict` function.
- When you train a regression tree model by using `fitrtree`, the following restrictions apply.
  - The value of the `'ResponseTransform'` name-value pair argument must be `'none'` (default).
  - You cannot use surrogate splits, that is, the value of the `'Surrogate'` name-value pair argument must be `'off'`.
  - Fixed-point code generation and code generation with a coder configurer do not support categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). You cannot use the `'CategoricalPredictors'` name-value argument. To include categorical predictors in a model, preprocess them by using `dummyvar` before fitting the model.

For more information, see “Introduction to Code Generation” on page 32-2.

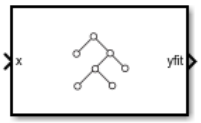
RegressionTree Predict

Predict responses using regression tree model
Library: Statistics and Machine Learning Toolbox / Regression



Description

The RegressionTree Predict block predicts responses using a regression tree object (`RegressionTree` or `CompactRegressionTree`).

Import a trained regression object into the block by specifying the name of a workspace variable that contains the object. The input port **x** receives an observation (predictor data), and the output port **yfit** returns a predicted response for the observation.

Ports

Input

x — Predictor data
row vector | column vector

Predictor data, specified as a column vector or row vector of one observation.

Dependencies

- The variables in **x** must have the same order as the predictor variables that trained the model specified by **`Select trained machine learning model`**.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Output

yfit — Predicted response
scalar

Predicted response, returned as a scalar.

Data Types: `single` | `double` | `half` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point`

Parameters

Main

Select trained machine learning model — Regression tree model
`treeMdl` (default) | `RegressionTree` object | `CompactRegressionTree` object

Specify the name of a workspace variable that contains a `RegressionTree` object or `CompactRegressionTree` object.

When you train the model by using `fitrtree`, the following restrictions apply:

- The predictor data cannot include categorical predictors (`logical`, `categorical`, `char`, `string`, or `cell`). If you supply training data in a table, the predictors must be numeric (`double` or `single`). Also, you cannot use the `'CategoricalPredictors'` name-value argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
- The value of the `'ResponseTransform'` name-value argument must be `'none'` (default).
- You cannot use surrogate splits, that is, the value of the `'Surrogate'` name-value argument must be `'off'` (default).

Programmatic Use

Block Parameter: `TrainedLearner`
Type: workspace variable
Values: `RegressionTree` object | `CompactRegressionTree` object
Default: `'treeMdl'`

Data Types

Fixed-Point Operational Parameters

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of –128.
Clear this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Troubleshoot Signal Range Errors" (Simulink).	Overflows wrap to the appropriate value that the data type can represent.	The maximum value that the `int8` (signed 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8` is –126.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data type
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data type you specify for the block. For more information, see "Use Lock Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Data Type

`Output data type` — Data type of yfit output
`Inherit: auto` (default) | `double` | `single` | `half` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `int64` | `uint64` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the data type for the **yfit** output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select `Inherit: auto`, the block uses a rule that inherits a data type.

For more information about data types, see “Control Signal Data Types” (Simulink).

Click the **Show data type assistant** button  to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant” (Simulink).

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: auto'` | `'double'` | `'single'` | `'half'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'int64'` | `'uint64'` | `'boolean'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: auto'`

`Output minimum` — Minimum value of yfit output for range checking
`[]` (default) | scalar

Lower value of the **yfit** output range that Simulink checks.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Output minimum** parameter does not saturate or clip the actual **yfit** signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

`Output maximum` — Maximum value of yfit output for range checking
`[]` (default) | scalar

Upper value of the **yfit** output range that Simulink checks.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)) for some blocks.
- Simulation range checking (see “Specify Signal Ranges” (Simulink) and “Enable Simulation Range Checking” (Simulink)).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Embedded Coder).

Note The **Output maximum** parameter does not saturate or clip the actual **yfit** signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

Block Characteristics

Data Types	`Boolean` | `double` | `fixed point` | `half` | `integer` | `single`
Direct Feedthrough	`yes`
Multidimensional Signals	`no`
Variable-Size Signals	`no`
Zero-Crossing Detection	`no`

Alternative Functionality

You can use a MATLAB Function block with the `predict` object function of a regression tree object (`RegressionTree` or `CompactRegressionTree`). For an example, see “Predict Class Labels Using MATLAB Function Block” on page 32-40.

When deciding whether to use the RegressionTree Predict block in the Statistics and Machine Learning Toolbox library or a MATLAB Function block with the `predict` function, consider the following:

- If you use the Statistics and Machine Learning Toolbox library block, you can use the **Fixed-Point Tool** to convert a floating-point model to fixed point.

- Support for variable-size arrays must be enabled for a MATLAB Function block with the `predict` function.
- If you use a MATLAB Function block, you can use MATLAB functions for preprocessing or post-processing before or after predictions in the same MATLAB Function block.

RegressionTreeCoderConfigurer

Coder configurer of binary decision tree model for regression

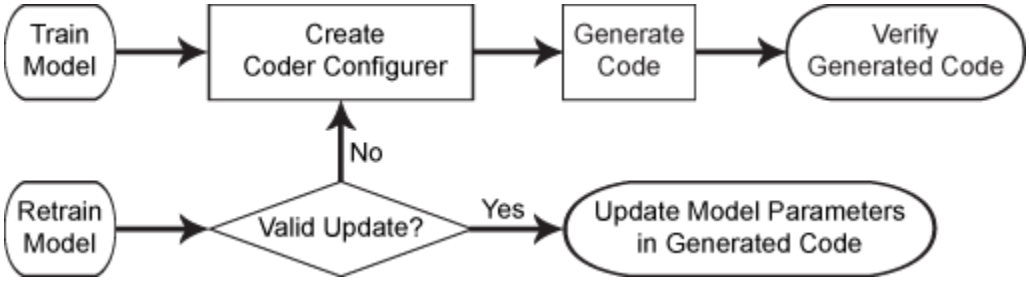
Description

A `RegressionTreeCoderConfigurer` object is a coder configurer of a binary decision tree model for regression (`RegressionTree` or `CompactRegressionTree`).

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes for tree model parameters by using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the regression tree model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the tree model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.



For the code generation usage notes and limitations of a regression tree model, see the Code Generation sections of `CompactRegressionTree`, `predict`, and `update`.

Creation

After training a regression tree model by using `fitrtree`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of the `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

`predict` Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data
`LearnerCoderInput` object

Coder attributes of the predictor data to pass to the generated C/C++ code for the `predict` function of the regression tree model, specified as a `LearnerCoderInput` on page 33-5445 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, to generate C/C++ code that accepts predictor data with 100 observations of three predictor variables, specify these coder attributes of `X` for the coder configurer `configurer`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [0 0];
```

`[0 0]` indicates that the first and second dimensions of `X` (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify these coder attributes of `X`:

```
configurer.X.SizeVector = [100 3];
configurer.X.DataType = 'double';
configurer.X.VariableDimensions = [1 0];
```

`[1 0]` indicates that the first dimension of `X` (number of observations) has a variable size and the second dimension of `X` (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

NumOutputs — Number of outputs in `predict`
1 (default) | 2

Number of output arguments to return from the generated C/C++ code for the `predict` function of the regression tree model, specified as 1 or 2.

The output arguments of `predict` are `Yfit` (predicted responses) and `node` (node numbers for predictions), in that order. `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function, where `n` is the `NumOutputs` value.

After creating the coder configurer `configurer`, you can specify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of a regression tree model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `double`

`update` Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 33-5445 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

`Children` — Coder attributes of child nodes for each node

`LearnerCoderInput` object

Coder attributes of the child nodes for each node in the tree (`Children` of a regression tree model), specified as a `LearnerCoderInput` on page 33-5445 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 2]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `CutPoint`, `CutPredictorIndex`, and `NodeMean`. Similarly, if you modify the first dimension of `VariableDimensions` to be `1`, then the software modifies the first dimension of the `VariableDimensions` attribute to be `1` for these properties.

`CutPoint` — Coder attributes of cut point for each node

`LearnerCoderInput` object

Coder attributes of the cut point for each node in the tree (`CutPoint` of a regression tree model), specified as a `LearnerCoderInput` on page 33-5445 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 1]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `Children`, `CutPredictorIndex`, and `NodeMean`. Similarly, if you modify the first dimension of `VariableDimensions` to be `1`, then the software modifies the first dimension of the `VariableDimensions` attribute to be `1` for these properties.

`CutPredictorIndex` — Coder attributes of cut predictor index for each node
`LearnerCoderInput` object

Coder attributes of the cut predictor index for each node in the tree (`CutPredictorIndex` of a regression tree model), specified as a `LearnerCoderInput` on page 33-5445 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 1]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `Children`, `CutPoint`, and `NodeMean`. Similarly, if you modify the first dimension of `VariableDimensions` to be `1`, then the software modifies the first dimension of the `VariableDimensions` attribute to be `1` for these properties.

`NodeMean` — Coder attributes of mean response value for each node
`LearnerCoderInput` object

Coder attributes of the mean response value for each node in the tree (`NodeMean` of a regression tree model), specified as a `LearnerCoderInput` on page 33-5445 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is `[nd 1]`, where `nd` is the number of nodes in `Mdl`.
- `VariableDimensions` — This value is `[0 0]`(default) or `[1 0]`.
  - `[0 0]` indicates that the array size is fixed as specified in `SizeVector`.
  - `[1 0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `'single'` or `'double'`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — This value must be `true`.

If you modify the first dimension of `SizeVector` to be `newnd`, then the software modifies the first dimension of the `SizeVector` attribute to be `newnd` for the properties `Children`, `CutPoint`, and `CutPredictorIndex`. Similarly, if you modify the first dimension of `VariableDimensions` to be `1`, then the software modifies the first dimension of the `VariableDimensions` attribute to be `1` for these properties.

Other Configurer Options

`OutputFileName` — File name of generated C/C++ code
`'RegressionTreeModel'` (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function `generateCode` of `RegressionTreeCoderConfigurer` generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer `configurer`, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

`Verbose` — Verbosity level
`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
`true` (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.

Value	Description
`false` (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the `codegen` arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the `codegen` arguments.

`CodeGenerationArguments` — `codegen` arguments
cell array

This property is read-only.

`codegen` arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

`PredictInputs` — Input argument of `predict`
cell array of a `coder.PrimitiveType` object

This property is read-only.

Input argument of the entry-point function `predict.m` for code generation, specified as a cell array of a `coder.PrimitiveType` object. The `coder.PrimitiveType` object includes the coder attributes of the predictor data stored in the `X` property.

If you modify the coder attributes of the predictor data, then the software updates the `coder.PrimitiveType` object accordingly.

The `coder.PrimitiveType` object in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: `cell`

`UpdateInputs` — List of tunable input arguments of `update`
cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (`update` Arguments on page 33-5435 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: `cell`

Object Functions

generateCode	Generate C/C++ code using coder configurer
generateFiles	Generate MATLAB files for code generation using coder configurer
validatedUpdateInputs	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carbig` data set, which contains car data, and train a regression tree model.

```
load carbig
X = [Displacement Horsepower Weight];
```

```
Y = MPG;
Mdl = fitrtree(X,Y);
```

`Mdl` is a `RegressionTree` object.

Create a coder configurer for the `RegressionTree` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)
```

```
configurer =
  RegressionTreeCoderConfigurer with properties:

   Update Inputs:
             Children: [1x1 LearnerCoderInput]
             NodeMean: [1x1 LearnerCoderInput]
             CutPoint: [1x1 LearnerCoderInput]
    CutPredictorIndex: [1x1 LearnerCoderInput]

   Predict Inputs:
                   X: [1x1 LearnerCoderInput]

   Code Generation Parameters:
           NumOutputs: 1
       OutputFileName: 'RegressionTreeModel'

  Properties, Methods
```

`configurer` is a `RegressionTreeCoderConfigurer` object, which is a coder configurer of a `RegressionTree` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the regression tree model (`Mdl`) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionTreeModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionTreeModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionTreeModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:29
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:29
initialize('update',varargin{:});
end
```

```
type initialize.m
```

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 25-Feb-2021 14:01:29
coder.inline('always')
persistent model
if isempty(model)
    model = loadLearnerForCoder('RegressionTreeModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Children
        %                       NodeMean
        %                       CutPoint
        %                       CutPredictorIndex
        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X
        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end
```

Update Parameters of Regression Tree Model in Generated Code

Train a regression tree using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the entire data set, and update parameters in the generated code without regenerating the code.

Train Model

Load the `carbig` data set, and train a regression tree model using half of the observations.

```
load carbig
X = [Displacement Horsepower Weight];
Y = MPG;

rng('default') % For reproducibility
n = length(Y);
idxTrain = randsample(n,n/2);
XTrain = X(idxTrain,:);
YTrain = Y(idxTrain);

Mdl = fitrtree(XTrain,YTrain);
```

`Mdl` is a `RegressionTree` object.

Create Coder Configurer

Create a coder configurer for the `RegressionTree` model by using `learnerCoderConfigurer`. Specify the predictor data `XTrain`. The `learnerCoderConfigurer` function uses the input `XTrain` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted responses and node numbers for the predictions.

```
configurer = learnerCoderConfigurer(Mdl,XTrain,'NumOutputs',2);
```

`configurer` is a `RegressionTreeCoderConfigurer` object, which is a coder configurer of a `RegressionTree` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the regression tree model parameters so that you can update the parameters in the generated code after retraining the model.

Specify the coder attributes of the `X` property of `configurer` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 3];
configurer.X.VariableDimensions
```

```
ans = 1x2 logical array

   1   0
```

The size of the first dimension is the number of observations. Setting the value of the `SizeVector` attribute to `Inf` causes the software to change the value of the `VariableDimensions` attribute to `1`. In other words, the upper bound of the size is `Inf` and the size is variable, meaning that the predictor data can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. Because the predictor data contains 3 predictors, the value of the `SizeVector` attribute must be `3` and the value of the `VariableDimensions` attribute must be `0`.

If you retrain the tree model using new data or different settings, the number of nodes in the tree can vary. Therefore, specify the first dimension of the `SizeVector` attribute of one of these properties so

that you can update the number of nodes in the generated code: `Children`, `CutPoint`, `CutPredictorIndex`, or `NodeMean`. The software then modifies the other properties automatically.

For example, set the first value of the `SizeVector` attribute of the `NodeMean` property to `Inf`. The software modifies the `SizeVector` and `VariableDimensions` attributes of `Children`, `CutPoint`, and `CutPredictorIndex` to match the new upper bound on the number of nodes in the tree. Additionally, the first value of the `VariableDimensions` attribute of `NodeMean` changes to `1`.

```
configurer.NodeMean.SizeVector = [Inf 1];
```

```
SizeVector attribute for Children has been modified to satisfy configuration constraints.
SizeVector attribute for CutPoint has been modified to satisfy configuration constraints.
SizeVector attribute for CutPredictorIndex has been modified to satisfy configuration constraints
VariableDimensions attribute for Children has been modified to satisfy configuration constraints
VariableDimensions attribute for CutPoint has been modified to satisfy configuration constraints
VariableDimensions attribute for CutPredictorIndex has been modified to satisfy configuration co
```

```
configurer.NodeMean.VariableDimensions
```

```
ans = 1x2 logical array

   1   0
```

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler”.

Generate code for the `predict` and `update` functions of the regression tree model (`Mdl`).

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionTreeModel.mat'
Code generation successful.
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionTreeModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionTreeModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[Yfit,node] = predict(Mdl,XTrain);
[Yfit_mex,node_mex] = RegressionTreeModel('predict',XTrain);
```

Compare `Yfit` to `Yfit_mex` and `node` to `node_mex`.

```
max(abs(Yfit-Yfit_mex),[],'all')

ans = 0

isequal(node,node_mex)

ans = logical
   1
```

In general, `Yfit_mex` might include round-off differences compared to `Yfit`. In this case, the comparison confirms that `Yfit` and `Yfit_mex` are equal.

`isequal` returns logical 1 (`true`) if all the input arguments are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same node numbers.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrtree(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionTreeModel('update',params)
```

Verify Generated Code

Compare the output arguments from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[Yfit,node] = predict(retrainedMdl,X);
[Yfit_mex,node_mex] = RegressionTreeModel('predict',X);

max(abs(Yfit-Yfit_mex),[],'all')

ans = 0

isequal(node,node_mex)

ans = logical
   1
```

The comparison confirms that the predicted responses and node numbers are equal.

More About

`LearnerCoderInput` Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
`SizeVector`	Array size if the corresponding `VariableDimensions` value is `false`. Upper bound of the array size if the corresponding `VariableDimensions` value is `true`. To allow an unbounded array, specify the bound as `Inf`.
`VariableDimensions`	Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as `true` (logical 1) or `false` (logical 0): • A value of `true` (logical 1) means that the corresponding dimension has a variable size. • A value of `false` (logical 0) means that the corresponding dimension has a fixed size.
`DataType`	Data type of the array
`Tunability`	Indicator specifying whether or not `predict` or `update` includes the argument as an input in the generated code, specified as `true` (logical 1) or `false` (logical 0). If you specify other attribute values when `Tunability` is `false`, the software sets `Tunability` to `true`.

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the `CutPoint` property of the coder configurer `configurer`:

```
configurer.CutPoint.SizeVector = [40 1];
configurer.CutPoint.VariableDimensions = [1 0];
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

Topics

“Introduction to Code Generation” on page 32-2
“Code Generation for Prediction and Update Using Coder Configurer” on page 32-80

Introduced in R2019b

regstats

Regression diagnostics

Syntax

```
regstats(y,X,model)
stats = regstats(...)
stats = regstats(y,X,model,whichstats)
```

Description

`regstats(y,X,model)` performs a multilinear regression of the responses in `y` on the predictors in `X`. `X` is an *n*-by-*p* matrix of *p* predictors at each of *n* observations. `y` is an *n*-by-1 vector of observed responses.

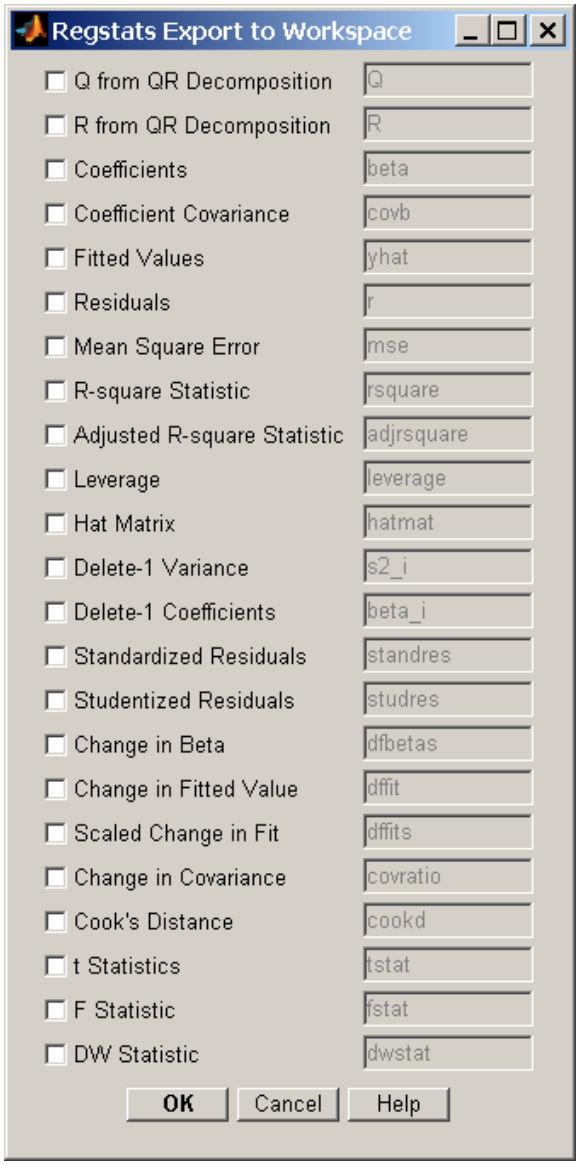
Note By default, `regstats` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`.

The optional input `model` controls the regression model. By default, `regstats` uses a linear additive model with a constant term. `model` can be any one of the following:

- `'linear'` — Constant and linear terms (the default)
- `'interaction'` — Constant, linear, and interaction terms
- `'quadratic'` — Constant, linear, interaction, and squared terms
- `'purequadratic'` — Constant, linear, and squared terms

Alternatively, `model` can be a matrix of model terms accepted by the `x2fx` function. See `x2fx` for a description of this matrix and for a description of the order in which terms appear. You can use this matrix to specify other models including ones without a constant term.

With this syntax, the function displays a graphical user interface (GUI) with a list of diagnostic statistics, as shown in the following figure.



When you select check boxes corresponding to the statistics you want to compute and click **OK**, `regstats` returns the selected statistics to the MATLAB workspace. The names of the workspace variables are displayed on the right-hand side of the interface. You can change the name of the workspace variable to any valid MATLAB variable name.

`stats = regstats(...)` creates the structure `stats`, whose fields contain all of the diagnostic statistics for the regression. This syntax does not open the GUI. The fields of `stats` are listed in the following table.

Field	Description
`Q`	*Q* from the *QR* decomposition of the design matrix
`R`	*R* from the *QR* decomposition of the design matrix
`beta`	Regression coefficients

Field	Description
`covb`	Covariance of regression coefficients
`yhat`	Fitted values of the response data
`r`	Residuals
`mse`	Mean squared error
`rsquare`	R^2 statistic
`adjrsquare`	Adjusted R^2 statistic
`leverage`	Leverage
`hatmat`	Hat matrix
`s2_i`	Delete-1 variance
`beta_i`	Delete-1 coefficients
`standres`	Standardized residuals
`studres`	Studentized residuals
`dfbetas`	Scaled change in regression coefficients
`dffit`	Change in fitted values
`dffits`	Scaled change in fitted values
`covratio`	Change in covariance
`cookd`	Cook's distance
`tstat`	*t* statistics and *p*-values for coefficients
`fstat`	*F* statistic and *p*-value
`dwstat`	Durbin-Watson statistic and *p*-value

Note that the fields names of `stats` correspond to the names of the variables returned to the MATLAB workspace when you use the GUI. For example, `stats.beta` corresponds to the variable `beta` that is returned when you select **Coefficients** in the GUI and click **OK**.

`stats = regstats(y,X,model,whichstats)` returns only the statistics that you specify in *`whichstats`*. *`whichstats`* can be a single character vector such as `'leverage'`, a string array such as `["leverage","standres","studres"]`, or a cell array of character vectors such as `{'leverage','standres','studres'}`. Set *`whichstats`* to `'all'` to return all of the statistics.

Note The *F* statistic is computed under the assumption that the model contains a constant term. It is not correct for models without a constant. The R^2 statistic can be negative for models without a constant, which indicates that the model is not appropriate for the data.

Examples

Open the `regstats` GUI using data from `hald.mat`:

```
load hald
regstats(heat,ingredients,'linear');
```

Select **Fitted Values** and **Residuals** in the GUI:

Click **OK** to export the fitted values and residuals to the MATLAB workspace in variables named `yhat` and `r`, respectively.

You can create the same variables using the `stats` output, without opening the GUI:

```
whichstats = {'yhat','r'};
stats = regstats(heat,ingredients,'linear',whichstats);
yhat = stats.yhat;
r = stats.r;
```

Tips

- `regstats` treats `NaN` values in `X` or `y` as missing values. `regstats` omits observations with missing values from the regression fit.

Introduced before R2006a

regularize

Find weights to minimize resubstitution error plus penalty term

Syntax

```
ens1 = regularize(ens)
ens1 = regularize(ens,Name,Value)
```

Description

`ens1 = regularize(ens)` finds optimal weights for learners in `ens` by lasso regularization. `regularize` returns a regression ensemble identical to `ens`, but with a populated `Regularization` property.

`ens1 = regularize(ens,Name,Value)` computes optimal weights with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

A regression ensemble, created by `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`lambda`

Vector of nonnegative regularization parameter values for lasso. For the default setting of `lambda`, `regularize` calculates the smallest value `lambda_max` for which all optimal weights for learners are `0`. The default value of `lambda` is a vector including `0` and nine exponentially-spaced numbers from `lambda_max/1000` to `lambda_max`.

Default: `[0 logspace(log10(lambda_max/1000),log10(lambda_max),9)]`

`MaxIter`

Maximum number of iterations allowed, specified as a positive integer. If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance, then the function stops iterating and returns a warning message. The function can return more than one warning when either `npass` or the number of `lambda` values is greater than 1.

Default: `1e3`

`npass`

Maximal number of passes for lasso optimization, a positive integer.

Default: `10`

`reltol`

Relative tolerance on the regularized loss for lasso, a numeric positive scalar.

Default: `1e-3`

`verbose`

Verbosity level, either `0` or `1`. When set to `1`, `regularize` displays more information as it runs.

Default: `0`

Output Arguments

`ens1`

A regression ensemble. Usually you set `ens1` to the same name as `ens`.

Examples

Regularize Ensemble of Bagged Trees

Regularize an ensemble of bagged trees.

Generate sample data.

```
rng(10,'twister') % For reproducibility
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
```

You can create a bagged classification ensemble of 300 trees from the sample data.

```
bag = fitrensemble(X,Y,'Method','Bag','NumLearningCycles',300);
```

`fitrensemble` uses a default template tree object `templateTree()` as a weak learner when `'Method'` is `'Bag'`. In this example, for reproducibility, specify `'Reproducible',true` when you create a tree template object, and then use the object as a weak learner.

```
t = templateTree('Reproducible',true); % For reproducibiliy of random predictor selections
bag = fitrensemble(X,Y,'Method','Bag','NumLearningCycles',300,'Learners',t);
```

Regularize the ensemble of bagged regression trees.

```
bag = regularize(bag,'lambda',[0.001 0.1],'verbose',1);
```

        Number of learners with non-zero weights = 88
    Lasso minimization completed pass 8 for Lambda=0.1
        MSE = 0.078447
        Relative change in MSE = 5.24449e-05
        Number of learners with non-zero weights = 88
    Completed lasso minimization for Lambda=0.1.
    Resubstitution MSE changed from 0.109923 to 0.078447.
    Number of learners reduced from 300 to 88.
```

`regularize` reports on its progress.

Inspect the resulting regularization structure.

```
bag.Regularization
```

```
ans = struct with fields:
               Method: 'Lasso'
       TrainedWeights: [300x2 double]
               Lambda: [1.0000e-03 0.1000]
    ResubstitutionMSE: [0.0599 0.0784]
       CombineWeights: @classreg.learning.combiner.WeightedSum
```

Check how many learners in the regularized ensemble have positive weights. These are the learners included in a shrunken ensemble.

```
sum(bag.Regularization.TrainedWeights > 0)
```

```
ans = 1×2

   115    88
```

Shrink the ensemble using the weights from `Lambda = 0.1`.

```
cmp = shrink(bag,'weightcolumn',2)
```

```
cmp =
  CompactRegressionEnsemble
             ResponseName: 'Y'
    CategoricalPredictors: []
        ResponseTransform: 'none'
               NumTrained: 88

  Properties, Methods
```

The compact ensemble contains `87` members, less than 1/3 of the original `300`.

More About

Lasso

The lasso algorithm finds an optimal set of learner weights α_t that minimize

$$\sum_{n=1}^{N} w_n g\left(\left(\sum_{t=1}^{T} \alpha_t h_t(x_n)\right), y_n\right) + \lambda \sum_{t=1}^{T} |\alpha_t| .$$

Here

- $\lambda \geq 0$ is a parameter you provide, called the lasso parameter.
- h_t is a weak learner in the ensemble trained on N observations with predictors x_n, responses y_n, and weights w_n.
- $g(f,y) = (f - y)^2$ is the squared error.

relieff

Rank importance of predictors using ReliefF or RReliefF algorithm

Syntax

```
[idx,weights] = relieff(X,y,k)
[idx,weights] = relieff(X,y,k,Name,Value)
```

Description

`[idx,weights] = relieff(X,y,k)` ranks predictors using either the ReliefF or RReliefF algorithm with `k` nearest neighbors. The input matrix `X` contains predictor variables, and the vector `y` contains a response vector. The function returns `idx`, which contains the indices of the most important predictors, and `weights`, which contains the weights of the predictors.

If `y` is numeric, `relieff` performs RReliefF analysis for regression by default. Otherwise, `relieff` performs ReliefF analysis for classification using `k` nearest neighbors per class. For more information on ReliefF and RReliefF, see “Algorithms” on page 33-5461.

`[idx,weights] = relieff(X,y,k,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, `'updates',10` sets the number of observations randomly selected for computing weights to 10.

Examples

Determine Important Predictors

Load the sample data.

```
load fisheriris
```

Find the important predictors using 10 nearest neighbors.

```
[idx,weights] = relieff(meas,species,10)
```

```
idx = 1×4

     4     3     1     2

weights = 1×4

    0.1399    0.1226    0.3590    0.3754
```

`idx` shows the predictor numbers listed according to their ranking. The fourth predictor is the most important, and the second predictor is the least important. `weights` gives the weight values in the same order as the predictors. The first predictor has a weight of 0.1399, and the fourth predictor has a weight of 0.3754.

Rank Predictors by Importance

Load the sample data.

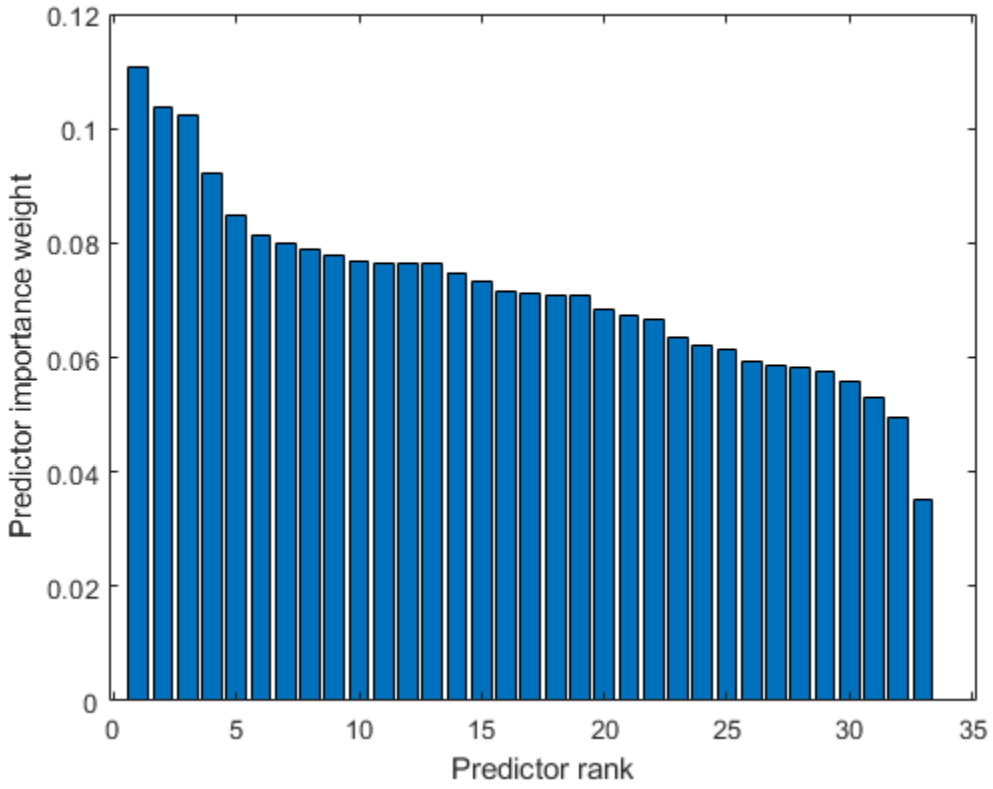
```
load ionosphere
```

Rank the predictors based on importance using 10 nearest neighbors.

```
[idx,weights] = relieff(X,Y,10);
```

Create a bar plot of predictor importance weights.

```
bar(weights(idx))
xlabel('Predictor rank')
ylabel('Predictor importance weight')
```



Select the top 5 most important predictors. Find the columns of these predictors in X.

```
idx(1:5)
```

```
ans = 1×5

    24     3     8     5    14
```

The 24th column of X is the most important predictor of Y.

Determine Important Categorical Predictors

Rank categorical predictors using `relieff`.

Load the sample data.

```
load carbig
```

Convert the categorical predictor variables `Mfg`, `Model`, and `Origin` to numerical values, and combine them into an input matrix. Specify the response variable `MPG`.

```
X = [grp2idx(Mfg) grp2idx(Model) grp2idx(Origin)];
y = MPG;
```

Find the ranks and weights of the predictor variables using 10 nearest neighbors and treating the data in `X` as categorical.

```
[idx,weights] = relieff(X,y,10,'categoricalx','on')
```

```
idx = 1×3

     2     3     1

weights = 1×3

   -0.0019    0.0501    0.0114
```

The `Model` predictor is the most important in predicting `MPG`. The `Mfg` variable has a negative weight, indicating it is not a good predictor of `MPG`.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one variable.

Data Types: `single` | `double`

y — Response data

numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response data, specified as a numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

k — Number of nearest neighbors

positive integer scalar

Number of nearest neighbors, specified as a positive integer scalar.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `relieff(X,y,5,'method','classification','categoricalx','on')` specifies 5 nearest neighbors and treats the response variable and predictor data as categorical.

`method` — Method for computing weights

`'regression'` | `'classification'`

Method for computing weights, specified as the comma-separated pair consisting of `'method'` and either `'regression'` or `'classification'`. If `y` is numeric, `'regression'` is the default method. Otherwise, `'classification'` is the default.

Example: `'method','classification'`

`prior` — Prior probabilities for each class

`'empirical'` (default) | `'uniform'` | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'prior'` and a value in this table.

Value	Description
`'empirical'`	The class probabilities are determined from class frequencies in `y`.
`'uniform'`	All class probabilities are equal.
numeric vector	One value exists for each distinct group name.
structure	A structure `S` with two fields: • `S.group` contains the group names as a variable of the same type as `y`. • `S.prob` contains a vector of corresponding probabilities.

Example: `'prior','uniform'`

Data Types: `single` | `double` | `char` | `string` | `struct`

`updates` — Number of observations for computing weights

`'all'` (default) | positive integer scalar

Number of observations to select at random for computing weights, specified as the comma-separated pair consisting of `'updates'` and either `'all'` or a positive integer scalar. By default, `relieff` uses all observations.

Example: `'updates',25`

Data Types: `single` | `double` | `char` | `string`

`categoricalx` — Categorical predictors flag
`'off'` (default) | `'on'`

Categorical predictors flag, specified as the comma-separated pair consisting of `'categoricalx'` and either `'on'` or `'off'`. If you specify `'on'`, then `relieff` treats all predictors in `X` as categorical. Otherwise, it treats all predictors in `X` as numeric. You cannot mix numeric and categorical predictors.

Example: `'categoricalx','on'`

`sigma` — Distance scaling factor
numeric positive scalar

Distance scaling factor, specified as the comma-separated pair consisting of `'sigma'` and a numeric positive scalar. For observation i, influence on the predictor weight from its nearest neighbor j is multiplied by $e^{-(\text{rank}(i,j)/\text{sigma})^2}$. rank($i$,$j$) is the position of the jth observation among the nearest neighbors of the ith observation, sorted by distance. The default is `Inf` for classification (all nearest neighbors have the same influence) and 50 for regression.

Example: `'sigma',20`

Data Types: `single` | `double`

Output Arguments

`idx` — Indices of predictors ordered by predictor importance
numeric vector

Indices of predictors in `X` ordered by predictor importance, returned as a numeric vector. For example, if `idx(3)` is `5`, then the third most important predictor is the fifth column in `X`.

Data Types: `double`

`weights` — Weights of predictors
numeric vector

Weights of the predictors, returned as a numeric vector. The values in `weights` have the same order as the predictors in `X`. `weights` range from `−1` to `1`, with large positive weights assigned to important predictors.

Data Types: `double`

Tips

- Predictor ranks and weights usually depend on `k`. If you set `k` to 1, then the estimates can be unreliable for noisy data. If you set `k` to a value comparable with the number of observations (rows) in `X`, `relieff` can fail to find important predictors. You can start with `k = 10` and investigate the stability and reliability of `relieff` ranks and weights for various values of `k`.
- `relieff` removes observations with `NaN` values.

Algorithms

ReliefF

ReliefF finds the weights of predictors in the case where `y` is a multiclass categorical variable. The algorithm penalizes the predictors that give different values to neighbors of the same class, and rewards predictors that give different values to neighbors of different classes.

ReliefF first sets all predictor weights W_j to 0. Then, the algorithm iteratively selects a random observation x_r, finds the k-nearest observations to x_r for each class, and updates, for each nearest neighbor x_q, all the weights for the predictors F_j as follows:

If x_r and x_q are in the same class,

$$W_j{}^i = W_j{}^{i-1} - \frac{\Delta_j(x_r, x_q)}{m} \cdot d_{rq}\,.$$

If x_r and x_q are in different classes,

$$W_j{}^i = W_j{}^{i-1} + \frac{p_{y_q}}{1 - p_{y_r}} \cdot \frac{\Delta_j(x_r, x_q)}{m} \cdot d_{rq}\,.$$

- W_j^i is the weight of the predictor F_j at the ith iteration step.
- p_{y_r} is the prior probability of the class to which x_r belongs, and p_{y_q} is the prior probability of the class to which x_q belongs.
- m is the number of iterations specified by `'updates'`.
- $\Delta_j(x_r, x_q)$ is the difference in the value of the predictor F_j between observations x_r and x_q. Let x_{rj} denote the value of the jth predictor for observation x_r, and let x_{qj} denote the value of the jth predictor for observation x_q.
  - For discrete F_j,

    $$\Delta_j(x_r, x_q) = \begin{cases} 0, & x_{rj} = x_{qj} \\ 1, & x_{rj} \neq x_{qj} \end{cases}.$$

  - For continuous F_j,

    $$\Delta_j(x_r, x_q) = \frac{\left|x_{rj} - x_{qj}\right|}{\max(F_j) - \min(F_j)}\,.$$
- d_{rq} is a distance function of the form

  $$d_{rq} = \frac{\tilde{d}_{rq}}{\sum_{l=1}^{k} \tilde{d}_{rl}}\,.$$

  The distance is subject to the scaling

  $$\tilde{d}_{rq} = e^{-(\mathrm{rank}(r,\,q)/\mathrm{sigma})^2}$$

where rank(r,q) is the position of the qth observation among the nearest neighbors of the rth observation, sorted by distance. k is the number of nearest neighbors, specified by `k`. You can change the scaling by specifying `'sigma'`.

RReliefF

RReliefF works with continuous `y`. Similar to ReliefF, RReliefF also penalizes the predictors that give different values to neighbors with the same response values, and rewards predictors that give different values to neighbors with different response values. However, RReliefF uses intermediate weights to compute the final predictor weights.

Given two nearest neighbors, assume the following:

- W_{dy} is the weight of having different values for the response y.
- W_{dj} is the weight of having different values for the predictor F_j.
- $W_{dy \wedge dj}$ is the weight of having different response values and different values for the predictor F_j.

RReliefF first sets the weights W_{dy}, W_{dj}, $W_{dy \wedge dj}$, and W_j equal to 0. Then, the algorithm iteratively selects a random observation x_r, finds the k-nearest observations to x_r, and updates, for each nearest neighbor x_q, all the intermediate weights as follows:

$$W_{dy}^{i} = W_{dy}^{i-1} + \Delta_y(x_r, x_q) \cdot d_{rq}\,.$$

$$W_{dj}^{i} = W_{dj}^{i-1} + \Delta_j(x_r, x_q) \cdot d_{rq}\,.$$

$$W_{dy \wedge dj}^{i} = W_{dy \wedge dj}^{i-1} + \Delta_y(x_r, x_q) \cdot \Delta_j(x_r, x_q) \cdot d_{rq}\,.$$

- The i and i-1 superscripts denote the iteration step number. m is the number of iterations specified by `'updates'`.
- $\Delta_y(x_r, x_q)$ is the difference in the value of the continuous response y between observations x_r and x_q. Let y_r denote the value of the response for observation x_r, and let y_q denote the value of the response for observation x_q.

$$\Delta_y(x_r, x_q) = \frac{|y_r - y_q|}{\max(y) - \min(y)}\,.$$

- The $\Delta_j(x_r, x_q)$ and d_{rq} functions are the same as for “ReliefF” on page 33-5461.

RReliefF calculates the predictor weights W_j after fully updating all the intermediate weights.

$$W_j = \frac{W_{dy \wedge dj}}{W_{dy}} - \frac{W_{dj} - W_{dy \wedge dj}}{m - W_{dy}}\,.$$

For more information, see [2].

“Sequential Feature Selection” on page 15-61

Introduced in R2010b

removeLearners

Remove members of compact classification ensemble

Syntax

```
cens1 = removeLearners(cens,idx)
```

Description

`cens1 = removeLearners(cens,idx)` creates a compact classification ensemble identical to `cens` only without the ensemble members in the `idx` vector.

Input Arguments

cens

Compact classification ensemble, constructed with `compact`.

idx

Vector of positive integers with entries from `1` to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains all members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

Output Arguments

cens1

Compact classification ensemble, identical to `cens` except `cens1` does not contain those members of `cens` with indices in `idx`.

Examples

Remove Learners from an Ensemble

Create a compact classification ensemble. Compact it further by removing members of the ensemble.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble for the `ionosphere` data using AdaBoostM1. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Create a compact classification ensemble `cens` from `ens`.

```
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;
cens1 = removeLearners(cens,idx);
```

Tips

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

removeLearners

Remove members of compact regression ensemble

Syntax

```
cens1 = removeLearners(cens,idx)
```

Description

`cens1 = removeLearners(cens,idx)` creates a compact regression ensemble identical to `cens` only without the ensemble members in the `idx` vector.

Input Arguments

cens

Compact regression ensemble, constructed with `compact`.

idx

Vector of positive integers with entries from `1` to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains the members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

Output Arguments

cens1

Compact regression ensemble, identical to `cens` except `cens1` does not contain members of `cens` with indices in `idx`.

Examples

Remove Learners from an Ensemble

Create a compact regression ensemble. Compact it further by removing members of the ensemble.

Load the `carsmall` data set and select `Weight` and `Cylinders` as predictors.

```
load carsmall
X = [Weight Cylinders];
```

Train a regression ensemble using LSBoost. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitrensemble(X,MPG,'Method','LSBoost','Learners',t,...
    'CategoricalPredictors',2);
```

Create a compact classification ensemble `cens` from `ens`.

```
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;
cens1 = removeLearners(cens,idx);
```

Tips

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

`CompactRegressionEnsemble`

removeTerms

Remove terms from generalized linear regression model

Syntax

```
NewMdl = removeTerms(mdl,terms)
```

Description

`NewMdl = removeTerms(mdl,terms)` returns a generalized linear regression model fitted using the input data and settings in `mdl` with the terms `terms` removed.

Examples

Remove Terms from Generalized Linear Regression Model

Create a generalized linear regression model using two predictors, and then remove one predictor.

Generate sample data using Poisson random numbers with two underlying predictors `X(:,1)` and `X(:,2)`.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2 + rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
    log(y) ~ 1 + x1 + x2
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE        tStat     pValue
                   ________    _________    ______    ______

    (Intercept)     1.0405      0.022122    47.034      0
    x1              0.9968      0.003362    296.49      0
    x2               1.987     0.0063433    313.24      0

100 observations, 97 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

Remove the second predictor from the model.

```
mdl1 = removeTerms(mdl,'x2')
```

```
mdl1 =
Generalized linear regression model:
    log(y) ~ 1 + x1
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE        tStat     pValue
                   ________    _________    ______    ______

    (Intercept)     2.7784      0.014043    197.85      0
    x1              1.1732     0.0033653     348.6      0

100 observations, 98 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 1.25e+05, p-value = 0
```

Input Arguments

`mdl` — Generalized linear regression model

`GeneralizedLinearModel` object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

`terms` — Terms to remove from regression model

character vector or string scalar formula in Wilkinson notation | *t*-by-*p* terms matrix

Terms to remove from the regression model `mdl`, specified as one of the following:

- Character vector or string scalar formula in "Wilkinson Notation" on page 33-5470 representing one or more terms. The variable names in the formula must be valid MATLAB identifiers.
- Terms matrix `T` of size *t*-by-*p*, where *t* is the number of terms and *p* is the number of predictor variables in `mdl`. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

  For example, suppose `mdl` has three variables `A`, `B`, and `C` in that order. Each row of `T` represents one term:

  - `[0 0 0]` — Constant term or intercept
  - `[0 1 0]` — `B`; equivalently, `A^0 * B^1 * C^0`
  - `[1 0 1]` — `A*C`
  - `[2 0 0]` — `A^2`
  - `[0 1 2]` — `B*(C^2)`

`removeTerms` treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to remove from the model. If you specify a categorical predictor to remove from the model, `removeTerms` removes a group of indicator variables for the predictor in one step.

Output Arguments

`NewMdl` — Generalized linear regression model with fewer terms

`GeneralizedLinearModel` object

Generalized linear regression model with fewer terms, returned as a `GeneralizedLinearModel` object. `NewMdl` is a newly fitted model that uses the input data and settings in `mdl` with the terms specified in `terms` removed from `mdl`.

To overwrite the input argument `mdl`, assign the newly fitted model to `mdl`:

```
mdl = removeTerms(mdl,terms);
```

More About

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- − means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
1	Constant (intercept) term
x1^k, where k is a positive integer	x1, $x1^2$, ..., $x1^k$
x1 + x2	x1, x2
x1*x2	x1, x2, x1*x2
x1:x2	x1*x2 only
−x2	Do not include x2
x1*x2 + x3	x1, x2, x3, x1*x2
x1 + x2 + x3 + x1:x2	x1, x2, x3, x1*x2
x1*x2*x3 − x1:x2:x3	x1, x2, x3, x1*x2, x1*x3, x2*x3
x1*(x2 + x3)	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Algorithms

- `removeTerms` treats a categorical predictor as follows:
  - A model with a categorical predictor that has L levels (categories) includes L – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `removeTerms` treats the group of L – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the L – 1 indicator variables with the continuous predictor.
  - Interaction terms between two categorical predictors with L and M levels consist of the (L – 1)*(M – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
  - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternative Functionality

- Use `stepwiseglm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `addTerms` to add specific terms to a model.
- Use `step` to optimally improve a model by adding or removing terms.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2012a

removeTerms

Remove terms from linear regression model

Syntax

```
NewMdl = removeTerms(mdl,terms)
```

Description

`NewMdl = removeTerms(mdl,terms)` returns a linear regression model fitted using the input data and settings in `mdl` with the terms `terms` removed.

Examples

Remove Terms from Linear Regression Model

Create a linear regression model using the `hald` data set. Remove terms that have high *p*-values.

Load the data set.

```
load hald
X = ingredients; % predictor variables
y = heat; % response variable
```

Fit a linear regression model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
Linear regression model:
    y ~ 1 + x1 + x2 + x3 + x4

Estimated Coefficients:
                   Estimate      SE        tStat       pValue
                   ________    _______    ________    ________

    (Intercept)      62.405     70.071      0.8906     0.39913
    x1               1.5511    0.74477      2.0827    0.070822
    x2              0.51017    0.72379     0.70486      0.5009
    x3              0.10191    0.75471     0.13503     0.89592
    x4             -0.14406    0.70905    -0.20317     0.84407

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.45
R-squared: 0.982,  Adjusted R-Squared: 0.974
F-statistic vs. constant model: 111, p-value = 4.76e-07
```

Remove the `x3` and `x4` terms because their *p*-values are high.

```
terms = 'x3 + x4'; % terms to remove
NewMdl = removeTerms(mdl,terms)
```

```
NewMdl =
Linear regression model:
    y ~ 1 + x1 + x2

Estimated Coefficients:
                   Estimate       SE       tStat       pValue
                   ________    ________    ______    __________

    (Intercept)     52.577       2.2862    22.998    5.4566e-10
    x1              1.4683       0.1213    12.105    2.6922e-07
    x2             0.66225     0.045855    14.442     5.029e-08

Number of observations: 13, Error degrees of freedom: 10
Root Mean Squared Error: 2.41
R-squared: 0.979,  Adjusted R-Squared: 0.974
F-statistic vs. constant model: 230, p-value = 4.41e-09
```

`NewMdl` has the same adjusted R-squared value (0.974) as the previous model, meaning the fit is as good in the new model. All the terms in the new model have extremely low *p*-values.

Input Arguments

`mdl` — Linear regression model

`LinearModel` object

Linear regression model, specified as a `LinearModel` object created using `fitlm` or `stepwiselm`.

`terms` — Terms to remove from regression model

character vector or string scalar formula in Wilkinson notation | *t*-by-*p* terms matrix

Terms to remove from the regression model `mdl`, specified as one of the following:

- Character vector or string scalar formula in "Wilkinson Notation" on page 33-5475 representing one or more terms. The variable names in the formula must be valid MATLAB identifiers.
- Terms matrix `T` of size *t*-by-*p*, where *t* is the number of terms and *p* is the number of predictor variables in `mdl`. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

  For example, suppose `mdl` has three variables `A`, `B`, and `C` in that order. Each row of `T` represents one term:

  - `[0 0 0]` — Constant term or intercept
  - `[0 1 0]` — `B`; equivalently, `A^0 * B^1 * C^0`
  - `[1 0 1]` — `A*C`
  - `[2 0 0]` — `A^2`
  - `[0 1 2]` — `B*(C^2)`

`removeTerms` treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to remove from the model. If you specify a categorical predictor to remove from the model, `removeTerms` removes a group of indicator variables for the predictor in one step. See "Modify Linear Regression Model Using step" on page 33-5990 for an example that describes how to create indicator variables manually and treat each one as a separate variable.

Output Arguments

`NewMdl` — Linear regression model with fewer terms

`LinearModel` object

Linear regression model with fewer terms, returned as a `LinearModel` object. `NewMdl` is a newly fitted model that uses the input data and settings in `mdl` with the terms specified in `terms` removed from `mdl`.

To overwrite the input argument `mdl`, assign the newly fitted model to `mdl`:

```
mdl = removeTerms(mdl,terms);
```

More About

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- − means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
1	Constant (intercept) term
x1^k, where k is a positive integer	x1, $x1^2$, ..., $x1^k$
x1 + x2	x1, x2
x1*x2	x1, x2, x1*x2
x1:x2	x1*x2 only
−x2	Do not include x2
x1*x2 + x3	x1, x2, x3, x1*x2
x1 + x2 + x3 + x1:x2	x1, x2, x3, x1*x2
x1*x2*x3 − x1:x2:x3	x1, x2, x3, x1*x2, x1*x3, x2*x3
x1*(x2 + x3)	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Algorithms

- `removeTerms` treats a categorical predictor as follows:
  - A model with a categorical predictor that has L levels (categories) includes L – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see "Automatic Creation of Dummy Variables" on page 2-49.
  - `removeTerms` treats the group of L – 1 indicator variables as a single variable. reorderlevels

(Not Recommended) Reorder levels of nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the "Categorical Arrays" data type instead.

Syntax

```
B = reorderlevels(A,newlevels)
```

Description

`B = reorderlevels(A,newlevels)` returns a `nominal` or `ordinal` array object of the same type as `A`, but with levels in the new order specified by `newlevels`.

For ordinal arrays, the order of the levels has significance for relational operators, finding minimum and maximum values, and sorting.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

newlevels — New order of levels

string array | cell array of character vectors | 2-D character matrix

New order of levels, specified as a string array, cell array of character vectors, or 2-D character matrix. `newlevels` must be a reordering of the labels returned by `getlabels`.

Data Types: `char` | `string` | `cell`

Output Arguments

B — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

See Also

`addlevels` | `droplevels` | `getlabels` | `nominal` | `ordinal` | `reorderlevels`

Introduced in R2007a

repartition

Repartition data for cross-validation

Syntax

```
cnew = repartition(c)
cnew = repartition(c,s)
```

Description

`cnew = repartition(c)` creates a `cvpartition` object `cnew` that defines a random partition of the same type as `c`, where `c` is also a `cvpartition` object. That is, `repartition` takes the same observations in `c` and repartitions them into new training and test sets.

`cnew = repartition(c,s)` uses the `RandStream` object `s` as the random number generator for the new partition.

Examples

Repartition Data for Cross-Validation

Repartition observations in a `cvpartition` object. The type of validation partition remains the same.

Partition 100 observations for 3-fold cross-validation.

```
c = cvpartition(100,'KFold',3)
```

```
c =
K-fold cross validation partition
   NumObservations: 100
       NumTestSets: 3
         TrainSize: 67  66  67
          TestSize: 33  34  33
```

Repartition the observations.

```
cnew = repartition(c)
```

```
cnew =
K-fold cross validation partition
   NumObservations: 100
       NumTestSets: 3
         TrainSize: 67  66  67
          TestSize: 33  34  33
```

Notice that the set of observations in the first test set (fold) of `c` is not the same as the set of observations in the first test set of `cnew`.

```
isequal(test(c,1),test(cnew,1))
```

```
ans = logical
   0
```

View the validation partition type of `c` and `cnew`. Both `c` and `cnew` are validation partitions of the same type, `'kfold'`.

```
isequal(c.Type,cnew.Type)
```

```
ans = logical
   1
```

```
c.Type
```

```
ans =
'kfold'
```

Input Arguments

c — Validation partition

`cvpartition` object

Validation partition, specified as a `cvpartition` object. The validation partition type of `c`, `c.Type`, is the same as the validation partition type of the new partition `cnew`.

s — Random number generator

`RandStream` object

Random number generator for the new partition, specified as a `RandStream` object.

Tips

- Repartitioning is useful for Monte Carlo repetitions of cross-validation analyses. `crossval` calls `repartition` when you specify the `'MCReps'` name-value pair argument.

See Also

`RandStream` | `crossval` | `cvpartition`

Introduced in R2008a

RepeatedMeasuresModel class

Repeated measures model class

Description

A `RepeatedMeasuresModel` object represents a model fitted to data with multiple measurements per subject. The object comprises data, fitted coefficients, covariance parameters, design matrix, error degrees of freedom, and between- and within-subjects factor names for a repeated measures model. You can predict model responses using the `predict` method and generate random data at new design points using the `random` method.

Construction

You can fit a repeated measures model using `fitrm(t,modelspec)`.

Input Arguments

`t` — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

Data Types: `table`

`modelspec` — Formula for model specification

character vector or string scalar of the form `'y1-yk ~ terms'`

Formula for model specification, specified as a character vector or string scalar of the form `'y1-yk ~ terms'`. Specify the terms using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, character arrays, string arrays, or a cell array of character vectors.

Example: `'y1-y4 ~ x1 + x2 * x3'`

Data Types: `char` | `string`

Properties

`BetweenDesign` — Design for between-subject factors

table

Design for between-subject factors and values of repeated measures, stored as a table.

Data Types: `table`

`BetweenModel` — Model for between-subjects factors

character vector

Model for between-subjects factors, stored as a character vector. This character vector is the text representation to the right of the tilde in the model specification you provide when fitting the repeated measures model using `fitrm`.

Data Types: `char`

`BetweenFactorNames` — Names of variables used as between-subject factors
cell array of character vectors

Names of variables used as between-subject factors in the repeated measures model, `rm`, stored as a cell array of character vectors.

Data Types: `cell`

`ResponseNames` — Names of variables used as response variables
cell array of character vectors

Names of variables used as response variables in the repeated measures model, `rm`, stored as a cell array of character vectors.

Data Types: `cell`

`WithinDesign` — Values of within-subject factors
table

Values of the within-subject factors, stored as a table.

Data Types: `table`

`WithinModel` — Model for within-subjects factors
character vector

Model for within-subjects factors, stored as a character vector.

You can specify `WithinModel` as a character vector or a string scalar using dot notation: `Mdl.WithinModel = newWithinModelValue`.

`WithinFactorNames` — Names of within-subject factors
cell array of character vectors

Names of the within-subject factors, stored as a cell array of character vectors.

Data Types: `cell`

`Coefficients` — Values of estimated coefficients
table

Values of the estimated coefficients for fitting the repeated measures as a function of the terms in the between-subjects model, stored as a table.

`fitrm'` defines the coefficients for a categorical term using 'effects' coding, which means coefficients sum to 0. There is one coefficient for each level except the first. The implied coefficient for the first level is the sum of the other coefficients for the term.

You can display the coefficient values as a matrix rather than a table using `coef = r.Coefficients{:,:}`.

You can display marginal means for all levels using the `margmean` method.

Data Types: `table`

`Covariance` — Estimated response covariances
table

Estimated response covariances, that is, covariance of the repeated measures, stored as a table. `fitrm` computes the covariances around the mean returned by the fitted repeated measures model `rm`.

You can display the covariance values as a matrix rather than a table using `coef = r.Covariance{:,:}`.

Data Types: `table`

`DFE` — Error degrees of freedom
scalar value

Error degrees of freedom, stored as a scalar value. `DFE` is the number of observations minus the number of estimated coefficients in the between-subjects model.

Data Types: `double`

Methods

anova	Analysis of variance for between-subject effects
epsilon	Epsilon adjustment for repeated measures anova
grpstats	Compute descriptive statistics of repeated measures data by group
manova	Multivariate analysis of variance
margmean	Estimate marginal means
mauchly	Mauchly's test for sphericity
multcompare	Multiple comparison of estimated marginal means
plot	Plot data with optional grouping
plotprofile	Plot expected marginal means with optional grouping
predict	Compute predicted values given predictor values
random	Generate new random response values given predictor values
ranova	Repeated measures analysis of variance

Examples

Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: setosa, versicolor, virginica. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas)
```

```
rm =
  RepeatedMeasuresModel with properties:

   Between Subjects:
         BetweenDesign: [150x5 table]
         ResponseNames: {'meas1'  'meas2'  'meas3'  'meas4'}
    BetweenFactorNames: {'species'}
         BetweenModel: '1 + species'

   Within Subjects:
         WithinDesign: [4x1 table]
     WithinFactorNames: {'Measurements'}
          WithinModel: 'separatemeans'

   Estimates:
         Coefficients: [3x4 table]
           Covariance: [4x4 table]
```

Display the coefficients.

```
rm.Coefficients
```

```
ans=3×4 table
                          meas1       meas2      meas3      meas4
                        ________    ________    ______    ________

    (Intercept)           5.8433      3.0573     3.758      1.1993
    species_setosa       -0.83733     0.37067   -2.296     -0.95333
    species_versicolor    0.092667   -0.28733    0.502      0.12667
```

`fitrm` uses the `'effects'` contrasts, which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species\_setosa} = \begin{cases} 1, & \textit{if setosa} \\ 0, & \textit{if versicolor} \\ -1, & \textit{if virginica} \end{cases}$$

and

$$\text{species\_versicolor} = \begin{cases} 0, & \textit{if setosa} \\ 1, & \textit{if versicolor} \\ -1, & \textit{if virginica} \end{cases}.$$

Display the covariance matrix.

```
rm.Covariance
```

```
ans=4×4 table
              meas1       meas2       meas3       meas4
            ________    ________    ________    ________

    meas1     0.26501    0.092721     0.16751    0.038401
    meas2    0.092721     0.11539    0.055244     0.03271
    meas3     0.16751    0.055244     0.18519    0.042665
    meas4    0.038401     0.03271    0.042665    0.041882
```

Display the error degrees of freedom.

```
rm.DFE
```

```
ans = 147
```

The error degrees of freedom is the number of observations minus the number of estimated coefficients in the between-subjects model, e.g. 150 – 3 = 147.

More About

Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

Use these rules to specify the responses in `modelspec`.

Wilkinson Notation	Description
`Y1,Y2,Y3`	Specific list of variables
`Y1-Y5`	All table variables from `Y1` through `Y5`

Use these rules to specify terms in `modelspec`.

Wilkinson Notation	Factors in Standard Notation
`1`	Constant (intercept) term
`X^k`, where `k` is a positive integer	X, X^2, ..., X^k
`X1 + X2`	X1, X2
`X1*X2`	X1, X2, X1*X2
`X1:X2`	X1*X2 only
`-X2`	Do not include X2
`X1*X2 + X3`	X1, X2, X3, X1*X2
`X1 + X2 + X3 + X1:X2`	X1, X2, X3, X1*X2
`X1*X2*X3 - X1:X2:X3`	X1, X2, X3, X1*X2, X1*X3, X2*X3
`X1*(X2 + X3)`	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

Topics

Class Attributes
Property Attributes

replacedata

Class: `dataset`

(Not Recommended) Replace dataset variables

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = replacedata(A,X)
B = replacedata(A,X,vars)
B = replacedata(A,fun)
B = replacedata(A,fun,vars)
```

Description

`B = replacedata(A,X)` creates a dataset array `B` with the same variables as the dataset array `A`, but with the data for those variables replaced by the data in the array `X`. `replacedata` creates each variable in `B` using one or more columns from `X`, in order. `X` must have as many columns as the total number of columns in all of the variables in `A`, and as many rows as `A` has observations.

`B = replacedata(A,X,vars)` creates a dataset array `B` with the same variables as the dataset array `A`, but with the data for the variables specified in `vars` replaced by the data in the array `X`. The remaining variables in `B` are copies of the corresponding variables in `A`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. Each variable in `B` has as many columns as the corresponding variable in `A`. `X` must have as many columns as the total number of columns in all the variables specified in `vars`.

`B = replacedata(A,fun)` or `B = replacedata(A,fun,vars)` creates a dataset array `B` by applying the function `fun` to the values in `A`'s variables. `replacedata` first horizontally concatenates `A`'s variables into a single array, then applies the function `fun`. The specified variables in `A` must have types and sizes compatible with the concatenation. `fun` is a function handle that accepts a single input array and returns an array with the same number of rows and columns as the input.

Examples

```
data = dataset({rand(3,3),'Var1','Var2','Var3'})

% Use ZSCORE to normalize each variable in a dataset array
% separately, by explicitly extracting and transforming the
% data, and then replacing it.
X = double(data);
X = zscore(X);
data = replacedata(data,X)

% Equivalently, provide a handle to ZSCORE.
data = replacedata(data,@zscore)
```

```
% Use ZSCORE to normalize each observation in a dataset
% array separately by creating an anonymous function.
data = replacedata(data,@(x) zscore(x,[],2))
```

See Also

dataset

replaceWithMissing

Class: `dataset`

(Not Recommended) Insert missing data indicators into a dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds2 = replaceWithMissing(ds,Name,Value)
```

Description

`ds2 = replaceWithMissing(ds,Name,Value)` replaces specified values in a dataset array with standard missing data indicators using options specified by one or more `Name,Value` pair arguments. Use `replaceWithMissing` to specify:

- Which numeric missing value indicators to replace with `NaN`.
- Which character missing value indicators to replace with `''`.
- Which categorical levels to replace with `<undefined>`.

Input Arguments

`ds`

`dataset` array.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`NumericValues`

Vector of numeric values that `replaceWithMissing` replaces with `NaN`.

`CategoricalLevels`

Character vector or cell array of character vectors naming the categorical levels that `replaceWithMissing` replaces with `<undefined>`.

`Strings`

Character vector or cell array of character vectors containing the text that `replaceWithMissing` replaces with `''`.

`DataVars`

Specified set of variables in `ds` for which `replaceWithMissing` replaces values. You can specify a positive integer or vector of positive integers indicating the variable column numbers, a variable name or a cell array of variables names, or a logical vector indicating which variables to replace missing values in.

Default: All variables in `ds`.

Output Arguments

`ds2`

`dataset` array that has the specified missing value indicators, in the specified variables of `ds`, replaced with standard missing value indicators.

Examples

Replace Nonstandard Missing Value Indicators

Replace nonstandard missing value indicators with standard missing value indicators.

Replace numeric missing values coded `99` with `NaN`, and character missing values coded `'.'` with `''`.

```
ds = replaceWithMissing(ds,'NumericValues',99,'Strings','.');
```

“Dataset Arrays” on page 2-112

reset

Class: `qrandstream`

Reset state

Syntax

```
reset(q)
```

Description

`reset(q)` resets the state of the quasi-random number stream `q` of the `qrandstream` on page 33-5078 class back to its initial state, `1`. Subsequent points drawn from the stream will be the same as those drawn from a new stream. The command is equivalent to `q.State = 1`.

Examples

Use `qrandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = qrandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
   Halton quasi-random stream in 3 dimensions
   Point set properties:
               Skip : 1000
               Leap : 100
    ScrambleMethod : none

nextIdx = q.State
nextIdx =
     1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
     5

X2 = qrand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
     9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
     1

X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

See Also

`qrand` | `qrandstream`

residuals

Class: `GeneralizedLinearMixedModel`

Residuals of fitted generalized linear mixed-effects model

Syntax

```
r = residuals(glme)
r = residuals(glme,Name,Value)
```

Description

`r = residuals(glme)` returns the raw conditional residuals from a fitted generalized linear mixed-effects model `glme`.

`r = residuals(glme,Name,Value)` returns the residuals using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to return Pearson residuals for the model.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Conditional` — Indicator for conditional residuals

`true` (default) | `false`

Indicator for conditional residuals, specified as the comma-separated pair consisting of `'Conditional'` and one of the following.

Value	Description
`true`	Contributions from both fixed effects and random effects (conditional)
`false`	Contribution from only fixed effects (marginal)

Conditional residuals include contributions from both fixed- and random-effects predictors. Marginal residuals include contribution from only fixed effects. To obtain marginal residual values, `residuals` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects, b, set to 0.

Example: `'Conditional',false`

`ResidualType` — Residual type
`'raw'` (default) | `'Pearson'`

Residual type, specified as the comma-separated pair consisting of `'ResidualType'` and one of the following.

Residual Type	Conditional	Marginal
`'raw'`	$r_{ci} = y_i - g^{-1}\left(x_i^T\widehat{\beta} + z_i^T\widehat{b} + \delta_i\right)$	$r_{mi} = y_i - g^{-1}\left(x_i^T\widehat{\beta} + \delta_i\right)$
`'Pearson'`	$r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\frac{\widehat{\sigma^2}}{w_i}v_i\left(\mu_i\left(\widehat{\beta},\widehat{b}\right)\right)}}$	$r_{mi}^{pearson} = \frac{r_{mi}}{\sqrt{\frac{\widehat{\sigma^2}}{w_i}v_i\left(\mu_i\left(\widehat{\beta},0\right)\right)}}$

In each of these equations:

- y_i is the ith element of the n-by-1 response vector, y, where $i = 1, \ldots, n$.
- g^{-1} is the inverse link function for the model.
- x_i^T is the ith row of the fixed-effects design matrix X.
- z_i^T is the ith row of the random-effects design matrix Z.
- δ_i is the ith offset value.
- σ^2 is the dispersion parameter.
- w_i is the ith observation weight.
- v_i is the variance term for the ith observation.
- μ_i is the mean of the response for the ith observation.
- $\widehat{\beta}$ and $\widehat{b}$ are estimated values of β and b.

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: `'ResidualType','Pearson'`

Output Arguments

`r` — Residuals
n-by-1 vector

Residuals of the fitted generalized linear mixed-effects model `glme` returned as an n-by-1 vector, where n is the number of observations.

Examples

Plot Residuals Versus Fitted Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)',...
    'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Generate the conditional Pearson residuals and the conditional fitted values from the model.

```
r = residuals(glme,'ResidualType','Pearson');
mufit = fitted(glme);
```

Display the first ten rows of the Pearson residuals.

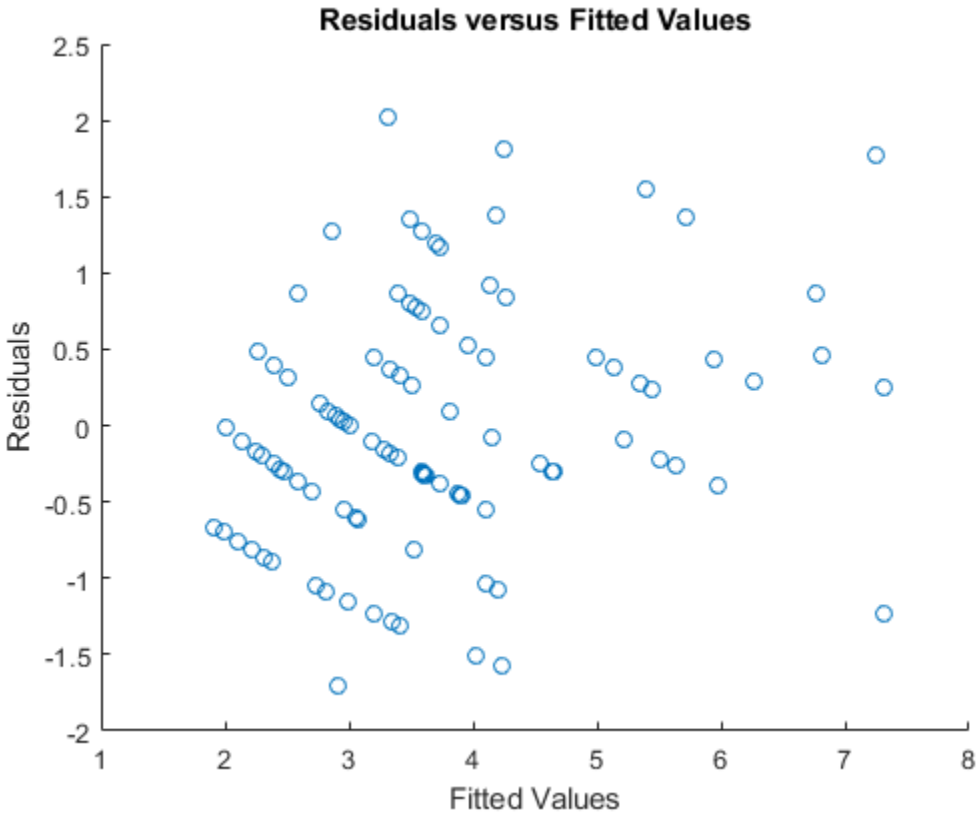
```
r(1:10)
```

```
ans = 10×1

    0.4530
    0.4339
    0.3833
   -0.2653
    0.2811
   -0.0935
   -0.2984
   -0.2509
    1.5547
   -0.3027
```

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity).

```
figure
scatter(mufit,r)
title('Residuals versus Fitted Values')
xlabel('Fitted Values')
ylabel('Residuals')
```



The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

`GeneralizedLinearMixedModel` | `designMatrix` | `fitted` | `response`

residuals

Class: `LinearMixedModel`

Residuals of fitted linear mixed-effects model

Syntax

```
R = residuals(lme)
R = residuals(lme,Name,Value)
```

Description

`R = residuals(lme)` returns the raw conditional residuals from a fitted linear mixed-effects model `lme`.

`R = residuals(lme,Name,Value)` returns the residuals from the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify Pearson or standardized residuals, or residuals with contributions from only fixed effects.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Conditional` — Indicator for conditional residuals

`True` (default) | `False`

Indicator for conditional residuals, specified as the comma-separated pair consisting of `'Conditional'` and one of the following.

`True`	Contribution from both fixed effects and random effects (conditional)
`False`	Contribution from only fixed effects (marginal)

Example: `'Conditional,'False'`

`ResidualType` — Residual type

`'Raw'` (default) | `'Pearson'` | `'Standardized'`

Residual type, specified by the comma-separated pair consisting of `ResidualType` and one of the following.

Residual Type	Conditional	Marginal
`'Raw'`	$r_i^C = \left[y - X\widehat{\beta} - Z\widehat{b}\right]_i$	$r_i^M = \left[y - X\widehat{\beta}\right]_i$
`'Pearson'`	$pr_i^C = \frac{r_i^C}{\sqrt{\left[\widehat{Var}_{y,b}(y - X\beta - Zb)\right]_{ii}}}$	$pr_i^M = \frac{r_i^M}{\sqrt{\left[\widehat{Var}_y(y - X\beta)\right]_{ii}}}$
`'Standardized'`	$st_i^C = \frac{r_i^C}{\sqrt{\left[\widehat{Var}_y(r^C)\right]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{\left[\widehat{Var}_y(r^M)\right]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see `Definitions` at the end of this page.

Example: `'ResidualType','Standardized'`

Output Arguments

R — Residuals

n-by-1 vector

Residuals of the fitted linear mixed-effects model `lme`returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Plot Residuals vs. Fitted Values

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

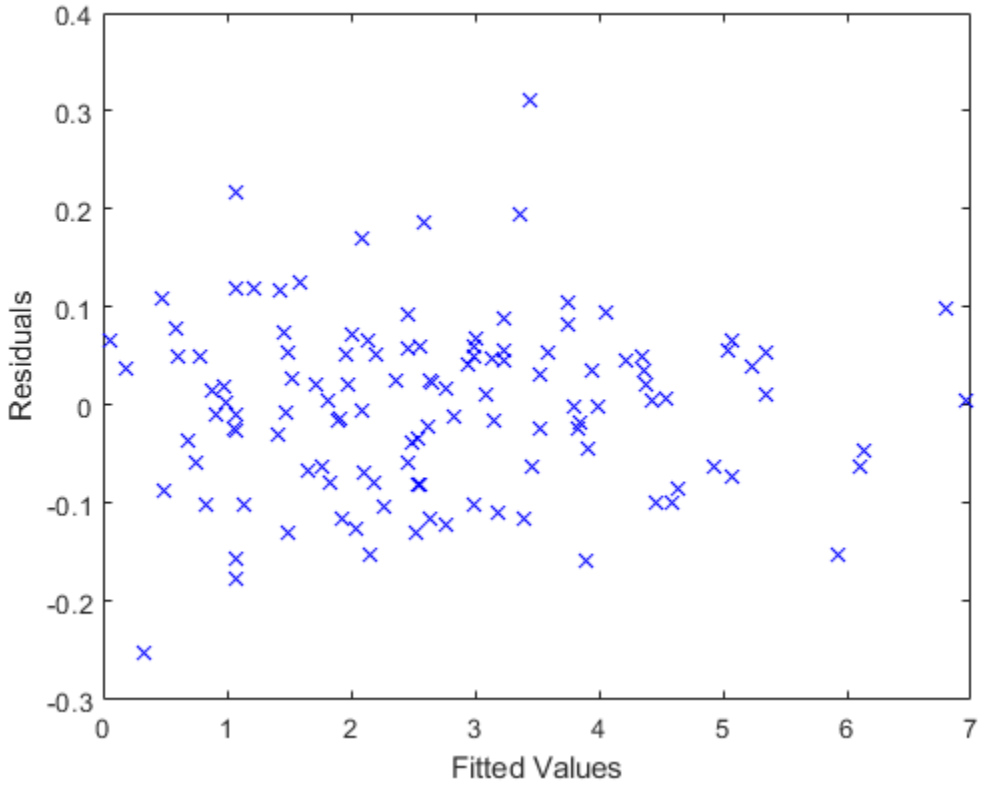
```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);
R = residuals(lme);
```

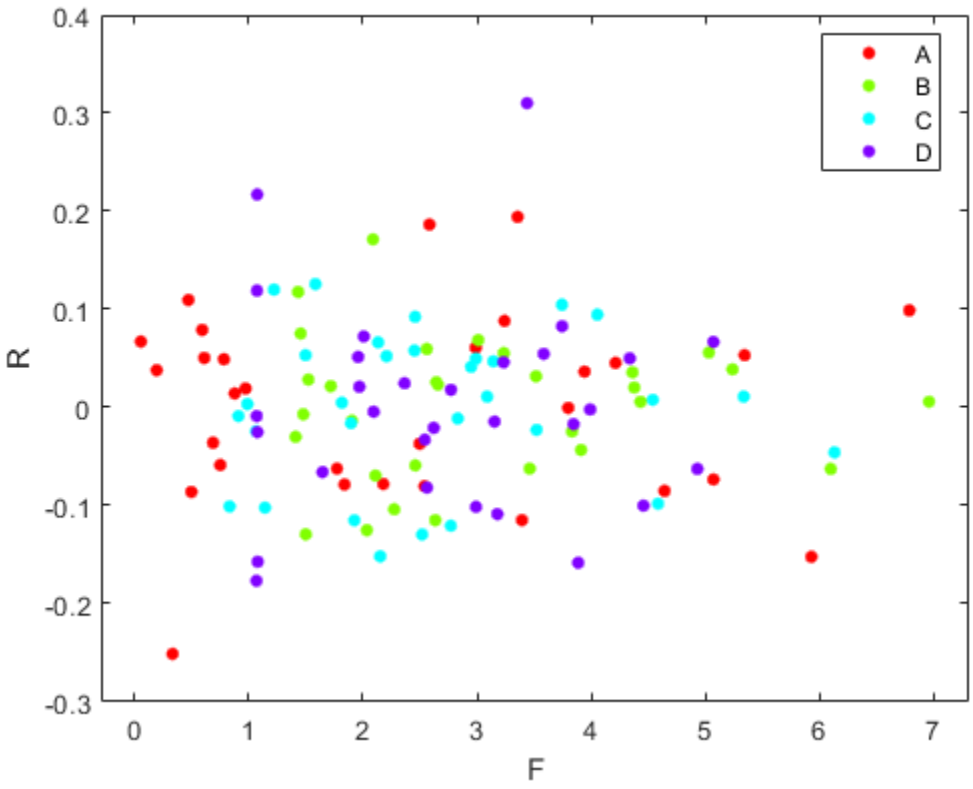
Plot the residuals versus the fitted values.

```
plot(F,R,'bx')
xlabel('Fitted Values')
ylabel('Residuals')
```



Now, plot the residuals versus the fitted values, grouped by program.

```
figure();
gscatter(F,R,Program)
```



The residuals seem to behave similarly across levels of the program as expected.

Compute Conditional and Marginal Pearson Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Cylinders,Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + Cylinders + (Acceleration|Model_Year)');
```

Compute the conditional Pearson residuals and display the first five residuals.

```
PR = residuals(lme,'ResidualType','Pearson');
PR(1:5)
```

```
ans = 5×1
```

```
   -0.0533
    0.0652
    0.3655
   -0.0106
   -0.3340
```

Compute the marginal Pearson residuals and display the first five residuals.

```
PRM = residuals(lme,'ResidualType','Pearson','Conditional',false);
PRM(1:5)
```

```
ans = 5×1

   -0.1250
    0.0130
    0.3242
   -0.0861
   -0.3006
```

Examine Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

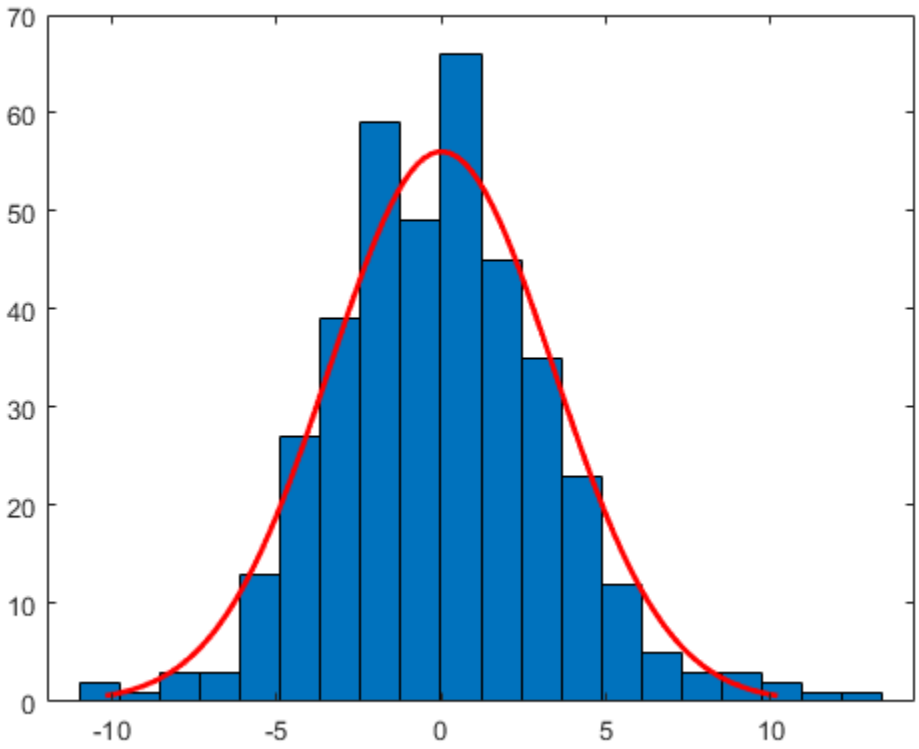
```
tbl = table(MPG,Acceleration,Horsepower,Cylinders,Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + Cylinders + (Acceleration|Model_Year)');
```

Draw a histogram of the raw residuals with a normal fit.

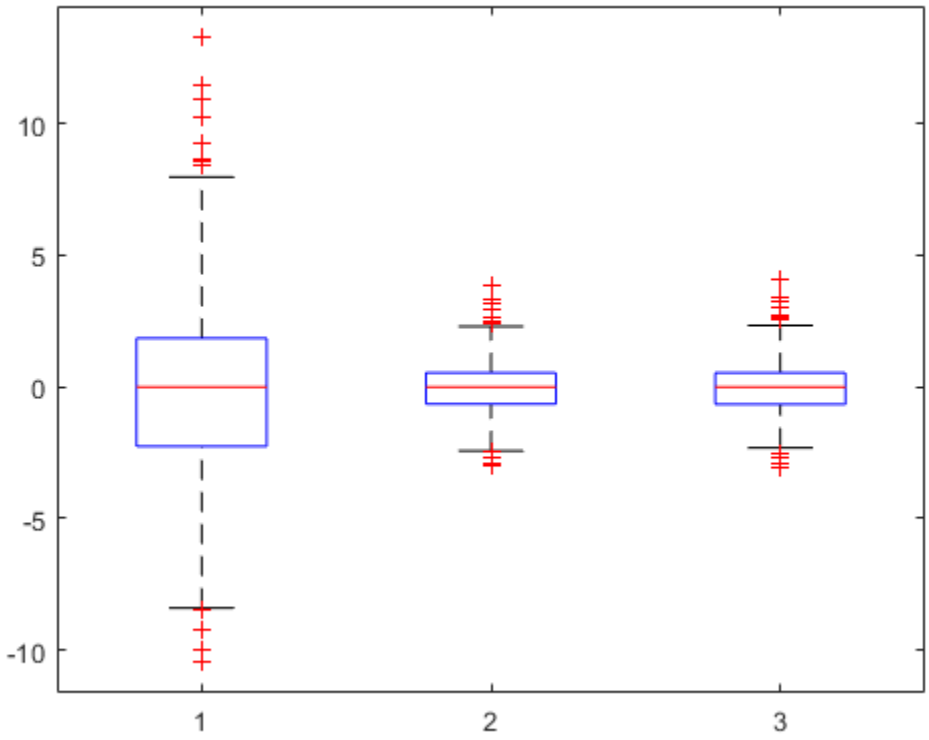
```
r = residuals(lme);
histfit(r)
```



Normal distribution seems to be a good fit for the residuals.

Compute the conditional Pearson and standardized residuals and create box plots of all three types of residuals.

```
pr = residuals(lme,'ResidualType','Pearson');
st = residuals(lme,'ResidualType','Standardized');
X = [r pr st];
boxplot(X)
```



Red plus signs show the observations with residuals above or below $q3 + 1.5(q3 - q1)$ and $q1 - 1.5(q3 - q1)$, where $q1$ and $q3$ are the 25th and 75th percentiles, respectively.

Find the observations with residuals that are 2.5 standard deviations above and below the mean.

```
find(r > mean(r,'omitnan') + 2.5*std(r,'omitnan'))
```

```
ans = 7×1

    62
   252
   255
   330
   337
   341
   396
```

```
find(r < mean(r,'omitnan') - 2.5*std(r,'omitnan'))
```

```
ans = 3×1

   119
   324
   375
```

More About

Conditional and Marginal Residuals

Conditional residuals include contributions from both fixed and random effects, whereas marginal residuals include contribution from only fixed effects.

Suppose the linear mixed-effects model `lme`has an n-by-p fixed-effects design matrix X and an n-by-q random-effects design matrix Z. Also, suppose the p-by-1 estimated fixed-effects vector is $\widehat{\beta}$, and the q-by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is $\widehat{b}$. The fitted conditional response is

$$\widehat{y}_{Cond} = X\widehat{\beta} + Z\widehat{b},$$

and the fitted marginal response is

$$\widehat{y}_{Mar} = X\widehat{\beta},$$

`residuals` can return three types of residuals: raw, Pearson, and standardized. For any type, you can compute the conditional or the marginal residuals. For example, the conditional raw residual is

$$r_{Cond} = y - X\widehat{\beta} - Z\widehat{b},$$

and the marginal raw residual is

$$r_{Mar} = y - X\widehat{\beta}.$$

For more information on other types of residuals, see the `ResidualType` name-value pair argument.

See Also

`LinearMixedModel` | `fitted` | `plotResiduals` | `response`

response

Class: `GeneralizedLinearMixedModel`

Response vector of generalized linear mixed-effects model

Syntax

```
y = response(glme)
[y,binomialsize] = response(glme)
```

Description

`y = response(glme)` returns the response vector `y` used to fit the generalized linear mixed effects model `glme`.

`[y,binomialsize] = response(glme)` also returns the binomial size associated with each element of `y` if the conditional distribution of response given the random effects is binomial.

Input Arguments

`glme` — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Output Arguments

`y` — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

For an observation i with prior weights w_i^p and binomial size n_i (when applicable), the response values y_i can have the following values.

Distribution	Permitted Values	Notes
`Binomial`	$\left\{0, \frac{1}{w_i^p n_i}, \frac{2}{w_i^p n_i}, \ldots, 1\right\}$	w_i^p and n_i are integer values > 0
`Poisson`	$\left\{0, \frac{1}{w_i^p}, \frac{2}{w_i^p}, \ldots\right\}$	w_i^p is an integer value > 0
`Gamma`	$(0,\infty)$	$w_i^p \geq 0$
`InverseGaussian`	$(0,\infty)$	$w_i^p \geq 0$
`normal`	$(-\infty,\infty)$	$w_i^p \geq 0$

You can access the prior weights property w_i^p using dot notation. For example, to access the prior weights property for a model `glme`:

```
glme.ObservationInfo.Weights
```

`binomialsize` — Binomial size
vector

Binomial size associated with each element of `y`, returned as an *n*-by-1 vector, where *n* is the number of observations. `response` only returns `binomialsize` if the conditional distribution of response given the random effects is binomial. `binomialsize` is empty for other distributions.

Examples

Plot Response Versus Fitted Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (`A`, `B`, or `C`) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time\_dev}_{ij} + \beta_3 \text{temp\_dev}_{ij} + \beta_4 \text{supplier\_C}_{ij} + \beta_5 \text{supplier\_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j.
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \ldots, 20$) during batch j (where $j = 1, 2, \ldots, 5$).
- newprocess_{ij}, time_dev_{ij}, and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j. For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company `C` or `B`, respectively, supplied the process chemicals for the batch produced by factory i during batch j.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

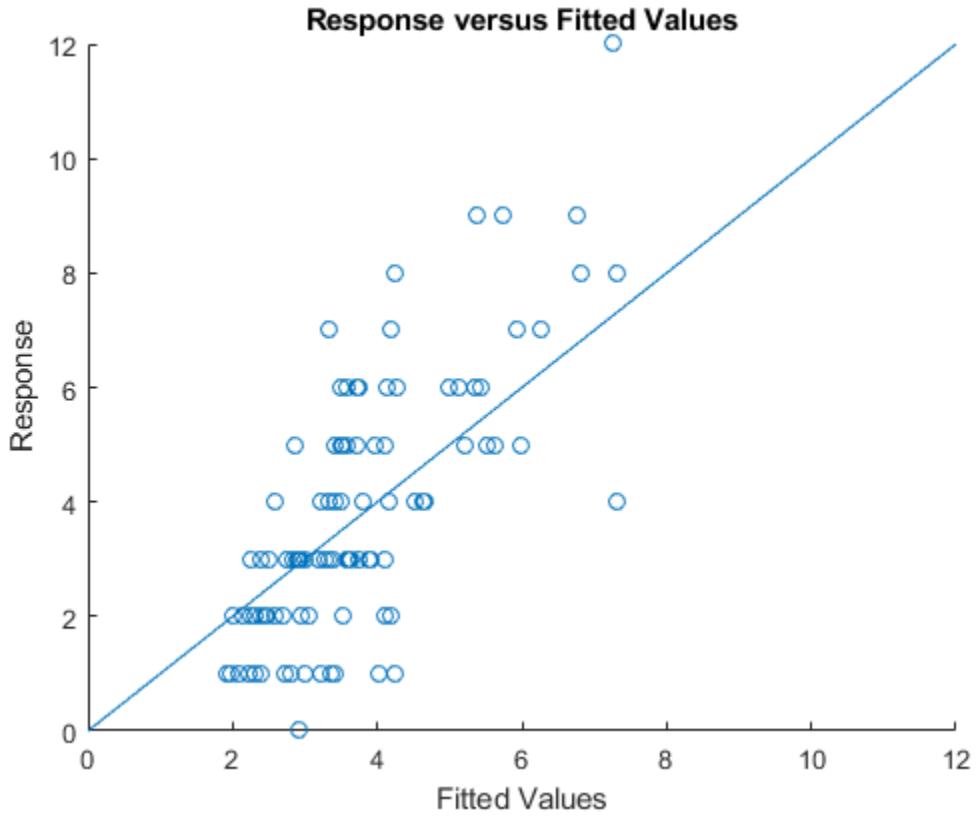
```
glme = fitglme(mfr,'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)',...
    'Distribution','Poisson','Link','log','FitMethod','Laplace','DummyVarCoding','effects');
```

Extract the observed response values for the model, then use `fitted` to generate the fitted conditional mean values.

```
y = response(glme);   % Observed response values
yfit = fitted(glme);  % Fitted response values
```

Create a scatterplot of the observed response values versus fitted values. Add a reference line to improve the visualization.

```
figure
scatter(yfit,y)
xlim([0,12])
ylim([0,12])
refline(1,0)
title('Response versus Fitted Values')
xlabel('Fitted Values')
ylabel('Response')
```



The plot shows a positive correlation between the fitted values and the observed response values.

`GeneralizedLinearMixedModel` | `fitted` | `residuals`

response

Class: `LinearMixedModel`

Response vector of the linear mixed-effects model

Syntax

```
y = response(lme)
```

Description

`y = response(lme)` returns the response vector `y` used to fit the linear mixed-effects model `lme`.

Input Arguments

`lme` — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

Output Arguments

`y` — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Examples

Plot Response versus Fitted Values

Load the sample data.

```
load('weight.mat');
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and the response.

```
F = fitted(lme);
y = response(lme);
```

Plot the response versus the fitted values.

```
plot(F,y,'bs')
xlabel('Fitted Values')
ylabel('Response')
```

`LinearMixedModel` | `fitted` | `residuals`

resubEdge

Resubstitution classification edge

Syntax

```
e = resubEdge(Mdl)
e = resubEdge(Mdl,'IncludeInteractions',includeInteractions)
```

Description

`e = resubEdge(Mdl)` returns the weighted resubstitution "Classification Edge" on page 33-1294 (`e`) for the trained classification model `Mdl` using the predictor data stored in `Mdl.X`, the corresponding true class labels stored in `Mdl.Y`, and the observation weights stored in `Mdl.W`.

`e = resubEdge(Mdl,'IncludeInteractions',includeInteractions)` specifies whether to include interaction terms in computations. This syntax applies only to generalized additive models.

Examples

Estimate Resubstitution Edge of SVM Classifiers

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a support vector machine (SVM) classifier. Standardize the data and specify that `'g'` is the positive class.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVMModel` is a trained `ClassificationSVM` classifier.

Estimate the resubstitution edge, which is the mean of the training sample margins.

```
e = resubEdge(SVMModel)
```

```
e = 5.1000
```

Select Naive Bayes Classifier Features by Comparing In-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare training sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the `ionosphere` data set. Remove the first two predictors for stability.

```
load ionosphere
X = X(:,3:end);
```

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the 10 most important predictors.

```
fullX = X;
idx = fscmrmr(X,Y);
partX = X(:,idx(1:10));
```

Train a naive Bayes classifier for each predictor set.

```
FullMdl = fitcnb(fullX,Y);
PartMdl = fitcnb(partX,Y);
```

`FullMdl` and `PartMdl` are trained `ClassificationNaiveBayes` classifiers.

Estimate the training sample edge for each classifier.

```
fullEdge = resubEdge(FullMdl)
```

```
fullEdge = 0.6554
```

```
partEdge = resubEdge(PartMdl)
```

```
partEdge = 0.7796
```

The edge of the classifier trained on the 10 most important predictors is larger. This result suggests that the classifier trained using only those predictors has a better in-sample fit.

Compare GAMs by Examining Training Sample Margins and Edge

Compare a generalized additive model (GAM) with linear terms to a GAM with both linear and interaction terms by examining the training sample margins and edge. Based solely on this comparison, the classifier with the highest margins and edge is the best model.

Load the 1994 census data stored in `census1994.mat`. The data set consists of demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. The classification task is to fit a model that predicts the salary category of people given their age, working class, education level, marital status, race, and so on.

```
load census1994
```

`census1994` contains the training data set `adultdata` and the test data set `adulttest`. To reduce the running time for this example, subsample 500 training observations from `adultdata` by using the `datasample` function.

```
rng('default') % For reproducibility
NumSamples = 5e2;
adultdata = datasample(adultdata,NumSamples,'Replace',false);
```

Train a GAM that contains both linear and interaction terms for predictors. Specify to include all available interaction terms whose *p*-values are not greater than 0.05.

```
Mdl = fitcgam(adultdata,'salary','Interactions','all','MaxPValue',0.05)
```

```
Mdl =
  ClassificationGAM
             PredictorNames: {1x14 cell}
               ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
                ClassNames: [<=50K    >50K]
             ScoreTransform: 'logit'
                  Intercept: -32.0842
               Interactions: [82x2 double]
           NumObservations: 500

  Properties, Methods
```

`Mdl` is a `ClassificationGAM` model object. `Mdl` includes 82 interaction terms.

Estimate the training sample margins and edge for `Mdl`.

```
M = resubMargin(Mdl);
E = resubEdge(Mdl)
```

```
E = 1.0000
```

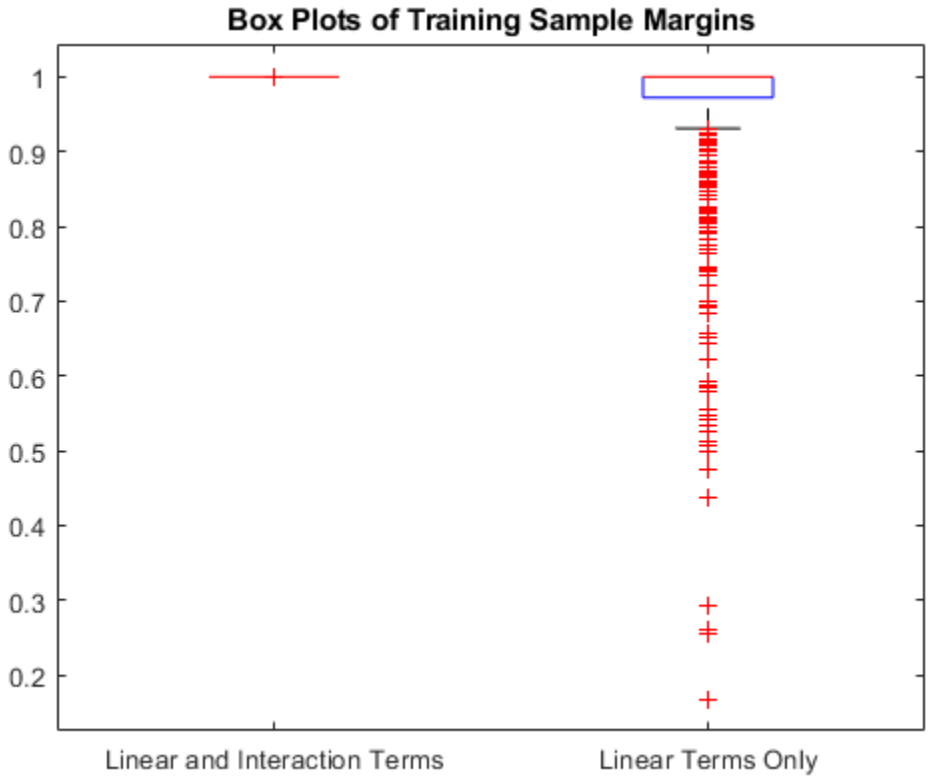
Estimate the training sample margins and edge for `Mdl` without including interaction terms.

```
M_nointeractions = resubMargin(Mdl,'IncludeInteractions',false);
E_nointeractions = resubEdge(Mdl,'IncludeInteractions',false)
```

```
E_nointeractions = 0.9516
```

Display the distributions of the margins using box plots.

```
boxplot([M M_nointeractions],'Labels',{'Linear and Interaction Terms','Linear Terms Only'})
title('Box Plots of Training Sample Margins')
```



When you include the interaction terms in the computation, all the resubstitution margin values for `Mdl` are 1, and the resubstitution edge value (average of the margins) is 1. The margins and edge decrease when you do not include the interaction terms in `Mdl`.

Input Arguments

`Mdl` — Classification machine learning model

full classification model object

Classification machine learning model, specified as a full classification model object, as given in the following table of supported models.

Model	Classification Model Object
Generalized additive model	`ClassificationGAM`
k-nearest neighbor model	`ClassificationKNN`
Naive Bayes model	`ClassificationNaiveBayes`
Neural network model	`ClassificationNeuralNetwork`
Support vector machine for one-class and binary classification	`ClassificationSVM`

`includeInteractions` — Flag to include interaction terms

`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `Mdl` is `ClassificationGAM`.

The default value is `true` if `Mdl` contains interaction terms. The value must be `false` if the model does not contain interaction terms.

Data Types: `logical`

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class. The classification margin for multiclass classification is the difference between the classification score for the true class and the maximal classification score for the false classes.

If the margins are on the same scale (that is, the score values are based on the same score transformation), then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Algorithms

`resubEdge` computes the classification edge according to the corresponding `edge` function of the object (`Mdl`). For a model-specific description, see the `edge` function reference pages in the following table.

Model	Classification Model Object (`Mdl`)	edge Object Function
Generalized additive model	`ClassificationGAM`	`edge`
k-nearest neighbor model	`ClassificationKNN`	`edge`
Naive Bayes model	`ClassificationNaiveBayes`	`edge`
Neural network model	`ClassificationNeuralNetwork`	`edge`
Support vector machine for one-class and binary classification	`ClassificationSVM`	`edge`

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports `ClassificationKNN` and `ClassificationSVM` objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`resubLoss` | `resubMargin` | `resubPredict`

Introduced in R2012a

resubEdge

Class: `ClassificationDiscriminant`

Classification edge by resubstitution

Syntax

```
edge = resubEdge(obj)
```

Description

`edge = resubEdge(obj)` returns the classification edge obtained by `obj` on its training data.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

edge

Classification edge obtained by resubstituting the training data into the calculation of edge.

Examples

Estimate the Resubstitution Edge of Discriminant Analysis Classifiers

Estimate the quality of a discriminant analysis classifier for Fisher's iris data by resubstitution.

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis classifier.

```
Mdl = fitcdiscr(meas,species);
```

Compute the resubstitution edge.

```
redge = resubEdge(Mdl)
```

```
redge = 0.9454
```

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

resubEdge

Resubstitution classification edge for multiclass error-correcting output codes (ECOC) model

Syntax

```
e = resubEdge(Mdl)
e = resubEdge(Mdl,Name,Value)
```

Description

`e = resubEdge(Mdl)` returns the resubstitution classification edge on page 33-5525 (`e`) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`.

The classification edge is a scalar value that represents the weighted mean of the classification margins on page 33-5525.

`e = resubEdge(Mdl,Name,Value)` computes the resubstitution classification edge with additional options specified by one or more name-value pair arguments. For example, you can specify a decoding scheme, binary learner loss function, and verbosity level.

Examples

Resubstitution Edge of ECOC Model

Compute the resubstitution edge for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Compute the resubstitution edge, which is the mean of the training-sample margins.

```
e = resubEdge(Mdl)
```

```
e = 0.4960
```

Select ECOC Model Features by Comparing Training-Sample Edges

Perform feature selection by comparing training-sample edges from multiple models. Based solely on this comparison, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements only.

```
load fisheriris
X = meas;
fullX = X;
partX = X(:,1:2);
Y = species;
```

Train an ECOC model using SVM binary learners for each predictor set. Standardize the predictors using an SVM template, specify the class order, and compute the posterior probabilities.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
FullMdl = fitcecoc(fullX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
PartMdl = fitcecoc(partX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
```

The default SVM score is the distance from the decision boundary. If you specify to compute posterior probabilities, then the software uses posterior probabilities as scores.

Compute the resubstitution edge for each classifier. The quadratic loss function operates on scores in the domain [0,1]. Specify to use quadratic loss when aggregating the binary learners for both models.

```
fullEdge = resubEdge(FullMdl,'BinaryLoss','quadratic')
```

```
fullEdge = 0.9896
```

```
partEdge = resubEdge(PartMdl,'BinaryLoss','quadratic')
```

```
partEdge = 0.5059
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained with all the predictors has a better training-sample fit.

Input Arguments

`Mdl` — Full, trained multiclass ECOC model

`ClassificationECOC` model

Full, trained multiclass ECOC model, specified as a `ClassificationECOC` model trained with `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `resubEdge(Mdl,'BinaryLoss','quadratic')` specifies a quadratic binary learner loss function.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.
  - `s` is the 1-by-L row vector of classification scores.

- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- *K* is the number of classes.
- *L* is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-5525.

Example: `'Decoding','lossbased'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

More About

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Tips

- To compare the margins or edges of several ECOC classifiers, use template objects to specify a common score transform function among the classifiers during training.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

resubEdge

Classification edge by resubstitution

Syntax

```
edge = resubEdge(ens)
edge = resubEdge(ens,Name,Value)
```

Description

`edge = resubEdge(ens)` returns the classification edge obtained by `ens` on its training data.

`edge = resubEdge(ens,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `resubEdge` uses only these learners for calculating edge.

Default: `1:NumTrained`

`mode`

Character vector or string scalar representing the meaning of the output `edge`:

- `'ensemble'` — `edge` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `edge` is a vector with one element per trained learner.
- `'cumulative'` — `edge` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

edge

Classification edge obtained by `ens` by resubstituting the training data into the calculation of edge. Classification edge is classification margin averaged over the entire data. `edge` can be a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

Find Classification Edge by Resubstitution of Training Data

Find the resubstitution edge for an ensemble that classifies the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the resubstitution edge.

```
edge = resubEdge(ens)
```

```
edge = 3.2486
```

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from –∞ to ∞.
- `Bag` scores range from `0` to `1`.

resubEdge | resubLoss | resubMargin | resubPredict

resubEdge

Class: `ClassificationTree`

Classification edge by resubstitution

Syntax

```
edge = resubEdge(tree)
```

Description

`edge = resubEdge(tree)` returns the classification edge obtained by `tree` on its training data.

Input Arguments

`tree`

A classification tree created using `fitctree`.

Output Arguments

`edge`

Classification edge obtained by resubstituting the training data into the calculation of edge.

Examples

Estimate the quality of a classification tree for the Fisher iris data by resubstitution.

```
load fisheriris
tree = fitctree(meas,species);
redge = resubEdge(tree)
```

```
redge =
    0.9384
```

More About

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

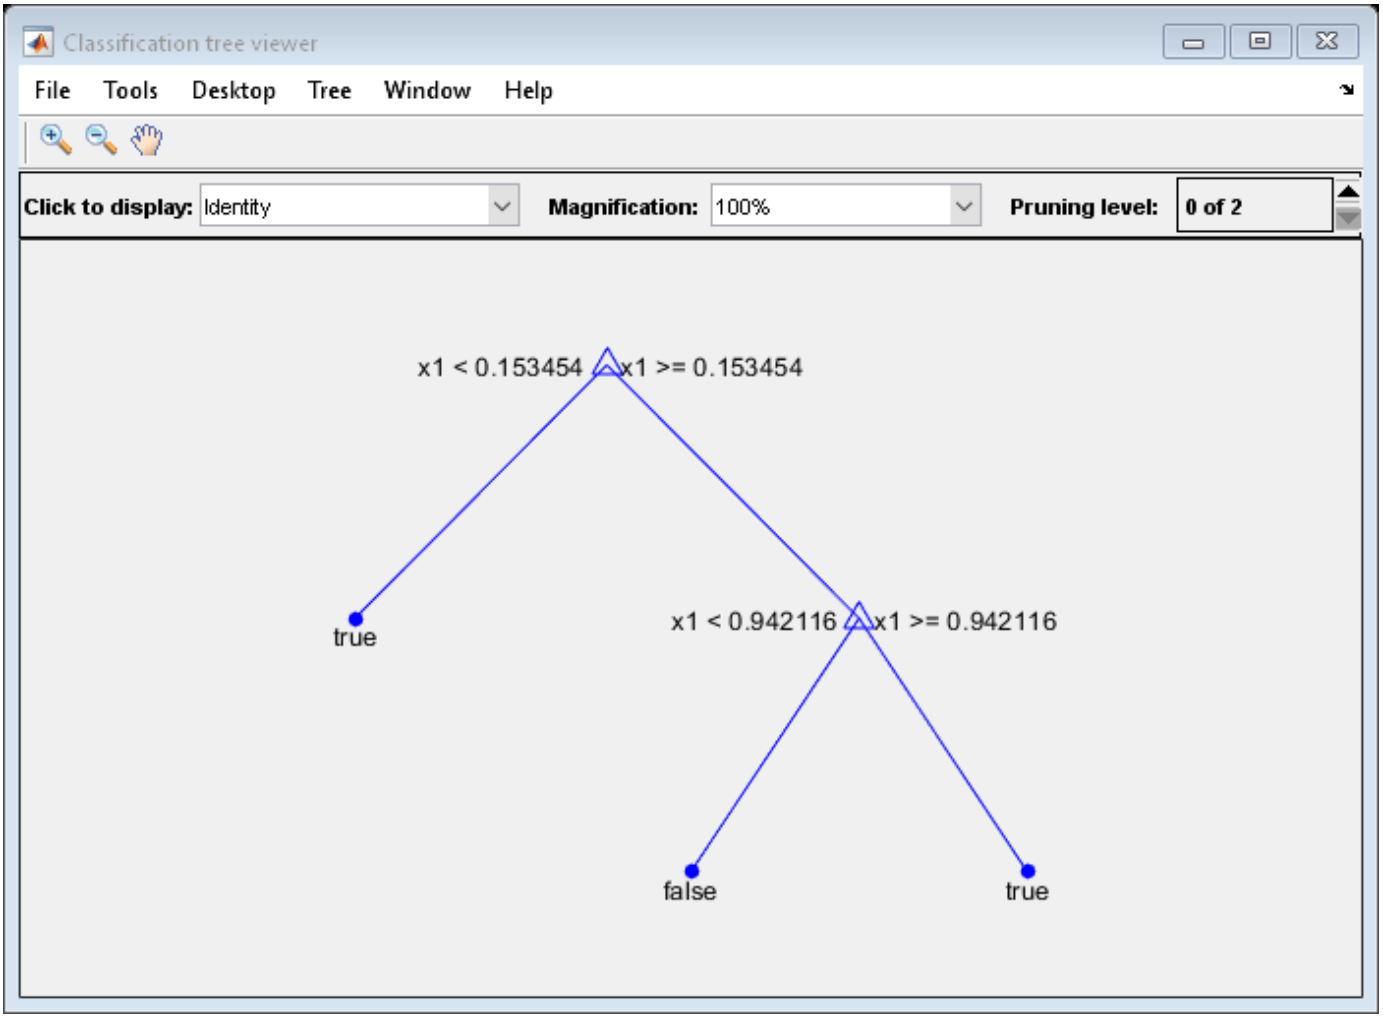
Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

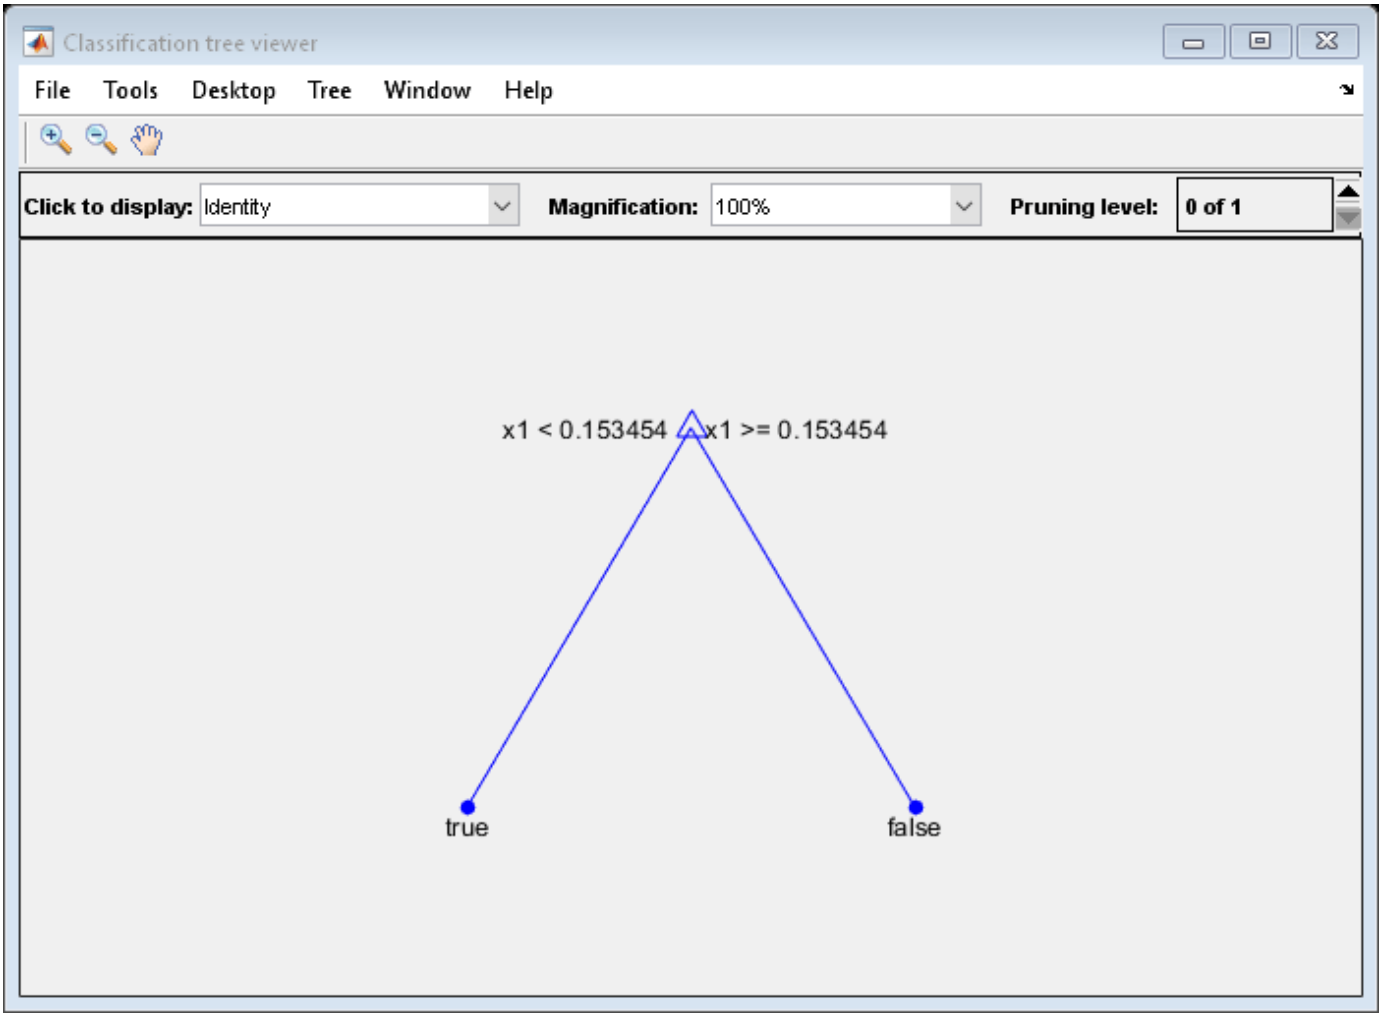
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10×3

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
```

```
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

resubLoss

Class: `ClassificationDiscriminant`

Classification error by resubstitution

Syntax

```
L = resubLoss(obj)
L = resubLoss(obj,Name,Value)
```

Description

`L = resubLoss(obj)` returns the resubstitution loss, meaning the loss computed for the data that `fitcdiscr` used to create `obj`.

`L = resubLoss(obj,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`obj`

Discriminant analysis classifier, produced using `fitcdiscr`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`LossFun` — Loss function

`'mincost'` (default) | `'binodeviance'` | `'classiferror'` | `'exponential'` | `'hinge'` | `'logit'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using the corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss

Value	Description
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic loss

'mincost' is appropriate for classification scores that are posterior probabilities. Discriminant analysis models return posterior probabilities as classification scores by default (see predict).

- Specify your own function using function handle notation.

  Suppose that n be the number of observations in X and K be the number of distinct classes (numel(obj.ClassNames)). Your function must have this signature

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  where:

  - The output argument lossvalue is a scalar.
  - You choose the function name (*lossfun*).
  - C is an n-by-K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in obj.ClassNames.

    Construct C by setting C(p,q) = 1 if observation p is in class q, for each row. Set all other elements of row p to 0.
  - S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in obj.ClassNames. S is a matrix of classification scores, similar to the output of predict.
  - W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes them to sum to 1.
  - Cost is a *K*-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) - eye(K) specifies a cost of 0 for correct classification, and 1 for misclassification.

  Specify your function using 'LossFun',@*lossfun*.

For more details on loss functions, see “Classification Loss” on page 33-5537.

Data Types: char | string | function_handle

Output Arguments

L

Classification error, a scalar. The meaning of the error depends on the values in weights and lossfun. See “Classification Loss” on page 33-5537.

Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
```

```
L = resubLoss(obj)

L =
    0.0200
```

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

  $$\sum_{j=1}^{n} w_j = 1.$$

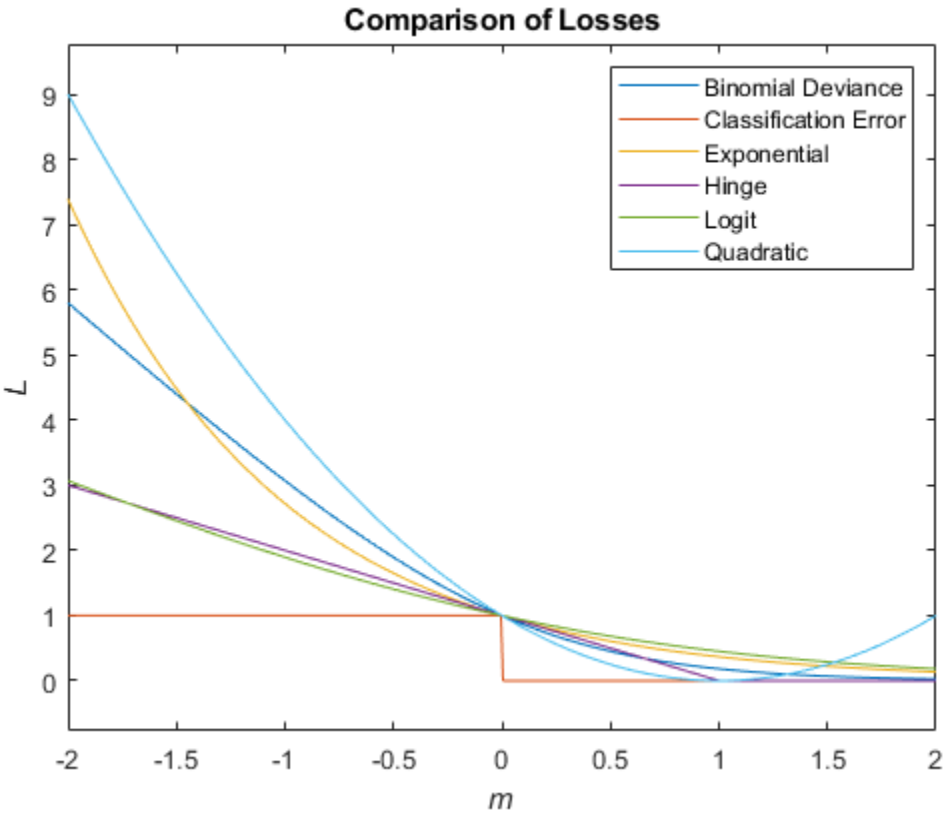
Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$

Loss Function	Value of LossFun	Equation
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$. $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn}$, where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



Posterior Probability

The posterior probability that a point x belongs to class k is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with 1-by-d mean μ_k and d-by-d covariance Σ_k at a 1-by-d point x is

$$P(x|k) = \frac{1}{\left((2\pi)^d|\Sigma_k|\right)^{1/2}}\exp\left(-\frac{1}{2}(x-\mu_k)\Sigma_k^{-1}(x-\mu_k)^T\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k, and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k. Then the posterior probability that an observation x is of class k is

$$\widehat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- `'uniform'` — The prior probability of class `k` is one over the total number of classes.
- `'empirical'` — The prior probability of class `k` is the number of training samples of class `k` divided by the total number of training samples.

- Custom — The prior probability of class `k` is the `k`th element of the `prior` vector. See `fitcdiscr`.

After creating a classification model (`Mdl`) you can set the prior using dot notation:

```
Mdl.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 20-7.

“Discriminant Analysis Classification” on page 20-2

resubLoss

Resubstitution classification loss for multiclass error-correcting output codes (ECOC) model

Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl,Name,Value)
```

Description

`L = resubLoss(Mdl)` returns the classification loss by resubstitution (`L`) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`. By default, `resubLoss` uses the classification error on page 33-5546 to compute `L`.

The classification loss (`L`) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but in general, better classifiers yield smaller classification loss values.

`L = resubLoss(Mdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, you can specify the loss function, decoding scheme, and verbosity level.

Examples

Resubstitution Loss of ECOC Model

Compute the resubstitution loss for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Estimate the resubstitution classification error, which is the default classification loss.

```
L = resubLoss(Mdl)
```

```
L = 0.0267
```

The ECOC model misclassifies 2.67% of the training-sample irises.

Determine ECOC Model Quality Using Custom Resubstitution Loss

Determine the quality of an ECOC model by using a custom loss function that considers the minimal binary loss for each observation.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y)  % Class order
```

```
classOrder = 3x1 categorical
     setosa
     versicolor
     virginica
```

```
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Create a function that takes the minimal loss for each observation, then averages the minimal losses for all observations. `S` corresponds to the `NegLoss` output of `resubPredict`.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the custom classification loss for the training data.

```
resubLoss(Mdl,'LossFun',lossfun)
```

```
ans = 0.0065
```

The average minimal binary loss for the training data is `0.0065`.

Input Arguments

`Mdl` — Full, trained multiclass ECOC model

`ClassificationECOC` model

Full, trained multiclass ECOC model, specified as a `ClassificationECOC` model trained with `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `resubLoss(Mdl,'BinaryLoss','hamming','LossFun',@lossfun)` specifies `'hamming'` as the binary learner loss function and the custom function handle `@lossfun` as the overall loss function.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

  where:

  - `M` is the K-by-L coding matrix stored in `Mdl.CodingMatrix`.

- `s` is the 1-by-*L* row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- *K* is the number of classes.
- *L* is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-5547.

Example: `'Decoding','lossbased'`

`LossFun` — Loss function
`'classiferror'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'classiferror'` or a function handle.

- Specify the built-in function `'classiferror'`. In this case, the loss function is the classification error on page 33-5546, which is the proportion of misclassified observations.
- Or, specify your own function using function handle notation.

  Assume that `n = size(X,1)` is the sample size and `K` is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You specify the function name (*`lossfun`*).
- `C` is an `n`-by-`K` logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

  Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
- `S` is an `n`-by-`K` numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `Mdl.ClassNames`. The input `S` resembles the output argument `NegLoss` of `resubPredict`.
- `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes its elements to sum to `1`.
- `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `string` | `function_handle`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

More About

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^{n} w_j e_j}{\sum_{j=1}^{n} w_j},$$

where:

- w_j is the weight for observation j. The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	$(-\infty,\infty)$	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	$[0,1]$ or $(-\infty,\infty)$	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	$(-\infty,\infty)$	$(1 - y_js_j)/2$

Value	Description	Score Domain	$g(y_j,s_j)$
`'logit'`	Logistic	$(-\infty,\infty)$	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

resubLoss

Classification error by resubstitution

Syntax

```
L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
```

Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the loss computed for the data that `fitcensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

`lossfun`

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss

Value	Description
'hinge'	Hinge loss
'logit'	Logistic loss
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic loss

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (ens.Method is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', GentleBoost, or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

  ```
  ens.ScoreTransform = 'doublelogit';
  ```
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.

- Specify your own function using function handle notation.

  Suppose that n be the number of observations in X and K be the number of distinct classes (numel(ens.ClassNames), ens is the input model). Your function must have this signature

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  where:

  - The output argument lossvalue is a scalar.
  - You choose the function name (*lossfun*).
  - C is an n-by-K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in ens.ClassNames.

    Construct C by setting C(p,q) = 1 if observation p is in class q, for each row. Set all other elements of row p to 0.
  - S is an n-by-K numeric matrix of classification scores. The column order corresponds to the class order in ens.ClassNames. S is a matrix of classification scores, similar to the output of predict.
  - W is an n-by-1 numeric vector of observation weights. If you pass W, the software normalizes them to sum to 1.
  - Cost is a *K*-by-K numeric matrix of misclassification costs. For example, Cost = ones(K) - eye(K) specifies a cost of 0 for correct classification, and 1 for misclassification.

  Specify your function using 'LossFun',@*lossfun*.

For more details on loss functions, see “Classification Loss” on page 33-5551.

Default: 'classiferror'

`mode`

Character vector or string scalar representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

`L`

Classification loss on page 33-5551, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Classification Error for Training Observations

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification ensemble of 100 decision trees using AdaBoostM2. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the resubstitution classification error.

```
loss = resubLoss(ens)
```

```
loss = 0.0333
```

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:

- y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
- $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.

- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\hat{y}_j \neq y_j\right\}.$ $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn},$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.

Loss Function	Value of LossFun	Equation
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = (f(X_j)'C)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\hat{y}_j = \underset{k=1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j (1 - m_j)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).

resubLoss

Resubstitution classification loss

Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl,Name,Value)
```

Description

`L = resubLoss(Mdl)` returns the "Classification Loss" on page 33-5559 by resubstitution (L), or the in-sample classification loss, for the trained classification model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`.

The interpretation of `L` depends on the loss function (`'LossFun'`) and weighting scheme (`Mdl.W`). In general, better classifiers yield smaller classification loss values. The default `'LossFun'` value varies depending on the model object `Mdl`.

`L = resubLoss(Mdl,Name,Value)` specifies additional options using one or more name-value arguments. For example, `'LossFun','binodeviance'` sets the loss function to the binomial deviance function.

Examples

Determine Resubstitution Loss of Naive Bayes Classifier

Determine the in-sample classification error (resubstitution loss) of a naive Bayes classifier. In general, a smaller loss indicates a better classifier.

Load the `fisheriris` data set. Create `X` as a numeric matrix that contains four measurements for 150 irises. Create `Y` as a cell array of character vectors that contains the corresponding iris species.

```
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using the predictors `X` and class labels `Y`. A recommended practice is to specify the class names. `fitcnb` assumes that each predictor is conditionally and normally distributed.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'})
```

```
Mdl =
  ClassificationNaiveBayes
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
        DistributionNames: {'normal'  'normal'  'normal'  'normal'}
```

```
    DistributionParameters: {3x4 cell}

  Properties, Methods
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

Estimate the in-sample classification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0400
```

The naive Bayes classifier misclassifies 4% of the training observations.

Determine Resubstitution Hinge Loss of SVM Classifier

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a support vector machine (SVM) classifier. Standardize the data and specify that `'g'` is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a trained `ClassificationSVM` classifier.

Estimate the in-sample hinge loss.

```
L = resubLoss(SVMModel,'LossFun','hinge')
```

```
L = 0.1603
```

The hinge loss is `0.1603`. Classifiers with hinge losses close to 0 are preferred.

Compare GAMs by Examining Classification Loss

Train a generalized additive model (GAM) that contains both linear and interaction terms for predictors, and estimate the classification loss with and without interaction terms. Specify whether to include interaction terms when estimating the classification loss for training and test data.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Partition the data set into two sets: one containing training data, and the other containing new, unobserved test data. Reserve 50 observations for the new test data set.

```
rng('default') % For reproducibility
n = size(X,1);
```

```
newInds = randsample(n,50);
inds = ~ismember(1:n,newInds);
XNew = X(newInds,:);
YNew = Y(newInds);
```

Train a GAM using the predictors `X` and class labels `Y`. A recommended practice is to specify the class names. Specify to include the 10 most important interaction terms.

```
Mdl = fitcgam(X(inds,:),Y(inds),'ClassNames',{'b','g'},'Interactions',10)
```

```
Mdl =
  ClassificationGAM
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}
           ScoreTransform: 'logit'
                Intercept: 2.0026
             Interactions: [10x2 double]
          NumObservations: 301

  Properties, Methods
```

`Mdl` is a `ClassificationGAM` model object.

Compute the resubstitution classification loss both with and without interaction terms in `Mdl`. To exclude interaction terms, specify `'IncludeInteractions',false`.

```
resubl = resubLoss(Mdl)
```

```
resubl = 0
```

```
resubl_nointeraction = resubLoss(Mdl,'IncludeInteractions',false)
```

```
resubl_nointeraction = 0
```

Estimate the classification loss both with and without interaction terms in `Mdl`.

```
l = loss(Mdl,XNew,YNew)
```

```
l = 0.0615
```

```
l_nointeraction = loss(Mdl,XNew,YNew,'IncludeInteractions',false)
```

```
l_nointeraction = 0.0615
```

Including interaction terms does not change the classification loss for `Mdl`. The trained model classifies all training samples correctly and misclassifies approximately 6% of the test samples.

Input Arguments

`Mdl` — Classification machine learning model

full classification model object

Classification machine learning model, specified as a full classification model object, as given in the following table of supported models.

Model	Classification Model Object
Generalized additive model	`ClassificationGAM`
k-nearest neighbor model	`ClassificationKNN`
Naive Bayes model	`ClassificationNaiveBayes`
Neural network model	`ClassificationNeuralNetwork`
Support vector machine for one-class and binary classification	`ClassificationSVM`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `resubLoss(Mdl,'LossFun','logit')` estimates the logit resubstitution loss.

`IncludeInteractions` — Flag to include interaction terms
`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `Mdl` is `ClassificationGAM`.

The default value is `true` if `Mdl` contains interaction terms. The value must be `false` if the model does not contain interaction terms.

Data Types: `logical`

`LossFun` — Loss function
`'binodeviance'` | `'classiferror'` | `'crossentropy'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'crossentropy'`	Cross-entropy loss (for neural networks only)
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  The default value depends on the trained model (`Mdl`).

- The default value is `'classiferror'` if `Mdl` is a `ClassificationGAM`, `ClassificationNeuralNetwork`, or `ClassificationSVM` object.
- The default value is `'mincost'` if `Mdl` is a `ClassificationKNN` or `ClassificationNaiveBayes` object.

For more details on loss functions, see “Classification Loss” on page 33-5559.

- To specify a custom loss function, use function handle notation. The function must have this form:

  `lossvalue = lossfun(C,S,W,Cost)`

  - The output argument `lossvalue` is a scalar.
  - You specify the function name (`lossfun`).
  - `C` is an `n`-by-`K` logical matrix with rows indicating the class to which the corresponding observation belongs. `n` is the number of observations in `Tbl` or `X`, and `K` is the number of distinct classes (`numel(Mdl.ClassNames)`). The column order corresponds to the class order in `Mdl.ClassNames`. Create `C` by setting `C(p,q) = 1`, if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights.
  - `Cost` is a `K`-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) – eye(K)` specifies a cost of `0` for correct classification and `1` for misclassification.

Example: `'LossFun','binodeviance'`

Data Types: `char` | `string` | `function_handle`

More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):

- y_j^* is a vector of K – 1 zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
- $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
- $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

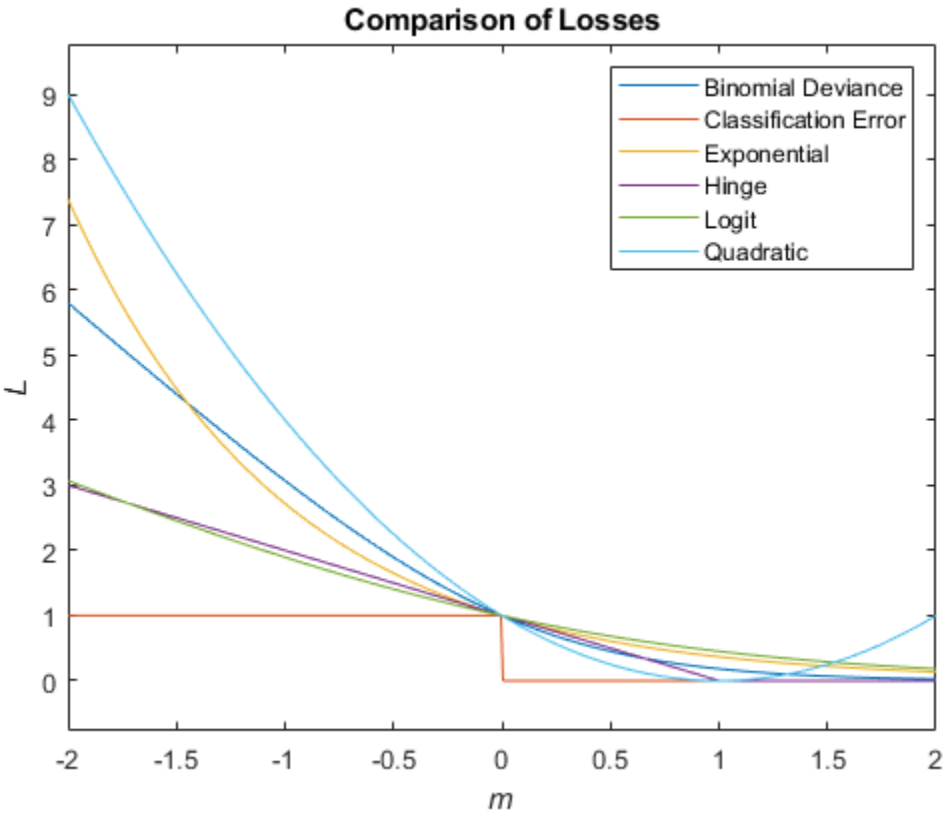
$$\sum_{j=1}^{n} w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\left\{\widehat{y}_j \neq y_j\right\}.$ $\widehat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn},$ where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp\left(-m_j\right).$
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\left\{0, 1 - m_j\right\}.$
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log\left(1 + \exp\left(-m_j\right)\right).$

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



Algorithms

`resubLoss` computes the classification loss according to the corresponding `loss` function of the object (`Mdl`). For a model-specific description, see the `loss` function reference pages in the following table.

Model	Classification Model Object (`Mdl`)	`loss` Object Function
Generalized additive model	`ClassificationGAM`	`loss`
k-nearest neighbor model	`ClassificationKNN`	`loss`
Naive Bayes model	`ClassificationNaiveBayes`	`loss`
Neural network model	`ClassificationNeuralNetwork`	`loss`
Support vector machine for one-class and binary classification	`ClassificationSVM`	`loss`

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports `ClassificationKNN` and `ClassificationSVM` objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`resubEdge` | `resubMargin` | `resubPredict`

Introduced in R2012a

resubLoss

Class: `ClassificationTree`

Classification error by resubstitution

Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'Subtrees',subtreevector)
[L,se] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)
[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)
```

Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitctree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

`L = resubLoss(tree,'Subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`tree`

A classification tree constructed by `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`LossFun` — Loss function
`'mincost'` (default) | `'binodeviance'` | `'classiferror'` | `'exponential'` | `'hinge'` | `'logit'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
`'binodeviance'`	Binomial deviance
`'classiferror'`	Misclassified rate in decimal
`'exponential'`	Exponential loss
`'hinge'`	Hinge loss
`'logit'`	Logistic loss
`'mincost'`	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
`'quadratic'`	Quadratic loss

  `'mincost'` is appropriate for classification scores that are posterior probabilities. Classification trees return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

  Suppose that `n` be the number of observations in `X` and `K` be the number of distinct classes (`numel(tree.ClassNames)`). Your function must have this signature

  ```
  lossvalue = lossfun(C,S,W,Cost)
  ```

  where:

  - The output argument `lossvalue` is a scalar.
  - You choose the function name (*`lossfun`*).
  - `C` is an `n`-by-`K` logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `tree.ClassNames`.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in `tree.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to `1`.

- `Cost` is a *K*-by-`K` numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification, and `1` for misclassification.

Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see "Classification Loss" on page 33-5570.

Data Types: `char` | `string` | `function_handle`

`Name,Value` arguments associated with pruning subtrees:

`Subtrees` — Pruning level
0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `resubLoss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubLoss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single` | `double` | `char` | `string`

`TreeSize` — Tree size
`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following values:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

`L`

Classification loss on page 33-5570, a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

`se`

Standard error of loss, a vector the length of `Subtrees`.

`NLeaf`

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

`bestlevel`

A scalar whose value depends on `TreeSize`:

- `TreeSize` = `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L+se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize` = `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Examples

Compute the In-Sample Classification Error

Compute the resubstitution classification error for the `ionosphere` data.

```
load ionosphere
tree = fitctree(X,Y);
L = resubLoss(tree)
```

```
L = 0.0114
```

Examine the Classification Error for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

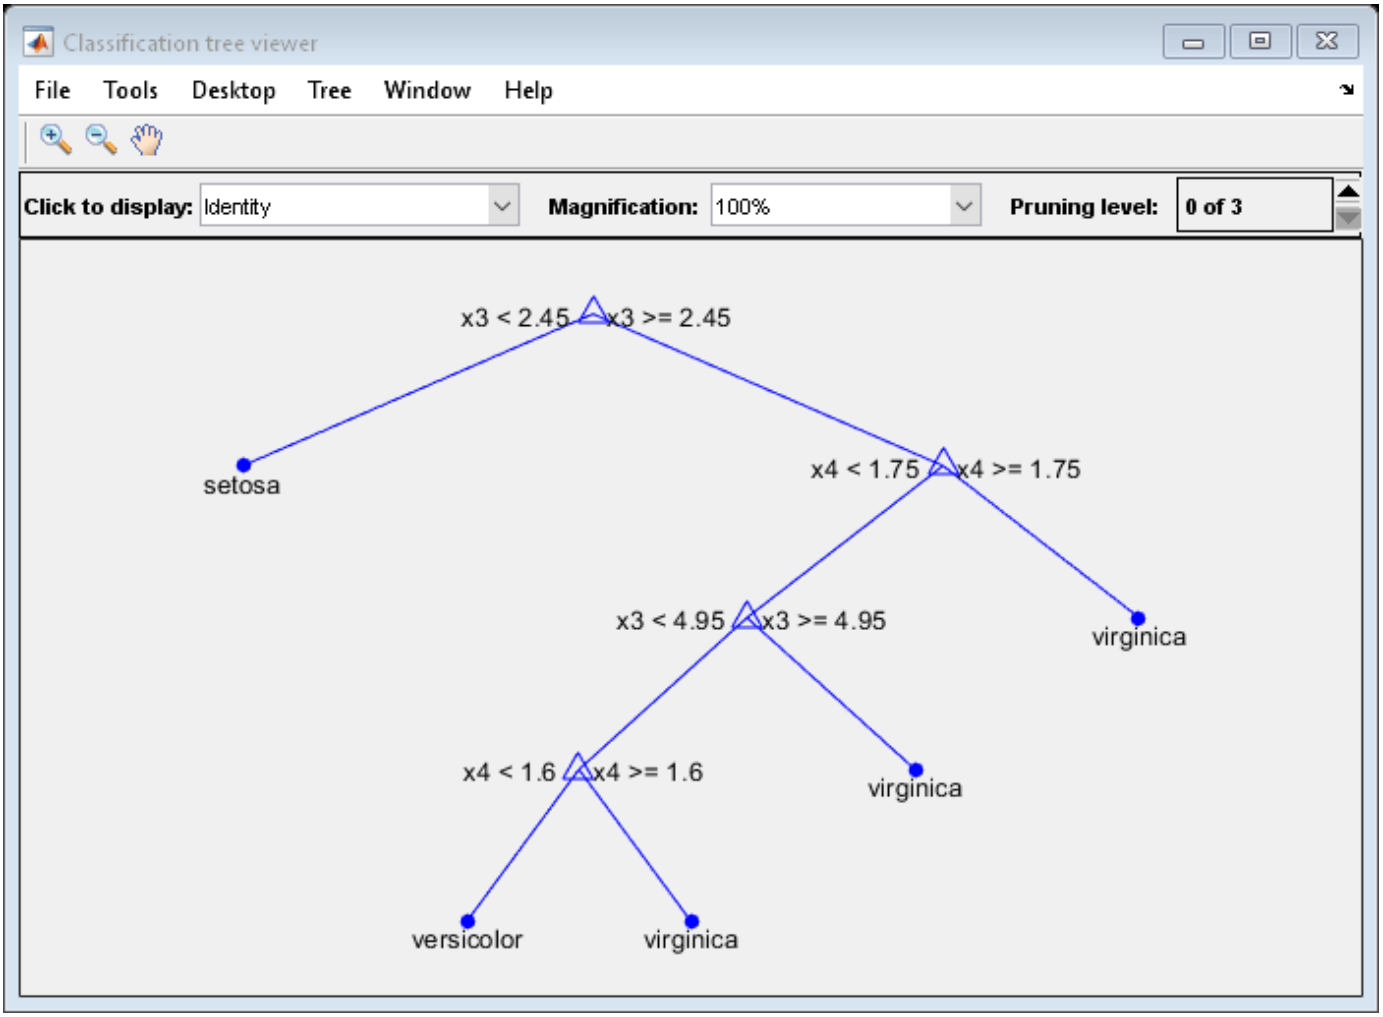
```
load fisheriris
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

View the classification tree.

```
view(Mdl,'Mode','graph');
```



The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
```

```
trnLoss = 3×1

    0.0267
    0.0533
    0.3067
```

- The full, unpruned tree misclassifies about 2.7% of the training observations.
- The tree pruned to level 1 misclassifies about 5.3% of the training observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

```
valLoss = loss(Mdl,meas(idxVal,:),species(idxVal),'SubTrees',0:m)
```

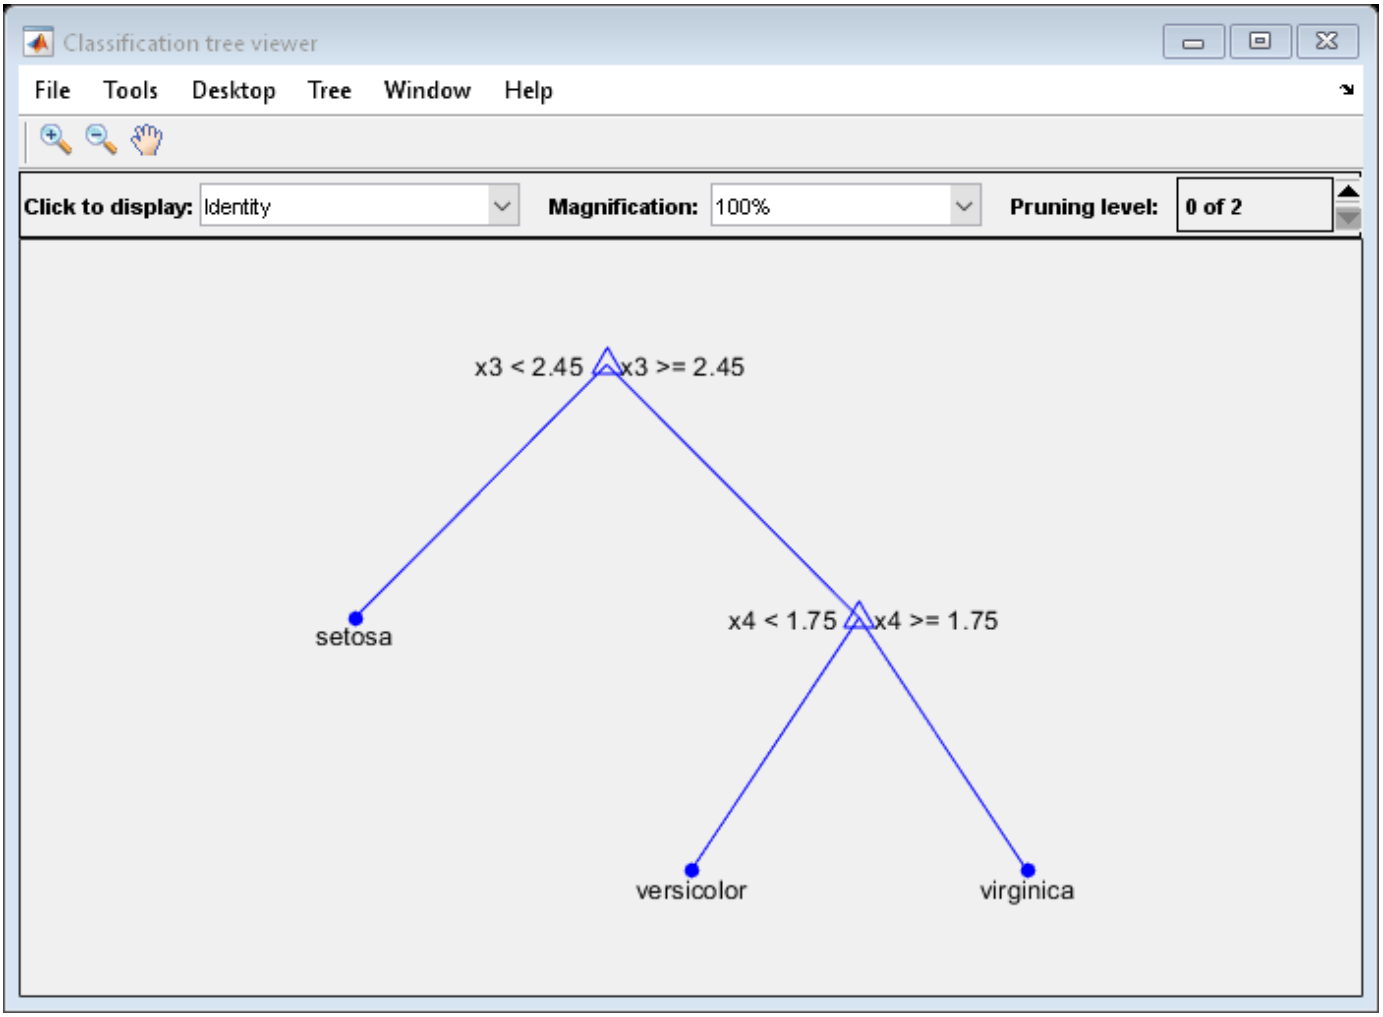
```
valLoss = 3×1

    0.0369
    0.0237
    0.3067
```

- The full, unpruned tree misclassifies about 3.7% of the validation observations.
- The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 1.

```
pruneMdl = prune(Mdl,'Level',1);
view(pruneMdl,'Mode','graph')
```



More About

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
  - y_j is the observed class label. The software codes it as –1 or 1, indicating the negative or positive class (or the first or second class in the `ClassNames` property), respectively.
  - $f(X_j)$ is the positive-class classification score for observation (row) j of the predictor data X.
  - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j. Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
  - y_j^* is a vector of $K – 1$ zeros, with 1 in the position corresponding to the true, observed class y_j. For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0\ 0\ 1\ 0]'$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
  - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X. The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
  - $m_j = y_j^{*\prime} f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j. The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^{n} w_j = 1.$$

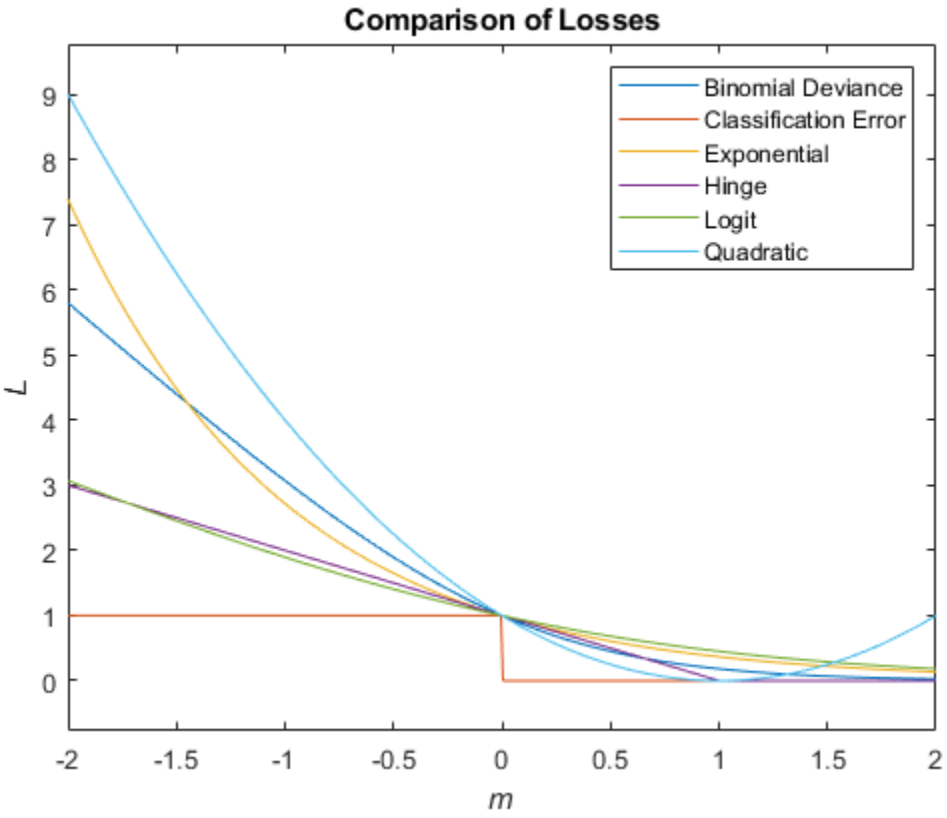
Given this scenario, the following table describes the supported loss functions that you can specify by using the `'LossFun'` name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	`'binodeviance'`	$L = \sum_{j=1}^{n} w_j \log\left\{1 + \exp\left[-2m_j\right]\right\}.$

Loss Function	Value of LossFun	Equation
Misclassified rate in decimal	`'classiferror'`	$L = \sum_{j=1}^{n} w_j I\{\hat{y}_j \neq y_j\}$. $\hat{y}_j$ is the class label corresponding to the class with the maximal score. $I\{\cdot\}$ is the indicator function.
Cross-entropy loss	`'crossentropy'`	`'crossentropy'` is appropriate only for neural network models. The weighted cross-entropy loss is $L = -\sum_{j=1}^{n} \frac{\tilde{w}_j \log(m_j)}{Kn}$, where the weights $\tilde{w}_j$ are normalized to sum to n instead of 1.
Exponential loss	`'exponential'`	$L = \sum_{j=1}^{n} w_j \exp(-m_j)$.
Hinge loss	`'hinge'`	$L = \sum_{j=1}^{n} w_j \max\{0, 1 - m_j\}$.
Logit loss	`'logit'`	$L = \sum_{j=1}^{n} w_j \log(1 + \exp(-m_j))$.

Loss Function	Value of LossFun	Equation
Minimal expected misclassification cost	`'mincost'`	`'mincost'` is appropriate only if classification scores are posterior probabilities. The software computes the weighted minimal expected classification cost using this procedure for observations $j = 1,...,n$. **1** Estimate the expected misclassification cost of classifying the observation X_j into the class k: $\gamma_{jk} = \left(f(X_j)'C\right)_k$. $f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification for the observation X_j. C is the cost matrix stored in the `Cost` property of the model. **2** For observation j, predict the class label corresponding to the minimal expected misclassification cost: $\widehat{y}_j = \underset{k = 1,...,K}{\operatorname{argmin}} \gamma_{jk}$. **3** Using C, identify the cost incurred (c_j) for making the prediction. The weighted average of the minimal expected misclassification cost loss is $L = \sum_{j=1}^{n} w_j c_j$. If you use the default cost matrix (whose element value is 0 for correct classification and 1 for incorrect classification), then the `'mincost'` loss is equivalent to the `'classiferror'` loss.
Quadratic loss	`'quadratic'`	$L = \sum_{j=1}^{n} w_j \left(1 - m_j\right)^2$.

This figure compares the loss functions (except `'crossentropy'` and `'mincost'`) over the score m for one observation. Some functions are normalized to pass through the point (0,1).



True Misclassification Cost

The true misclassification cost is the cost of classifying an observation into an incorrect class.

You can set the true misclassification cost per class by using the `'Cost'` name-value argument when you create the classifier. `Cost(i,j)` is the cost of classifying an observation into class `j` when its true class is `i`. By default, `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is `0` for correct classification and `1` for incorrect classification.

Expected Misclassification Cost

The expected misclassification cost per observation is an averaged cost of classifying the observation into each class.

Suppose you have `Nobs` observations that you want to classify with a trained classifier, and you have `K` classes. You place the observations into a matrix `X` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n,k)` is

$$\sum_{i=1}^{K}\widehat{P}(i|X(n))C(k|i),$$

where:

- K is the number of classes.
- $\widehat{P}(i|X(n))$ is the posterior probability of class i for observation $X(n)$.
- $C(k|i)$ is the true misclassification cost of classifying an observation as k when its true class is i.

`fitctree` | `loss` | `resubEdge` | `resubMargin` | `resubPredict`

resubLoss

Regression error by resubstitution

Syntax

```
L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
```

Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the mean squared error computed for the data that `fitrensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

`lossfun`

Function handle for loss function, or `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `resubLoss` calls it as

```
FUN(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length. `Y` is the observed response, `Yfit` is the predicted response, and `W` is the observation weights.

Default: `'mse'`

`mode`

Character vector or string scalar representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: `'ensemble'`

Output Arguments

L

Loss, by default the mean squared error. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Resubstitution Loss

Find the mean-squared difference between resubstitution predictions and training data.

Load the `carsmall` data set and select horsepower and vehicle weight as predictors.

```
load carsmall
X = [Horsepower Weight];
```

Train an ensemble of regression trees, and find the mean-squared difference of predictions from the training data.

```
ens = fitrensemble(X,MPG);
MSE = resubLoss(ens)
```

```
MSE = 0.5836
```

See Also

`loss` | `resubLoss` | `resubPredict`

resubLoss

Resubstitution regression loss

Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl,Name,Value)
```

Description

`L = resubLoss(Mdl)` returns the regression loss by resubstitution (L), or the in-sample regression loss, for the trained regression model `Mdl` using the training data stored in `Mdl.X` and the corresponding responses stored in `Mdl.Y`.

The interpretation of `L` depends on the loss function (`'LossFun'`) and weighting scheme (`Mdl.W`). In general, better models yield smaller loss values. The default `'LossFun'` value is `'mse'` (mean squared error).

`L = resubLoss(Mdl,Name,Value)` specifies additional options using one or more name-value arguments. For example, `'IncludeInteractions',false` specifies to exclude interaction terms from a generalized additive model `Mdl`.

Examples

Resubstitution Loss

Train a generalized additive model (GAM), then calculate the resubstitution loss using the mean squared error (MSE).

Load the `patients` data set.

```
load patients
```

Create a table that contains the predictor variables (`Age`, `Diastolic`, `Smoker`, `Weight`, `Gender`, `SelfAssessedHealthStatus`) and the response variable (`Systolic`).

```
tbl = table(Age,Diastolic,Smoker,Weight,Gender,SelfAssessedHealthStatus,Systolic);
```

Train a univariate GAM that contains the linear terms for the predictors in `tbl`.

```
Mdl = fitrgam(tbl,"Systolic")
```

```
Mdl =
  RegressionGAM
             PredictorNames: {1x6 cell}
               ResponseName: 'Systolic'
    CategoricalPredictors: [3 5 6]
        ResponseTransform: 'none'
                Intercept: 122.7800
          NumObservations: 100
```

```
  Properties, Methods
```

`Mdl` is a `RegressionGAM` model object.

Calculate the resubstitution loss using the mean squared error (MSE).

```
L = resubLoss(Mdl)
```

```
L = 4.1957
```

Compare GAMs by Examining Regression Loss

Train a generalized additive model (GAM) that contains both linear and interaction terms for predictors, and estimate the regression loss (mean squared error, MSE) with and without interaction terms for the training data and test data. Specify whether to include interaction terms when estimating the regression loss.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Specify `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Acceleration,Displacement,Horsepower,Weight];
Y = MPG;
```

Partition the data set into two sets: one containing training data, and the other containing new, unobserved test data. Reserve 10 observations for the new test data set.

```
rng('default') % For reproducibility
n = size(X,1);
newInds = randsample(n,10);
inds = ~ismember(1:n,newInds);
XNew = X(newInds,:);
YNew = Y(newInds);
```

Train a generalized additive model that contains all the available linear and interaction terms in `X`.

```
Mdl = fitrgam(X(inds,:),Y(inds),'Interactions','all');
```

`Mdl` is a `RegressionGAM` model object.

Compute the resubstitution MSEs (that is, the in-sample MSEs) both with and without interaction terms in `Mdl`. To exclude interaction terms, specify `'IncludeInteractions',false`.

```
resubl = resubLoss(Mdl)
```

```
resubl = 0.0292
```

```
resubl_nointeraction = resubLoss(Mdl,'IncludeInteractions',false)
```

```
resubl_nointeraction = 4.7330
```

Compute the regression MSEs both with and without interaction terms for the test data set. Use a memory-efficient model object for the computation.

```
CMdl = compact(Mdl);
```

`CMdl` is a `CompactRegressionGAM` model object.

```
l = loss(CMdl,XNew,YNew)
```

```
l = 12.8604
```

```
l_nointeraction = loss(CMdl,XNew,YNew,'IncludeInteractions',false)
```

```
l_nointeraction = 15.6741
```

Including interaction terms achieves a smaller error for the training data set and test data set.

Input Arguments

`Mdl` — Regression machine learning model

full regression model object

Regression machine learning model, specified as a full regression model object, as given in the following table of supported models.

Model	Regression Model Object
Generalized additive model	`RegressionGAM`
Neural network model	`RegressionNeuralNetwork`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `resubLoss(Mdl,'IncludeInteractions',false)` excludes interaction terms from a generalized additive model `Mdl`.

`IncludeInteractions` — Flag to include interaction terms

`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `Mdl` is `RegressionGAM`.

The default value is `true` if `Mdl` contains interaction terms. The value must be `false` if the model does not contain interaction terms.

Example: `'IncludeInteractions',false`

Data Types: `logical`

`LossFun` — Loss function

`'mse'` (default) | function handle

Loss function, specified as `'mse'` or a function handle.

- `'mse'` — Weighted mean squared error.
- Function handle — To specify a custom loss function, use a function handle. The function must have this form:

  ```
  lossval = lossfun(Y,YFit,W)
  ```

  - The output argument `lossval` is a floating-point scalar.
  - You specify the function name (*`lossfun`*).
  - `Y` is a length *n* numeric vector of observed responses, where *n* is the number of observations in `Tbl` or `X`.
  - `YFit` is a length *n* numeric vector of corresponding predicted responses.
  - `W` is an *n*-by-1 numeric vector of observation weights.

Example: `'LossFun',@lossfun`

Data Types: `char` | `string` | `function_handle`

More About

Weighted Mean Squared Error

The weighted mean squared error measures the predictive inaccuracy of regression models. When you compare the same type of loss among many models, a lower error indicates a better predictive model.

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^{n} w_j \left(f\left(x_j\right) - y_j\right)^2}{\sum_{j=1}^{n} w_j},$$

where:

- n is the number of rows of data.
- x_j is the jth row of data.
- y_j is the true response to x_j.
- $f(x_j)$ is the response prediction of the model `Mdl` to x_j.
- w is the vector of observation weights.

Algorithms

`resubLoss` computes the regression loss according to the corresponding `loss` function of the object (`Mdl`). For a model-specific description, see the `loss` function reference pages in the following table.

Model	Regression Model Object (`Mdl`)	`loss` Object Function
Generalized additive model	`RegressionGAM`	`loss`
Neural network model	`RegressionNeuralNetwork`	`loss`

See Also

`resubPredict`

Introduced in R2021a

resubLoss

Class: `RegressionGP`

Resubstitution loss for a trained Gaussian process regression model

Syntax

```
L = resubLoss(gprMdl)
L = resubLoss(gprMdl,Name,Value)
```

Description

`L = resubLoss(gprMdl)` returns the resubstitution mean squared error for the Gaussian process regression (GPR) model, `gprMdl`.

`L = resubLoss(gprMdl,Name,Value)` returns the resubstitution loss for the GPR model, `gprMdl`, with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify a custom loss function or the observation weights.

Input Arguments

`gprMdl` — Gaussian process regression model

`RegressionGP` object

Gaussian process regression model, specified as a `RegressionGP` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`lossfun` — Loss function

`'mse'` (default) | function handle

Loss function for the trained GPR model, specified as `'mse'` or a function handle. `'mse'` stands for the mean squared error.

If you pass a function handle, say `fun`, `resubLoss` calls it as : `fun(Y,Ypred,W)`, where `Y`, `Ypred`, and `W` are numeric vectors of length *n*, and *n* is the number of observations in the training data. `Y` is the observed response, `Ypred` is the predicted response, and `W` is the observation weights.

Example: `'lossfun',Fct` calls the loss function `Fct`.

Data Types: `char` | `string` | `function_handle`

`weights` — Observation weights

vector of 1s (default) | *n*-by-1 vector

Observation weights, specified as an *n*-by-1 vector, where *n* is the number of observations in the training data. By default, weight of each observation is 1.

Data Types: `double` | `single`

Output Arguments

L — Resubstitution error

scalar value

Resubstitution error for the GPR model, returned as a scalar value.

Examples

Compute the Resubstitution Loss

This example uses "Housing" data set [1] from the UCI machine learning archive [2] described in http://archive.ics.uci.edu/ml/datasets/Housing. Download the data and save it in your current directory as a data file named `housing.data`.

The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in the Boston suburb area as a function of 13 predictors.

Load the data and define the response vector and predictor matrix.

```
load('housing.data');
X = housing(:,1:13);
y = housing(:,end);
```

Fit a GPR model using subset of regressors (`'sr'`) approximation method with Matern 3/2 (`'Matern32'`) kernel function. Predict using the fully independent conditional (`'fic'`) method.

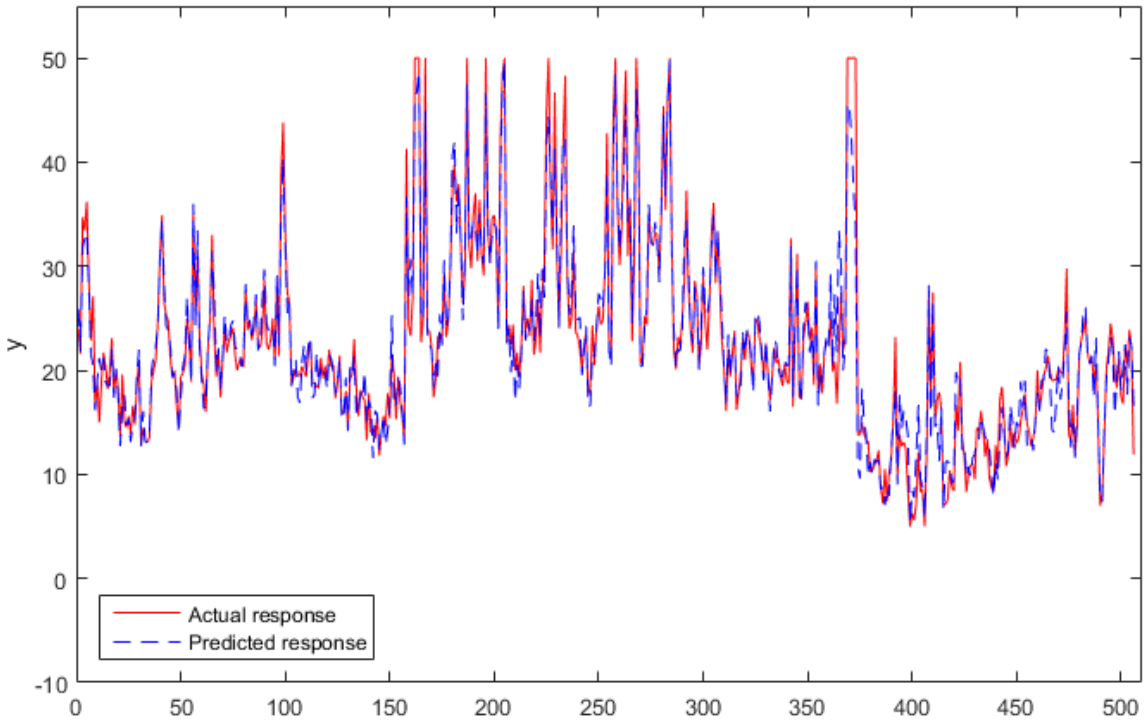
```
gprMdl = fitrgp(X,y,'KernelFunction','Matern32',...
'FitMethod','sr','PredictMethod','fic');
```

Compute the resubstitution predictions.

```
ypred = resubPredict(gprMdl);
```

Plot the predicted response values along with the actual response values.

```
plot(y,'r'); % Plot original response values
hold on;
plot(ypred,'b--'); % Plot predicted response values
ylabel('y');
legend('Actual response','Predicted response','Location','SouthWest');
axis([0 510 -10 55]);
hold off
```



Compute the resubstitution loss.

```
L = resubLoss(gprMdl)
```

```
L =

    4.8478
```

Manually compute the regression loss.

```
n = length(y);
L = (y-ypred)'*(y-ypred)/n
```

```
L =

    4.8478
```

Compute Custom Resubstitution Loss

Load the sample data and store in a `table`.

```
load fisheriris
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...
'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```
mdl = fitrgp(tbl,'meas1');
```

Predict the responses using the trained model.

```
ypred = predict(mdl,tbl);
```

Compute the mean absolute error.

```
n = height(tbl);
y = tbl.meas1;
fun = @(y,ypred,w) sum(abs(y-ypred))/n;
L = resubLoss(mdl,'lossfun',fun)
```

```
L = 0.2345
```

Alternatives

To compute the regression error for new data, use `loss`.

`RegressionGP` | `fitrgp` | `loss` | `resubPredict`

Introduced in R2015b

resubLoss

Class: RegressionSVM

Resubstitution loss for support vector machine regression model

Syntax

```
L = resubLoss(mdl)
L = resubLoss(mdl,Name,Value)
```

Description

`L = resubLoss(mdl)` returns the resubstitution loss for the support vector machine (SVM) regression model `mdl`, using the training data stored in `mdl.X` and corresponding response values stored in `mdl.Y`.

`L = resubLoss(mdl,Name,Value)` returns the resubstitution loss with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the loss function or observation weights.

Input Arguments

`mdl` — Full, trained SVM regression model

`RegressionSVM` model

Full, trained SVM regression model, specified as a `RegressionSVM` model returned by `fitrsvm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`LossFun` — Loss function

`'mse'` (default) | `'epsiloninsensitive'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'mse'`, `'epsiloninsensitive'`, or a function handle.

- The following table lists the available loss functions. Specify one using its corresponding value.

Value	Loss Function
`'mse'`	“Mean Squared Error” on page 33-5588
`'epsiloninsensitive'`	“Epsilon-Insensitive Loss Function” on page 33-5588

- Specify your own function using function handle notation.

  Suppose that `n = size(X,1)` is the sample size. Your function must have the signature `lossvalue = lossfun(Y,Yfit,W)`, where:

- The output argument `lossvalue` is a numeric value.
- You choose the function name (*`lossfun`*).
- `Y` is an *n*-by-1 numeric vector of observed response values.
- `Yfit` is an *n*-by-1 numeric vector of predicted response values, calculated using the corresponding predictor values in `X` (similar to the output of `predict`).
- `W` is an *n*-by-1 numeric vector of observation weights.

Specify your function using `'LossFun',@`*`lossfun`*.

Example: `'LossFun','epsiloninsensitive'`

Data Types: `char` | `string` | `function_handle`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector. `Weights` must be the same length as the number of rows in `X`. The software weighs the observations in each row of `X` using the corresponding weight value in `Weights`.

Data Types: `single` | `double`

Output Arguments

`L` — Resubstitution loss
scalar value

Resubstitution loss, returned as a scalar value.

The resubstitution loss is the loss calculated between the response training data and the model's predicted response values based on the input training data.

Resubstitution loss can be an overly optimistic estimate of the predictive error on new data. If the resubstitution loss is high, the model's predictions are not likely to be very good. However, having a low resubstitution loss does not guarantee good predictions for new data.

To better assess the predictive accuracy of your model, cross validate the model using `crossval`.

Examples

Resubstitution Loss for SVM Regression Model

This example shows how to train an SVM regression model, then calculate the resubstitution loss using mean square error (MSE) and epsilon-insensitive loss.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`.

Read the data into a `table`.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default  % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model to the data, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale','auto','Standardize',true);
```

Calculate the resubstitution loss using mean square error (MSE).

```
mse_loss = resubLoss(mdl)
```

```
mse_loss =

    4.0603
```

Calculate the epsilon-insensitive loss.

```
eps_loss = resubLoss(mdl,'LossFun','epsiloninsensitive')
```

```
eps_loss =

    1.1027
```

More About

Mean Squared Error

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^{n} w_j \left(f\left(x_j\right) - y_j\right)^2}{\sum_{j=1}^{n} w_j},$$

where:

- n is the number of rows of data
- x_j is the jth row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model `mdl` to x_j
- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the `'Weights'` name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Epsilon-Insensitive Loss Function

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (ε) of the function value. It is formally described as:

$$Loss_\varepsilon = \begin{cases} 0\,,\ if\ |y - f(x)| \le \varepsilon \\ |y - f(x)| - \varepsilon\,,\ otherwise\,. \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^{n} w_j \max\left(0, \left|y_j - f\left(x_j\right)\right| - \varepsilon\right)}{\sum_{j=1}^{n} w_j},$$

`RegressionSVM` | `fitrsvm` | `loss` | `resubPredict`

Introduced in R2015b

resubLoss

Class: RegressionTree

Regression error by resubstitution

Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'Subtrees',subtreevector)
[L,se] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)
[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)
```

Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitrtree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

`L = resubLoss(tree,'Subtrees',subtreevector)` returns a vector of mean squared errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`tree` — Regression tree

`RegressionTree` model object

A regression tree (`RegressionTree` model object) constructed using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`LossFun` — Loss function
`'mse'` (default) | function handle

Loss function, specified as a function handle or `'mse'` meaning mean squared error.

You can write your own loss function in the syntax described in “Loss Functions” on page 33-5595.

Data Types: `char` | `string` | `function_handle`

`Name,Value` arguments associated with pruning subtrees:

`Subtrees` — Pruning level
0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `resubLoss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubLoss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single` | `double` | `char` | `string`

`TreeSize` — Tree size
`'se'` (default) | `'min'`

Tree size, specified as one of the following:

- `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L` + `se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

`L` — Regression loss
numeric vector of positive values

Regression loss (mean squared error), a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

`se` — Standard error of loss
numeric vector of positive values

Standard error of loss, a vector the length of `Subtrees`.

`NLeaf` — Number of leaves
numeric vector of nonnegative integers

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

`bestlevel` — Optimal pruning level
nonnegative numeric scalar

A scalar whose value depends on `TreeSize`:

- `TreeSize` = `'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum (`L` + `se`, where `L` and `se` relate to the smallest value in `Subtrees`).
- `TreeSize` = `'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

Compute the resubstitution MSE.

```
resubLoss(Mdl)
```

```
ans = 4.8952
```

Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
Y = MPG;
```

Partition the data into training (50%) and validation (50%) sets.

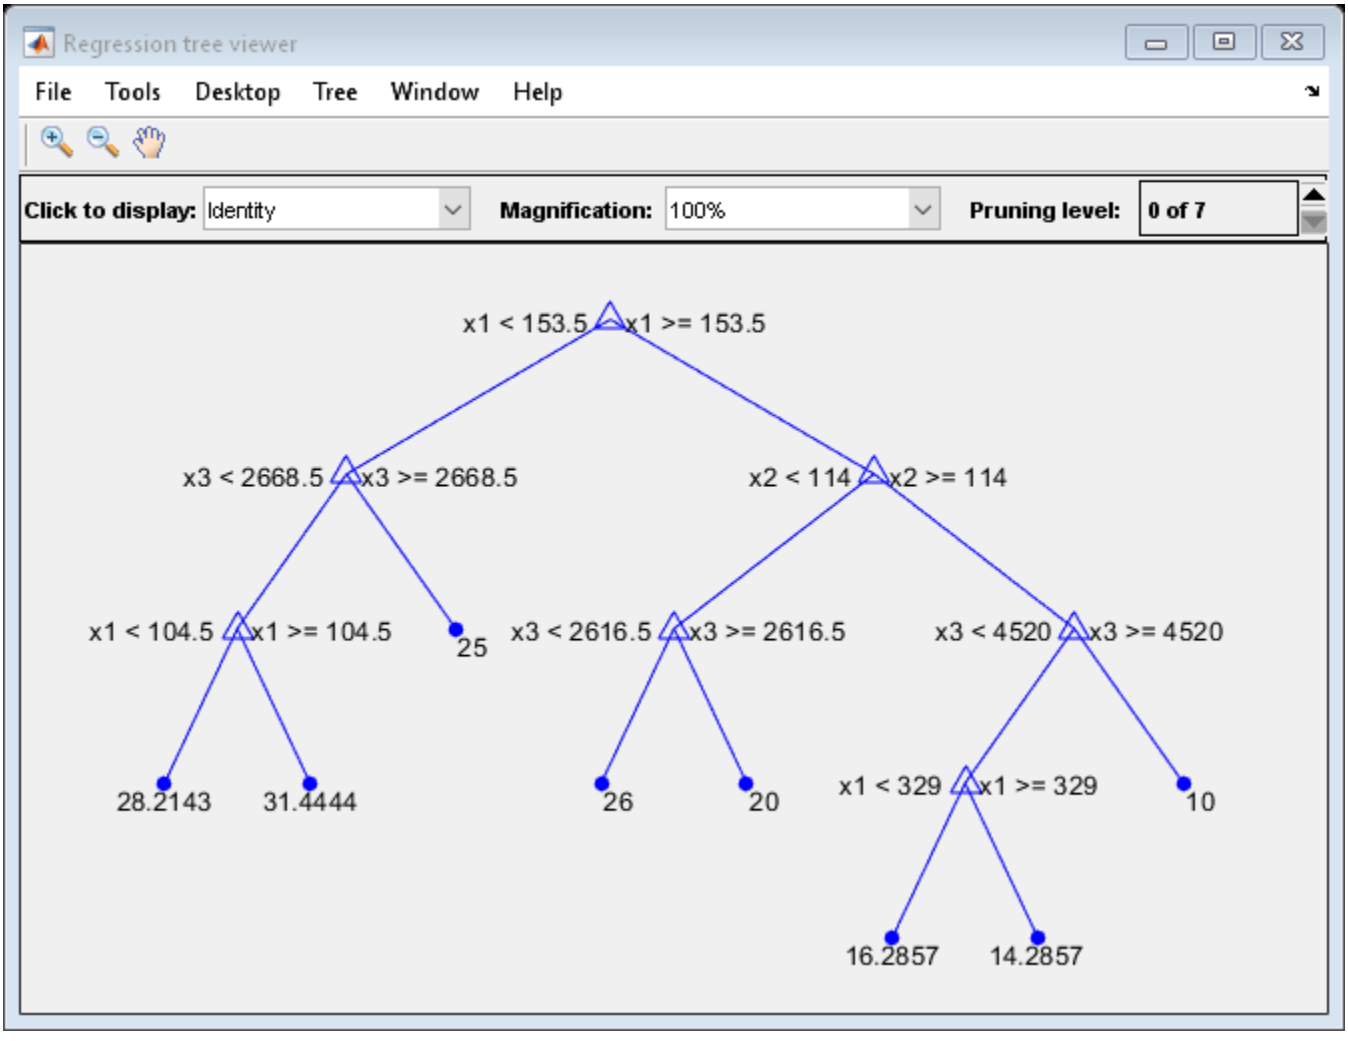
```
n = size(X,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false;                  % Validation set logical indices
```

Grow a regression tree using the training set.

```
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));
```

View the regression tree.

```
view(Mdl,'Mode','graph');
```



The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl,'SubTrees',0:m)
```

```
trnLoss = 7×1

    5.9789
    6.2768
    6.8316
    7.5209
    8.3951
   10.7452
   14.8445
```

- The MSE for the full, unpruned tree is about 6 units.
- The MSE for the tree pruned to level 1 is about 6.3 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

```
valLoss = loss(Mdl,X(idxVal,:),Y(idxVal),'SubTrees',0:m)
```

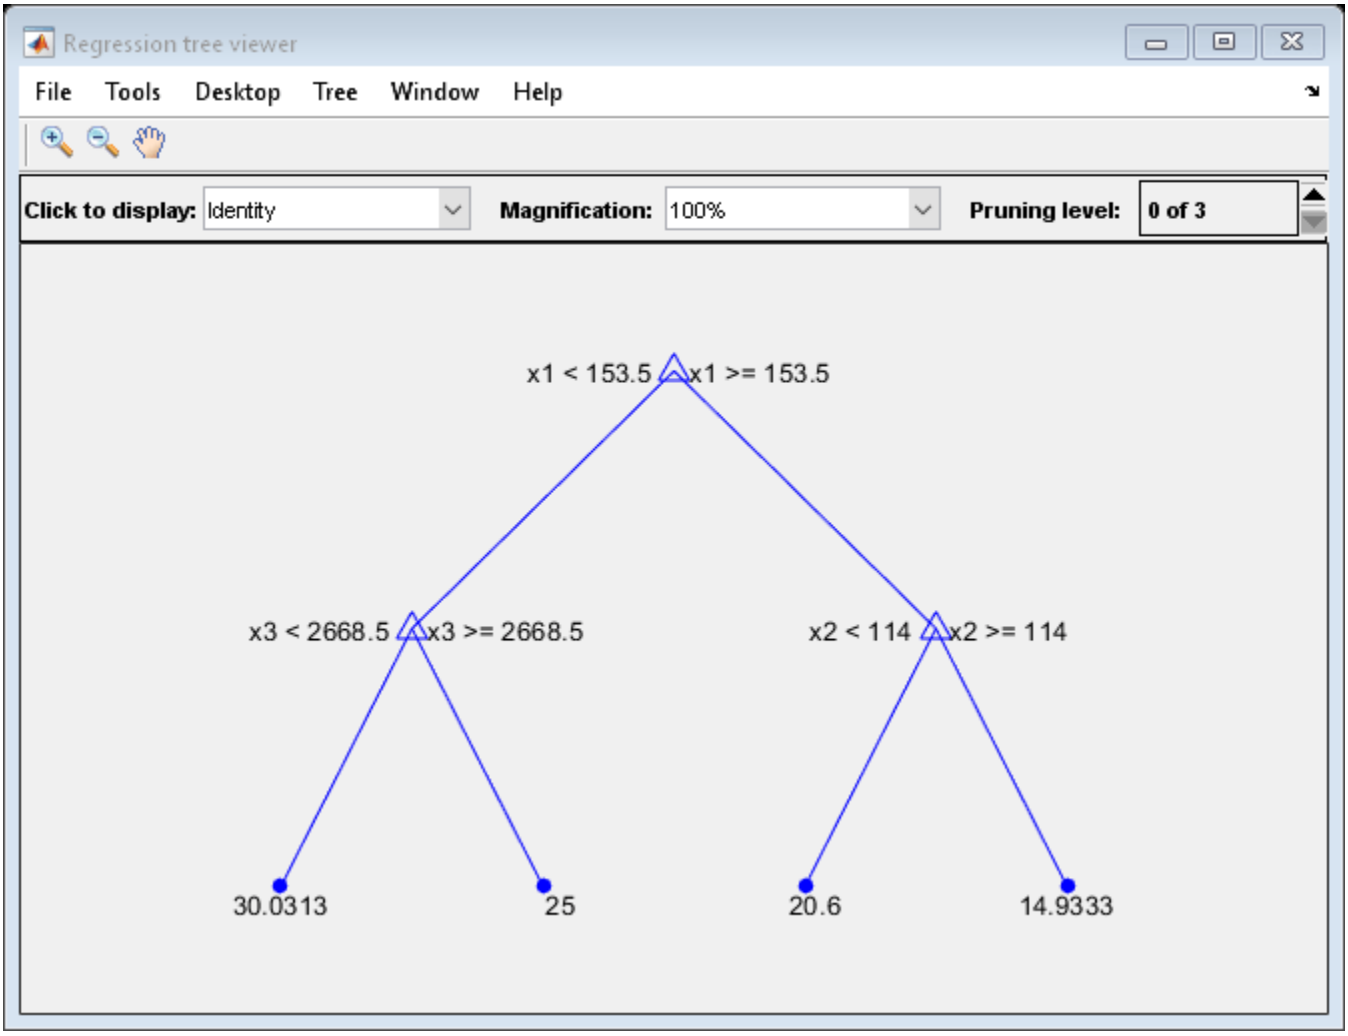
```
valLoss = 7×1

   32.1205
   31.5035
   32.0541
   30.8183
   26.3535
   30.0137
   38.4695
```

- The MSE for the full, unpruned tree (level 0) is about 32.1 units.
- The MSE for the tree pruned to level 4 is about 26.4 units.
- The MSE for the tree pruned to level 5 is about 30.0 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 4.

```
pruneMdl = prune(Mdl,'Level',4);
view(pruneMdl,'Mode','graph')
```



More About

Loss Functions

The built-in loss function is `'mse'`, meaning mean squared error.

To write your own loss function, create a function file of the form

`function loss = lossfun(Y,Yfit,W)`

- `N` is the number of rows of `tree.X`.
- `Y` is an `N`-element vector representing the observed response.
- `Yfit` is an `N`-element vector representing the predicted responses.
- `W` is an `N`-element vector representing the observation weights.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

See Also

`fitrtree` | `loss` | `resubPredict`

resubMargin

Resubstitution classification margin

Syntax

```
m = resubMargin(Mdl)
m = resubMargin(Mdl,'IncludeInteractions',includeInteractions)
```

Description

`m = resubMargin(Mdl)` returns the resubstitution "Classification Margin" on page 33-5602 (`m`) for the trained classification model `Mdl` using the predictor data stored in `Mdl.X` and the corresponding true class labels stored in `Mdl.Y`.

`m` is returned as an *n*-by-1 numeric column vector, where *n* is the number of observations in the predictor data.

`m = resubMargin(Mdl,'IncludeInteractions',includeInteractions)` specifies whether to include interaction terms in computations. This syntax applies only to generalized additive models.

Examples

Estimate Resubstitution Classification Margins of Naive Bayes Classifier

Estimate the resubstitution (in-sample) classification margins of a naive Bayes classifier. An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class.

Load the `fisheriris` data set. Create `X` as a numeric matrix that contains four measurements for 150 irises. Create `Y` as a cell array of character vectors that contains the corresponding iris species.

```
load fisheriris
X = meas;
Y = species;
```

Train a naive Bayes classifier using the predictors `X` and class labels `Y`. A recommended practice is to specify the class names. `fitcnb` assumes that each predictor is conditionally and normally distributed.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'})
```

```
Mdl =
  ClassificationNaiveBayes
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
        DistributionNames: {'normal'  'normal'  'normal'  'normal'}
   DistributionParameters: {3x4 cell}
```

```
  Properties, Methods
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

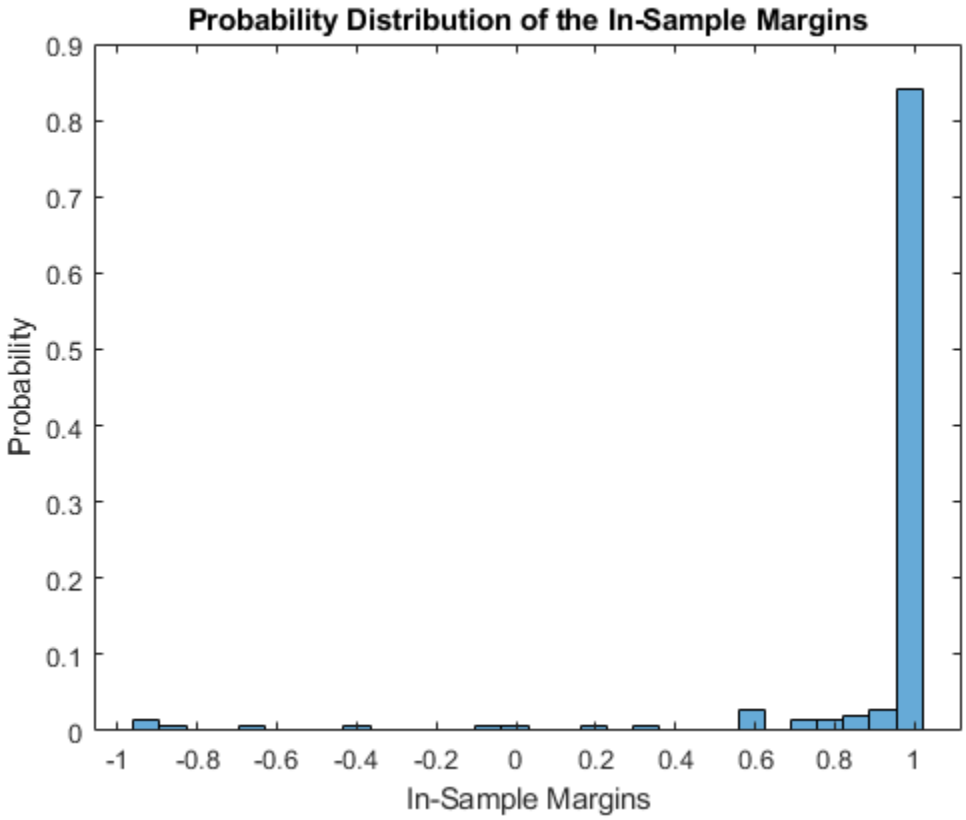
Estimate the resubstitution classification margins.

```
m = resubMargin(Mdl);
median(m)
```

```
ans = 1.0000
```

Display the histogram of the in-sample classification margins.

```
histogram(m,30,'Normalization','probability')
xlabel('In-Sample Margins')
ylabel('Probability')
title('Probability Distribution of the In-Sample Margins')
```



Classifiers that yield relatively large margins are preferred.

Select SVM Classifier Features by Examining In-Sample Margins

Perform feature selection by comparing in-sample margins from multiple models. Based solely on this comparison, the model with the highest margins is the best model.

Load the `ionosphere` data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train a support vector machine (SVM) classifier for each predictor set.

```
FullSVMModel = fitcsvm(fullX,Y);
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the in-sample margins for each classifier.

```
fullMargins = resubMargin(FullSVMModel);
partMargins = resubMargin(PartSVMModel);
n = size(X,1);
p = sum(fullMargins < partMargins)/n
```

```
p = 0.2222
```

Approximately 22% of the margins from the full model are less than those from the model with fewer predictors. This result suggests that the model trained with all the predictors is better.

Compare GAMs by Examining Training Sample Margins and Edge

Compare a generalized additive model (GAM) with linear terms to a GAM with both linear and interaction terms by examining the training sample margins and edge. Based solely on this comparison, the classifier with the highest margins and edge is the best model.

Load the 1994 census data stored in `census1994.mat`. The data set consists of demographic data from the US Census Bureau to predict whether an individual makes over $50,000 per year. The classification task is to fit a model that predicts the salary category of people given their age, working class, education level, marital status, race, and so on.

```
load census1994
```

`census1994` contains the training data set `adultdata` and the test data set `adulttest`. To reduce the running time for this example, subsample 500 training observations from `adultdata` by using the `datasample` function.

```
rng('default') % For reproducibility
NumSamples = 5e2;
adultdata = datasample(adultdata,NumSamples,'Replace',false);
```

Train a GAM that contains both linear and interaction terms for predictors. Specify to include all available interaction terms whose *p*-values are not greater than 0.05.

```
Mdl = fitcgam(adultdata,'salary','Interactions','all','MaxPValue',0.05)
```

```
Mdl =
  ClassificationGAM
             PredictorNames: {1x14 cell}
               ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
                ClassNames: [<=50K    >50K]
             ScoreTransform: 'logit'
                  Intercept: -32.0842
               Interactions: [82x2 double]
           NumObservations: 500

  Properties, Methods
```

`Mdl` is a `ClassificationGAM` model object. `Mdl` includes 82 interaction terms.

Estimate the training sample margins and edge for `Mdl`.

```
M = resubMargin(Mdl);
E = resubEdge(Mdl)
```

```
E = 1.0000
```

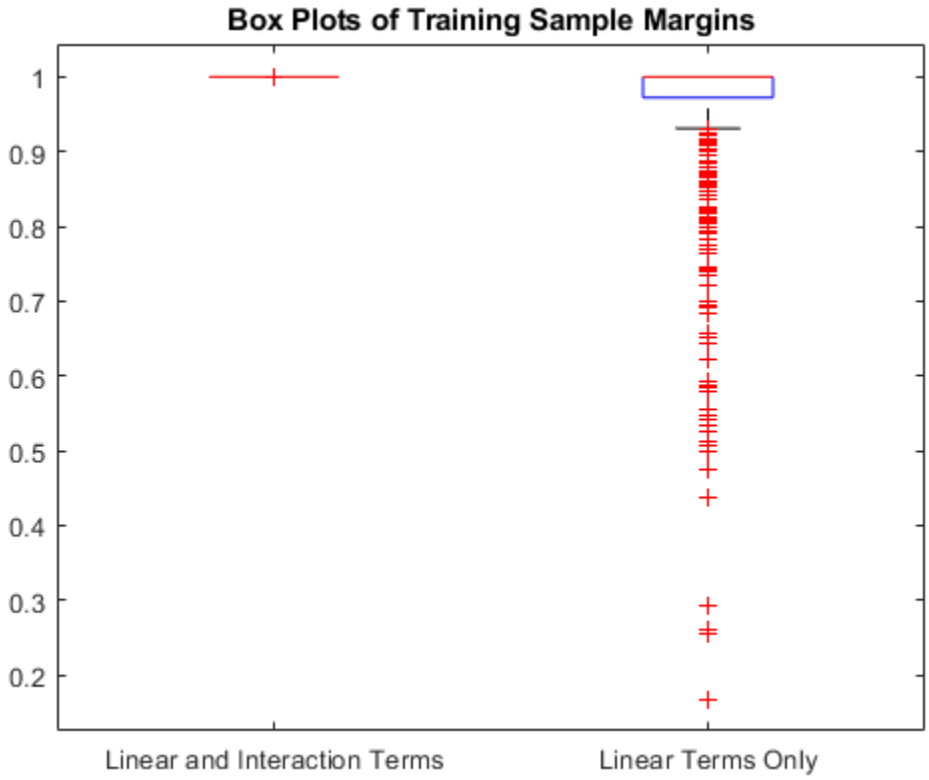
Estimate the training sample margins and edge for `Mdl` without including interaction terms.

```
M_nointeractions = resubMargin(Mdl,'IncludeInteractions',false);
E_nointeractions = resubEdge(Mdl,'IncludeInteractions',false)
```

```
E_nointeractions = 0.9516
```

Display the distributions of the margins using box plots.

```
boxplot([M M_nointeractions],'Labels',{'Linear and Interaction Terms','Linear Terms Only'})
title('Box Plots of Training Sample Margins')
```



When you include the interaction terms in the computation, all the resubstitution margin values for `Mdl` are 1, and the resubstitution edge value (average of the margins) is 1. The margins and edge decrease when you do not include the interaction terms in `Mdl`.

Input Arguments

`Mdl` — Classification machine learning model

full classification model object

Classification machine learning model, specified as a full classification model object, as given in the following table of supported models.

Model	Classification Model Object
Generalized additive model	`ClassificationGAM`
k-nearest neighbor model	`ClassificationKNN`
Naive Bayes model	`ClassificationNaiveBayes`
Neural network model	`ClassificationNeuralNetwork`
Support vector machine for one-class and binary classification	`ClassificationSVM`

`includeInteractions` — Flag to include interaction terms

`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `Mdl` is `ClassificationGAM`.

The default value is `true` if `Mdl` contains interaction terms. The value must be `false` if the model does not contain interaction terms.

Data Types: `logical`

More About

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class. The classification margin for multiclass classification is the difference between the classification score for the true class and the maximal classification score for the false classes.

If the margins are on the same scale (that is, the score values are based on the same score transformation), then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Algorithms

`resubMargin` computes the classification margin according to the corresponding `margin` function of the object (`Mdl`). For a model-specific description, see the `margin` function reference pages in the following table.

Model	Classification Model Object (`Mdl`)	`margin` Object Function
Generalized additive model	`ClassificationGAM`	`margin`
k-nearest neighbor model	`ClassificationKNN`	`margin`
Naive Bayes model	`ClassificationNaiveBayes`	`margin`
Neural network model	`ClassificationNeuralNetwork`	`margin`
Support vector machine for one-class and binary classification	`ClassificationSVM`	`margin`

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports `ClassificationKNN` and `ClassificationSVM` objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2012a

resubMargin

Class: `ClassificationDiscriminant`

Classification margins by resubstitution

Syntax

```
M = resubMargin(obj)
```

Description

`M = resubMargin(obj)` returns resubstitution classification margins for `obj`.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

M

Numeric column-vector of length `size(obj.X,1)` containing the classification margins.

Examples

Estimate Resubstitution Margins for Discriminant Analysis Classifiers

Find the margins for a discriminant analysis classifier for Fisher's iris data by resubstitution. Examine several entries.

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis classifier.

```
Mdl = fitcdiscr(meas,species);
```

Compute the resubstitution margins, and display several of them.

```
m = resubMargin(Mdl);
m(1:25:end)
```

```
ans = 6×1

    1.0000
    1.0000
```

```
    0.9998
    0.9998
    1.0000
    0.9946
```

More About

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

`ClassificationDiscriminant` | `fitcdiscr` | `margin`

Topics

“Discriminant Analysis Classification” on page 20-2

resubMargin

Resubstitution classification margins for multiclass error-correcting output codes (ECOC) model

Syntax

```
m = resubMargin(Mdl)
m = resubMargin(Mdl,Name,Value)
```

Description

`m = resubMargin(Mdl)` returns the resubstitution classification margins on page 33-5611 (`m`) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`.

`m` is returned as a numeric column vector with the same length as `Mdl.Y`. The software estimates each entry of `m` using the trained ECOC model `Mdl`, the corresponding row of `Mdl.X`, and the true class label `Mdl.Y`.

`m = resubMargin(Mdl,Name,Value)` returns the classification margins with additional options specified by one or more name-value pair arguments. For example, you can specify a decoding scheme, binary learner loss function, and verbosity level.

Examples

Resubstitution Classification Margins of ECOC Model

Calculate the resubstitution classification margins for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

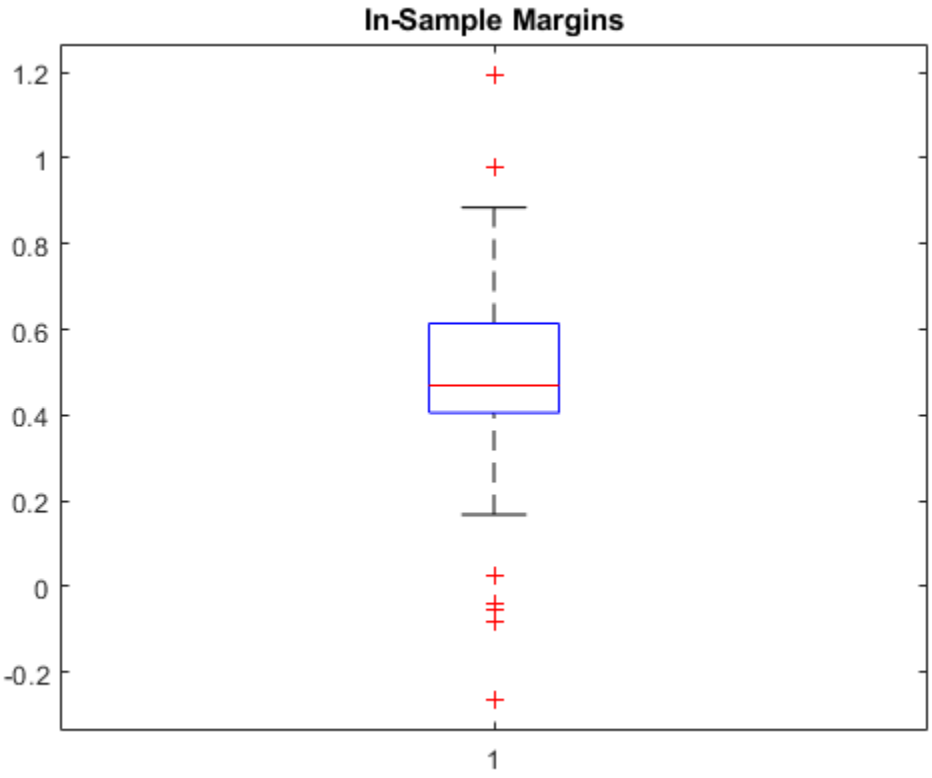
```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Calculate the classification margins for the observations used to train `Mdl`. Display the distribution of the margins using a boxplot.

```
m = resubMargin(Mdl);

boxplot(m)
title('In-Sample Margins')
```



The classification margin of an observation is the positive-class negated loss minus the maximum negative-class negated loss. Choose classifiers that yield relatively large margins.

Select ECOC Model Features by Examining Training-Sample Margins

Perform feature selection by comparing training-sample margins from multiple models. Based solely on this comparison, the model with the greatest margins is the best model.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements only.

```
load fisheriris
X = meas;
fullX = X;
```

```
partX = X(:,1:2);
Y = species;
```

Train an ECOC model using SVM binary learners for each predictor set. Standardize the predictors using an SVM template, specify the class order, and compute posterior probabilities.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

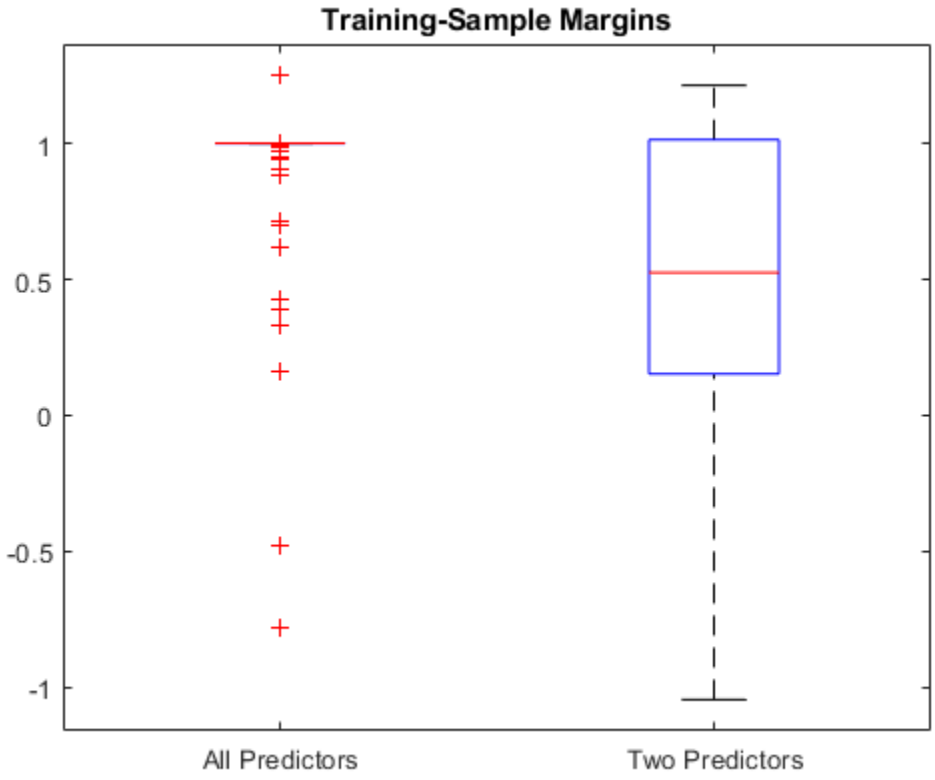
```
classOrder = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
FullMdl = fitcecoc(fullX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
PartMdl = fitcecoc(partX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
```

Compute the resubstitution margins for each classifier. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = resubMargin(FullMdl);
partMargins = resubMargin(PartMdl);

boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'})
title('Training-Sample Margins')
```



The margin distribution of `FullMdl` is situated higher and has less variability than the margin distribution of `PartMdl`. This result suggests that the model trained with all the predictors fits the training data better.

Input Arguments

`Mdl` — Full, trained multiclass ECOC model

`ClassificationECOC` model

Full, trained multiclass ECOC model, specified as a `ClassificationECOC` model trained with `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `resubMargin(Mdl,'Verbose',1)` specifies to display diagnostic messages in the Command Window.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

  `customFunction` has this form:

  ```
  bLoss = customFunction(M,s)
  ```

where:

- `M` is the *K*-by-*L* coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by-*L* row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- *K* is the number of classes.
- *L* is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-5611.

Example: `'Decoding','lossbased'`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.

- Specify `'Options',statset('UseParallel',true)`.

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

More About

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|} .$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Tips

- To compare the margins or edges of several ECOC classifiers, use template objects to specify a common score transform function among the classifiers during training.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

resubMargin

Classification margins by resubstitution

Syntax

```
margin = resubMargin(ens)
margin = resubMargin(ens,Name,Value)
```

Description

`margin = resubMargin(ens)` returns the classification margin obtained by `ens` on its training data.

`margin = resubMargin(ens,Name,Value)` calculates margins with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `resubMargin` uses only these learners for calculating margin.

Default: `1:NumTrained`

Output Arguments

`margin`

A numeric column-vector of length `size(ens.X,1)` containing the classification margins.

Examples

Compute Resubstitution Margins for Classification Ensemble

Find the resubstitution margins for an ensemble that classifies the Fisher iris data.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the resubstitution margins.

```
margin = resubMargin(ens);
[min(margin) mean(margin) max(margin)]
```

```
ans = 1×3

   -0.5674    3.2486    4.6245
```

More About

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from –∞ to ∞.
- `Bag` scores range from `0` to `1`.

`resubEdge` | `resubLoss` | `resubMargin` | `resubPredict`

resubMargin

Class: `ClassificationTree`

Classification margins by resubstitution

Syntax

```
M = resubMargin(tree)
```

Description

`M = resubMargin(tree)` returns resubstitution classification margins for `tree`.

Input Arguments

`tree`

A classification tree created by `fitctree`.

Output Arguments

`M`

A numeric column-vector of length `size(tree.X,1)` containing the classification margins.

Examples

Find the margins for a classification tree for the Fisher iris data by resubstitution. Examine several entries:

```
load fisheriris
tree = fitctree(meas,species);
M = resubMargin(tree);
M(1:25:end)
```

```
ans =
    1.0000
    1.0000
    1.0000
    1.0000
    0.9565
    0.9565
```

More About

Margin

Classification margin is the difference between classification score for the true class and maximal classification score for the false classes. A high value of margin indicates a more reliable prediction than a low value.

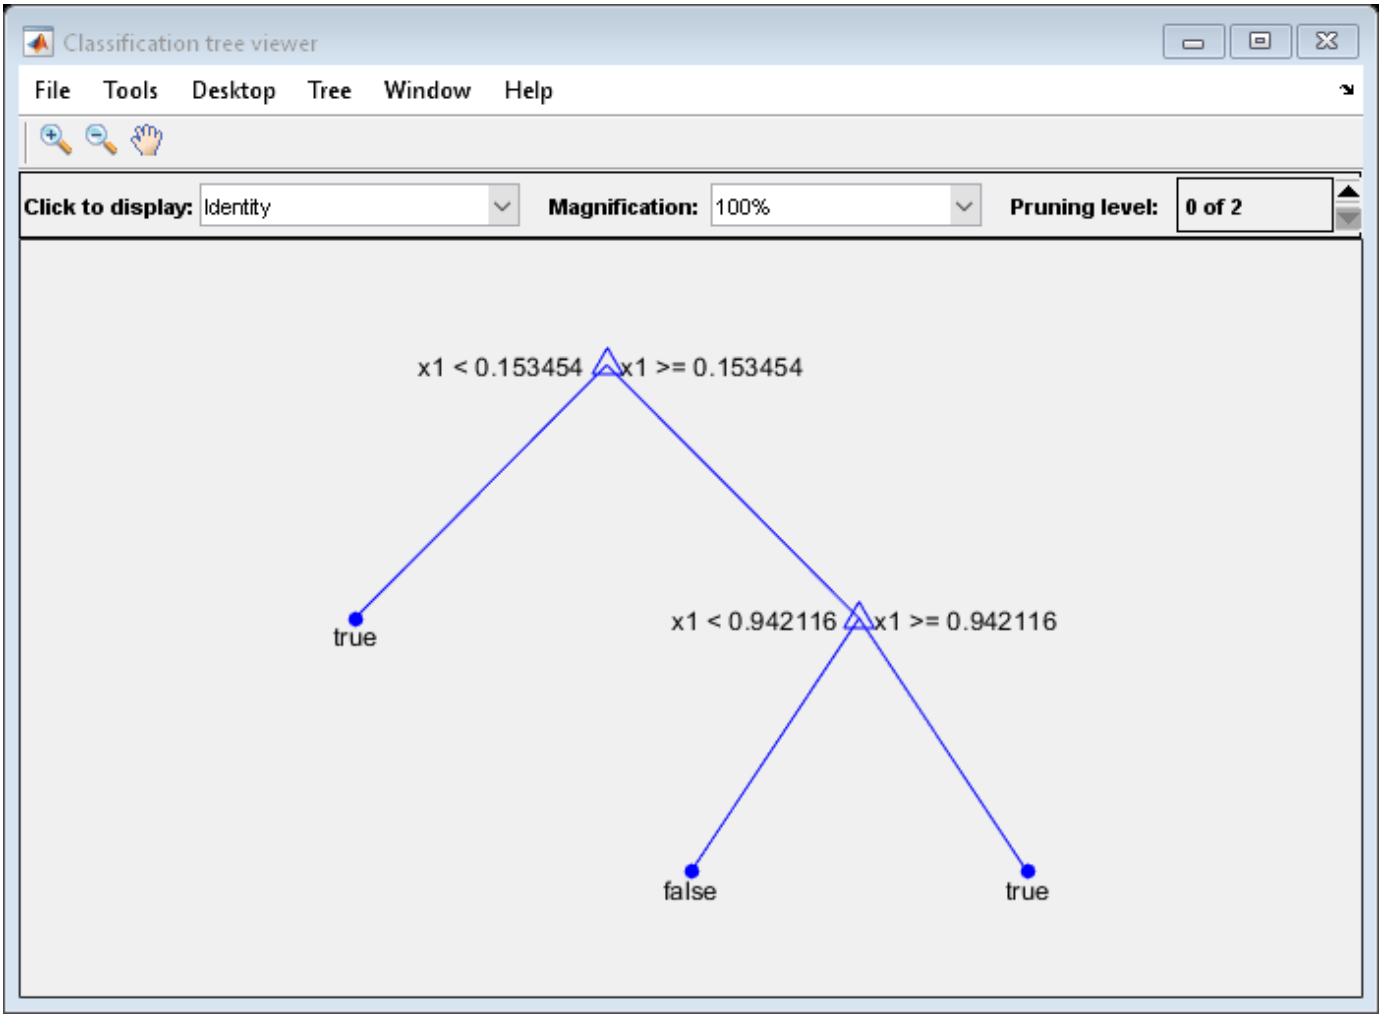
Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

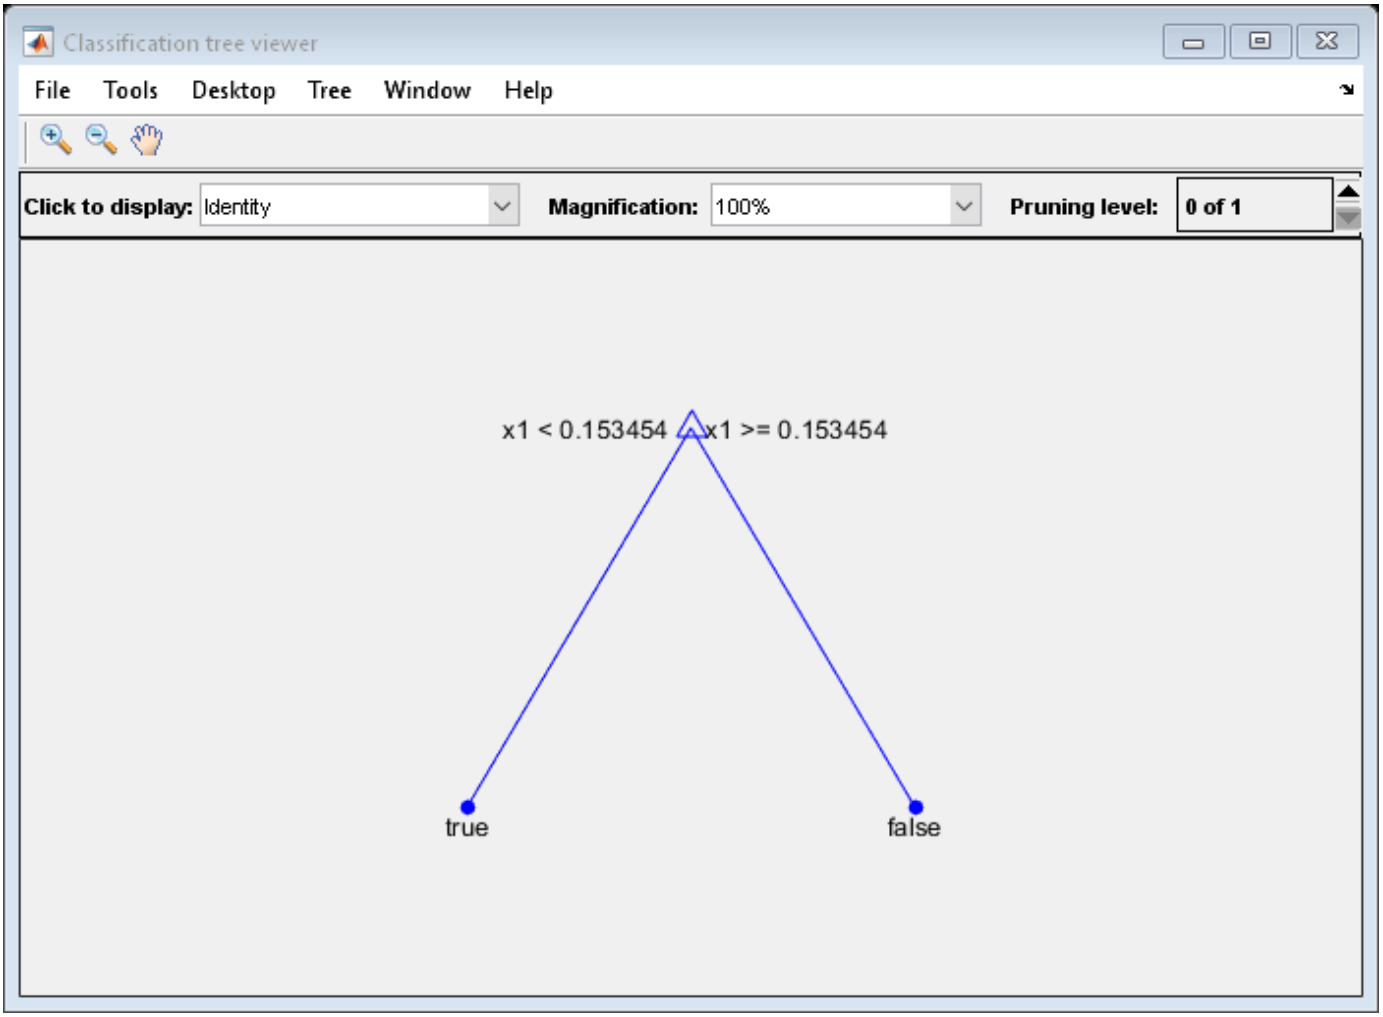
Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```



Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10×3

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
```

```
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.91` and `0.09`. The difference (score `0.09` instead of the expected `.06`) is due to a statistical fluctuation: there are `8` observations in `X` in the range `(.95,1)` instead of the expected `5` observations.

`fitctree` | `margin` | `resubEdge` | `resubLoss` | `resubPredict`

resubPredict

Class: `ClassificationDiscriminant`

Predict resubstitution labels of discriminant analysis classification model

Syntax

```
label = resubPredict(obj)
[label,posterior] = resubPredict(obj)
[label,posterior,cost] = resubPredict(obj)
```

Description

`label = resubPredict(obj)` returns the labels `obj` predicts for the data `obj.X`. `label` is the predictions of `obj` on the data that `fitcdiscr` used to create `obj`.

`[label,posterior] = resubPredict(obj)` returns the posterior class probabilities for the predictions.

`[label,posterior,cost] = resubPredict(obj)` returns the predicted misclassification costs per class for the resubstituted data.

Input Arguments

`obj`

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

`label`

Response `obj` predicts for the training data. `label` is the same data type as the training response data `obj.Y`. The predicted class labels are those with minimal expected misclassification cost; see “Prediction Using Discriminant Analysis Models” on page 20-6.

`posterior`

`N`-by-`K` matrix of posterior probabilities for classes `obj` predicts, where `N` is the number of observations and `K` is the number of classes.

`cost`

`N`-by-`K` matrix of predicted misclassification costs. Each cost is the average misclassification cost with respect to the posterior probability.

Examples

Find the total number of misclassifications of the Fisher iris data for a discriminant analysis classifier:

```
load fisheriris
obj = fitcdiscr(meas,species);
Ypredict = resubPredict(obj); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?

ans =
     3
```

More About

Posterior Probability

`posterior(i,k)` is the posterior probability of class `k` for observation `i`. For the mathematical definition, see “Posterior Probability” on page 20-6.

`ClassificationDiscriminant` | `fitcdiscr` | `predict`

Topics

“Discriminant Analysis Classification” on page 20-2

resubPredict

Classify observations in multiclass error-correcting output codes (ECOC) model

Syntax

```
label = resubPredict(Mdl)
label = resubPredict(Mdl,Name,Value)
[label,NegLoss,PBScore] = resubPredict( ___ )
[label,NegLoss,PBScore,Posterior] = resubPredict( ___ )
```

Description

`label = resubPredict(Mdl)` returns a vector of predicted class labels (`label`) for the trained multiclass error-correcting output codes (ECOC) model `Mdl` using the predictor data stored in `Mdl.X`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = resubPredict(Mdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = resubPredict( ___ )` uses any of the input argument combinations in the previous syntaxes and additionally returns the negated average binary loss on page 33-5632 per class (`NegLoss`) for observations, and the positive-class scores (`PBScore`) for the observations classified by each binary learner.

`[label,NegLoss,PBScore,Posterior] = resubPredict( ___ )` additionally returns posterior class probability estimates for observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',true` when training the ECOC model using `fitcecoc`. Otherwise, `resubPredict` throws an error.

Examples

Predict Labels of Training Data Using ECOC Model

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Predict the labels of the training data. Print a random subset of true and predicted labels.

```
labels = resubPredict(Mdl);

rng(1); % For reproducibility
n = numel(Y); % Sample size
idx = randsample(n,10);
table(Y(idx),labels(idx),'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans=10×2 table
    TrueLabels    PredictedLabels
    __________    _______________

    setosa          setosa
    versicolor      versicolor
    virginica       virginica
    setosa          setosa
    versicolor      versicolor
    setosa          setosa
    versicolor      versicolor
    versicolor      versicolor
    setosa          setosa
    setosa          setosa
```

`Mdl` correctly labels the observations with indices `idx`.

Predict Resubstitution Labels of ECOC Model Using Custom Binary Loss Function

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that does the following:

- Map the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation.

- Use linear loss.
- Aggregate the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function. In this case, create a function handle (`customBL`) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict labels for the training data and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 observations.

```
[label,NegLoss] = resubPredict(Mdl,'BinaryLoss',customBL);

rng(1); % For reproducibility
n = numel(Y); % Sample size
idx = randsample(n,10);
classOrder
```

```
classOrder = 3x1 categorical
     setosa
     versicolor
     virginica
```

```
table(Y(idx),label(idx),NegLoss(idx,:),'VariableNames',...
    {'TrueLabel','PredictedLabel','NegLoss'})
```

```
ans=10×3 table
    TrueLabel     PredictedLabel                NegLoss
    __________    ______________    ___________________________________

    setosa          versicolor       0.1237       1.957     -3.5807
    versicolor      versicolor       -1.017     0.62917     -1.1122
    virginica       virginica       -1.9082    -0.21802     0.62618
    setosa          versicolor      0.43842      2.2443     -4.1827
    versicolor      versicolor      -1.0733     0.39627    -0.82294
    setosa          versicolor      0.26668      2.2004      -3.967
    versicolor      versicolor      -1.1234     0.69883     -1.0754
    versicolor      versicolor      -1.2709     0.51788    -0.74697
    setosa          versicolor      0.35181       2.068     -3.9198
    setosa          versicolor      0.23355      2.1886     -3.9221
```

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.

Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the `'FitPosterior'` name-value pair argument. Specify the class order using the `'ClassNames'` name-value pair argument. Display diagnostic messages during training by using the `'Verbose'` name-value pair argument.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',true,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);

Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 2
Positive class indices: 1

Fitting posterior probabilities for learner 1 (SVM).

Negative class indices: 3
Positive class indices: 1

Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations.
Negative class indices: 3
Positive class indices: 2

Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the training-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities by using the `'Verbose'` name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);

Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...
```

```
Mdl.BinaryLoss

ans =
'quadratic'
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
```

```
ans = 3x1 cell
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10×3 table

```

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

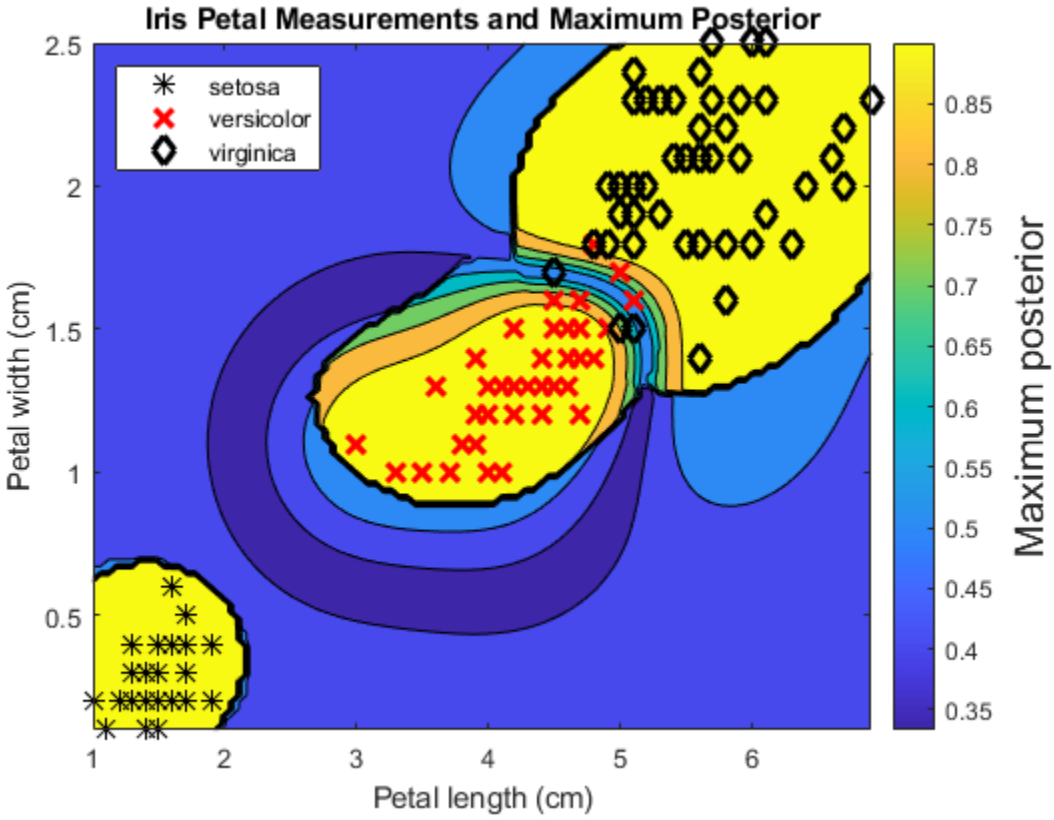
[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
contourf(x1Grid,x2Grid,...
        reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;

hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;
```

```
title('Iris Petal Measurements and Maximum Posterior')
xlabel('Petal length (cm)')
ylabel('Petal width (cm)')
axis tight
legend(gh,'Location','NorthWest')
hold off
```



Estimate Posterior Probabilities Using Parallel Computing

Train a multiclass ECOC model and estimate the posterior probabilities using parallel computing.

Load the `arrhythmia` data set. Examine the response data `Y`, and determine the number of classes.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
```

```
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
     15        5      1.11%
     16       22      4.87%
```

```
K = numel(unique(Y));
```

Several classes are not represented in the data, and many other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of its properties are empty (`[]`). The software uses default values for all empty properties during training.

Because the response variable contains many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparserandom');
```

Train an ECOC model using parallel computing. Specify to fit posterior probabilities.

```
pool = parpool;                     % Invokes workers
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',true);
```

`Mdl` is a `ClassificationECOC` model. You can access its properties using dot notation.

The pool invokes six workers, although the number of workers might vary among systems.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given a random subset of the training data.

```
[~,~,~,posterior] = resubPredict(Mdl);

n = numel(Y);
idx = randsample(n,10,1);
table(idx,Y(idx),posterior(idx,1),...
    'VariableNames',{'ObservationIndex','TrueLabel','PosteriorNoArrythmia'})
```

```
ans=10×3 table
    ObservationIndex    TrueLabel    PosteriorNoArrythmia

    406             1               0.94861
```

Input Arguments

`Mdl` — Full, trained multiclass ECOC model

`ClassificationECOC` model

Full, trained multiclass ECOC model, specified as a `ClassificationECOC` model trained with `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `resubPredict(Mdl,'BinaryLoss','linear','Decoding','lossbased')` specifies a linear binary learner loss function and a loss-based decoding scheme for aggregating the binary losses.

`BinaryLoss` — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

  The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- `M` is the *K*-by-*L* coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by-*L* row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- *K* is the number of classes.
- *L* is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 33-4811.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	`'hinge'`
All binary learners are ensembles trained by `AdaboostM1` or `GentleBoost`.	`'exponential'`
All binary learners are ensembles trained by `LogitBoost`.	`'binodeviance'`
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting `'FitPosterior',true` in `fitcecoc`.	`'quadratic'`

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

`Decoding` — Decoding scheme
`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 33-5632.

Example: `'Decoding','lossbased'`

`NumKLInitializations` — Number of random initial values
`0` (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of `'NumKLInitializations'` and a nonnegative integer scalar.

If you do not request the fourth output argument (`Posterior`) and set `'PosteriorMethod','kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 33-5633.

Example: `'NumKLInitializations',5`

Data Types: `single` | `double`

`Options` — Estimation options
`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

`PosteriorMethod` — Posterior probability estimation method
`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 33-5633.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 33-5635.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`label` — Predicted class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type as `Mdl.ClassNames` and has the same number of rows as `Mdl.X`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`NegLoss` — Negated average binary losses
numeric matrix

Negated average binary losses on page 33-5632, returned as a numeric matrix. `NegLoss` is an *n*-by-*K* matrix, where *n* is the number of observations (`size(Mdl.X,1)`) and *K* is the number of unique classes (`size(Mdl.ClassNames,1)`).

`PBScore` — Positive-class scores
numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an *n*-by-*L* matrix, where *n* is the number of observations (`size(Mdl.X,1)`) and *L* is the number of binary learners (`size(Mdl.CodingMatrix,2)`).

`Posterior` — Posterior class probabilities
numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an *n*-by-*K* matrix, where *n* is the number of observations (`size(Mdl.X,1)`) and *K* is the number of unique classes (`size(Mdl.ClassNames,1)`).

To request `Posterior`, you must set `'FitPosterior',true` when training the ECOC model using `fitcecoc`. Otherwise, the software throws an error.

More About

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- $\widehat{k}$ is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-279, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\arg\min} \sum_{j=1}^{L} \left|m_{kj}\right| g(m_{kj}, s_j) .$$

In loss-weighted decoding [Escalera et al.] on page 18-279, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\widehat{k} = \underset{k}{\operatorname{argmin}} \frac{\sum_{j=1}^{L} |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^{L} |m_{kj}|}.$$

Allwein et al. on page 18-279 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set {–1,1,0}), s_j is the score for observation j, and $g(y_j,s_j)$.

Value	Description	Score Domain	$g(y_j,s_j)$
`'binodeviance'`	Binomial deviance	(–∞,∞)	$\log[1 + \exp(-2y_js_j)]/[2\log(2)]$
`'exponential'`	Exponential	(–∞,∞)	$\exp(-y_js_j)/2$
`'hamming'`	Hamming	[0,1] or (–∞,∞)	$[1 - \text{sign}(y_js_j)]/2$
`'hinge'`	Hinge	(–∞,∞)	$\max(0,1 - y_js_j)/2$
`'linear'`	Linear	(–∞,∞)	$(1 - y_js_j)/2$
`'logit'`	Logistic	(–∞,∞)	$\log[1 + \exp(-y_js_j)]/[2\log(2)]$
`'quadratic'`	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-279.

Do not confuse the binary loss with the overall classification loss (specified by the `'LossFun'` name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k,j) of the coding design matrix M.
- I is the indicator function.
- $\widehat{p}_k$ is the class posterior probability estimate for class k of an observation, $k = 1,...,K$.
- r_j is the positive-class posterior probability for binary learner j. That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r,\widehat{r}) = \sum_{j=1}^{L} w_j\left[r_j\log\frac{r_j}{\widehat{r}_j} + (1-r_j)\log\frac{1-r_j}{1-\widehat{r}_j}\right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j.

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i.

The software minimizes the divergence iteratively. The first step is to choose initial values $\widehat{p}_k^{(0)};\ k = 1,\ldots,K$ for the class posterior probabilities.

- If you do not specify `'NumKLIterations'`, then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ.
  - $\widehat{p}_k^{(0)} = 1/K;\ k = 1,\ldots,K$.
  - $\widehat{p}_k^{(0)};\ k = 1,\ldots,K$ is the solution of the system

    $$M_{01}\widehat{p}^{(0)} = r,$$

    where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-279. The software uses `lsqnonneg` to solve the system.
- If you specify `'NumKLIterations',c`, where `c` is a natural number, then the software does the following to choose the set $\widehat{p}_k^{(0)};\ k = 1,\ldots,K$, and selects the set that minimizes Δ.
  - The software tries both sets of deterministic initial values as described previously.
  - The software randomly generates `c` vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t, the software completes these steps:

1 Compute

$$\widehat{r}_j^{(t)} = \frac{\sum_{k=1}^{K}\widehat{p}_k^{(t)}I(m_{kj} = +1)}{\sum_{k=1}^{K}\widehat{p}_k^{(t)}I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

2 Estimate the next class posterior probability using

$$\widehat{p}_k^{(t+1)} = \widehat{p}_k^{(t)}\frac{\sum_{j=1}^{L} w_j\left[r_j I\left(m_{kj} = +1\right) + \left(1-r_j\right)I\left(m_{kj} = -1\right)\right]}{\sum_{j=1}^{L} w_j\left[\widehat{r}_j^{(t)}I\left(m_{kj} = +1\right) + \left(1-\widehat{r}_j^{(t)}\right)I\left(m_{kj} = -1\right)\right]}.$$

3 Normalize $\widehat{p}_k^{(t+1)};\ k = 1,\ldots,K$ so that they sum to 1.

4 Check for convergence.

For more details, see [Hastie et al.] on page 18-280 and [Zadrozny] on page 18-281.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

1. Estimate the positive-class posterior probabilities, r_j, for binary learners $j = 1,...,L$.
2. Using the relationship between r_j and $\widehat{p}_k$ [Wu et al.] on page 18-281, minimize

$$\sum_{j=1}^{L}\left[-r_j\sum_{k=1}^{K}\widehat{p}_k I\left(m_{kj}=-1\right)+\left(1-r_j\right)\sum_{k=1}^{K}\widehat{p}_k I\left(m_{kj}=+1\right)\right]^2$$

with respect to $\widehat{p}_k$ and the restrictions

$$0\le\widehat{p}_k\le 1$$

$$\sum_k\widehat{p}_k=1.$$

The software performs minimization using `quadprog`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

resubPredict

Classify observations in ensemble of classification models

Syntax

```
label = resubPredict(ens)
[label,score] = resubPredict(ens)
[label,score] = resubPredict(ens,Name,Value)
```

Description

`label = resubPredict(ens)` returns the labels `ens` predicts for the data `ens.X`. `label` is the predictions of `ens` on the data that `fitcensemble` used to create `ens`.

`[label,score] = resubPredict(ens)` also returns scores for all classes.

`[label,score] = resubPredict(ens,Name,Value)` finds resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`label`

The response `ens` predicts for the training data. `label` is the same data type as the training response data `ens.Y`, and has the same number of entries as the number of rows in `ens.X`.

`score`

An `N`-by-`K` matrix, where `N` is the number of rows in `ens.X`, and `K` is the number of classes in `ens`. High score value indicates that an observation likely comes from this class.

Examples

Find Number of Ensemble Misclassifications

Find the total number of misclassifications of the `fisheriris` data for a classification ensemble.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the total number of misclassifications.

```
Ypredict = resubPredict(ens); % The predictions
Ysame = strcmp(Ypredict,species); % True when Ypredict and species are equal
sum(~Ysame) % Number of different predictions
```

```
ans = 5
```

More About

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from –∞ to ∞.
- `Bag` scores range from `0` to `1`.

See Also

`resubEdge` | `resubLoss` | `resubMargin` | `resubPredict`

resubPredict

Classify training data using trained classifier

Syntax

```
label = resubPredict(Mdl)
label = resubPredict(Mdl,'IncludeInteractions',includeInteractions)
[label,Score] = resubPredict( ___ )
[label,Score,Cost] = resubPredict(Mdl)
```

Description

`label = resubPredict(Mdl)` returns a vector of predicted class labels (`label`) for the trained classification model `Mdl` using the predictor data stored in `Mdl.X`.

`label = resubPredict(Mdl,'IncludeInteractions',includeInteractions)` specifies whether to include interaction terms in computations. This syntax applies only to generalized additive models.

`[label,Score] = resubPredict( ___ )` also returns classification scores using any of the input argument combinations in the previous syntaxes.

`[label,Score,Cost] = resubPredict(Mdl)` also returns the expected misclassification cost. This syntax applies only to *k*-nearest neighbor and naive Bayes models.

Examples

Label Training Sample Observations of Naive Bayes Classifier

Load the `fisheriris` data set. Create `X` as a numeric matrix that contains four measurements for 150 irises. Create `Y` as a cell array of character vectors that contains the corresponding iris species.

```
load fisheriris
X = meas;
Y = species;
rng('default') % For reproducibility
```

Train a naive Bayes classifier using the predictors `X` and class labels `Y`. A recommended practice is to specify the class names. `fitcnb` assumes that each predictor is conditionally and normally distributed.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'})
```

```
Mdl =
  ClassificationNaiveBayes
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
```

```
         DistributionNames: {'normal'  'normal'  'normal'  'normal'}
    DistributionParameters: {3x4 cell}

  Properties, Methods
```

`Mdl` is a trained `ClassificationNaiveBayes` classifier.

Predict the training sample labels.

```
label = resubPredict(Mdl);
```

Display the results for a random set of 10 observations.

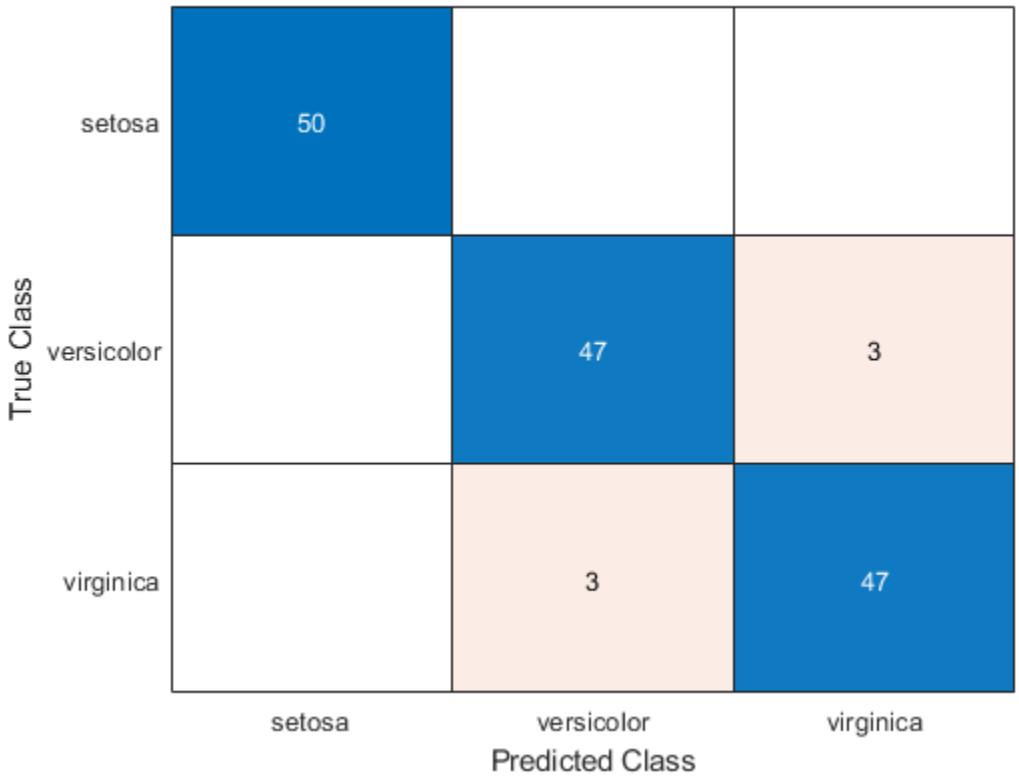
```
idx = randsample(size(X,1),10);
table(Y(idx),label(idx),'VariableNames', ...
    {'True Label','Predicted Label'})
```

```
ans=10×2 table
      True Label      Predicted Label
    _____________    _______________

    {'virginica' }    {'virginica' }
    {'setosa'    }    {'setosa'    }
    {'virginica' }    {'virginica' }
    {'versicolor'}    {'versicolor'}
    {'virginica' }    {'virginica' }
    {'versicolor'}    {'versicolor'}
    {'virginica' }    {'virginica' }
    {'setosa'    }    {'setosa'    }
    {'virginica' }    {'virginica' }
    {'setosa'    }    {'setosa'    }
```

Create a confusion chart from the true labels `Y` and the predicted labels `label`.

```
cm = confusionchart(Y,label);
```



Estimate In-Sample Posterior Probabilities of SVM Classifier

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a support vector machine (SVM) classifier. Standardize the data and specify that `'g'` is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)
```

```
ScoreSVMModel =
  ClassificationSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}
          ScoreTransform: '@(S)sigmoid(S,-9.481840e-01,-1.218721e-01)'
```

```
          NumObservations: 351
                    Alpha: [90x1 double]
                     Bias: -0.1343
        KernelParameters: [1x1 struct]
                      Mu: [1x34 double]
                    Sigma: [1x34 double]
           BoxConstraints: [351x1 double]
          ConvergenceInfo: [1x1 struct]
          IsSupportVector: [351x1 logical]
                   Solver: 'SMO'

  Properties, Methods
```

Because the classes are inseparable, the score transformation function (`ScoreSVMModel.ScoreTransform`) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);
[~,postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2),'VariableNames',...
    {'TrueLabel','PredictedLabel','Score','PosteriorProbability'})
```

```
ans=10×4 table
    TrueLabel    PredictedLabel     Score     PosteriorProbability
    _________    ______________    _______    ____________________

      {'g'}          {'g'}          1.4861           0.82215
      {'b'}          {'b'}         -1.0002           0.30439
      {'g'}          {'g'}          1.8686           0.86917
      {'b'}          {'b'}         -2.6456          0.084197
      {'g'}          {'g'}          1.2806           0.79185
      {'b'}          {'b'}         -1.4617           0.22026
      {'g'}          {'g'}          2.1671           0.89814

      {'g'}          {'g'}          2.4796           0.92223
      {'b'}          {'b'}         -2.7812          0.074801
```

Compare GAMs by Examining Logit of Posterior Probabilities

Estimate the logit of posterior probabilities (classification scores) for training data using a classification generalized additive model (GAM) that contains both linear and interaction terms for predictors. Specify whether to include interaction terms when computing the classification scores.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a GAM using the predictors `X` and class labels `Y`. A recommended practice is to specify the class names. Specify to include the 10 most important interaction terms.

```
Mdl = fitcgam(X,Y,'ClassNames',{'b','g'},'Interactions',10)

Mdl =
  ClassificationGAM
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}
           ScoreTransform: 'logit'
                Intercept: 3.2565
             Interactions: [10x2 double]
          NumObservations: 351

  Properties, Methods
```

`Mdl` is a `ClassificationGAM` model object.

Predict the labels using both linear and interaction terms, and then using only linear terms. To exclude interaction terms, specify `'IncludeInteractions',false`. Estimate the logit of posterior probabilities by specifying the `ScoreTransform` property as `'none'`.

```
Mdl.ScoreTransform = 'none';
[labels,scores] = resubPredict(Mdl);
[labels_nointeraction,scores_nointeraction] = resubPredict(Mdl,'IncludeInteractions',false);
```

Create a table containing the true labels, predicted labels, and scores. Display the first eight rows of the table.

```
t = table(Y,labels,scores,labels_nointeraction,scores_nointeraction, ...
    'VariableNames',{'True Labels','Predicted Labels','Scores' ...
    'Predicted Labels Without Interactions','Scores Without Interactions'});
head(t)
```

```
ans=8×5 table
    True Labels    Predicted Labels          Scores          Predicted Labels Without Interactio
    ___________    ________________    ___________________    ___________________________________

       {'g'}           {'g'}          -51.628     51.628                  {'g'}
       {'b'}           {'b'}           37.433    -37.433                  {'b'}
       {'g'}           {'g'}          -62.061     62.061                  {'g'}
       {'b'}           {'b'}           37.666    -37.666                  {'b'}
       {'g'}           {'g'}          -47.361     47.361                  {'g'}
       {'b'}           {'b'}           106.48    -106.48                  {'b'}
       {'g'}           {'g'}          -62.665     62.665                  {'g'}
       {'b'}           {'b'}           201.46    -201.46                  {'b'}
```

The predicted labels for the training data `X` do not vary depending on the inclusion of interaction terms, but the estimated score values are different.

Input Arguments

`Mdl` — Classification machine learning model

full classification model object

Classification machine learning model, specified as a full classification model object, as given in the following table of supported models.

Model	Classification Model Object
Generalized additive model	`ClassificationGAM`
k-nearest neighbor model	`ClassificationKNN`
Naive Bayes model	`ClassificationNaiveBayes`
Neural network model	`ClassificationNeuralNetwork`
Support vector machine for one-class and binary classification	`ClassificationSVM`

`includeInteractions` — Flag to include interaction terms
`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `Mdl` is `ClassificationGAM`.

The default value is `true` if `Mdl` contains interaction terms. The value must be `false` if the model does not contain interaction terms.

Data Types: `logical`

Output Arguments

`label` — Predicted class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type as the observed class labels that trained `Mdl`, and its length is equal to the number of observations in `Mdl.X`. (The software treats string arrays as cell arrays of character vectors.)

`Score` — Class scores
numeric matrix

Class scores, returned as a numeric matrix. `Score` has rows equal to the number of observations in `Mdl.X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

`Cost` — Expected misclassification costs
numeric matrix

Expected misclassification costs, returned as a numeric matrix. This output applies only to *k*-nearest neighbor and naive Bayes models. That is, `resubPredict` returns `Cost` only when `Mdl` is `ClassificationKNN` or `ClassificationNaiveBayes`.

`Cost` has rows equal to the number of observations in `Mdl.X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

`Cost(j,k)` is the expected misclassification cost of the observation in row `j` of `Mdl.X` predicted into class `k` (in class `Mdl.ClassNames(k)`).

Algorithms

`resubPredict` computes predictions according to the corresponding `predict` function of the object (`Mdl`). For a model-specific description, see the `predict` function reference pages in the following table.

Model	Classification Model Object (`Mdl`)	`predict` Object Function
Generalized additive model	`ClassificationGAM`	`predict`
k-nearest neighbor model	`ClassificationKNN`	`predict`
Naive Bayes model	`ClassificationNaiveBayes`	`predict`
Neural network model	`ClassificationNeuralNetwork`	`predict`
Support vector machine for one-class and binary classification	`ClassificationSVM`	`predict`

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports `ClassificationKNN` and `ClassificationSVM` objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also

`resubEdge` | `resubLoss` | `resubMargin`

Introduced in R2012a

resubPredict

Class: `ClassificationTree`

Predict resubstitution labels of classification tree

Syntax

```
label = resubPredict(tree)
[label,posterior] = resubPredict(tree)
[label,posterior,node] = resubPredict(tree)
[label,posterior,node,cnum] = resubPredict(tree)
[label,...] = resubPredict(tree,Name,Value)
```

Description

`label = resubPredict(tree)` returns the labels `tree` predicts for the data `tree.X`. `label` is the predictions of `tree` on the data that `fitctree` used to create `tree`.

`[label,posterior] = resubPredict(tree)` returns the posterior class probabilities for the predictions.

`[label,posterior,node] = resubPredict(tree)` returns the node numbers of `tree` for the resubstituted data.

`[label,posterior,node,cnum] = resubPredict(tree)` returns the predicted class numbers for the predictions.

`[label,...] = resubPredict(tree,Name,Value)` returns resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`tree`

A classification tree constructed by `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Subtrees` — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `resubPredict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubPredict` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`label`

The response `tree` predicts for the training data. `label` is the same data type as the training response data `tree.Y`.

If the `Subtrees` name-value argument contains `m>1` entries, `label` has `m` columns, each of which represents the predictions of the corresponding subtree. Otherwise, `label` is a vector.

`posterior`

Matrix or array of posterior probabilities for classes `tree` predicts.

If the `Subtrees` name-value argument is a scalar or is missing, `posterior` is an `n`-by-`k` matrix, where `n` is the number of rows in the training data `tree.X`, and `k` is the number of classes.

If `Subtrees` contains `m>1` entries, `posterior` is an `n`-by-`k`-by-`m` array, where the matrix for each `m` gives posterior probabilities for the corresponding subtree.

`node`

The node numbers of `tree` where each data row resolves.

If the `Subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with `n` rows, the same number of rows as `tree.X`.

If `Subtrees` contains `m>1` entries, `node` is a `n`-by-`m` matrix. Each column represents the node predictions of the corresponding subtree.

`cnum`

The class numbers that `tree` predicts for the resubstituted data.

If the `Subtrees` name-value argument is a scalar or is missing, `cnum` is a numeric column vector with `n` rows, the same number of rows as `tree.X`.

If `Subtrees` contains `m>1` entries, `cnum` is a `n`-by-`m` matrix. Each column represents the class predictions of the corresponding subtree.

Examples

Compute Number of Misclassified Observations

Find the total number of misclassifications of the Fisher iris data for a classification tree.

```
load fisheriris
tree = fitctree(meas,species);
Ypredict = resubPredict(tree);    % The predictions
Ysame = strcmp(Ypredict,species); % True when ==
sum(~Ysame) % How many are different?
```

```
ans = 3
```

Compare In-Sample Posterior Probabilities for Each Subtree

Load Fisher's iris data set. Partition the data into training (50%)

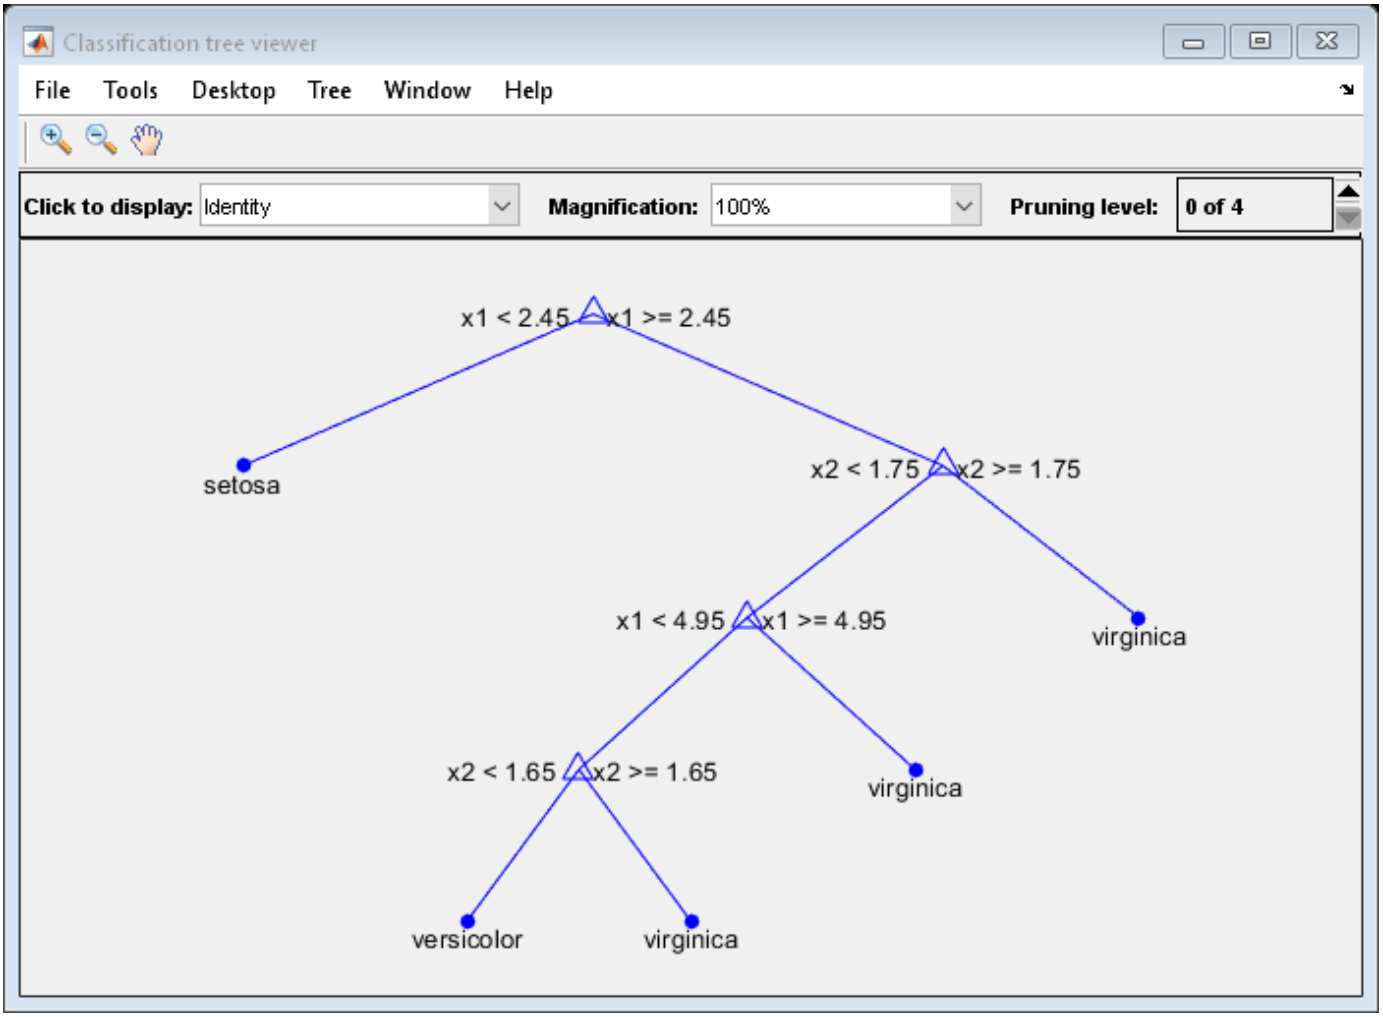
```
load fisheriris
```

Grow a classification tree using the all petal measurements.

```
Mdl = fitctree(meas(:,3:4),species);
n = size(meas,1); % Sample size
K = numel(Mdl.ClassNames); % Number of classes
```

View the classification tree.

```
view(Mdl,'Mode','graph');
```



The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 4 is just the root node (i.e., no splits).

Estimate the posterior probabilities for each class using the subtrees pruned to levels 1 and 3.

```
[~,Posterior] = resubPredict(Mdl,'SubTrees',[1 3]);
```

`Posterior` is an n-by- K-by- 2 array of posterior probabilities. Rows of `Posterior` correspond to observations, columns correspond to the classes with order `Mdl.ClassNames`, and pages correspond to pruning level.

Display the class posterior probabilities for iris 125 using each subtree.

```
Posterior(125,:,:)
```

```
ans =
ans(:,:,1) =

         0    0.0217    0.9783

ans(:,:,2) =
```

```
         0    0.5000    0.5000
```

The decision stump (page 2 of `Posterior`) has trouble predicting whether iris 125 is versicolor or virginica.

More About

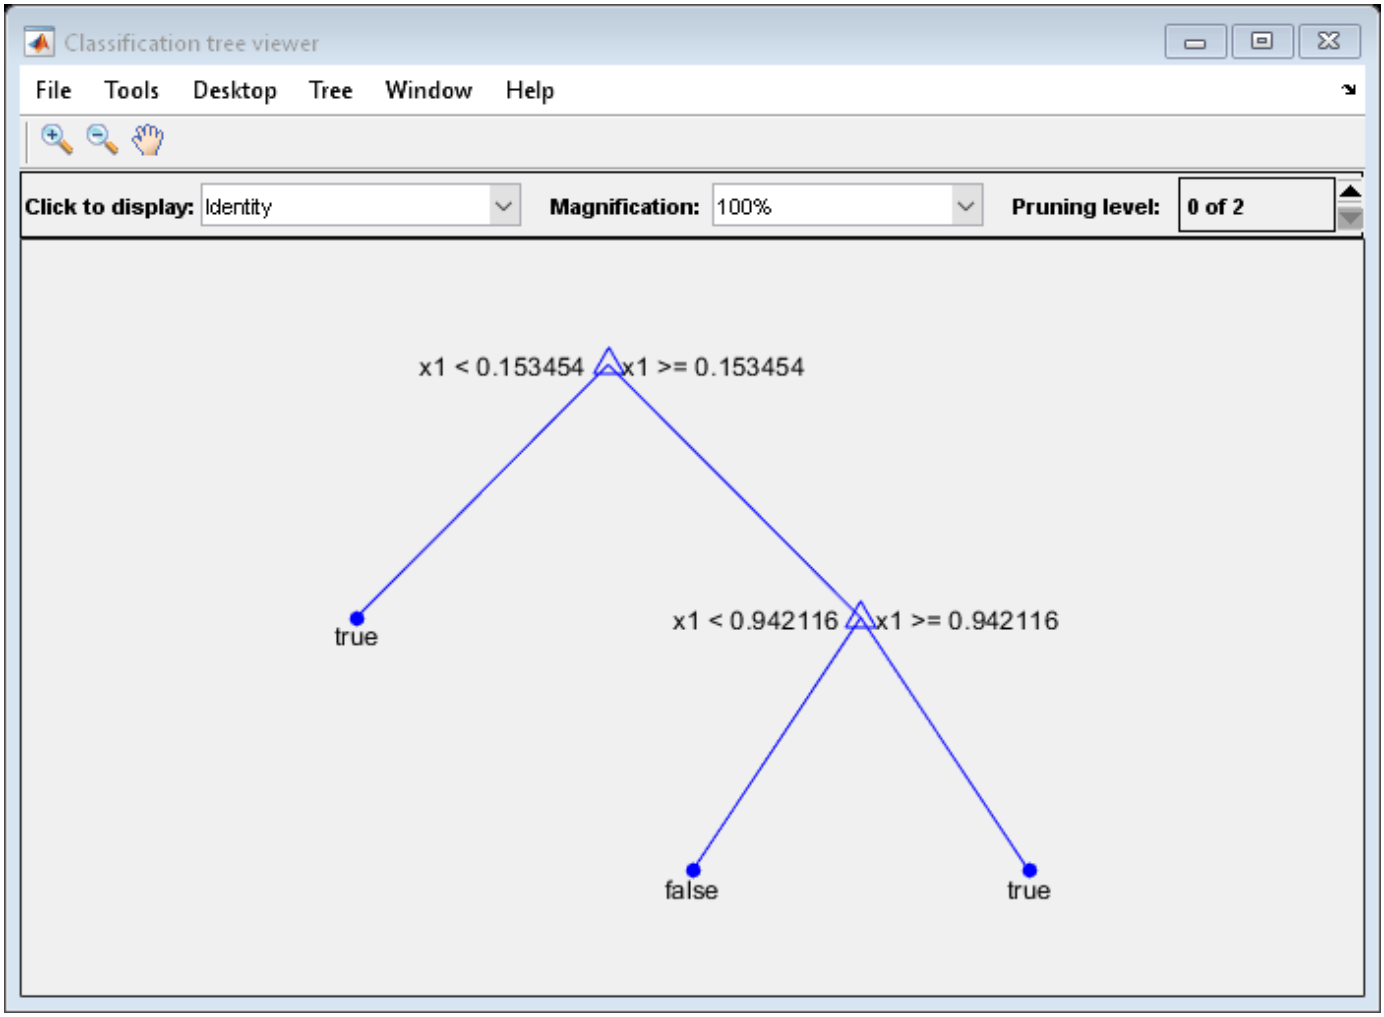
Posterior Probability

The posterior probability of the classification at a node is the number of training sequences that lead to that node with this classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X<0.15` or `X>0.95`, and `X` is false otherwise.

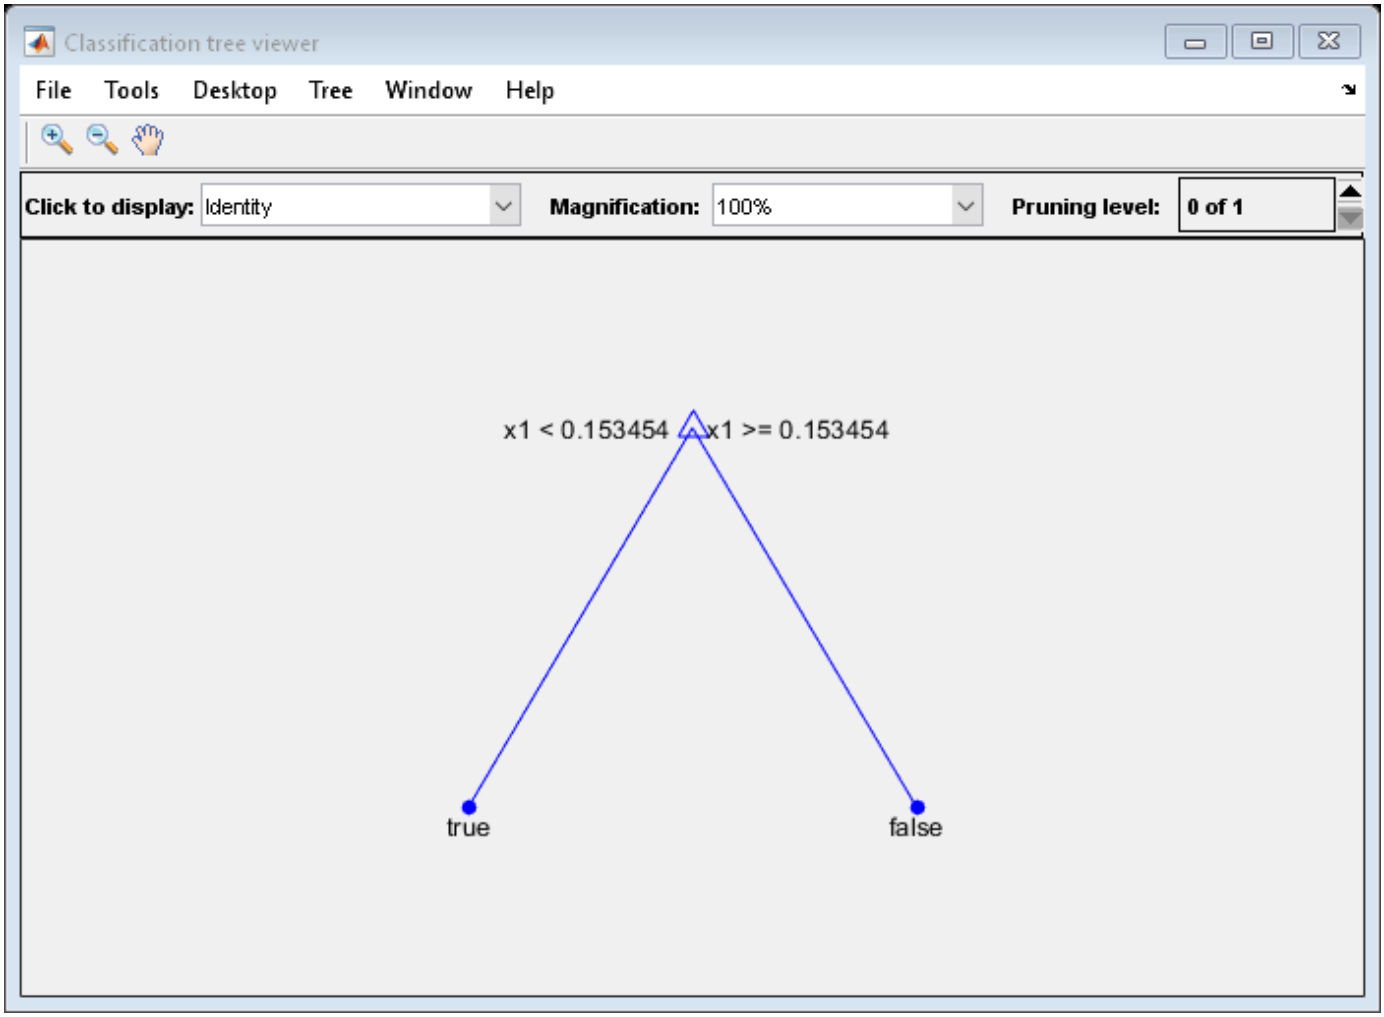
1 Generate 100 random points and classify them:

```
rng(0) % For reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','graph')
```



2 Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','graph')
```



The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations between .15 and .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore the score for observations that are greater than .15 should be about .05/.85=.06 for `true`, and about .8/.85=.94 for `false`.

3 Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10×3

    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0    1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0    1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
```

```
    0.9059    0.0941    0.9649
```

Indeed, every value of `X` (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of `0` and `1`, while the other values of `X` have associated scores of `0.94` and `0.06`.

`fitctree` | `predict` | `resubEdge` | `resubLoss` | `resubMargin`

resubPredict

Predict response of ensemble by resubstitution

Syntax

```
Yfit = resubPredict(ens)
Yfit = resubPredict(ens,Name,Value)
```

Description

`Yfit = resubPredict(ens)` returns the response `ens` predicts for the data `ens.X`. `Yfit` is the predictions of `ens` on the data that `fitrensemble` used to create `ens`.

`Yfit = resubPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from `1` to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

`Yfit`

A vector of predicted responses to the training data, with `ens.X` elements.

Examples

Find Mean-Squared Error of Resubstitution Predictions

Find the resubstitution predictions of mileage from the `carsmall` data, and look at their mean-squared difference from the training data.

Load the `carsmall` data set and select horsepower and vehicle weight as predictors.

```
load carsmall
X = [Horsepower Weight];
```

Train an ensemble of regression trees.

```
ens = fitrensemble(X,MPG,'Method','LSBoost','Learners','Tree');
```

Find the resubstitution predictions of `MPG`.

```
Yfit = resubPredict(ens);
```

Calculate the mean-squared difference of the resubstitution predictions from the training data.

```
MSE = mean((Yfit - ens.Y).^2)
```

```
MSE = 0.5836
```

Confirm that the result is the same as the result of `resubLoss`.

```
resubLoss(ens)
```

```
ans = 0.5836
```

See Also

`predict` | `resubLoss` | `resubPredict`

resubPredict

Predict responses for training data using trained regression model

Syntax

```
yFit = resubPredict(Mdl)
yFit = resubPredict(Mdl,'IncludeInteractions',includeInteractions)
```

Description

`yFit = resubPredict(Mdl)` returns a vector of predicted responses for the trained regression model `Mdl` using the predictor data stored in `Mdl.X`.

`yFit = resubPredict(Mdl,'IncludeInteractions',includeInteractions)` specifies whether to include interaction terms in computations. This syntax applies only to generalized additive models.

Examples

Resubstitution Predictions

Train a generalized additive model (GAM), then predict responses for the training data.

Load the `patients` data set.

```
load patients
```

Create a table that contains the predictor variables (`Age`, `Diastolic`, `Smoker`, `Weight`, `Gender`, `SelfAssessedHealthStatus`) and the response variable (`Systolic`).

```
tbl = table(Age,Diastolic,Smoker,Weight,Gender,SelfAssessedHealthStatus,Systolic);
```

Train a univariate GAM that contains the linear terms for the predictors in `tbl`.

```
Mdl = fitrgam(tbl,"Systolic")
```

```
Mdl =

```

Compare GAMs by Examining Resubstitution Predictions

Predict responses for a training data set using a generalized additive model (GAM) that contains both linear and interaction terms for predictors. Specify whether to include interaction terms when predicting responses.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Specify `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Acceleration,Displacement,Horsepower,Weight];
Y = MPG;
```

Train a generalized additive model that contains all the available linear and interaction terms in `X`.

```
Mdl = fitrgam(X,Y,'Interactions','all');
```

`Mdl` is a `RegressionGAM` model object.

Predict the responses using both linear and interaction terms, and then using only linear terms. To exclude interaction terms, specify `'IncludeInteractions',false`.

```
yFit = resubPredict(Mdl);
yFit_nointeraction = resubPredict(Mdl,'IncludeInteractions',false);
```

Create a table containing the observed response values and the predicted response values. Display the first eight rows of the table.

```
t = table(Mdl.Y,yFit,yFit_nointeraction, ...
    'VariableNames',{'Observed Response', ...
    'Predicted Response','Predicted Response Without Interactions'});
head(t)
```

```
ans=8×3 table

```

Input Arguments

`Mdl` — Regression machine learning model

full regression model object

Regression machine learning model, specified as a full regression model object, as given in the following table of supported models.

Model	Regression Model Object
Generalized additive model	`RegressionGAM`
Neural network model	`RegressionNeuralNetwork`

`includeInteractions` — Flag to include interaction terms

`true` | `false`

Flag to include interaction terms of the model, specified as `true` or `false`. This argument is valid only for a generalized additive model (GAM). That is, you can specify this argument only when `Mdl` is `RegressionGAM`.

The default value is `true` if `Mdl` contains interaction terms. The value must be `false` if the model does not contain interaction terms.

Data Types: `logical`

Output Arguments

`yFit` — Predicted responses

vector

Predicted responses, returned as a vector of length *n*, where *n* is the number of observations in the predictor data (`Mdl.X`).

Algorithms

`resubPredict` predicts responses according to the corresponding `predict` function of the object (`Mdl`). For a model-specific description, see the `predict` function reference pages in the following table.

Model	Regression Model Object (`Mdl`)	`predict` Object Function
Generalized additive model	`RegressionGAM`	`predict`
Neural network model	`RegressionNeuralNetwork`	`predict`

`resubLoss`

Introduced in R2021a

resubPredict

Class: RegressionGP

Resubstitution prediction from a trained Gaussian process regression model

Syntax

```
ypred = resubPredict(gprMdl)
[ypred,ysd] = resubPredict(gprMdl)
[ypred,ysd,yint] = resubPredict(gprMdl)
[ypred,ysd,yint] = resubPredict(gprMdl,Name,Value)
```

Description

`ypred = resubPredict(gprMdl)` returns the predicted responses, `ypred`, for the trained Gaussian process regression (GPR) model, `gprMdl`.

`[ypred,ysd] = resubPredict(gprMdl)` also returns the estimated standard deviations of the predicted responses corresponding to the rows of `gprMdl.X`.

`[ypred,ysd,yint] = resubPredict(gprMdl)` also returns the 95% prediction intervals, `yint`, for the true responses corresponding to each row of training data, `gprMdl.X`.

`[ypred,ysd,yint] = resubPredict(gprMdl,Name,Value)` returns the prediction intervals with additional options, specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level of the prediction interval.

Input Arguments

`gprMdl` — Gaussian process regression model

`RegressionGP` object

Gaussian process regression model, specified as a `RegressionGP` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Alpha` — Significance level

0.05 (default) | scalar value in the range from 0 to 1

Significance level for the prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range from 0 to 1.

Example: `'Alpha',0.01` specifies 99% prediction intervals.

Data Types: `single` | `double`

Output Arguments

`ypred` — Predicted response values

n-by-1 vector

Predicted response values, returned as an *n*-by-1 vector, where *n* is the number of observations in the training data.

`ysd` — Standard deviation of the predicted response values

n-by-1 vector

Standard deviation of the predicted response values corresponding to the rows of `gprMdl.X`, returned as an *n*-by-1 vector. `ysd`(*i*), *i* = 1, 2, ..., *n*, contains the estimated standard deviation of the new response corresponding to the predictor values at the i^{th} observation in the training data.

`yint` — Prediction intervals for the true response values

n-by-2 matrix

Prediction intervals for the true response values corresponding to the rows of `gprMdl.X`, returned as an *n*-by-2 matrix, where *n* is the number of observations in the training data. The first column of `yint` contains the lower limits and the second column contains the upper limits of the prediction intervals.

Examples

Plot Predicted Response and Prediction Intervals

This example uses "Housing" data set [1] from the UCI machine learning archive [2] described in http://archive.ics.uci.edu/ml/datasets/Housing. Download the data and save it in your current directory as a data file named `housing.data`.

The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in the Boston suburb area as a function of 13 predictors.

Load the data and define the response vector and predictor matrix.

```
load('housing.data');
X = housing(:,1:13);
y = housing(:,end);
```

Train a GPR model using subset of regressors (`'sr'`) approximation method with Matern 3/2 (`'Matern32'`) kernel function. Predict using the fully independent conditional (`'fic'`) method.

```
gprMdl = fitrgp(X,y,'KernelFunction','Matern32',...
'FitMethod','sr','PredictMethod','fic');
```

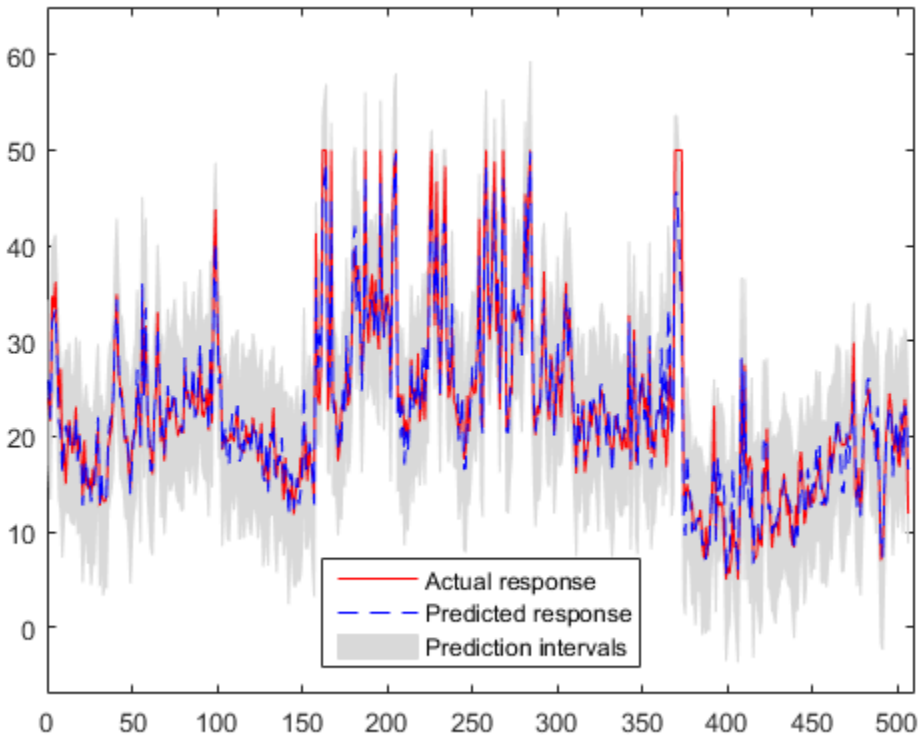
Predict the responses using the trained GPR model. Compute the 99% prediction intervals.

```
[ypred,~,yint] = resubPredict(gprMdl,'Alpha',0.01);
```

Plot the actual response values along with predictions from the GPR model.

```
figure;
h1 = area([yint(:,1) yint(:,2)-yint(:,1)],-8,...
```

```
'FaceColor',[0.85,0.85,0.85],'EdgeColor',[0.85,0.85,0.85]);
hold on;
h1(1).FaceColor = 'none'; % remove color from bottom area
h1(1).EdgeColor = 'none';
h2 = plot(y,'r'); % Plot original response values
h3 = plot(ypred,'b--'); % Plot predicted response values
legend([h2 h3 h1(2)],'Actual response','Predicted response',...
'Prediction intervals','Location','South');
axis([0 510 -7 65]);
hold off
```



The gray area shows the 99% prediction intervals.

Tips

- You can choose the prediction method while training the GPR model using the `PredictMethod` name-value pair argument in `fitrgp`. The default prediction method is `'exact'` for $n \le 10000$, where n is the number of observations in the training data, and `'bcd'` (block coordinate descent), otherwise.
- Computation of standard deviations, `ysd`, and prediction intervals, `yint`, is not supported when `PredictMethod` is `'bcd'`.

Alternatives

To compute the predicted responses for new data, use `predict`.

Introduced in R2015b

resubPredict

Class: `RegressionSVM`

Predict resubstitution response of support vector machine regression model

Syntax

```
yfit = resubPredict(mdl)
```

Description

`yfit = resubPredict(mdl)` returns a vector of predicted response values, `yfit`, for the trained support vector machine (SVM) regression model `mdl` using the predictor data stored in `mdl.X`.

Input Arguments

`mdl` — Full, trained SVM regression model

`RegressionSVM` model

Full, trained SVM regression model, specified as a `RegressionSVM` model returned by `fitrsvm`.

Output Arguments

`yfit` — Predicted response

vector of numeric values

Predicted responses, returned as a vector of numeric values. The length of `yfit` is equal to the number of observations in the training data, `mdl.NumObservations`.

For details about how to predict responses, see “Equation 25-1” and “Equation 25-2” in “Understanding Support Vector Machine Regression” on page 25-2.

Examples

Resubstitution Predictions for SVM Regression Model

This example shows how to train an SVM regression model, then use the model to generate predicted response values from the training data.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);
rng default  % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model to the data, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl,'Var9','KernelFunction','gaussian','KernelScale','auto','Standardize',true);
```

Use the trained model to predict response values based on the original data.

```
yfit = resubPredict(mdl);
```

Display the first ten predicted responses alongside the actual response values.

```
[mdl.Y(1:10),yfit(1:10)]
```

```
ans =

   15.0000    8.1836
    7.0000    8.3545
    9.0000   10.9383
   10.0000    9.3446
    7.0000    6.4042
    8.0000    7.7910
   20.0000   13.8275
   16.0000   11.7959
    9.0000    9.5724
   19.0000   13.6909
```

The left column shows the actual response and the right column shows the corresponding predicted response.

`RegressionSVM` | `fitrsvm` | `predict` | `resubLoss`

Introduced in R2015b

resubPredict

Class: `RegressionTree`

Predict resubstitution response of tree

Syntax

```
Yfit = resubPredict(tree)
[Yfit,node] = resubPredict(tree)
[Yfit,node] = resubPredict(tree,Name,Value)
```

Description

`Yfit = resubPredict(tree)` returns the responses `tree` predicts for the data `tree.X`. `Yfit` is the predictions of `tree` on the data that `fitrtree` used to create `tree`.

`[Yfit,node] = resubPredict(tree)` returns the node numbers of `tree` for the resubstituted data.

`[Yfit,node] = resubPredict(tree,Name,Value)` predicts with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`tree`

A regression tree constructed using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Subtrees` — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least `0` and at most `max(tree.PruneList)`. `0` indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `resubPredict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubPredict` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune','on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees','all'`

Data Types: `single` | `double` | `char` | `string`

Output Arguments

`Yfit`

The response `tree` predicts for the training data.

If the `Subtrees` name-value argument is a scalar or is missing, `label` is the same data type as the training response data `tree.Y`.

If `Subtrees` contains `m>1` entries, `label` has `m` columns, each of which represents the predictions of the corresponding subtree.

`node`

The `tree` node numbers where `tree` sends each data row.

If the `Subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with `n` rows, the same number of rows as `tree.X`.

If `Subtrees` contains `m>1` entries, `node` is a `n`-by-`m` matrix. Each column represents the node predictions of the corresponding subtree.

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

Compute the resubstitution MSE.

```
Yfit = resubPredict(Mdl);
mean((Yfit - Mdl.Y).^2)
```

```
ans = 4.8952
```

You can get the same result using `resubLoss`.

```
resubLoss(Mdl)
```

```
ans = 4.8952
```

Estimate In-Sample Responses For Each Subtree

Load the `carsmall` data set. Consider `Weight` as a predictor of the response `MPG`.

```
load carsmall
idxNaN = isnan(MPG + Weight);
X = Weight(~idxNaN);
Y = MPG(~idxNaN);
n = numel(X);
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,Y);
```

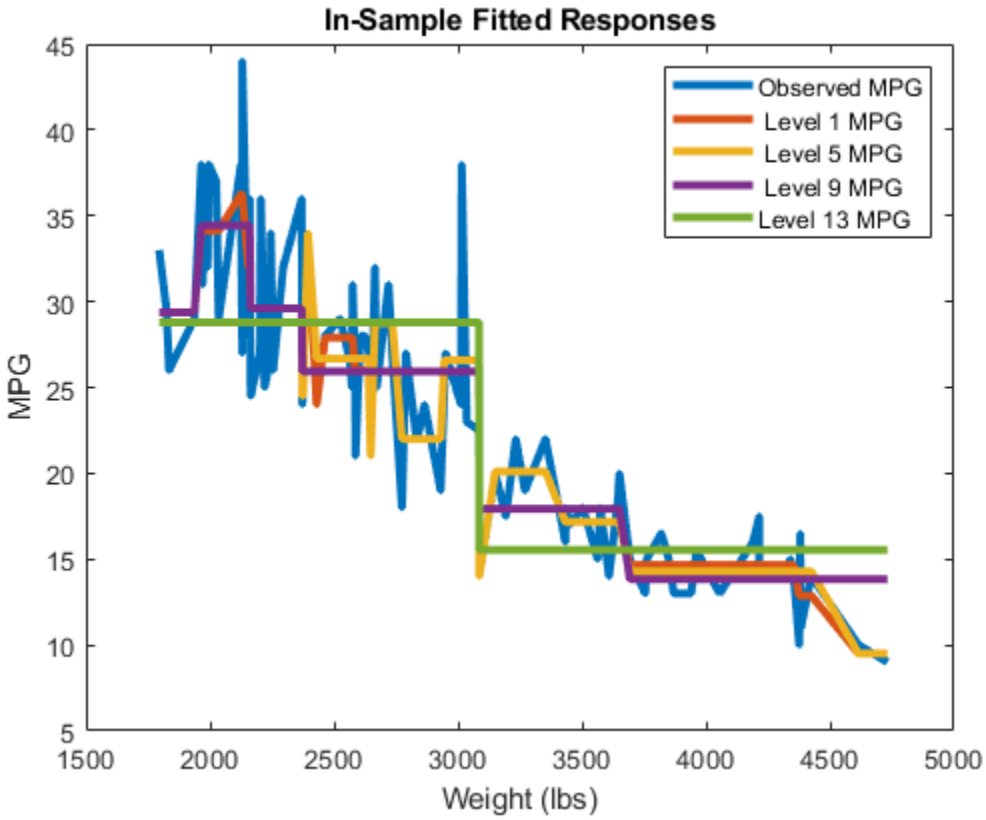
Compute resubstitution fitted values for the subtrees at several pruning levels.

```
m = max(Mdl.PruneList);
pruneLevels = 1:4:m; % Pruning levels to consider
z = numel(pruneLevels);
Yfit = resubPredict(Mdl,'SubTrees',pruneLevels);
```

`Yfit` is an `n`-by- `z` matrix of fitted values in which the rows correspond to observations and the columns correspond to a subtree.

Plot several columns of `Yfit` and `Y` against `X`.

```
figure;
sortDat = sortrows([X Y Yfit],1); % Sort all data with respect to X
plot(repmat(sortDat(:,1),1,size(Yfit,2) + 1),sortDat(:,2:end))...
    % Vectorize for efficiency
lev = cellstr(num2str((pruneLevels)','Level %d MPG'));
legend(['Observed MPG'; lev])
title 'In-Sample Fitted Responses'
xlabel 'Weight (lbs)';
ylabel 'MPG';
h = findobj(gcf);
set(h(4:end),'LineWidth',3) % Widen all lines
```



The values of `Yfit` for lower pruning levels tend to follow the data more closely than higher levels. Higher pruning levels tend to be flat for large `X` intervals.

`fitrtree` | `predict` | `resubLoss`

resume

Resume a Bayesian optimization

Syntax

```
newresults = resume(results,Name,Value)
```

Description

`newresults = resume(results,Name,Value)` resumes the optimization that produced `results` with additional options specified by one or more `Name,Value` pair arguments.

Examples

Resume a Bayesian Optimization

This example shows how to resume a Bayesian optimization. The optimization is for a deterministic function known as Rosenbrock's function, which is a well-known test case for nonlinear optimization. The function has a global minimum value of `0` at the point `[1,1]`.

Create two real variables bounded by `-5` and `5`.

```
x1 = optimizableVariable('x1',[-5,5]);
x2 = optimizableVariable('x2',[-5,5]);
vars = [x1,x2];
```

Create the objective function.

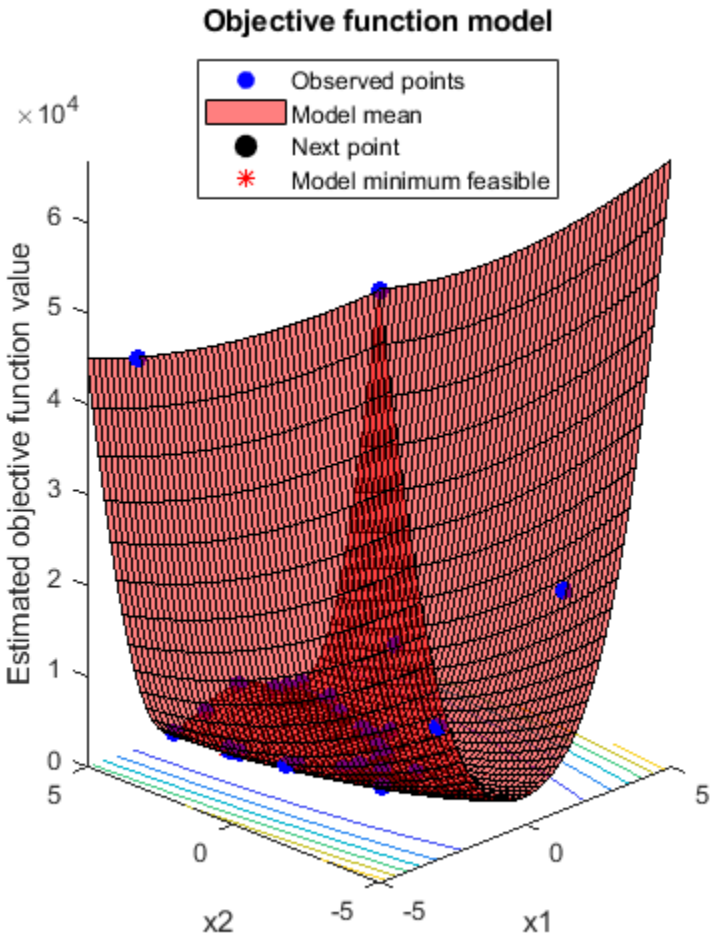
```
function f = rosenbrocks(x)

f = 100*(x.x2 - x.x1^2)^2 + (1 - x.x1)^2;

fun = @rosenbrocks;
```

For reproducibility, set the random seed, and set the acquisition function to `'expected-improvement-plus'` in the optimization.

```
rng default
results = bayesopt(fun,vars,'Verbose',0,...
    'AcquisitionFunctionName','expected-improvement-plus');
```



Objective function model

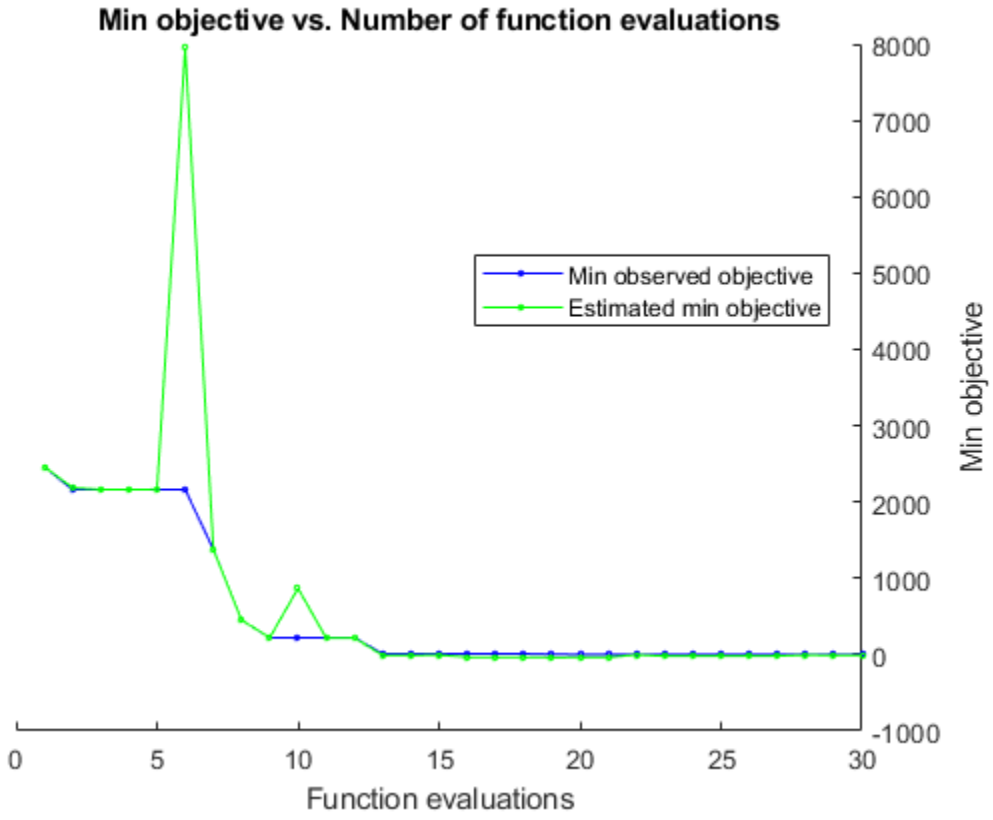
2
1
0
5
0
-5
x2
-5
0
5
x1



View the best point found and the best modeled objective.

```
results.XAtMinObjective
results.MinEstimatedObjective
```

```
ans =

  1x2 table

      x1         x2
    _____    _____

    1.2421    1.5299

ans =

   -9.5402
```

The best point is somewhat close to the optimum, but the function model is inaccurate. Resume the optimization for 30 more points (a total of 60 points), this time telling the optimizer that the objective function is deterministic.

```
newresults = resume(results,'IsObjectiveDeterministic',true,'MaxObjectiveEvaluations',30);
newresults.XAtMinObjective
newresults.MinEstimatedObjective
```

```
ans =

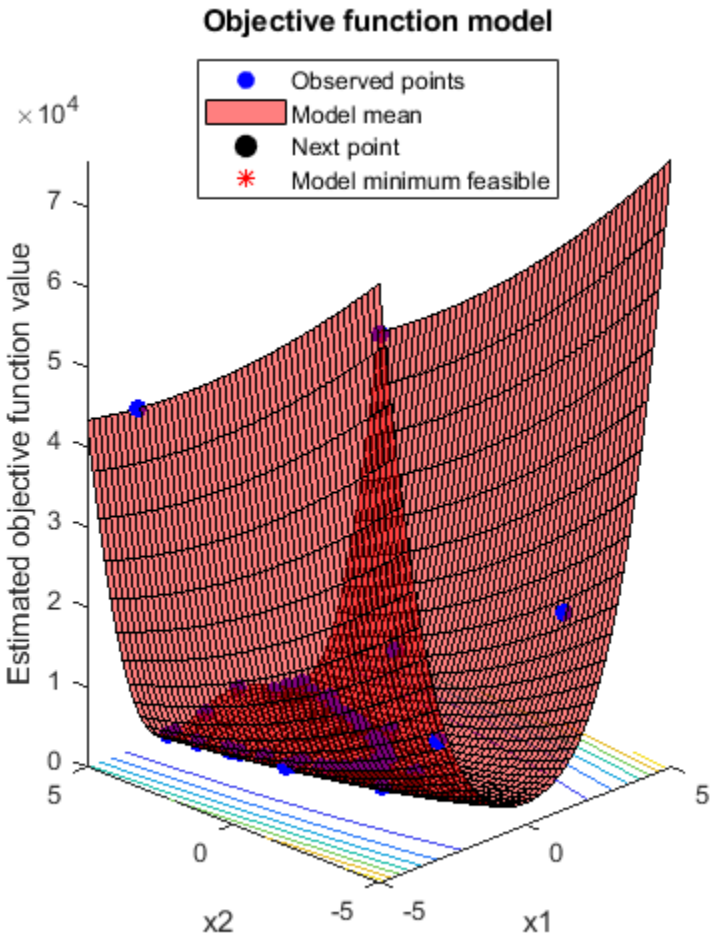
  1x2 table

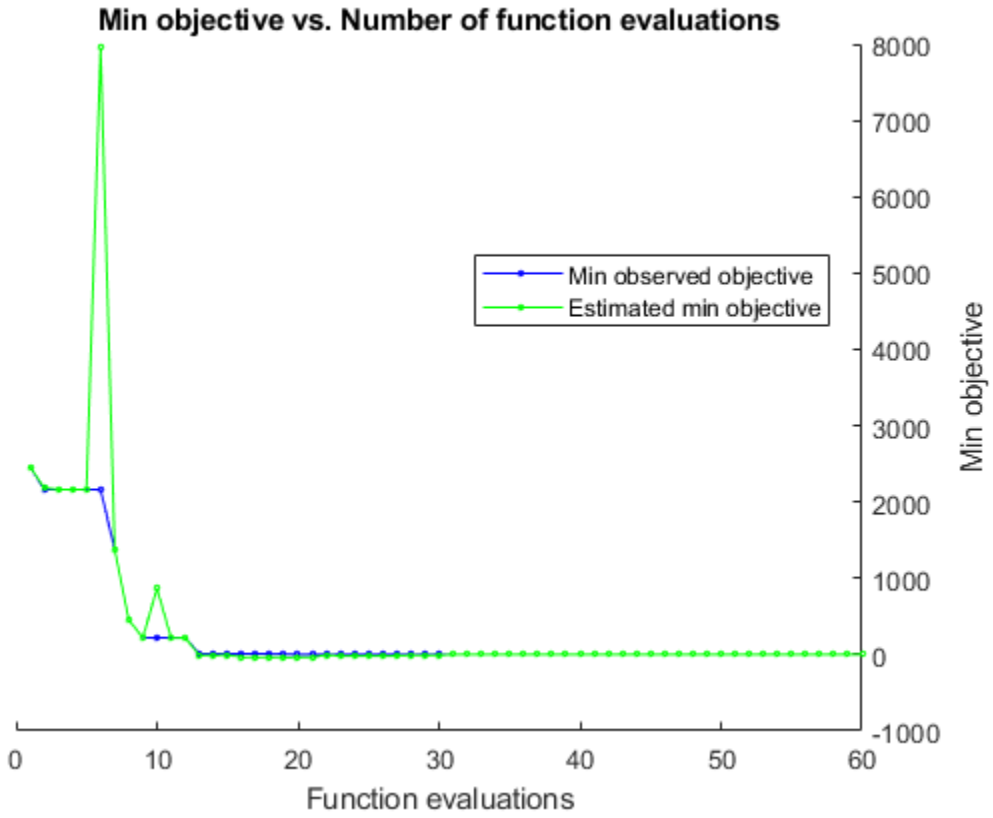
      x1         x2
    _______    _______

    1.0473     1.1002

ans =

   -0.0066
```





The objective function model is much closer to the true function this time. The best point is closer to the true optimum.

Input Arguments

`results` — Bayesian optimization results

`BayesianOptimization` object

Bayesian optimization results, specified as a `BayesianOptimization` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

You can use any name-value pair accepted by `bayesopt` except for those beginning with `Initial`. See the `bayesopt` “Input Arguments” on page 33-132.

Note The `MaxObjectiveEvaluations` and `MaxTime` name-value pairs mean *additional* time or evaluations, above the numbers stored in `results`. So, for example, the default number of evaluations is `30` in addition to the original specification.

Additionally, you can use the following name-value pair.

Example: `resume(results,'MaxObjectiveEvaluations',60)`

`VariableDescriptions` — Modify variable
`OptimizableVariable` object

Modify variable, specified as an `OptimizableVariable` object.

You can change only the following properties of a variable in an optimization.

- `Range` of real or integer variables. For example,

```
xvar = optimizableVariable('x',[-10,10]);
% Modify the range:
xvar.Range = [1,5];
```

- `Type` between `'integer'` and `'real'`. For example,

```
xvar.Type = 'integer';
```

- `Transform` of real or integer variables between `'log'` and `'none'`. For example,

```
xvar.Transform = 'log';
```

Output Arguments

`newresults` — Optimization results
`BayesianOptimization` object

Optimization results, returned as a `BayesianOptimization` object.

Introduced in R2016b

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitcensemble` used to create `ens`, except for parallel training options. If you want to resume training in parallel, pass the `'Options'` name-value pair.

Note You cannot `resume` training when `ens` is a `Subspace` ensemble created with `'AllPredictorCombinations'` number of learners.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A classification ensemble, created with `fitcensemble`.

`nlearn`

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`NPrint`

Printout frequency, a positive integer scalar or `'off'` (no printouts). When `NPrint` is a positive integer, displays a message to the command line after training `NPrint` weak learners.

Tip For fastest training of some boosted decision trees, set `NPrint` to the default value `'off'`. This tip holds when the classification `Method` is `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, or `'LogitBoost'`, or when the regression `Method` is `'LSBoost'`.

Default: `'off'`

`Options`

Options for computing in parallel and setting random numbers, specified as a structure. Create the `Options` structure with `statset`.

Note You need Parallel Computing Toolbox to compute in parallel.

You can use the same parallel options for `resume` as you used for the original training. However, you can change the parallel options as needed. This table lists the option fields and their values.

Field Name	Value	Default
`UseParallel`	Set this value to `true` to compute in parallel. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.	`false`
`UseSubstreams`	Set this value to `true` to run computations in parallel in a reproducible manner. To compute reproducibly, set `Streams` to a type that allows substreams: `'mlfg6331_64'` or `'mrg32k3a'`.	`false`
`Streams`	Specify this value as a `RandStream` object or cell array of such objects. Use a single object except when the `UseParallel` value is `true` and the `UseSubstreams` value is `false`. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify `Streams`, then `resume` uses the default stream or streams.

For dual-core systems and above, `resume` parallelizes training using Intel Threading Building Blocks (TBB). Therefore, specifying the `UseParallel` option as `true` might not provide a significant speedup on a single computer. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Example: `'Options',statset('UseParallel',true)`

Output Arguments

`ens1`

The classification ensemble `ens`, augmented with additional training.

Examples

Train Classification Ensemble for Additional Cycles

Train a classification ensemble for three cycles, and compare the resubstitution error obtained after training the ensemble for more cycles.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble for three cycles and examine the resubstitution error.

```
ens = fitcensemble(X,Y,'Method','GentleBoost','NumLearningCycles',3);
L = resubLoss(ens)
```

```
L = 0.0085
```

Train for three more cycles and examine the new resubstitution error.

```
ens1 = resume(ens,3);
L = resubLoss(ens1)
```

```
L = 0
```

The resubstitution error is much lower in the new ensemble than the original.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

`resume` supports parallel training using the `'Options'` name-value argument. Create options using `statset`, such as `options = statset('UseParallel',true)`. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.

resume

Resume training learners on cross-validation folds

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitcensemble` used to create `ens`, except for parallel training options. If you want to resume training in parallel, pass the `'Options'` name-value pair.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A cross-validated classification ensemble. `ens` is the result of either:

- The `fitcensemble` function with a cross-validation name-value pair. The names are `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.
- The `crossval` method applied to a classification ensemble.

`nlearn`

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`NPrint`

Printout frequency, a positive integer scalar or `'off'` (no printouts). When `NPrint` is a positive integer, displays a message to the command line after training `NPrint` folds.

Tip For fastest training of some boosted decision trees, set `NPrint` to the default value `'off'`. This tip holds when the classification `Method` is `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, or `'LogitBoost'`, or when the regression `Method` is `'LSBoost'`.

Default: `'off'`

Options

Options for computing in parallel and setting random numbers, specified as a structure. Create the `Options` structure with `statset`.

Note You need Parallel Computing Toolbox to compute in parallel.

You can use the same parallel options for `resume` as you used for the original training. However, you can change the parallel options as needed. This table lists the option fields and their values.

Field Name	Value	Default
`UseParallel`	Set this value to `true` to compute in parallel. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.	`false`
`UseSubstreams`	Set this value to `true` to run computations in parallel in a reproducible manner. To compute reproducibly, set `Streams` to a type that allows substreams: `'mlfg6331_64'` or `'mrg32k3a'`.	`false`
`Streams`	Specify this value as a `RandStream` object or cell array of such objects. Use a single object except when the `UseParallel` value is `true` and the `UseSubstreams` value is `false`. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify `Streams`, then `resume` uses the default stream or streams.

For dual-core systems and above, `resume` parallelizes training using Intel Threading Building Blocks (TBB). Therefore, specifying the `UseParallel` option as `true` might not provide a significant speedup on a single computer. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Example: `'Options',statset('UseParallel',true)`

Output Arguments

ens1

The cross-validated classification ensemble `ens`, augmented with additional training.

Examples

Train Partitioned Classification Ensemble for More Cycles

Train a partitioned classification ensemble for 10 cycles, and compare the classification loss obtained after training the ensemble for more cycles.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a partitioned classification ensemble for 10 cycles and examine the error.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
cvens = fitcensemble(X,Y,'Method','GentleBoost','NumLearningCycles',10,'Learners',t,'crossval','
rng(10,'twister') % For reproducibility
L = kfoldLoss(cvens)
```

```
L = 0.0940
```

Train for 10 more cycles and examine the new error.

```
cvens = resume(cvens,10);
L = kfoldLoss(cvens)
```

```
L = 0.0712
```

The cross-validation error is lower in the ensemble after training for 10 more cycles.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

`resume` supports parallel training using the `'Options'` name-value argument. Create options using `statset`, such as `options = statset('UseParallel',true)`. resume

Resume training support vector machine (SVM) classifier

Syntax

```
UpdatedSVMModel = resume(SVMModel,numIter)
UpdatedSVMModel = resume(SVMModel,numIter,Name,Value)
```

Description

`UpdatedSVMModel = resume(SVMModel,numIter)` returns an updated support vector machine (SVM) classifier `UpdatedSVMModel` by training the SVM classifier `SVMModel` for `numIter` more iterations. Like `SVMModel`, the updated SVM classifier is a `ClassificationSVM` classifier.

`resume` continues applying the training options set when `SVMModel` was trained with `fitcsvm`.

`UpdatedSVMModel = resume(SVMModel,numIter,Name,Value)` returns `UpdatedSVMModel` with additional options specified by one or more name-value pair arguments. For example, you can specify the verbosity level.

Examples

Resume Training SVM Classifier

Train an SVM classifier and intentionally cause the solver to fail to converge onto a solution. Then resume training the classifier without having to restart the entire learning process.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify that the optimization routine uses at most 50 iterations.

```
SVMModel = fitcsvm(X,Y,'IterationLimit',50);
DidConverge = SVMModel.ConvergenceInfo.Converged
```

```
DidConverge = logical
   0
```

```
Reason = SVMModel.ConvergenceInfo.ReasonForConvergence
```

```
Reason =
'NoConvergence'
```

`DidConverge = 0` indicates that the optimization routine did not converge onto a solution. `Reason` states the reason why the routine did not converge. Therefore, `SVMModel` is a partially trained SVM classifier.

Resume training the SVM classifier for another `1500` iterations.

```
UpdatedSVMModel = resume(SVMModel,1500);
DidConverge = UpdatedSVMModel.ConvergenceInfo.Converged
```

```
DidConverge = logical
   1
```

```
Reason = UpdatedSVMModel.ConvergenceInfo.ReasonForConvergence
```

```
Reason =
'DeltaGradient'
```

`DidConverge` indicates that the optimization routine converged onto a solution. `Reason` indicates that the gradient difference (`DeltaGradient`) reached its tolerance level (`DeltaGradientTolerance`). Therefore, `SVMModel` is a fully trained SVM classifier.

Monitor Training of SVM Classifier

Train an SVM classifier and intentionally cause the solver to fail to converge onto a solution. Then resume training the classifier without having to restart the entire learning process. Compare values of the resubstitution loss for the partially trained classifier and the fully trained classifier.

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Specify that the optimization routine uses at most 100 iterations. Monitor the algorithm specifying that the software prints diagnostic information every `50` iterations.

```
SVMModel = fitcsvm(X,Y,'IterationLimit',100,'Verbose',1,'NumPrint',50);
```

```
|=============================================================================================================
|   Iteration  | Set  |   Set Size   |  Feasibility  |     Delta     |      KKT      |  Number o
|              |      |              |      Gap      |    Gradient   |   Violation   |  Supp. Ve
|=============================================================================================================

SVM optimization did not converge to the required tolerance.
```

The software prints an iterative display to the Command Window. The printout indicates that the optimization routine has not converged onto a solution.

Estimate the resubstitution loss of the partially trained SVM classifier.

```
partialLoss = resubLoss(SVMModel)
```

```
partialLoss = 0.1054
```

The training sample misclassification error is approximately 12%.

Resume training the classifier for another `1500` iterations. Specify that the software print diagnostic information every `250` iterations.

```
UpdatedSVMModel = resume(SVMModel,1500,'NumPrint',250)
```

```
|=============================================================================================================

 Exiting Active Set upon convergence due to DeltaGradient.

UpdatedSVMModel =
  ClassificationSVM
             ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'b'  'g'}
           ScoreTransform: 'none'
          NumObservations: 351
                    Alpha: [103x1 double]
                     Bias: -3.8828
         KernelParameters: [1x1 struct]
           BoxConstraints: [351x1 double]
          ConvergenceInfo: [1x1 struct]
          IsSupportVector: [351x1 logical]
                   Solver: 'SMO'

  Properties, Methods
```

The software resumes at iteration `1000` and uses the same verbosity level as the one set when you trained the model using `fitcsvm`. The printout indicates that the algorithm converged. Therefore, `UpdatedSVMModel` is a fully trained `ClassificationSVM` classifier.

```
updatedLoss = resubLoss(UpdatedSVMModel)

updatedLoss = 0.0769
```

The training sample misclassification error of the fully trained classifier is approximately 8%.

Input Arguments

`SVMModel` — Full, trained SVM classifier

`ClassificationSVM` classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained with `fitcsvm`.

`numIter` — Number of iterations

positive integer

Number of iterations to continue training the SVM classifier, specified as a positive integer.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `resume(SVMModel,500,'Verbose',2)` trains `SVMModel` for `500` more iterations and specifies displaying diagnostic messages and saving convergence criteria at every iteration.

`Verbose` — Verbosity level

`0` | `1` | `2`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0`, `1`, or `2`. `Verbose` controls the amount of optimization information displayed in the Command Window and saved as a structure to `SVMModel.ConvergenceInfo.History`.

This table summarizes the verbosity level values.

Value	Description
`0`	The software does not display or save convergence information.
`1`	The software displays diagnostic messages and saves convergence criteria every *`numprint`* iterations, where *`numprint`* is the value of the `'NumPrint'` name-value pair argument.
`2`	The software displays diagnostic messages and saves convergence criteria at every iteration.

By default, `Verbose` is the value that `fitcsvm` uses to train `SVMModel`.

Example: `'Verbose',1`

Data Types: `single`

`NumPrint` — Number of iterations between diagnostic message printouts

nonnegative integer

Number of iterations between diagnostic message printouts, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you set `'Verbose',1` and `'NumPrint',`*`numprint`*, then the software displays all optimization diagnostic messages from SMO [1] and ISDA [2] every *`numprint`* iterations in the Command Window.

By default, `NumPrint` is the value that `fitcsvm` uses to train `SVMModel`.

Example: `'NumPrint',500`

Data Types: `single`

Tips

If optimization does not converge and the solver is `'SMO'` or `'ISDA'`, then try to resume training the SVM classifier.

resume

Resume training of generalized additive model (GAM)

Syntax

```
UpdatedMdl = resume(Mdl,numTrees)
UpdatedMdl = resume(Mdl,numTrees,Name,Value)
```

Description

`UpdatedMdl = resume(Mdl,numTrees)` returns an updated generalized additive model `UpdatedMdl` by training `Mdl` for `numTrees` more iterations with the same options used to train `Mdl`.

For each iteration, `resume` trains one predictor tree per linear term or one interaction tree per interaction term.

- If `Mdl` contains only linear terms for predictors (predictor trees), then `resume` trains an additional `numTrees` number of trees per predictor.
- If `Mdl` contains both linear and interaction terms for predictors (predictor trees and interaction trees), then `resume` trains an additional `numTrees` number of trees per interaction term.

`resume` does not add new terms to the model. If you want to add interaction terms to a model that contains only linear terms, use the `addInteractions` function.

`UpdatedMdl = resume(Mdl,numTrees,Name,Value)` specifies additional options using one or more name-value arguments. For example, `'Verbose',2` specifies the verbosity level as 2 to display diagnostic messages at every iteration.

Examples

Resume Training Predictor Trees in GAM

Train a univariate classification GAM (which contains only linear terms) for a small number of iterations. After training the model for more iterations, compare the resubstitution loss.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Train a univariate GAM that identifies whether the radar return is bad (`'b'`) or good (`'g'`). Specify the number of trees per linear term as 2. `fitcgam` iterates the boosting algorithm for the specified number of iterations. For each boosting iteration, the function adds one tree per linear term. Specify `'Verbose'` as 2 to display diagnostic messages at every iteration.

```
Mdl = fitcgam(X,Y,'NumTreesPerPredictor',2,'Verbose',2);
```

```
|=====================================================|
| Type | NumTrees |  Deviance  |   RelTol   | LearnRate  |
```

```
|=========================================================|
|    1D|         0|      486.59|      -     |      -     |
|    1D|         1|      166.71|         Inf|           1|
|    1D|         2|      78.336|     0.58205|           1|
```

To check whether `fitcgam` trains the specified number of trees, display the `ReasonForTermination` property of the trained model and view the displayed message.

```
Mdl.ReasonForTermination
```

```
ans = struct with fields:
      PredictorTrees: 'Terminated after training the requested number of trees.'
    InteractionTrees: ''
```

Compute the classification loss for the training data.

```
resubLoss(Mdl)
```

```
ans = 0.0142
```

Resume training the model for another 100 iterations. Because `Mdl` contains only linear terms, the `resume` function resumes training for the linear terms and adds more trees for them (predictor trees). Specify `'Verbose'` and `'NumPrint'` to display diagnostic messages at every 10 iterations.

```
UpdatedMdl = resume(Mdl,100,'Verbose',1,'NumPrint',10);
```

```
|=========================================================|
| Type | NumTrees |  Deviance  |   RelTol   | LearnRate  |
|=========================================================|

|    1D|         1|      38.364|     0.17429|           1|
|    1D|        10|     0.16311|    0.011894|           1|
|    1D|        20|  0.00035693|   0.0025178|           1|
|    1D|        30|  8.1191e-07|   0.0011006|           1|
|    1D|        40|  1.7978e-09|  0.00074607|           1|
|    1D|        50|  3.6113e-12|  0.00034404|           1|
|    1D|        60|  1.7497e-13|  0.00016541|           1|
```

```
UpdatedMdl.ReasonForTermination
```

```
ans = struct with fields:
      PredictorTrees: 'Unable to improve the model fit.'
    InteractionTrees: ''
```

`resume` terminates training when adding more trees does not improve the deviance of the model fit.

Compute the classification loss using the updated model.

```
resubLoss(UpdatedMdl)
```

```
ans = 0
```

The classification loss decreases after `resume` updates the model with more iterations.

Resume Training Interaction Trees in GAM

Train a regression GAM that contains both linear and interaction terms. Specify to train the interaction terms for a small number of iterations. After training the interaction terms for more iterations, compare the resubstitution loss.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Specify `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Acceleration,Displacement,Horsepower,Weight];
Y = MPG;
```

Train a GAM that includes all available linear and interaction terms in `X`. Specify the number of trees per interaction term as 2. `fitrgam` iterates the boosting algorithm 300 times (default) for linear terms, and iterates the algorithm the specified number of iterations for interaction terms. For each boosting iteration, the function adds one tree per linear term or one tree per interaction term. Specify `'Verbose'` as 1 to display diagnostic messages at every 10 iterations.

```
Mdl = fitrgam(X,Y,'Interactions','all','NumTreesPerInteraction',2,'Verbose',1);
```

```
|=========================================================|
| Type | NumTrees |  Deviance  |   RelTol   | LearnRate   |
|=========================================================|

```

```
|    1D|       300|      2019.7|  6.6719e-06|           1|
|=====================================================|
| Type | NumTrees |  Deviance  |   RelTol   | LearnRate  |
|=====================================================|
|    2D|         0|      2019.7|          -     |      -     |
|    2D|         1|      1795.5|   0.0005975|           1|
|    2D|         2|      1523.4|   0.0010079|           1|
```

To check whether `fitrgam` trains the specified number of trees, display the `ReasonForTermination` property of the trained model and view the displayed messages.

```
Mdl.ReasonForTermination
```

```
ans = struct with fields:
      PredictorTrees: 'Terminated after training the requested number of trees.'
    InteractionTrees: 'Terminated after training the requested number of trees.'
```

Compute the regression loss for the training data.

```
resubLoss(Mdl)
```

```
ans = 3.8277
```

Resume training the model for another 100 iterations. Because `Mdl` contains both linear and interaction terms, the `resume` function resumes training for the interaction terms and adds more trees for them (interaction trees).

```
UpdatedMdl = resume(Mdl,100);
```

```
|=====================================================|
| Type | NumTrees |  Deviance  |   RelTol   | LearnRate  |
|=====================================================|
|    2D|         0|      1523.4|          -     |      -     |
|    2D|         1|      1363.9|  0.00039695|           1|
|    2D|        10|      594.04|  8.0295e-05|           1|
|    2D|        20|      359.44|  4.3201e-05|           1|
|    2D|        30|      238.51|  2.6869e-05|           1|
|    2D|        40|      153.98|  2.6271e-05|           1|
|    2D|        50|      91.464|  8.0936e-06|           1|
|    2D|        60|      61.882|  3.8528e-06|           1|
|    2D|        70|      43.206|  5.9888e-06|           1|
```

```
UpdatedMdl.ReasonForTermination
```

```
ans = struct with fields:
      PredictorTrees: 'Terminated after training the requested number of trees.'
    InteractionTrees: 'Unable to improve the model fit.'
```

`resume` terminates training when adding more trees does not improve the deviance of the model fit.

Compute the regression loss using the updated model.

```
resubLoss(UpdatedMdl)
```

```
ans = 0.0944
```

The regression loss decreases after `resume` updates the model with more iterations.

Input Arguments

`Mdl` — Generalized additive model

`ClassificationGAM` model object | `RegressionGAM` model object

Generalized additive model, specified as a `ClassificationGAM` or `RegressionGAM` model object.

`numTrees` — Number of trees to add

positive integer scalar

Number of trees to add, specified as a positive integer scalar.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Verbose',1,'NumPrint',100` specifies to print diagnostic messages in the Command Window every 100 iterations.

`NumPrint` — Number of iterations between diagnostic message printouts

`Mdl.ModelParameters.NumPrint` (default) | nonnegative integer scalar

Number of iterations between diagnostic message printouts, specified as a nonnegative integer scalar. This argument is valid only when you specify `'Verbose'` as 1.

If you specify `'Verbose',1` and `'NumPrint',numPrint`, then the software displays diagnostic messages every `numPrint` iterations in the Command Window.

The default value is `Mdl.ModelParameters.NumPrint`, which is the `NumPrint` value that you specify when creating the GAM object `Mdl`.

Example: `'NumPrint',500`

Data Types: `single` | `double`

`Verbose` — Verbosity level

`Mdl.ModelParameters.VerbosityLevel` (default) | `0` | `1` | `2`

Verbosity level, specified as `0`, `1`, or `2`. The `Verbose` value controls the amount of information that the software displays in the Command Window.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software displays no information.
`1`	The software displays diagnostic messages every `numPrint` iterations, where `numPrint` is the `'NumPrint'` value.
`2`	The software displays diagnostic messages at every iteration.

Each line of the diagnostic messages shows the information about each boosting iteration and includes the following columns:

- `Type` — Type of trained trees, `1D` (predictor trees, or boosted trees for linear terms for predictors) or `2D` (interaction trees, or boosted trees for interaction terms for predictors)
- `NumTrees` — Number of trees per linear term or interaction term that `resume` added to the model so far
- `Deviance` — "Deviance" on page 33-5692 of the model
- `RelTol` — Relative change of model predictions: $(\widehat{y}_k - \widehat{y}_{k-1})'(\widehat{y}_k - \widehat{y}_{k-1})/\widehat{y}_k'\widehat{y}_k$, where $\widehat{y}_k$ is a column vector of model predictions at iteration k
- `LearnRate` — Learning rate used for the current iteration

The default value is `Mdl.ModelParameters.VerbosityLevel`, which is the `Verbose` value that you specify when creating the GAM object `Mdl`.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`UpdatedMdl` — Updated generalized additive model

`ClassificationGAM` model object | `RegressionGAM` model object

Updated generalized additive model, returned as a `ClassificationGAM` or `RegressionGAM` model object. `UpdatedMdl` has the same object type as the input model `Mdl`.

To overwrite the input argument `Mdl`, assign the output of `resume` to `Mdl`:

```
Mdl = resume(Mdl,numTrees);
```

More About

Deviance

Deviance is a generalization of the residual sum of squares. It measures the goodness of fit compared to the saturated model.

The deviance of a fitted model is twice the difference between the loglikelihoods of the model and the saturated model:

$$-2(\log L - \log L_s),$$

where L and L_s are the likelihoods of the fitted model and the saturated model, respectively. The saturated model is the model with the maximum number of parameters that you can estimate.

`resume` uses the deviance to measure the goodness of model fit and finds a learning rate that reduces the deviance at each iteration. Specify `'Verbose'` as 1 or 2 to display the deviance and learning rate in the Command Window.

Introduced in R2021a

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitrensemble` used to create `ens`, except for parallel training options. If you want to resume training in parallel, pass the `'Options'` name-value pair.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A regression ensemble, created with `fitrensemble`.

`nlearn`

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`NPrint`

Printout frequency, a positive integer scalar or `'off'` (no printouts). When `NPrint` is a positive integer, displays a message to the command line after training `NPrint` weak learners.

Tip For fastest training of some boosted decision trees, set `NPrint` to the default value `'off'`. This tip holds when the classification `Method` is `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, or `'LogitBoost'`, or when the regression `Method` is `'LSBoost'`.

Default: `'off'`

`Options`

Options for computing in parallel and setting random numbers, specified as a structure. Create the `Options` structure with `statset`.

Note You need Parallel Computing Toolbox to compute in parallel.

You can use the same parallel options for `resume` as you used for the original training. However, you can change the parallel options as needed. This table lists the option fields and their values.

Field Name	Value	Default
`UseParallel`	Set this value to `true` to compute in parallel. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.	`false`
`UseSubstreams`	Set this value to `true` to run computations in parallel in a reproducible manner. To compute reproducibly, set `Streams` to a type that allows substreams: `'mlfg6331_64'` or `'mrg32k3a'`.	`false`
`Streams`	Specify this value as a `RandStream` object or cell array of such objects. Use a single object except when the `UseParallel` value is `true` and the `UseSubstreams` value is `false`. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify `Streams`, then `resume` uses the default stream or streams.

For dual-core systems and above, `resume` parallelizes training using Intel Threading Building Blocks (TBB). Therefore, specifying the `UseParallel` option as `true` might not provide a significant speedup on a single computer. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Example: `'Options',statset('UseParallel',true)`

Output Arguments

`ens1`

The regression ensemble `ens`, augmented with additional training.

Examples

Train Regression Ensemble for Additional Cycles

Train a regression ensemble for 50 cycles, and compare the resubstitution error obtained after training the ensemble for more cycles.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train a regression ensemble for 50 cycles and examine the resubstitution error.

```
ens = fitrensemble(X,MPG,'NumLearningCycles',50);
L = resubLoss(ens)
```

```
L = 0.5563
```

Train for 50 more cycles and examine the new resubstitution error.

```
ens = resume(ens,50);
L = resubLoss(ens)
```

```
L = 0.3463
```

The resubstitution error is lower in the new ensemble than in the original.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

`resume` supports parallel training using the `'Options'` name-value argument. Create options using `statset`, such as `options = statset('UseParallel',true)`. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.

`RegressionBaggedEnsemble` | `RegressionEnsemble` | `fitrensemble`

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitrensemble` used to create `ens`, except for parallel training options. If you want to resume training in parallel, pass the `'Options'` name-value pair.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A cross-validated regression ensemble. `ens` is the result of either:

- The `fitrensemble` function with a cross-validation name-value pair. The names are `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.
- The `crossval` method applied to a regression ensemble.

`nlearn`

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`NPrint`

Printout frequency, a positive integer scalar or `'off'` (no printouts). When `NPrint` is a positive integer, displays a message to the command line after training `NPrint` folds.

Tip For fastest training of some boosted decision trees, set `NPrint` to the default value `'off'`. This tip holds when the classification `Method` is `'AdaBoostM1'`, `'AdaBoostM2'`, `'GentleBoost'`, or `'LogitBoost'`, or when the regression `Method` is `'LSBoost'`.

Default: `'off'`

Options

Options for computing in parallel and setting random numbers, specified as a structure. Create the `Options` structure with `statset`.

Note You need Parallel Computing Toolbox to compute in parallel.

You can use the same parallel options for `resume` as you used for the original training. However, you can change the parallel options as needed. This table lists the option fields and their values.

Field Name	Value	Default
`UseParallel`	Set this value to `true` to compute in parallel. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.	`false`
`UseSubstreams`	Set this value to `true` to run computations in parallel in a reproducible manner. To compute reproducibly, set `Streams` to a type that allows substreams: `'mlfg6331_64'` or `'mrg32k3a'`.	`false`
`Streams`	Specify this value as a `RandStream` object or cell array of such objects. Use a single object except when the `UseParallel` value is `true` and the `UseSubstreams` value is `false`. In that case, use a cell array that has the same size as the parallel pool.	If you do not specify `Streams`, then `resume` uses the default stream or streams.

For dual-core systems and above, `resume` parallelizes training using Intel Threading Building Blocks (TBB). Therefore, specifying the `UseParallel` option as `true` might not provide a significant speedup on a single computer. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Example: `'Options',statset('UseParallel',true)`

Output Arguments

ens1

The cross-validated regression ensemble `ens`, augmented with additional training.

Examples

Cross-Validate Regression Ensemble Augmented with Additional Training

Examine the cross-validation error after training a regression ensemble for more cycles.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train a regression ensemble for 50 cycles.

```
ens = fitrensemble(X,MPG,'NumLearningCycles',50);
```

Cross-validate the ensemble and examine the cross-validation error.

```
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L = 27.9435
```

Train for 50 more cycles and examine the new cross-validation error.

```
cvens = resume(cvens,50);
L = kfoldLoss(cvens)
```

```
L = 28.7114
```

The additional training did not improve the cross-validation error.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

`resume` supports parallel training using the `'Options'` name-value argument. Create options using `statset`, such as `options = statset('UseParallel',true)`. Parallel ensemble training requires you to set the `'Method'` name-value argument to `'Bag'`. Parallel training is available only for tree learners, the default type for `'Bag'`.

resume

Class: RegressionSVM

Resume training support vector machine regression model

Syntax

```
updatedMdl = resume(mdl,numIter)
updatedMdl = resume(mdl,numIter,Name,Value)
```

Description

`updatedMdl = resume(mdl,numIter)` returns an updated support vector machine (SVM) regression model, `updatedMdl`, by training the model for an additional number of iterations as specified by `numIter`.

`resume` applies the same training options to `updatedMdl` that you set when using `fitrsvm` to train `mdl`.

`updatedMdl = resume(mdl,numIter,Name,Value)` returns an updated SVM regression model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`mdl` — Full, trained SVM regression model

`RegressionSVM` model

Full, trained SVM regression model, specified as a `RegressionSVM` model trained using `fitrsvm`.

`numIter` — Number of iterations

positive integer value

Number of iterations to continue training the SVM regression model, specified as a positive integer value.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Verbose` — Verbosity level

`0` | `1` | `2`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either `0`, `1`, or `2`. `Verbose` controls the amount of optimization information that the software displays to the Command Window and is saved in the model as `mdl.ModelParameters.VerbosityLevel`.

By default, `Verbose` is the value that `fitrsvm` used to train `mdl`.

Example: `'Verbose',1`

Data Types: `single` | `double`

`NumPrint` — Number of iterations between diagnostic message printouts
nonnegative integer value

Number of iterations between diagnostic message printouts, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you set `'Verbose',1` and `'NumPrint',`*`numprint`*, then the software displays optimization diagnostic messages to the Command Window every *numprint* number of iterations .

By default, `NumPrint` is the value that `fitrsvm` used to train `mdl`.

Example: `'NumPrint',500`

Data Types: `single` | `double`

Output Arguments

`updatedMdl` — Updated SVM regression model
`RegressionSVM` model

Updated SVM regression model, returned as a `RegressionSVM` model.

Examples

Resume Training an SVM Regression Model

This example shows how to resume training an SVM regression model that failed to converge without restarting the entire learning process.

Load the `carsmall` data set.

```
load carsmall
rng default  % for reproducibility
```

Specify `Acceleration`, `Cylinders`, `Displacement`, `Horsepower`, and `Weight` as the predictor variables (`X`) and `MPG` as the response variable (`Y`).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model. For illustration purposes, set the iteration limit to 50. Standardize the data.

```
mdl = fitrsvm(X,Y,'IterationLimit',50,'Standardize',true);
```

Check to confirm whether the model converged.

```
mdl.ConvergenceInfo.Converged
```

```
ans =

     0
```

The returned value of `0` indicates that the model did not converge.

Resume training the model for up to an additional 100 iterations.

```
updatedMdl = resume(mdl,100);
```

Check to confirm whether the updated model converged.

```
updatedMdl.ConvergenceInfo.Converged
```

```
ans =

     1
```

The returned value of `1` indicates that the updated model did converge.

Check the reason for convergence and the total number of iterations required.

```
updatedMdl.ConvergenceInfo.ReasonForConvergence
updatedMdl.NumIterations
```

```
ans =

FeasibilityGap

ans =

    97
```

The model converged because the feasibility gap reached its tolerance value after 97 iterations.

Tips

If optimization has not converged and `'Solver'` is set to `'SMO'` or `'ISDA'`, then try to resume training the SVM regression model.

`RegressionSVM` | `fitrsvm`

Introduced in R2015b

rica

Feature extraction by using reconstruction ICA

Syntax

```
Mdl = rica(X,q)
Mdl = rica(X,q,Name,Value)
```

Description

`Mdl = rica(X,q)` returns a reconstruction independent component analysis (RICA) model object that contains the results from applying RICA to the table or matrix of predictor data `X` containing *p* variables. `q` is the number of features to extract from `X`, therefore `rica` learns a *p*-by-`q` matrix of transformation weights. For undercomplete or overcomplete feature representations, `q` can be less than or greater than the number of predictor variables, respectively.

- To access the learned transformation weights, use `Mdl.TransformWeights`.
- To transform `X` to the new set of features by using the learned transformation, pass `Mdl` and `X` to `transform`.

`Mdl = rica(X,q,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can standardize the predictor data or specify the value of the penalty coefficient in the reconstruction term of the objective function.

Examples

Create Reconstruction ICA Object

Create a `ReconstructionICA` object by using the `rica` function.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1×2

        5000         363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
q = 100;
Mdl = rica(data.X,q,'IterationLimit',100)
```

```
Warning: Solver LBFGS was not able to converge to a solution.
```

```
Mdl =
  ReconstructionICA
            ModelParameters: [1x1 struct]
              NumPredictors: 363
          NumLearnedFeatures: 100
                         Mu: []
                      Sigma: []
                    FitInfo: [1x1 struct]
           TransformWeights: [363x100 double]
    InitialTransformWeights: []
    NonGaussianityIndicator: [100x1 double]

  Properties, Methods
```

`rica` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Input Arguments

X — Predictor data

numeric matrix | table

Predictor data, specified as an *n*-by-*p* numeric matrix or table. Rows correspond to individual observations and columns correspond to individual predictor variables. If `X` is a table, then all of its variables must be numeric vectors.

Data Types: `single` | `double` | `table`

q — Number of features to extract

positive integer

Number of features to extract from the predictor data, specified as a positive integer.

`rica` stores a *p*-by-`q` transform weight matrix in `Mdl.TransformWeights`. Therefore, setting very large values for `q` can result in greater memory consumption and increased computation time.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `Mdl = rica(X,q,'IterationLimit',200,'Standardize',true)` runs `rica` with optimization iterations limited to 200 and standardized predictor data.

IterationLimit — Maximum number of iterations

`1000` (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit',1e6`

Data Types: `single` | `double`

`VerbosityLevel` — Verbosity level

`0` (default) | nonnegative integer

Verbosity level for monitoring algorithm convergence, specified as the comma-separated pair consisting of `'VerbosityLevel'` and a value in this table.

Value	Description
`0`	`rica` does not display convergence information at the command line.
Positive integer	`rica` displays convergence information at the command line.

Convergence Information

Heading	Meaning
`FUN VALUE`	Objective function value.
`NORM GRAD`	Norm of the gradient of the objective function.
`NORM STEP`	Norm of the iterative step, meaning the distance between the previous point and the current point.
`CURV`	`OK` means the weak Wolfe condition is satisfied. This condition is a combination of sufficient decrease of the objective function and a curvature condition.
`GAMMA`	Inner product of the step times the gradient difference, divided by the inner product of the gradient difference with itself. The gradient difference is the gradient at the current point minus the gradient at the previous point. Gives diagnostic information on the objective function curvature.
`ALPHA`	Step direction multiplier, which differs from `1` when the algorithm performed a line search.
`ACCEPT`	`YES` means the algorithm found an acceptable step to take.

Example: `'VerbosityLevel',1`

Data Types: `single` | `double`

`Lambda` — Regularization coefficient value

`1` (default) | positive numeric scalar

Regularization coefficient value for the transform weight matrix, specified as the comma-separated pair consisting of `'Lambda'` and a positive numeric scalar. If you specify `0`, then there is no regularization term in the objective function.

Example: `'Lambda',0.1`

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictor data

`false` (default) | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and `true` (`1`) or `false` (`0`).

If `Standardize` is `true`, then:

- `rica` centers and scales each column of the predictor data (`X`) by the column mean and standard deviation, respectively.
- `rica` extracts new features by using the standardized predictor matrix, and stores the predictor variable means and standard deviations in properties `Mu` and `Sigma` of `Mdl`.

Example: `'Standardize',true`

Data Types: `logical`

`ContrastFcn` — Contrast function
`'logcosh'` (default) | `'exp'` | `'sqrt'`

Contrast function, specified as `'logcosh'`, `'exp'`, or `'sqrt'`. The contrast function is a smooth function that is similar to an absolute value function. The `rica` objective function contains a term

$$\sum_{j=1}^{q}\frac{1}{n}\sum_{i=1}^{n}g\left(w_j^T\tilde{x}_i\right),$$

where g represents the contrast function, the w_j are the variables over which the optimization takes place, and the $\tilde{x}_i$ are data.

The three available contrast functions are:

- `'logcosh'` — $g=\frac{1}{2}\log(\cosh(2x))$
- `'exp'` — $g=-\exp\left(-\frac{x^2}{2}\right)$
- `'sqrt'` — $g=\sqrt{x^2+10^{-8}}$

Example: `'ContrastFcn','exp'`

`InitialTransformWeights` — Transformation weights that initialize optimization
`randn(p,q)` (default) | numeric matrix

Transformation weights that initialize optimization, specified as the comma-separated pair consisting of `'InitialTransformWeights'` and a *p*-by-`q` numeric matrix. *p* must be the number of columns or variables in `X` and `q` is the value of `q`.

Tip You can continue optimizing a previously returned transform weight matrix by passing it as an initial value in another call to `rica`. The output model object `Mdl` stores a learned transform weight matrix in the `TransformWeights` property.

Example: `'InitialTransformWeights',Mdl.TransformWeights`

Data Types: `single` | `double`

`NonGaussianityIndicator` — Non-Gaussianity of sources
`ones(q,1)` (default) | length-`q` vector of ±1

Non-Gaussianity of sources, specified as a length-`q` vector of ±1.

- `NonGaussianityIndicator(k) = 1` means `rica` models the `k`th source as super-Gaussian, with a sharp peak at 0.
- `NonGaussianityIndicator(k) = -1` means `rica` models the `k`th source as sub-Gaussian.

Data Types: `single` | `double`

`GradientTolerance` — Relative convergence tolerance on gradient norm
`1e-6` (default) | positive numeric scalar

Relative convergence tolerance on gradient norm, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive numeric scalar. This gradient is the gradient of the objective function.

Example: `'GradientTolerance',1e-4`

Data Types: `single` | `double`

`StepTolerance` — Absolute convergence tolerance on step size
`1e-6` (default) | positive numeric scalar

Absolute convergence tolerance on the step size, specified as the comma-separated pair consisting of `'StepTolerance'` and a positive numeric scalar.

Example: `'StepTolerance',1e-4`

Data Types: `single` | `double`

Output Arguments

`Mdl` — Learned reconstruction ICA model
`ReconstructionICA` model object

Learned reconstruction ICA model, returned as a `ReconstructionICA` model object.

To access properties of `Mdl`, use dot notation. For example:

- To access the learned transform weights, use `Mdl.TransformWeights`.
- To access the structure of fitting information, use `Mdl.FitInfo`.

Algorithms

The `rica` function creates a linear transformation of input features to output features. The transformation is based on optimizing a nonlinear objective function that roughly balances statistical independence of the output features versus the ability to reconstruct the input data using the output features.

For details, see “Reconstruction ICA Algorithm” on page 15-132.

Introduced in R2017a

ridge

Ridge regression

Syntax

```
B = ridge(y,X,k)
B = ridge(y,X,k,scaled)
```

Description

`B = ridge(y,X,k)` returns coefficient estimates for ridge regression models on page 33-5713 of the predictor data `X` and the response `y`. Each column of `B` corresponds to a particular ridge parameter `k`. By default, the function computes `B` after centering and scaling the predictors to have mean 0 and standard deviation 1. Because the model does not include a constant term, do not add a column of 1s to `X`.

`B = ridge(y,X,k,scaled)` specifies the scaling for the coefficient estimates in `B`. When `scaled` is `1` (default), `ridge` does not restore the coefficients to the original data scale. When `scaled` is `0`, `ridge` restores the coefficients to the scale of the original data. For more information, see “Coefficient Scaling” on page 33-5714.

Examples

Ridge Regression

Perform ridge regression for a range of ridge parameters and observe how the coefficient estimates change.

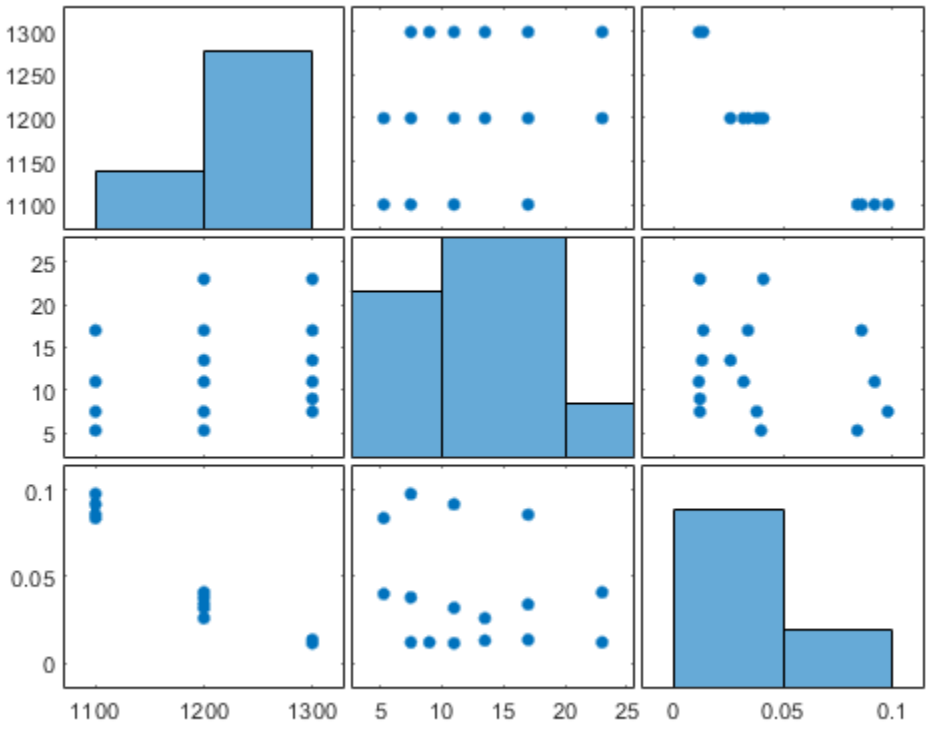
Load the `acetylene` data set.

```
load acetylene
```

`acetylene` contains observations for the predictor variables `x1`, `x2`, and `x3`, and the response variable `y`.

Plot the predictor variables against each other. Observe any correlation between the variables.

```
plotmatrix([x1 x2 x3])
```



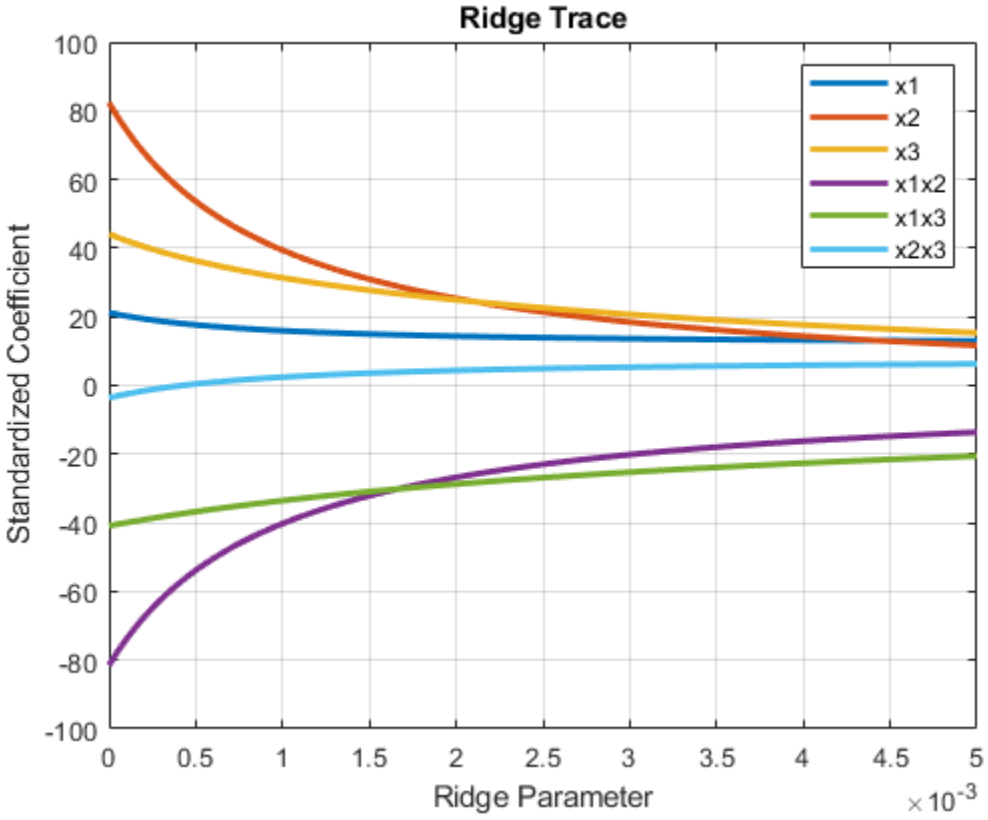
For example, note the linear correlation between `x1` and `x3`.

Compute coefficient estimates for a multilinear model with interaction terms, for a range of ridge parameters. Use `x2fx` to create interaction terms and `ridge` to perform ridge regression.

```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
k = 0:1e-5:5e-3;
B = ridge(y,D,k);
```

Plot the ridge trace.

```
figure
plot(k,B,'LineWidth',2)
ylim([-100 100])
grid on
xlabel('Ridge Parameter')
ylabel('Standardized Coefficient')
title('Ridge Trace')
legend('x1','x2','x3','x1x2','x1x3','x2x3')
```



The estimates stabilize to the right of the plot. Note that the coefficient of the `x2x3` interaction term changes sign at a value of the ridge parameter $\approx 5*10^{-4}$.

Predict Values Using Ridge Regression

Predict miles per gallon (MPG) values using ridge regression.

Load the `carbig` data set.

```
load carbig
X = [Acceleration Weight Displacement Horsepower];
y = MPG;
```

Split the data into training and test sets.

```
n = length(y);
rng('default') % For reproducibility
c = cvpartition(n,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
```

Find the coefficients of a ridge regression model (with k = 5).

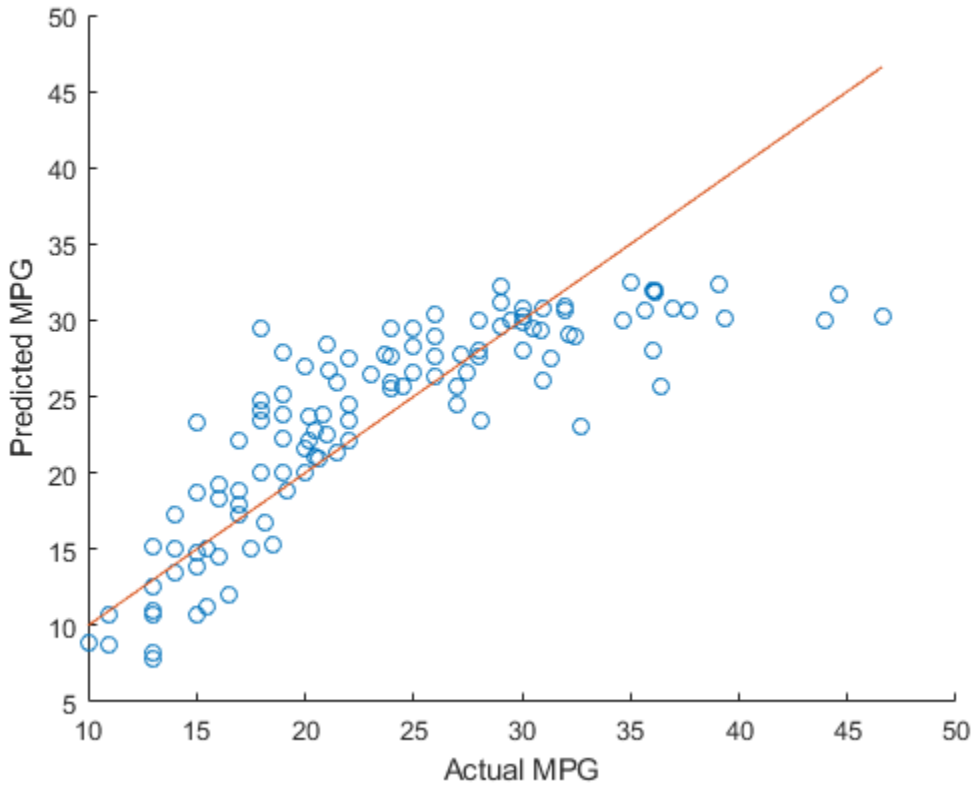
```
k = 5;
b = ridge(y(idxTrain),X(idxTrain,:),k,0);
```

Predict MPG values for the test data using the model.

```
yhat = b(1) + X(idxTest,:)*b(2:end);
```

Compare the predicted values to the actual miles per gallon (MPG) values using a reference line.

```
scatter(y(idxTest),yhat)
hold on
plot(y(idxTest),y(idxTest))
xlabel('Actual MPG')
ylabel('Predicted MPG')
hold off
```



Input Arguments

y — Response data

numeric vector

Response data, specified as an *n*-by-1 numeric vector, where *n* is the number of observations.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix. The rows of X correspond to the *n* observations, and the columns of X correspond to the *p* predictors.

Data Types: `single` | `double`

k — Ridge parameters
numeric vector

Ridge parameters, specified as a numeric vector.

Example: `[0.2 0.3 0.4 0.5]`

Data Types: `single` | `double`

`scaled` — Scaling flag
`1` (default) | `0`

Scaling flag that determines whether the coefficient estimates in `B` are restored to the scale of the original data, specified as either `0` or `1`. If `scaled` is `0`, then `ridge` performs this additional transformation. In this case, `B` contains $p+1$ coefficients for each value of `k`, with the first row of `B` corresponding to a constant term in the model. If `scaled` is `1`, then the software omits the additional transformation, and `B` contains p coefficients without a constant term coefficient.

Output Arguments

`B` — Coefficient estimates
numeric matrix

Coefficient estimates, returned as a numeric matrix. The rows of `B` correspond to the predictors in `X`, and the columns of `B` correspond to the ridge parameters `k`.

If `scaled` is `1`, then `B` is a p-by-m matrix, where m is the number of elements in `k`. If `scaled` is `0`, then `B` is a $(p+1)$-by-m matrix.

More About

Ridge Regression

Ridge regression is a method for estimating coefficients of linear models that include linearly correlated predictors.

Coefficient estimates for multiple linear regression models rely on the independence of the model terms. When terms are correlated and the columns of the design matrix X have an approximate linear dependence, the matrix $(X^TX)^{-1}$ is close to singular. Therefore, the least-squares estimate

$$\widehat{\beta} = (X^TX)^{-1}X^Ty$$

is highly sensitive to random errors in the observed response y, producing a large variance. This situation of multicollinearity can arise, for example, when you collect data without an experimental design.

Ridge regression addresses the problem of multicollinearity by estimating regression coefficients using

$$\widehat{\beta} = (X^TX + kI)^{-1}X^Ty$$

where k is the ridge parameter and I is the identity matrix. Small, positive values of k improve the conditioning of the problem and reduce the variance of the estimates. While biased, the reduced

variance of ridge estimates often results in a smaller mean squared error when compared to least-squares estimates.

Coefficient Scaling

The scaling of the coefficient estimates for the ridge regression models depends on the value of the `scaled` input argument.

Suppose the ridge parameter k is equal to 0. The coefficients returned by `ridge`, when `scaled` is equal to `1`, are estimates of the b_i^1 in the multilinear model

$$y - \mu_y = b_1^1 z_1 + \ldots + b_p^1 z_p + \varepsilon$$

where $z_i = (x_i - \mu_i)/\sigma_i$ are the centered and scaled predictors, $y - \mu_y$ is the centered response, and ε is an error term. You can rewrite the model as

$$y = b_0^0 + b_1^0 x_1 + \ldots + b_p^0 x_p + \varepsilon$$

with $b_0^0 = \mu_y - \sum_{i=1}^{p} \frac{b_i^1 \mu_i}{\sigma_i}$ and $b_i^0 = \frac{b_i^1}{\sigma_i}$. The b_i^0 terms correspond to the coefficients returned by `ridge` when `scaled` is equal to `0`.

More generally, for any value of `k`, if `B1 = ridge(y,X,k,1)`, then

```
m = mean(X);
s = std(X,0,1)';
B1_scaled = B1./s;
B0 = [mean(y)-m*B1_scaled; B1_scaled]
```

where `B0 = ridge(y,X,k,0)`.

Tips

- `ridge` treats `NaN` values in `X` or `y` as missing values. `ridge` omits observations with missing values from the ridge regression fit.
- In general, set `scaled` equal to `1` to produce plots where the coefficients are displayed on the same scale. See “Ridge Regression” on page 33-5709 for an example using a ridge trace plot, where the regression coefficients are displayed as a function of the ridge parameter. When making predictions, set `scaled` equal to `0`. For an example, see “Predict Values Using Ridge Regression” on page 33-5711.

Alternative Functionality

- Ridge, lasso, and elastic net regularization are all methods for estimating the coefficients of a linear model while penalizing large coefficients. The type of penalty depends on the method (see “More About” on page 33-3431 for more details). To perform lasso or elastic net regularization, use `lasso` instead.
- If you have high-dimensional full or sparse predictor data, you can use `fitrlinear` instead of `ridge`. When using `fitrlinear`, specify the `'Regularization','ridge'` name-value pair argument. Set the value of the `'Lambda'` name-value pair argument to a vector of the ridge parameters of your choice. `fitrlinear` returns a trained linear model `Mdl`. You can access the coefficient estimates stored in the `Beta` property of the model by using `Mdl.Beta`.

Introduced before R2006a

robustcov

Robust multivariate covariance and mean estimate

Syntax

```
sig = robustcov(x)
[sig,mu] = robustcov(x)
[sig,mu,mah] = robustcov(x)
[sig,mu,mah,outliers] = robustcov(x)
[sig,mu,mah,outliers,s] = robustcov(x)
[___] = robustcov(x,Name,Value)
```

Description

`sig = robustcov(x)` returns the robust covariance estimate `sig` of the multivariate data contained in `x`.

`[sig,mu] = robustcov(x)` also returns an estimate of the robust Minimum Covariance Determinant (MCD) mean, `mu`.

`[sig,mu,mah] = robustcov(x)` also returns the robust distances `mah`, computed as the Mahalanobis distances of the observations using the robust estimates of the mean and covariance.

`[sig,mu,mah,outliers] = robustcov(x)` also returns the indices of the observations retained as outliers in the sample data, `outliers`.

`[sig,mu,mah,outliers,s] = robustcov(x)` also returns a structure `s` that contains information about the estimate.

`[___] = robustcov(x,Name,Value)` returns any of the arguments shown in the previous syntaxes, using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify which robust estimator to use or the start method to use for the attractors.

Examples

Detect Outliers Using Distance-Distance Plots

Use a Gaussian copula to generate random data points from a bivariate distribution.

```
rng default
rho = [1,0.05;0.05,1];
u = copularnd('Gaussian',rho,50);
```

Modify 5 randomly selected observations to be outliers.

```
noise = randperm(50,5);
u(noise,1) = u(noise,1)*5;
```

Calculate the robust covariance matrices using the three available methods: Fast-MCD, Orthogonalized Gnanadesikan-Kettenring (OGK), and Olive-Hawkins.

```
[Sfmcd, Mfmcd, dfmcd, Outfmcd] = robustcov(u);
[Sogk, Mogk, dogk, Outogk] = robustcov(u,'Method','ogk');
[Soh, Moh, doh, Outoh] = robustcov(u,'Method','olivehawkins');
```

Calculate the classical distance values for the sample data using the Mahalanobis measure.

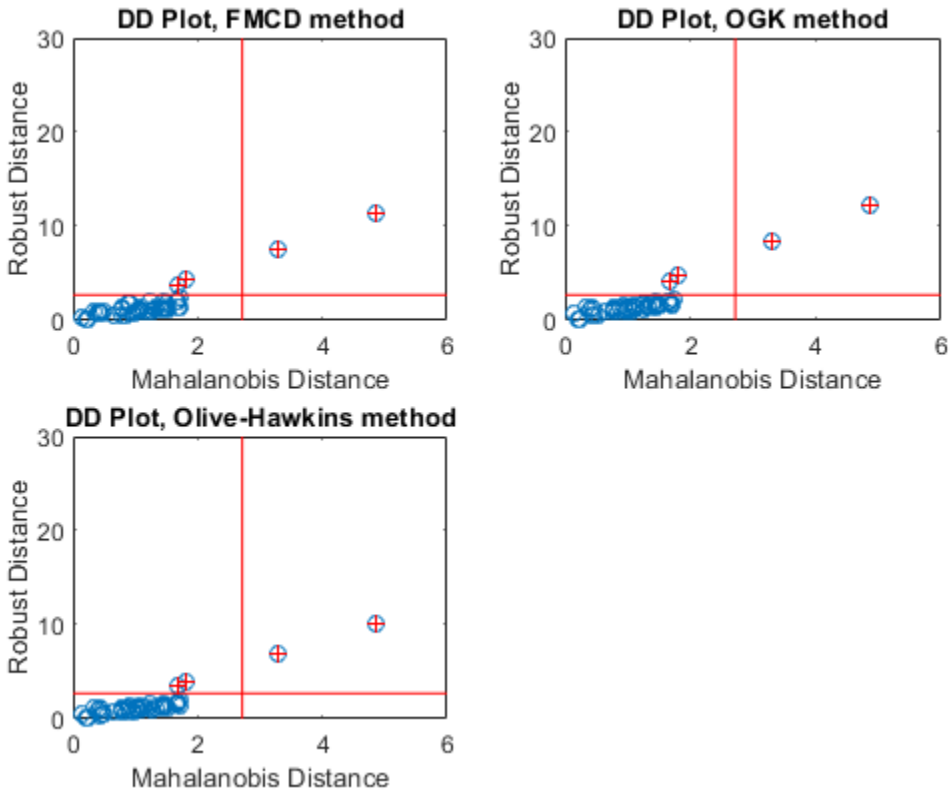
```
d_classical = pdist2(u, mean(u),'mahal');
p = size(u,2);
chi2quantile = sqrt(chi2inv(0.975,p));
```

Create DD Plots for each robust covariance calculation method.

```
figure
subplot(2,2,1)
plot(d_classical, dfmcd, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outfmcd), dfmcd(Outfmcd), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, FMCD method')
hold off

subplot(2,2,2)
plot(d_classical, dogk, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outogk), dogk(Outogk), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, OGK method')
hold off

subplot(2,2,3)
plot(d_classical, doh, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outoh), doh(Outoh), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, Olive-Hawkins method')
hold off
```



In a DD plot, the data points tend to cluster in a straight line that passes through the origin. Points that are far removed from this line are generally considered outliers. In each of the previous plots, the red '+' symbol indicates the data points that `robustcov` considers to be outliers.

Evaluate Data for Multivariate Normal Distribution

This example shows how to use `robustcov` to evaluate sample data for multivariate normal or other elliptically-contoured (EC) distributions.

Generate random sample data from a multivariate normal distribution. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

```
rng('default')
x1 = mvnrnd(zeros(1,3),eye(3),200);
[~, ~, d1] = robustcov(x1,'Method','olivehawkins');
d_classical1 = pdist2(x1,mean(x1),'mahalanobis');
```

Generate random sample data from an elliptically-contoured (EC) distribution. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

```
mu1 = [0 0 0];
sig1 = eye(3);
```

```
mu2 = [0 0 0];
sig2 = 25*eye(3);
x2 = [mvnrnd(mu1,sig1,120);mvnrnd(mu2,sig2,80)];
[~, ~, d2] = robustcov(x2, 'Method','olivehawkins');
d_classical2 = pdist2(x2, mean(x2), 'mahalanobis');
```

Generate random sample data from a multivariate lognormal distribution, which is neither multivariate normal or elliptically-contoured. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

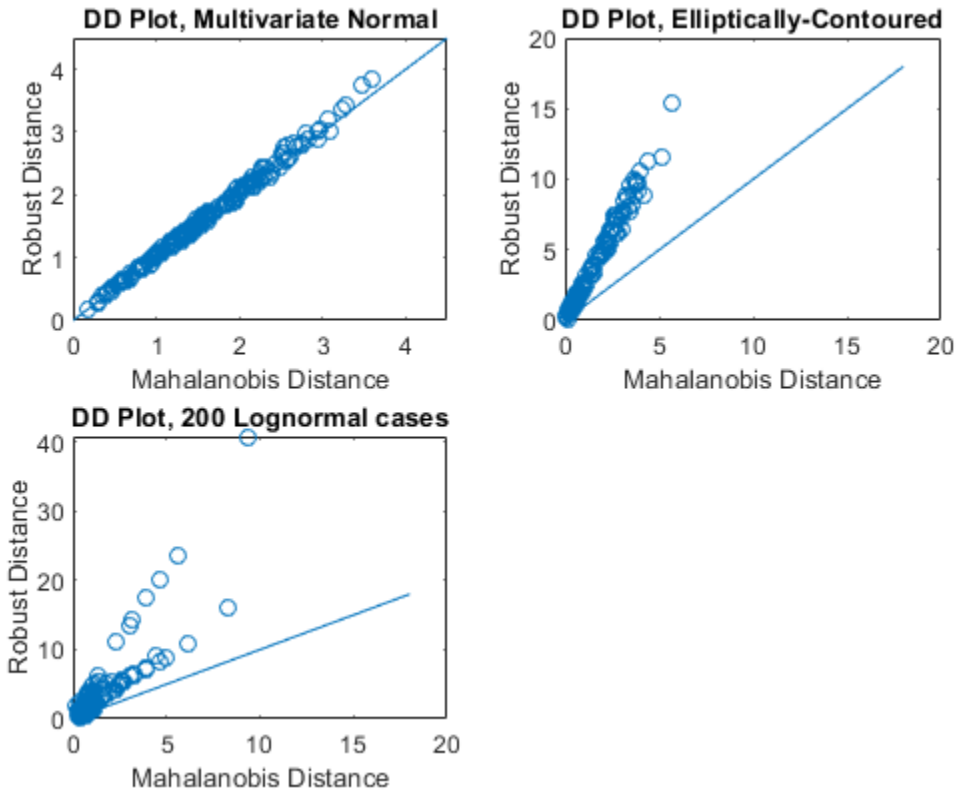
```
x3 = exp(x1);
[~, ~, d3] = robustcov(x3, 'Method','olivehawkins');
d_classical3 = pdist2(x3, mean(x3), 'mahalanobis');
```

Create a D-D Plot for each of the three sets of sample data to compare.

```
figure
subplot(2,2,1)
plot(d_classical1,d1, 'o')
line([0 4.5], [0, 4.5])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, Multivariate Normal')

subplot(2,2,2)
plot(d_classical2, d2, 'o')
line([0 18], [0, 18])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, Elliptically-Contoured')

subplot(2,2,3)
plot(d_classical3, d3, 'o')
line([0 18], [0, 18])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, 200 Lognormal cases')
```



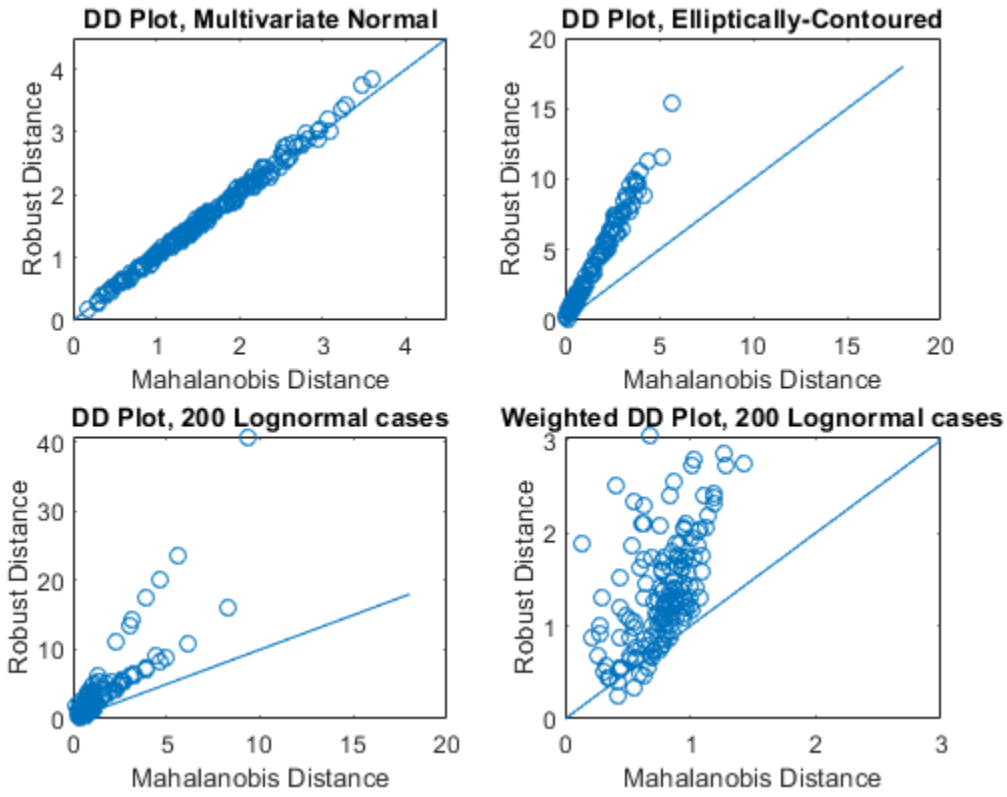
For data with a multivariate normal distribution (as shown in the upper left), the plotted points follow a straight, 45-degree line extending from the origin. For data with an elliptically-contoured distribution (as shown in the upper right), the plotted points follow a straight line, but are not at a 45-degree angle to the origin. For the lognormal distribution (as shown in the lower left), the plotted points do not follow a straight line.

It is difficult to identify any pattern in the lognormal distribution plot because most of the points are in the lower left of the plot. Use a weighted DD plot to magnify this corner and reveal features that are obscured when large robust distances exist.

```
d3_weighted = d3(d3 < sqrt(chi2inv(0.975,3)));
d_classical_weighted = d_classical3(d3 < sqrt(chi2inv(0.975,3)));
```

Add a fourth subplot to the figure to show the results of the weighting process on the lognormally distributed data.

```
subplot(2,2,4)
plot(d_classical_weighted, d3_weighted, 'o')
line([0 3], [0, 3])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('Weighted DD Plot, 200 Lognormal cases')
```



The scale on this plot indicates that it represents a magnified view of the original DD plot for the lognormal data. This view more clearly shows the lack of pattern to the plot, which indicates that the data is neither multivariate normal nor elliptically contoured.

Compute Robust Covariance and Plot the Outliers

Use a Gaussian copula to generate random data points from a bivariate distribution.

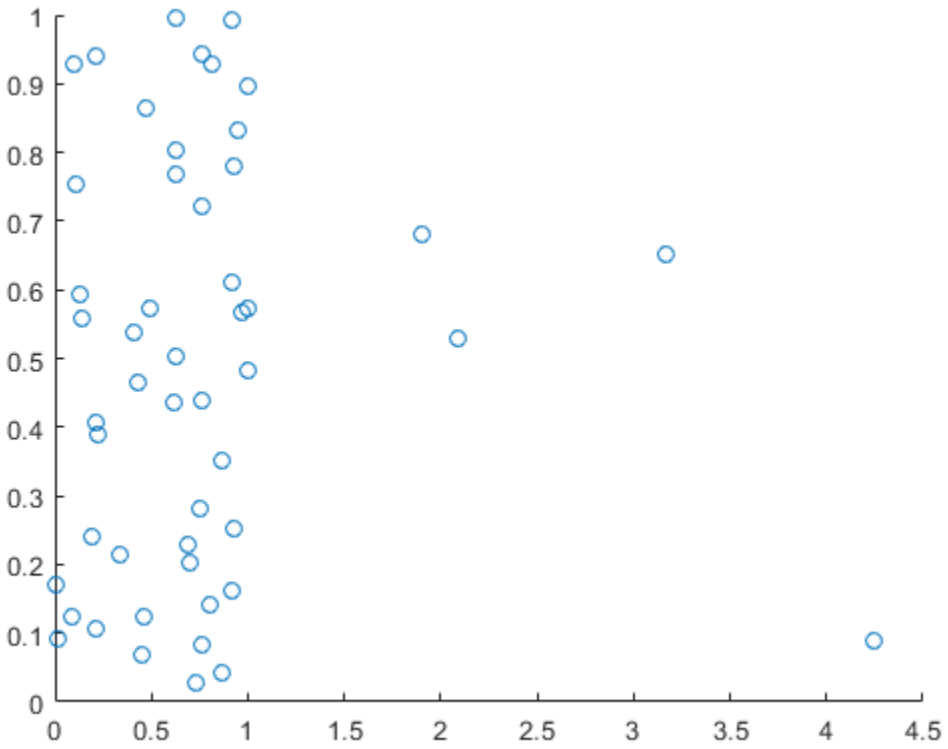
```
rng default
rho = [1,0.05;0.05,1];
u = copularnd('Gaussian',rho,50);
```

Modify 5 randomly selected observations to be outliers.

```
noise = randperm(50,5);
u(noise,1) = u(noise,1)*5;
```

Visualize the bivariate data using a scatter plot.

```
figure
scatter(u(:,1),u(:,2))
```



Most of the data points appear on the left side of the plot. However, some of the data points appear further to the right. These points are possible outliers that could affect the covariance matrix calculation.

Compare the classical and robust covariance matrices.

```
c = cov(u)
```

```
c = 2×2

    0.5523    0.0000
    0.0000    0.0913
```

```
rc = robustcov(u)
```

```
rc = 2×2

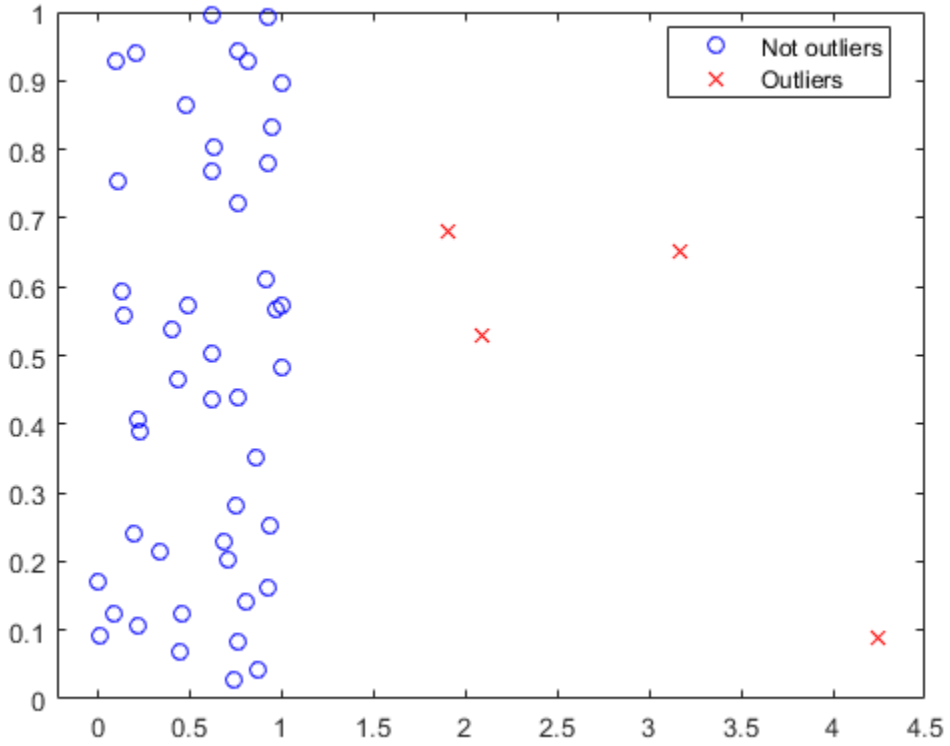
    0.1117    0.0364
    0.0364    0.1695
```

The classical and robust covariance matrices differ because the outliers present in the sample data influence the results.

Identify and plot the data points that `robustcov` considers outliers.

```
[sig,mu,mah,outliers] = robustcov(u);
figure
```

```
gscatter(u(:,1),u(:,2),outliers,'br','ox')
legend({'Not outliers','Outliers'})
```



`robustcov` identifies the data points on the right side of the plot as potential outliers, and treats them accordingly when calculating the robust covariance matrix.

Input Arguments

x — Sample data

matrix of numeric values

Sample data used to estimate the robust covariance matrix, specified as a matrix of numeric values. `x` is an *n*-by-*p* matrix where each row is an observation and each column is a variable.

`robustcov` removes any rows with missing predictor values when calculating the robust covariance matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Method','ogk','NumOGKIterations',1` specifies the robust estimator as the Orthogonalized Gnanadesikan-Kettenring method and sets the number of orthogonalization iterations to 1.

For All Estimators

`Method` — Robust estimator

`'fmcd'` (default) | `'ogk'` | `'olivehawkins'`

Robust estimator, specified as one of the following.

Name	Value
`'fmcd'`	FAST-MCD (Minimum Covariance Determinant) on page 33-5727 method
`'ogk'`	Orthogonalized Gnanadesikan-Kettenring (OGK) on page 33-5728 estimate
`'olivehawkins'`	Concentration algorithm on page 33-5728 techniques, a family of fast, consistent and highly outlier-resistant methods

Example: `'Method','ogk'`

For the FMCD and OliveHawkins Methods Only

`OutlierFraction` — Outlier fraction

0.5 (default) | numeric value in the range [0,0.5]

Outlier fraction, specified as the comma-separated pair consisting of `'OutlierFraction'` and a numeric value in the range [0,0.5]. The value 1 – *OutlierFraction* specifies the fraction of observations over which to minimize the covariance determinant.

The algorithm chooses a subsample of size h = ceiling(n + p + 1) / 2), where n is the number of observations and p is the number of dimensions. `OutlierFraction` is the value for which the maximum possible breakdown is achieved, and controls the size of the subsets h over which the covariance determinant is minimized. The algorithm then chooses h to approximately equal (1 – *OutlierFraction*) × n observations per subset.

Example: `'OutlierFraction',0.25`

Data Types: `single` | `double`

`NumTrials` — Number of trials

positive integer value

Number of trials, specified as the comma-separated pair consisting of `'NumTrials'` and a positive integer value.

If `'Method'` is `'fmcd'`, then `NumTrials` is the number of random subsamples of size (p + 1) drawn from the sample data as starting points in the algorithm. p is the number of dimensions in the sample data. In this case, the default value for `NumTrials` is 500.

If `'Method'` is `'olivehawkins'`, then `NumTrials` is the number of trial fits, or attractors, to be used. In this case, the default value for `NumTrials` is 2. This option is only useful for non-deterministic starts.

Example: `'NumTrials',300`

Data Types: `single` | `double`

For the FMCD Method Only

`BiasCorrection` — Flag to apply small-sample correction factor

`1` (default) | `0`

Flag to apply small-sample correction factor, specified as the comma-separated pair consisting of `'BiasCorrection'` and either `1` or `0`. A `1` value indicates that `robustcov` corrects for bias in the covariance estimate for small samples. A `0` value indicates that `robustcov` does not apply this correction.

Example: `'BiasCorrection',0`

Data Types: `logical`

For the OGK Method Only

`NumOGKIterations` — Number of orthogonalization iterations

2 (default) | positive integer value

Number of orthogonalization iterations, specified as the comma-separated pair consisting of `'NumOGKIterations'` and a positive integer value. Generally, this value is set to 1 or 2, and further steps are unlikely to improve the estimation.

Example: `'NumIter',1`

Data Types: `single` | `double`

`UnivariateEstimator` — Function for computing univariate robust estimates

`'tauscale'` (default) | `'qn'`

Function for computing univariate robust estimates, specified as the comma-separated pair consisting of `'UnivariateEstimator'` and one of the following.

Name	Value
`'tauscale'`	Use the “tau-scale” estimate of Yohai and Zamar, which is a truncated standard deviation and a weighted mean.
`'qn'`	Use the Qn scale estimate of Croux and Rousseeuw.

Example: `'UnivariateEstimator','qn'`

For the OliveHawkins Method Only

`ReweightingMethod` — Method for reweighting

`'rfch'` (default) | `'rmvn'`

Method for reweighting in the efficiency step, specified as the comma-separated pair consisting of `'ReweightingMethod'` and one of the following.

Name	Value
'rfch'	Uses two reweighting steps. This is a standard method of reweighting to improve efficiency.
'rmvn'	Reweighted multivariate normal. Uses two reweighting steps that can be useful for estimating the true covariance matrix under a variety of outlier configurations when the clean data are multivariate normal.

Example: 'ReweightingMethod','rmvn'

NumConcentrationSteps — Number of concentration steps
10 (default) | positive integer value

Number of concentration steps, specified as the comma-separated pair consisting of 'NumConcentrationSteps' and a positive integer value.

Example: 'NumConcentrationSteps',8

Data Types: single | double

StartMethod — Start method for each attractor
'classical' (default) | 'medianball' | 'elemental' | function handle | cell array

Start method for each attractor, specified as the comma-separated pair consisting of 'Start' and one of the following.

Name	Value
'classical'	Use the classical estimator as the start. This is the DGK attractor which, used on its own, is known as the DGK estimator.
'medianball'	Use the Median Ball as the start. The Median Ball is (med(x),eye(p)). So 50% of cases furthest in Euclidean distance from the sample median are trimmed for computing the MB start. This is the MB attractor which, used on its own, is known as the MB estimator.
'elemental'	The attractor is generated by concentration where the start is a randomly selected elemental start: the classical estimator applied to a randomly selected “elemental set” of p + 1 cases. This “elemental” attractor is computationally efficient, but suffers from theoretical drawbacks, as it is inconsistent and zero breakdown.

By default, the attractor is chosen as follows: If one of the attractors is 'medianball', then any attractor whose location estimate has greater Euclidean distance from median(X) than half the data (in other words, is outside the median ball) is not used. Then the final attractor is chosen based on the MCD criterion.

You can also specify a function handle for a function that returns two output arguments used for computing the initial location and scatter estimates..

You can also specify a cell array containing any combination of the options given in the previous table and function handles. The number of attractors used is equal to the length of the cell array. This option allows more control over the algorithm and the ability to specify a custom number of attractors and starts.

Example: `'StartMethod','medianball'`

Output Arguments

`sig` — Robust covariance matrix estimates

numeric matrix

Robust covariance matrix estimates, returned as a *p*-by-*p* numeric matrix. *p* is the number of predictors contained in the sample data.

`mu` — Robust mean estimates

array of numeric values

Robust mean estimates, returned as a 1-by-*p* array of numeric values. *p* is the number of predictors contained in the sample data.

`mah` — Robust distances

array of numeric values

Robust distances, returned as a 1-by-*n* array of numeric values. `robustcov` removes any rows of `x` that contain missing data, so the number of rows of `mah` might be smaller than the number of rows in `x`.

`outliers` — Indices of outliers

array of logical values

Indices of observations retained as outliers in the sample data `x`, returned as a 1-by-*n* array of logical values. A `0` value indicates that the observation is not an outlier. A `1` value indicates that the observation is an outlier.

`robustcov` removes any rows of `x` that contain missing data, so the number of rows of `outliers` might be smaller than the number of rows in `x`.

`s` — Structure containing estimate information

structure

Structure containing estimate information, returned as a structure.

Algorithms

Minimum Covariance Determinant Estimate

Minimum covariance determinant (MCD) is the fastest estimator of multivariate location and scatter that is both consistent and robust. However, an exact evaluation of the MCD is impractical because it is computationally expensive to evaluate all possible subsets of the sample data. `robustcov` uses the FAST-MCD method to implement MCD [3]

The FAST-MCD method selects h observations out of n (where $n/2 < h \le n$) whose classical covariance matrix has the lowest possible determinant. The MCD mean is the mean of the h selected observations.

The MCD covariance is the covariance matrix of the h selected points, multiplied by a consistency factor to obtain consistency at the multivariate normal distribution, and by a correction factor to correct for bias at small sample sizes.

Orthogonalized Gnanadesikan-Kettenring Estimate

Orthogonalized Gnanadesikan-Kettenring (OGK) estimate is a positive definite estimate of the scatter starting from the Gnanadesikan and Kettering (GK) estimator, a pairwise robust scatter matrix that may be non-positive definite [1]. The estimate uses a form of principal components called an orthogonalization iteration on the pairwise scatter matrix, replacing its eigenvalues, which could be negative, with robust variances. This procedure can be iterated for improved results, and convergence is usually obtained after 2 or 3 iterations.

Olive Hawkins Estimate

The Olive-Hawkins estimate uses the “concentration algorithm” techniques proposed by Olive and Hawkins. This is a family of fast, consistent, and highly outlier-resistant methods. The estimate is a robust root n-consistent estimator of covariance for elliptically contoured distributions with fourth moments. This estimate is obtained by first generating trial estimates, or starts, and then using the concentration technique from each trial fit to obtain attractors.

Suppose (T_{0j},C_{0j}) is a start, then at the next iteration the classical mean and covariance estimators are computed from the approximately n / 2 cases (where n is the number of observations) with the smallest Mahalanobis distances based on the estimates from the previous iteration. This iteration can be continued for a fixed number of steps k, with the estimate at the last step, k, being the attractor. The final estimate is chosen based on a given criterion.

By default, two attractors are used. The first attractor is the Devlin-Gnanadesikan-Kettering (DGK) attractor, where the start used is the classical estimator. The second attractor is the Median Ball (MB) attractor, where the start used is `(median(x),eye(p))`, in other words the half set of data closest to `median(x)` in Euclidean distance. The MB attractor is used if the location estimator of the DGK attractor is outside of the median ball, and the attractor with the smallest determinant is used otherwise. The final mean estimate is the mean estimate of the chosen attractor, and the final covariance estimate is the covariance estimate of the chosen attractor, multiplied by a scaling factor to make the estimate consistent at the normal distribution.

Introduced in R2016a

robustdemo

Interactive robust regression

Syntax

```
robustdemo
robustdemo(x,y)
```

Description

`robustdemo` shows the difference between ordinary least squares and robust regression for data with a single predictor. With no input arguments, `robustdemo` displays a scatter plot of a sample of roughly linear data with one outlier. The bottom of the figure displays equations of lines fitted to the data using ordinary least squares and robust methods, together with estimates of the root mean squared errors.

Use the right mouse button to click on a point and view its least-squares leverage and robust weight.

Use the left mouse button to click-and-drag a point. The displays will update.

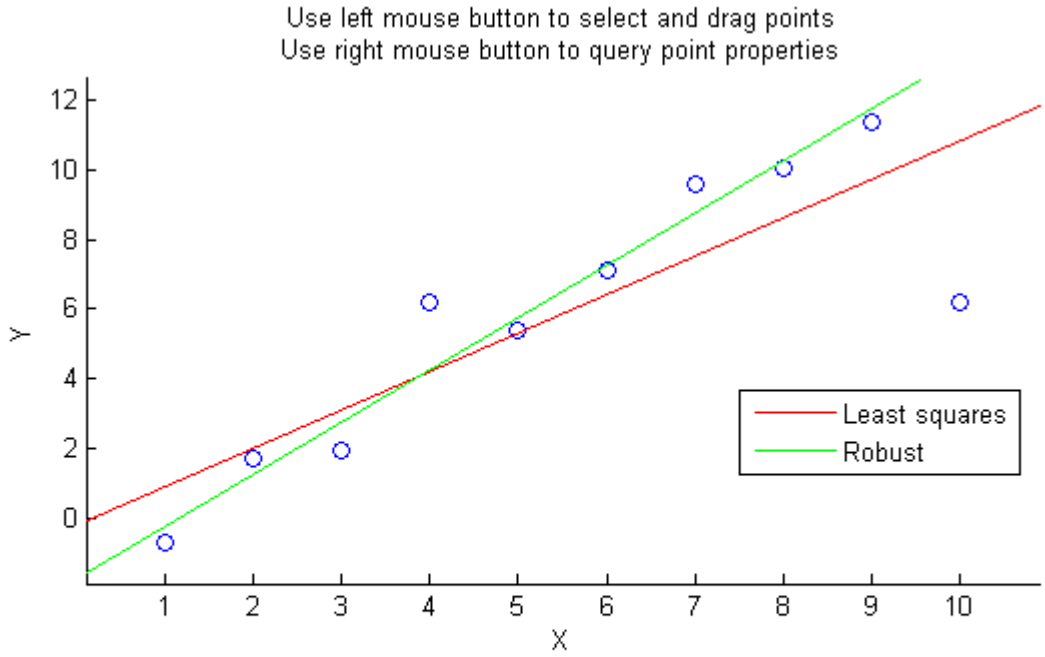
`robustdemo(x,y)` uses `x` and `y` data vectors you supply, in place of the sample data supplied with the function.

Examples

The following steps show you how to use `robustdemo`.

1 **Start the example.** To begin using `robustdemo` with the built-in data, simply type the function name:

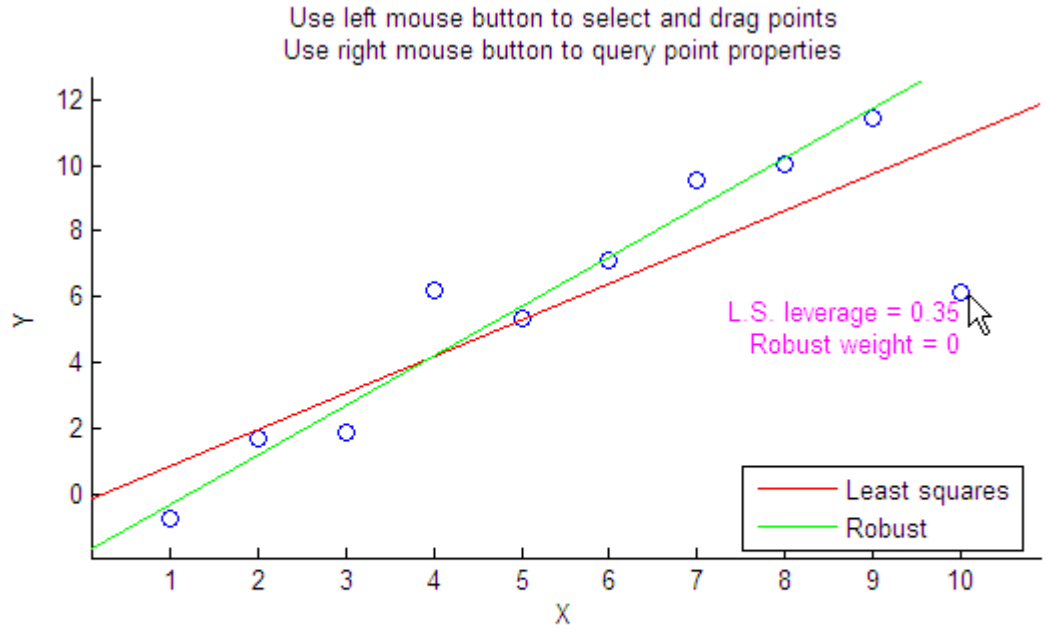
```
robustdemo
```



Least squares:	Y = -0.188327 + 1.10351*X	RMS error = 2.21375
Robust:	Y = -1.77278 + 1.50415*X	RMS error = 1.43663

The resulting figure shows a scatter plot with two fitted lines. The red line is the fit using ordinary least-squares regression. The green line is the fit using robust regression. At the bottom of the figure are the equations for the fitted lines, together with the estimated root mean squared errors for each fit.

2 **View leverages and robust weights.** Right-click on any data point to see its least-squares leverage and robust weight:

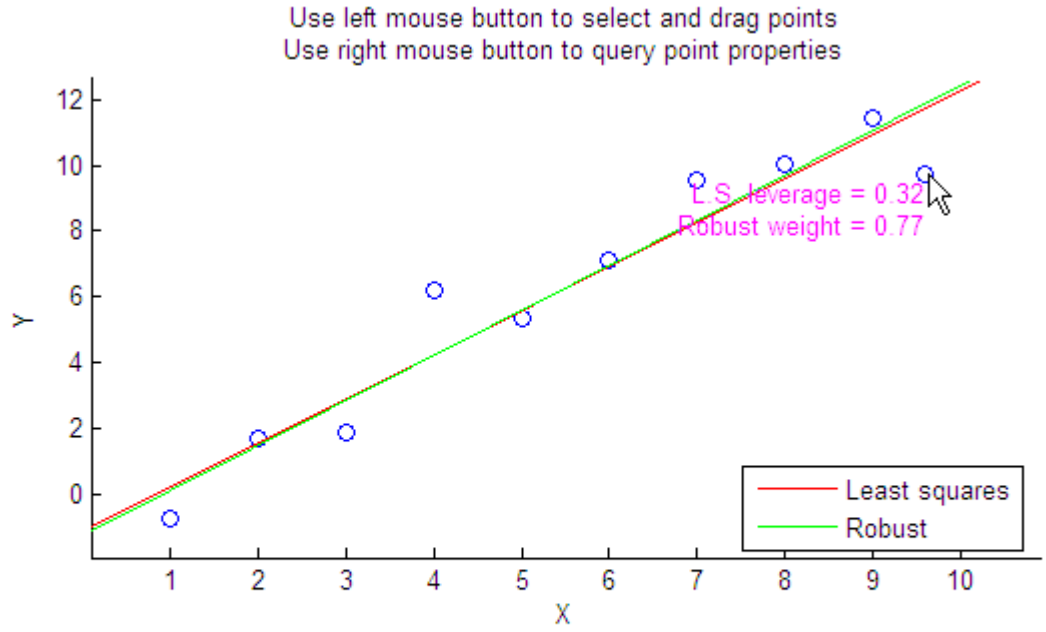


Least squares: Y = -0.188327 + 1.10351*X RMS error = 2.21375

Robust: Y = -1.77278 + 1.50415*X RMS error = 1.43663

In the built-in data, the right-most point has a relatively high leverage of 0.35. The point exerts a large influence on the least-squares fit, but its small robust weight shows that it is effectively excluded from the robust fit.

3 **See how changes in the data affect the fits.** With the left mouse button, click and hold on any data point and drag it to a new location. When you release the mouse button, the displays update:



Least squares:	Y = -1.0661 + 1.33785*X	RMS error = 1.21477
Robust:	Y = -1.18916 + 1.36459*X	RMS error = 1.27697

Bringing the right-most data point closer to the least-squares line makes the two fitted lines nearly identical. The adjusted right-most data point has significant weight in the robust fit.

`leverage` | `robustfit`

Introduced before R2006a

robustfit

Fit robust linear regression

Syntax

```
b = robustfit(X,y)
b = robustfit(X,y,wfun,tune,const)
[b,stats] = robustfit( ___ )
```

Description

`b = robustfit(X,y)` returns a vector `b` of coefficient estimates for a robust multiple linear regression of the responses in vector `y` on the predictors in matrix `X`.

`b = robustfit(X,y,wfun,tune,const)` specifies the fitting weight function options `wfun` and `tune`, and the indicator `const`, which determines if the model includes a constant term. You can pass in `[]` for `wfun`, `tune`, and `const` to use their default values.

`[b,stats] = robustfit( ___ )` also returns a structure `stats` containing estimated statistics, using any of the input argument combinations in previous syntaxes.

Examples

Estimate Robust Regression Coefficients

Estimate robust regression coefficients for a multiple linear model.

Load the `carsmall` data set. Specify car weight and horsepower as predictors and mileage per gallon as the response.

```
load carsmall
x1 = Weight;
x2 = Horsepower;
X = [x1 x2];
y = MPG;
```

Compute the robust regression coefficients.

```
b = robustfit(X,y)
```

```
b = 3×1

   47.1975
   -0.0068
   -0.0333
```

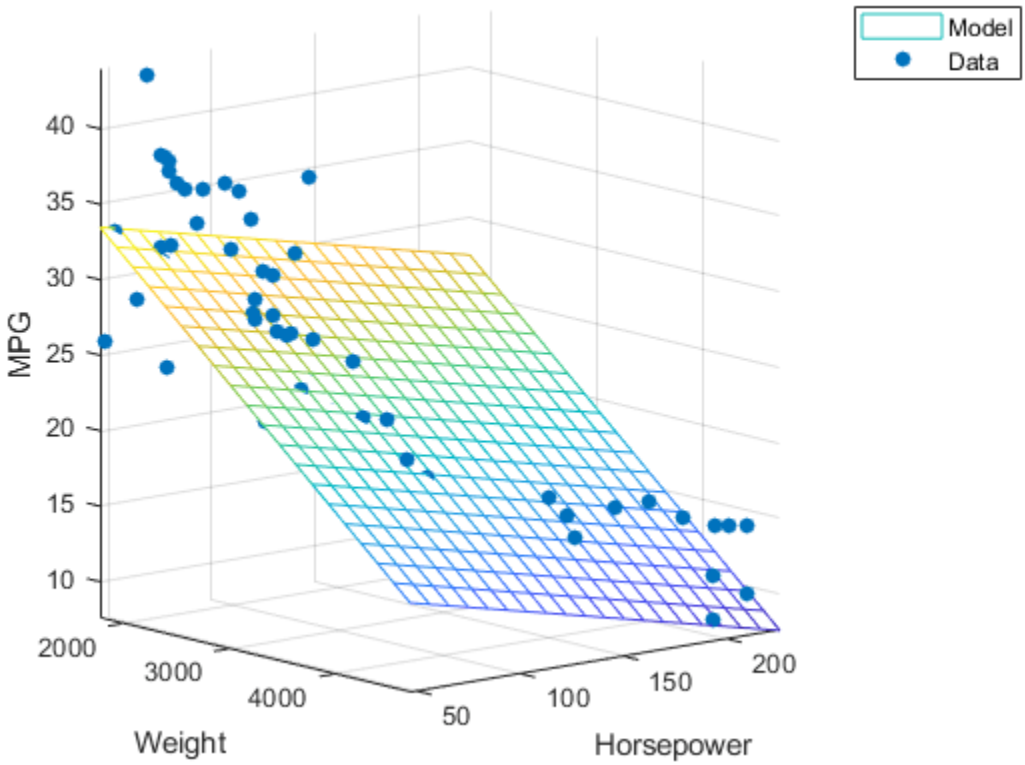
Plot the fitted model.

```
x1fit = linspace(min(x1),max(x1),20);
x2fit = linspace(min(x2),max(x2),20);
```

```
[X1FIT,X2FIT] = meshgrid(x1fit,x2fit);
YFIT = b(1) + b(2)*X1FIT + b(3)*X2FIT;
mesh(X1FIT,X2FIT,YFIT)
```

Plot the data.

```
hold on
scatter3(x1,x2,y,'filled')
hold off
xlabel('Weight')
ylabel('Horsepower')
zlabel('MPG')
legend('Model','Data')
view(50,10)
axis tight
```



Tune Robust Weight Function

Tune the weight function for robust regression by using different tuning constants.

Generate data with the trend $y = 10 - 2x$, and then change one value to simulate an outlier.

```
x = (1:10)';
rng ('default') % For reproducibility
y = 10 - 2*x + randn(10,1);
y(10) = 0;
```

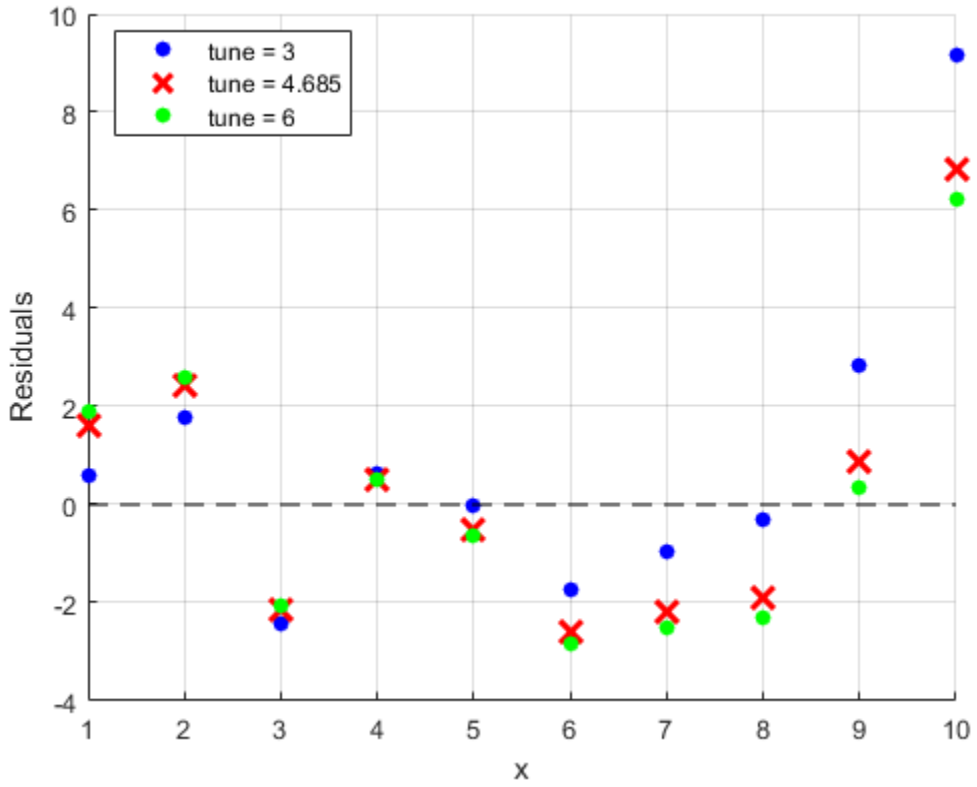
Compute the robust regression residuals using the bisquare weight function for three different tuning constants. The default tuning constant is 4.685.

```
tune_const = [3 4.685 6];

for i = 1:length(tune_const)
    [~,stats] = robustfit(x,y,'bisquare',tune_const(i));
    resids(:,i) = stats.resid;
end
```

Create a plot of the residuals.

```
scatter(x,resids(:,1),'b','filled')
hold on
plot(resids(:,2),'rx','MarkerSize',10,'LineWidth',2)
scatter(x,resids(:,3),'g','filled')
plot([min(x) max(x)],[0 0],'--k')
hold off
grid on
xlabel('x')
ylabel('Residuals')
legend('tune = 3','tune = 4.685','tune = 6','Location','best')
```



Compute the root mean squared error (RMSE) of residuals for the three different tuning constants.

```
rmse = sqrt(mean(resids.^2))
```

```
rmse = 1×3
```

```
    3.2577    2.7576    2.7099
```

Because increasing the tuning constant decreases the downweight assigned to outliers, the RMSE decreases as the tuning constant increases.

Compare Robust and Least-Squares Regression

Generate data with the trend $y = 10 - 2x$, and then change one value to simulate an outlier.

```
x = (1:10)';
rng('default') % For reproducibility
y = 10 - 2*x + randn(10,1);
y(10) = 0;
```

Fit a straight line using ordinary least-squares regression. To compute coefficient estimates for a model with a constant term, include a column of ones in x.

```
bls = regress(y,[ones(10,1) x])
```

```
bls = 2×1

    7.8518
   -1.3644
```

Estimate a straight-line fit using robust regression. `robustfit` adds a constant term to the model by default.

```
[brob,stats] = robustfit(x,y);
brob
```

```
brob = 2×1

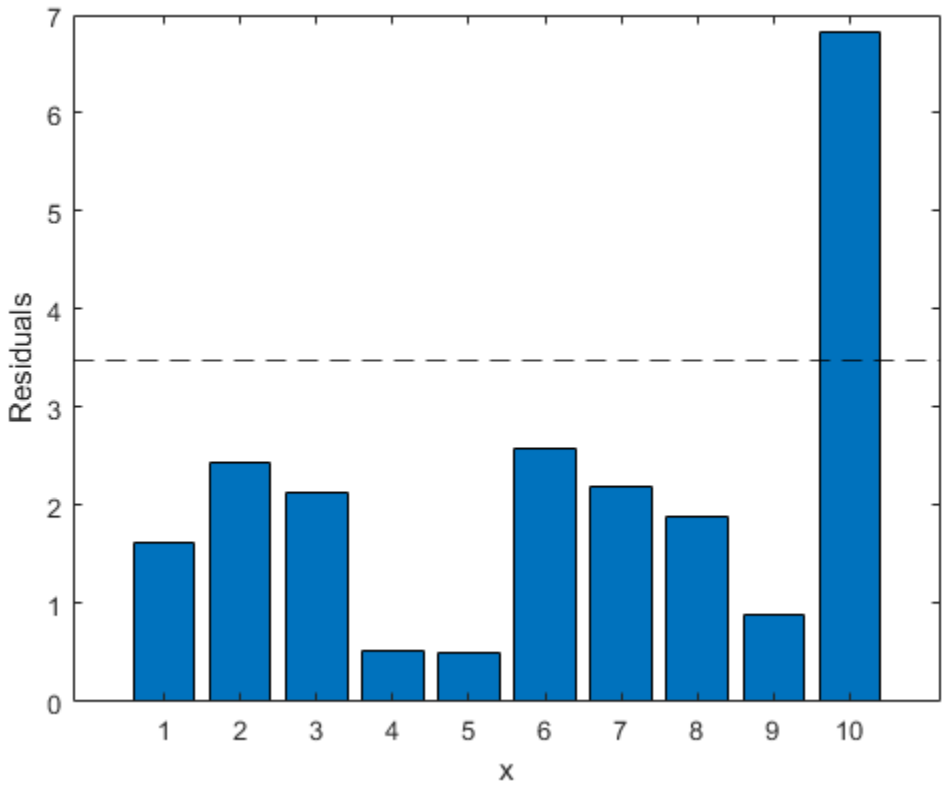
    8.4504
   -1.5278
```

Identify potential outliers by comparing the residuals to the median absolute deviation of the residuals.

```
outliers_ind = find(abs(stats.resid)>stats.mad_s);
```

Plot a bar graph of the residuals for robust regression.

```
bar(abs(stats.resid))
hold on
yline(stats.mad_s,'k--')
hold off
xlabel('x')
ylabel('Residuals')
```



Create a scatter plot of the data.

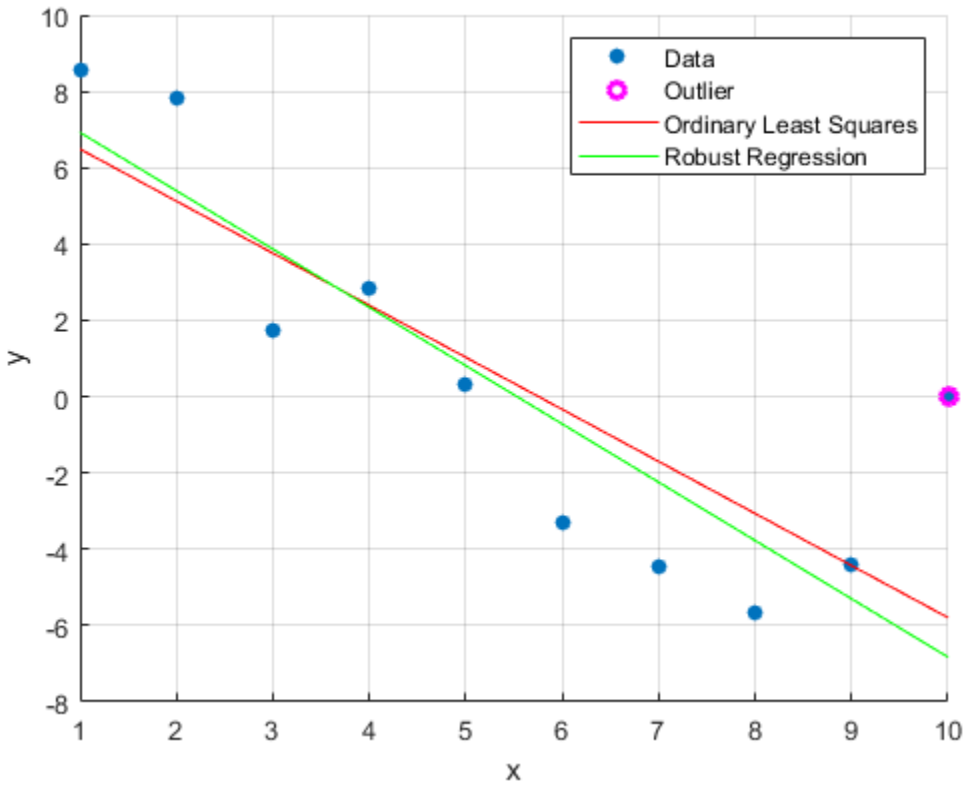
```
scatter(x,y,'filled')
```

Plot the outlier.

```
hold on
plot(x(outliers_ind),y(outliers_ind),'mo','LineWidth',2)
```

Plot the least-squares and robust fit.

```
plot(x,bls(1)+bls(2)*x,'r')
plot(x,brob(1)+brob(2)*x,'g')
hold off
xlabel('x')
ylabel('y')
legend('Data','Outlier','Ordinary Least Squares','Robust Regression')
grid on
```



The outlier influences the robust fit less than the least-squares fit.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix. Rows of X correspond to observations, and columns correspond to predictor variables. X must have the same number of rows as y.

By default, `robustfit` adds a constant term to the model, unless you explicitly remove it by specifying `const` as `'off'`. So, do not include a column of 1s in X.

Data Types: `single` | `double`

y — Response data

numeric vector

Response data, specified as an *n*-by-1 numeric vector. Rows of y correspond to different observations. y must have the same number of rows as X.

Data Types: `single` | `double`

wfun — Robust fitting weight function

`'bisquare'` (default) | `'andrews'` | `'cauchy'` | `'fair'` | function handle | ...

Robust fitting weight function, specified as the name of a weight function described in the following table, or a function handle. `robustfit` uses the corresponding default tuning constant, unless otherwise specified by `tune`.

Weight Function	Description	Default Tuning Constant
`'andrews'`	`w = (abs(r)<pi) .* sin(r) ./ r`	1.339
`'bisquare'`	`w = (abs(r)<1) .* (1 - r.^2).^2` (also called biweight)	4.685
`'cauchy'`	`w = 1 ./ (1 + r.^2)`	2.385
`'fair'`	`w = 1 ./ (1 + abs(r))`	1.400
`'huber'`	`w = 1 ./ max(1, abs(r))`	1.345
`'logistic'`	`w = tanh(r) ./ r`	1.205
`'ols'`	Ordinary least squares (no weighting function)	None
`'talwar'`	`w = 1 * (abs(r)<1)`	2.795
`'welsch'`	`w = exp(-(r.^2))`	2.985
function handle	Custom weight function that accepts a vector `r` of scaled residuals, and returns a vector of weights the same size as `r`	1

The value *r* in the weight functions is

`r = resid/(tune*s*sqrt(1–h))`,

where

- `resid` is the vector of residuals from the previous iteration.
- `tune` is the tuning constant.
- `h` is the vector of leverage values from a least-squares fit.
- `s` is an estimate of the standard deviation of the error term given by `s = MAD/0.6745`.

`MAD` is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If `X` has *p* columns, the software excludes the smallest *p* absolute deviations when computing the median.

Data Types: `char` | `string` | `function handle`

`tune` — Tuning constant
positive scalar

Tuning constant, specified as a positive scalar. If you do not set `tune`, `robustfit` uses the corresponding default tuning constant for each weight function (see the table in `wfun`).

The default tuning constants of built-in weight functions give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided that the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

Data Types: `single` | `double`

`const` — Indicator for constant term

`'on'` (default) | `'off'`

Indicator for a constant term in the fit, specified as `'on'` or `'off'`. If `const` is `'on'`, then `robustfit` adds a first column of 1s to the predictor matrix `X`, and the output `b` becomes a (p + 1)-by-1 vector. If `const` is `'off'`, then `X` remains unchanged and `b` is a p-by-1 vector.

Data Types: `char` | `string`

Output Arguments

`b` — Coefficient estimates for robust multiple linear regression

numeric vector

Coefficient estimates for robust multiple linear regression, returned as a numeric vector. `b` is a p-by-1 vector, where p is the number of predictors in `X`.

By default, `robustfit` adds a constant term to the model, unless you explicitly remove it by specifying `const` as `'off'`.

`stats` — Model statistics

structure

Model statistics, returned as a structure. The following table describes the fields of the diagnostic statistics structure from the robust regression.

Field	Description
`ols_s`	Sigma estimate (root mean squared error) from ordinary least squares
`robust_s`	Robust estimate of sigma
`mad_s`	Estimate of sigma computed using the median absolute deviation of the residuals from their median; used for scaling residuals during iterative fitting
`s`	Final estimate of sigma, the largest between `robust_s` and a weighted average of `ols_s` and `robust_s`
`resid`	Residuals, observed minus fitted values (see “Raw Residuals” on page 11-80)
`rstud`	Studentized residuals, the residuals divided by an independent estimate of the residual standard deviation (see “Studentized Residuals” on page 11-80)
`se`	Standard error of the estimated coefficient value `b`
`covb`	Estimated covariance matrix for coefficient estimates
`coeffcorr`	Estimated correlation of coefficient estimates
`t`	t-statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that `t = b/se`.
`p`	p-values for the t-statistic of the hypothesis test that the corresponding coefficient is equal to zero or not
`w`	Vector of weights for a robust fit
`R`	R factor in the QR decomposition of `X`

Field	Description
dfe	Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients
h	Vector of leverage values for a least-squares fit

More About

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the ith diagonal term h_{ii} of the hat matrix H. The hat matrix H is defined in terms of the data matrix X:

$$H = X(X^TX)^{-1}X^T.$$

The hat matrix is also known as the *projection matrix* because it projects the vector of observations y onto the vector of predictions $\widehat{y}$, thus putting the "hat" on y.

Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n, where n is the number of observations.

For more details, see “Hat Matrix and Leverage” on page 11-77.

Tips

- `robustfit` treats `NaN` values in `X` or `y` as missing values. `robustfit` omits observations with missing values from the robust fit.

Algorithms

- `robustfit` uses iteratively reweighted least squares to compute the coefficients `b`. The input `wfun` specifies the weights.
- `robustfit` estimates the variance-covariance matrix of the coefficient estimates `stats.covb` using the formula `inv(X'*X)*stats.s^2`. This estimate produces the standard error `stats.se` and correlation `stats.coeffcorr`.
- In a linear model, observed values of `y` and their residuals are random variables. Residuals have normal distributions with zero mean but with different variances at different values of the predictors. To put residuals on a comparable scale, `robustfit` “Studentizes” the residuals. That is, `robustfit` divides the residuals by an estimate of their standard deviation that is independent of their value. Studentized residuals have t-distributions with known degrees of freedom. `robustfit` returns the Studentized residuals in `stats.rstud`.

Alternative Functionality

`robustfit` is useful when you simply need the output arguments of the function or when you want to repeat fitting a model multiple times in a loop. If you need to investigate a robust fitted regression model further, create a linear regression model object `LinearModel` by using `fitlm`. Set the value for the name-value pair argument `'RobustOpts'` to `'on'`.

Topics

“What Is a Linear Regression Model?” on page 11-6
“Reduce Outlier Effects Using Robust Regression” on page 11-104

Introduced before R2006a

rotatefactors

Rotate factor loadings

Syntax

```
B = rotatefactors(A)
B = rotatefactors(A,'Method','orthomax','Coeff',gamma)
B = rotatefactors(A,'Method','procrustes','Target',target)
B = rotatefactors(A,'Method','pattern','Target',target)
B = rotatefactors(A,'Method','promax')
[B,T] = rotatefactors(A,...)
```

Description

`B = rotatefactors(A)` rotates the *d*-by-*m* loadings matrix `A` to maximize the varimax criterion, and returns the result in `B`. Rows of `A` and `B` correspond to variables and columns correspond to factors, for example, the (*i*, *j*)th element of `A` is the coefficient for the *i* th variable on the *j* th factor. The matrix `A` usually contains principal component coefficients created with `pca` or `pcacov`, or factor loadings estimated with `factoran`.

`B = rotatefactors(A,'Method','orthomax','Coeff',gamma)` rotates `A` to maximize the orthomax criterion with the coefficient `gamma`, i.e., `B` is the orthogonal rotation of `A` that maximizes

```
sum(D*sum(B.^4,1) - GAMMA*sum(B.^2,1).^2)
```

The default value of 1 for `gamma` corresponds to varimax rotation. Other possibilities include `gamma` = 0, *m*/2, and *d*(*m* - 1)/(*d* + *m* - 2), corresponding to quartimax, equamax, and parsimax. You can also supply `'varimax'`, `'quartimax'`, `'equamax'`, or `'parsimax'` for the `'method'` parameter and omit the `'Coeff'` parameter.

If `'Method'` is `'orthomax'`, `'varimax'`, `'quartimax'`, `'equamax'`, or `'parsimax'`, then additional parameters are

- `'Normalize'` — Flag indicating whether the loadings matrix should be row-normalized for rotation. If `'on'` (the default), rows of `A` are normalized prior to rotation to have unit Euclidean norm, and unnormalized after rotation. If `'off'`, the raw loadings are rotated and returned.
- `'Reltol'` — Relative convergence tolerance in the iterative algorithm used to find `T`. The default is `sqrt(eps)`.
- `'Maxit'` — Iteration limit in the iterative algorithm used to find `T`. The default is `250`.

`B = rotatefactors(A,'Method','procrustes','Target',target)` performs an oblique procrustes rotation of `A` to the *d*-by-*m* target loadings matrix `target`.

`B = rotatefactors(A,'Method','pattern','Target',target)` performs an oblique rotation of the loadings matrix `A` to the *d*-by-*m* target pattern matrix `target`, and returns the result in `B`. `target` defines the "restricted" elements of `B`, i.e., elements of `B` corresponding to zero elements of `target` are constrained to have small magnitude, while elements of `B` corresponding to nonzero elements of `target` are allowed to take on any magnitude.

If `'Method'` is `'procrustes'` or `'pattern'`, an additional parameter is `'Type'`, the type of rotation. If `'Type'` is `'orthogonal'`, the rotation is orthogonal, and the factors remain

uncorrelated. If `'Type'` is `'oblique'` (the default), the rotation is oblique, and the rotated factors might be correlated.

When `'Method'` is `'pattern'`, there are restrictions on `target`. If `A` has *m* columns, then for orthogonal rotation, the *j*th column of `target` must contain at least *m* - *j* zeros. For oblique rotation, each column of `target` must contain at least *m* - 1 zeros.

`B = rotatefactors(A,'Method','promax')` rotates A to maximize the promax criterion, equivalent to an oblique Procrustes rotation with a target created by an orthomax rotation. Use the four orthomax parameters to control the orthomax rotation used internally by promax.

An additional parameter for 'promax' is `'Power'`, the exponent for creating promax target matrix. `'Power'` must be `1` or greater. The default is `4`.

`[B,T] = rotatefactors(A,...)` returns the rotation matrix `T` used to create `B`, that is, `B = A*T`. You can find the correlation matrix of the rotated factors by using `inv(T'*T)`. For orthogonal rotation, this is the identity matrix, while for oblique rotation, it has unit diagonal elements but nonzero off-diagonal elements.

Examples

```
rng('default') % for reproducibility
X = randn(100,10);

% Default (normalized varimax) rotation:
% first three principal components.
LPC = pca(X);
[L1,T] = rotatefactors(LPC(:,1:3));

% Equamax rotation:
% first three principal components.
[L2,T] = rotatefactors(LPC(:,1:3),...
                       'method','equamax');

% Promax rotation:
% first three factors.
LFA = factoran(X,3,'Rotate','none');
[L3,T] = rotatefactors(LFA(:,1:3),...
                       'method','promax',...
                       'power',2);

% Pattern rotation:
% first three factors.
Tgt = [1 1 1 1 1 0 1 0 1 1; ...
       0 0 0 1 1 1 0 0 0 0; ...
       1 0 0 1 0 1 1 1 1 0]';
[L4,T] = rotatefactors(LFA(:,1:3),...
                       'method','pattern',...
                       'target',Tgt);
inv(T'*T) % Correlation matrix of the rotated factors
ans =

    1.0000   -0.9593   -0.7098
   -0.9593    1.0000    0.5938
   -0.7098    0.5938    1.0000
```

Introduced before R2006a

rowexch

Row exchange

Syntax

```
dRE = rowexch(nfactors,nruns)
[dRE,X] = rowexch(nfactors,nruns)
[dRE,X] = rowexch(nfactors,nruns,model)
[dRE,X] = rowexch(...,param1,val1,param2,val2,...)
```

Description

`dRE = rowexch(nfactors,nruns)` uses a row-exchange algorithm to generate a *D*-optimal design `dRE` with `nruns` runs (the rows of `dRE`) for a linear additive model with `nfactors` factors (the columns of `dRE`). The model includes a constant term.

`[dRE,X] = rowexch(nfactors,nruns)` also returns the associated design matrix `X`, whose columns are the model terms evaluated at each treatment (row) of `dRE`.

`[dRE,X] = rowexch(nfactors,nruns,model)` uses the linear regression model specified in `model`. `model` is one of the following:

- `'linear'` — Constant and linear terms. This is the default.
- `'interaction'` — Constant, linear, and interaction terms
- `'quadratic'` — Constant, linear, interaction, and squared terms
- `'purequadratic'` — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with *n* terms is:

1. The constant term
2. The linear terms in order 1, 2, ..., *n*
3. The interaction terms in order (1, 2), (1, 3), ..., (1, *n*), (2, 3), ..., (*n*–1, *n*)
4. The squared terms in order 1, 2, ..., *n*

Other models use a subset of these terms, in the same order.

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each factor and one row for each term in the model. The entries in any row of `model` are powers for the factors in the columns. For example, if a model has factors `X1`, `X2`, and `X3`, then a row `[0 1 2]` in `model` specifies the term `(X1.^0).*(X2.^1).*(X3.^2)`. A row of all zeros in `model` specifies a constant term, which can be omitted.

`[dRE,X] = rowexch(...,param1,val1,param2,val2,...)` specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

Parameter	Value
'bounds'	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
'categorical'	Indices of categorical predictors.
'display'	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
'excludefun'	Handle to a function that excludes undesirable runs. If the function is *f*, it must support the syntax $b = f(S)$, where S is a matrix of treatments with nfactors columns and b is a vector of Boolean values with the same number of rows as S. $b(i)$ is true if the ith row S should be excluded.
'init'	Initial design as an nruns-by-nfactors matrix. The default is a randomly selected set of points.
'levels'	Vector of number of levels for each factor.
'maxiter'	Maximum number of iterations. The default is 10.

options	A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the options structure with statset. This option requires Parallel Computing Toolbox. Option fields are:
	• UseParallel — Set to true to compute in parallel. Default is false.
	• UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
	• Streams — A RandStream object or cell array of such objects. If you do not specify Streams, rowexch uses the default stream or streams. If you choose to specify Streams, use a single object except in the case
	  • UseParallel is true
	  • UseSubstreams is false
	  In that case, use a cell array the same size as the Parallel pool.

'tries'	Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.

Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_{12} x_1 x_2 + \beta_{13} x_1 x_3 + \beta_{23} x_2 x_3 + \varepsilon$$

Use rowexch to generate a *D*-optimal design with seven runs:

```
nfactors = 3;
nruns = 7;
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
dRE =
```

```
    -1    -1     1
     1    -1     1
     1    -1    -1
     1     1     1
    -1    -1    -1
    -1     1    -1
    -1     1     1
X =
     1    -1    -1     1     1    -1    -1
     1     1    -1     1    -1     1    -1
     1     1    -1    -1    -1    -1     1
     1     1     1     1     1     1     1
     1    -1    -1    -1     1     1     1
     1    -1     1    -1    -1     1    -1
     1    -1     1     1    -1    -1     1
```

Columns of the design matrix `X` are the model terms evaluated at each row of the design `dRE`. The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use `X` to fit the model, as described in “Linear Regression” on page 11-9, to response data measured at the design points in `dRE`.

Algorithms

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^TX|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D-optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a `'tries'` parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of X with a row from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly. In either case, if C is large, its static presence in memory can affect computation.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

rsmdemo

Interactive response surface demonstration

Syntax

```
rsmdemo
```

Description

`rsmdemo` opens a group of three graphical user interfaces for interactively investigating response surface methodology (RSM), nonlinear fitting, and the design of experiments.

The interfaces allow you to collect and model data from a simulated chemical reaction. Experimental predictors are concentrations of three reactants (hydrogen, *n*-pentane, and isopentane) and the response is the reaction rate. The reaction rate is simulated by a Hougen-Watson model (Bates and Watts, [2] on page C-2, pp. 271–272):

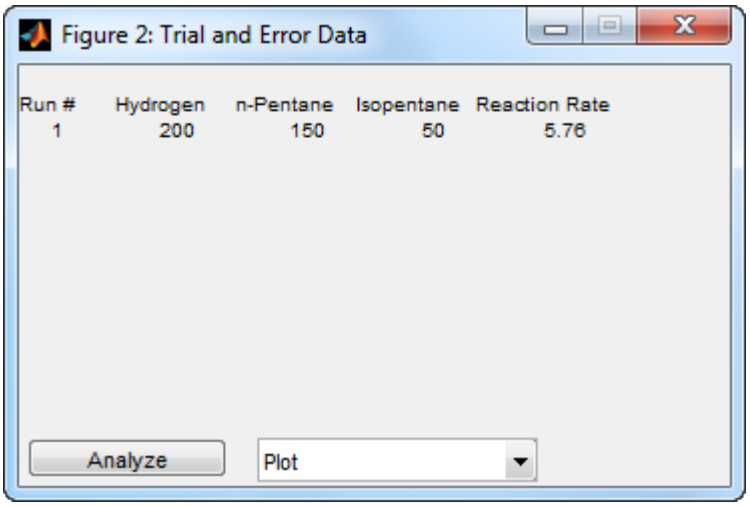
$$rate = \frac{\beta_1 x_2 - x_3/\beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

where *rate* is the reaction rate, x_1, x_2, and x_3 are the concentrations of hydrogen, *n*-pentane, and isopentane, respectively, and β_1, β_2, ... , β_5 are fixed parameters. Random errors are used to perturb the reaction rate for each combination of reactants.

Collect data using one of two methods:

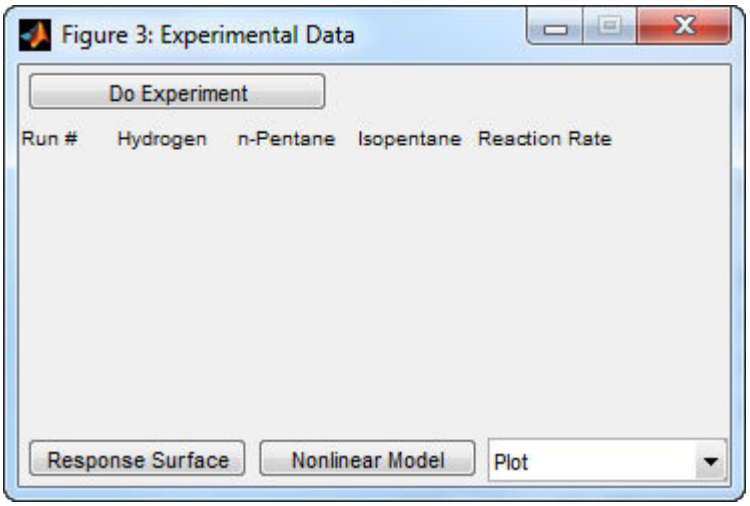
1. Manually set reactant concentrations in the **Reaction Simulator** interface by editing the text boxes or by adjusting the associated sliders.

   When you click **Run**, the concentrations and simulated reaction rate are recorded on the **Trial and Error Data** interface.

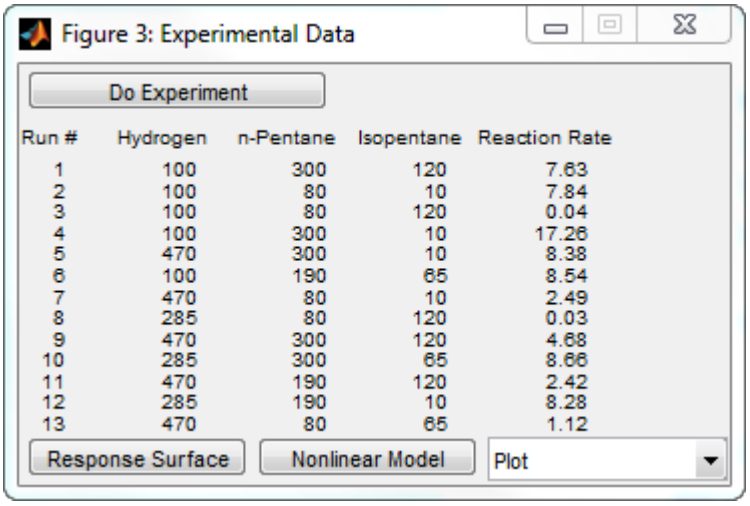


You are allowed up to 13 independent experimental runs for data collection.

2 Use a designed experiment to set reactant concentrations in the **Experimental Data** interface by clicking the **Do Experiment** button.



A 13-run *D*-optimal design for a full quadratic model is generated by the `cordexch` function, and the concentrations and simulated reaction rates are recorded on the same interface.



Once data is collected, scatter plots of reaction rates vs. individual predictors are generated by selecting one of the following from the **Plot** pop-up menu below the recorded data:

- **Hydrogen vs. Rate**
- **n-Pentane vs. Rate**
- **Isopentane vs. Rate**

Fit a response surface model to the data by clicking the **Analyze** button below the trial-and-error data or the **Response Surface** button below the experimental data. Both buttons load the data into the Response Surface Tool `rstool`. By default, trial-and-error data is fit with a linear additive model and experimental data is fit with a full quadratic model, but the models can be adjusted in the Response Surface Tool.

For experimental data, you have the additional option of fitting a Hougen-Watson model. Click the **Nonlinear Model** button to load the data and the model in `hougen` into the Nonlinear Fitting Tool `nlintool`.

`cordexch` | `hougen` | `nlintool` | `rstool`

Introduced before R2006a

rstool

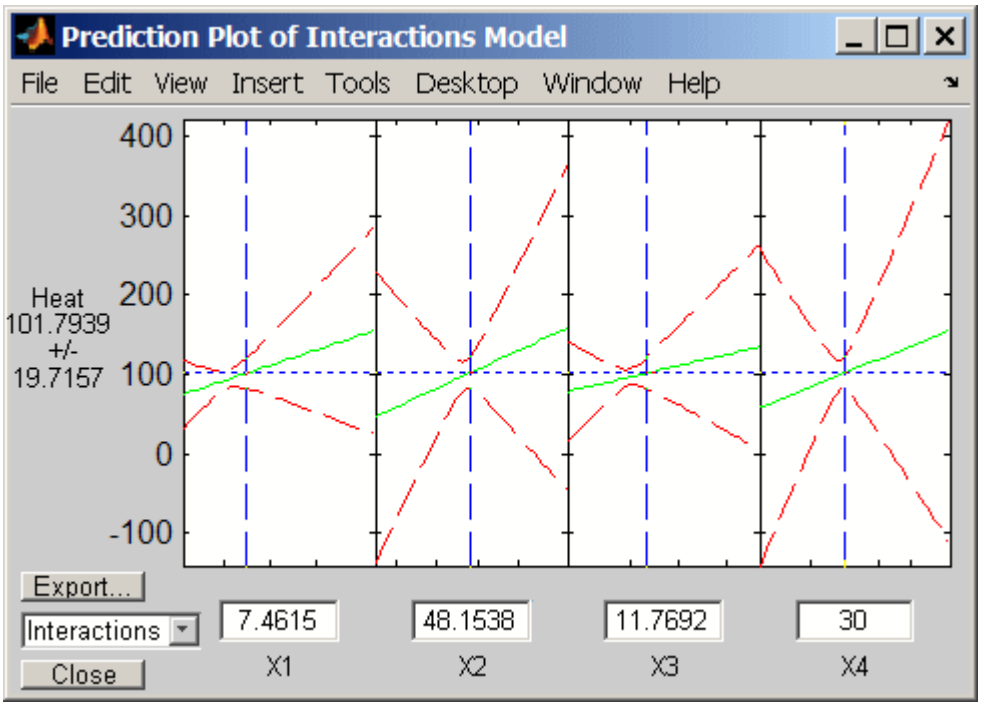
Interactive response surface modeling

Syntax

```
rstool
rstool(X,Y,model)
rstool(x,y,model,alpha)
rstool(x,y,model,alpha,xname,yname)
```

Description

`rstool` opens a graphical user interface for interactively investigating one-dimensional contours of multidimensional response surface models.



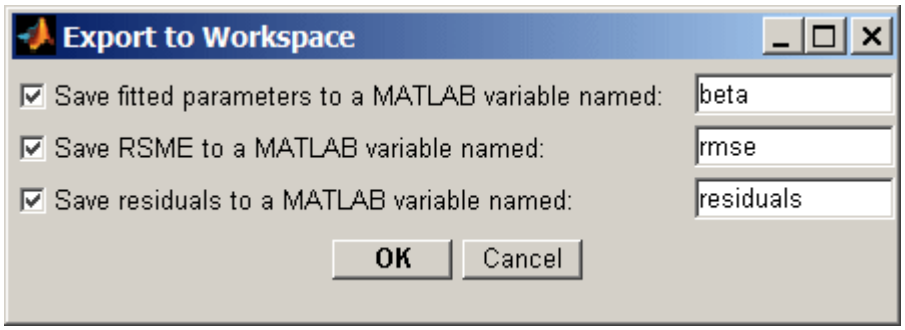
By default, the interface opens with the data from `hald.mat` and a fitted response surface with constant, linear, and interaction terms.

A sequence of plots is displayed, each showing a contour of the response surface against a single predictor, with all other predictors held fixed. `rstool` plots a 95% simultaneous confidence band for the fitted response surface as two red curves. Predictor values are displayed in the text boxes on the horizontal axis and are marked by vertical dashed blue lines in the plots. Predictor values are changed by editing the text boxes or by dragging the dashed blue lines. When you change the value of a predictor, all plots update to show the new point in predictor space.

The pop-up menu at the lower left of the interface allows you to choose among the following models:

- `Linear` — Constant and linear terms (the default)
- `Pure Quadratic` — Constant, linear, and squared terms
- `Interactions` — Constant, linear, and interaction terms
- `Full Quadratic` — Constant, linear, interaction, and squared terms

Click **Export** to open the following dialog box:



The dialog allows you to save information about the fit to MATLAB workspace variables with valid names.

`rstool(X,Y,model)` opens the interface with the predictor data in `X`, the response data in `Y`, and the fitted model `model`. Distinct predictor variables should appear in different columns of `X`. `Y` can be a vector, corresponding to a single response, or a matrix, with columns corresponding to multiple responses. `Y` must have as many elements (or rows, if it is a matrix) as `X` has rows.

The optional input `model` can be any one of the following:

- `'linear'` — Constant and linear terms (the default)
- `'purequadratic'` — Constant, linear, and squared terms
- `'interaction'` — Constant, linear, and interaction terms
- `'quadratic'` — Constant, linear, interaction, and squared terms

To specify a polynomial model of arbitrary order, or a model without a constant term, use a matrix for `model` as described in `x2fx`.

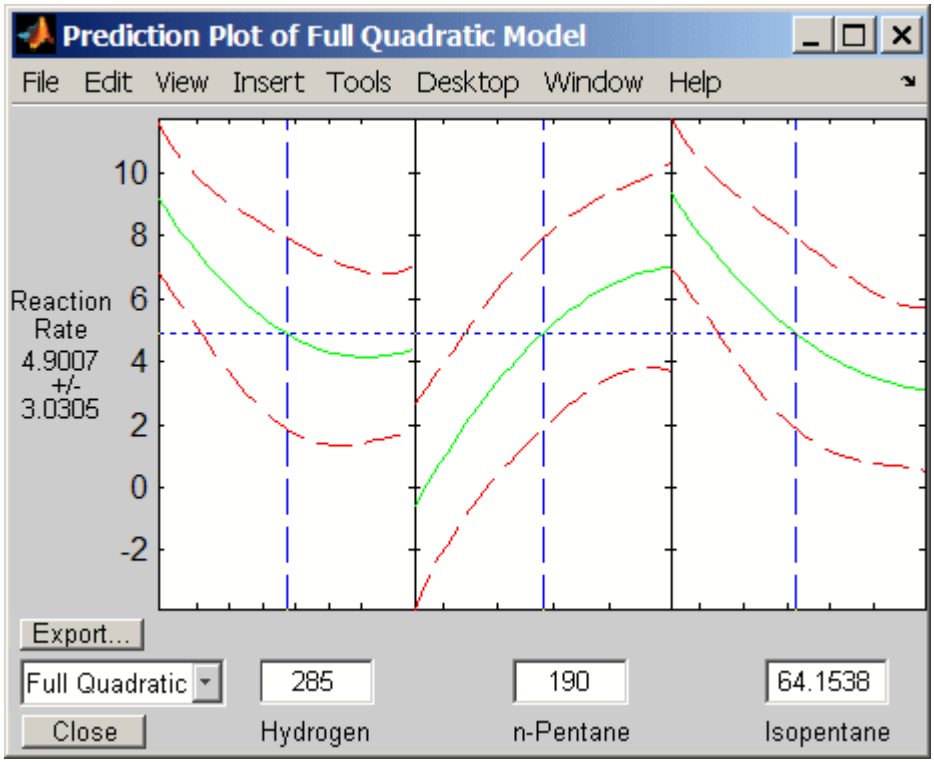
`rstool(x,y,model,alpha)` uses `100(1-alpha)`% global confidence intervals for new observations in the plots.

`rstool(x,y,model,alpha,xname,yname)` labels the axes using `xname` and `yname`. To label each subplot differently, `xname` and `yname` can be string arrays or cell arrays of character vectors.

Examples

The following uses `rstool` to visualize a quadratic response surface model of the 3-D chemical reaction data in `reaction.mat`:

```
load reaction
alpha = 0.01; % Significance level
rstool(reactants,rate,'quadratic',alpha,xn,yn)
```



The `rstool` interface is used by `rsmdemo` to visualize the results of simulated experiments with data like that in `reaction.mat`. As described in “Response Surface Designs” on page 28-8, `rsmdemo` uses a response surface model to generate simulated data at combinations of predictors specified by either the user or by a designed experiment.

Introduced before R2006a

runstest

Run test for randomness

Syntax

```
h = runstest(x)
h = runstest(x,v)
h = runstest(x,'ud')
h = runstest( ___ ,Name,Value)
[h,p,stats] = runstest( ___ )
```

Description

`h = runstest(x)` returns a test decision for the null hypothesis that the values in the data vector `x` come in random order, against the alternative that they do not. The test is based on the number of runs of consecutive values above or below the mean of `x`. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`h = runstest(x,v)` returns a test decision based on the number of runs of consecutive values above or below the specified reference value `v`. Values exactly equal to `v` are discarded.

`h = runstest(x,'ud')` returns a test decision based on the number of runs up or down. Too few runs indicate a trend, while too many runs indicate an oscillation. Values exactly equal to the preceding value are discarded.

`h = runstest( ___ ,Name,Value)` returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test, specify the algorithm used to calculate the *p*-value, or conduct a one-sided test.

`[h,p,stats] = runstest( ___ )` also returns the *p*-value of the test `p`, and a structure `stats` containing additional data about the test.

Examples

Test Data for Randomness Using Sample Median

Generate a vector of 40 random numbers from a standard normal distribution.

```
rng default;  % for reproducibility
x = randn(40,1);
```

Test whether the values in `x` appear in random order, using the sample median as the reference value.

```
[h,p] = runstest(x,median(x))
```

```
h = 0
```

```
p = 0.8762
```

The returned value of `h = 0` indicates that `runstest` does not reject the null hypothesis that the values in `x` are in random order at the default 5% significance level.

Input Arguments

`x` — Data vector

vector of scalar values

Data vector, specified as a vector of scalar values. `runstest` treats `NaN` values in `x` as missing values, and ignores them.

Data Types: `single` | `double`

`v` — Reference value

mean of `x` (default) | scalar value

Reference value, specified as a scalar value. If you specify a value for `v`, then `runstest` performs the hypothesis test based on the number of runs of consecutive values above or below `v`. `runstest` discards values exactly equal to `v`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'Method','Approximate','Tail','right'` specifies a right-tailed test with 1% significance level, which returns the approximate p-value.

`Alpha` — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`Method` — Method used to compute *p*-value

`'exact'` | `'approximate'`

Method used to compute *p*-value, specified as the comma-separated pair consisting of `'Method'` and either `'exact'` to use an exact algorithm, or `'approximate'` to use a normal approximation. The default is `'exact'` for runs above/below, and for runs up/down when the length of `x` is less than or equal to 50. If `runstest` tests for runs up/down and the length of `x` is greater than 50, then the default is `'approximate'`, and the `'exact'` method is not available.

Example: `'Method','approximate'`

`Tail` — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

`'both'`	Two-tailed test (sequence is not random)
`'right'`	Right-tailed test (like values separate for runs above/below, direction alternates for runs up/down)
`'left'`	Left-tailed test (like values cluster for runs above/below, values trend for runs up/down)

Example: `'Tail','right'`

Output Arguments

`h` — Hypothesis test result

`1` | `0`

Hypothesis test result, returned as `1` or `0`.

- If `h = 1`, then `runstest` rejects the null hypothesis at the `Alpha` significance level.
- If `h = 0`, then `runstest` fails to reject the null hypothesis at the `Alpha` significance level.

The result in `runstest` is based on the number of runs of consecutive values above or below the mean of `x`. Too few runs indicate a tendency for high and low values to cluster. Too many runs indicate a tendency for high and low values to alternate.

`runstest` uses a test statistic which is the difference between the number of runs and its mean, divided by its standard deviation. The test statistic is approximately normally distributed when the null hypothesis is true.

`p` — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. `p` is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of `p` cast doubt on the validity of the null hypothesis.

`p` is computed from either the test statistic or the exact distribution of the number of runs, depending on the value specified for the `'Method'` name-value pair argument.

`stats` — Test data

structure

Test data, returned as a structure with the following fields.

- `nruns` — The number of runs
- `n1` — The number of values above `v`
- `n0` — The number of values below `v`
- `z` — The test statistic

`signrank` | `signtest`

Introduced before R2006a

sampsizepwr

Sample size and power of test

Syntax

```
nout = sampsizepwr(testtype,p0,p1)
nout = sampsizepwr(testtype,p0,p1,pwr)

pwrout = sampsizepwr(testtype,p0,p1,[],n)

p1out = sampsizepwr(testtype,p0,[],pwr,n)

___ = sampsizepwr(testtype,p0,p1,pwr,n,Name,Value)
```

Description

`sampsizepwr` computes the sample size, power, or alternative parameter value for a hypothesis test, given the other two values. For example, you can compute the sample size required to obtain a particular power for a hypothesis test, given the parameter value of the alternative hypothesis.

`nout = sampsizepwr(testtype,p0,p1)` returns the sample size, `nout`, required for a two-sided test of the type specified by `testtype` to have a power (probability of rejecting the null hypothesis when the alternative hypothesis is true) of 0.90 when the significance level (probability of rejecting the null hypothesis when the null hypothesis is true) is 0.05. `p0` specifies parameter values under the null hypothesis. `p1` specifies the value, or an array of values, of the single parameter being tested under the alternative hypothesis.

`nout = sampsizepwr(testtype,p0,p1,pwr)` returns the sample size, `nout`, that corresponds to the specified power, `pwr`, and the parameter value under the alternative hypothesis, `p1`.

`pwrout = sampsizepwr(testtype,p0,p1,[],n)` returns the power achieved for a sample size of `n` when the true parameter value is `p1`.

`p1out = sampsizepwr(testtype,p0,[],pwr,n)` returns the parameter value detectable with the specified sample size, `n`, and the specified power, `pwr`.

`___ = sampsizepwr(testtype,p0,p1,pwr,n,Name,Value)` returns any of the previous arguments using one or more name-value pair arguments. For example, you can change the significance level of the test, or specify a right- or left-tailed test. The name-value pairs can appear in any order but must begin in the sixth argument position.

Examples

Compute Sample Size for Selected Power Value

A company runs a manufacturing process that fills empty bottles with 100 mL of liquid. To monitor quality, the company randomly selects several bottles and measures the volume of liquid inside.

Determine the sample size the company must use for a *t*-test to detect a difference between 100 mL and 102 mL with a power of 0.80. Assume that a standard deviation is 5 mL.

```
nout = sampsizepwr('t',[100 5],102,0.80)
```

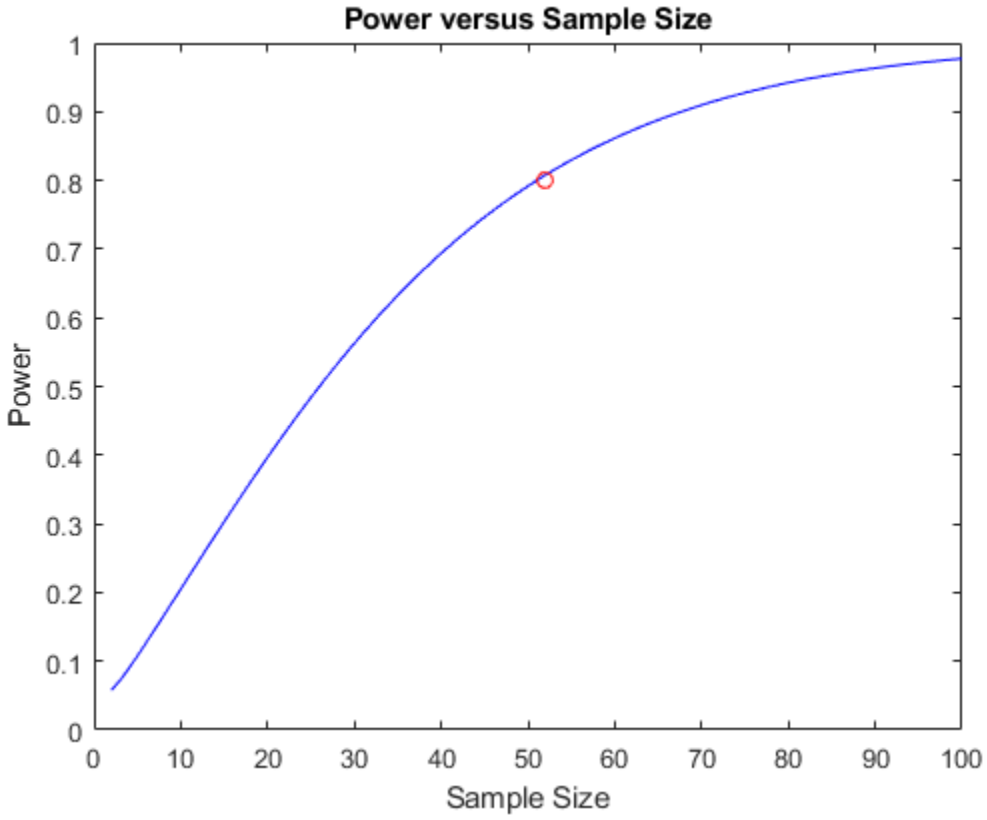
```
nout = 52
```

The company must test 52 bottles to detect the difference between a mean volume of 100 mL and 102 mL with a power of 0.80.

Generate a power curve to visualize how the sample size affects the power of the test.

```
nn = 1:100;
pwrout = sampsizepwr('t',[100 5],102,[],nn);

figure;
plot(nn,pwrout,'b-',nout,0.8,'ro')
title('Power versus Sample Size')
xlabel('Sample Size')
ylabel('Power')
```



Compute Power and Sample Size for One-Sided Test

An employee wants to buy a house near her office. She decides to eliminate from consideration any house that has a mean morning commute time greater than 20 minutes. The null hypothesis for this

right-sided test is H0: $\mu = 20$, and the alternative hypothesis is HA: $\mu > 20$. The selected significance level is 0.05.

To determine the mean commute time, the employee takes a test drive from the house to her office during rush hour every morning for one week, so her total sample size is 5. She assumes that the standard deviation, σ, is equal to 5.

The employee decides that a true mean commute time of 25 minutes is too different from her targeted 20-minute limit, so she wants to detect a significant departure if the true mean is 25 minutes. Find the probability of incorrectly concluding that the mean commute time is no greater than 20 minutes.

Compute the power of the test, and then subtract the power from 1 to obtain β.

```
power = sampsizepwr('t',[20 5],25,[],5,'Tail','right');
beta = 1 - power
```

```
beta = 0.4203
```

The β value indicates a probability of 0.4203 that the employee concludes incorrectly that the morning commute is not greater than 20 minutes.

The employee decides that this risk is too high, and she wants no more than a 0.01 probability of reaching an incorrect conclusion. Calculate the number of test drives the employee must take to obtain a power of 0.99.

```
nout = sampsizepwr('t',[20 5],25,0.99,[],'Tail','right')
```

```
nout = 18
```

The results indicate that she must take 18 test drives from a candidate house to achieve this power level.

The employee decides that she only has time to take 10 test drives. She also accepts a 0.05 probability of making an incorrect conclusion. Calculate the smallest true parameter value that produces a detectable difference in mean commute time.

```
p1out = sampsizepwr('t',[20 5],[],0.95,10,'Tail','right')
```

```
p1out = 25.6532
```

Given the employee's target power level and sample size, her test detects a significant difference from a mean commute time of at least 25.6532 minutes.

Compute Sample Size for a Binomial Test

Compute the sample size, n, required to distinguish $p = 0.30$ from $p = 0.36$, using a binomial test with a power of 0.8.

```
napprox = sampsizepwr('p',0.30,0.36,0.8)
```

```
Warning: Values N>200 are approximate.  Plotting the power as a function
of N may reveal lower N values that have the required power.

napprox = 485
```

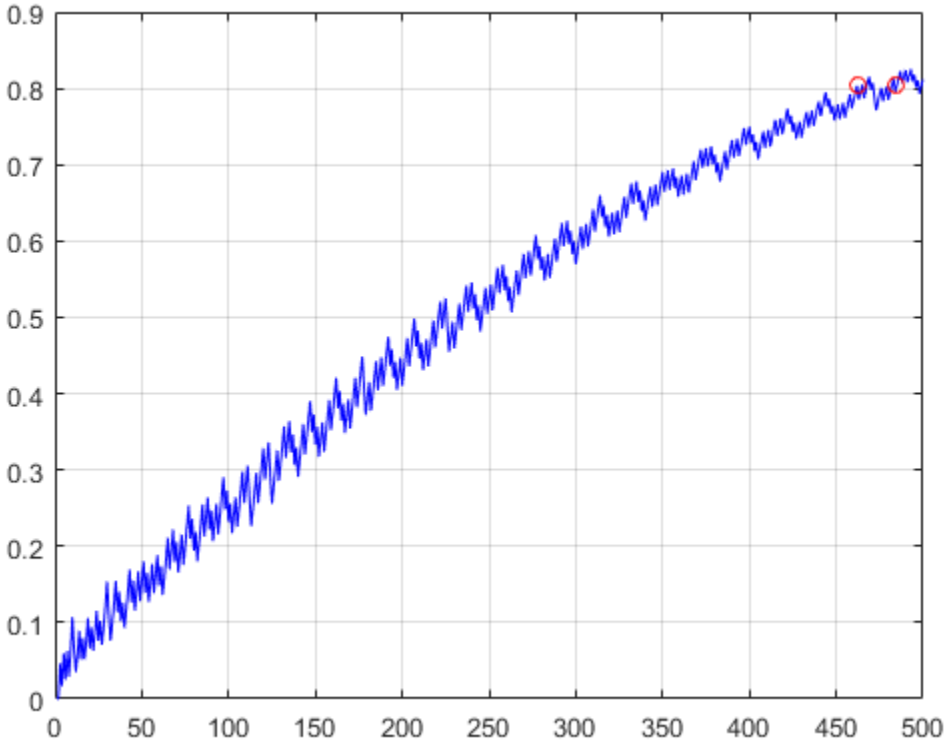
The result indicates that a power of 0.8 requires a sample size of 485. However, this result is approximate.

Make a plot to see if any smaller *n* values provide the required power of 0.8.

```
nn = 1:500;
pwrout = sampsizepwr('p',0.3,0.36,[],nn);
nexact = min(nn(pwrout>=0.8))
```

```
nexact = 462
```

```
figure
plot(nn,pwrout,'b-',[napprox nexact],pwrout([napprox nexact]),'ro')
grid on
```



The result indicates that a sample size of 462 also provides a power of 0.8 for this test.

Compute Power for a Two-Sample t-Test

A farmer wants to test the impact of two different types of fertilizer on the yield of his bean crops. He currently uses Fertilizer A, but believes that Fertilizer B might improve crop yield. Because Fertilizer B is more expensive than Fertilizer A, the farmer wants to limit the number of plans he treats with Fertilizer B in this experiment.

The farmer uses a 2:1 ratio of plants in each treatment group. He tests 10 plants with Fertilizer A, and 5 plants with Fertilizer B. The mean yield using Fertilizer A is 1.4 kg per plant, with a standard deviation of 0.2. The mean yield using Fertilizer B is 1.7 kg per plant. The significance level of the test is 0.05.

Compute the power of the test.

```
pwr = sampsizepwr('t2',[1.4 0.2],1.7,[],5,'Ratio',2)
```

```
pwr = 0.7165
```

The farmer wants to increase the power of the test to 0.90. Calculate how many plants he must treat with each type of fertilizer.

```
n = sampsizepwr('t2',[1.4 0.2],1.7,0.9,[])
```

```
n = 11
```

To increase the power of the test to 0.90, the farmer must test 11 plants with each type of fertilizer.

The farmer wants to reduce the number of plants he must treat with Fertilizer B, but keep the power of the test at 0.90 and maintain the initial 2:1 ratio of plants in each treatment group

Using a 2:1 ratio of plants in each treatment group, calculate how many plants the farmer must test to obtain a power of 0.90. Use the mean and standard deviation values obtained in the previous test.

```
[n1out,n2out] = sampsizepwr('t2',[1.4,0.2],1.7,0.9,[],'Ratio',2)
```

```
n1out = 8
```

```
n2out = 16
```

To obtain a power of 0.90, the farmer must treat 16 plants with Fertilizer A and 8 plants with Fertilizer B.

Input Arguments

`testtype` — Test type

`'z'` | `'t'` | `'t2'` | `'var'` | `'p'`

Test type, specified as one of the following.

- `'z'` — *z*-test for normally distributed data with known standard deviation.
- `'t'` — *t*-test for normally distributed data with unknown standard deviation.
- `'t2'` — Two-sample pooled *t*-test for normally distributed data with unknown standard deviation and equal variances.
- `'var'` — Chi-square test of variance for normally distributed data.
- `'p'` — Test of the *p* parameter (success probability) for a binomial distribution. The `'p'` test is a discrete test for which increasing the sample size does not always increase the power. For `n` values larger than 200, there may exist values smaller than the returned `n` value that also produce the specified power.

`p0` — Parameter value under null hypothesis

scalar value | two-element array of scalar values

Parameter value under the null hypothesis, specified as a scalar value or a two-element array of scalar values.

- If `testtype` is `'z'` or `'t'`, then `p0` is a two-element array `[mu0,sigma0]` of the mean and standard deviation, respectively, under the null hypothesis.
- If `testtype` is `'t2'`, then `p0` is a two-element array `[mu0,sigma0]` of the mean and standard deviation, respectively, of the first sample under the null and alternative hypotheses.
- If `testtype` is `'var'`, then `p0` is the variance under the null hypothesis.
- If `testtype` is `'p'`, then `p0` is the value of *p* under the null hypothesis.

Data Types: `single` | `double`

`p1` — Parameter value under alternative hypothesis
scalar value | array of scalar values | `[]`

Parameter value under the alternative hypothesis, specified as a scalar value or as an array of scalar values.

- If `testtype` is `'z'` or `'t'`, then `p1` is the value of the mean under the alternative hypothesis.
- If `testtype` is `'t2'`, then `p1` is the value of the mean of the second sample under the alternative hypothesis.
- If `testtype` is `'var'`, then `p1` is the variance under the alternative hypothesis.
- If `testtype` is `'p'`, then `p1` is the value of *p* under the alternative hypothesis.

If you specify `p1` as an array, then `sampsizepwr` returns an array for `nout` or `pwrout` that is the same length as `p1`.

To return the alternative parameter value, `p1out`, specify `p1` using empty brackets (`[]`), as shown in the syntax description on page 33-5761.

Data Types: `single` | `double`

`pwr` — Power of the test
0.90 (default) | scalar value in the range (0,1) | array of scalar values in the range (0,1) | `[]`

Power of the test, specified as a scalar value in the range (0,1) or as an array of scalar values in the range (0,1). The power of a test is the probability of rejecting the null hypothesis when the alternative hypothesis is true, given a particular significance level.

If you specify `pwr` as an array, then `sampsizepwr` returns an array for `nout` or `p1out` that is the same length as `pwr`.

To return a power value, `pwrout`, specify `pwr` using empty brackets (`[]`), as shown in the syntax description on page 33-5761.

Data Types: `single` | `double`

`n` — Sample size
positive integer value | array of positive integer values

Sample size, specified as a positive integer value or as an array of positive integer values.

If `testtype` is `'t2'`, then `sampsizepwr` assumes that the two sample sizes are equal. For unequal sample sizes, specify `n` as the smaller of the two sample sizes, and use the `'Ratio'` name-value pair

argument to indicate the sample size ratio. For example, if the smaller sample size is 5 and the larger sample size is 10, specify `n` as 5, and the `'Ratio'` name-value pair as 2.

If you specify `n` as an array, then `sampsizepwr` returns an array for `pwrout` or `p1out` that is the same length as `n`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'Tail','right'` specifies a right-tailed test with a 0.01 significance level.

`Alpha` — Significance level
0.05 (default) | scalar value in the range (0,1)

Significance value of the test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

`Ratio` — Sample size ratio
1 (default) | scalar value greater than or equal to 1

Sample size ratio for a two-sample *t*-test, specified as the comma-separated pair consisting of `'Ratio'` and a scalar value greater than or equal to 1. The value of `Ratio` is equal to `n2/n1`, where `n2` is the larger sample size, and `n1` is the smaller sample size.

To return the power, `pwrout`, or alternative parameter value, `p1out`, specify the smaller of the two sample sizes for `n`, and use `'Ratio'` to indicate the sample size ratio.

Example: `'Ratio',2`

`Tail` — Test type
`'both'` (default) | `'right'` | `'left'`

Test type, specified as the comma-separated pair consisting of `'Tail'` and one of the following:

- `'both'` — Two-sided test for an alternative not equal to `p0`
- `'right'` — One-sided test for an alternative larger than `p0`
- `'left'` — One-sided test for an alternative smaller than `p0`

Example: `'Tail','right'`

Output Arguments

`nout` — Sample size
positive integer value | array of positive integer values

Sample size, returned as a positive integer value or as an array of positive integer values.

If `testtype` is `t2`, and you use the `'Ratio'` name-value pair argument to specify the ratio of the two unequal sample sizes, then `nout` returns the smaller of the two sample sizes.

Alternatively, to return both sample sizes, specify this argument as `[n1out,n2out]`. In this case, `sampsizepwr` returns the smaller sample size as `n1out`, and the larger sample size as `n2out`.

If you specify `pwr` or `p1` as an array, then `sampsizepwr` returns an array for `nout` that is the same length as `pwr` or `p1`.

`pwrout` — Power
scalar value in the range (0,1) | array of scalar values in the range (0,1)

Power achieved by the test, returned as a scalar value in the range (0,1) or as an array of scalar values in the range (0,1).

If you specify `n` or `p1` as an array, then `sampsizepwr` returns an array for `pwrout` that is the same length as `n` or `p1`.

`p1out` — Parameter value for the alternative hypothesis
scalar value | array of scalar values

Parameter value for the alternative hypothesis, returned as a scalar value or as an array of scalar values.

When computing `p1out` for the `'p'` test, if no alternative can be rejected for a given null hypothesis and significance level, the function displays a warning message and returns `NaN`.

Introduced in R2006b

saveCompactModel

(To be removed) Save model object in file for code generation

Note `saveCompactModel` will be removed in a future release. Use `saveLearnerForCoder` instead. To update your code, simply replace instances of `saveCompactModel` with `saveLearnerForCoder`.

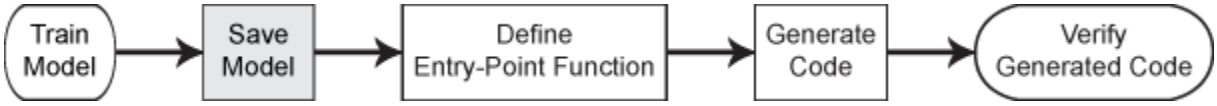
Syntax

```
saveCompactModel(Mdl,filename)
```

Description

To generate C/C++ code for the object functions (`predict`, `random`, `knnsearch`, or `rangesearch`) of machine learning models, use `saveCompactModel`, `loadCompactModel`, and `codegen`. After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls an object function. Then use `codegen` or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use `saveCompactModel` for the highlighted step.



`saveCompactModel(Mdl,filename)` prepares a classification model, regression model, or nearest neighbor searcher (`Mdl`) for code generation and saves it in the MATLAB formatted binary file (MAT-file) named `filename`. You can pass `filename` to `loadCompactModel` to reconstruct the model object from the `filename` file.

Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls the `predict` function of the trained model. Then use `codegen` (MATLAB Coder) to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 32-19.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that `X` and `Y` contain data for two classes only.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `SVMIris.mat` by using `saveCompactModel`.

```
saveCompactModel(Mdl,'SVMIris');
```

```
Warning: saveCompactModel will be removed in a future release. Use <a href="matlab:doc saveLearne
```

Define Entry-Point Function

Define an entry-point function named `classifyIrises` that does the following:

- Accept iris flower measurements with columns corresponding to `meas`, and return predicted labels.
- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

```
type classifyIrises.m % Display contents of classifyIrises.m file
```

```
function label = classifyIrises(X) %#codegen
%CLASSIFYIRISES Classify iris species using SVM Model
%   CLASSIFYIRISES classifies the iris flower measurements in X using the
%   compact SVM model in the file SVMIris.mat, and then returns class
%   labels in label.
CompactMdl = loadCompactModel('SVMIris');
label = predict(CompactMdl,X);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen` (MATLAB Coder). Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point

function at compile time. Pass `X` as the value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof` (MATLAB Coder). For details, see "Specify Variable-Size Arguments for Code Generation" on page 32-45 and "Specify Properties of Entry-Point Function Inputs" (MATLAB Coder).

```
codegen classifyIrises -args {X}
```

```
Code generation successful.
```

`codegen` generates the MEX function `classifyIrises_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIrises`, and `classifyIrises_mex`.

```
label1 = predict(Mdl,X);
label2 = classifyIrises(X);
```

```
Warning: loadCompactModel will be removed in a future release. Use <a href="matlab:doc loadLearne
```

```
label3 = classifyIrises_mex(X);
```

```
Warning: loadCompactModel will be removed in a future release. Use <a href="matlab:doc loadLearne
```

```
verify_label = isequal(label1,label2,label3)
```

```
verify_label = logical
   1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

Input Arguments

`Mdl` — Machine learning model

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in the following tables of supported models.

- **Classification Model Object**

Model	Full/Compact Model Objects	Training Function
Binary decision tree for classification	`ClassificationTree`, `CompactClassificationTree`	`fitctree`
Discriminant analysis classification	`ClassificationDiscriminant`, `CompactClassificationDiscriminant`	`fitcdiscr`
Ensemble classifier	`ClassificationEnsemble`, `CompactClassificationEnsemble`, `ClassificationBaggedEnsemble`	`fitcensemble`
k-nearest neighbor classification	`ClassificationKNN`	`fitcknn`
Linear model for binary classification of high-dimensional data	`ClassificationLinear`	`fitclinear`
Multiclass model for support vector machines (SVMs) or other classifiers	`ClassificationECOC`, `CompactClassificationECOC`	`fitcecoc`
Naive Bayes classifier	`ClassificationNaiveBayes`, `CompactClassificationNaiveBayes`	`fitcnb`
SVM for one-class and binary classification	`ClassificationSVM`, `CompactClassificationSVM`	`fitcsvm`

- **Regression Model Object**

Model	Full/Compact Model Object	Training Function
Ensemble regression	`RegressionEnsemble`, `CompactRegressionEnsemble`, `RegressionBaggedEnsemble`	`fitrensemble`
Gaussian process regression	`RegressionGP`, `CompactRegressionGP`	`fitrgp`
Generalized linear model	`GeneralizedLinearModel`, `CompactGeneralizedLinearModel`	`fitglm`, `stepwiseglm`
Linear regression model	`LinearModel`, `CompactLinearModel`	`fitlm`, `stepwiselm`
Linear regression for high-dimensional data	`RegressionLinear`	`fitrlinear`
Regression tree	`RegressionTree`, `CompactRegressionTree`	`fitrtree`
SVM regression	`RegressionSVM`, `CompactRegressionSVM`	`fitrsvm`

- **Nearest Neighbor Searcher Object**

Model	Model Object	Training Function
Exhaustive nearest neighbor searcher	`ExhaustiveSearcher`	`ExhaustiveSearcher`, `createns`
Nearest neighbor searcher using *K*d-tree	`KDTreeSearcher`	`KDTreeSearcher`, `createns`

`filename` — File name
character vector | string scalar

File name, specified as a character vector or string scalar.

If the `filename` file exists, then `saveCompactModel` overwrites the file.

The extension of the `filename` file must be `.mat`. If `filename` has no extension, then `saveCompactModel` appends `.mat`.

If `filename` does not include a full path, then `saveCompactModel` saves the file to the current folder.

Example: `'SVMMdl'`

Data Types: `char` | `string`

Algorithms

`saveCompactModel` prepares a machine learning model (`Mdl`) for code generation. The function removes some properties that are not required for prediction.

- For a model that has a corresponding compact model, the `saveCompactModel` function applies the appropriate `compact` function to the model before saving it.
- For a model that does not have a corresponding compact model, such as `ClassificationKNN`, `ClassificationLinear`, `RegressionLinear`, `ExhaustiveSearcher`, and `KDTreeSearcher`, the `saveCompactModel` function removes properties such as hyperparameter optimization properties, training solver information, and others.

`loadCompactModel` loads the model saved by `saveCompactModel`.

Alternative Functionality

- Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	`ClassificationTreeCoderConfigurer`
SVM for one-class and binary classification	`ClassificationSVMCoderConfigurer`
Linear model for binary classification	`ClassificationLinearCoderConfigurer`
Multiclass model for SVMs and linear models	`ClassificationECOCCoderConfigurer`
Binary decision tree for regression	`RegressionTreeCoderConfigurer`
Support vector machine (SVM) regression	`RegressionSVMCoderConfigurer`
Linear regression	`RegressionLinearCoderConfigurer`

  After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 32-80.

Compatibility Considerations

`saveCompactModel` will be removed
Warns starting in R2020b

`saveCompactModel` will be removed in a future release. Use `saveLearnerForCoder` instead.

`saveLearnerForCoder` and `loadLearnerForCoder` provide broader functionality, including fixed-point code generation for supported models.

This table shows how to update your code to use `saveLearnerForCoder`.

Not Recommended	Recommended
`saveCompactModel(Model,'MyModel');`	`saveLearnerForCoder(Model,'MyModel');`

Introduced in R2016b

saveLearnerForCoder

Save model object in file for code generation

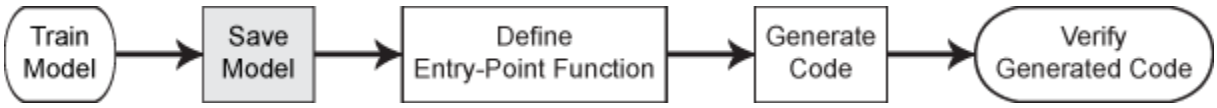
Syntax

```
saveLearnerForCoder(Mdl,filename)
```

Description

To generate C/C++ code for the object functions of machine learning models (including `predict`, `random`, `knnsearch`, `rangesearch`, and incremental learning functions), use `saveLearnerForCoder`, `loadLearnerForCoder`, and `codegen`. After training a machine learning model, save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls an object function. Then use `codegen` or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use `saveLearnerForCoder` for the highlighted step.



Fixed-point C/C++ code generation requires an additional step that defines the fixed-point data types of the variables required for prediction. Create a fixed-point data type structure by using the data type function generated by `generateLearnerDataTypeFcn`, and use the structure as an input argument of `loadLearnerForCoder` in an entry-point function. Generating fixed-point C/C++ code requires MATLAB Coder and Fixed-Point Designer.

This flow chart shows the fixed-point code generation workflow for the `predict` function of a machine learning model. Use `saveLearnerForCoder` for the highlighted step.

`saveLearnerForCoder(Mdl,filename)` prepares a classification model, regression model, or nearest neighbor searcher (`Mdl`) for code generation and saves it in the MATLAB formatted binary file (MAT-file) named `filename`. You can pass `filename` to `loadLearnerForCoder` to reconstruct the model object from the `filename` file.

Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveLearnerForCoder`. Define an entry-point function that loads the model by using `loadLearnerForCoder` and calls the `predict` function of the trained model. Then use `codegen` (MATLAB Coder) to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 32-9. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 32-22 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 32-19.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that `X` and `Y` contain data for two classes only.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `SVMIris.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'SVMIris');
```

Define Entry-Point Function

Define an entry-point function named `classifyIris` that does the following:

- Accept iris flower measurements with columns corresponding to `meas`, and return predicted labels.
- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

```
type classifyIris.m % Display contents of classifyIris.m file
```

```
function label = classifyIris(X) %#codegen
%CLASSIFYIRIS Classify iris species using SVM Model
%   CLASSIFYIRIS classifies the iris flower measurements in X using the SVM
%   model in the file SVMIris.mat, and then returns class labels in label.
Mdl = loadLearnerForCoder('SVMIris');
label = predict(Mdl,X);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen` (MATLAB Coder). Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass `X` as the value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof` (MATLAB Coder). For details, see “Specify Variable-Size Arguments for Code Generation” on page 32-45 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen classifyIris -args {X}
```

```
Code generation successful.
```

`codegen` generates the MEX function `classifyIris_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIris`, and `classifyIris_mex`.

```
label1 = predict(Mdl,X);
label2 = classifyIris(X);
label3 = classifyIris_mex(X);
verify_label = isequal(label1,label2,label3)
```

```
verify_label = logical
   1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

Generate Fixed-Point C/C++ Code for Prediction

After training a machine learning model, save the model using `saveLearnerForCoder`. For fixed-point code generation, specify the fixed-point data types of the variables required for prediction by using the data type function generated by `generateLearnerDataTypeFcn`. Then, define an entry-point function that loads the model by using both `loadLearnerForCoder` and the specified fixed-point data types, and calls the `predict` function of the model. Use `codegen` (MATLAB Coder) to generate fixed-point C/C++ code for the entry-point function, and then verify the generated code.

Before generating code using `codegen`, you can use `buildInstrumentedMex` (Fixed-Point Designer) and `showInstrumentationResults` (Fixed-Point Designer) to optimize the fixed-point data types to improve the performance of the fixed-point code. Record minimum and maximum values of named and internal variables for prediction by using `buildInstrumentedMex`. View the instrumentation results using `showInstrumentationResults`; then, based on the results, tune the fixed-point data type properties of the variables. For details regarding this optional step, see “Fixed-Point Code Generation for Prediction of SVM” on page 32-87.

Train Model

Load the `ionosphere` data set and train a binary SVM classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y,'KernelFunction','gaussian');
```

`Mdl` is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `myMdl.mat` by using `saveLearnerForCoder`.

```
saveLearnerForCoder(Mdl,'myMdl');
```

Define Fixed-Point Data Types

Use `generateLearnerDataTypeFcn` to generate a function that defines the fixed-point data types of the variables required for prediction of the SVM model.

```
generateLearnerDataTypeFcn('myMdl',X)
```

`generateLearnerDataTypeFcn` generates the `myMdl_datatype` function.

Create a structure `T` that defines the fixed-point data types by using `myMdl_datatype`.

```
T = myMdl_datatype('Fixed')
```

```
T = struct with fields:
              XDataType: [0x0 embedded.fi]
          ScoreDataType: [0x0 embedded.fi]
    InnerProductDataType: [0x0 embedded.fi]
```

The structure `T` includes the fields for the named and internal variables required to run the `predict` function. Each field contains a fixed-point object, returned by `fi` (Fixed-Point Designer). The fixed-point object specifies fixed-point data type properties, such as word length and fraction length. For example, display the fixed-point data type properties of the predictor data.

```
T.XDataType
```

```
ans =

[]

          DataTypeMode: Fixed-point: binary point scaling
            Signedness: Signed
            WordLength: 16
        FractionLength: 14

        RoundingMethod: Floor
        OverflowAction: Wrap
           ProductMode: FullPrecision
  MaxProductWordLength: 128
               SumMode: FullPrecision
     MaxSumWordLength: 128
```

Define Entry-Point Function

Define an entry-point function named `myFixedPointPredict` that does the following:

- Accept the predictor data `X` and the fixed-point data type structure `T`.
- Load a fixed-point version of a trained SVM classification model by using both `loadLearnerForCoder` and the structure `T`.

- Predict labels and scores using the loaded model.

```
type myFixedPointPredict.m % Display contents of myFixedPointPredict.m file
```

```
function [label,score] = myFixedPointPredict(X,T) %#codegen
Mdl = loadLearnerForCoder('myMdl','DataType',T);
[label,score] = predict(Mdl,X);
end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the entry-point function file.

Generate Code

The `XDataType` field of the structure `T` specifies the fixed-point data type of the predictor data. Convert `X` to the type specified in `T.XDataType` by using the `cast` (Fixed-Point Designer) function.

```
X_fx = cast(X,'like',T.XDataType);
```

Generate code for the entry-point function using `codegen`. Specify `X_fx` and constant folded `T` as input arguments of the entry-point function.

```
codegen myFixedPointPredict -args {X_fx,coder.Constant(T)}
```

```
Code generation successful.
```

`codegen` generates the MEX function `myFixedPointPredict_mex` with a platform-dependent extension.

Verify Generated Code

Pass predictor data to `predict` and `myFixedPointPredict_mex` to compare the outputs.

```
[labels,scores] = predict(Mdl,X);
[labels_fx,scores_fx] = myFixedPointPredict_mex(X_fx,T);
```

Compare the outputs from `predict` and `myFixedPointPredict_mex`.

```
verify_labels = isequal(labels,labels_fx)
```

```
verify_labels = logical
   1
```

`isequal` returns logical 1 (true), which means `labels` and `labels_fx` are equal. If the labels are not equal, you can compute the percentage of incorrectly classified labels as follows.

```
sum(strcmp(labels_fx,labels)==0)/numel(labels_fx)*100
```

```
ans = 0
```

Find the maximum of the relative differences between the score outputs.

```
relDiff_scores = max(abs((scores_fx.double(:,1)-scores(:,1))./scores(:,1)))
```

```
relDiff_scores = 0.0055
```

If you are not satisfied with the comparison results and want to improve the precision of the generated code, you can tune the fixed-point data types and regenerate the code. For details, see

"Tips" on page 33-2632 in `generateLearnerDataTypeFcn`, "Data Type Function" on page 33-2631, and "Fixed-Point Code Generation for Prediction of SVM" on page 32-87.

Input Arguments

`Mdl` — Machine learning model

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in the following tables of supported models. The tables also show whether each model supports fixed-point code generation.

- **Classification Model Object**

Model	Full/Compact Model Objects	Fixed-Point Code Generation Support	Single-Precision Code Generation Support
Binary decision tree for classification	`ClassificationTree`, `CompactClassificationTree`	Yes	Yes
Discriminant analysis classification	`ClassificationDiscriminant`, `CompactClassificationDiscriminant`	No	Yes
Ensemble classifier	`ClassificationEnsemble`, `CompactClassificationEnsemble`, `ClassificationBaggedEnsemble`	Yes (Only for ensembles of decision trees)	Yes
Binary classification linear model for incremental learning	`incrementalClassificationLinear`	No	Yes
k-nearest neighbor classification	`ClassificationKNN`	No	Yes
Linear model for binary classification of high-dimensional data	`ClassificationLinear`	No	Yes
Multiclass model for support vector machines (SVMs) or other classifiers	`ClassificationECOC`, `CompactClassificationECOC`	No	Yes
Naive Bayes classifier	`ClassificationNaiveBayes`, `CompactClassificationNaiveBayes`	No	Yes
SVM for one-class and binary classification	`ClassificationSVM`, `CompactClassificationSVM`	Yes	Yes

- **Regression Model Object**

Model	Full/Compact Model Object	Fixed-Point Code Generation Support	Single-Precision Code Generation Support
Ensemble regression	`RegressionEnsemble`, `CompactRegressionEnsemble`, `RegressionBaggedEnsemble`	Yes	Yes
Gaussian process regression	`RegressionGP`, `CompactRegressionGP`	No	Yes (see "Tips" on page 33-3574)
Generalized linear model	`GeneralizedLinearModel`, `CompactGeneralizedLinearModel`	No	No
Linear regression model for incremental learning	`incrementalRegressionLinear`	No	Yes
Linear regression model	`LinearModel`, `CompactLinearModel`	No	Yes
Linear regression for high-dimensional data	`RegressionLinear`	No	No
Regression tree	`RegressionTree`, `CompactRegressionTree`	Yes	Yes
SVM regression	`RegressionSVM`, `CompactRegressionSVM`	Yes	Yes

- **Nearest Neighbor Searcher Object**

Model	Model Object	Fixed-Point Code Generation Support	Single-Precision Code Generation Support
Exhaustive nearest neighbor searcher	`ExhaustiveSearcher`	No	No
Nearest neighbor searcher using *K*d-tree	`KDTreeSearcher`	No	No

`filename` — File name
character vector | string scalar

File name, specified as a character vector or string scalar.

If the `filename` file exists, then `saveLearnerForCoder` overwrites the file.

The extension of the `filename` file must be `.mat`. If `filename` has no extension, then `saveLearnerForCoder` appends `.mat`.

If `filename` does not include a full path, then `saveLearnerForCoder` saves the file to the current folder.

Example: `'SVMMdl'`

Data Types: `char` | `string`

Algorithms

`saveLearnerForCoder` prepares a machine learning model (`Mdl`) for code generation. The function removes some unnecessary properties.

- For a model that has a corresponding compact model, the `saveLearnerForCoder` function applies the appropriate `compact` function to the model before saving it.
- For a model that does not have a corresponding compact model, such as `ClassificationKNN`, `ClassificationLinear`, `RegressionLinear`, `ExhaustiveSearcher`, and `KDTreeSearcher`, the `saveLearnerForCoder` function removes properties such as hyperparameter optimization properties, training solver information, and others.

`loadLearnerForCoder` loads the model saved by `saveLearnerForCoder`.

Alternative Functionality

- Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.

Model	Coder Configurer Object
Binary decision tree for multiclass classification	`ClassificationTreeCoderConfigurer`
SVM for one-class and binary classification	`ClassificationSVMCoderConfigurer`
Linear model for binary classification	`ClassificationLinearCoderConfigurer`
Multiclass model for SVMs and linear models	`ClassificationECOCCoderConfigurer`
Binary decision tree for regression	`RegressionTreeCoderConfigurer`
Support vector machine (SVM) regression	`RegressionSVMCoderConfigurer`
Linear regression	`RegressionLinearCoderConfigurer`

  After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 32-80.

Introduced in R2019b

scatterhist

Scatter plot with marginal histograms

Syntax

```
scatterhist(x,y)
scatterhist(x,y,Name,Value)

h = scatterhist( ___ )
```

Description

`scatterhist(x,y)` creates a 2-D scatter plot of the data in vectors `x` and `y`, and displays the marginal distributions of `x` and `y` as univariate histograms on the horizontal and vertical axes of the scatter plot, respectively.

`scatterhist(x,y,Name,Value)` creates the plot using additional options specified by one or more name-value pair arguments. For example, you can specify a grouping variable or change the display options.

`h = scatterhist( ___ )` returns a vector of three axis handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively, using any of the input arguments in the previous syntaxes.

Examples

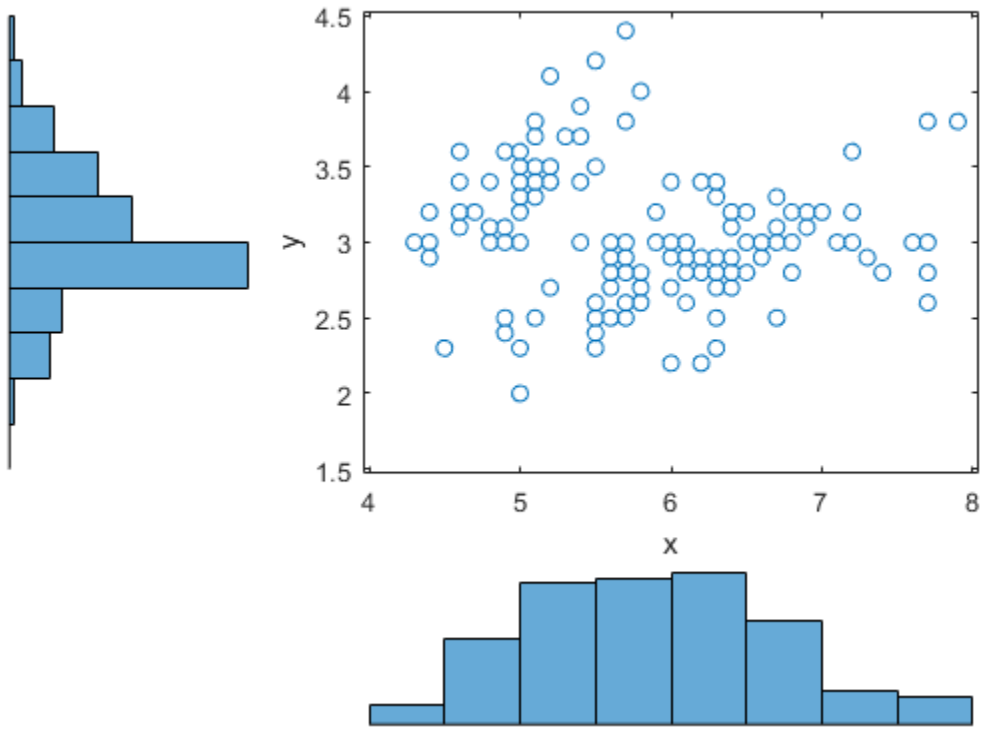
Create a `scatterhist` Plot

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

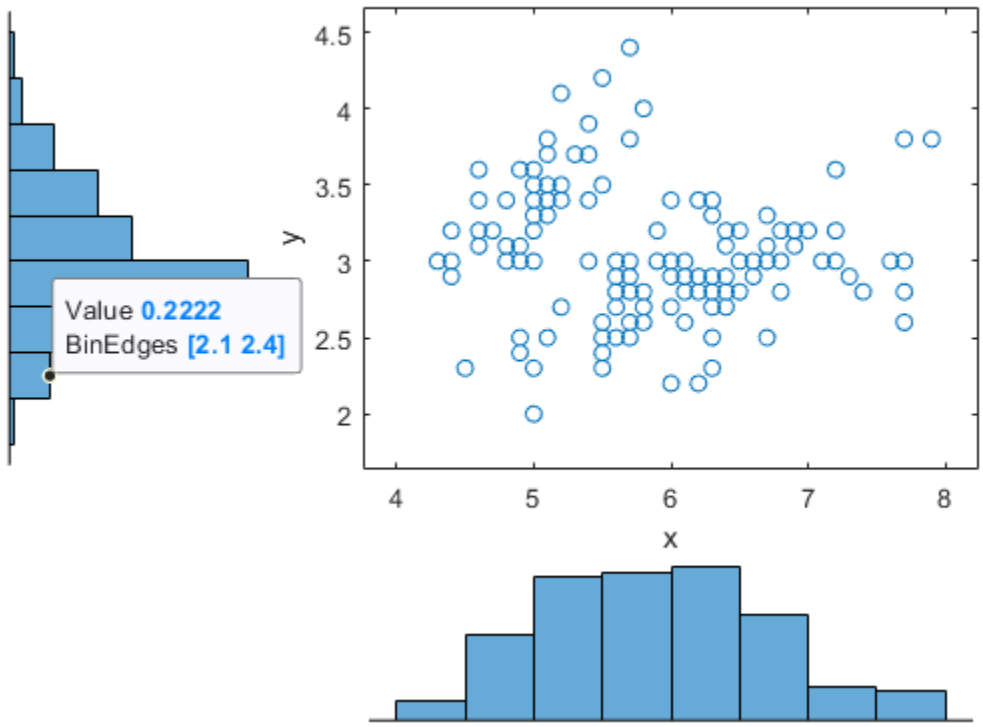
```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and two marginal histograms to visualize the relationship between sepal length and sepal width.

```
scatterhist(x,y)
```



Display a data tip for a bin in a histogram. A data tip appears when you hover over a bin in a histogram.



The data tip displays the probability density function estimate of the selected bin and the lower and upper values for the bin edges.

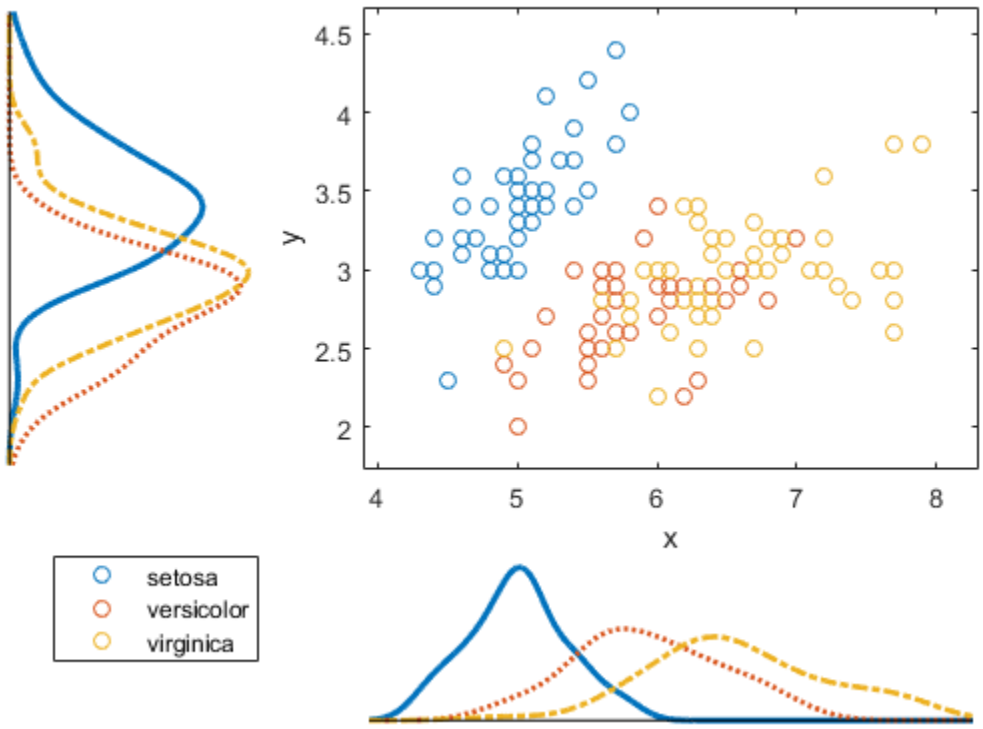
Plot Grouped Data

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width, grouped by species.

```
scatterhist(x,y,'Group',species,'Kernel','on')
```



The plot shows that the relationship between sepal length and width varies depending on the flower species.

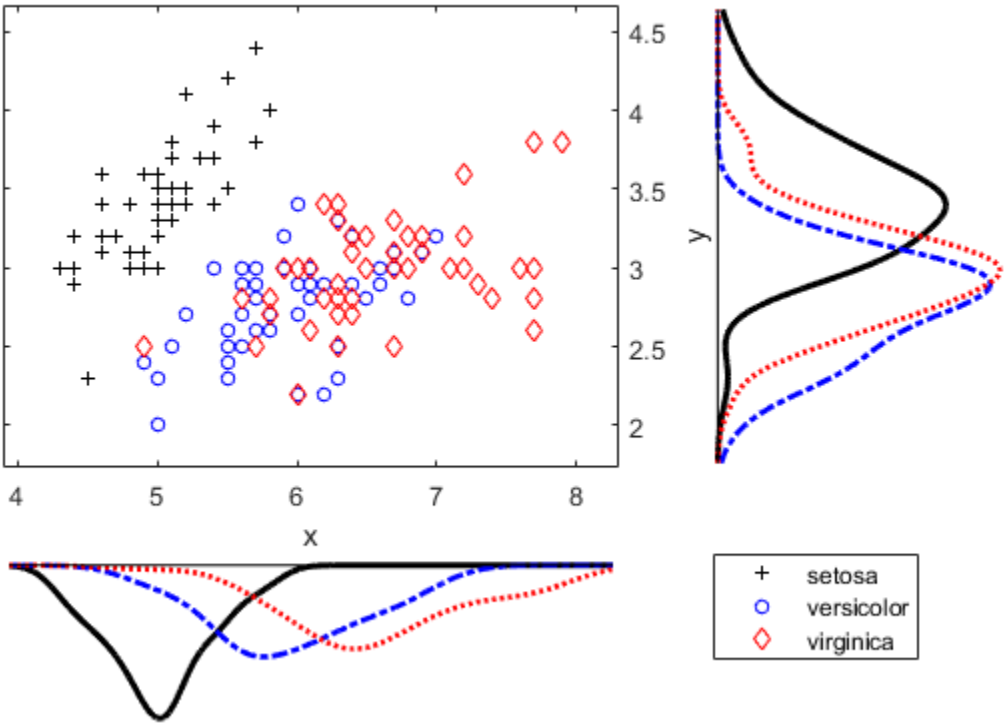
Customize the Plot Display

Load the sample data. Create data vector x from the first column of the data matrix, which contains sepal length measurements from three different species of iris flowers. Create data vector y from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width as measured on three species of iris flowers, grouped by species. Customize the appearance of the plots.

```
scatterhist(x,y,'Group',species,'Kernel','on','Location','SouthEast',...
    'Direction','out','Color','kbr','LineStyle',{'-','-.',':'},...
    'LineWidth',[2,2,2],'Marker','+od','MarkerSize',[4,5,6]);
```



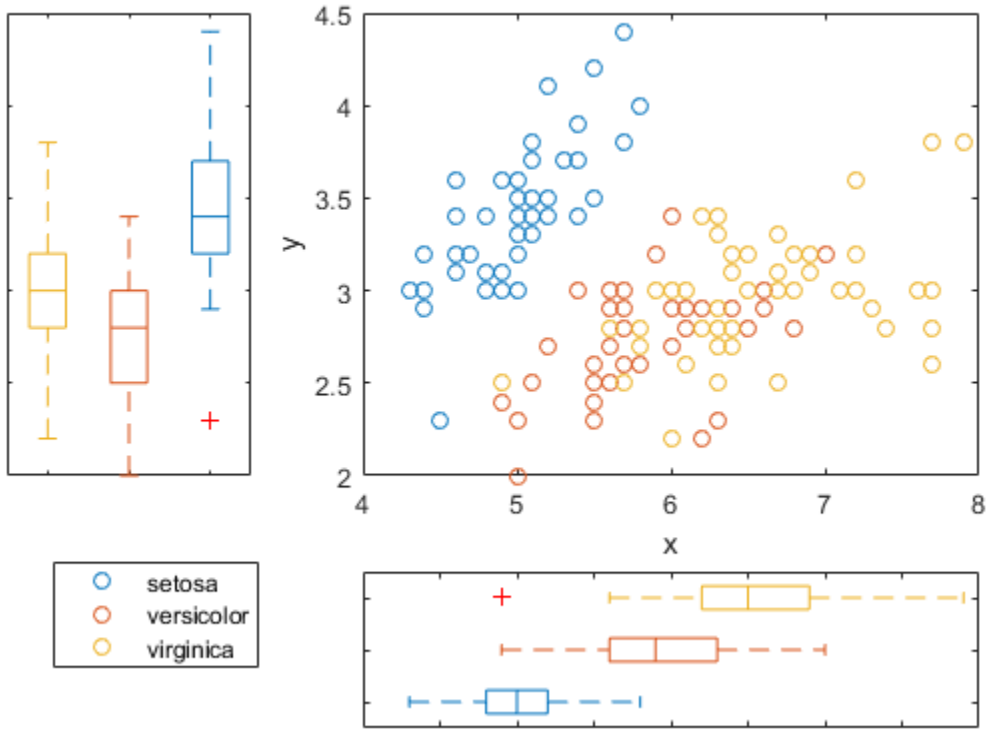
Customize Plots Using Axes Handles

Load the sample data. Create data vector x from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector y from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Use axis handles to replace the marginal histograms with box plots.

```
h = scatterhist(x,y,'Group',species);
hold on;
clr = get(h(1),'colororder');
boxplot(h(2),x,species,'orientation','horizontal',...
     'label',{'','',''},'color',clr);
boxplot(h(3),y,species,'orientation','horizontal',...
     'label', {'','',''},'color',clr);
set(h(2:3),'XTickLabel','');
view(h(3),[270,90]);  % Rotate the Y plot
axis(h(1),'auto');  % Sync axes
hold off;
```



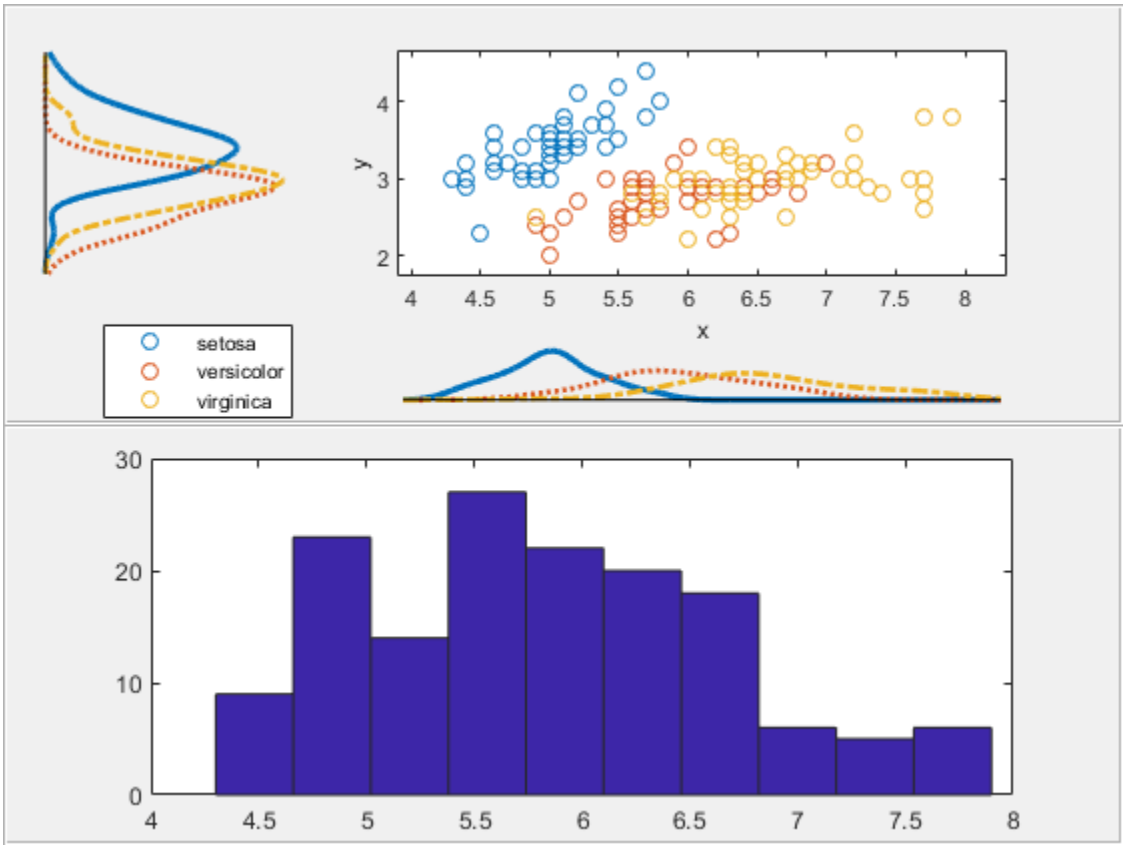
Create a `scatterhist` Plot in a Specified Parent Container

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris
x = meas(:,1);
y = meas(:,2);
```

Create a new figure and define two `uipanel` objects to divide the figure into two parts. In the upper half of the figure, plot the sample data using `scatterhist`. Include marginal kernel density plots grouped by species. In the lower half of the figure, plot a histogram of the sepal length measurements contained in `x`.

```
figure
hp1 = uipanel('position',[0 .5 1 .5]);
hp2 = uipanel('position',[0 0 1 .5]);
scatterhist(x,y,'Group',species,'Kernel','on','Parent',hp1);
axes('Parent',hp2);
hist(x);
```



Input Arguments

x — Sample data

vector

Sample data, specified as a vector. The data vectors `x` and `y` must be the same length.

If `x` or `y` contain `NaN` values, then `scatterhist`:

- Removes rows with `NaN` values in either `x` or `y` from both data vectors when generating the scatter plot
- Removes rows with `NaN` values only from the corresponding `x` or `y` data vector when generating the marginal histograms

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. The data vectors `x` and `y` must be the same length.

If `x` or `y` contain `NaN` values, then `scatterhist`:

- Removes rows with `NaN` values in either `x` or `y` from both data vectors when generating the scatter plot

- Removes rows with `NaN` values only from the corresponding `x` or `y` data vector when generating the marginal histograms

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Location','SouthEast','Direction','out'` specifies a plot with histograms located below and to the right of the scatter plot, with the bars directed away from the scatter plot.

`NBins` — Number of bins for histograms

positive integer value | vector

Number of bins for histograms, specified as the comma-separated pair consisting of `'NBins'` and a positive integer value greater than or equal to 2, or vector of two such values. If the number of bins is specified as a positive integer value, that value is the number of bins for both the `x` and `y` histograms. If the number of bins is specified by a vector, the first value is the number of bins for the `x` data, and the second value is the number of bins for the `y` data. By default, the number of bins is computed based on the sample standard deviation using Scott's rule.

Example: `'NBins',[5,7]`

Data Types: `single` | `double`

`Location` — Location of marginal histograms

`'SouthWest'` (default) | `'SouthEast'` | `'NorthEast'` | `'NorthWest'`

Location of the marginal histograms in the figure, specified as the comma-separated pair consisting of `'Location'` and one of the following.

`'SouthWest'`	Plot the histograms below and to the left of the scatter plot.
`'SouthEast'`	Plot the histograms below and to the right of the scatter plot.
`'NorthEast'`	Plot the histograms above and to the right of the scatter plot.
`'NorthWest'`	Plot the histograms above and to the left of the scatter plot.

Example: `'Location','SouthEast'`

`Direction` — Direction of marginal histograms

`'in'` (default) | `'out'`

Direction of the marginal histograms, specified as the comma-separated pair consisting of `'Direction'` and one of the following.

`'in'`	Plot the histograms with the bars directed toward the scatter plot.
`'out'`	Plot the histograms with the bars directed away from the scatter plot.

Example: `'Direction','out'`

`Group` — Grouping variable
categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as the comma-separated pair consisting of `'Group'` and a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of character vectors with values `'Male'` and `'Female'`, you can use `Gender` as a grouping variable to plot your data by gender.

The number of rows in the grouping variable must be equal to the length of `x`.

Example: `'Group',Gender`

Data Types: `categorical` | `single` | `double` | `logical` | `char` | `string` | `cell`

`PlotGroup` — Grouped plot indicator
`'on'` | `'off'`

Grouped plot indicator, specified as the comma-separated pair consisting of `'PlotGroup'` and one of the following.

`'on'`	Display grouped histograms or grouped kernel density plots. This is the default if a `Group` parameter is specified.
`'off'`	Display histograms or kernel density plots of the whole data set. This is the default if a `Group` parameter is not specified.

Example: `'PlotGroup','off'`

`Style` — Histogram display style
`'stairs'` | `'bar'`

Histogram display style, specified as the comma-separated pair consisting of `'PlotGroup'` and one of the following.

`'stairs'`	Display a stairstep plot that shows the outline of the histogram without filling the bars. This is the default if you specify a grouping variable that contains more than one group.
`'bar'`	Display a histogram bar plot. This is the default if you specify a grouping variable that contains only one group or if `PlotGroup` is specified as `'off'`.

Example: `'Style','bar'`

`Kernel` — Kernel density plot indicator
`'off'` (default) | `'on'` | `'overlay'`

Kernel density plot indicator, specified as the comma-separated pair consisting of `'Kernel'` and one of the following.

`'off'`	Display the marginal distributions as histograms.
`'on'`	Display the marginal distributions as kernel density plots.

`'overlay'`	Display the marginal distributions as kernel density plots overlaid onto histograms, similar to `histfit`.

Example: `'Kernel','overlay'`

`Bandwidth` — Bandwidth of kernel smoothing window
matrix

Bandwidth of kernel smoothing window, specified as the comma-separated pair consisting of `'Bandwidth'` and a matrix of size 2-by-*K*, where *K* is the number of unique groups. The first row of the matrix gives the bandwidth of each group in `x`, and the second row gives the bandwidth of each group in `y`. By default, `scatterhist` finds the optimal bandwidth for estimating normal densities. Specifying a different bandwidth value changes the smoothing characteristics of the resulting kernel density plot. The value specified is a scaling factor for the normal distribution used to generate the kernel density plot.

Example: `'Bandwidth',[.5,.2,.1;.15,.25,.35]`

Data Types: `single` | `double`

`Legend` — Legend visibility indicator
`'on'` | `'off'`

Legend visibility indicator, specified as the comma-separated pair consisting of `'Legend'` and one of the following.

`'on'`	Set legend visible. This is the default if a `Group` parameter is specified.
`'off'`	Set legend invisible. This is the default if a `Group` parameter is not specified.

Example: `'Legend','on'`

`Parent` — Parent container of the plot
`uipanel` container object | `figure` container object

Parent container for the plot, specified as a `uipanel` container object or `figure` container object. You can create panel container objects using `uipanel` or `figure`, respectively.

For example, if `h1` is a panel container object, specify the parent container of the plot as follows.

Example: `'Parent',h1`

`LineStyle` — Style of kernel density plot line
valid line style | string array or cell array of line styles

Style of kernel density plot line, specified as the comma-separated pair consisting of `'LineStyle'` and a valid line style or a string array or cell array of valid line styles. See `plot` for valid line styles. The default is a solid line. Use a string array or cell array to specify different line styles for each group. When the total number of groups exceeds the number of specified values, `scatterhist` cycles through the specified values.

Example: `'LineStyle',{'-',':','-.'}`

Data Types: `char` | `string` | `cell`

`LineWidth` — Width of kernel density plot line
`0.5` (default) | nonnegative scalar value | vector

Width of kernel density plot line, specified as the comma-separated pair consisting of `'LineWidth'` and a nonnegative scalar value or vector of nonnegative scalar values. The specified value is the size of the kernel density plot line measured in points. The default size is 0.5 points. Use a vector to specify different line widths for each group. When the total number of groups is greater than the number of specified values, `scatterhist` cycles through the specified values.

Example: `'LineWidth',[0.5,1,2]`

Data Types: `single` | `double`

`Color` — Marker color for each scatter plot group
character vector or string scalar of color names | matrix of RGB values

Marker color for each scatter plot group, specified as the comma-separated pair consisting of `'Color'` and a character vector or string scalar of color names, or a three-column matrix of RGB values in the range [0,1]. If you specify colors using a matrix, then each row of the matrix is an RGB triplet that represents a group. The three columns of the matrix represent the R value, G value, and B value, respectively. When the total number of groups exceeds the number of specified colors, `scatterhist` cycles through the specified colors.

This table lists the predefined colors and their equivalent RGB triplet values.

Option	Description	Equivalent RGB Triplet
`'red'` or `'r'`	Red	`[1 0 0]`
`'green'` or `'g'`	Green	`[0 1 0]`
`'blue'` or `'b'`	Blue	`[0 0 1]`
`'yellow'` or `'y'`	Yellow	`[1 1 0]`
`'magenta'` or `'m'`	Magenta	`[1 0 1]`
`'cyan'` or `'c'`	Cyan	`[0 1 1]`
`'white'` or `'w'`	White	`[1 1 1]`
`'black'` or `'k'`	Black	`[0 0 0]`

Example: `'Color','kcm'`

Example: `'Color',[.5,0,1;0,.5,.5]`

Data Types: `single` | `double` | `char` | `string`

`Marker` — Marker symbol for each scatterplot group
`'o'` (default) | character vector | string scalar

Marker symbol for each scatter plot group, specified as the comma-separated pair consisting of `'Marker'` and a character vector or string scalar of one or more valid marker symbols. See `plot` for valid symbols. The default is `'o'`, a circle. When the total number of groups exceeds the number of specified symbols, `scatterhist` cycles through the specified symbols.

Example: `'Marker','+do'`

Data Types: `char` | `string`

`MarkerSize` — Marker size for each scatter plot group
6 (default) | nonnegative scalar value | vector

Marker size for each scatter plot group, specified as the comma-separated pair consisting of `'MarkerSize'` and a nonnegative scalar value or a vector of nonnegative scalar values, measured in points. When the total number of groups exceeds the number of specified values, `scatterhist` cycles through the specified values.

Example: `'MarkerSize',10`

Data Types: `single` | `double`

Output Arguments

h — Axes handles

vector

Axes handles for the three plots, returned as a vector. The vector contains the handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively.

Alternative Functionality

Alternatively, you can create a `ScatterHistogramChart` object by using the `scatterhistogram` function.

- Explore the data interactively in the object by panning, zooming, and using data tips. Unlike the `scatterhist` function, `scatterhistogram` updates the marginal histograms based on the data within the current scatter plot limits.
- Control the appearance and behavior of the scatter histogram chart by changing the ScatterHistogramChart Properties.

“Grouping Variables” on page 2-45

Introduced in R2007a

scramble

Scramble quasirandom point set

Syntax

```
ps = scramble(p,type)
ps = scramble(p,'clear')
ps = scramble(p)
```

Description

`ps = scramble(p,type)` returns a scrambled copy `ps` of the point set `p`, created using the scramble type specified by `type`. The point set `p` is either a `haltonset` or `sobolset` object, and each type of point set supports a different scramble type.

The scrambled point set `ps` is the same kind of object as `p`.

`ps = scramble(p,'clear')` removes the scramble setting from `p` and returns the result in `ps`.

`ps = scramble(p)` reapplies the existing scramble setting to `p`, which typically results in a different point set because of the randomness of the scrambling algorithms.

Examples

Create Halton Point Set

Generate a three-dimensional Halton point set, skip the first 1000 values, and then retain every 101st point.

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
```

```
p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : none
```

Apply reverse-radix scrambling by using `scramble`.

```
p = scramble(p,'RR2')
```

```
p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
              Skip : 1000
              Leap : 100
```

```
    ScrambleMethod : RR2
```

Generate the first four points by using `net`.

```
X0 = net(p,4)
```

```
X0 = 4×3

    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11,:)
```

```
X = 4×3

    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

Scramble and Unscramble Sobol Point Set

Create and scramble a five-dimensional Sobol point set. Specify the `'MatousekAffineOwen'` scramble type.

```
p = sobolset(5);
ps = scramble(p,'MatousekAffineOwen');
```

Compare the first four points in the two point sets.

```
X = net(p,4)
```

```
X = 4×5

         0         0         0         0         0
    0.5000    0.5000    0.5000    0.5000    0.5000
    0.2500    0.7500    0.2500    0.7500    0.2500
    0.7500    0.2500    0.7500    0.2500    0.7500
```

```
X2 = net(ps,4)
```

```
X2 = 4×5

    0.6681    0.2784    0.2476    0.5688    0.0513
    0.4485    0.6735    0.5417    0.3285    0.9719
    0.9940    0.9606    0.3515    0.1586    0.4742
    0.1550    0.1202    0.9226    0.9262    0.5491
```

Remove the scramble setting from `ps` by using the `'clear'` option. The point set `clearps` matches the original point set `p`.

```
clearps = scramble(ps,'clear');
clearX = net(clearps,4)
```

```
clearX = 4×5

         0         0         0         0         0
    0.5000    0.5000    0.5000    0.5000    0.5000
    0.2500    0.7500    0.2500    0.7500    0.2500
    0.7500    0.2500    0.7500    0.2500    0.7500
```

Pass `ps` to the `scramble` function without additional input arguments. The software removes the scramble setting from `ps` and then reapplies it. Because of the randomness of the scrambling algorithm, the new scrambled point set `newps` differs from the original scrambled point set `ps`.

```
newps = scramble(ps);
newX = net(newps,4)
```

```
newX = 4×5

    0.6882    0.6261    0.9298    0.3314    0.4169
    0.2442    0.1978    0.4307    0.6286    0.8666
    0.7827    0.2868    0.5172    0.8430    0.1261
    0.2772    0.8576    0.0164    0.1404    0.5905
```

Input Arguments

p — Point set

`haltonset` object | `sobolset` object

Point set, specified as either a `haltonset` or `sobolset` object.

Example: `sobolset(5)`

type — Scramble type

`'RR2'` | `'MatousekAffineOwen'`

Scramble type, specified as `'RR2'` or `'MatousekAffineOwen'`. Different point sets support different scramble types, as indicated in this table.

Object	Scramble Type
`haltonset`	`'RR2'` — A permutation of the radical inverse coefficients derived by applying a reverse-radix operation to all of the possible coefficient values. The scramble is described in [1].
`sobolset`	`'MatousekAffineOwen'` — A random linear scramble combined with a random digital shift. The scramble is described in [2].

Introduced in R2008a

segment

Piecewise distribution segments containing input values

Syntax

```
s = segment(pd,x)
s = segment(pd,[],p)
```

Description

`s = segment(pd,x)` returns a vector `s` of positive integers indicating which segment in the piecewise distribution `pd` contains each quantile value in `x`.

The values 1, 2, and 3 in `s` indicate the lower tail, center, and upper tail segments in `pd`, respectively. If `pd` does not include a lower tail segment, then 1 and 2 indicate the center and upper tail segments, respectively.

`s = segment(pd,[],p)` returns a vector `s` of positive integers indicating which segment in the piecewise distribution `pd` contains each cumulative probability value in `p`.

Examples

Find Segment in `paretotails` Object

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the segment containing the specified quantile values by using the object function `segment`.

Generate a sample data set containing 20% outliers.

```
rng('default');  % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to x. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)
```

```
pd =
Piecewise distribution with 3 segments
      -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
   -1.33251 < x < 1.80149  (0.1 < p < 0.9): interpolated empirical cdf
        1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Find the segment containing the specified points by using the `segment` function.

```
xpts = -3:3;
s = segment(pd,xpts)
```

```
s = 1×7

     1     1     2     2     2     3     3
```

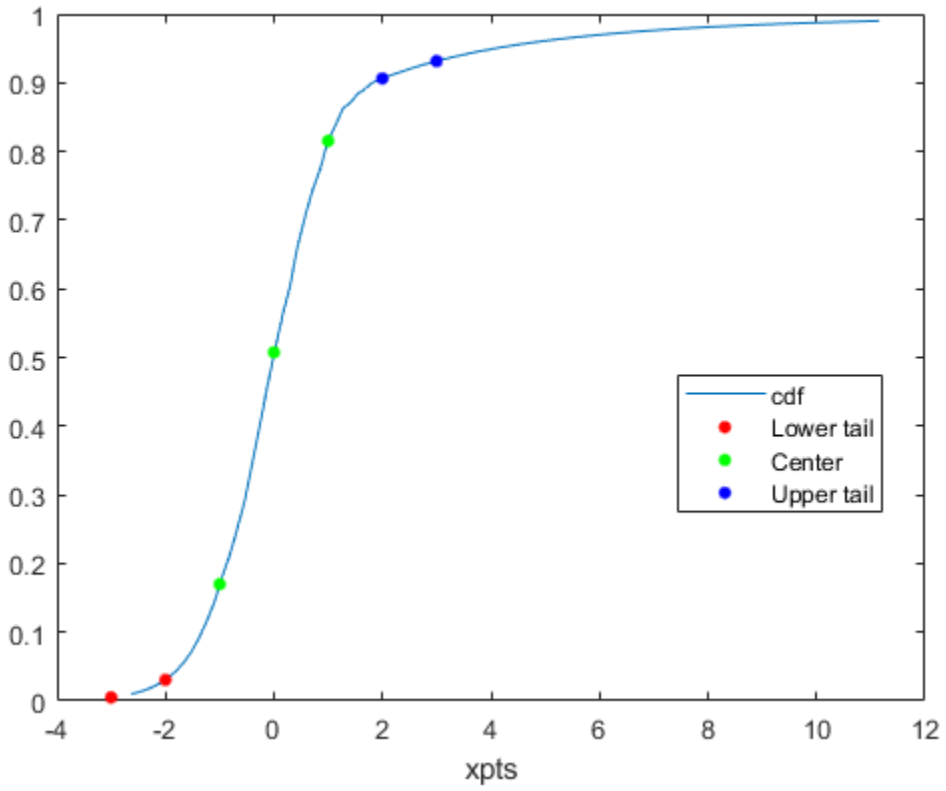
1, 2, and 3 indicate the lower tail, center, and upper tail segments in `pd`, respectively.

Draw the scatter plot of the points (`xpts`) grouped by their segments over the cumulative distribution function (cdf) plot. Plot the cdf of `pd`.

```
xgrid = linspace(icdf(pd,.01), icdf(pd,.99));
ygrid = cdf(pd,xgrid);
plot(xgrid,ygrid)
```

Superimpose the scatter plot of `xpts` by using `gscatter`.

```
hold on
gscatter(xpts,cdf(pd,xpts),s)
legend('cdf','Lower tail','Center','Upper tail')
hold off
```



Find Segment Containing Boundary Points

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the segment containing the boundary points by using the object function `segment`.

Generate a sample data set containing 20% outliers.

```
rng('default');  % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)
```

```
pd =
Piecewise distribution with 3 segments
      -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
   -1.33251 < x < 1.80149  (0.1 < p < 0.9): interpolated empirical cdf
        1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the boundary values between the piecewise segments by using the `boundary` function.

```
[p,q] = boundary(pd)
```

```
p = 2×1

    0.1000
    0.9000

q = 2×1

   -1.3325
    1.8015
```

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles.

Find the segment containing the boundary points by using the quantile values.

```
s1 = segment(pd,q)
```

```
s1 = 2×1

     2
     3
```

1, 2, and 3 indicate the lower tail, center, and upper tail segments in `pd`, respectively. The output `s1` implies that the first boundary between the lower tail segment and the center segment belongs to the

center segment, and the second boundary between the center segment and the upper tail segment belongs to the upper tail segment.

You can also use the cumulative probability values to find the corresponding segments.

```
s2 = segment(pd,[],[0;p;1])
```

```
s2 = 4×1

     1
     2
     3
     3
```

Input Arguments

pd — Piecewise distribution with Pareto tails

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

x — Quantile

numeric vector

Quantile values, specified as a numeric vector.

Data Types: `single` | `double`

p — Cumulative probability

numeric vector of range `[0,1]` values

Cumulative probability values, specified as a numeric vector of range `[0,1]` values.

Data Types: `single` | `double`

selectModels

Class: `ClassificationLinear`

Choose subset of regularized, binary linear classification models

Syntax

```
SubMdl = selectModels(Mdl,idx)
```

Description

`SubMdl = selectModels(Mdl,idx)` returns a subset of trained, binary linear classification models from a set of binary linear classification models (`Mdl`) trained using various regularization strengths. The indices (`idx`) correspond to the regularization strengths in `Mdl.Lambda`, and specify which models to return.

Input Arguments

`Mdl` — Binary linear classification models trained using various regularization strengths

`ClassificationLinear` model object

Binary linear classification models trained using various regularization strengths, specified as a `ClassificationLinear` model object. You can create a `ClassificationLinear` model object using `fitclinear`.

Although `Mdl` is one model object, if `numel(Mdl.Lambda)` = $L \geq 2$, then you can think of `Mdl` as L trained models.

`idx` — Indices corresponding to regularization strengths

numeric vector of positive integers

Indices corresponding to regularization strengths, specified as a numeric vector of positive integers. Values of `idx` must be in the interval [1,L], where L = `numel(Mdl.Lambda)`.

Data Types: `double` | `single`

Output Arguments

`SubMdl` — Subset of binary linear classification models trained using various regularization strengths

`ClassificationLinear` model object

Subset of binary linear classification models trained using various regularization strengths, returned as a `ClassificationLinear` model object.

Examples

Find Good Lasso Penalty Using Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 33-3644.

```
load nlpdata
Ystats = Y == 'stats';
X = X';

rng(10); % For reproducibility
Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6,-0.5,11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to `1e-8`.

```
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'CVPartition',Partition,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
  ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
        NumObservations: 31572
                  KFold: 1
              Partition: [1x1 cvpartition]
             ClassNames: [0 1]
         ScoreTransform: 'none'

  Properties, Methods
```

Extract the trained linear classification model.

```
Mdl = CVMdl.Trained{1}
```

```
Mdl =
  ClassificationLinear
      ResponseName: 'Y'
        ClassNames: [0 1]
    ScoreTransform: 'logit'
              Beta: [34023x11 double]
              Bias: [1x11 double]
            Lambda: [1x11 double]
           Learner: 'logistic'
```

```
  Properties, Methods
```

`Mdl` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample classification error.

```
ce = loss(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
```

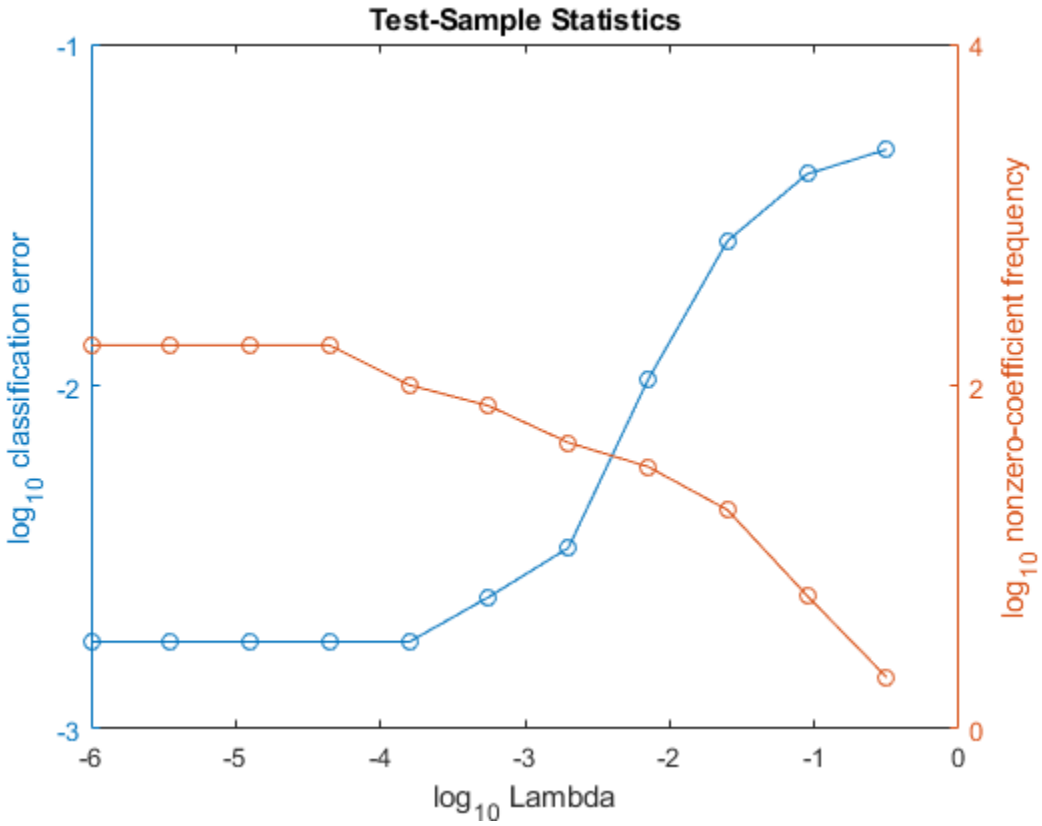
Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
```



Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Tip

One way to build several predictive, binary linear classification models is:

1. Hold out a portion of the data for testing.
2. Train a binary, linear classification model using `fitclinear`. Specify a grid of regularization strengths using the `'Lambda'` name-value pair argument and supply the training data. `fitclinear` returns one `ClassificationLinear` model object, but it contains a model for each regularization strength.
3. To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.

4. Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. `selectModels` returns one `ClassificationLinear` model object, but it contains `numel(idx)` regularized models.
5. To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

See Also

`ClassificationLinear` | `fitclinear` | `loss` | `predict`

Introduced in R2016a

selectModels

Package: `classreg.learning.classif`

Choose subset of multiclass ECOC models composed of binary `ClassificationLinear` learners

Syntax

```
SubMdl = selectModels(Mdl,idx)
```

Description

`SubMdl = selectModels(Mdl,idx)` returns a subset of trained error-correcting output codes (ECOC) models composed of `ClassificationLinear` binary models from a set of multiclass ECOC models (`Mdl`) trained using various regularization strengths. The indices (`idx`) correspond to the regularization strengths in `Mdl.BinaryLearners{1}.Lambda` and specify which models to return.

`SubMdl` is returned as a `CompactClassificationECOC` model object.

Examples

Select Best Regularized Models

Choose a subset of trained ECOC models composed of linear binary learners with various regularization strengths.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

Create a set of 11 logarithmically spaced regularization strengths from 10^{-8} through 10^{-1}.

```
Lambda = logspace(-8,-1,11);
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA. Use lasso penalties with the strengths specified in `Lambda`.

```
t = templateLinear('Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda);
```

Hold out 30% of the data for testing. Identify the test-sample indices.

```
rng(1); % For reproducibility
cvp = cvpartition(Y,'Holdout',0.30);
idxTest = test(cvp);
```

Train an ECOC model composed of linear classification models. For quicker execution time, orient the predictor data so that individual observations correspond to columns.

```
X = X';
PMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','CVPartition',cvp);
Mdl = PMdl.Trained{1};
numel(Mdl.BinaryLearners{1}.Lambda)

ans = 11
```

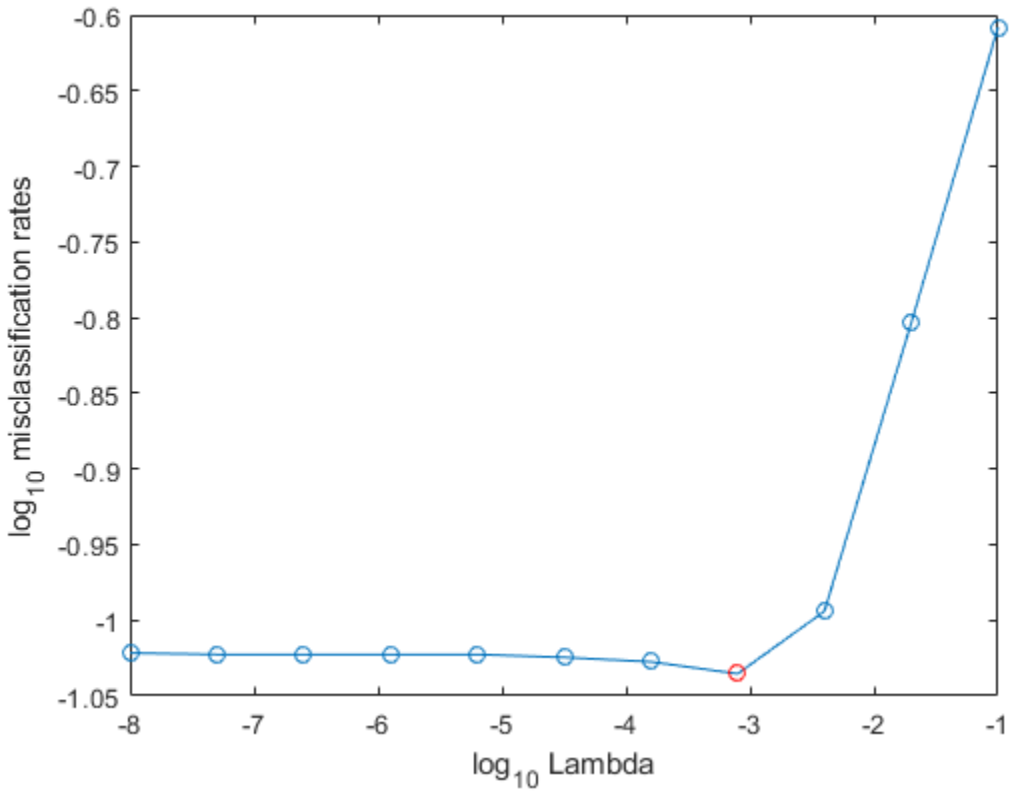
`Mdl` is a `CompactClassificationECOC` model object. Because `Lambda` is an 11-dimensional vector of regularization strengths, you can think of `Mdl` as eleven trained models, each corresponding to a regularization strength.

Estimate the test-sample misclassification rates for each regularized model.

```
ce = loss(Mdl,X(:,idxTest),Y(idxTest),'ObservationsIn','columns');
```

Plot the misclassification rates with respect to regularization strength on the log scale.

```
figure
plot(log10(Lambda),log10(ce),'-o')
ylabel('log_{10} misclassification rates')
xlabel('log_{10} Lambda')
[~,minCEIdx] = min(ce);
minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda),log10(ce(minCEIdx)),'ro');
hold off
```



Several values of `Lambda` yield similarly small classification error values. Consider choosing greater values of `Lambda` (that still yield good classification rates) because they lead to predictor variable sparsity.

Select the four models with regularization strengths that occur around the point at which the classification error starts increasing.

```
idx = 7:10;
MdlFinal = selectModels(Mdl,idx)
```

```
MdlFinal =
  CompactClassificationECOC
      ResponseName: 'Y'
        ClassNames: [1x13 categorical]
    ScoreTransform: 'none'
    BinaryLearners: {78x1 cell}
      CodingMatrix: [13x78 double]

  Properties, Methods
```

```
LambdaFinal = MdlFinal.BinaryLearners{1}.Lambda
```

```
LambdaFinal = 1×4

    0.0002    0.0008    0.0040    0.0200
```

`MdlFinal` is a `CompactClassificationECOC` model object. You can think of it as four models trained using the four regularization strengths in `LambdaFinal`.

Input Arguments

`Mdl` — Multiclass ECOC model composed of binary linear classifiers

`CompactClassificationECOC` model object

Multiclass ECOC model composed of binary linear classifiers, trained using various regularization strengths, specified as a `CompactClassificationECOC` model object.

When creating `Mdl`, you must:

- Use `fitcecoc`.
- Specify `ClassificationLinear` binary learners (see `Learners`).
- Specify the same regularization strengths for each linear binary learner.

Although `Mdl` is one model object, if `numel(Mdl.BinaryLearners{1}.Lambda)` = $L \geq 2$, then you can think of `Mdl` as L trained models.

`idx` — Indices corresponding to regularization strengths

positive integer vector

Indices corresponding to regularization strengths, specified as a positive integer vector. Values of `idx` must be in the interval [1,L], where L = `numel(Mdl.BinaryLearners{1}.Lambda)`.

Data Types: `double` | `single`

Tips

- One way to build several predictive ECOC models composed of binary linear classification models is:

  1. Create a linear classification model template using `templateLinear` and specify a grid of regularization strengths using the `'Lambda'` name-value pair argument.
  2. Hold out a portion of the data for testing.
  3. Train an ECOC model using `fitcecoc`. Specify the template using the `'Learners'` name-value pair argument and supply the training data. `fitcecoc` returns one `CompactClassificationECOC` model object containing `ClassificationLinear` binary learners, but all binary learners contain a model for each regularization strength.
  4. To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.
  5. Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. The function `selectModels` returns one `CompactClassificationECOC` model object, but it contains `numel(idx)` regularized models.
  6. To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

Introduced in R2016a

selectModels

Class: `RegressionLinear`

Select fitted regularized linear regression models

Syntax

```
SubMdl = selectModels(Mdl,idx)
```

Description

`SubMdl = selectModels(Mdl,idx)` returns a subset of trained linear regression models from a set of linear regression models (`Mdl`) trained using various regularization strengths. The indices `idx` correspond to the regularization strengths in `Mdl.Lambda`, and specify which models to return.

Input Arguments

`Mdl` — Linear regression models trained using various regularization strengths

`RegressionLinear` model object

Linear regression models trained using various regularization strengths, specified as a `RegressionLinear` model object. You can create a `RegressionLinear` model object using `fitrlinear`.

Although `Mdl` is one model object, if `numel(Mdl.Lambda)` = $L \geq 2$, then you can think of `Mdl` as L trained models.

`idx` — Indices corresponding to regularization strengths

numeric vector of positive integers

Indices corresponding to regularization strengths, specified as a numeric vector of positive integers. Values of `idx` must be in the interval [1,L], where L = `numel(Mdl.Lambda)`.

Data Types: `double` | `single`

Output Arguments

`SubMdl` — Subset of linear regression models trained using various regularization strengths

`RegressionLinear` model object

Subset of linear regression models trained using various regularization strengths, returned as a `RegressionLinear` model object.

Examples

Find Good Lasso Penalty Using Regression Loss

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e\,.$$

- $X = \{x_1, \ldots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-4} through 10^{-1}.

```
Lambda = logspace(-4,-1,15);
```

Hold out 30% of the data for testing. Identify the test-sample indices.

```
cvp = cvpartition(numel(Y),'Holdout',0.30);
idxTest = test(cvp);
```

Train a linear regression model using lasso penalties with the strengths in `Lambda`. Specify the regularization strengths, optimizing the objective function using SpaRSA, and the data partition. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Solver','sparsa','Regularization','lasso','CVPartition',cvp);
Mdl1 = CVMdl.Trained{1};
numel(Mdl1.Lambda)
```

```
ans = 15
```

`Mdl1` is a `RegressionLinear` model. Because `Lambda` is a 15-dimensional vector of regularization strengths, you can think of `Mdl1` as 15 trained models, one for each regularization strength.

Estimate the test-sample mean squared error for each regularized model.

```
mse = loss(Mdl1,X(:,idxTest),Y(idxTest),'ObservationsIn','columns');
```

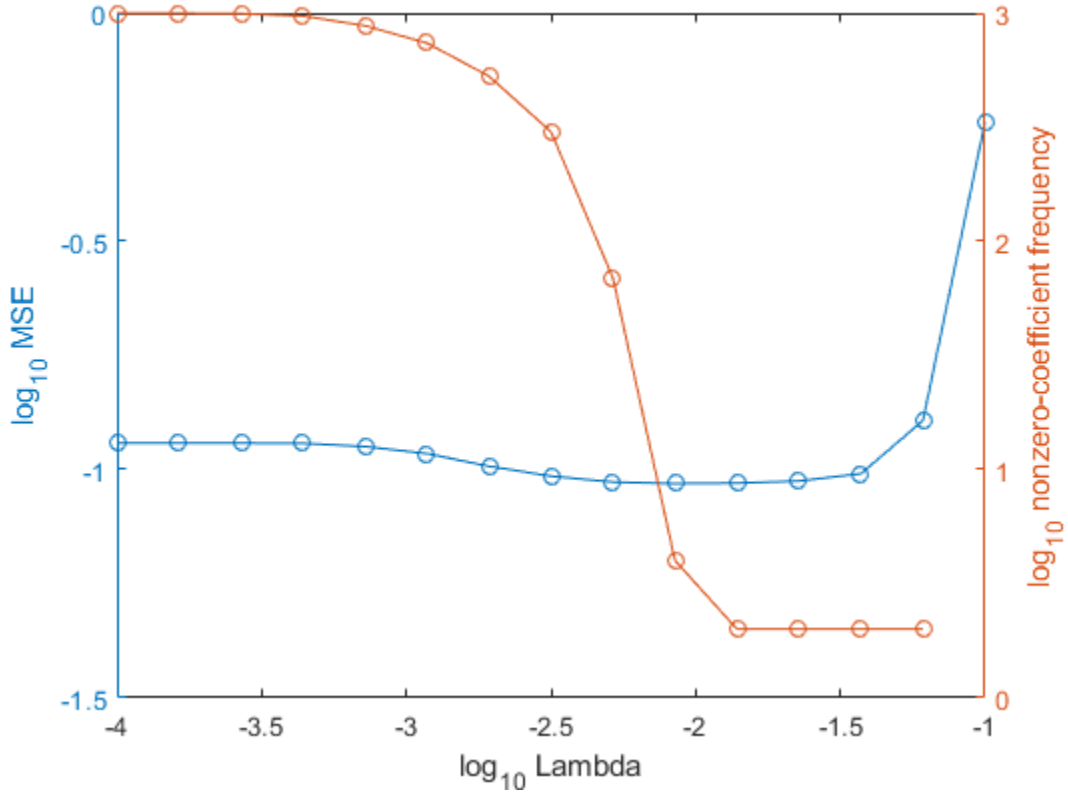
Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. Retrain the model using the entire data set and all options used previously, except the data-partition specification. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
```

```
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```



Select the index or indices of `Lambda` that balance minimal classification error and predictor-variable sparsity (for example, `Lambda(11)`).

```
idx = 11;
MdlFinal = selectModels(Mdl,idx);
```

`MdlFinal` is a trained `RegressionLinear` model object that uses `Lambda(11)` as a regularization strength.

Tip

One way to build several predictive linear regression models is:

1. Hold out a portion of the data for testing.
2. Train a linear regression model using `fitrlinear`. Specify a grid of regularization strengths using the `'Lambda'` name-value pair argument and supply the training data. `fitrlinear` returns one `RegressionLinear` model object, but it contains a model for each regularization strength.

3. To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.
4. Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. `selectModels` returns one `RegressionLinear` model object, but it contains `numel(idx)` regularized models.
5. To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

Introduced in R2016a

SemiSupervisedGraphModel

Semi-supervised graph-based model for classification

Description

You can use a semi-supervised graph-based method to label unlabeled data by using the `fitsemigraph` function. The resulting `SemiSupervisedGraphModel` object contains the fitted labels for the unlabeled observations (`FittedLabels`) and their scores (`LabelScores`). You can also use the `SemiSupervisedGraphModel` object as a classifier, trained on both the labeled and unlabeled data, to classify new data by using the `predict` function.

Creation

Create a `SemiSupervisedGraphModel` object by using `fitsemigraph`.

Properties

`FittedLabels` — Labels fitted to unlabeled data
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Labels fitted to the unlabeled data, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `FittedLabels` has the same data type as the class labels in the response variable in the call to `fitsemigraph`. (The software treats string arrays as cell arrays of character vectors.)

Each row of `FittedLabels` represents the fitted label of the corresponding row of `UnlabeledX` or `UnlabeledTbl`.

For more information on how `fitsemigraph` fits labels, see “Algorithms” on page 33-2062.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

`LabelScores` — Scores for fitted labels
numeric matrix

This property is read-only.

Scores for the fitted labels, specified as a numeric matrix. `LabelScores` has size *u*-by-*K*, where *u* is the number of observations (or rows) in the unlabeled data and *K* is the number of classes in `ClassNames`.

`score(u,k)` is the likelihood that the observation `u` belongs to class `k`, where a higher score value indicates a higher likelihood.

For more information on how `fitsemigraph` computes label scores, see “Algorithms” on page 33-2062.

Data Types: `double`

`Method` — Labeling technique
`'labelpropagation'` | `'labelpropagationexact'` | `'labelspreading'` | `'labelspreadingexact'`

This property is read-only.

Labeling technique used to label the unlabeled data, specified as `'labelpropagation'`, `'labelpropagationexact'`, `'labelspreading'`, or `'labelspreadingexact'`.

Data Types: `char`

`CategoricalPredictors` — Categorical predictor indices
positive integer vector | `[]`

This property is read-only.

Categorical predictor indices, specified as a positive integer vector. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

`ClassNames` — Unique class labels
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used to label the unlabeled data, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. The order of the elements of `ClassNames` determines the order of the classes.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

`PredictorNames` — Predictor variable names
cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the predictor data.

Data Types: `cell`

`ResponseName` — Response variable name
character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

Object Functions

predict Label new data using semi-supervised graph-based classifier

Examples

Fit Labels to Unlabeled Data

Fit labels to unlabeled data by using a semi-supervised graph-based method.

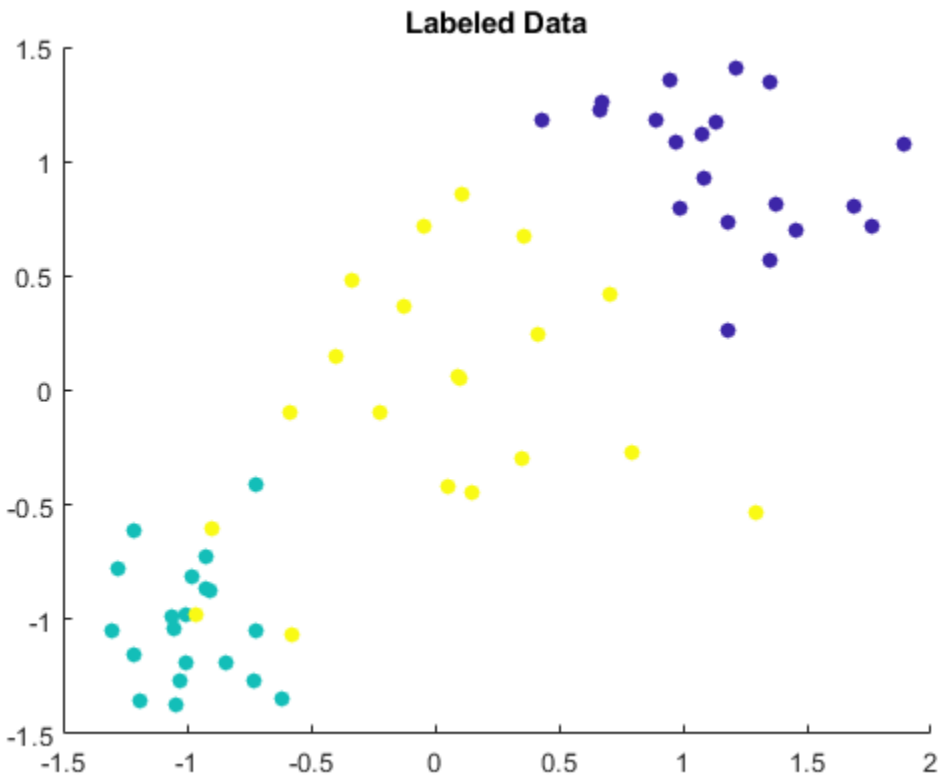
Randomly generate 60 observations of labeled data, with 20 observations in each of three classes.

```
rng('default') % For reproducibility

labeledX = [randn(20,2)*0.25 + ones(20,2);
            randn(20,2)*0.25 - ones(20,2);
            randn(20,2)*0.5];
Y = [ones(20,1); ones(20,1)*2; ones(20,1)*3];
```

Visualize the labeled data by using a scatter plot. Observations in the same class have the same color. Notice that the data is split into three clusters with very little overlap.

```
scatter(labeledX(:,1),labeledX(:,2),[],Y,'filled')
title('Labeled Data')
```



Randomly generate 300 additional observations of unlabeled data, with 100 observations per class. For the purposes of validation, keep track of the true labels for the unlabeled data.

```
unlabeledX = [randn(100,2)*0.25 + ones(100,2);
              randn(100,2)*0.25 - ones(100,2);
              randn(100,2)*0.5];
trueLabels = [ones(100,1); ones(100,1)*2; ones(100,1)*3];
```

Fit labels to the unlabeled data by using a semi-supervised graph-based method. The function `fitsemigraph` returns a `SemiSupervisedGraphModel` object whose `FittedLabels` property contains the fitted labels for the unlabeled data and whose `LabelScores` property contains the associated label scores.

```
Mdl = fitsemigraph(labeledX,Y,unlabeledX)
```

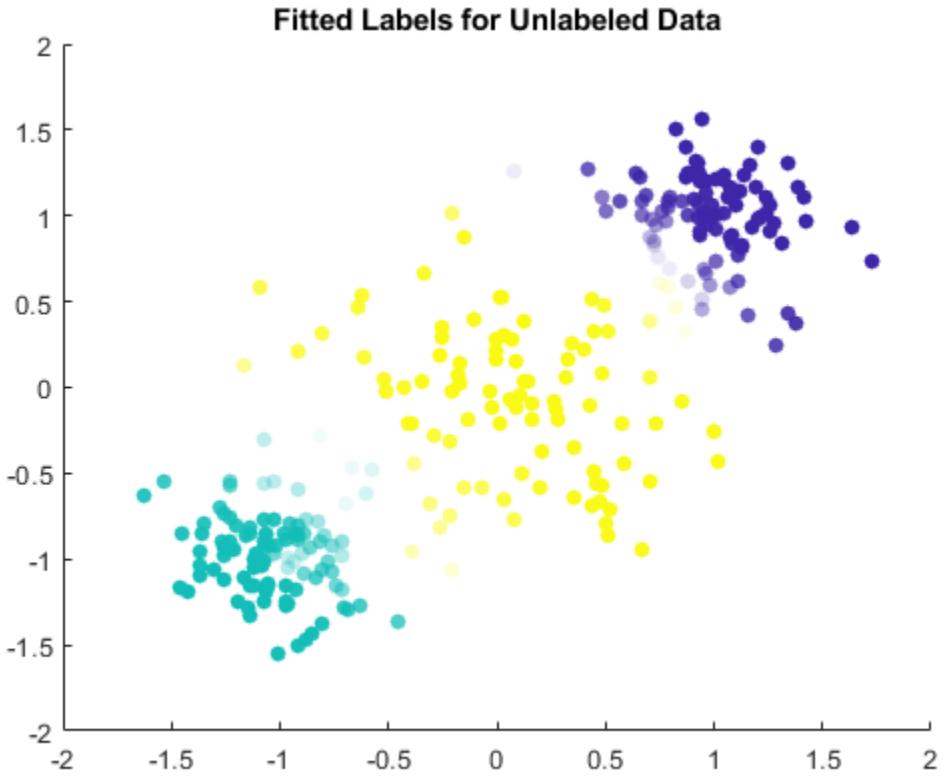
```
Mdl =
  SemiSupervisedGraphModel with properties:

             FittedLabels: [300x1 double]
              LabelScores: [300x3 double]
                ClassNames: [1 2 3]
             ResponseName: 'Y'
    CategoricalPredictors: []
                   Method: 'labelpropagation'

  Properties, Methods
```

Visualize the fitted label results by using a scatter plot. Use the fitted labels to set the color of the observations, and use the maximum label scores to set the transparency of the observations. Observations with less transparency are labeled with greater confidence. Notice that observations that lie closer to the cluster boundaries are labeled with more uncertainty.

```
maxLabelScores = max(Mdl.LabelScores,[],2);
rescaledScores = rescale(maxLabelScores,0.05,0.95);
scatter(unlabeledX(:,1),unlabeledX(:,2),[],Mdl.FittedLabels,'filled', ...
    'MarkerFaceAlpha','flat','AlphaData',rescaledScores);
title('Fitted Labels for Unlabeled Data')
```



Determine the accuracy of the labeling by using the true labels for the unlabeled data.

```
numWrongLabels = sum(trueLabels ~= Mdl.FittedLabels)
```

```
numWrongLabels = 10
```

Only 10 of the 300 observations in `unlabeledX` are mislabeled.

Classify New Data Using Model Trained on Labeled and Unlabeled Data

Use both labeled and unlabeled data to train a `SemiSupervisedGraphModel` object. Label new data using the trained model.

Randomly generate 15 observations of labeled data, with 5 observations in each of three classes.

```
rng('default') % For reproducibility
labeledX = [randn(5,2)*0.25 + ones(5,2);
            randn(5,2)*0.25 - ones(5,2);
            randn(5,2)*0.5];
Y = [ones(5,1); ones(5,1)*2; ones(5,1)*3];
```

Randomly generate 300 additional observations of unlabeled data, with 100 observations per class.

```
unlabeledX = [randn(100,2)*0.25 + ones(100,2);
              randn(100,2)*0.25 - ones(100,2);
              randn(100,2)*0.5];
```

Fit labels to the unlabeled data by using a semi-supervised graph-based method. Specify label spreading as the labeling algorithm, and use an automatically selected kernel scale factor. The function `fitsemigraph` returns a `SemiSupervisedGraphModel` object whose `FittedLabels` property contains the fitted labels for the unlabeled data and whose `LabelScores` property contains the associated label scores.

```
Mdl = fitsemigraph(labeledX,Y,unlabeledX,'Method','labelspreading', ...
    'KernelScale','auto')
```

```
Mdl =
  SemiSupervisedGraphModel with properties:

             FittedLabels: [300x1 double]
              LabelScores: [300x3 double]
                ClassNames: [1 2 3]
             ResponseName: 'Y'
    CategoricalPredictors: []
                   Method: 'labelspreading'

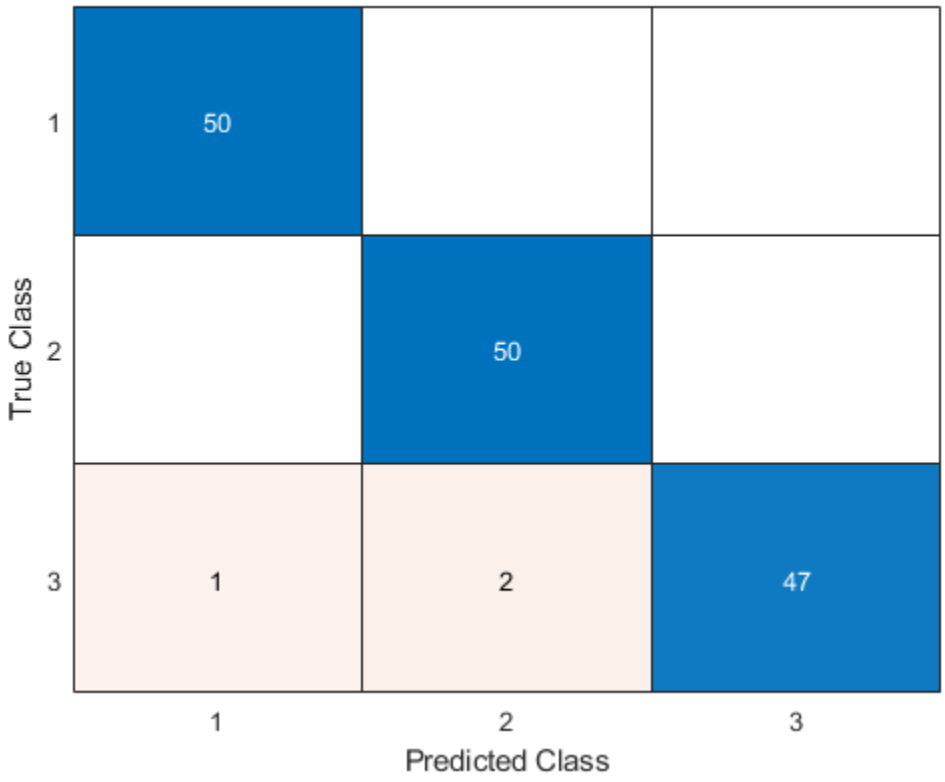
  Properties, Methods
```

Randomly generate 150 observations of new data, with 50 observations per class. For the purposes of validation, keep track of the true labels for the new data.

```
newX = [randn(50,2)*0.25 + ones(50,2);
        randn(50,2)*0.25 - ones(50,2);
        randn(50,2)*0.5];
trueLabels = [ones(50,1); ones(50,1)*2; ones(50,1)*3];
```

Predict the labels for the new data by using the `predict` function of the `SemiSupervisedGraphModel` object. Compare the true labels to the predicted labels by using a confusion matrix.

```
predictedLabels = predict(Mdl,newX);
confusionchart(trueLabels,predictedLabels)
```



Only 3 of the 150 observations in `newX` are mislabeled.

Introduced in R2020b

SemiSupervisedSelfTrainingModel

Semi-supervised self-trained model for classification

Description

You can use a semi-supervised self-training method to label unlabeled data by using the `fitsemiself` function. The resulting `SemiSupervisedSelfTrainingModel` object contains the fitted labels for the unlabeled observations (`FittedLabels`) and their scores (`LabelScores`). You can also use the `SemiSupervisedSelfTrainingModel` object as a classifier, trained on both the labeled and unlabeled data, to classify new data by using the `predict` function.

Creation

Create a `SemiSupervisedSelfTrainingModel` object by using `fitsemiself`.

Properties

`FittedLabels` — Labels fitted to unlabeled data
categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Labels fitted to the unlabeled data, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `FittedLabels` has the same data type as the class labels in the response variable in the call to `fitsemiself`. (The software treats string arrays as cell arrays of character vectors.)

Each row of `FittedLabels` represents the fitted label of the corresponding observation of `UnlabeledX` or `UnlabeledTbl`.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

`LabelScores` — Scores for fitted labels
numeric matrix

This property is read-only.

Scores for the fitted labels, specified as a numeric matrix. `LabelScores` has size *u*-by-*K*, where *u* is the number of observations in the unlabeled data and *K* is the number of classes in `ClassNames`.

`score(u,k)` is the likelihood that the observation `u` belongs to class `k`, where a higher score value indicates a higher likelihood. The range of score values depends on the underlying classifier `Learner`.

Data Types: `single` | `double`

`Learner` — Underlying classifier
classification model object

This property is read-only.

Underlying classifier, specified as a classification model object. `fitsemiself` uses this classifier in a loop to label and score the unlabeled data. You can use dot notation to display the parameter and hyperparameter values of the underlying classifier.

For example, if you specify `'Learner','svm'` in the call to `fitsemiself`, then you can enter `Mdl.Learner.KernelParameters` to display the kernel parameters of the final support vector machine (SVM) model trained on both the labeled and unlabeled data.

Note Because the `Mdl.Learner` model has some limitations (for example, lack of support for tabular data), avoid using it directly with its object functions, such as `loss` and `predict`. To predict on new data, use the `predict` object function of `SemiSupervisedSelfTrainingModel`.

`CategoricalPredictors` — Categorical predictor indices

positive integer vector | `[]`

This property is read-only.

Categorical predictor indices, specified as a positive integer vector. Assuming that the predictor data contains observations in rows, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `double`

`ClassNames` — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

This property is read-only.

Unique class labels used to label the unlabeled data, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. The order of the elements of `ClassNames` determines the order of the classes.

Data Types: `single` | `double` | `logical` | `char` | `cell` | `categorical`

`PredictorNames` — Predictor variable names

cell array of character vectors

This property is read-only.

Predictor variable names, specified as a cell array of character vectors. The order of the elements of `PredictorNames` corresponds to the order in which the predictor names appear in the predictor data.

Data Types: `cell`

`ResponseName` — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

Object Functions

predict Label new data using semi-supervised self-trained classifier

Examples

Fit Labels to Unlabeled Data

Fit labels to unlabeled data by using a semi-supervised self-training method.

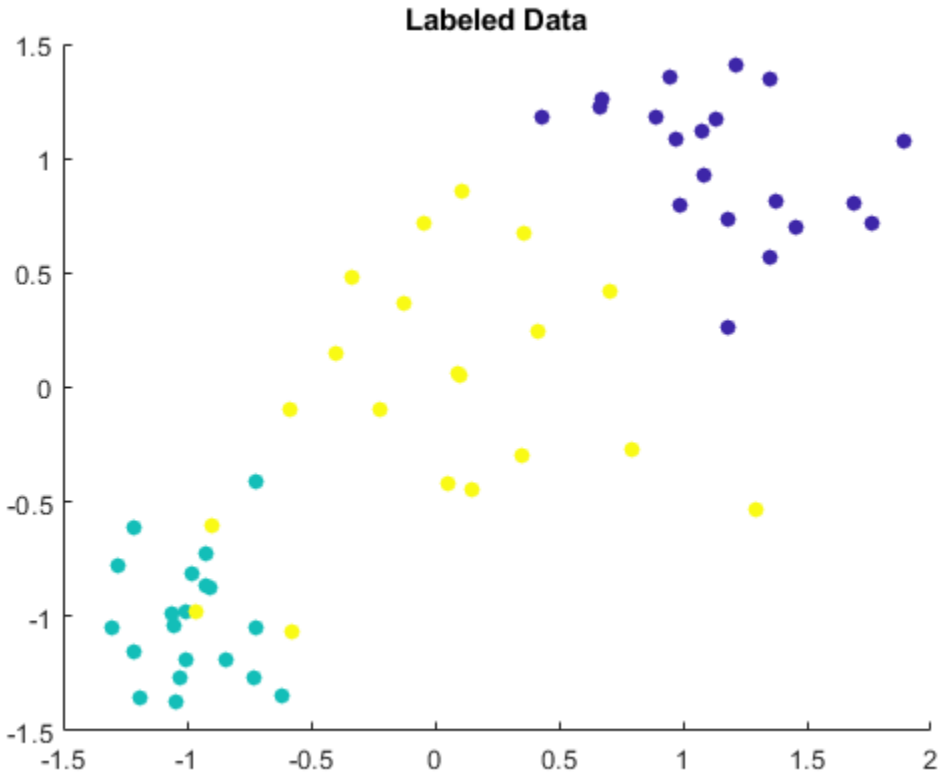
Randomly generate 60 observations of labeled data, with 20 observations in each of three classes.

```
rng('default') % For reproducibility

labeledX = [randn(20,2)*0.25 + ones(20,2);
            randn(20,2)*0.25 - ones(20,2);
            randn(20,2)*0.5];
Y = [ones(20,1); ones(20,1)*2; ones(20,1)*3];
```

Visualize the labeled data by using a scatter plot. Observations in the same class have the same color. Notice that the data is split into three clusters with very little overlap.

```
scatter(labeledX(:,1),labeledX(:,2),[],Y,'filled')
title('Labeled Data')
```



Randomly generate 300 additional observations of unlabeled data, with 100 observations per class. For the purposes of validation, keep track of the true labels for the unlabeled data.

```
unlabeledX = [randn(100,2)*0.25 + ones(100,2);
              randn(100,2)*0.25 - ones(100,2);
              randn(100,2)*0.5];
trueLabels = [ones(100,1); ones(100,1)*2; ones(100,1)*3];
```

Fit labels to the unlabeled data by using a semi-supervised self-training method. The function `fitsemiself` returns a `SemiSupervisedSelfTrainingModel` object whose `FittedLabels` property contains the fitted labels for the unlabeled data and whose `LabelScores` property contains the associated label scores.

```
Mdl = fitsemiself(labeledX,Y,unlabeledX)
```

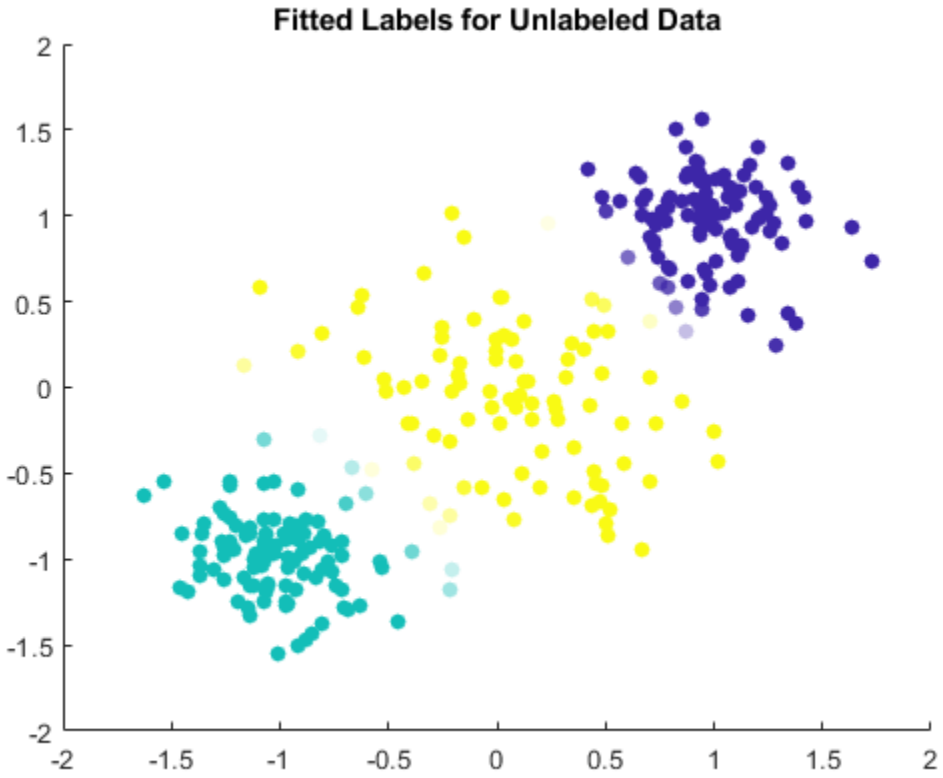
```
Mdl =
  SemiSupervisedSelfTrainingModel with properties:

             FittedLabels: [300x1 double]
              LabelScores: [300x3 double]
                ClassNames: [1 2 3]
             ResponseName: 'Y'
    CategoricalPredictors: []
                  Learner: [1x1 classreg.learning.classif.CompactClassificationECOC]

  Properties, Methods
```

Visualize the fitted label results by using a scatter plot. Use the fitted labels to set the color of the observations, and use the maximum label scores to set the transparency of the observations. Observations with less transparency are labeled with greater confidence. Notice that observations that lie closer to the cluster boundaries are labeled with more uncertainty.

```
maxLabelScores = max(Mdl.LabelScores,[],2);
rescaledScores = rescale(maxLabelScores,0.05,0.95);
scatter(unlabeledX(:,1),unlabeledX(:,2),[],Mdl.FittedLabels,'filled', ...
    'MarkerFaceAlpha','flat','AlphaData',rescaledScores);
title('Fitted Labels for Unlabeled Data')
```



Determine the accuracy of the labeling by using the true labels for the unlabeled data.

```
numWrongLabels = sum(trueLabels ~= Mdl.FittedLabels)
```

```
numWrongLabels = 8
```

Only 8 of the 300 observations in `unlabeledX` are mislabeled.

Classify New Data Using Model Trained on Labeled and Unlabeled Data

Use both labeled and unlabeled data to train a `SemiSupervisedSelfTrainingModel` object. Label new data using the trained model.

Randomly generate 15 observations of labeled data, with 5 observations in each of three classes.

```
rng('default') % For reproducibility
labeledX = [randn(5,2)*0.25 + ones(5,2);
            randn(5,2)*0.25 - ones(5,2);
            randn(5,2)*0.5];
Y = [ones(5,1); ones(5,1)*2; ones(5,1)*3];
```

Randomly generate 300 additional observations of unlabeled data, with 100 observations per class.

```
unlabeledX = [randn(100,2)*0.25 + ones(100,2);
              randn(100,2)*0.25 - ones(100,2);
              randn(100,2)*0.5];
```

Fit labels to the unlabeled data by using a semi-supervised self-training method. The function `fitsemiself` returns a `SemiSupervisedSelfTrainingModel` object whose `FittedLabels` property contains the fitted labels for the unlabeled data and whose `LabelScores` property contains the associated label scores.

```
Mdl = fitsemiself(labeledX,Y,unlabeledX)
```

```
Mdl =
  SemiSupervisedSelfTrainingModel with properties:

             FittedLabels: [300x1 double]
              LabelScores: [300x3 double]
                ClassNames: [1 2 3]
             ResponseName: 'Y'
    CategoricalPredictors: []
                  Learner: [1x1 classreg.learning.classif.CompactClassificationECOC]

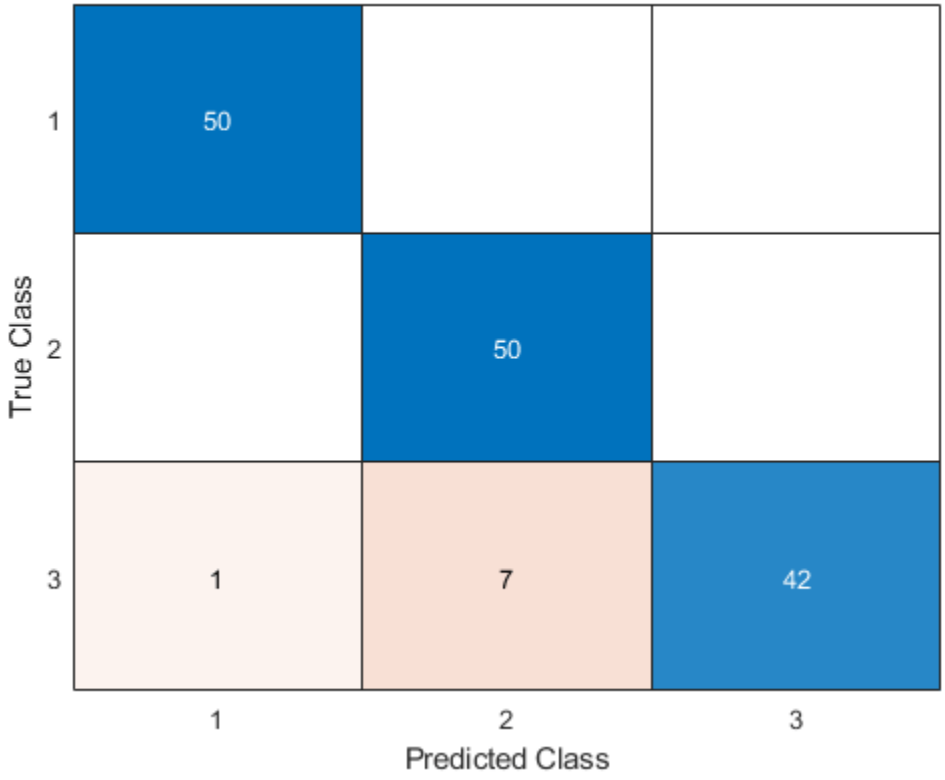
  Properties, Methods
```

Randomly generate 150 observations of new data, with 50 observations per class. For the purposes of validation, keep track of the true labels for the new data.

```
newX = [randn(50,2)*0.25 + ones(50,2);
        randn(50,2)*0.25 - ones(50,2);
        randn(50,2)*0.5];
trueLabels = [ones(50,1); ones(50,1)*2; ones(50,1)*3];
```

Predict the labels for the new data by using the `predict` function of the `SemiSupervisedSelfTrainingModel` object. Compare the true labels to the predicted labels by using a confusion matrix.

```
predictedLabels = predict(Mdl,newX);
confusionchart(trueLabels,predictedLabels)
```



Only 8 of the 150 observations in `newX` are mislabeled.

Introduced in R2020b

sequentialfs

Sequential feature selection using custom criterion

Syntax

```
inmodel = sequentialfs(fun,X,y)
inmodel = sequentialfs(fun,X,Y,Z,...)
[inmodel,history] = sequentialfs(fun,X,...)
[] = sequentialfs(...,param1,val1,param2,val2,...)
```

Description

`inmodel = sequentialfs(fun,X,y)` selects a subset of features from the data matrix `X` that best predict the data in `y` by sequentially selecting features until there is no improvement in prediction. Rows of `X` correspond to observations; columns correspond to variables or features. `y` is a column vector of response values or class labels for each observation in `X`. `X` and `y` must have the same number of rows. `fun` is a function handle to a function that defines the criterion used to select features and to determine when to stop. The output `inmodel` is a logical vector indicating which features are finally chosen.

Starting from an empty feature set, `sequentialfs` creates candidate feature subsets by sequentially adding each of the features not yet selected. For each candidate feature subset, `sequentialfs` performs 10-fold cross-validation by repeatedly calling `fun` with different training subsets of `X` and `y`, `XTRAIN` and `ytrain`, and test subsets of `X` and `y`, `XTEST` and `ytest`, as follows:

```
criterion = fun(XTRAIN,ytrain,XTEST,ytest)
```

`XTRAIN` and `ytrain` contain the same subset of rows of `X` and `Y`, while `XTEST` and `ytest` contain the complementary subset of rows. `XTRAIN` and `XTEST` contain the data taken from the columns of `X` that correspond to the current candidate feature set.

Each time it is called, `fun` must return a scalar value `criterion`. Typically, `fun` uses `XTRAIN` and `ytrain` to train or fit a model, then predicts values for `XTEST` using that model, and finally returns some measure of distance, or loss, of those predicted values from `ytest`. In the cross-validation calculation for a given candidate feature set, `sequentialfs` sums the values returned by `fun` and divides that sum by the total number of test observations. It then uses that mean value to evaluate each candidate feature subset.

Typical loss measures include sum of squared errors for regression models (`sequentialfs` computes the mean-squared error in this case), and the number of misclassified observations for classification models (`sequentialfs` computes the misclassification rate in this case).

Note `sequentialfs` divides the sum of the values returned by `fun` across all test sets by the total number of test observations. Accordingly, `fun` should not divide its output value by the number of test observations.

After computing the mean `criterion` values for each candidate feature subset, `sequentialfs` chooses the candidate feature subset that minimizes the mean criterion value. This process continues until adding more features does not decrease the criterion.

`inmodel = sequentialfs(fun,X,Y,Z,...)` allows any number of input variables `X`, `Y`, `Z`, ... `sequentialfs` chooses features (columns) only from `X`, but otherwise imposes no interpretation on `X`, `Y`, `Z`, ... All data inputs, whether column vectors or matrices, must have the same number of rows. `sequentialfs` calls `fun` with training and test subsets of `X`, `Y`, `Z`, ... as follows:

```
criterion = fun(XTRAIN,YTRAIN,ZTRAIN,...,
                XTEST,YTEST,ZTEST,...)
```

`sequentialfs` creates `XTRAIN`, `YTRAIN`, `ZTRAIN`, ... , `XTEST`, `YTEST`, `ZTEST`, ... by selecting subsets of the rows of `X`, `Y`, `Z`, ... `fun` must return a scalar value `criterion`, but may compute that value in any way. Elements of the logical vector `inmodel` correspond to columns of `X` and indicate which features are finally chosen.

`[inmodel,history] = sequentialfs(fun,X,...)` returns information on which feature is chosen at each step. `history` is a scalar structure with the following fields:

- `Crit` — A vector containing the criterion values computed at each step.
- `In` — A logical matrix in which row `i` indicates the features selected at step `i`.

`[] = sequentialfs(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

Parameter	Value
`'cv'`	The validation method used to compute the criterion for each candidate feature subset. • When the value is a positive integer `k`, `sequentialfs` uses `k`-fold cross-validation without stratification. • When the value is an object of the `cvpartition` class, other forms of cross-validation can be specified. • When the value is `'resubstitution'`, the original data are passed to `fun` as both the training and test data to compute the criterion. • When the value is `'none'`, `sequentialfs` calls `fun` as `criterion = fun(X,Y,Z,...)`, without separating test and training sets. The default value is `10`, that is, 10-fold cross-validation without stratification. So-called wrapper methods use a function `fun` that implements a learning algorithm. These methods usually apply cross-validation to select features. So-called filter methods use a function `fun` that measures characteristics of the data (such as correlation) to select features.
`'mcreps'`	A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is `1`. The value must be `1` if the value of `'cv'` is `'resubstitution'` or `'none'`.
`'direction'`	The direction of the sequential search. The default is `'forward'`. A value of `'backward'` specifies an initial candidate set including all features and an algorithm that removes features sequentially until the criterion increases.

Parameter	Value
'keepin'	A logical vector or a vector of column numbers specifying features that must be included. The default is empty.
'keepout'	A logical vector or a vector of column numbers specifying features that must be excluded. The default is empty.
'nfeatures'	The number of features at which sequentialfs should stop. inmodel includes exactly this many features. The default value is empty, indicating that sequentialfs should stop when a local minimum of the criterion is found. A nonempty value overrides values of 'MaxIter' and 'TolFun' in 'options'.
'nullmodel'	A logical value, indicating whether or not the null model (containing no features from X) should be included in feature selection and in the history output. The default is false.
'options'	Options structure for the iterative sequential search algorithm, as created by statset. sequentialfs uses the following statset parameters: • Display — Amount of information displayed by the algorithm. The default is 'off'. • MaxIter — Maximum number of iterations allowed. The default is Inf. • TolFun — Termination tolerance for the objective function value. The default is 1e-6 if 'direction' is 'forward'; 0 if 'direction' is 'backward'. • TolTypeFun — Use absolute or relative objective function tolerances. The default is 'rel'. • UseParallel — Set to true to compute in parallel. Default is false. • UseSubstreams — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. • Streams — A RandStream object or cell array consisting of one such object. If you do not specify Streams, sequentialfs uses the default stream. To compute in parallel, you need Parallel Computing Toolbox.

Examples

Perform sequential feature selection for classification of noisy features:

```
load fisheriris
rng('default') % For reproducibility
X = randn(150,10);
X(:,[1 3 5 7])= meas;
y = species;
```

```
c = cvpartition(y,'k',10);
opts = statset('Display','iter');
fun = @(XT,yT,Xt,yt)loss(fitcecoc(XT,yT),Xt,yt);

[fs,history] = sequentialfs(fun,X,y,'cv',c,'options',opts)

Start forward sequential feature selection:
Initial columns included:  none
Columns that can not be included:  none
Step 1, added column 5, criterion value 0.00266667
Step 2, added column 7, criterion value 0.00222222
Step 3, added column 1, criterion value 0.00177778
Step 4, added column 3, criterion value 0.000888889
Final columns included:  1 3 5 7

fs =

  1×10 logical array

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

set

Class: `dataset`

(Not Recommended) Set and display dataset array properties

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
set(A)
set(A,PropertyName)
A = set(A,PropertyName,PropertyValue,...)
B = set(A,PropertyName,value)
```

Description

`set(A)` displays all properties of the dataset array `A` and their possible values.

`set(A,PropertyName)` displays possible values for the property specified by *`PropertyName`*.

`A = set(A,PropertyName,PropertyValue,...)` sets property name/value pairs.

`B = set(A,PropertyName,value)` returns a dataset array `B` that is a copy of `A`, but with the property `'PropertyName'` set to the value `value`.

Note Using `set(A,'PropertyName',value)` without assigning to a variable does not modify A's properties. Use `A = set(A,'PropertyName',value)` to modify `A`.

Examples

Create a dataset array from Fisher's iris data and add a description:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
               {meas,'SL','SW','PL','PW'},...
               'ObsNames',NameObs);
iris = set(iris,'Description','Fisher''s Iris Data');
get(iris)
   Description: 'Fisher's Iris Data'
   Units: {}
   DimNames: {'Observations' 'Variables'}
   UserData: []
   ObsNames: {150x1 cell}
   VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}
```

See Also

get | summary

setDefaultYfit

Class: `CompactTreeBagger`

Set default value for `predict`

Syntax

```
B = setDefaultYfit(B,Yfit)
```

Description

`B = setDefaultYfit(B,Yfit)` sets the default prediction for ensemble `B` to `Yfit`. The default prediction must be specified as a character vector or string scalar for classification or as a numeric scalar for regression. This setting controls what predicted value `CompactTreeBagger` returns when no prediction is possible, for example when the `predict` method needs to predict for an observation which has only false values in the matrix supplied through `'UseInstanceForTree'` argument.

See Also

`predict`

setdiff

Class: `dataset`

(Not Recommended) Set difference for dataset array observations

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = setdiff(A,B)
C = setdiff(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA] = setxor( ___ )
```

Description

`C = setdiff(A,B)` for `dataset` arrays `A` and `B` returns the set of observations that are in `A` but not `B`, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = setdiff(A,B,vars)` returns the set of observations that are in `A` but not `B`, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA] = setxor( ___ )` also returns the index vector `iA` such that `C = A(iA,:)`. If there are repeated observations in `A`, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

`A,B`

Input dataset arrays.

`vars`

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables that `setdiff` considers.

Specify `vars` as `[]` to use its default value of all variables.

`setOrder`

Flag indicating the sorting order for the observations in `C`. The possible values of `setOrder` are:

`'sorted'`	Observations in `C` are in sorted order (default).
`'stable'`	Observations in `C` are in the same order that they appear in `A`.

Output Arguments

`C`

Dataset array with the observations that are in `A` but not `B`, with repetitions removed. `C` is in sorted order (by default), or the order specified by `setOrder`.

`iA`

Index vector, indicating the observations from `A` that are in `C`. The vector `iA` contains the index to the first occurrence of any repeated observations in `A`.

Examples

Set Difference of Two Dataset Arrays

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;

A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));
```

The intersection of `A` and `B` is the second observation, with last name `BROWN`.

Return the set difference of `A` and `B`.

```
[C,iA] = setdiff(A,B)
```

```
C =
    Name             Gender       SystolicBP    DiastolicBP
    {'CLARK'}        {'M'}        124           93

iA = 1
```

The first observation in `A` is not present in `B`.

setlabels

(Not Recommended) Assign labels to levels of nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types are not recommended. To represent ordered and unordered discrete, nonnumeric data, use the "Categorical Arrays" data type instead.

Syntax

```
B = setlabels(A,labels)
B = setlabels(A,labels,levels)
```

Description

`B = setlabels(A,labels)` returns a `nominal` or `ordinal` array object of the same type as `A`, but with levels labeled in the order specified by `labels`.

`B = setlabels(A,labels,levels)` labels only the levels specified in `levels`.

Input Arguments

`A` — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

`labels` — Labels to assign

string array | cell array of character vectors | 2-D character matrix

Labels to assign to levels, specified as a string array, cell array of character vectors, or 2-D character matrix.

Data Types: `char` | `string` | `cell`

`levels` — Levels to assign labels

string array | cell array of character vectors | 2-D character matrix

Level to assign labels to, specified as a string array, cell array of character vectors, or 2-D character matrix.

Data Types: `char` | `string` | `cell`

Output Arguments

`B` — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

“Change Category Labels” on page 2-7

Introduced in R2007a

setxor

Class: `dataset`

(Not Recommended) Set exclusive or for dataset array observations

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = setxor(A,B)
C = setxor(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA,iB] = setxor( ___ )
```

Description

`C = setxor(A,B)` for `dataset` arrays `A` and `B` returns the set of observations that are not in the intersection of the two arrays, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = setxor(A,B,vars)` returns the set of observations that are not in the intersection of the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = setxor( ___ )` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA,:)` and `B(iB,:)`. If there are repeated observations in `A` or `B`, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

`A,B`

Input dataset arrays.

`vars`

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables in `A` and `B` that `setxor` considers.

Specify `vars` as `[]` to use its default value of all variables.

`setOrder`

Flag indicating the sorting order for the observations in `C`. The possible values of `setOrder` are:

`'sorted'`	Observations in `C` are in sorted order (default).
`'stable'`	Observations in `C` are in the same order that they appear in `A`, then `B`.

Output Arguments

`C`

Dataset array with the observations not in the intersection of `A` and `B`, with repetitions removed. `C` is in sorted order (by default), or the order specified by `setOrder`.

`iA`

Index vector, indicating the observations from `A` that are in `C`. The vector `iA` contains the index to the first occurrence of any repeated observations in `A`.

`iB`

Index vector, indicating the observations from `B` that are in `C`. The vector `iB` contains the index to the first occurrence of any repeated observations in `B`.

Examples

Symmetric Difference of Two Dataset Arrays

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;

A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));
```

The intersection of `A` and `B` is the second observation, with last name `BROWN`.

Return the symmetric difference of `A` and `B`.

```
[C,iA,iB] = setxor(A,B);
C
```

```
C =
    Name              Gender       SystolicBP    DiastolicBP
    {'CLARK' }        {'M'}        124           93
    {'MARTIN'}        {'M'}        130           92
```

```
[iA iB]
```

```
ans = 1×2

     1     2
```

The symmetric difference contains the first observation from `A`, and the second observation from `B`.

“Dataset Arrays” on page 2-112

shapley

Shapley values

Description

The Shapley on page 33-5863 value of a feature for a query point explains the deviation of the prediction for the query point from the average prediction, due to the feature. For each query point, the sum of the Shapley values for all features corresponds to the total deviation of the prediction from the average.

You can create a `shapley` object for a machine learning model with a specified query point (`queryPoint`). The software creates an object and computes the Shapley values of all features for the query point.

Use the Shapley values to explain the contribution of individual features to a prediction at the specified query point. Use the `plot` function to create a bar graph of the Shapley values. You can compute the Shapley values for another query point by using the `fit` function.

Creation

Syntax

```
explainer = shapley(blackbox)
explainer = shapley(blackbox,X)

explainer = shapley(___,'QueryPoint',queryPoint)

explainer = shapley(___,Name,Value)
```

Description

`explainer = shapley(blackbox)` creates a `shapley` object using a machine learning model object `blackbox` that contains predictor data. To compute Shapley values, use the `fit` function with `explainer`.

`explainer = shapley(blackbox,X)` creates a `shapley` object using the predictor data in `X`.

`explainer = shapley(___,'QueryPoint',queryPoint)` also computes the Shapley values for the query point `queryPoint` and stores the computed Shapley values in the `ShapleyValues` property of `explainer`. You can specify `queryPoint` in addition to any of the input argument combinations in the previous syntaxes.

`explainer = shapley(___,Name,Value)` specifies additional options using one or more name-value arguments. For example, specify `'UseParallel',true` to compute Shapley values in parallel.

Input Arguments

`blackbox` — Machine learning model to be interpreted
regression model object | classification model object | function handle

Machine learning model to be interpreted, specified as a full or compact regression or classification model object or a function handle.

- Full or compact model object — You can specify a full or compact regression or classification model object, which has a `predict` object function. The software uses the `predict` function to compute Shapley values.
  - If you specify a model object that does not contain predictor data (for example, a compact model), then you must provide the predictor data using `X`.
  - When you train a model, use a numeric matrix or table for the predictor data where rows correspond to individual observations.

  Regression Model Object

Supported Model	Full or Compact Regression Model Object
Ensemble of regression models	`RegressionEnsemble`, `RegressionBaggedEnsemble`, `CompactRegressionEnsemble`
Gaussian kernel regression model using random feature expansion	`RegressionKernel`
Gaussian process regression	`RegressionGP`, `CompactRegressionGP`
Generalized additive model	`RegressionGAM`, `CompactRegressionGAM`
Linear regression for high-dimensional data	`RegressionLinear`
Neural network regression model	`RegressionNeuralNetwork`, `CompactRegressionNeuralNetwork`
Regression tree	`RegressionTree`, `CompactRegressionTree`
Support vector machine regression	`RegressionSVM`, `CompactRegressionSVM`

Classification Model Object

Supported Model	Full or Compact Classification Model Object
Discriminant analysis classifier	`ClassificationDiscriminant`, `CompactClassificationDiscriminant`
Multiclass model for support vector machines or other classifiers	`ClassificationECOC`, `CompactClassificationECOC`
Ensemble of learners for classification	`ClassificationEnsemble`, `CompactClassificationEnsemble`, `ClassificationBaggedEnsemble`
Gaussian kernel classification model using random feature expansion	`ClassificationKernel`
Generalized additive model	`ClassificationGAM`, `CompactClassificationGAM`
k-nearest neighbor classifier	`ClassificationKNN`
Linear classification model	`ClassificationLinear`
Multiclass naive Bayes model	`ClassificationNaiveBayes`, `CompactClassificationNaiveBayes`
Neural network classifier	`ClassificationNeuralNetwork`, `CompactClassificationNeuralNetwork`
Support vector machine classifier for one-class and binary classification	`ClassificationSVM`, `CompactClassificationSVM`
Binary decision tree for multiclass classification	`ClassificationTree`, `CompactClassificationTree`

- Function handle — You can specify a function handle that accepts predictor data and returns a column vector containing a prediction for each observation in the predictor data. The prediction is a predicted response for regression or a predicted score of a single class for classification. You must provide the predictor data using `X`.

`X` — Predictor data
numeric matrix | table

Predictor data, specified as a numeric matrix or table. Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
  - The variables that makes up the columns of `X` must have the same order as the predictor variables that trained `blackbox`, stored in `blackbox.X`.
  - If you trained `blackbox` using a table, then `X` can be a numeric matrix if the table contains all numeric predictor variables.
- For a table:
  - If you trained `blackbox` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those in `Tbl`. However, the column order of `X` does not need to correspond to the column order of `Tbl`.

- If you trained `blackbox` using a numeric matrix, then the predictor names in `blackbox.PredictorNames` and the corresponding predictor variable names in `X` must be the same. To specify predictor names during training, use the `'PredictorNames'` name-value argument. All predictor variables in `X` must be numeric vectors.
- `X` can contain additional variables (response variables, observation weights, and so on), but `shapley` ignores them.
- `shapley` does not support multicolumn variables or cell arrays other than cell arrays of character vectors.

If `blackbox` is a model object that does not contain predictor data or a function handle, you must provide `X`. If `blackbox` is a full machine learning model object and you specify this argument, then `shapley` does not use the predictor data in `blackbox`; it uses the specified predictor data only.

Data Types: `single` | `double`

`queryPoint` — Query point
row vector of numeric values | single-row table

Query point at which `shapley` explains a prediction, specified as a row vector of numeric values or a single-row table.

- For a row vector of numeric values:
  - The variables that makes up the columns of `queryPoint` must have the same order as `X` or the predictor variables that trained `blackbox`, stored in `blackbox.X`.
  - If you trained `blackbox` using a table, then `queryPoint` can be a numeric vector if the table contains all numeric variables.
- For a single-row table:
  - If you trained `blackbox` using a table (for example, `Tbl`), then all predictor variables in `queryPoint` must have the same variable names and data types as those in `Tbl`. However, the column order of `queryPoint` does not need to correspond to the column order of `Tbl`.
  - If you trained `blackbox` using a numeric matrix, then the predictor names in `blackbox.PredictorNames` and the corresponding predictor variable names in `queryPoint` must be the same. To specify predictor names during training, use the `'PredictorNames'` name-value argument. All predictor variables in `queryPoint` must be numeric vectors.
  - `queryPoint` can contain additional variables (response variables, observation weights, and so on), but `shapley` ignores them.
  - `shapley` does not support multicolumn variables or cell arrays other than cell arrays of character vectors.

If `queryPoint` contains `NaN`s for continuous predictors and `'Method'` is `'conditional-kernel'`, then the Shapley values (`ShapleyValues`) in the returned object are `NaN`s. Otherwise, `shapley` handles `NaN`s in `queryPoint` in the same way as `blackbox` (the `predict` object function of `blackbox` or the function handle specified by `blackbox`).

Example: `blackbox.X(1,:)` specifies the query point as the first observation of the predictor data in the full machine learning model `blackbox`.

Data Types: `single` | `double` | `table`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `shapley(blackbox,'QueryPoint',q,'Method','conditional-kernel')` creates a `shapley` object and computes the Shapley values for the query point `q` using the extension to the kernelSHAP algorithm.

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as one of the values in this table.

Value	Description
Vector of positive integers	Each entry in the vector is an index value corresponding to the column of the predictor data that contains a categorical variable. The index values are between 1 and `p`, where `p` is the number of predictors used to train the model. If `blackbox` uses a subset of input variables as predictors, then the software indexes the predictors using only the subset. The `'CategoricalPredictors'` values do not count the response variable, the observation weight variable, and any other variables that the function does not use.
Logical vector	A `true` entry means that the corresponding column of predictor data is a categorical variable. The length of the vector is `p`.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the variable names of the predictor data in the form of a table. Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the variable names of the predictor data in the form of a table.
`'all'`	All predictors are categorical.

- If you specify `blackbox` as a function handle, then `shapley` identifies categorical predictors from the predictor data `X`. If the predictor data is in a table, `shapley` assumes that a variable is categorical if it is a logical vector, unordered categorical vector, character array, string array, or cell array of character vectors. If the predictor data is a matrix, `shapley` assumes that all predictors are continuous. To identify any other predictors as categorical predictors, specify them by using the `'CategoricalPredictors'` name-value argument.
- If you specify `blackbox` as a regression or classification model object, then `shapley` identifies categorical predictors by using the `CategoricalPredictors` property of the model object.

`shapley` supports an ordered categorical predictor when `blackbox` supports ordered categorical predictors and `'Method'` is `'interventional-kernel'`.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

`MaxNumSubsets` — Maximum number of predictor subsets
`min(2^M,1024)` where `M` is the number of predictors (default) | positive integer

Maximum number of predictor subsets to use for Shapley value computation, specified as a positive integer.

For details on how `shapley` chooses the subsets to use, see “Complexity of Computing Shapley Values” on page 18-277.

Example: `'MaxNumSubsets',100`

Data Types: `single` | `double`

`Method` — Shapley value computation algorithm
`'interventional-kernel'` (default) | `'conditional-kernel'`

Shapley value computation algorithm, specified as `'interventional-kernel'` or `'conditional-kernel'`.

- `'interventional-kernel'` (default) — `shapley` uses the kernelSHAP algorithm [1] with an interventional value function.
- `'conditional-kernel'` — `shapley` uses the extension to the kernelSHAP algorithm [2] with a conditional value function.

For details about these algorithms, see “Shapley Value Computation Algorithms” on page 18-272.

Example: `'Method','conditional-kernel'`

Data Types: `char` | `string`

`UseParallel` — Flag to run in parallel
`false` (default) | `true`

Flag to run in parallel, specified as `true` or `false`. If you specify `'UseParallel',true`, the `shapley` function executes for-loop iterations in parallel by using `parfor`. This option requires Parallel Computing Toolbox.

Example: `'UseParallel',true`

Data Types: `logical`

Properties

`BlackboxModel` — Machine learning model to be interpreted
regression model object | classification model object | function handle

This property is read-only.

Machine learning model to be interpreted, specified as a regression or classification model object or a function handle.

The `blackbox` argument sets this property.

`BlackboxFitted` — Prediction for query point computed by machine learning model
scalar

This property is read-only.

Prediction for the query point computed by the machine learning model (`BlackboxModel`), specified as a scalar.

- If `BlackboxModel` is a model object, then `BlackboxFitted` is a predicted response for regression or a classified label for classification.
- If `BlackboxModel` is a function handle, then `BlackboxFitted` is a value returned by the function handle, either a predicted response for regression or a predicted score of a single class for classification.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

`CategoricalPredictors` — Categorical predictor indices
vector of positive integers | `[]`

This property is read-only.

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

- If you specify `blackbox` using a function handle, then `shapley` identifies categorical predictors from the predictor data `X`. If you specify the `'CategoricalPredictors'` name-value argument, then the argument sets this property.
- If you specify `blackbox` as a regression or classification model object, then `shapley` determines this property by using the `CategoricalPredictors` property of the model object.

`shapley` supports an ordered categorical predictor when `blackbox` supports ordered categorical predictors and `'Method'` is `'interventional-kernel'`.

Data Types: `single` | `double`

`Method` — Shapley value computation algorithm
`'interventional-kernel'` | `'conditional-kernel'`

This property is read-only.

Shapley value computation algorithm, specified as `'interventional-kernel'` or `'conditional-kernel'`.

- `'interventional-kernel'` — `shapley` uses the kernelSHAP algorithm [1] with an interventional value function.
- `'conditional-kernel'` — `shapley` uses the extension to the kernelSHAP algorithm [2] with a conditional value function.

The `'Method'` argument of `shapley` or the `'Method'` argument of `fit` sets this property.

For details about these algorithms, see “Shapley Value Computation Algorithms” on page 18-272.

Data Types: `char` | `string`

`NumSubsets` — Number of predictor subsets
positive integer

This property is read-only.

Number of predictor subsets to use for Shapley value computation, specified as a positive integer.

The 'MaxNumSubsets' argument of shapley or the 'MaxNumSubsets' argument of fit sets this property.

For details on how shapley chooses the subsets to use, see “Complexity of Computing Shapley Values” on page 18-277.

Data Types: single | double

QueryPoint — Query point
row vector of numeric values | single-row table

This property is read-only.

Query point at which shapley explains a prediction using the Shapley values (ShapleyValues), specified as a row vector of numeric values or single-row table.

The queryPoint argument of shapley or the queryPoint argument of fit sets this property.

Data Types: single | double | table

ShapleyValues — Shapley values for query point
table

This property is read-only.

Shapley values for the query point (QueryPoint), specified as a table.

- For regression, the table has two columns. The first column contains the predictor variable names, and the second column contains the Shapley values of the predictors.
- For classification, the table has two or more columns, depending on the number of classes in BlackboxModel. The first column contains the predictor variable names, and the rest of the columns contain the Shapley values of the predictors for each class.

Data Types: table

X — Predictor data
numeric matrix | table

This property is read-only.

Predictor data, specified as a numeric matrix or table.

Each row of X corresponds to one observation, and each column corresponds to one variable.

- If you specify the X argument, then it sets this property.
- If you specify blackbox as a full machine learning model object and do not specify X, then this property value is the predictor data used to train blackbox.

If an observation contains NaNs for continuous predictors and Method is 'conditional-kernel', then shapley does not use the observation for the Shapley value computation. Otherwise, shapley handles NaNs in X in the same way as BlackboxModel (the predict object function of BlackboxModel or the function handle specified by BlackboxModel).

shapley stores all observations, including the rows with missing values, in this property.

Data Types: single | double | table

Object Functions

fit Compute Shapley values for query point
plot Plot Shapley values

Examples

Compute Shapley Values When Creating shapley Object

Train a classification model and create a `shapley` object. When you create a `shapley` object, specify a query point so that the software computes the Shapley values for the query point. Then create a bar graph of the Shapley values by using the object function `plot`.

Load the `CreditRating_Historical` data set. The data set contains customer IDs and their financial ratios, industry labels, and credit ratings.

```
tbl = readtable('CreditRating_Historical.dat');
```

Display the first three rows of the table.

```
head(tbl,3)
```

```
ans=3×8 table
     ID      WC_TA    RE_TA    EBIT_TA    MVE_BVTD    S_TA     Industry    Rating
    _____    _____    _____    _______    ________    _____    ________    ______

    62394    0.013    0.104     0.036      0.447      0.142       3        {'BB'}
    48608    0.232    0.335     0.062      1.969      0.281       8        {'A' }
    42444    0.311    0.367     0.074      1.935      0.366       1        {'A' }
```

Train a blackbox model of credit ratings by using the `fitcecoc` function. Use the variables from the second through seventh columns in `tbl` as the predictor variables. A recommended practice is to specify the class names to set the order the classes.

```
blackbox = fitcecoc(tbl,'Rating', ...
    'PredictorNames',tbl.Properties.VariableNames(2:7), ...
    'CategoricalPredictors','Industry', ...
    'ClassNames',{'AAA' 'AA' 'A' 'BBB' 'BB' 'B' 'CCC'});
```

Create a `shapley` object that explains the prediction for the last observation. Specify a query point so that the software computes Shapley values and stores them in the `ShapleyValues` property.

```
queryPoint = tbl(end,:)
```

```
queryPoint=1×8 table
     ID      WC_TA    RE_TA    EBIT_TA    MVE_BVTD    S_TA    Industry    Rating
    _____    _____    _____    _______    ________    ____    ________    ______

    73104    0.239    0.463     0.065      2.924      0.34       2        {'AA'}
```

```
explainer = shapley(blackbox,'QueryPoint',queryPoint)
```

```
Warning: Computation can be slow because the predictor data has over 1000 observations. Use a sma
```

```
explainer =
  shapley with properties:
```

```
          BlackboxModel: [1x1 ClassificationECOC]
             QueryPoint: [1x8 table]
         BlackboxFitted: {'AA'}
          ShapleyValues: [6x8 table]
             NumSubsets: 64
                      X: [3932x6 table]
    CategoricalPredictors: 6
                 Method: 'interventional-kernel'
```

As the warning message indicates, the computation can be slow because the predictor data has over 1000 observations. For faster computation, use a smaller sample of the training set or specify `'UseParallel'` as `true`.

For a classification model, `shapley` computes Shapley values using the predicted class score for each class. Display the values in the `ShapleyValues` property.

```
explainer.ShapleyValues
```

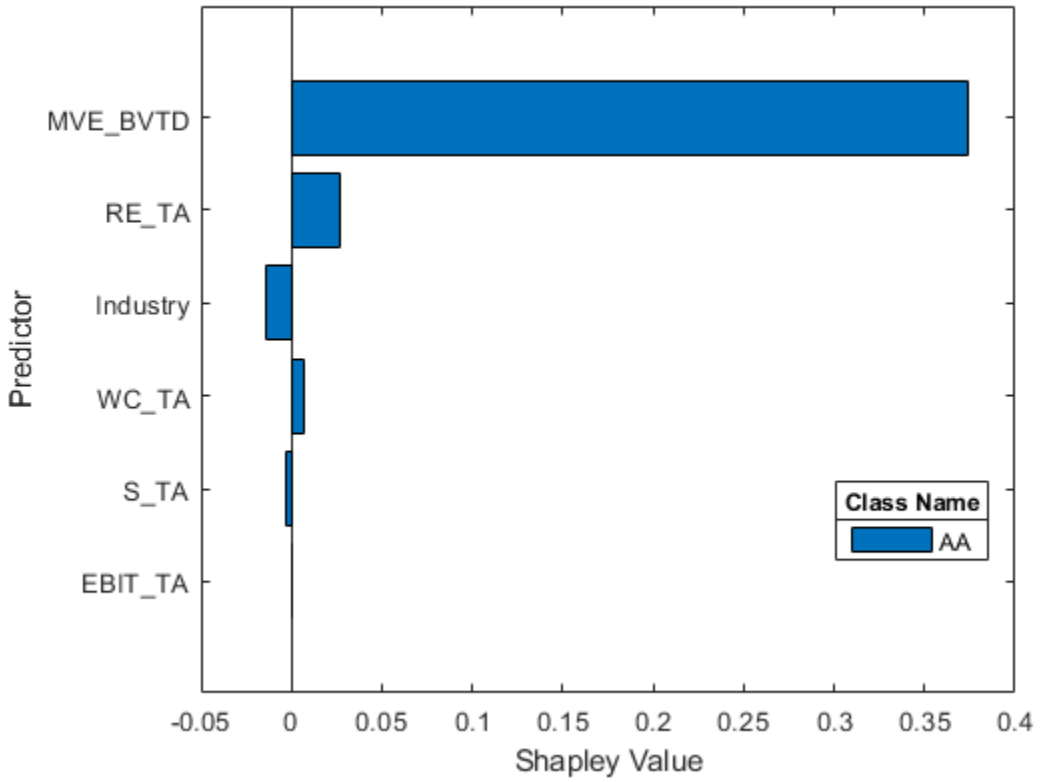
```
ans=6×8 table
    Predictor        AAA           AA            A            BBB            BB            B
    _________    __________    __________    __________    ___________    ___________    _____

    "WC_TA"         0.014715      0.006439      0.002669     0.00048882     -0.0079015     -0.0
    "RE_TA"         0.047918      0.026904      0.014759     -0.0031481       -0.02512     -0.0
    "EBIT_TA"      0.0003427    0.00015023    0.00011977     3.3904e-05    -0.00018925    -0.000
    "MVE_BVTD"       0.38334       0.37376       0.17563      -0.032136       -0.18729       -0
    "S_TA"        -0.0037303    -0.0026019    -8.9059e-05    -0.00081782    -5.4905e-05      0.0
    "Industry"     -0.028974     -0.013901      0.0010365       0.023298       0.026474       0.0
```

The `ShapleyValues` property contains the Shapley values of all features for each class.

Plot the Shapley values for the predicted class by using the `plot` function. To display an existing underscore in any predictor name, change the `TickLabelInterpreter` value of the axes to `'none'`.

```
f = figure;
plot(explainer)
f.CurrentAxes.TickLabelInterpreter = 'none';
```



The horizontal bar graph shows the Shapley values for all variables, sorted by their absolute values. Each Shapley value explains the deviation of the score for the query point from the average score of the predicted class, due to the corresponding variable.

Create `shapley` Object and Compute Shapley Values Using `fit`

Train a regression model and create a `shapley` object. When you create a `shapley` object, if you do not specify a query point, then the software does not compute Shapley values. Use the object function `fit` to compute the Shapley values for the specified query point. Then create a bar graph of the Shapley values by using the object function `plot`.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table containing the predictor variables `Acceleration`, `Cylinders`, and so on, as well as the response variable `MPG`.

```
tbl = table(Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight,MPG);
```

Removing missing values in a training set can help reduce memory consumption and speed up training for the `fitrkernel` function. Remove missing values in `tbl`.

```
tbl = rmmissing(tbl);
```

Train a blackbox model of MPG by using the `fitrkernel` function

```
rng('default') % For reproducibility
mdl = fitrkernel(tbl,'MPG','CategoricalPredictors',[2 5]);
```

Create a `shapley` object. Specify the data set `tbl`, because `mdl` does not contain training data.

```
explainer = shapley(mdl,tbl)
```

```
explainer =
  shapley with properties:

            BlackboxModel: [1x1 RegressionKernel]
               QueryPoint: []
           BlackboxFitted: []
            ShapleyValues: []
               NumSubsets: 64
                        X: [392x7 table]
    CategoricalPredictors: [2 5]
                   Method: 'interventional-kernel'
```

`explainer` stores the training data `tbl` in the `X` property.

Compute the Shapley values of all predictor variables for the first observation in `tbl`.

```
queryPoint = tbl(1,:)
```

```
queryPoint=1×7 table
    Acceleration    Cylinders    Displacement    Horsepower    Model_Year    Weight    MPG
    ____________    _________    ____________    __________    __________    ______    ___

         12             8            307            130            70          3504     18
```

```
explainer = fit(explainer,queryPoint);
```

For a regression model, `shapley` computes Shapley values using the predicted response, and stores them in the `ShapleyValues` property. Display the values in the `ShapleyValues` property.

```
explainer.ShapleyValues
```

```
ans=6×2 table
      Predictor       ShapleyValue
    _______________    ____________

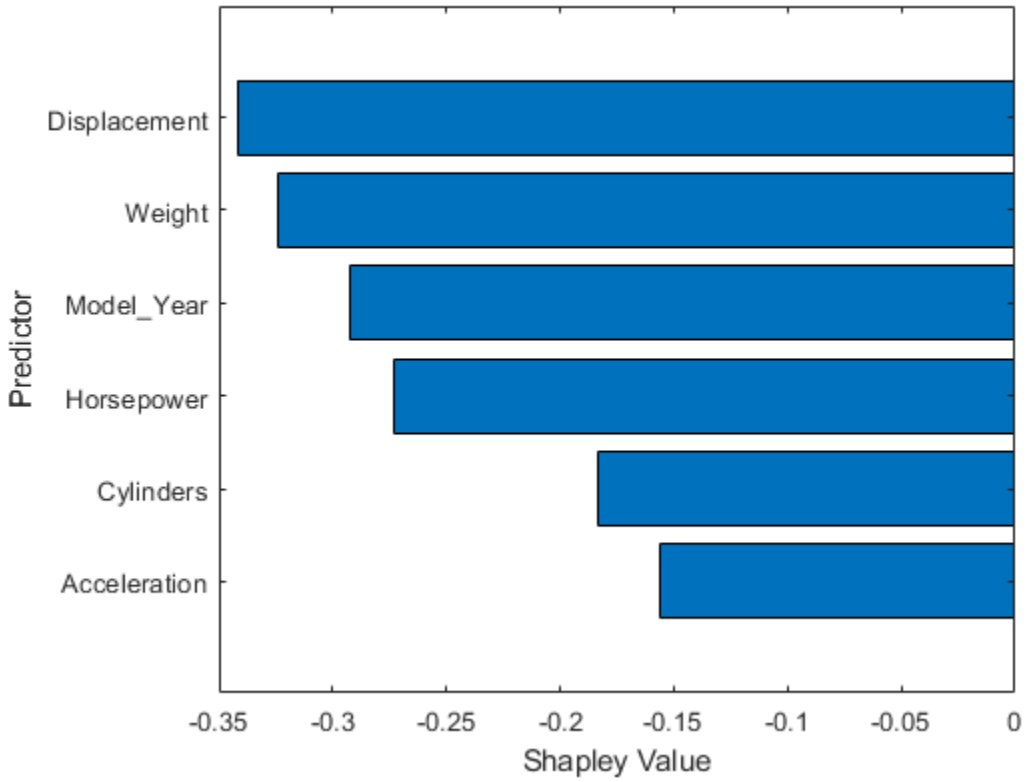
    "Acceleration"       -0.1561
    "Cylinders"         -0.18306
    "Displacement"      -0.34203
    "Horsepower"        -0.27291
    "Model_Year"         -0.2926
    "Weight"            -0.32402
```

Display the predicted response for the query point, and plot the Shapley values for the query point by using the `plot` function. To display an existing underscore in any predictor name, change the `TickLabelInterpreter` value of the axes to `'none'`.

```
explainer.BlackboxFitted
```

```
ans = 21.0495
```

```
f = figure;
plot(explainer)
f.CurrentAxes.TickLabelInterpreter = 'none';
```



The horizontal bar graph shows the Shapley values for all variables, sorted by their absolute values. Each Shapley value explains the deviation of the prediction for the query point from the average, due to the corresponding variable.

Specify Blackbox Model Using Function Handle

Train a regression model and create a `shapley` object using a function handle to the `predict` function of the model. Use the object function `fit` to compute the Shapley values for the specified query point. Then plot the Shapley values by using the object function `plot`.

Load the `carbig` data set, which contains measurements of cars made in the 1970s and early 1980s.

```
load carbig
```

Create a table containing the predictor variables `Acceleration`, `Cylinders`, and so on.

```
tbl = table(Acceleration,Cylinders,Displacement,Horsepower,Model_Year,Weight);
```

Train a blackbox model of `MPG` by using the `TreeBagger` function.

```
rng('default') % For reproducibility
Mdl = TreeBagger(100,tbl,MPG,'Method','regression','CategoricalPredictors',[2 5]);
```

`shapley` does not support a `TreeBagger` object directly, so you cannot specify the first input argument (blackbox model) of `shapley` as a `TreeBagger` object. Instead, you can use a function handle to the `predict` function. You can also specify options of the `predict` function using name-value arguments of the function.

Create the function handle to the `predict` function of the `TreeBagger` object `Mdl`. Specify the array of tree indices to use as `1:50`.

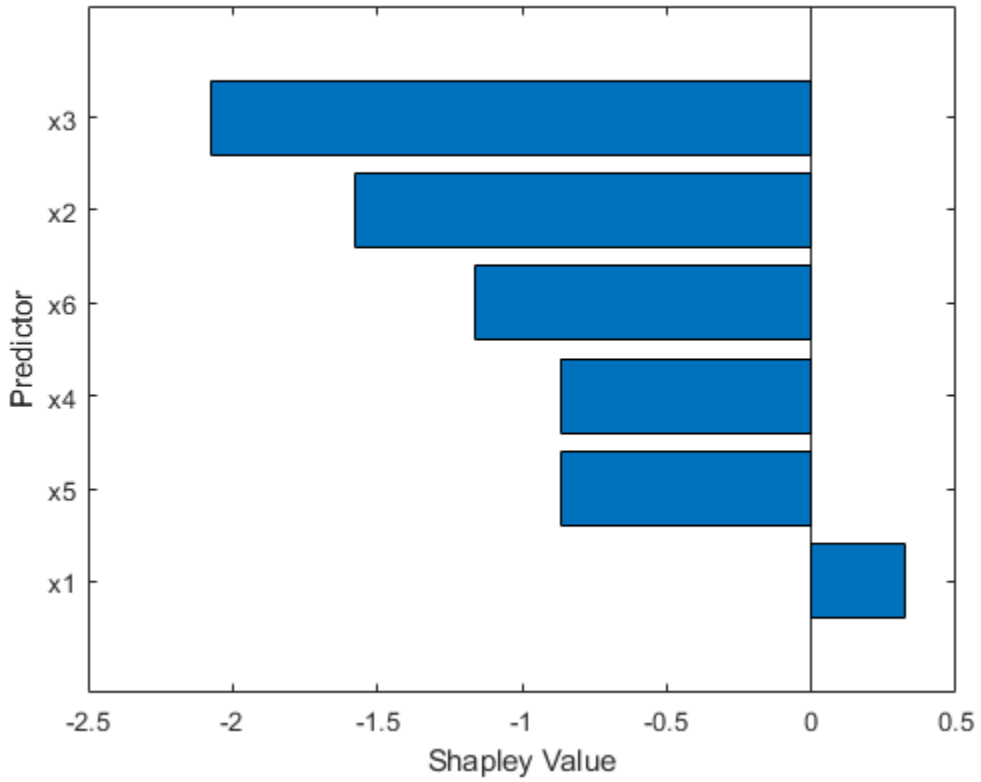
```
f = @(tbl) predict(Mdl,tbl,'Trees',1:50);
```

Create a `shapley` object using the function handle `f`. When you specify a blackbox model as a function handle, you must provide the predictor data. `tbl` includes categorical predictors (`Cylinder` and `Model_Year`) with the `double` data type. By default, `shapley` does not treat variables with the `double` data type as categorical predictors. Specify the second (`Cylinder`) and fifth (`Model_Year`) variables as categorical predictors.

```
explainer = shapley(f,tbl,'CategoricalPredictors',[2 5]);
explainer = fit(explainer,tbl(1,:));
```

Plot the Shapley values.

```
plot(explainer)
```



Display the predictor names in order of importance.

```
tbl.Properties.VariableNames([3 2 6 4 5 1])

ans = 1x6 cell
  Columns 1 through 4

    {'Displacement'}    {'Cylinders'}    {'Weight'}    {'Horsepower'}

  Columns 5 through 6

    {'Model_Year'}    {'Acceleration'}
```

More About

Shapley Values

In game theory, the Shapley value of a player is the average marginal contribution of the player in a cooperative game. In the context of machine learning prediction, the Shapley value of a feature for a query point explains the contribution of the feature to a prediction (response for regression or score of each class for classification) at the specified query point.

The Shapley value corresponds to the deviation of the prediction for the query point from the average prediction, due to the feature. For a query point, the sum of the Shapley values for all features corresponds to the total deviation of the prediction from the average.

For more details, see “Shapley Values for Machine Learning Model” on page 18-272.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` name-value argument to `true` in the call to this function.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2021a

shrink

Prune ensemble

Syntax

```
cmp = shrink(ens)
cmp = shrink(ens,Name,Value)
```

Description

`cmp = shrink(ens)` returns a compact shrunken version of `ens`, a regularized ensemble. `cmp` retains only learners with weights above a threshold.

`cmp = shrink(ens,Name,Value)` returns an ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,…,NameN,ValueN`.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`lambda`

Vector of nonnegative regularization parameter values for lasso. If `ens.Regularization` is nonempty (populate it with `regularize`), `shrink` regularizes `ens` using `lambda`. If `ens` contains a `Regularization` structure, you cannot pass `lambda`.

Default: `[]`

`threshold`

Lower cutoff on weights for weak learners, a numeric nonnegative scalar. `shrink` creates `cmp` from those learners with weights above `threshold`.

Default: `0`

`weightcolumn`

Column index of `ens.Regularization.TrainedWeights`, a positive integer. `shrink` creates `cmp` with learner weights from this column.

Default: `1`

Output Arguments

cmp

A regression ensemble of class `CompactRegressionEnsemble`. Use `cmp` for making predictions exactly as you use `ens`, with the `predict` method.

`shrink` orders the members of `cmp` from largest to smallest.

Examples

Shrink Bagged Regression Ensemble

Shrink a 300-member bagged regression ensemble, and view the number of members of the resulting ensemble.

Generate sample data.

```
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
```

Shrink a 300-member bagged regression ensemble using `0.1` for the parameter `lambda`.

```
bag = fitrensemble(X,Y,'Method','Bag','NumLearningCycles',300);
cmp = shrink(bag,'lambda',0.1);
```

View the number of members of the resulting ensemble.

```
cmp.NumTrained
```

```
ans = 94
```

“Ensemble Regularization” on page 18-70

signrank

Wilcoxon signed rank test

Syntax

```
p = signrank(x)
p = signrank(x,y)
p = signrank(x,y,Name,Value)
[p,h] = signrank( ___ )
[p,h,stats] = signrank( ___ )

[ ___ ] = signrank(x,m)
[ ___ ] = signrank(x,m,Name,Value)
```

Description

`p = signrank(x)` returns the *p*-value of a two-sided Wilcoxon signed rank test on page 33-5872.

`signrank` tests the null hypothesis that data in the vector `x` come from a distribution whose median is zero at the 5% significance level. The test assumes that the data in `x` come from a continuous distribution symmetric about its median.

`p = signrank(x,y)` returns the *p*-value of a paired, two-sided test for the null hypothesis that `x – y` comes from a distribution with zero median.

`p = signrank(x,y,Name,Value)` returns the *p*-value for the sign test with additional options specified by one or more `Name`,`Value` pair arguments.

`[p,h] = signrank( ___ )` also returns a logical value indicating the test decision. `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signrank( ___ )` also returns the structure `stats` with information about the test statistic.

`[ ___ ] = signrank(x,m)` returns any of the output arguments in the previous syntaxes for the null hypothesis that the data in `x` are observations from a distribution with median `m`.

`[ ___ ] = signrank(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the signed rank test with additional options specified by one or more `Name`,`Value` pair arguments.

Examples

Test for Zero Median of a Single Population

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25) + 1.30;
```

Test the hypothesis that the data in x has zero median.

```
[p,h] = signrank(x)
```

```
p = 3.2229e-05
```

```
h = logical
   1
```

At the default 5% significance level, the value h = 1 indicates that the test rejects the null hypothesis of zero median.

Test the Median of Differences of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2,.25,10,1);
y = x + trnd(2,10,1);
```

Test the hypothesis that x – y has zero median.

```
[p,h] = signrank(x,y)
```

```
p = 0.3223
```

```
h = logical
   0
```

The results indicate that the test fails to reject the null hypothesis of zero median in the difference at the default 5% significance level.

Signed Rank Test for Large Samples

Conduct a -sided test on a large sample using approximation.

Load the sample data.

```
load('gradespaired.mat');
```

Test the null hypothesis that the median of the grade differences of students before and after participating in a tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signrank(gradespaired(:,1),...
        gradespaired(:,2),'tail','left')
```

```
p = 0.0047
```

```
h = logical
   1

stats = struct with fields:
          zval: -2.5982
    signedrank: 2.0175e+03
```

Because the sample size is greater than 15, `signrank` uses an approximate method to calculate the *p*-value and also returns the value of the *z*-statistic. The value `h = 1` indicates that the test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level. There is enough statistical evidence to conclude that the median grade before the tutoring program is less than the median grade after the tutoring program.

Repeat the test using the exact method.

```
[p,h,stats] = signrank(gradespaired(:,1),gradespaired(:,2),...
        'tail','left','method','exact')
```

```
p = 0.0045
```

```
h = logical
   1

stats = struct with fields:
    signedrank: 2.0175e+03
```

The results obtained using the approximate method are consistent with the exact method.

Two-Sided Test for the Median of a Single Population

Load the sample data.

```
load mileage
```

The data contains the mileages per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second column differs from 33.

```
[p,h,stats] = signrank(mileage(:,2),33)
```

```
p = 0.0313
```

```
h = logical
   1

stats = struct with fields:
    signedrank: 21
```

At the 5% significance level, the results indicate that the median mileage for the second type of cars differs from 33. Note that `signrank` uses an exact method to calculate the *p*-value for small samples and does not return the *z*-statistic.

Right-Sided Test for the Median of a Single Population

Use the name-value pair arguments in `signrank`.

Load the sample data.

```
load mileage
```

The data contains the mileage per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second row are larger than 33.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right')
```

```
p = 0.0156

h = logical
   1

stats = struct with fields:
    signedrank: 21
```

Repeat the same test at the 1% significance level using the approximate method.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right',...
'alpha',0.01,'method','approximate')
```

```
p = 0.0180

h = logical
   0

stats = struct with fields:
          zval: 2.0966
    signedrank: 21
```

This result, `h = 0`, indicates that the null hypothesis cannot be rejected at the 1% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. `y` must be the same length as `x`.

Data Types: `single` | `double`

`m` — Hypothesized value of the median

scalar

Hypothesized value of the median, specified as a scalar.

Example: `signrank(x,10)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'alpha',0.01,'method','approximate','tail','right'` specifies a right-tailed signed rank test with 1% significance level, which returns the approximate p-value.

`alpha` — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. Significance level of `h` is 100 * `alpha`%.

Example: `'alpha', 0.01`

Data Types: `double` | `single`

`method` — Computation method of `p`

`'exact'` | `'approximate'`

Computation method of `p`, specified as the comma-separated pair consisting of `'method'` and one of the following.

`'exact'`	Exact computation of the *p*-value, `p`. Default value for 15 or fewer observations in `x`, `x – m`, or `x – y` when `method` is unspecified.
`'approximate'`	Normal approximation while computing the *p*-value, `p`. Default value for more than 15 observations in `x`, `x – m`, or `x – y` when `'method'` is unspecified because the exact method can be slow on large samples.

Example: `'method','exact'`

`tail` — Type of test

`'both'` (default) | `'right'` | `'left'`

Type of test, specified as the comma-separated pair consisting of `'tail'` and one of the following:

`'both'`	Two-sided hypothesis test, which is the default test type. • For a one-sample test, the alternate hypothesis states that the data in `x` come from a continuous distribution with median different than 0 or `m`. • For a two-sample test, the alternate hypothesis states that the data in `x – y` come from a distribution with median different than 0.

`'right'`	Right-tailed hypothesis test. • For a one-sample test, the alternate hypothesis states that the data in `x` come from a continuous distribution with median greater than 0 or `m`. • For a two-sample test, the alternate hypothesis states the data in `x – y` come from a distribution with median greater than 0.
`'left'`	Left-tailed hypothesis test. • For a one-sample test, the alternate hypothesis states that the data in `x` come from a continuous distribution with median less than 0 or `m`. • For a two-sample test, the alternate hypothesis states the data in `x – y` come from a distribution with median less than 0.

Example: `'tail','left'`

Output Arguments

p — *p*-value of the test

nonnegative scalar

p-value of the test, returned as a nonnegative scalar from 0 to 1. `p` is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signrank` computes the two-sided *p*-value by doubling the most significant one-sided value.

h — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If `h` = 1, this indicates the rejection of the null hypothesis at the 100 * `alpha`% significance level.
- If `h` = 0, this indicates a failure to reject the null hypothesis at the 100 * `alpha`% significance level.

stats — Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `signrank`: Value of the sign rank test statistic.
- `zval`: Value of the *z*- statistic on page 33-5873 (computed when `'method'` is `'approximate'`).

More About

Wilcoxon Signed Rank Test

The Wilcoxon signed rank test is a nonparametric test for two populations when the observations are paired. In this case, the test statistic, W, is the sum of the ranks of positive differences between the observations in the two samples (that is, `x – y`). When you use the test for one sample, then W is the sum of the ranks of positive differences between the observations and the hypothesized median value M_0 (which is 0 when you use `signrank(x)` and `m` when you use `signrank(x,m)`).

z-Statistic

For large samples, or when `method` is `approximate`, the `signrank` function calculates the *p*-value using the *z*-statistic, given by

$$z = \frac{(W - n(n+1)/4)}{\sqrt{\frac{n(n+1)(2n+1) - tieadj}{24}}},$$

where *n* is the sample size of the difference `x − y` or `x – m`. For the two-sample case, `signrank` uses `[tie_rank,tieadj] = tiedrank(abs(diffxy),0,0,epsdiff)` to obtain the tie adjustment value `tieadj`.

Algorithms

`signrank` treats `NaN`s in `x` and `y` as missing values and ignores them.

For the two-sample case, `signrank` uses a tolerance based on the values `epsdiff = eps(x) + eps(y)`. `signrank` computes the absolute values of the differences (`abs(d(i))` where `d(i) = x(i) − y(i)`) and compares them to `epsdiff`. Values with an absolute value less than `epsdiff` (`abs(d(i)) < epsdiff(i)`) are treated as ties.

Introduced before R2006a

signtest

Sign test

Syntax

```
p = signtest(x)
p = signtest(x,y)
p = signtest(x,y,Name,Value)
[p,h] = signtest( ___ )
[p,h,stats] = signtest( ___ )

[ ___ ] = signtest(x,m)
[ ___ ] = signtest(x,m,Name,Value)
```

Description

`p = signtest(x)` returns the *p*-value for a two-sided sign test on page 33-5880.

`signtest` tests the hypothesis that data in `x` has a continuous distribution with zero median against the alternative that the distribution does not have zero median at the 5% significance level.

`p = signtest(x,y)` returns the *p*-value of a two-sided sign test on page 33-5880. Here,`signtest` tests for the hypothesis that the data in `x – y` has a distribution with zero median against the alternative that the distribution does not have zero median. Note that a hypothesis of zero median for `x – y` is not equivalent to a hypothesis of equal median for `x` and `y`.

`p = signtest(x,y,Name,Value)` returns the *p*-value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signtest( ___ )` also returns a logical value indicating the test decision. The value `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signtest( ___ )` also returns the structure `stats` containing information about the test statistic.

`[ ___ ] = signtest(x,m)` returns any of the output arguments in the previous syntaxes for the test whether the data in `x` are observations from a distribution with median `m` against the alternative that the median is different from `m`.

`[ ___ ] = signtest(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the sign test with additional options specified by one or more `Name,Value` pair arguments.

Examples

Test for Zero Median of a Single Population

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25);
```

The sampling distribution of `x` is symmetric with zero median.

Test the null hypothesis that `x` comes from a distribution with a median different from zero median.

```
[p,h,stats] = signtest(x,0)
```

```
p = 0.1078

h = logical
   0

stats = struct with fields:
    zval: NaN
    sign: 17
```

At the default 5% significance level, the result `h = 0` indicates that `signtest` fails to reject to the null hypothesis of zero median. `signtest` calculates the *p*-value using the exact method, hence it does not calculate `zval` and returns it as a `NaN`.

Test for Zero Median for the Difference of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
before = lognrnd(2,.25,10,1);
after = before + (lognrnd(0,.5,10,1) - 1);
```

The sampling distribution of the difference between `before` and `after` is symmetric with zero median.

Test the null hypothesis that the difference of `before` and `after` has zero median.

```
[p,h] = signtest(before,after)
```

```
p = 0.7539

h = logical
   0
```

At the default 5% significance level, the value `h = 0` indicates that `signtest` fails to reject to the null hypothesis of zero median in the difference.

Medians of Paired Samples

Test the hypothesis of zero median for the difference between two paired samples using the exact and approximate methods.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2,.25,15,1);
y = x + trnd(2,15,1);
display([x y])
```

```
    8.4521    7.8047
   11.6869   11.4094
    4.2009    5.1133
    9.1664   12.1655
    8.0020   10.0300
    5.3285    6.0153
    6.6300    5.1235
    8.0499    8.6737
   18.0763   19.2164
   14.7665   15.3380
    5.2726    8.4187
   15.7798   16.2093
    8.8583    8.5575
    7.2735    7.4783
    8.8347    7.8894
```

Test the hypothesis that x – y has zero median.

```
[p,h,stats] = signtest(x,y)
```

```
p = 0.3018

h = logical
   0

stats = struct with fields:
    zval: NaN
    sign: 5
```

At the default 5% significance level, the value h = 0 indicates that the test fails to reject the null hypothesis of zero median in the difference.

Repeat the test using the approximate method.

```
[p,h,stats] = signtest(x,y,'Method','approximate')
```

```
p = 0.3017

h = logical
   0

stats = struct with fields:
    zval: -1.0328
    sign: 5
```

The approximate *p*-value, which `signtest` obtains using the z-statistic, is really close to the exact *p*-value.

Test for Large Samples

Perform a left-sided sign test for large samples.

Load the sample data.

```
load gradespaired
```

Test the null hypothesis that the median of the grade differences before and after the tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signtest(gradespaired(:,1),gradespaired(:,2),'Tail','left')
```

```
p = 0.0013
```

```
h = logical
   1
```

```
stats = struct with fields:
    zval: -3.0110
    sign: 37
```

Because the sample size is large (greater than 100), `signtest` uses an approximate method to calculate the *p*-value and also returns the value of the *z*-statistic. The test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level.

Test for Median of a Single Population

Test the hypothesis that the population median is different from a specified value.

Load the sample data.

```
load lawdata
```

The data set has 15 observations for variables `gpa` and `lsat`.

Test the hypothesis that the median `lsat` score is higher than 570.

```
[p,h,stats] = signtest(lsat,570,'Tail','right')
```

```
p = 0.0176
```

```
h = logical
   1
```

```
stats = struct with fields:
    zval: NaN
```

```
    sign: 12
```

Both the *p*-value, 0.0176, and `h` = 1 indicate that at the 5% significance level the test concludes in favor of the alternate hypothesis.

Input Arguments

`x` — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

`y` — Sample data

vector

Sample data, specified as a vector. `y` must be the same length as `x`.

Data Types: `single` | `double`

`m` — Hypothesized value of the median

scalar

Hypothesized value of the median, specified as a scalar.

Example: `signtest(x,35)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'Method','approximate','Tail','right'` specifies a right-tailed sign test with 1% significance level, which returns the approximate p-value.

`Alpha` — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. The default value of `Alpha` is 0.05. Significance level of `h` is 100 * `Alpha`%.

Example: `'Alpha', 0.01`

Data Types: `double` | `single`

`Method` — *p*-value computation method

`'exact'` | `'approximate'`

p-value computation method, specified as the comma-separated pair consisting of `'Method'` and one of the following:

`'exact'`	Exact computation of the *p*-value, `p`.
`'approximate'`	Normal approximation for computing the *p*-value, `p`.

The default computation method is `'exact'`, if there are fewer than 100 observations and `'approximate'` if there are 100 observations or more.

Example: `'Method','exact'`

`Tail` — Type of test
`'both'` (default) | `'right'` | `'left'`

Type of test, specified as the comma-separated pair consisting of `'Tail'` and one of the following:

`'both'`	Two-sided hypothesis test, which is the default test type. • For a one-sample test, the alternate hypothesis states that the data in `x` come from a continuous distribution with median different than zero (or `m`). • For a two-sample test, the alternate hypothesis states that the data in `x-y` come from a distribution with median different than zero.
`'right'`	Right-tailed hypothesis test. • For a one-sample test, the alternate hypothesis states that the data in `x` come from a continuous distribution with median greater than zero (or `m`). • For a two-sample test, the alternate hypothesis states the data in `x-y` come from a distribution with median greater than zero.
`'left'`	Left-tailed hypothesis test. • For a one-sample test, the alternate hypothesis states that the data in `x` come from a continuous distribution with median less than zero (or `m`). • For a two-sample test, the alternative hypothesis states the data in `x-y` come from a distribution with median less than zero.

Example: `'Tail','left'`

Output Arguments

`p` — *p*-value of the test
nonnegative scalar

p-value of the test, returned as a nonnegative scalar from 0 to 1. `p` is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signtest` computes the two-sided *p*-value by doubling the most significant one-sided value.

`h` — Result of the hypothesis test
1 | 0

Result of the hypothesis test, returned as a logical value.

- If `h` = 1, this indicates rejection of the null hypothesis at the 100 * `Alpha`% significance level.
- If `h` = 0, this indicates a failure to reject the null hypothesis at the 100 * `Alpha`% significance level.

`stats` — Test statistics
structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `sign`: Value of the sign test statistic.
- `zval`: Value of the z-statistic on page 33-5880 (computed only for large samples).

More About

Sign Test

The sign test is a nonparametric test for the median of a population or median of the difference of two populations.

For example, for tests on a single population median:

- If the test is two-sided, then the test statistic, S, is the minimum of the number of observations that are smaller or larger than the hypothesized median value, M_0.
- If the test is right-sided, then S is the number of observations that are larger than the hypothesized median value M_0.
- If the test is left-sided, then S is the number of observations that are smaller than the hypothesized median value M_0.

z-Statistic

For a large sample, `signtest` uses the z-statistic to approximate the p-value.

The `signtest` test statistic is the number of elements that are greater than `0` (for `signtest(x)` or `signtest(x-y)`), or `m` (for `signtest(x,m)`). Hence, the z-statistic of the sign test, with the continuity correction, is:

$$z = \frac{(S - E(S))}{\sqrt{V(S)}} = \frac{(S - (0.5)n - 0.5sign(npos - nneg))}{\sqrt{(0.5)(0.5)n}},$$

where *npos* and *nneg* are the number of positive and negative differences from the hypothesized median value, respectively.

Algorithms

For a one-sample test, `signtest` omits values in `x` that are zero or `NaN`.

For a two-sample test, `signtest` omits values in `x – y` that are zero or `NaN`.

Introduced before R2006a

silhouette

Silhouette plot

Syntax

```
silhouette(X,clust)
silhouette(X,clust,Distance)
silhouette(X,clust,Distance,DistParameter)

s = silhouette( ___ )
[s,h] = silhouette( ___ )
```

Description

`silhouette(X,clust)` plots cluster silhouettes for the *n*-by-*p* input data matrix `X`, given the cluster assignment `clust` of each point (observation) in `X`.

`silhouette(X,clust,Distance)` plots the silhouettes using the inter-point distance metric specified in `Distance`.

`silhouette(X,clust,Distance,DistParameter)` accepts one or more additional distance metric parameter values when you specify `Distance` as a custom distance function handle `@`*`distfun`* that accepts the additional parameter values.

`s = silhouette( ___ )` returns the silhouette values in `s` for any of the input argument combinations in the previous syntaxes without plotting the cluster silhouettes.

`[s,h] = silhouette( ___ )` plots the silhouettes and returns the figure handle `h` in addition to the silhouette values in `s`.

Examples

Create Silhouette Plot

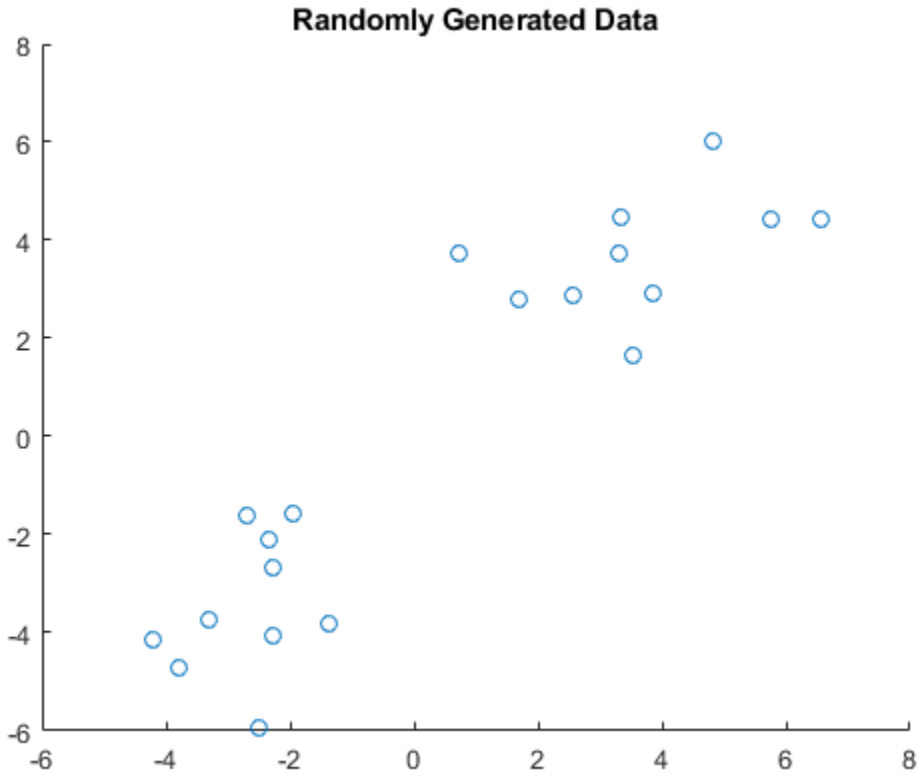
Create silhouette plots from clustered data using different distance metrics.

Generate random sample data.

```
rng('default')  % For reproducibility
X = [randn(10,2)+3;randn(10,2)-3];
```

Create a scatter plot of the data.

```
scatter(X(:,1),X(:,2));
title('Randomly Generated Data');
```



The scatter plot shows that the data appears to be split into two clusters of equal size.

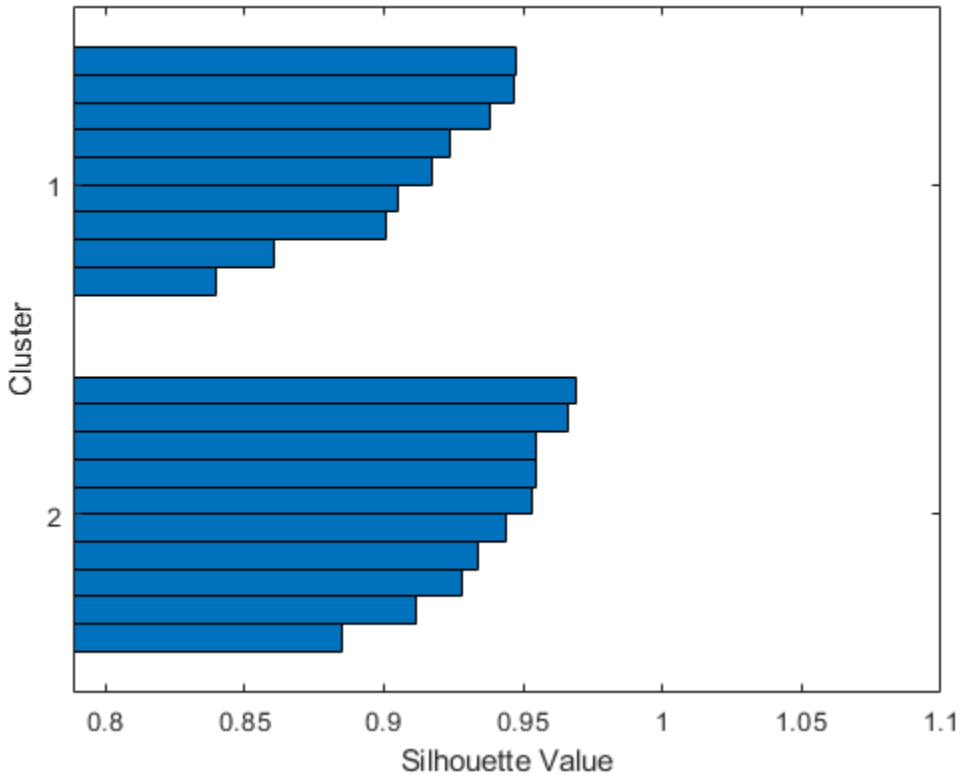
Partition the data into two clusters using `kmeans` with the default squared Euclidean distance metric.

```
clust = kmeans(X,2);
```

`clust` contains the cluster indices of the data.

Create a silhouette plot from the clustered data using the default squared Euclidean distance metric.

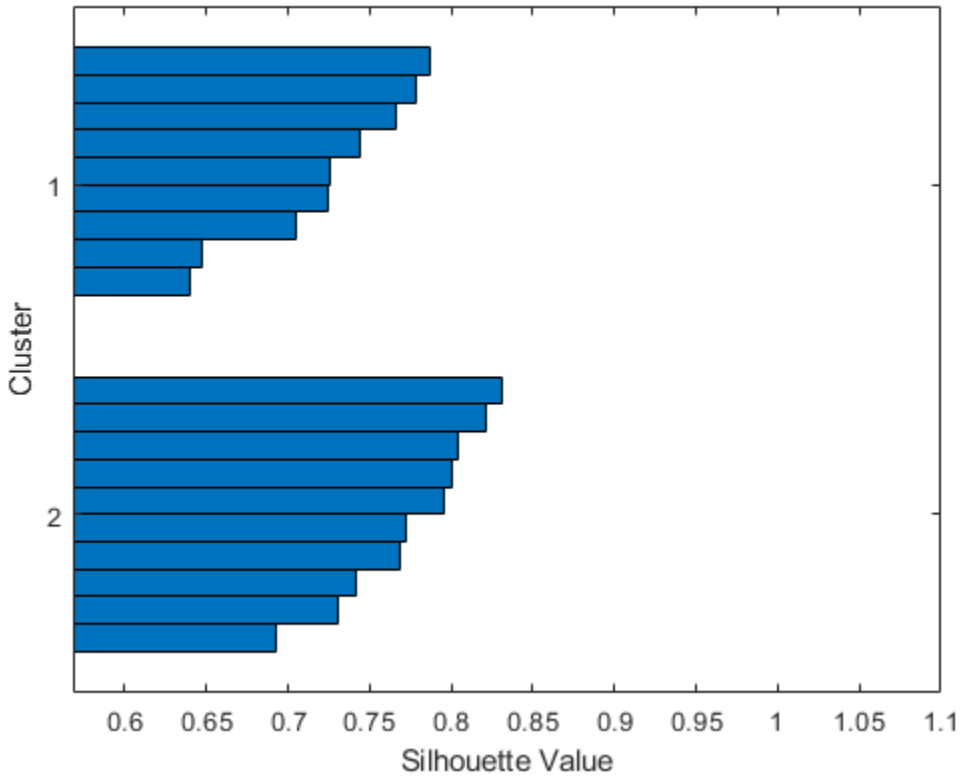
```
silhouette(X,clust)
```



The silhouette plot shows that the data is split into two clusters of equal size. All the points in the two clusters have large silhouette values (0.8 or greater), indicating that the clusters are well separated.

Create a silhouette plot from the clustered data using the Euclidean distance metric.

```
silhouette(X,clust,'Euclidean')
```



The silhouette plot shows that the data is split into two clusters of equal size. All the points in the two clusters have large silhouette values (0.6 or greater), indicating that the clusters are well separated.

Compute Silhouette Values

Compute the silhouette values from clustered data.

Generate random sample data.

```
rng('default')  % For reproducibility
X = [randn(10,2)+1;randn(10,2)-1];
```

Cluster the data in `X` based on the sum of absolute differences in distance by using `kmeans`.

```
clust = kmeans(X,2,'distance','cityblock');
```

`clust` contains the cluster indices of the data.

Compute the silhouette values from the clustered data. Specify the distance metric as `'cityblock'` to indicate that the `kmeans` clustering is based on the sum of absolute differences.

```
s = silhouette(X,clust,'cityblock')
```

```
s = 20×1
```

```

    0.6664
      ⋮
```

Find Silhouette Values Using Custom Distance Metric

Find silhouette values from clustered data using a custom chi-square distance metric. Verify that the chi-square distance metric is equivalent to the Euclidean distance metric, but with an optional scaling parameter.

Generate random sample data.

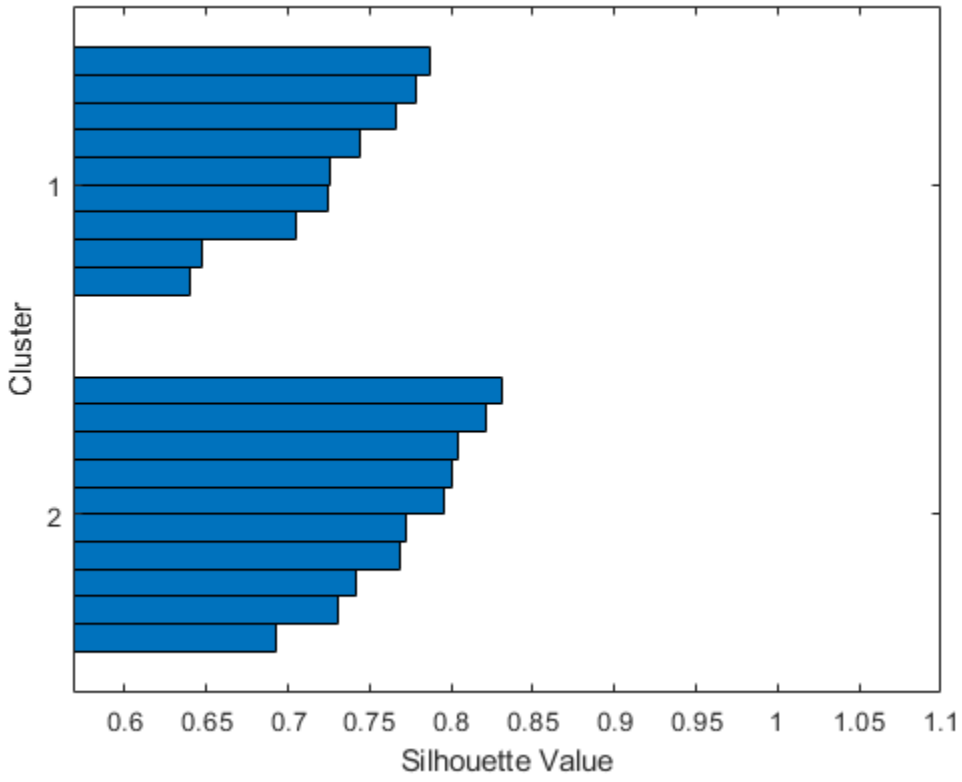
```
rng('default'); % For reproducibility
X = [randn(10,2)+3;randn(10,2)-3];
```

Cluster the data in `X` using `kmeans` with the default squared Euclidean distance metric.

```
clust = kmeans(X,2);
```

Find silhouette values and create a silhouette plot from the clustered data using the Euclidean distance metric.

```
[s,h] = silhouette(X,clust,'Euclidean')
```



```
s = 20×1

    0.6472
    0.7241
    0.5682
    0.7658
    0.7864

```
h =
  Figure (1) with properties:

      Number: 1
        Name: ''
       Color: [1 1 1]
    Position: [360 502 560 420]
       Units: 'pixels'

  Show all properties
```

The chi-square distance between J-dimensional points x and z is

$$\chi(x,z) = \sqrt{\sum_{j=1}^{J} w_j(x_j - z_j)^2},$$

where w_j is the weight associated with dimension j.

Set weights for each dimension and specify the chi-square distance function. The distance function must:

- Take as input arguments the n-by-p input data matrix `X`, one row of `X` (for example, `x`), and a scaling (or weight) parameter `w`.
- Calculate the distance from `x` to each row of `X`.
- Return a vector of length n. Each element of the vector is the distance between the observation corresponding to `x` and the observations corresponding to each row of `X`.

```
w = [0.4; 0.6]; % Set arbitrary weights for illustration
chiSqrDist = @(x,Z,w)sqrt((bsxfun(@minus,x,Z).^2)*w);
```

Find silhouette values from the clustered data using the custom distance metric `chiSqrDist`.

```
s1 = silhouette(X,clust,chiSqrDist,w)
```

```
s1 = 20×1

    0.6288
    0.7239
    0.6244
    0.7696
    0.7957
    0.6688
    0.7386
    0.7865
    0.7223
    0.7572
      ⋮
```

Set the weight for both dimensions to 1 to use `chiSqrDist` as the Euclidean distance metric. Find silhouette values and verify that they are the same as the values in `s`.

```
w2 = [1; 1];
s2 = silhouette(X,clust,chiSqrDist,w2);
AreValuesEqual = isequal(s2,s)
```

```
AreValuesEqual = logical
   1
```

The silhouette values are the same in `s` and `s2`.

Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix of size *n*-by-*p*. Rows correspond to points, and columns correspond to coordinates.

Data Types: `single` | `double`

`clust` — Cluster assignment
categorical variable | numeric vector | character matrix | string array | cell array of character vectors

Cluster assignment, specified as a categorical variable, numeric vector, character matrix, string array, or cell array of character vectors containing a cluster name for each point in `X`.

`silhouette` treats `NaN`s and empty values in `clust` as missing values and ignores the corresponding rows of `X`.

Data Types: `single` | `double` | `char` | `string` | `cell` | `categorical`

`Distance` — Distance metric
`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | function handle | vector of pairwise distances | ...

Distance metric, specified as a character vector, string scalar, or function handle, as described in this table.

Metric	Description
`'Euclidean'`	Euclidean distance
`'sqEuclidean'`	Squared Euclidean distance (default)
`'cityblock'`	Sum of absolute differences
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors)
`'correlation'`	One minus the sample correlation between points (treated as sequences of values)
`'Hamming'`	Percentage of coordinates that differ
`'Jaccard'`	Percentage of nonzero coordinates that differ
Vector	A numeric row vector of pairwise distances, in the form created by the `pdist` function. `X` is not used in this case, and can safely be set to `[]`.

`@`*`distfun`*	Custom distance function handle. A distance function has the form
	`function D = distfun(X0,X,DistParameter)`
	`% calculation of distance`
	`...`
	where
	• `X0` is a `1`-by-*p* vector containing a single point (observation) of the input data matrix `X`.
	• `X` is an *n*-by-*p* matrix of points.
	• `DistParameter` represents one or more additional parameter values specific to `@`*`distfun`*.
	• `D` is an *n*-by-`1` vector of distances, and `D(k)` is the distance between observations `X0` and `X(k,:)`.

For more information, see “Distance Metrics” on page 18-12.

Example: `'cosine'`

Data Types: `char` | `string` | `function_handle` | `single` | `double`

`DistParameter` — Distance metric parameter value
positive scalar | numeric vector | numeric matrix

Distance metric parameter value, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify a custom distance function handle `@distfun` that accepts one or more parameter values in addition to the input parameters `X0` and `X`.

Example: `silhouette(X,clust,distfun,p1,p2)` where `p1` and `p2` are additional distance metric parameter values for `@distfun`

Data Types: `single` | `double`

Output Arguments

`s` — Silhouette values
n-by-1 vector of values ranging from –1 to 1

Silhouette values, returned as an *n*-by-1 vector of values ranging from –1 to 1. A silhouette value measures how similar a point is to points in its own cluster, when compared to points in other clusters. Values range from –1 to 1. A high silhouette value indicates that a point is well matched to its own cluster, and poorly matched to other clusters.

Data Types: `single` | `double`

`h` — Figure handle
scalar

Figure handle, returned as a scalar. You can use the figure handle to query and modify figure properties. For more information, see Figure.

More About

Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters.

The silhouette value `Si` for the `i`th point is defined as

```
Si = (bi-ai)/ max(ai,bi)
```

where `ai` is the average distance from the `i`th point to the other points in the same cluster as `i`, and `bi` is the minimum average distance from the `i`th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from –1 to 1. A high silhouette value indicates that `i` is well matched to its own cluster, and poorly matched to other clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution might have too many or too few clusters. You can use silhouette values as a clustering evaluation criterion with any distance metric.

SilhouetteEvaluation

Package: clustering.evaluation
Superclasses: ClusterCriterion

Silhouette criterion clustering evaluation object

Description

SilhouetteEvaluation is an object consisting of sample data, clustering data, and silhouette criterion values used to evaluate the optimal number of data clusters. Create a silhouette criterion clustering evaluation object using evalclusters.

Construction

eva = evalclusters(x,clust,'Silhouette') creates a silhouette criterion clustering evaluation object.

eva = evalclusters(x,clust,'Silhouette',Name,Value) creates a silhouette criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an *N*-by-*P* matrix. *N* is the number of observations, and *P* is the number of variables.

Data Types: single | double

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in x using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in x using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in x using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle. The function must be of the form C = clustfun(DATA,K), where DATA is the data to be clustered, and K is the number of clusters. The output of clustfun must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric *n*-by-*K* matrix of score for *n* observations and *K* classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a *n*-by-*K* matrix containing the proposed clustering solutions. *n* is the number of observations in the sample data, and *K* is the number of proposed clustering solutions. Column *j* contains the cluster indices for each of the *N* points in the *j*th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

`ClusterPriors` — Prior probabilities for each cluster

`'empirical'` (default) | `'equal'`

Prior probabilities for each cluster, specified as the comma-separated pair consisting of `'ClusterPriors'` and one of the following.

`'empirical'`	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.
`'equal'`	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.

Example: `'ClusterPriors','empirical'`

`Distance` — Distance metric

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

`'sqEuclidean'`	Squared Euclidean distance
`'Euclidean'`	Euclidean distance. This option is not valid for the `kmeans` clustering algorithm.
`'cityblock'`	Sum of absolute differences
`'cosine'`	One minus the cosine of the included angle between points (treated as vectors)
`'correlation'`	One minus the sample correlation between points (treated as sequences of values)

`'Hamming'`	Percentage of coordinates that differ. This option is only valid for the `Silhouette` criterion.
`'Jaccard'`	Percentage of nonzero coordinates that differ. This option is only valid for the `Silhouette` criterion.

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric using a function handle. The distance function must be of the form `d2 = distfun(XI,XJ)`, where `XI` is a 1-by-*n* vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2-by-*n* matrix corresponding to multiple rows of `X`. `distfun` must return an m_2-by-1 vector of distances `d2`, whose *k*th element is the distance between `XI` and `XJ(k,:)`.

`Distance` only accepts a function handle if the clustering algorithm `clust` accepts a function handle as the distance metric. For example, the `kmeans` clustering algorithm does not accept a function handle as the distance metric. Therefore, if you use the `kmeans` algorithm and then specify a function handle for `Distance`, the software errors.

- If `criterion` is `'silhouette'`, you can also specify `Distance` as the output vector created by the function `pdist`.
- When `clust` is `'kmeans'` or `'gmdistribution'`, `evalclusters` uses the distance metric specified for `Distance` to cluster the data.
- If `clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses the Euclidean distance and Ward linkage.
- If `clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: `'Distance','Euclidean'`

Data Types: `single` | `double` | `char` | `string` | `function_handle`

`KList` — List of number of clusters to evaluate
vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of `'KList'` and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is `'gap'`, `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: `'KList',[1:6]`

Data Types: `single` | `double`

Properties

`ClusteringFunction`

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

`ClusterPriors`

Prior probabilities for each cluster, stored as valid prior probability name.

`ClusterSilhouettes`

Silhouette values corresponding to each proposed number of clusters in `InspectedK`, stored as a cell array of vectors.

`CriterionName`

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

`CriterionValues`

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

`Distance`

Distance metric used for clustering data, stored as a valid distance metric name.

`InspectedK`

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

`Missing`

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

`NumObservations`

Number of observations in the data matrix `X`, minus the number of missing (`NaN`) values in `X`, stored as a positive integer value.

`OptimalK`

Optimal number of clusters, stored as a positive integer value.

`OptimalY`

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

`X`

Data used for clustering, stored as a matrix of numerical values.

Methods

Inherited Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values
compact	Compact clustering evaluation object

Examples

Evaluate the Clustering Solution Using Silhouette Criterion

Evaluate the optimal number of clusters using the silhouette clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

```
rng('default');  % For reproducibility
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];

mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];

mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];

N = 200;

X = [mvnrnd(mu1,sigma1,N);...
     mvnrnd(mu2,sigma2,N);...
     mvnrnd(mu3,sigma3,N)];
```

Evaluate the optimal number of clusters using the silhouette criterion. Cluster the data using `kmeans`.

```
E = evalclusters(X,'kmeans','silhouette','klist',[1:6])
```

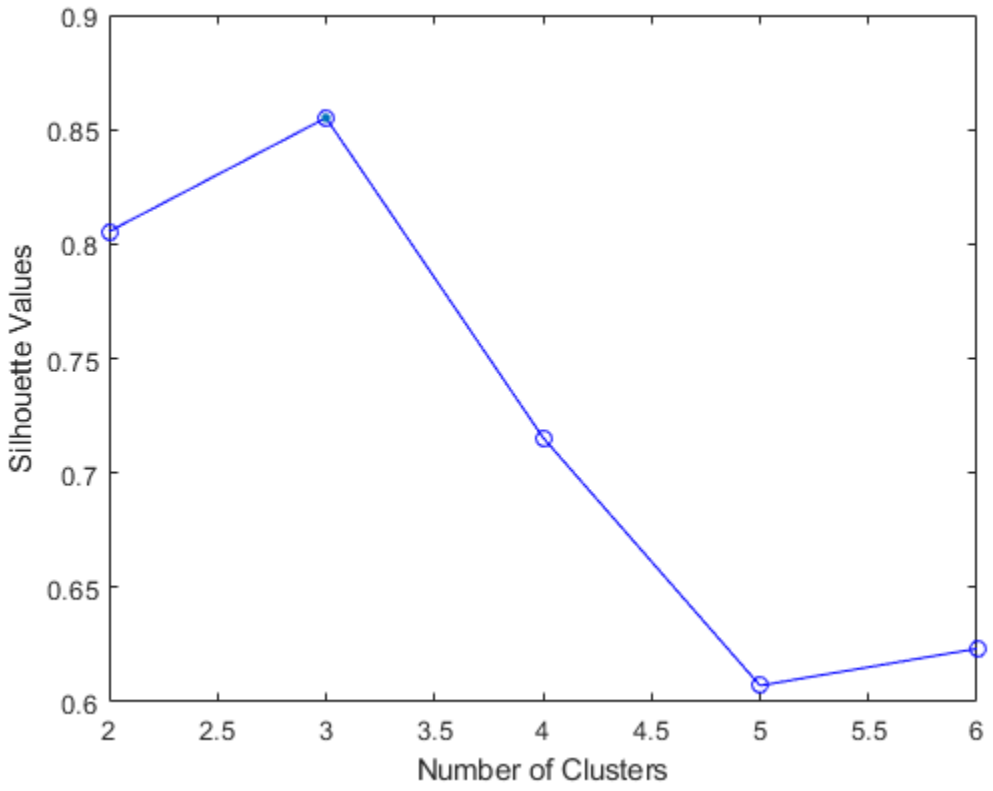
```
E =
  SilhouetteEvaluation with properties:

    NumObservations: 600
        InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 0.8055 0.8551 0.7155 0.6071 0.6232]
           OptimalK: 3
```

The `OptimalK` value indicates that, based on the silhouette criterion, the optimal number of clusters is three.

Plot the silhouette criterion values for each number of clusters tested.

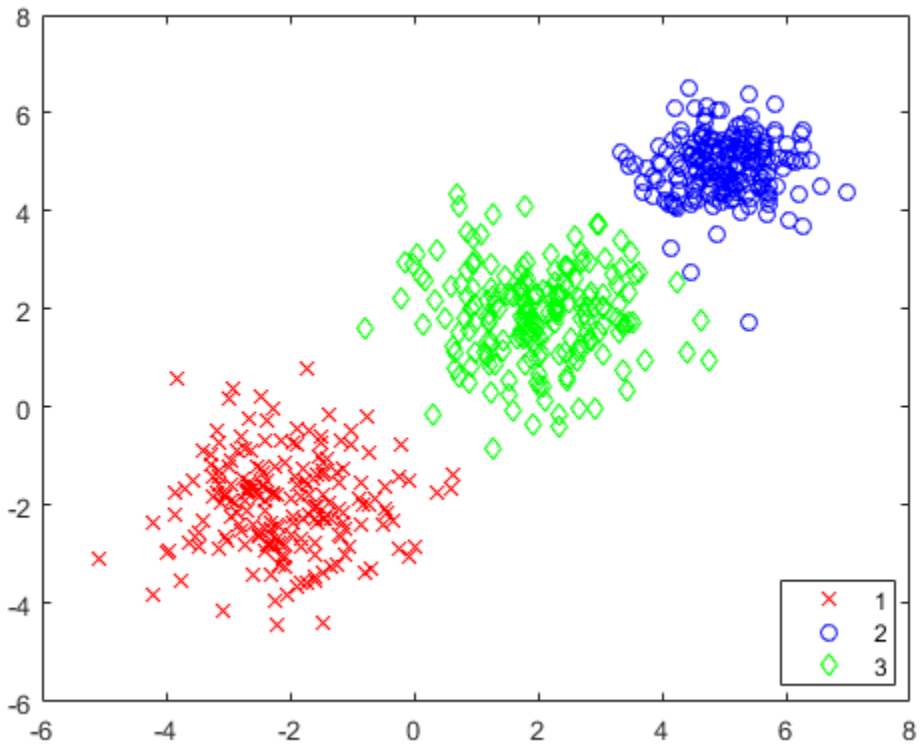
```
figure;
plot(E)
```



The plot shows that the highest silhouette value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```
figure;
gscatter(X(:,1),X(:,2),E.OptimalY,'rbg','xod')
```



The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is in the upper-right corner, and cluster 3 is near the center of the plot.

More About

Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters.

The silhouette value `Si` for the `i`th point is defined as

```
Si = (bi-ai)/ max(ai,bi)
```

where `ai` is the average distance from the `i`th point to the other points in the same cluster as `i`, and `bi` is the minimum average distance from the `i`th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from `−1` to `1`. A high silhouette value indicates that `i` is well matched to its own cluster, and poorly matched to other clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution might have too many or too few clusters. You can use silhouette values as a clustering evaluation criterion with any distance metric.

Property Attributes

single

Class: `dataset`

(Not Recommended) Convert dataset variables to single array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = single(A)
B = single(A,vars)
```

Description

`B = single(A)` returns the contents of the dataset `A`, converted to one single array. The classes of the variables in the dataset must support the conversion.

`B = single(A,vars)` returns the contents of the dataset variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

See Also

`dataset` | `double` | `replacedata`

size

Class: `dataset`

(Not Recommended) Size of dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
D = SIZE(A)
[NOBS,NVARS] = SIZE(A)
[M1,M2,M3,...,MN] = SIZE(A)
M = size(A,dim)
```

Description

`D = SIZE(A)` returns the two-element row vector `D = [NOBS,NVARS]` containing the number of observations and number of variables in the dataset `A`. A dataset array always has two dimensions.

`[NOBS,NVARS] = SIZE(A)` returns the numbers of observations and variables in the dataset `A` as separate output variables.

`[M1,M2,M3,...,MN] = SIZE(A)`, for `N > 2`, returns `M1 = NOBS`, `M2 = NVARS`, and `M3,..,MN = 1`.

`M = size(A,dim)` returns the length of the dimension specified by the scalar `dim`:

- `M = size(A,1)` returns `NOBS`
- `M = size(A,2)` returns `NVARS`
- `M = size(A,k)` returns `1` for `k > 2`

slicesample

Slice sampler

Syntax

```
rnd = slicesample(initial,nsamples,'pdf',pdf)
rnd = slicesample(initial,nsamples,'logpdf',logpdf)
[rnd,neval] = slicesample(initial,...)
[rnd,neval] = slicesample(initial,...,Name,Value)
```

Description

`rnd = slicesample(initial,nsamples,'pdf',pdf)` generates `nsamples` random samples using the slice sampling method (see “Algorithms” on page 33-5905). `pdf` gives the target probability density function (pdf). `initial` is a row vector or scalar containing the initial value of the random sample sequences.

`rnd = slicesample(initial,nsamples,'logpdf',logpdf)` generates samples using the logarithm of the pdf.

`[rnd,neval] = slicesample(initial,...)` returns the average number of function evaluations that occurred in the slice sampling.

`[rnd,neval] = slicesample(initial,...,Name,Value)` generates random samples with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`initial`

Initial point, a scalar or row vector. Set `initial` so `pdf(initial)` is a strictly positive scalar. `length(initial)` is the number of dimensions of each sample.

`nsamples`

Positive integer, the number of samples that `slicesample` generates.

`pdf`

Handle to a function that generates the probability density function, specified with `@`. `pdf` can be unnormalized, meaning it need not integrate to `1`.

`logpdf`

Handle to a function that generates the logarithm of the probability density function, specified with `@`. `logpdf` can be the logarithm of an unnormalized pdf.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`burnin`

Nonnegative integer, the number of samples to generate and discard before generating the samples to return. The slice sampling algorithm is a Markov chain whose stationary distribution is proportional to that of the `pdf` argument. Set `burnin` to a high enough value that you believe the Markov chain approximately reaches stationarity after `burnin` samples.

Default: `0`

`thin`

Positive integer, where `slicesample` discards every `thin - 1` samples and returns the next. The slice sampling algorithm is a Markov chain, so the samples are serially correlated. To reduce the serial correlation, choose a larger value of `thin`.

Default: `1`

`width`

Width of the interval around the current sample, a scalar or vector of positive values. `slicesample` begins with this interval and searches for an appropriate region containing the points of `pdf` that evaluate to a large enough value.

- If `width` is a scalar and the samples have multiple dimensions, `slicesample` uses `width` for each dimension.
- If `width` is a vector, it should have the same length as `initial`.

Default: `10`

Output Arguments

`rnd`

`nsamples`-by-`length(initial)` matrix, where each row is one sample.

`neval`

Scalar, the mean number of function evaluations per sample. `neval` includes the `burnin` and `thin` evaluations, not just the evaluations of samples returned in `rnd`. Therefore the total number of function evaluations is

`neval*(nsamples*thin + burnin)`.

Examples

Generate Random Samples From a Multimodal Density

This example shows how to generate random samples from a multimodal density using `slicesample`.

Define a function proportional to a multimodal density.

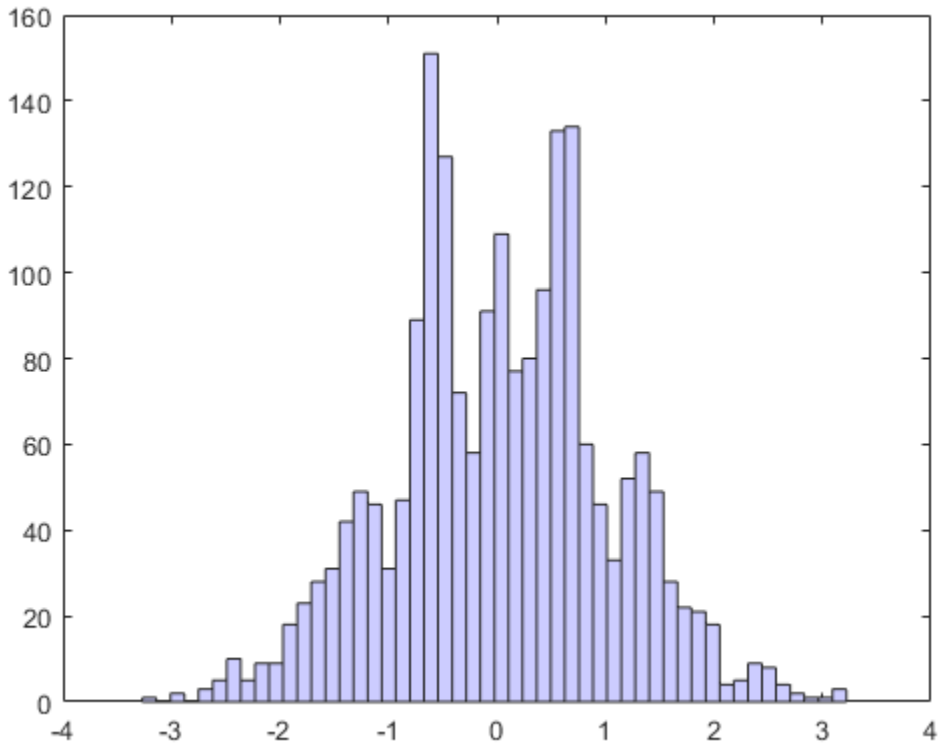
```
rng default  % For reproducibility
f = @(x) exp(-x.^2/2).*(1 + (sin(3*x)).^2).*...
    (1 + (cos(5*x).^2));
area = integral(f,-5,5);
```

Generate 2000 samples from the density, using a burn-in period of 1000, and keeping one in five samples.

```
N = 2000;
x = slicesample(1,N,'pdf',f,'thin',5,'burnin',1000);
```

Plot a histogram of the sample.

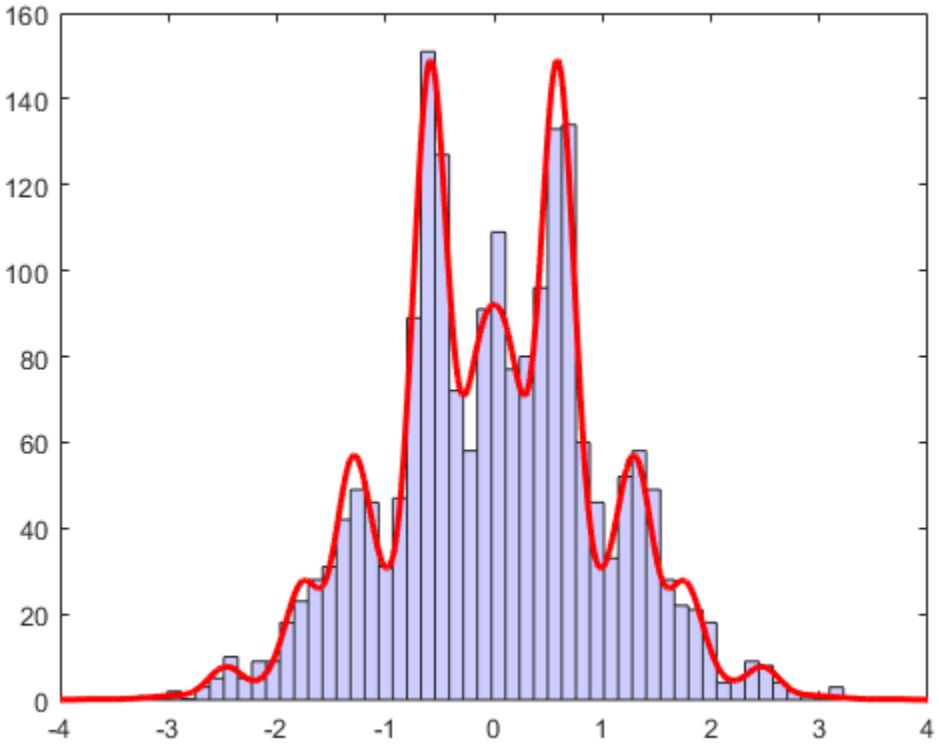
```
[binheight,bincenter] = hist(x,50);
h = bar(bincenter,binheight,'hist');
h.FaceColor = [.8 .8 1];
```



Scale the density to have the same area as the histogram, and superimpose it on the histogram.

```
hold on
h = gca;
```

```
xd = h.XLim;
xgrid = linspace(xd(1),xd(2),1000);
binwidth = (bincenter(2)-bincenter(1));
y = (N*binwidth/area) * f(xgrid);
plot(xgrid,y,'r','LineWidth',2)
hold off
```



The samples seem to fit the theoretical distribution well, so the `burnin` value seems adequate.

Tips

- There are no definitive suggestions for choosing appropriate values for `burnin`, `thin`, or `width`. Choose starting values of `burnin` and `thin`, and increase them, if necessary, to give the requisite independence and marginal distributions. See Neal [1] for details of the effect of adjusting `width`.

Algorithms

At each point in the sequence of random samples, `slicesample` selects the next point by “slicing” the density to form a neighborhood around the previous point where the density is above some value. Consequently, the sample points are not independent. Nearby points in the sequence tend to be closer together than they would be from a sample of independent values. For many purposes, the entire set of points can be used as a sample from the target distribution. However, when this type of serial correlation is a problem, the `burnin` and `thin` parameters can help reduce that correlation.

`slicesample` uses the slice sampling algorithm of Neal [1]. For numerical stability, it converts a `pdf` function into a `logpdf` function. The algorithm to resize the support region for each level, called "stepping-out" and "stepping-in," was suggested by Neal.

Topics

"Representing Sampling Distributions Using Markov Chain Samplers" on page 7-9

Introduced in R2006a

skewness

Skewness

Syntax

```
y = skewness(X)
y = skewness(X,flag)
y = skewness(X,flag,'all')
y = skewness(X,flag,dim)
y = skewness(X,flag,vecdim)
```

Description

`y = skewness(X)` returns the sample skewness of `X`.

- If `X` is a vector, then `skewness(X)` returns a scalar value that is the skewness of the elements in `X`.
- If `X` is a matrix, then `skewness(X)` returns a row vector containing the sample skewness of each column in `X`.
- If `X` is a multidimensional array, then `skewness(X)` operates along the first nonsingleton dimension of `X`.

`y = skewness(X,flag)` specifies whether to correct for bias (`flag = 0`) or not (`flag = 1`, the default). When `X` represents a sample from a population, the skewness of `X` is biased, meaning it tends to differ from the population skewness by a systematic amount based on the sample size. You can set `flag` to `0` to correct for this systematic bias.

`y = skewness(X,flag,'all')` returns the skewness of all elements of `X`.

`y = skewness(X,flag,dim)` returns the skewness along the operating dimension `dim` of `X`.

`y = skewness(X,flag,vecdim)` returns the skewness over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `skewness(X,1,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the biased skewness of the elements on the corresponding page of `X`.

Examples

Find Skewness of Matrix

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a matrix with 5 rows and 4 columns.

```
X = randn(5,4)
```

```
X = 5×4
```

```
    0.5377   -1.3077   -1.3499   -0.2050
    1.8339   -0.4336    3.0349   -0.1241
   -2.2588    0.3426    0.7254    1.4897
    0.8622    3.5784   -0.0631    1.4090
    0.3188    2.7694    0.7147    1.4172
```

Find the sample skewness of `X`.

```
y = skewness(X)
```

```
y = 1×4

   -0.9362    0.2333    0.4363   -0.4075
```

`y` is a row vector containing the sample skewness of each column in `X`.

Correct for Bias in Sample Skewness

For an input vector, correct for bias in the calculation of skewness by specifying the `flag` input argument.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a vector of length 10.

```
x = randn(10,1)
```

```
x = 10×1

    0.5377
    1.8339
   -2.2588
    0.8622
    0.3188
   -1.3077
   -0.4336
    0.3426
    3.5784
    2.7694
```

Find the biased skewness of `x`. By default, `skewness` sets the value of `flag` to `1` for computing the biased skewness.

```
y1 = skewness(x) % flag is 1 by default
```

```
y1 = 0.1061
```

Find the bias-corrected skewness of `x` by setting the value of `flag` to `0`.

```
y2 = skewness(x,0)
```

```
y2 = 0.1258
```

Find Skewness Along Given Dimension

Find the skewness along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4,3,2])
```

```
X =
X(:,:,1) =

    0.5377    0.3188    3.5784
    1.8339   -1.3077    2.7694
   -2.2588   -0.4336   -1.3499
    0.8622    0.3426    3.0349

X(:,:,2) =

    0.7254   -0.1241    0.6715
   -0.0631    1.4897   -1.2075
    0.7147    1.4090    0.7172
   -0.2050    1.4172    1.6302
```

Find the skewness of `X` along the default dimension.

```
Y1 = skewness(X)
```

```
Y1 =
Y1(:,:,1) =

   -0.8084   -0.5578   -1.0772

Y1(:,:,2) =

   -0.0403   -1.1472   -0.6632
```

By default, skewness operates along the first dimension of `X` whose size does not equal 1. In this case, this dimension is the first dimension of `X`. Therefore, `Y1` is a 1-by-3-by-2 array.

Find the biased skewness of `X` along the second dimension.

```
Y2 = skewness(X,1,2)
```

```
Y2 =
Y2(:,:,1) =

    0.6956
   -0.5575
```

```
    0.0049
    0.6033

Y2(:,:,2) =

   -0.6969
    0.1828
    0.7071
   -0.6714
```

`Y2` is a 4-by-1-by-2 array.

Find the biased skewness of `X` along the third dimension.

```
Y3 = skewness(X,1,3)
```

```
Y3 = 4×3
10^-15 ×

         0    0.1597    0.5062
    0.1952         0         0
         0   -0.2130         0
    0.3654         0    0.4807
```

`Y3` is a 4-by-3 matrix.

Find Skewness Along Vector of Dimensions

Find the skewness over multiple dimensions by using the `'all'` and `vecdim` input arguments.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4 3 2])
```

```
X =
X(:,:,1) =

    0.5377    0.3188    3.5784
    1.8339   -1.3077    2.7694
   -2.2588   -0.4336   -1.3499
    0.8622    0.3426    3.0349

X(:,:,2) =

    0.7254   -0.1241    0.6715
   -0.0631    1.4897   -1.2075
    0.7147    1.4090    0.7172
```

```
   -0.2050    1.4172    1.6302
```

Find the biased skewness of X.

```
yall = skewness(X,1,'all')
```

```
yall = 0.0916
```

`yall` is the biased skewness of the entire input data set X.

Find the biased skewness of each page of X by specifying the first and second dimensions.

```
ypage = skewness(X,1,[1 2])
```

```
ypage =
ypage(:,:,1) =

    0.1070

ypage(:,:,2) =

   -0.6263
```

For example, `ypage(1,1,2)` is the biased skewness of the elements in `X(:,:,2)`.

Find the biased skewness of the elements in each `X(:,i,:)` slice by specifying the first and third dimensions.

```
ycol = skewness(X,1,[1 3])
```

```
ycol = 1×3

   -1.0755   -0.3108   -0.2209
```

For example, `ycol(3)` is the biased skewness of the elements in `X(:,3,:)`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If X is a vector, then `skewness(X)` returns a scalar value that is the skewness of the elements in X.
- If X is a matrix, then `skewness(X)` returns a row vector containing the sample skewness of each column in X.
- If X is a multidimensional array, then `skewness(X)` operates along the first nonsingleton dimension of X.

To specify the operating dimension when X is a matrix or an array, use the `dim` input argument.

`skewness` treats `NaN` values in `X` as missing values and removes them.

Data Types: `single` | `double`

`flag` — Indicator for bias
1 (default) | 0

Indicator for the bias, specified as `0` or `1`.

- If `flag` is `1` (default), then the skewness of `X` is biased, meaning it tends to differ from the population skewness by a systematic amount based on the sample size.
- If `flag` is `0`, then `skewness` corrects for the systematic bias.

Data Types: `single` | `double` | `logical`

`dim` — Dimension
positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for `dim`, then the default is the first dimension of `X` whose size does not equal 1.

Consider the skewness of a matrix `X`:

- If `dim` is equal to 1, then `skewness` returns a row vector that contains the sample skewness of each column in `X`.
- If `dim` is equal to 2, then `skewness` returns a column vector that contains the sample skewness of each row in `X`.

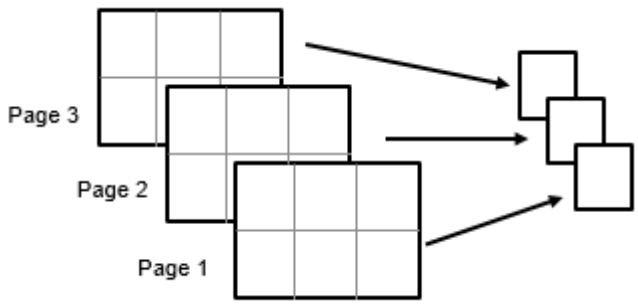
If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `skewness` returns an array of `NaN`s the same size as `X`.

Data Types: `single` | `double`

`vecdim` — Vector of dimensions
positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `skewness(X,1,[1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the biased skewness of the elements on the corresponding page of `X`.



Data Types: `single` | `double`

Output Arguments

y — Skewness

scalar | vector | matrix | multidimensional array

Skewness, returned as a scalar, vector, matrix, or multidimensional array.

Algorithms

Skewness is a measure of the asymmetry of the data around the sample mean. If skewness is negative, the data spreads out more to the left of the mean than to the right. If skewness is positive, the data spreads out more to the right. The skewness of the normal distribution on page B-119 (or any perfectly symmetric distribution) is zero.

The skewness of a distribution is defined as

$$s = \frac{E(x-\mu)^3}{\sigma^3},$$

where μ is the mean of x, σ is the standard deviation of x, and $E(t)$ represents the expected value of the quantity t. The `skewness` function computes a sample version of this population value.

When you set `flag` to `1`, the skewness is biased, and the following equation applies:

$$s_1 = \frac{\frac{1}{n}\sum_{i=1}^{n}(x_i-\bar{x})^3}{\left(\sqrt{\frac{1}{n}\sum_{i=1}^{n}(x_i-\bar{x})^2}\right)^3}.$$

When you set `flag` to `0`, `skewness` corrects for the systematic bias, and the following equation applies:

$$s_0 = \frac{\sqrt{n(n-1)}}{n-2}s_1.$$

This bias-corrected equation requires that `X` contain at least three elements.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see "Automatic dimension restriction" (MATLAB Coder).

For more information on code generation, see "Introduction to Code Generation" on page 32-2 and "General Code Generation Workflow" on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see "Run MATLAB Functions on a GPU" (Parallel Computing Toolbox).

Introduced before R2006a

sobolset

Sobol quasirandom point set

Description

`sobolset` is a quasirandom point set object that produces points from the Sobol sequence. The Sobol sequence is a base-2 digital sequence that fills space in a highly uniform manner.

Creation

Syntax

```
p = sobolset(d)
p = sobolset(d,Name,Value)
```

Description

`p = sobolset(d)` constructs a `d`-dimensional point set `p`, which is a `sobolset` object with default property settings. The input argument `d` corresponds to the `Dimensions` property of `p`.

`p = sobolset(d,Name,Value)` sets properties on page 33-5915 of `p` using one or more name-value pair arguments. Enclose each property name in quotes. For example, `sobolset(5,'Leap',2)` creates a five-dimensional point set from the first point, fourth point, seventh point, tenth point, and so on.

The returned object `p` encapsulates properties of a Sobol quasirandom sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of the point set indices (maximum value of 2^{53}). Values of the point set are generated whenever you access `p` using `net` or parenthesis indexing. Values are not stored within `p`.

Properties

`Dimensions` — Number of dimensions

positive integer scalar in interval [1,1111]

This property is read-only.

Number of dimensions of the points in the point set, specified as a positive integer scalar in the interval [1,1111]. For example, each point in the point set `p` with `p.Dimensions = 5` has five values.

Use the `d` input argument to specify the number of dimensions when you create a point set using the `sobolset` function.

Use the `reduceDimensions` object function to reduce the number of dimensions after you create a point set.

`Leap` — Interval between points

`0` (default) | positive integer scalar

Interval between points in the sequence, specified as a positive integer scalar. In other words, the `Leap` property of a point set specifies the number of points in the sequence to leap over and omit for every point taken. The default `Leap` value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the `Leap` values with care. Many `Leap` values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube and, therefore, fail to be a uniform quasirandom point set. For more information, see [4].

Example: `p = sobolset(__,'Leap',50);`

Example: `p.Leap = 100;`

`PointOrder` — Point generation method
`'standard'` (default) | `'graycode'`

Point generation method, specified as `'standard'` or `'graycode'`. The `PointOrder` property specifies the order in which the Sobol sequence points are produced. When `PointOrder` is set to `'standard'`, the points produced match the original Sobol sequence implementation. When `PointOrder` is set to `'graycode'`, the sequence is generated by an implementation that uses the Gray code of the index instead of the index itself.

You can use the `'graycode'` option for faster sequence generation, but the software then changes the order of the generated points. For more information on the Gray code implementation, see [1].

Example: `p = sobolset(__,'PointOrder','graycode');`

Example: `p.PointOrder = 'standard';`

`ScrambleMethod` — Settings that control scrambling
`0x0` structure (default) | structure with `Type` and `Options` fields

Settings that control the scrambling of the sequence, specified as a structure with these fields:

- `Type` — A character vector containing the name of the scramble
- `Options` — A cell array of parameter values for the scramble

Use the `scramble` object function to set scrambles. For a list of valid scramble types, see the `type` input argument of `scramble`. An error occurs if you set an invalid scramble type for a given point set.

The `ScrambleMethod` property also accepts an empty matrix as a value. The software then clears all scrambling and sets the property to contain a `0x0` structure.

`Skip` — Number of initial points in sequence to omit
`0` (default) | positive integer scalar

Number of initial points in the sequence to omit from the point set, specified as a positive integer scalar.

Initial points of a sequence sometimes exhibit undesirable properties. For example, the first point is often `(0,0,0,...)`, which can cause the sequence to be unbalanced because the counterpart of the point, `(1,1,1,...)`, never appears. Also, initial points often exhibit correlations among different dimensions, and these correlations disappear later in the sequence.

Example: `p = sobolset(__,'Skip',2e3);`

Example: `p.Skip = 1e3;`

Type — Sequence type
`'Sobol'` (default)

This property is read-only.

Sequence type on which the quasirandom point set `p` is based, specified as `'Sobol'`.

Object Functions

net	Generate quasirandom point set
reduceDimensions	Reduce dimensions of Sobol point set
scramble	Scramble quasirandom point set

You can also use the following MATLAB functions with a `sobolset` object. The software treats the point set object like a matrix of multidimensional points.

length	Length of largest array dimension
size	Array size

Examples

Create Sobol Point Set

Generate a three-dimensional Sobol point set, skip the first 1000 values, and then retain every 101st point.

```
p = sobolset(3,'Skip',1e3,'Leap',1e2)
```

```
p =
Sobol point set in 3 dimensions (89180190640991 points)

Properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : none
        PointOrder : standard
```

Apply a random linear scramble combined with a random digital shift by using `scramble`.

```
p = scramble(p,'MatousekAffineOwen')
```

```
p =
Sobol point set in 3 dimensions (89180190640991 points)

Properties:
              Skip : 1000
              Leap : 100
    ScrambleMethod : MatousekAffineOwen
        PointOrder : standard
```

Generate the first four points by using `net`.

```
X0 = net(p,4)
```

```
X0 = 4×3

    0.7601    0.5919    0.9529
    0.1795    0.0856    0.0491
    0.5488    0.0785    0.8483
    0.3882    0.8771    0.8755
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11,:)
```

```
X = 4×3

    0.7601    0.5919    0.9529
    0.3882    0.8771    0.8755
    0.6905    0.4951    0.8464
    0.1955    0.5679    0.3192
```

Tips

- The `Skip` and `Leap` properties are useful for parallel applications. For example, if you have a Parallel Computing Toolbox license, you can partition a sequence of points across *N* different workers by using the function `labindex`. On each *n*th worker, set the `Skip` property of the point set to *n* – 1 and the `Leap` property to *N* – 1. The following code shows how to partition a sequence across three workers.

  ```
  Nworkers = 3;
  p = sobolset(10,'Leap',Nworkers-1);
  spmd(Nworkers)
      p.Skip = labindex - 1;

      % Compute something using points 1,4,7...
      % or points 2,5,8... or points 3,6,9...
  end
  ```

Algorithms

Sobol Sequence Generation

Consider a default `sobolset` object `p` that contains `d`-dimensional points. Each `p(i,:)` is a point in a Sobol sequence. The *j*th coordinate of the *i*th point, `p(i,j)`, is equal to

$$\begin{cases} 0, & i = 1 \\ \gamma_i(1)v_j(1) \oplus \gamma_i(2)v_j(2) \oplus \ldots, & i > 1. \end{cases}$$

- The $\gamma_i(n)$ values are 0s or 1s such that

  $$i - 1 = \sum_{n=1} \gamma_i(n) 2^{n-1}.$$

  In other words, the $\gamma_i(n)$ values are the binary digits of the integer i – 1.

- The $v_j(n)$ values are called direction numbers. They are uniquely defined for each coordinate j. For more details on these values, see “Direction Numbers Generation” on page 33-5919.
- The $\oplus$ operator is the bitwise exclusive-or operator. For two numbers expressed in binary, the $\oplus$ operator compares the digits in each position. For a given digit position, the $\oplus$ operator returns a 1 if the digits in that position differ and returns a 0 if the digits in that position are the same.
  - For example, $19 \oplus 24 = (10011)_2 \oplus (11000)_2 = (01011)_2 = 11$.
  - Similarly, $\frac{1}{2} \oplus \frac{3}{4} = (0.1)_2 \oplus (0.11)_2 = (0.01)_2 = \frac{1}{4}$.

For more information, see [3].

Direction Numbers Generation

The set of direction numbers $v_j(n)$ depends on the coordinate j. Define the direction numbers in terms of $m_j(n)$ values:

$$v_j(n) := \frac{m_j(n)}{2^n}.$$

For each j, you can generate the direction numbers by selecting the following:

- A primitive polynomial in $\mathbb{Z}_2$ of some degree s_j

  $$x^{s_j} + a_j(1)x^{s_j-1} + a_j(2)x^{s_j-2} + \ldots + a_j(s_j-1)x + 1.$$

  Each coefficient in the polynomial is either 0 or 1.
- s_j initial direction numbers. For each initial direction number, the corresponding $m_j(n)$ value must be either 1 or an odd number less than 2^n.

The remaining direction numbers are determined by the following recurrence relation, which uses the coefficients of the primitive polynomial, the previous direction numbers, and the $\oplus$ bitwise exclusive-or operator.

$$m_j(n) := 2a_j(1)m_j(n-1) \oplus 2^2 a_j(2)m_j(n-2) \oplus \ldots \oplus 2^{s_j-1}a_j(s_j-1)m_j(n-s_j+1) \oplus 2^{s_j}m_j(n-s_j) \oplus m_j(n-s_j).$$

`sobolset` uses the same primitive polynomials and initial direction numbers described in [3]. These parameters are provided for the first 1111 dimensions.

Introduced in R2008a

sortClasses

Package: `mlearnlib.graphics.chart`

Sort classes of confusion matrix chart

Syntax

```
sortClasses(cm,order)
```

Description

`sortClasses(cm,order)` sorts the classes of the confusion matrix chart `cm` in the order specified by `order`. You can sort the classes in their natural order, by the values along the diagonal of the confusion matrix, or in fixed order that you specify.

Examples

Sort Classes by Precision or Recall

Create a confusion matrix chart and sort the classes of the chart according to the class-wise true positive rate (recall) or the class-wise positive predictive value (precision).

Load and inspect the `arrhythmia` data set.

```
load arrhythmia
isLabels = unique(Y);
nLabels = numel(isLabels)
```

```
nLabels = 13
```

```
tabulate(categorical(Y))
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
     15        5      1.11%
     16       22      4.87%
```

The data contains 16 distinct labels that describe various degrees of arrhythmia, but the response (Y) includes only 13 distinct labels.

Train a classification tree and predict the resubstitution response of the tree.

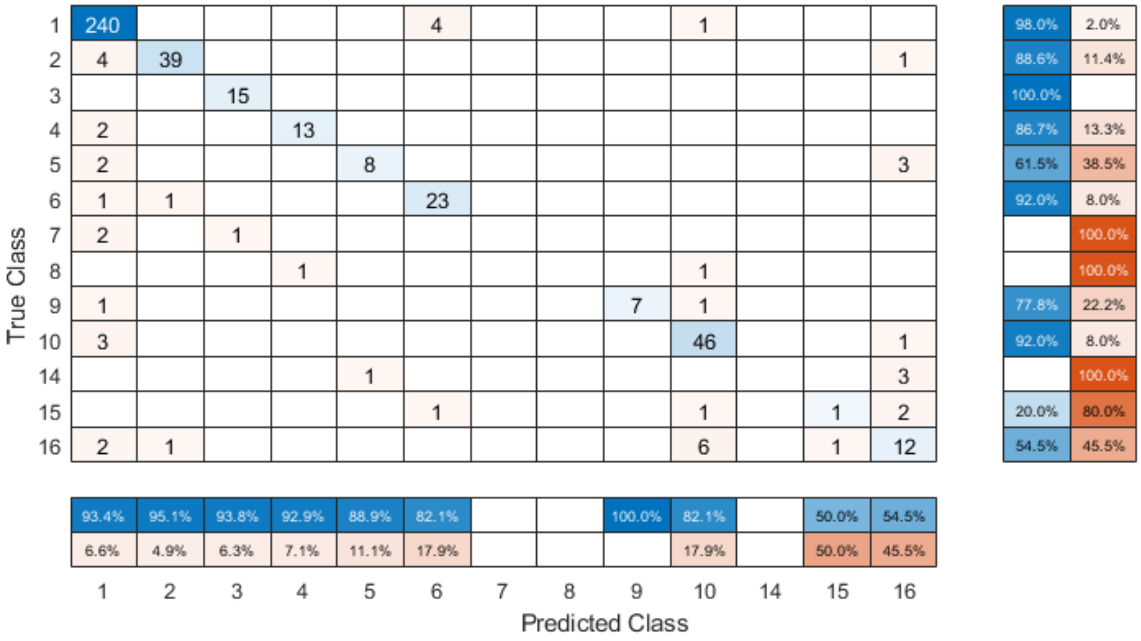
```
Mdl = fitctree(X,Y);
predictedY = resubPredict(Mdl);
```

Create a confusion matrix chart from the true labels `Y` and the predicted labels `predictedY`. Specify `'RowSummary'` as `'row-normalized'` to display the true positive rates and false positive rates in the row summary. Also, specify `'ColumnSummary'` as `'column-normalized'` to display the positive predictive values and false discovery rates in the column summary.

```
fig = figure;
cm = confusionchart(Y,predictedY,'RowSummary','row-normalized','ColumnSummary','column-normalized
```

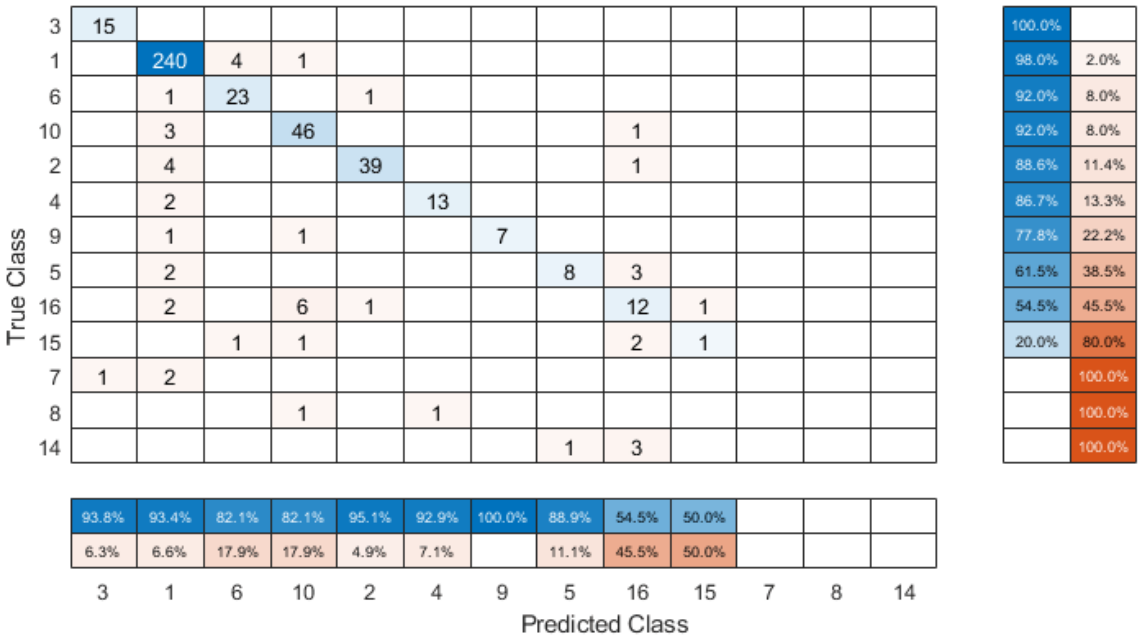
Resize the container of the confusion chart so percentages appear in the row summary.

```
fig_Position = fig.Position;
fig_Position(3) = fig_Position(3)*1.5;
fig.Position = fig_Position;
```



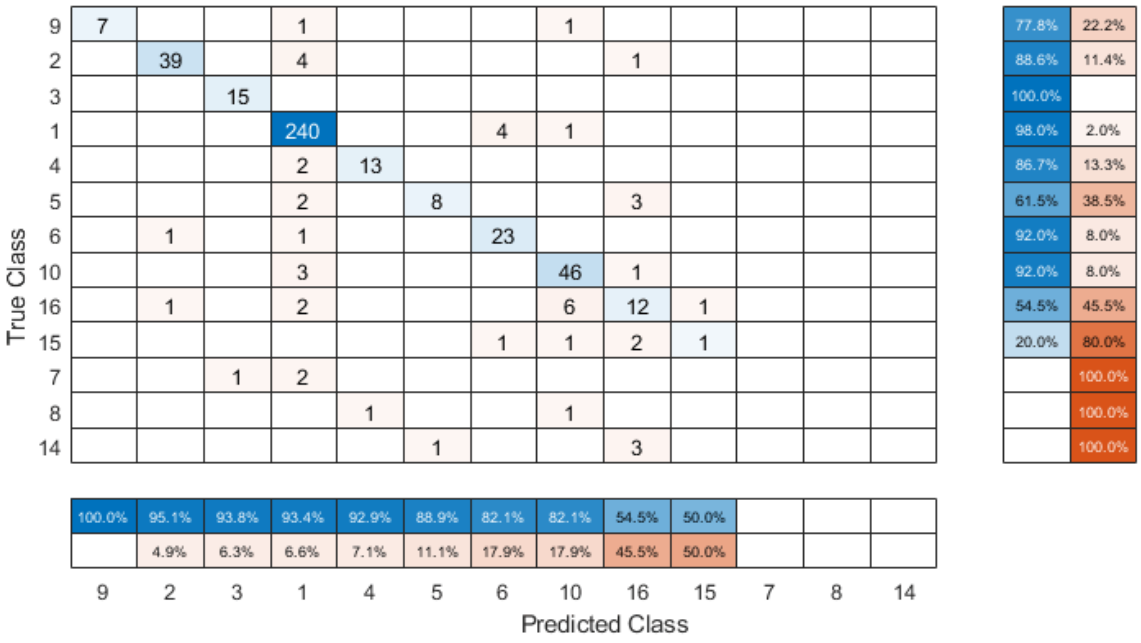
To sort the confusion matrix according to the true positive rate, normalize the cell values across each row by setting the `Normalization` property to `'row-normalized'` and then use `sortClasses`. After sorting, reset the `Normalization` property back to `'absolute'` to display the total number of observations in each cell.

```
cm.Normalization = 'row-normalized';
sortClasses(cm,'descending-diagonal')
cm.Normalization = 'absolute';
```



To sort the confusion matrix according to the positive predictive value, normalize the cell values across each column by setting the `Normalization` property to `'column-normalized'` and then use `sortClasses`. After sorting, reset the `Normalization` property back to `'absolute'` to display the total number of observations in each cell.

```
cm.Normalization = 'column-normalized';
sortClasses(cm,'descending-diagonal')
cm.Normalization = 'absolute';
```



Sort Classes to Cluster Similar Classes

Create a confusion matrix chart by using the `confusionchart` function, and sort the classes to cluster similar classes by using the `'cluster'` option of the `sortClasses` function. This example also shows how to cluster by using the `pdist`, `linkage`, and `optimalleaforder` functions.

Generate a sample data set that contains eight distinct classes.

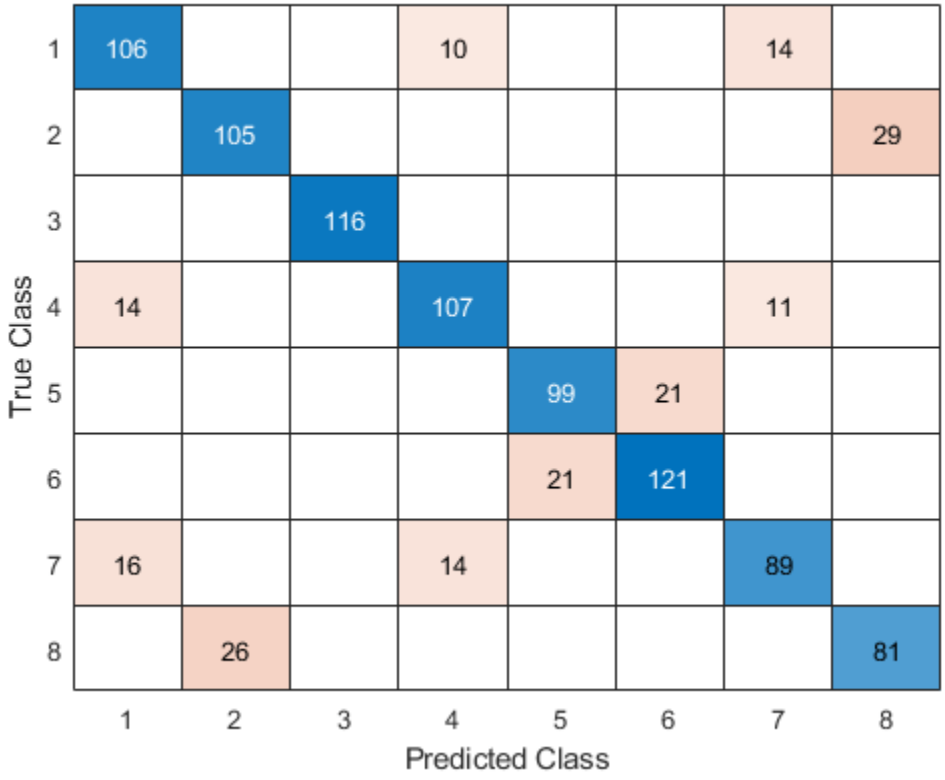
```
rng('default') % For reproducibility
trueLabels = randi(8,1000,1);
predictedLabels = trueLabels;
```

Insert confusion among classes {1,4,7}, {2,8}, and {5,6} for the first 200 samples.

```
rename = [4 8 3 7 6 5 1 2];
predictedLabels(1:100) = rename(predictedLabels(1:100));
rename = [7 8 3 1 6 5 4 2];
predictedLabels(101:200) = rename(predictedLabels(101:200));
```

Create a confusion matrix chart from the true labels `trueLabels` and the predicted labels `predictedLabels`.

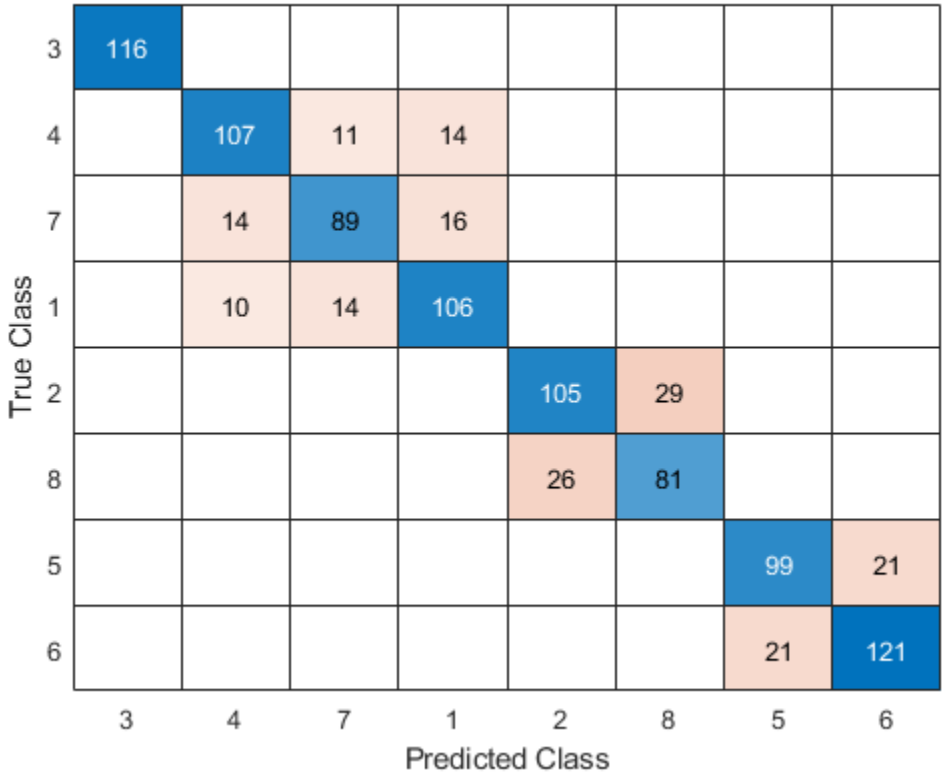
```
figure
cm1 = confusionchart(trueLabels,predictedLabels);
```



Cluster Using `'cluster'`

Sort the classes to cluster similar classes by using the `'cluster'` option.

```
sortClasses(cm1,'cluster')
```



Cluster Using `pdist`, `linkage`, and `optimalleaforder`

Instead of using the `'cluster'` option, you can use the `pdist`, `linkage`, and `optimalleaforder` functions to cluster confusion matrix values. You can customize clustering by using the options of these functions. For details, see the corresponding function reference pages.

Suppose you have a confusion matrix and class labels.

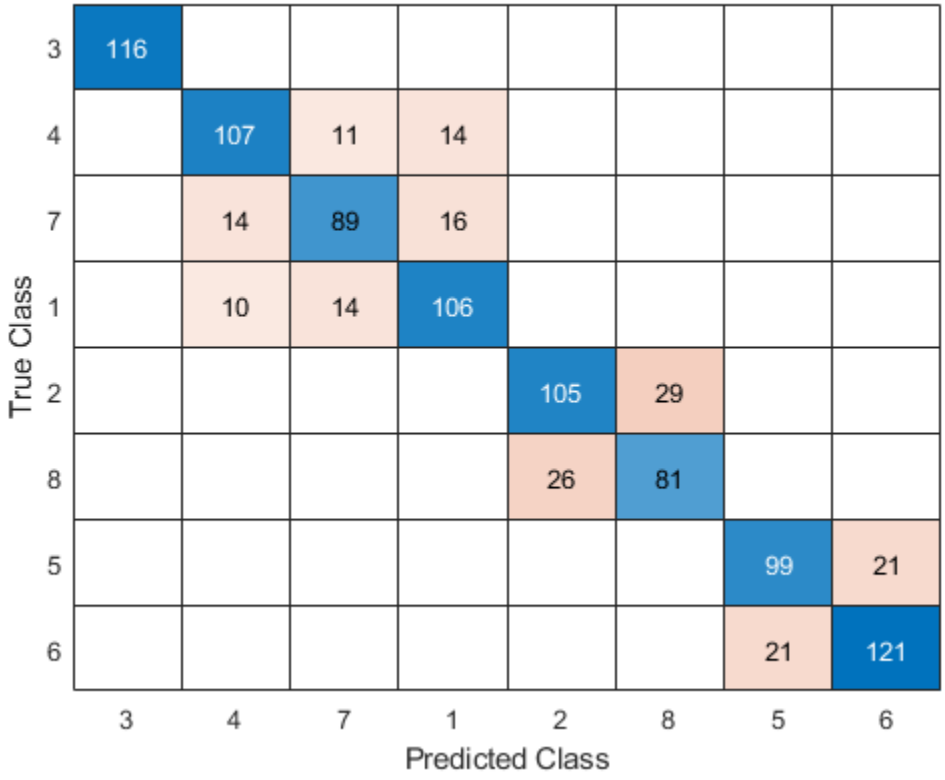
```
m = confusionmat(trueLabels,predictedLabels);
labels = [1 2 3 4 5 6 7 8];
```

Compute the clustered matrix and find the corresponding class labels by using `pdist`, `linkage`, and `optimalleaforder`. The `pdist` function computes the Euclidean distance `D` between pairs of the confusion matrix values. The `optimalleaforder` function returns an optimal leaf ordering for the hierarchical binary cluster tree `linkage(D)` using the distance `D`.

```
D = pdist(m);
idx = optimalleaforder(linkage(D),D);
clusteredM = m(idx,idx);
clusteredLabels = labels(idx);
```

Create a confusion matrix chart using the clustered matrix and the corresponding class labels. Then, sort the classes using the class labels.

```
cm2 = confusionchart(clusteredM,clusteredLabels);
sortClasses(cm2,clusteredLabels)
```



The sorted confusion matrix chart `cm2`, which you created by using `pdist`, `linkage`, and `optimalleaforder`, is identical to the sorted confusion matrix chart `cm1`, which you created by using the `'cluster'` option.

Sort Classes in Fixed Order

Create a confusion matrix chart and sort the classes of the chart in a fixed order.

Load Fisher's iris data set.

```
load fisheriris
X = meas([51:150,1:50],:);
Y = species([51:150,1:50],:);
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a *k*-nearest neighbor (KNN) classifier, where the number of nearest neighbors in the predictors (*k*) is 5. A good practice is to standardize numeric predictor data.

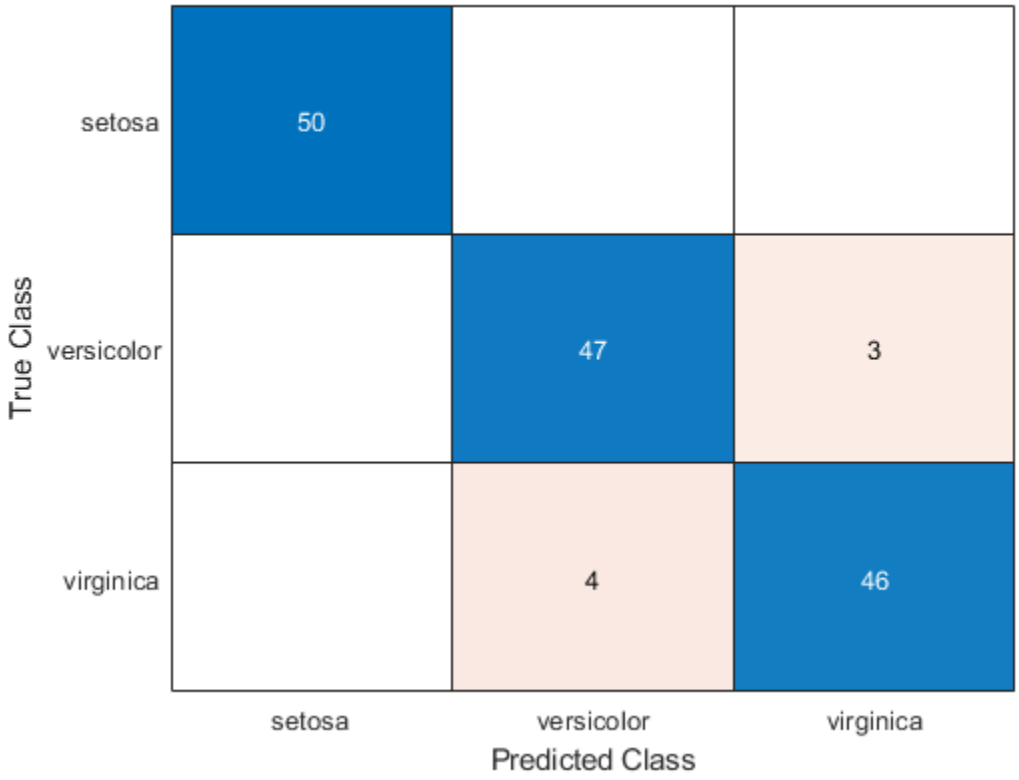
```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the labels of the training data.

```
predictedY = resubPredict(Mdl);
```

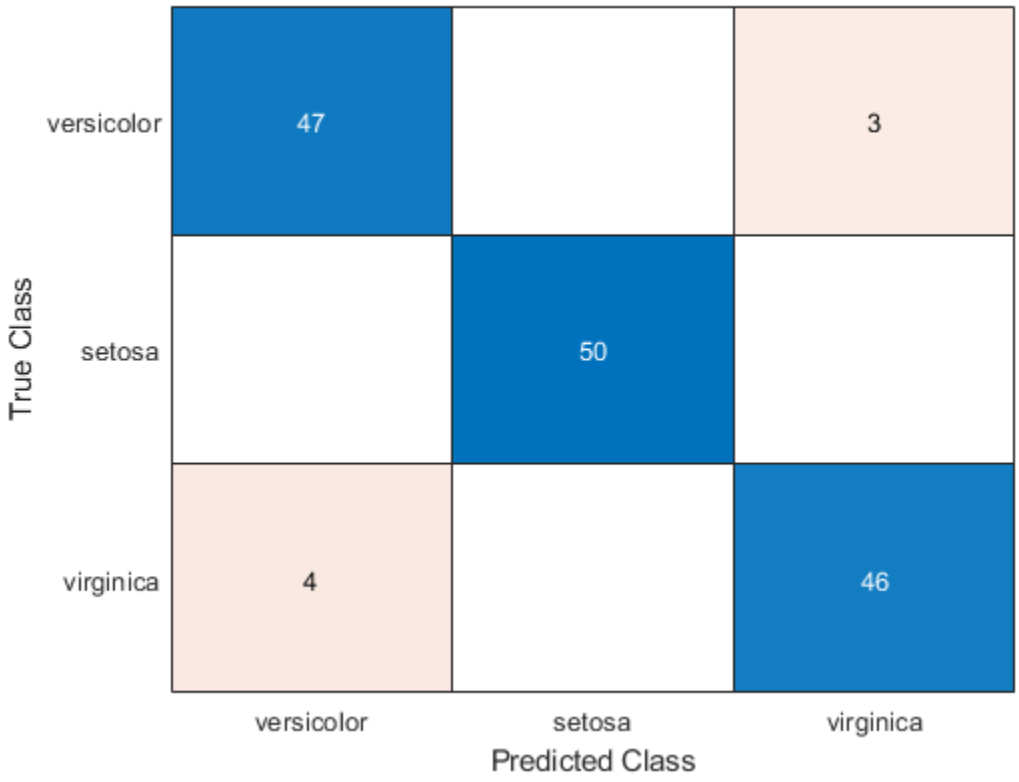
Create a confusion matrix chart from the true labels `Y` and the predicted labels `predictedY`.

```
cm = confusionchart(Y,predictedY);
```



By default, `confusionchart` sorts the classes into their natural order as defined by `sort`. In this example, the class labels are character vectors, so `confusionchart` sorts the classes alphabetically. Reorder the classes of the confusion matrix chart in a fixed order.

```
sortClasses(cm,["versicolor","setosa","virginica"])
```



Input Arguments

`cm` — Confusion matrix chart

`ConfusionMatrixChart` object

Confusion matrix chart, specified as a `ConfusionMatrixChart` object. To create a confusion matrix chart, use `confusionchart`,

`order` — Order in which to sort classes

`'auto'` | `'ascending-diagonal'` | `'descending-diagonal'` | `'cluster'` | array

Order in which to sort the classes of the confusion matrix chart, specified as one of these values:

- `'auto'` — Sorts the classes into their natural order as defined by the `sort` function. For example, if the class labels of the confusion matrix chart are a string vector, then sort alphabetically. If the class labels are an ordinal categorical vector, then use the order of the class labels.
- `'ascending-diagonal'` — Sort the classes so that the values along the diagonal of the confusion matrix increase from top left to bottom right.
- `'descending-diagonal'` — Sort the classes so that the values along the diagonal of the confusion matrix decrease from top left to bottom right.
- `'cluster'` — Sort the classes to cluster similar classes. You can customize clustering by using the `pdist`, `linkage`, and `optimalleaforder` functions. For details, see “Sort Classes to Cluster Similar Classes” on page 33-5924.

- Array — Sort the classes in a unique order specified by a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. The array must be a permutation of the `ClassLabels` property of the confusion matrix chart.

Example: `sortClasses(cm,'ascending-diagonal')`

Example: `sortClasses(cm,["owl","cat","toad"])`

Introduced in R2018b

sortrows

Class: `dataset`

(Not Recommended) Sort rows of dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = sortrows(A)
B = sortrows(A,vars)
B = sortrows(A,'obsnames')
B = sortrows(A,vars,mode)
[B,idx] = sortrows(A)
```

Description

`B = sortrows(A)` returns a copy of the dataset array `A`, with the observations sorted in ascending order by all of the variables in `A`. The observations in `B` are sorted first by the first variable, next by the second variable, and so on. Each variable in `A` must be a valid input to `sort`, or, if a variable has multiple columns, to the MATLAB `sortrows` function or to its own`sortrows` method.

`B = sortrows(A,vars)` sorts the observations in `A` by the variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

`B = sortrows(A,'obsnames')` sorts the observations in `A` by observation name.

`B = sortrows(A,vars,mode)` sorts in the direction specified by `mode`. When `mode` is `'ascend'` (the default) or `'descend'`, `sortrows` sorts `A` by the variables specified by `vars` in ascending or descending order, respectively. `mode` can also be a string array or cell array containing `'ascend'` or `'descend'`, to specify a different sorting direction for each variable in `vars`. Specify `[]` for `vars` to sort using all variables.

`[B,idx] = sortrows(A)` also returns an index vector `idx` such that `B = A(idx,:)`.

Examples

Sort the data in `hospital.mat` by age and then by last name:

```
load hospital
hospital(1:5,1:3)
ans =
            LastName       Sex       Age
 YPL-320    'SMITH'        Male      38
 GLI-532    'JOHNSON'      Male      43
 PNI-258    'WILLIAMS'     Female    38
 MIJ-579    'JONES'        Female    40
```

```
 XLK-030    'BROWN'        Female    49

hospital = sortrows(hospital,{'Age','LastName'});
hospital(1:5,1:3)
ans =
            LastName       Sex       Age
 REV-997    'ALEXANDER'    Male      25
 FZR-250    'HALL'         Male      25
 LIM-480    'HILL'         Female    25
 XUE-826    'JACKSON'      Male      25
 SCQ-914    'JAMES'        Male      25
```

Sort the data in `hospital` by gender in ascending order, and age in descending order.

```
hospital = sortrows(hospital,{'Sex','Age'},{'ascend','descend'});
hospital(1:5,1:3)
ans =

               LastName        Sex       Age
    XLK-030    'BROWN'         Female    49
    GGU-691    'HUGHES'        Female    49
    KKL-155    'ADAMS'         Female    48
    HQO-561    'BRYANT'        Female    48
    BKD-785    'CLARK'         Female    48

hospital(end-4:end,1:3)
ans =

               LastName           Sex     Age
    VNL-702    'MOORE'            Male    28
    REV-997    'ALEXANDER'        Male    25
    FZR-250    'HALL'             Male    25
    XUE-826    'JACKSON'          Male    25
    SCQ-914    'JAMES'            Male    25
```

sparsefilt

Feature extraction by using sparse filtering

Syntax

```
Mdl = sparsefilt(X,q)
Mdl = sparsefilt(X,q,Name,Value)
```

Description

`Mdl = sparsefilt(X,q)` returns a sparse filtering model object that contains the results from applying sparse filtering to the table or matrix of predictor data `X` containing p variables. `q` is the number of features to extract from `X`, therefore `sparsefilt` learns a p-by-`q` matrix of transformation weights. For undercomplete or overcomplete feature representations, `q` can be less than or greater than the number of predictor variables, respectively.

- To access the learned transformation weights, use `Mdl.TransformWeights`.
- To transform `X` to the new set of features by using the learned transformation, pass `Mdl` and `X` to `transform`.

`Mdl = sparsefilt(X,q,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can standardize the predictor data or apply L^2 regularization.

Examples

Create Sparse Filter

Create a `SparseFiltering` object by using the `sparsefilt` function.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1×2

        5000         363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
Q = 100;
obj = sparsefilt(data.X,Q,'IterationLimit',100)
```

```
Warning: Solver LBFGS was not able to converge to a solution.
```

```
obj =
  SparseFiltering
           ModelParameters: [1x1 struct]
             NumPredictors: 363
        NumLearnedFeatures: 100
                        Mu: []
                     Sigma: []
                   FitInfo: [1x1 struct]
          TransformWeights: [363x100 double]
    InitialTransformWeights: []

  Properties, Methods
```

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Restart `sparsefilt`

Continue optimizing a sparse filter.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1×2

        5000         363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data and use an iteration limit of 20.

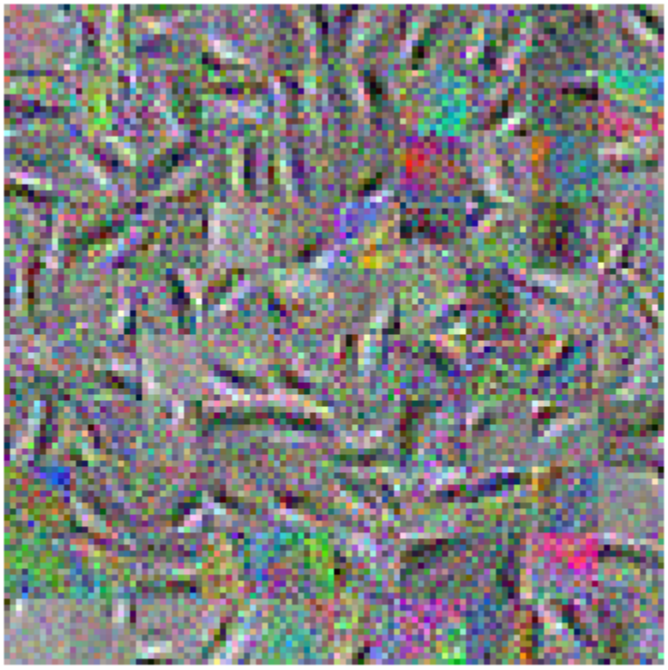
```
rng default % For reproducibility
q = 100;
Mdl = sparsefilt(data.X,q,'IterationLimit',20);
```

```
Warning: Solver LBFGS was not able to converge to a solution.
```

View the resulting transformation matrix as image patches.

```
wts = Mdl.TransformWeights;
W = reshape(wts,[11,11,3,q]);
[dx,dy,~,~] = size(W);
for f = 1:q
    Wvec = W(:,:,:,f);
    Wvec = Wvec(:);
    Wvec =(Wvec - min(Wvec))/(max(Wvec) - min(Wvec));
    W(:,:,:,f) = reshape(Wvec,dx,dy,3);
end
m   = ceil(sqrt(q));
n   = m;
```

```
img = zeros(m*dx,n*dy,3);
f   = 1;
for i = 1:m
    for j = 1:n
        if (f <= q)
            img((i-1)*dx+1:i*dx,(j-1)*dy+1:j*dy,:) = W(:,:,:,f);
            f = f+1;
        end
    end
end
imshow(img,'InitialMagnification',300);
```



The image patches appear noisy. To clean up the noise, try more iterations. Restart the optimization from where it stopped for another 40 iterations.

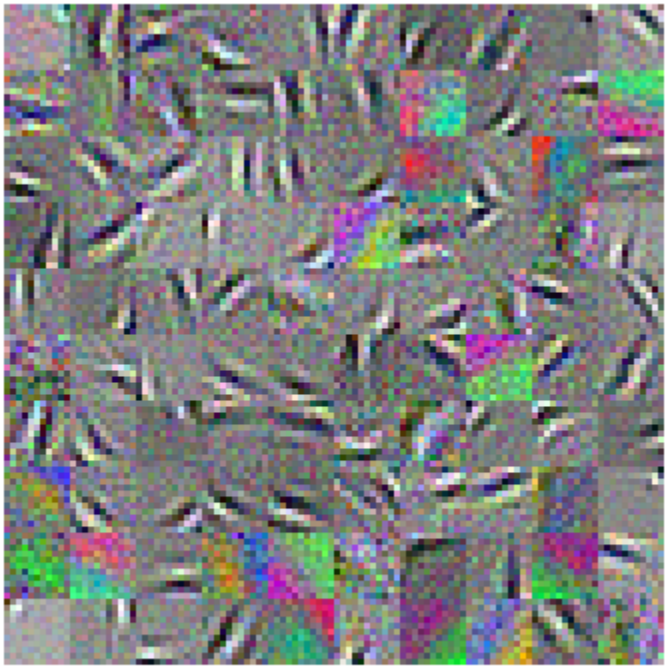
```
Mdl = sparsefilt(data.X,q,'IterationLimit',40,'InitialTransformWeights',wts);
```

```
Warning: Solver LBFGS was not able to converge to a solution.
```

View the updated transformation matrix as image patches.

```
wts = Mdl.TransformWeights;
W = reshape(wts,[11,11,3,q]);
[dx,dy,~,~] = size(W);
for f = 1:q
    Wvec = W(:,:,:,f);
    Wvec = Wvec(:);
    Wvec =(Wvec - min(Wvec))/(max(Wvec) - min(Wvec));
```

```
    W(:,:,:,f) = reshape(Wvec,dx,dy,3);
end
m   = ceil(sqrt(q));
n   = m;
img = zeros(m*dx,n*dy,3);
f   = 1;
for i = 1:m
    for j = 1:n
        if (f <= q)
            img((i-1)*dx+1:i*dx,(j-1)*dy+1:j*dy,:) = W(:,:,:,f);
            f = f+1;
        end
    end
end
imshow(img,'InitialMagnification',300);
```



These images are less noisy.

Input Arguments

X — Predictor data

numeric matrix | table

Predictor data, specified as an *n*-by-*p* numeric matrix or table. Rows correspond to individual observations and columns correspond to individual predictor variables. If X is a table, then all of its variables must be numeric vectors.

Data Types: `single` | `double` | `table`

q — Number of features to extract

positive integer

Number of features to extract from the predictor data, specified as a positive integer.

`sparsefilt` stores a *p*-by-`q` transform weight matrix in `Mdl.TransformWeights`. Therefore, setting very large values for `q` can result in greater memory consumption and increased computation time.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Standardize',true,'Lambda',1` standardizes the predictor data and applies a penalty of 1 to the transform weight matrix.

IterationLimit — Maximum number of iterations

`1000` (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit',1e6`

Data Types: `single` | `double`

VerbosityLevel — Verbosity level

`0` (default) | nonnegative integer

Verbosity level for monitoring algorithm convergence, specified as the comma-separated pair consisting of `'VerbosityLevel'` and a value in this table.

Value	Description
`0`	`sparsefilt` does not display convergence information at the command line.
Positive integer	`sparsefilt` displays convergence information at the command line.

Convergence Information

Heading	Meaning
FUN VALUE	Objective function value.
NORM GRAD	Norm of the gradient of the objective function.
NORM STEP	Norm of the iterative step, meaning the distance between the previous point and the current point.
CURV	OK means the weak Wolfe condition is satisfied. This condition is a combination of sufficient decrease of the objective function and a curvature condition.
GAMMA	Inner product of the step times the gradient difference, divided by the inner product of the gradient difference with itself. The gradient difference is the gradient at the current point minus the gradient at the previous point. Gives diagnostic information on the objective function curvature.
ALPHA	Step direction multiplier, which differs from 1 when the algorithm performed a line search.
ACCEPT	YES means the algorithm found an acceptable step to take.

Example: `'VerbosityLevel',1`

Data Types: `single` | `double`

`Lambda` — L^2 regularization coefficient value
`0` (default) | positive numeric scalar

L^2 regularization coefficient value for the transform weight matrix, specified as the comma-separated pair consisting of `'Lambda'` and a positive numeric scalar. If you specify `0`, the default, then there is no regularization term in the objective function.

Example: `'Lambda',0.1`

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictor data
`false` (default) | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and `true` (`1`) or `false` (`0`).

If `Standardize` is `true`, then:

- `sparsefilt` centers and scales each column of the predictor data (`X`) by the column mean and standard deviation, respectively.
- `sparsefilt` extracts new features by using the standardized predictor matrix, and stores the predictor variable means and standard deviations in properties `Mu` and `Sigma` of `Mdl`.

Example: `'Standardize',true`

Data Types: `logical`

`InitialTransformWeights` — Transformation weights that initialize optimization
`randn(p,q)` (default) | numeric matrix

Transformation weights that initialize optimization, specified as the comma-separated pair consisting of `'InitialTransformWeights'` and a *p*-by-`q` numeric matrix. *p* must be the number of columns or variables in `X` and `q` is the value of `q`.

Tip You can continue optimizing a previously returned transform weight matrix by passing it as an initial value in another call to `sparsefilt`. The output model object `Mdl` stores a learned transform weight matrix in the `TransformWeights` property.

Example: `'InitialTransformWeights',Mdl.TransformWeights`

Data Types: `single` | `double`

`GradientTolerance` — Relative convergence tolerance on gradient norm
`1e-6` (default) | positive numeric scalar

Relative convergence tolerance on gradient norm, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive numeric scalar. This gradient is the gradient of the objective function.

Example: `'GradientTolerance',1e-4`

Data Types: `single` | `double`

`StepTolerance` — Absolute convergence tolerance on step size
`1e-6` (default) | positive numeric scalar

Absolute convergence tolerance on the step size, specified as the comma-separated pair consisting of `'StepTolerance'` and a positive numeric scalar.

Example: `'StepTolerance',1e-4`

Data Types: `single` | `double`

Output Arguments

`Mdl` — Learned sparse filtering model
`SparseFiltering` model object

Learned sparse filtering model, returned as a `SparseFiltering` model object.

To access properties of `Mdl`, use dot notation. For example:

- To access the learned transform weights, use `Mdl.TransformWeights`.
- To access the fitting information structure, use `Mdl.FitInfo`.

To find sparse filtering coefficients for new data, use the `transform` function.

Algorithms

The `sparsefilt` function creates a nonlinear transformation of input features to output features. The transformation is based on optimizing an objective function that encourages the representation of each example by as few output features as possible while at the same time keeping the output features equally active across examples.

For details, see “Sparse Filtering Algorithm” on page 15-130.

“Feature Extraction” on page 15-130

Introduced in R2017a

SparseFiltering

Feature extraction by sparse filtering

Description

`SparseFiltering` uses sparse filtering to learn a transformation that maps input predictors to new predictors.

Creation

Create a `SparseFiltering` object using the `sparsefilt` function.

Properties

`FitInfo` — Fitting history
structure

This property is read-only.

Fitting history, returned as a structure with two fields:

- `Iteration` — Iteration numbers from 0 through the final iteration.
- `Objective` — Objective function value at each corresponding iteration. Iteration 0 corresponds to the initial values, before any fitting.

Data Types: `struct`

`InitialTransformWeights` — Initial feature transformation weights
`p`-by-`q` matrix

This property is read-only.

Initial feature transformation weights, returned as a `p`-by-`q` matrix, where `p` is the number of predictors passed in `X` and `q` is the number of features that you want. These weights are the initial weights passed to the creation function. The data type is single when the training data `X` is single.

Data Types: `single` | `double`

`ModelParameters` — Parameters used for training model
structure

This property is read-only.

Parameters used for training the model, returned as a structure. The structure contains a subset of the fields that corresponds to the `sparsefilt` name-value pairs that were in effect during model creation:

- `IterationLimit`

- `VerbosityLevel`
- `Lambda`
- `Standardize`
- `GradientTolerance`
- `StepTolerance`

For details, see the `sparsefilt` name-value pairs in the documentation.

Data Types: `struct`

`Mu` — Predictor means when standardizing
`p`-by-`1` vector

This property is read-only.

Predictor means when standardizing, returned as a `p`-by-`1` vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor means in the training data. The data type is single when the training data `X` is single.

Data Types: `single` | `double`

`NumLearnedFeatures` — Number of output features
positive integer

This property is read-only.

Number of output features, returned as a positive integer. This value is the `q` argument passed to the creation function, which is the requested number of features to learn.

Data Types: `double`

`NumPredictors` — Number of input predictors
positive integer

This property is read-only.

Number of input predictors, returned as a positive integer. This value is the number of predictors passed in `X` to the creation function.

Data Types: `double`

`Sigma` — Predictor standard deviations when standardizing
`p`-by-`1` vector

This property is read-only.

Predictor standard deviations when standardizing, returned as a `p`-by-`1` vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor standard deviations in the training data. The data type is single when the training data `X` is single.

Data Types: `single` | `double`

`TransformWeights` — Feature transformation weights
`p`-by-`q` matrix

This property is read-only.

Feature transformation weights, returned as a p-by-q matrix, where p is the number of predictors passed in X and q is the number of features that you want. The data type is single when the training data X is single.

Data Types: `single` | `double`

Object Functions

transform Transform predictors into extracted features

Examples

Create Sparse Filter

Create a `SparseFiltering` object by using the `sparsefilt` function.

Load the `SampleImagePatches` image patches.

```
data = load('SampleImagePatches');
size(data.X)
```

```
ans = 1×2

        5000         363
```

There are 5,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
Q = 100;
obj = sparsefilt(data.X,Q,'IterationLimit',100)
```

```
Warning: Solver LBFGS was not able to converge to a solution.

obj =
  SparseFiltering
           ModelParameters: [1x1 struct]
             NumPredictors: 363
         NumLearnedFeatures: 100
                         Mu: []
                      Sigma: []
                    FitInfo: [1x1 struct]
          TransformWeights: [363x100 double]
    InitialTransformWeights: []

  Properties, Methods
```

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Introduced in R2017a

spectralcluster

Spectral clustering

Syntax

```
idx = spectralcluster(X,k)

idx = spectralcluster(S,k,'Distance','precomputed')

idx = spectralcluster( ___ ,Name,Value)
[idx,V] = spectralcluster( ___ )
[idx,V,D] = spectralcluster( ___ )
```

Description

`idx = spectralcluster(X,k)` partitions observations in the *n*-by-*p* data matrix `X` into `k` clusters using the spectral clustering algorithm (see Algorithms on page 33-5959). `spectralcluster` returns an *n*-by-1 vector `idx` containing cluster indices of each observation.

`idx = spectralcluster(S,k,'Distance','precomputed')` returns a vector of cluster indices for `S`, the similarity matrix on page 33-5958 (or adjacency matrix) of a similarity graph on page 33-5958. `S` can be the output of `adjacency`.

To use a similarity matrix as the first input, you must specify `'Distance','precomputed'`.

`idx = spectralcluster( ___ ,Name,Value)` specifies additional options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify `'SimilarityGraph','epsilon'` to construct a similarity graph using the radius search method.

`[idx,V] = spectralcluster( ___ )` also returns the eigenvectors `V` corresponding to the `k` smallest eigenvalues of the Laplacian matrix on page 33-5959.

`[idx,V,D] = spectralcluster( ___ )` also returns a vector `D` containing the `k` smallest eigenvalues of the Laplacian matrix.

Examples

Perform Spectral Clustering on Input Data

Cluster a 2-D circular data set using spectral clustering with the default Euclidean distance metric.

Generate synthetic data that contains two noisy circles.

```
rng('default') % For reproducibility

% Parameters for data generation
N = 300;  % Size of each cluster
r1 = 2;   % Radius of first circle
r2 = 4;   % Radius of second circle
```

```
theta = linspace(0,2*pi,N)';

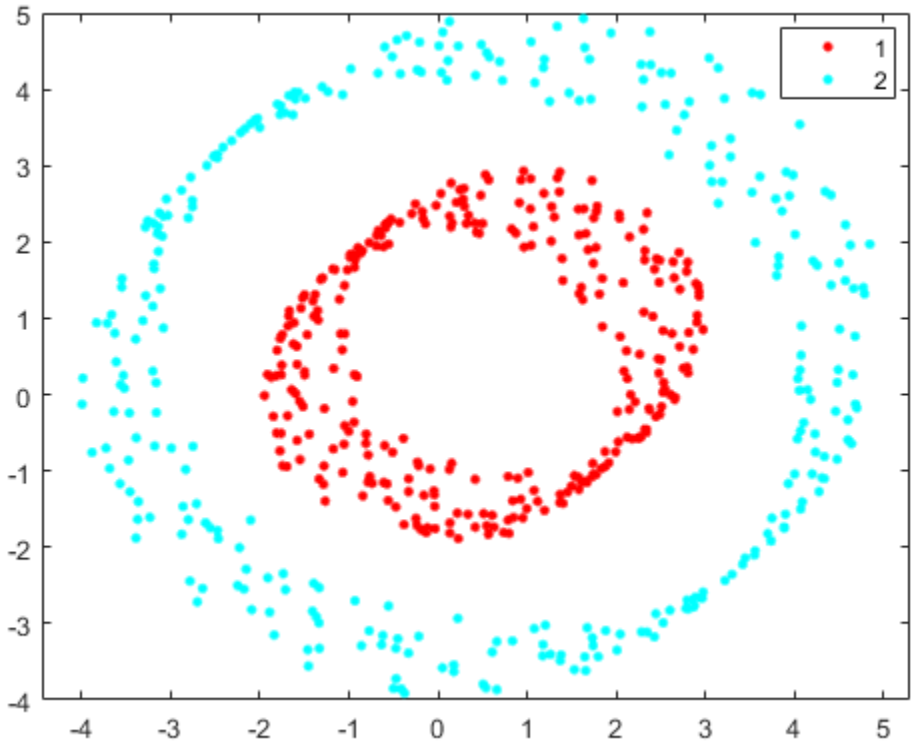
X1 = r1*[cos(theta),sin(theta)]+ rand(N,1);
X2 = r2*[cos(theta),sin(theta)]+ rand(N,1);
X = [X1;X2]; % Noisy 2-D circular data set
```

Find two clusters in the data by using spectral clustering.

```
idx = spectralcluster(X,2);
```

Visualize the result of clustering.

```
gscatter(X(:,1),X(:,2),idx);
```



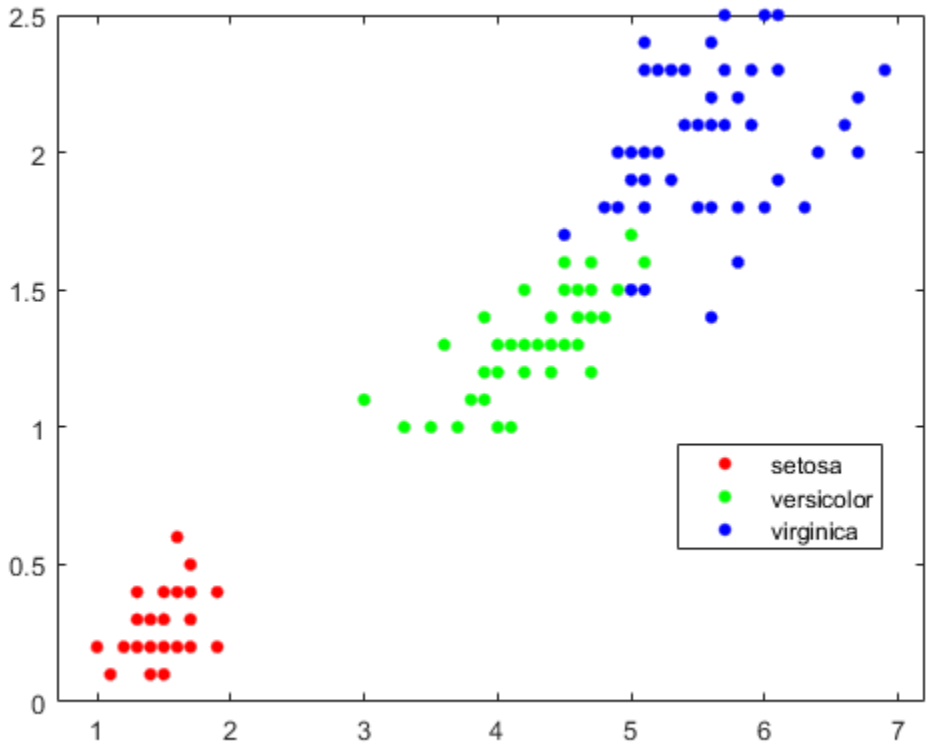
The `spectralcluster` function correctly identifies the two clusters in the data set.

Perform Spectral Clustering on Similarity Matrix

Compute a similarity matrix from Fisher's iris data set and perform spectral clustering on the similarity matrix.

Load Fisher's iris data set. Use the petal lengths and widths as features to consider for clustering.

```
load fisheriris
X = meas(:,3:4);
gscatter(X(:,1),X(:,2),species);
```



Find the distance between each pair of observations in X by using the `pdist` and `squareform` functions with the default Euclidean distance metric.

```
dist_temp = pdist(X);
dist = squareform(dist_temp);
```

Construct the similarity matrix and confirm that it is symmetric.

```
S = exp(-dist.^2);
issymmetric(S)
```

```
ans = logical
   1
```

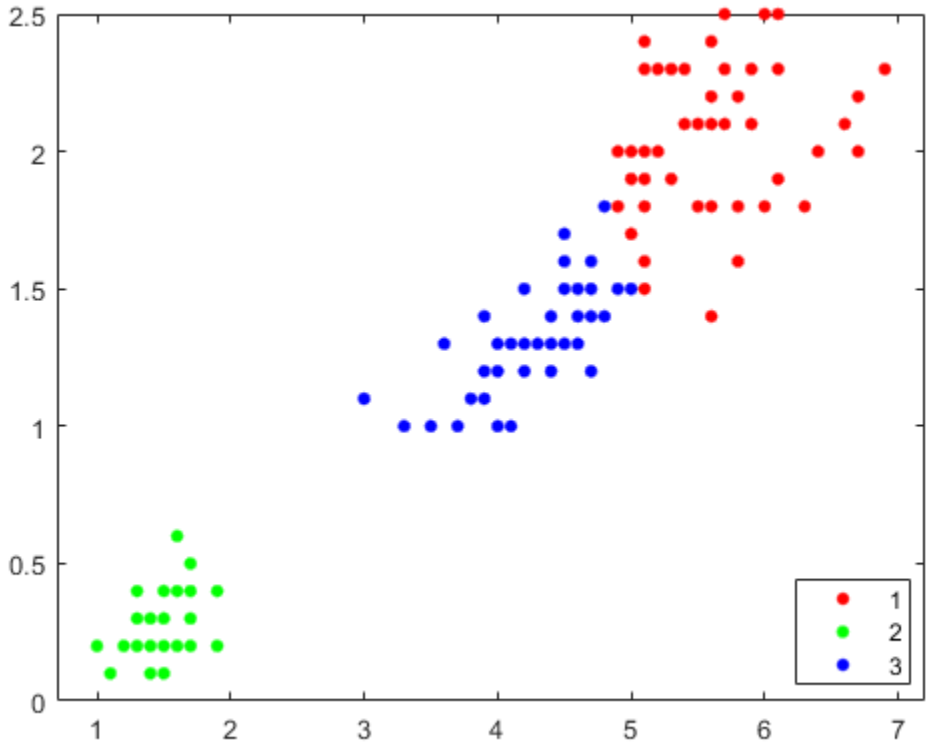
Perform spectral clustering. Specify `'Distance','precomputed'` to perform clustering using the similarity matrix. Specify `k=3` clusters, and set the `'LaplacianNormalization'` name-value pair argument to use the normalized symmetric Laplacian matrix.

```
k = 3; % Number of clusters
rng('default') % For reproducibility
idx = spectralcluster(S,k,'Distance','precomputed','LaplacianNormalization','symmetric');
```

`idx` contains the cluster indices for each observation in X.

Visualize the result of clustering.

```
gscatter(X(:,1),X(:,2),idx);
```



Tabulate the clustering results.

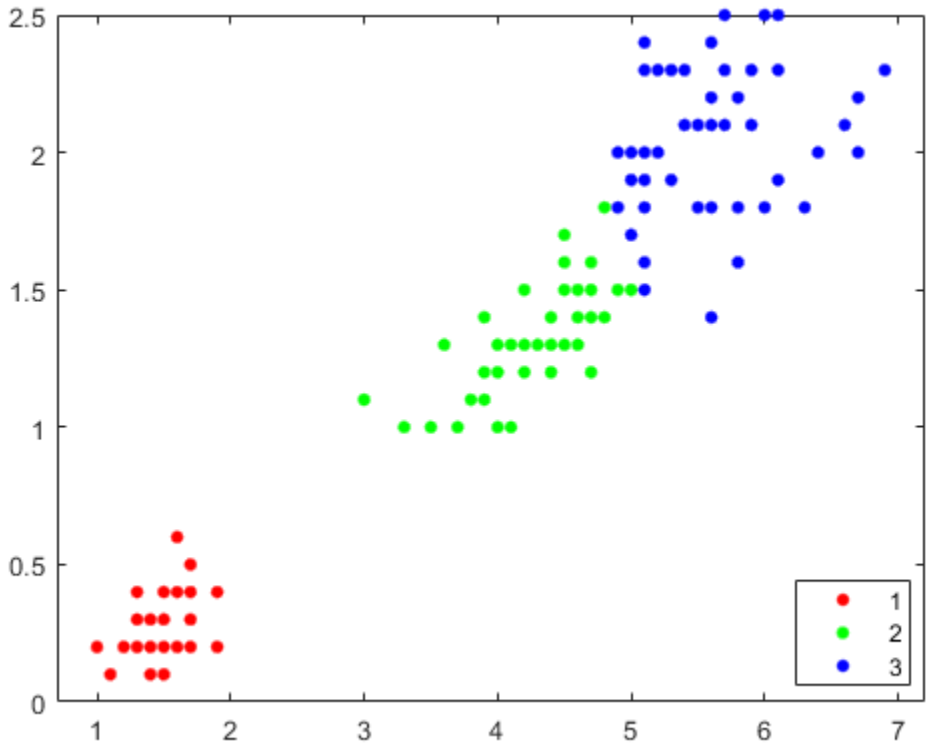
```
tabulate(idx)
```

```
  Value    Count   Percent
      1       48     32.00%
      2       50     33.33%
      3       52     34.67%
```

The `Percent` column shows the percentage of data points assigned to the three clusters.

Repeat spectral clustering using the data as input to `spectralcluster`. Specify `'NumNeighbors'` as `size(X,1)`, which corresponds to creating the similarity matrix `S` by connecting each point to all the remaining points.

```
idx2 = spectralcluster(X,k,'NumNeighbors',size(X,1),'LaplacianNormalization','symmetric');
gscatter(X(:,1),X(:,2),idx2);
```



```
tabulate(idx2)
```

```
  Value    Count   Percent
      1       50     33.33%
      2       52     34.67%
      3       48     32.00%
```

The clustering results for both approaches are the same. The order of cluster assignments is different, even though the data points are clustered in the same way.

Cluster Using Radius Search for Similarity Graph

Find clusters in a data set, based on a specified search radius for creating a similarity graph.

Create data with 3 clusters, each containing 500 points.

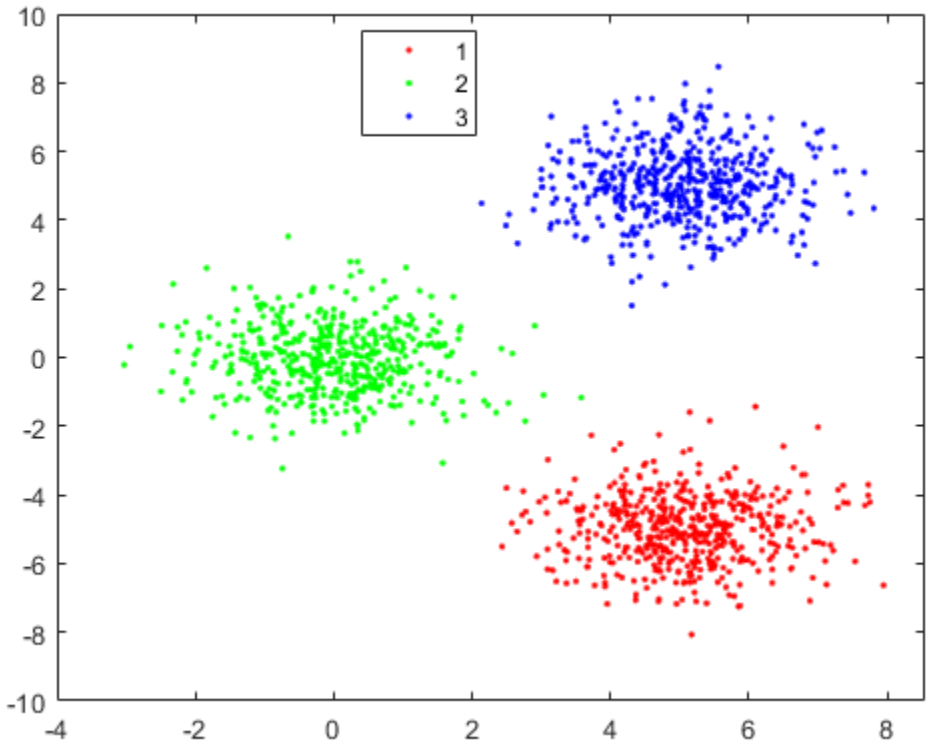
```
rng('default') % For reproducibility
N = 500;
X = [mvnrnd([0 0],eye(2),N); ...
    mvnrnd(5*[1 -1],eye(2),N); ...
    mvnrnd(5*[1 1],eye(2),N)];
```

Specify a search radius of 2 for creating a similarity graph, and find 3 clusters in the data.

```
idx = spectralcluster(X,3,'SimilarityGraph','epsilon','Radius',2);
```

Visualize the result of clustering.

```
gscatter(X(:,1),X(:,2),idx);
```



Find Eigenvalues and Eigenvectors of Laplacian Matrix

Find the eigenvalues and eigenvectors of the Laplacian matrix and use the values to confirm clustering results.

Randomly generate sample data with three well-separated clusters, each containing 100 points.

```
rng('default'); % For reproducibility
n = 100;
X = [randn(n,2)*0.5+3;
     randn(n,2)*0.5
     randn(n,2)*0.5-3];
```

Estimate the number of clusters in the data by using the eigenvalues of the Laplacian matrix. Compute the five smallest eigenvalues (in magnitude) of the Laplacian matrix.

```
[~,~,D_temp] = spectralcluster(X,5)
```

```
D_temp = 5×1

   -0.0000
```

```
   -0.0000
   -0.0000
    0.0277
    0.0296
```

Only the first three eigenvalues are approximately zero. The number of zero eigenvalues is a good indicator of the number of connected components in a similarity graph and, therefore, is a good estimate of the number of clusters in your data. So, `k=3` is a good estimate of the number of clusters in `X`.

Find `k=3` clusters and return the three smallest eigenvalues and corresponding eigenvectors of the Laplacian matrix.

```
[idx,V,D] = spectralcluster(X,3)
```

```
idx = 300×1

     3
     3
     3
     3
     3
     3
     3
     3
     3
     3
       ⋮

V = 300×3

   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
   -0.0000   -0.0000   -0.1000
      ⋮

D = 3×1
10^-16 ×

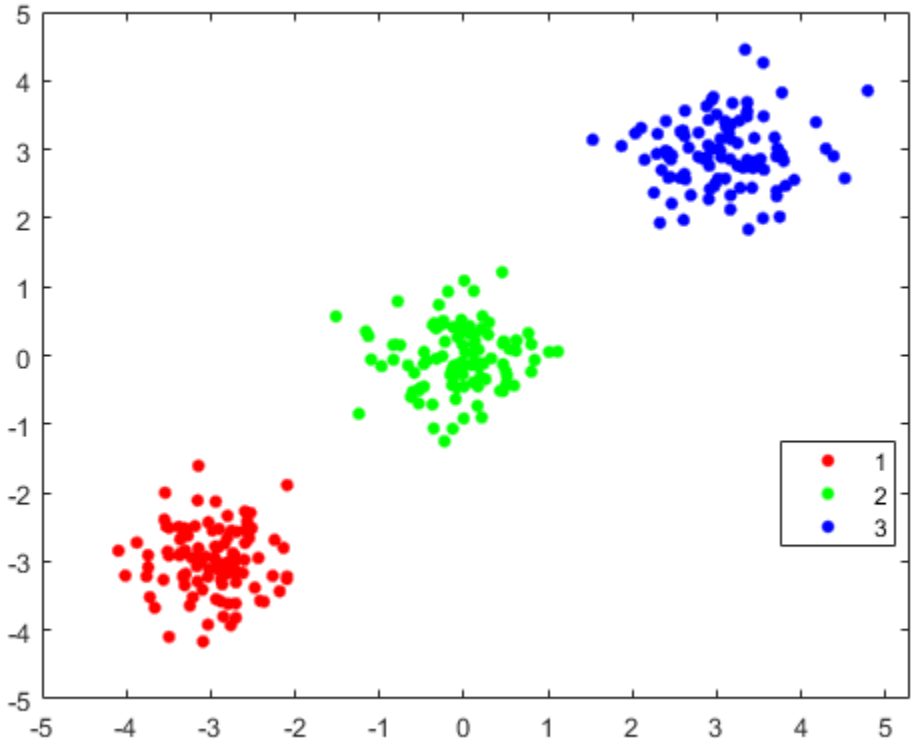
   -0.3308
   -0.3747
   -0.4167
```

Elements of `D` correspond to the three smallest eigenvalues of the Laplacian matrix. The columns of `V` contain the eigenvectors corresponding to the eigenvalues in `D`. For well-separated clusters, the eigenvectors are indicator vectors. The eigenvectors have values of zero (or close to zero) for points

that do not belong to a particular cluster, and nonzero values for points that belong to a particular cluster.

Visualize the result of clustering.

```
gscatter(X(:,1),X(:,2),idx);
```



Input Arguments

X — Input data

numeric matrix

Input data, specified as an *n*-by-*p* numeric matrix. The rows of `X` correspond to observations (or points), and the columns correspond to variables.

The software treats `NaN`s in `X` as missing data and ignores any row of `X` containing at least one `NaN`. The `spectralcluster` function returns `NaN` values for the corresponding row in the output arguments `idx` and `V`.

Data Types: `single` | `double`

S — Similarity matrix

symmetric matrix

Similarity matrix, specified as an *n*-by-*n* symmetric matrix, where *n* is the number of observations. A similarity matrix (or adjacency matrix) represents the input data by modeling local neighborhood

relationships among the data points. The values in a similarity matrix represent the edges (or connections) between nodes (data points) that are connected in a similarity graph on page 33-5958. For more information, see “Similarity Matrix” on page 33-5958.

`S` must not contain any `NaN` values.

To use a similarity matrix as the first input of `spectralcluster`, you must specify `'Distance','precomputed'`.

Data Types: `single` | `double`

k — Number of clusters

positive integer

Number of clusters in the data, specified as a positive integer.

For details about how to estimate the number of clusters, see “Tips” on page 33-5959.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `spectralcluster(X,3,'SimilarityGraph','epsilon','Radius',5)` specifies 3 clusters and uses the radius search method with a search radius of 5 to construct a similarity graph.

`Distance` — Distance metric

character vector | string scalar | function handle

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a character vector, string scalar, or function handle, as described in this table.

Value	Description
`'precomputed'`	Precomputed distance. You must specify this option if the first input to `spectralcluster` is a similarity matrix `S`.
`'euclidean'`	Euclidean distance (default)
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation computed from `X`. Use the `Scale` name-value pair argument to specify a different scaling factor.
`'mahalanobis'`	Mahalanobis distance using the sample covariance of `X`, `C = cov(X,'omitrows')`. Use the `Cov` name-value pair argument to specify a different covariance matrix.
`'cityblock'`	City block distance
`'minkowski'`	Minkowski distance. The default exponent is 2. Use the `P` name-value pair argument to specify a different exponent, where `P` is a positive scalar value.
`'chebychev'`	Chebychev distance (maximum coordinate difference)

Value	Description
`'cosine'`	One minus the cosine of the included angle between observations (treated as vectors)
`'correlation'`	One minus the sample correlation between observations (treated as sequences of values)
`'hamming'`	Hamming distance, which is the percentage of coordinates that differ
`'jaccard'`	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values)

`@`*`distfun`*	Custom distance function handle. A distance function has the form
	`function D2 = distfun(ZI,ZJ)`
	`% calculation of distance`
	`...`
	where
	• `ZI` is a `1`-by-`n` vector containing a single observation.
	• `ZJ` is an `m2`-by-`n` matrix containing multiple observations. `distfun` must accept a matrix `ZJ` with an arbitrary number of observations.
	• `D2` is an `m2`-by-`1` vector of distances, and `D2(k)` is the distance between observations `ZI` and `ZJ(k,:)`.
	If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.

For more information, see “Distance Metrics” on page 18-12.

When you use the `'seuclidean'`, `'minkowski'`, or `'mahalanobis'` distance metric, you can specify the additional name-value pair argument `'Scale'`, `'P'`, or `'Cov'`, respectively, to control the distance metric.

Example: `spectralcluster(X,5,'Distance','minkowski','P',3)` specifies 5 clusters and uses of the Minkowski distance metric with an exponent of 3 to perform the clustering algorithm.

P — Exponent for Minkowski distance metric
2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar.

This argument is valid only if `'Distance'` is `'minkowski'`.

Example: `'P',3`

Data Types: `single` | `double`

Cov — Covariance matrix for Mahalanobis distance metric
`cov(X,'omitrows')` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix.

This argument is valid only if `'Distance'` is `'mahalanobis'`.

Example: `'Cov',eye(4)`

Data Types: `single` | `double`

`Scale` — Scaling factors for standardized Euclidean distance metric
`std(X,'omitnan')` (default) | numeric vector of nonnegative values

Scaling factors for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of `'Scale'` and a numeric vector of nonnegative values.

`Scale` has length *p* (the number of columns in `X`), because each dimension (column) of `X` has a corresponding value in `Scale`. For each dimension of `X`, `spectralcluster` uses the corresponding value in `Scale` to standardize the difference between observations.

This argument is valid only if `'Distance'` is `'seuclidean'`.

Data Types: `single` | `double`

`SimilarityGraph` — Type of similarity graph
`'knn'` (default) | `'epsilon'`

Type of similarity graph to construct from the input data `X`, specified as the comma-separated pair consisting of `'SimilarityGraph'` and one of these values.

Value	Description	Graph-Specific Name-Value Pair Arguments
`'knn'`	(Default) Construct the graph using nearest neighbors.	`'NumNeighbors'` — Number of nearest neighbors used to construct the similarity graph `'KNNGraphType'` — Type of nearest neighbor graph
`'epsilon'`	Construct the graph using a radius search. You must specify a value for `Radius` if you use this option.	`'Radius'` — Search radius for the nearest neighbors used to construct the similarity graph

For more information, see “Similarity Graph” on page 33-5958.

This argument is valid only if `'Distance'` is not `'precomputed'`.

Example: `'SimilarityGraph','epsilon'`

`NumNeighbors` — Number of nearest neighbors
`log(size(X,1))` (default) | positive integer

Number of nearest neighbors used to construct the similarity graph, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer.

This argument is valid only if `'SimilarityGraph'` is `'knn'`. For more information, see “Similarity Graph” on page 33-5958.

Example: `'NumNeighbors',10`

Data Types: `single` | `double`

KNNGraphType — Type of nearest neighbor graph
`'complete'` (default) | `'mutual'`

Type of nearest neighbor graph, specified as the comma-separated pair consisting of `'KNNGraphType'` and one of these values.

Value	Description
`'complete'`	(Default) Connects two points *i* and *j*, when either *i* is a nearest neighbor of *j* or *j* is a nearest neighbor of *i*. This option leads to a denser representation of the similarity matrix.
`'mutual'`	Connects two points *i* and *j*, when *i* is a nearest neighbor of *j* and *j* is a nearest neighbor of *i*. This option leads to a sparser representation of the similarity matrix.

This argument is valid only if `'SimilarityGraph'` is `'knn'`.

Example: `'KNNGraphType','mutual'`

Radius — Search radius
nonnegative scalar

Search radius for the nearest neighbors used to construct the similarity graph, specified as the comma-separated pair consisting of `'Radius'` and a nonnegative scalar.

You must specify this argument if `'SimilarityGraph'` is `'epsilon'`. For more information, see “Similarity Graph” on page 33-5958.

Example: `'Radius',5`

Data Types: `single` | `double`

KernelScale — Scale factor
1 (default) | `'auto'` | positive scalar

Scale factor for the kernel, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar. The software uses the scale factor to transform distances to similarity measures. For more information, see “Similarity Graph” on page 33-5958.

- The `'auto'` option is supported only for the `'euclidean'` and `'seuclidean'` distance metrics.
- If you specify `'auto'`, then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. To reproduce results, set a random number seed using `rng` before calling `spectralcluster`.

This argument is valid only if `'Distance'` is not `'precomputed'`.

Example: `'KernelScale','auto'`

Data Types: `double` | `single` | `char` | `string`

LaplacianNormalization — Method to normalize Laplacian matrix
`'randomwalk'` (default) | `'symmetric'` | `'none'`

Method to normalize the Laplacian matrix L, specified as the comma-separated pair consisting of `'LaplacianNormalization'` and one of these values.

Value	Description
`'none'`	Use Laplacian matrix L without normalization.
`'randomwalk'`	(Default) Use the normalized random-walk Laplacian matrix L_{rw} (Shi-Malik [2]). $L_{rw} = D_g^{-1}L$. The matrix D_g is the degree matrix on page 33-5959.
`'symmetric'`	Use the normalized symmetric Laplacian matrix L_s (Ng-Jordan-Weiss [3]). $L_s = D_g^{-1/2}LD_g^{-1/2}$. The matrix D_g is the degree matrix.

For more information, see “Laplacian Matrix” on page 33-5959.

Example: `'LaplacianNormalization','randomwalk'`

`ClusterMethod` — Clustering method
`'kmeans'` (default) | `'kmedoids'`

Clustering method to cluster the eigenvectors of the Laplacian matrix, specified as the comma-separated pair consisting of `'ClusterMethod'` and either `'kmeans'` or `'kmedoids'`.

- `'kmeans'` — Perform k-means clustering by using the `kmeans` function.
- `'kmedoids'` — Perform k-medoids clustering by using the `kmedoids` function.

`kmeans` and `kmedoids` involve randomness in their algorithms. Therefore, to reproduce the results of `spectralcluster`, you must set the seed of the random number generator by using `rng`.

Example: `'ClusterMethod','kmedoids'`

Output Arguments

`idx` — Cluster indices
numeric column vector

Cluster indices, returned as a numeric column vector. `idx` has n rows, and each row of `idx` indicates the cluster assignment of the corresponding row (or observation) in `X`.

Data Types: `double`

`V` — Eigenvectors
numeric matrix

Eigenvectors, returned as an n-by-`k` numeric matrix. The columns of `V` are the eigenvectors corresponding to the `k` smallest eigenvalues of the Laplacian matrix on page 33-5959. These eigenvectors are a low-dimensional representation of the input data `X` in a new space where clusters are more widely separated.

For well-separated clusters, the eigenvectors are indicator vectors. That is, the eigenvectors have values of zero (or close to zero) for points that do not belong to a given cluster, and nonzero values for points that belong to a particular cluster.

Data Types: `single` | `double`

`D` — Eigenvalues
numeric vector

Eigenvalues, returned as a `k`-by-1 numeric vector that contains the `k` smallest eigenvalues of the Laplacian matrix. The number of zero eigenvalues in `D` is an indicator of the number of connected components in the similarity graph and, therefore, is a good estimate of the number of clusters in your data.

Data Types: `single` | `double`

More About

Similarity Graph

A similarity graph models the local neighborhood relationships between data points in `X` as an undirected graph. The nodes in the graph represent data points, and the edges, which are directionless, represent the connections between the data points.

If the pairwise distance $Dist_{i,j}$ between any two nodes i and j is positive (or larger than a certain threshold), then the similarity graph connects the two nodes using an edge [1]. The edge between the two nodes is weighted by the pairwise similarity $S_{i,j}$, where $S_{i,\,j} = \exp\left(-\left(\frac{Dist_{i,\,j}}{\sigma}\right)^2\right)$, for a specified kernel scale σ value.

`spectralcluster` supports these two methods of constructing a similarity graph:

- *Nearest neighbor* method (if `'SimilarityGraph'` is `'knn'`(default)): `spectralcluster` connects points in `X` that are nearest neighbors. You can use the `'NumNeighbors'` and `'KNNGraphType'` name-value pair arguments to specify the options for constructing the nearest neighbor graph.
  - Use `'NumNeighbors'` to specify the number of nearest neighbors.
  - Use `'KNNGraphType'` to specify whether to make a `'complete'` or `'mutual'` connection of points.
- *Radius search* method (if `'SimilarityGraph'` is `'epsilon'`): `spectralcluster` connects points whose pairwise distances are smaller than a search radius. You must specify the search radius for nearest neighbors used to construct the similarity graph by using the `'Radius'` name-value pair argument.

Similarity Matrix

A similarity matrix is a matrix representation of a similarity graph on page 33-5958. The n-by-n matrix $S = (S_{i,\,j})_{i,\,j\,=\,1,\,\ldots,\,n}$ contains pairwise similarity values between connected nodes in the similarity graph. The similarity matrix of a graph is also called an adjacency matrix.

The similarity matrix is symmetric because the edges of the similarity graph are directionless. A value of $S_{i,\,j} = 0$ means that nodes i and j of the similarity graph are not connected.

Degree Matrix

A degree matrix D_g is an n-by-n diagonal matrix obtained by summing the rows of the similarity matrix on page 33-5958 S. That is, the ith diagonal element of D_g is $D_g(i,i) = \sum_{j=1}^{n} S_{i,j}$.

Laplacian Matrix

A Laplacian matrix is one way of representing a similarity graph on page 33-5958. The `spectralcluster` function supports the unnormalized Laplacian matrix, the normalized Laplacian matrix using the Shi-Malik method [2], and the normalized Laplacian matrix using the Ng-Jordan-Weiss method [3].

- The *unnormalized Laplacian matrix L* is the difference between the degree matrix on page 33-5959 and the similarity matrix on page 33-5958.

  $$L = D_g - S.$$

- The *normalized random-walk Laplacian matrix (Shi-Malik)* is defined as:

  $$L_{rw} = D_g^{-1}L.$$

  To derive L_{rw}, solve the generalized eigenvalue problem $Lv = \lambda D_g v$, where v is a column vector of length n, and λ is a scalar. The values of λ that satisfy the equation are the generalized eigenvalues of the matrix $L_{rw} = D_g^{-1}L$.

  You can use the MATLAB function `eigs` to solve the generalized eigenvalue problem.

- The *normalized symmetric Laplacian matrix (Ng-Jordan-Weiss)* is defined as:

  $$L_s = D_g^{-1/2}LD_g^{-1/2}.$$

Use the `'LaplacianNormalization'` name-value pair argument to specify the method to normalize the Laplacian matrix.

Tips

- Consider using spectral clustering when the clusters in your data do not naturally correspond to convex regions.
- From the spectral clustering algorithm, you can estimate the number of clusters `k` as:
  - The number of eigenvalues of the Laplacian matrix that are equal to `0`.
  - The number of connected components in your similarity graph representation. Use `graph` to create a similarity graph from a similarity matrix, and use `conncomp` to find the number of connected components in the graph.

  For an example, see “Estimate Number of Clusters and Perform Spectral Clustering” on page 16-27.

Algorithms

Spectral clustering is a graph-based algorithm for clustering data points (or observations in `X`). The algorithm involves constructing a graph, finding its Laplacian matrix on page 33-5959, and using this

matrix to find k eigenvectors to split the graph k ways. By default, the algorithm for `spectralcluster` computes the normalized random-walk Laplacian matrix using the method described by Shi-Malik [2]. `spectralcluster` also supports the unnormalized Laplacian matrix and the normalized symmetric Laplacian matrix which uses the Ng-Jordan-Weiss method [3]. `spectralcluster` implements clustering as follows:

1. For each data point in `X`, define a local neighborhood using either the radius search method or nearest neighbor method, as specified by the `'SimilarityGraph'` name-value pair argument (see "Similarity Graph" on page 33-5958). Then, find the pairwise distances $Dist_{i,j}$ for all points i and j in the neighborhood.
2. Convert the distances to similarity measures using the kernel transformation $S_{i,j} = \exp\left(-\left(\frac{Dist_{i,j}}{\sigma}\right)^2\right)$. The matrix S is the similarity matrix on page 33-5958, and σ is the scale factor for the kernel, as specified using the `'KernelScale'` name-value pair argument.
3. Calculate the unnormalized Laplacian matrix on page 33-5959 L , the normalized random-walk Laplacian matrix L_{rw}, or the normalized symmetric Laplacian matrix L_s, depending on the value of the `'LaplacianNormalization'` name-value pair argument.
4. Create a matrix $V \in \mathbb{R}^{n \times k}$ containing columns $v_1, \ldots, v_k$, where the columns are the k eigenvectors that correspond to the k smallest eigenvalues of the Laplacian matrix. If using L_s, normalize each row of V to have unit length.
5. Treating each row of V as a point, cluster the n points using k-means clustering (default) or k-medoids clustering, as specified by the `'ClusterMethod'` name-value pair argument.
6. Assign the original points in `X` to the same clusters as their corresponding rows in V.

Topics

"Partition Data Using Spectral Clustering" on page 16-26

Introduced in R2019b

squareform

Format distance matrix

Syntax

```
ZOut = squareform(yIn)
yOut = squareform(ZIn)

ZOut = squareform(yIn,'tomatrix')
yOut = squareform(ZIn,'tovector')
```

Description

`ZOut = squareform(yIn)` converts `yIn`, a pairwise distance vector of length $m(m–1)/2$ for m observations, into `ZOut`, an m-by-m symmetric matrix with zeros along the diagonal.

The pairwise distances in `yIn` are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m–1). The pairwise distance between the `i`th and `j`th observations is in `ZOut(i,j)` and `yIn((i–1)*(m–i/2)+j–i)` for $i \le j$.

`yOut = squareform(ZIn)` converts `ZIn`, a square, symmetric matrix with zeros along the diagonal, into `yOut`, a vector containing the `ZIn` elements below the diagonal.

`ZOut = squareform(yIn,'tomatrix')` forces `squareform` to treat `yIn` as a vector and converts `yIn` into a matrix.

`yOut = squareform(ZIn,'tovector')` forces `squareform` to treat `ZIn` as a matrix and converts `ZIn` into a vector. If `ZIn` is a scalar (1-by-1), then `ZIn` must be zero.

The previous two syntaxes are useful when the input argument is a scalar. If you do not specify either `'tomatrix'` or `'tovector'`, then the default is `'tomatrix'`.

Examples

Compute Euclidean Distance and Convert Distance Vector to Matrix

Compute the Euclidean distance between pairs of observations, and convert the distance vector to a matrix using `squareform`.

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
```

Compute the Euclidean distance.

```
D = pdist(X)
```

```
D = 1×3
```

```
    0.2954    1.0670    0.9448
```

The pairwise distances are arranged in the order (2,1), (3,1), (3,2). You can easily locate the distance between observations `i` and `j` by using `squareform`.

```
Z = squareform(D)
```

```
Z = 3×3

         0    0.2954    1.0670
    0.2954         0    0.9448
    1.0670    0.9448         0
```

`squareform` returns a symmetric matrix where `Z(i,j)` corresponds to the pairwise distance between observations `i` and `j`. For example, you can find the distance between observations 2 and 3.

```
Z(2,3)
```

```
ans = 0.9448
```

Pass `Z` to the `squareform` function to reproduce the output of the `pdist` function.

```
y = squareform(Z)
```

```
y = 1×3

    0.2954    1.0670    0.9448
```

The outputs `y` from `squareform` and `D` from `pdist` are the same.

Input Arguments

`yIn` — Input distance vector

numeric vector | logical vector

Input distance vector, specified as a numeric or logical vector of length $m(m–1)/2$, where m is the number of observations.

The pairwise distances in `yIn` are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m–1), i.e., the lower-left triangle of the m-by-m distance matrix in column order. The pairwise distance between observations i and j is in `yIn((i–1)*(m–i/2)+j–i)` for $i \le j$.

You can create `yIn` by using the `pdist` function. m is the number of observations in the input data of `pdist`.

Data Types: `single` | `double` | `logical`

`ZIn` — Input distance matrix

numeric matrix | logical matrix

Input distance matrix, specified as a numeric or logical matrix. `ZIn` is an m-by-m symmetric matrix with zeros along the diagonal, where m is the number of observations. `ZIn(i,j)` denotes the distance between the `i`th and `j`th observations.

Data Types: `single` | `double` | `logical`

Output Arguments

`yOut` — Distance vector

numeric vector | logical vector

Distance vector, returned as a numeric or logical vector of length $m(m–1)/2$, where m is the number of observations.

The pairwise distances in `yOut` are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m–1), i.e., the lower-left triangle of the m-by-m distance matrix in column order. The pairwise distance between observations i and j is in `yOut((i–1)*(m–i/2)+j–i)` for $i \leq j$.

`yOut` has the same format as the output from the `pdist` function.

`ZOut` — Distance matrix

numeric matrix | logical matrix

Distance matrix, returned as a numeric or logical matrix. `ZOut` is an m-by-m symmetric matrix with zeros along the diagonal, where m is the number of observations. `ZOut(i,j)` denotes the distance between the `i`th and `j`th observations.

Tips

- You can use `squareform` to format a vector or matrix that is similar to a distance vector or matrix, such as the correlation coefficient matrix (`corrcoef`).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations: The conversion direction `'tomatrix'` or `'tovector'` must be a compile-time constant. For example, to specify the conversion direction as `'tovector'`, include `coder.Constant('tovector')` in the `-args` value of `codegen`.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

`pdist`

Introduced before R2006a

stack

Class: `dataset`

(Not Recommended) Stack dataset array from multiple variables into single variable

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = stack(A,datavars)
[B,iA] = stack(A,datavars)
B = stack(A,datavars,Parameter,value)
```

Description

`B = stack(A,datavars)` stacks multiple variables in dataset array `A` into a single variable in `B`. In general, `B` contains fewer variables but more observations than `A`.

`datavars` specifies a group of `m` data variables in `A`. `stack` creates a single data variable in `B` by interleaving their values, and if `A` has `n` observations, then `B` has `m`-by-`n` observations. In other words, `stack` takes the `m` data values from each observation in `A` and stacks them up to create `m` observations in `B`. `datavars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. `stack` also creates a grouping variable in `B` to indicate which of the `m` data variables in `A` each observation in `B` corresponds to.

`stack` assigns values for the "per-variable properties (e.g., `Units` and `VarDescription`) for the new data variable in `B` from the corresponding property values for the first variable listed in `datavars`.

`stack` copies the remaining variables from `A` to `B` without stacking, by replicating each of their values `m` times. These variables are typically grouping variables. Because their values are constant across each group of `m` observations in `B`, they identify which observation in `A` an observation in `B` came from.

`[B,iA] = stack(A,datavars)` returns an index vector `iA` indicating the correspondence between observations in `B` and those in `A`. `stack` creates `B(j,:)` using `A(iA(j),datavarss)`.

For more information on grouping variables, see “Grouping Variables” on page 2-45.

Input Arguments

`B = stack(A,datavars,Parameter,value)` uses the following parameter name/value pairs to control how `stack` converts variables in `A` to variables in `B`:

`'ConstVars'`	Variables in `A` to copy to `B` without stacking. `ConstVars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. The default is all variables in `A` not specified in `datavars`.
`'NewDataVarName'`	A name for the data variable to be created in `B`. The default is a concatenation of the names of the `m` variables that are stacked up.
`'IndVarName'`	A name for the grouping variable to create in `B` to indicate the source of each value in the new data variable. The default is based on the `'NewDataVarName'` parameter.

You can also specify multiple groups of data variables in `A`, each of which becomes a variable in `B`. All groups must contain the same number of variables. Use a string array or cell array of character vectors to contain multiple parameter values for `datavars` or to contain multiple values for `'NewDataVarName'`.

Examples

Combine several variables for estimated influenza rates into a single variable. Then unstack the estimated influenza rates by date.

```
load flu

% FLU has a 'Date' variable, and 10 variables for estimated influenza rates
% (in 9 different regions, estimated from Google searches, plus a
% nationwide estimate from the CDC). Combine those 10 variables into an
% array that has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName','Region')

% The second observation in FLU is for 10/16/2005.  Find the observations
% in FLU2 that correspond to that date.
flu(2,:)
flu2(iflu==2,:)

% Use the 'Date' variable from that array to split 'FluRate' into 52
% separate variables, each containing the estimated influenza rates for
% each unique date.  The new array has one observation for each region.  In
% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
    'NewDataVarNames',dateNames)

% Since observations in FLU3 represent regions, IFLU2 indicates the first
% occurrence in FLU2 of each region.
flu2(iflu2,:)
```

State property

Class: `qrandstream`

Current state of the stream

Description

The `State` property of a quasi-random stream contains the index into the associated point set of the next point to draw in the stream. Getting and resetting the `State` property allows you to return a stream to a previous state. The initial value of `State` is `1`.

Examples

```
Q = qrandstream('sobol', 5);
s = Q.State;
u1 = qrand(Q, 10)
Q.State = s;
u2 = qrand(Q, 10) % contains exactly the same values as u1
```

See Also

`qrand`

statget

Access values in statistics options structure

Syntax

```
val = statget(options,param)
val = statget(options,param,default)
```

Description

`val = statget(options,param)` returns the value of the parameter specified by `param` in the statistics options structure `options`. The input `param` is a character vector or a string scalar of the parameter name. If the parameter is undefined in `options`, `statget` returns `[]`. You need to type only enough leading characters to define the parameter name uniquely. `statget` ignores case for parameter names. For available `options`, see Inputs.

`val = statget(options,param,default)` returns `default` if the specified parameter is undefined in the optimization options structure `options`.

Input Arguments

`DerivStep`

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.

`Display`

Amount of information displayed by the algorithm.

- `'off'` — Displays no information.
- `'final'` — Displays the final output.
- `'iter'` — Displays iterative output to the command window for some functions; otherwise displays the final output.

`FunValCheck`

Check for invalid values, such as `NaN` or `Inf`, from the objective function.

- `'off'`
- `'on'`

`GradObj`

Flags whether the objective function returns a gradient vector as a second output.

- `'off'`
- `'on'`

`Jacobian`

Flags whether the objective function returns a Jacobian as a second output.

- `'off'`
- `'on'`

`MaxFunEvals`

Maximum number of objective function evaluations allowed. Positive integer.

`MaxIter`

Maximum number of iterations allowed. Positive integer.

`OutputFcn`

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

`Robust`

Invoke robust fitting option.

- `'off'`
- `'on'`

`RobustWgtFun`

A weight function for robust fitting. Valid only when `Robust` is `'on'`. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- `'bisquare'`
- `'andrews'`
- `'cauchy'`
- `'fair'`
- `'huber'`
- `'logistic'`
- `'talwar'`
- `'welsch'`

`Streams`

A single instance of the `RandStream` class, or a cell array of `RandStream` instances. The Streams option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If `'UseSubstreams'` is `true`, the Streams value must be a scalar, or must be empty. If `'UseParallel'` is `true` and `'UseSubstreams'` is `false`, then the Streams argument must either be empty, or its length must match the number of processors used in the computation: equal to the *parpool* size if a *parpool* is open, a scalar otherwise.

TolBnd

Parameter bound tolerance. Positive scalar.

TolFun

Termination tolerance for the objective function value. Positive scalar.

TolTypeFun

Use `TolFun` for absolute or relative objective function tolerances.

- `'abs'`
- `'rel'`

TolTypeX

Use `TolX` for absolute or relative parameter tolerances.

- `'abs'`
- `'rel'`

TolX

Termination tolerance for the parameters. Positive scalar.

Tune

The tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar.

UseParallel

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT `parpool` is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

UseSubstreams

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

WgtFun

A weight function for robust fitting. Valid only when `Robust` is `'on'`. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- `'bisquare'`
- `'andrews'`
- `'cauchy'`
- `'fair'`

- `'huber'`
- `'logistic'`
- `'talwar'`
- `'welsch'`

Examples

This statement returns the value of the `Display` statistics options parameter from the structure called `my_options`.

```
val = statget(my_options,'Display')
```

Return the value of the `Display` statistics options parameter from the structure called `my_options` (as in the previous example). If the `Display` parameter is undefined, `statget` returns the value `'final'`.

```
optnew = statget(my_options,'Display','final');
```

See Also

`statset`

Introduced before R2006a

statset

Create statistics options structure

Syntax

```
statset
statset(statfun)
options = statset(...)
options = statset(fieldname1,val1,fieldname2,val2,...)
options = statset(oldopts,fieldname1,val1,fieldname2,val2,...)
options = statset(oldopts,newopts)
```

Description

`statset` with no input arguments and no output arguments displays all fields of a statistics options structure and their possible values.

`statset(statfun)` displays fields and default values used by the Statistics and Machine Learning Toolbox function `statfun`. Specify `statfun` using a character vector, a string scalar, or a function handle.

`options = statset(...)` creates a statistics options structure `options`. With no input arguments, all fields of the options structure are an empty array (`[]`). With a specified `statfun`, function-specific fields are default values and the remaining fields are `[]`. Function-specific fields set to `[]` indicate that the function is to use its default value for that parameter. For available `options`, see Inputs.

`options = statset(fieldname1,val1,fieldname2,val2,...)` creates an options structure in which the named fields have the specified values. Any unspecified values are `[]`. Use character vectors or string scalars for field names. For named values, you must input the complete character vector or string scalar for the value. If you provide an invalid character vector or string scalar for a value, `statset` uses the default.

`options = statset(oldopts,fieldname1,val1,fieldname2,val2,...)` creates a copy of `oldopts` with the named parameters changed to the specified values.

`options = statset(oldopts,newopts)` combines an existing options structure, `oldopts`, with a new options structure, `newopts`. Any parameters in `newopts` with nonempty values overwrite corresponding parameters in `oldopts`.

Input Arguments

`DerivStep`

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.

`Display`

Amount of information displayed by the algorithm.

- `'off'` — Displays no information.
- `'final'` — Displays the final output.
- `'iter'` — Displays iterative output to the command window for some functions; otherwise displays the final output.

`FunValCheck`

Check for invalid values, such as `NaN` or `Inf`, from the objective function.

- `'off'`
- `'on'`

`GradObj`

Flags whether the objective function returns a gradient vector as a second output.

- `'off'`
- `'on'`

`Jacobian`

Flags whether the objective function returns a Jacobian as a second output.

- `'off'`
- `'on'`

`MaxFunEvals`

Maximum number of objective function evaluations allowed. Positive integer.

`MaxIter`

Maximum number of iterations allowed. Positive integer.

`OutputFcn`

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

`Robust`

(Not recommended) Invoke robust fitting option.

- `'off'`
- `'on'`

`Robust` is not recommended. Use `RobustWgtFun` for robust fitting.

RobustWgtFun

Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a `Tune` constant. See “Robust Options” on page 33-5976.

Streams

A single instance of the `RandStream` class, or a cell array of `RandStream` instances. The Streams option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If `'UseSubstreams'` is `true`, the Streams value must be a scalar, or must be empty. If `'UseParallel'` is `true` and `'UseSubstreams'` is `false`, then the Streams argument must either be empty, or its length must match the number of processors used in the computation: equal to the *parpool* size if a *parpool* is open, a scalar otherwise.

TolBnd

Parameter bound tolerance. Positive scalar.

TolFun

Termination tolerance for the objective function value. Positive scalar.

TolTypeFun

Use `TolFun` for absolute or relative objective function tolerances.

- `'abs'`
- `'rel'`

TolTypeX

Use `TolX` for absolute or relative parameter tolerances.

- `'abs'`
- `'rel'`

TolX

Termination tolerance for the parameters. Positive scalar.

Tune

Tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar. See “Robust Options” on page 33-5976.

UseParallel

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT `parpool` is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

UseSubstreams

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within

the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

`WgtFun`

(Not recommended) Weight function for robust fitting. Valid only when `Robust` is `'on'`. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. See “Robust Options” on page 33-5976.

`WgtFun` is not recommended. Use `RobustWgtFun` instead.

Examples

Suppose you want to change the default parameter values for the function `evfit`, which fits an extreme value distribution to data. The defaults parameter values are:

```
statset('evfit')
ans =
          Display: 'off'
      MaxFunEvals: []
          MaxIter: []
           TolBnd: []
           TolFun: []
       TolTypeFun: []
             TolX: 1.0000e-06
         TolTypeX: []
          GradObj: []
         Jacobian: []
        DerivStep: []
      FunValCheck: []
           Robust: []
     RobustWgtFun: []
           WgtFun: []
             Tune: []
      UseParallel: []
    UseSubstreams: []
          Streams: []
        OutputFcn: []
```

The only parameters that `evfit` uses are `Display` and `TolX`. To create an options structure with the value of `TolX` set to `1e-8`, enter:

```
options = statset('TolX',1e-8)
% Pass options to evfit:
mu = 1;
sigma = 1;
data = evrnd(mu,sigma,1,100);

paramhat = evfit(data,[],[],[],options)
```

`statget`

Introduced before R2006a

std

Package: prob

Standard deviation of probability distribution

Syntax

```
s = std(pd)
```

Description

`s = std(pd)` returns the standard deviation `s` of the probability distribution `pd`.

Examples

Standard Deviation of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
       mu = 75.0083   [73.4321, 76.5846]
    sigma =  8.7202   [7.7391, 9.98843]
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)
```

```
s = 8.7202
```

For a normal distribution, the standard deviation is equal to the parameter `sigma`.

Standard Deviation of a Skewed Distribution

Create a Weibull probability distribution object

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =
  WeibullDistribution
```

```
  Weibull distribution
    A = 5
    B = 2
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s = 2.3163
```

Standard Deviation of a Triangular Distribution

Create a triangular distribution object.

```
pd = makedist('Triangular','a',-3,'b',1,'c',3)
```

```
pd =
  TriangularDistribution

A = -3, B = 1, C = 3
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s = 1.2472
```

Standard Deviation of a Kernel Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;
x = grades(:,1);
```

Create a probability distribution object by fitting a kernel distribution to the data.

```
pd = fitdist(x,'Kernel')
```

```
pd =
  KernelDistribution

    Kernel = normal
    Bandwidth = 3.61677
    Support = unbounded
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)
```

```
s = 9.4069
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
`makedist`	Create a probability distribution object using specified parameter values.
`fitdist`	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

s — Standard deviation

nonnegative scalar value

Standard deviation of the probability distribution, returned as a nonnegative scalar value.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 32-82.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

Introduced in R2013a

step

Improve generalized linear regression model by adding or removing terms

Syntax

```
NewMdl = step(mdl)
NewMdl = step(mdl,Name,Value)
```

Description

`NewMdl = step(mdl)` returns a generalized linear regression model based on `mdl` using stepwise regression to add or remove one predictor.

`NewMdl = step(mdl,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the criterion to use to add or remove terms and the maximum number of steps to take.

Examples

Modify Generalized Linear Regression Model Using `step`

Fit a Poisson regression model using random data and a single predictor, and then use `step` to improve the model by adding or removing predictor terms.

Generate sample data that has 20 predictor variables. Use three of the predictors to generate the Poisson response variable.

```
rng('default') % For reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data using `X(:,2)` as the only predictor.

```
mdl = fitglm(X,y,'y ~ x2','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
    log(y) ~ 1 + x2
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE        tStat       pValue
                   ________    ________    _______    __________

    (Intercept)      1.1386    0.056722     20.073    1.2817e-89
    x2             0.010768    0.056564    0.19037       0.84902

100 observations, 98 error degrees of freedom
```

```
Dispersion: 1
Chi^2-statistic vs. constant model: 0.0362, p-value = 0.849
```

Improve `mdl` by using `step`. Specify `'NSteps'` as 5 to allow at most 5 steps of stepwise regression.

```
mdl1 = step(mdl,'NSteps',5)
```

```
1. Adding x5, Deviance = 134.4375, Chi2Stat = 52.21338, PValue = 4.978574e-13
2. Adding x15, Deviance = 106.1925, Chi2Stat = 28.24496, PValue = 1.068927e-07
3. Adding x10, Deviance = 94.708, Chi2Stat = 11.4845, PValue = 0.000701792
4. Removing x2, Deviance = 95.021, Chi2Stat = 0.31263, PValue = 0.57607

mdl1 =
Generalized linear regression model:
    log(y) ~ 1 + x5 + x10 + x15
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE       tStat       pValue
                   ________    ________    ______    __________

    (Intercept)     1.0115     0.064275    15.737    8.4217e-56
    x5             0.39508     0.066665    5.9263    3.0977e-09
    x10            0.18863      0.05534    3.4085     0.0006532
    x15            0.29295     0.053269    5.4995    3.8089e-08

100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

`step` adds the three predictor variables used to generate the response variable to the model and removes `X(:,2)` from the model.

Input Arguments

`mdl` — Generalized linear regression model

`GeneralizedLinearModel` object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Criterion','aic','Upper','quadratic','Verbose',2` instructs `step` to use the Akaike information criterion, include (at most) the quadratic terms in the model, and display the evaluation process and the decision taken at each step.

`Criterion` — Criterion to add or remove terms

`'Deviance'` (default) | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'Deviance'` — *p*-value for an *F*-test or chi-squared test of the change in the deviance that results from adding or removing the term. The *F*-test tests a single model, and the chi-squared test compares two different models.
- `'sse'` — *p*-value for an *F*-test of the change in the sum of squared error that results from adding or removing the term.
- `'aic'` — Change in the value of the Akaike information criterion (AIC).
- `'bic'` — Change in the value of the Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of R^2.
- `'adjrsquared'` — Increase in the value of adjusted R^2.

Example: `'Criterion','bic'`

`Lower` — Model specification describing terms that cannot be removed
`'constant'` (default) | character vector or string scalar naming the model | *t*-by-(*p* + 1) terms matrix | character vector or string scalar formula in the form `'Y ~ terms'`

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
`'constant'`	Model contains only a constant (intercept) term.
`'linear'`	Model contains an intercept and linear term for each predictor.
`'interactions'`	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
`'purequadratic'`	Model contains an intercept term and linear and squared terms for each predictor.
`'quadratic'`	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
`'poly`*`ijk`*`'`	Model is a polynomial with all terms up to degree *`i`* in the first predictor, degree *`j`* in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, `'poly13'` has an intercept and x_1, x_2, x_2^2, x_2^3, x_1*x_2, and x_1*x_2^2 terms, where x_1 and x_2 are the first and second predictors, respectively.

- A *t*-by-(*p* + 1) matrix, or a “Terms Matrix” on page 33-5986, specifying terms in the model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.

- A character vector or string scalar “Formula” on page 33-5986 in the form
  `'Y ~ terms'`,
  where the `terms` are in “Wilkinson Notation” on page 33-5986. The variable names in the formula must be valid MATLAB identifiers.

Example: `'Lower','linear'`

Data Types: `char` | `string` | `single` | `double`

`NSteps` — Maximum number of steps to take
1 (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of `'NSteps'` and a positive integer.

Example: `'NSteps',5`

Data Types: `single` | `double`

`PEnter` — Threshold for criterion to add term
scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of `'PEnter'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
`'Deviance'`	0.05	If the *p*-value of the *F*-statistic or chi-squared statistic is less than `PEnter` (*p*-value to enter), add the term to the model.
`'SSE'`	0.05	If the *p*-value of the *F*-statistic is less than `PEnter`, add the term to the model.
`'AIC'`	0	If the change in the AIC of the model is less than `PEnter`, add the term to the model.
`'BIC'`	0	If the change in the BIC of the model is less than `PEnter`, add the term to the model.
`'Rsquared'`	0.1	If the increase in the R-squared value of the model is greater than `PEnter`, add the term to the model.
`'AdjRsquared'`	0	If the increase in the adjusted R-squared value of the model is greater than `PEnter`, add the term to the model.

For more information, see the `Criterion` name-value pair argument.

Example: `'PEnter',0.075`

`PRemove` — Threshold for criterion to remove term
scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of `'PRemove'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
`'Deviance'`	0.10	If the *p*-value of the *F*-statistic or chi-squared statistic is greater than `PRemove` (*p*-value to remove), remove the term from the model.
`'SSE'`	0.10	If the *p*-value of the *F*-statistic is greater than `PRemove`, remove the term from the model.
`'AIC'`	0.01	If the change in the AIC of the model is greater than `PRemove`, remove the term from the model.
`'BIC'`	0.01	If the change in the BIC of the model is greater than `PRemove`, remove the term from the model.
`'Rsquared'`	0.05	If the increase in the R-squared value of the model is less than `PRemove`, remove the term from the model.
`'AdjRsquared'`	-0.05	If the increase in the adjusted R-squared value of the model is less than `PRemove`, remove the term from the model.

At each step, the `step` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When a term is linearly dependent on other terms in the current model, the `step` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove',0.05`

`Upper` — Model specification describing largest set of terms in fit

`'interactions'` (default) | character vector or string scalar naming the model | *t*-by-(*p* + 1) terms matrix | character vector or string scalar formula in the form `'Y ~ terms'`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
`'constant'`	Model contains only a constant (intercept) term.
`'linear'`	Model contains an intercept and linear term for each predictor.

Value	Model Type
`'interactions'`	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
`'purequadratic'`	Model contains an intercept term and linear and squared terms for each predictor.
`'quadratic'`	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
`'poly`*`ijk`*`'`	Model is a polynomial with all terms up to degree *`i`* in the first predictor, degree *`j`* in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, `'poly13'` has an intercept and x_1, x_2, x_2^2, x_2^3, x_1*x_2, and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A *t*-by-(*p* + 1) matrix, or a “Terms Matrix” on page 33-5986, specifying terms in the model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar “Formula” on page 33-5986 in the form
  `'Y ~ terms'`,
  where the `terms` are in “Wilkinson Notation” on page 33-5986. The variable names in the formula must be valid MATLAB identifiers.

Example: `'Upper','quadratic'`

Data Types: `char` | `string` | `single` | `double`

`Verbose` — Control for display of information
`1` (default) | `0` | `2`

Control for the display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of these values:

- `0` — Suppress all display.
- `1` — Display the action taken at each step.
- `2` — Display the evaluation process and the action taken at each step.

Example: `'Verbose',2`

Output Arguments

`NewMdl` — Generalized linear regression model
`GeneralizedLinearModel` object

Generalized linear regression model, returned as a `GeneralizedLinearModel` object.

To overwrite the input argument `mdl`, assign the new model to `mdl`.

```
mdl = step(mdl);
```

More About

Terms Matrix

A terms matrix `T` is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `x1`, `x2`, and `x3` and the response variable `y` in the order `x1`, `x2`, `x3`, and `y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `x2`; equivalently, `x1^0 * x2^1 * x3^0`
- `[1 0 1 0]` — `x1*x3`
- `[2 0 0 0]` — `x1^2`
- `[0 1 2 0]` — `x2*(x3^2)`

The `0` at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include `0` for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form `'`*`y ~ terms`*`'`.

- *`y`* is the response name.
- *`terms`* represents the predictor terms in a model using Wilkinson notation.

To represent predictor and response variables, use the variable names of the table input `tbl` or the variable names specified by using `VarNames`. The default value of `VarNames` is `{'x1','x2',...,'xn','y'}`.

For example:

- `'y ~ x1 + x2 + x3'` specifies a three-variable linear model with intercept.
- `'y ~ x1 + x2 + x3 − 1'` specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include `−1` in the formula.

A formula includes a constant term unless you explicitly remove the term using `−1`.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.

- – means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
1	Constant (intercept) term
x1^k, where k is a positive integer	x1, $x1^2$, ..., $x1^k$
x1 + x2	x1, x2
x1*x2	x1, x2, x1*x2
x1:x2	x1*x2 only
–x2	Do not include x2
x1*x2 + x3	x1, x2, x3, x1*x2
x1 + x2 + x3 + x1:x2	x1, x2, x3, x1*x2
x1*x2*x3 – x1:x2:x3	x1, x2, x3, x1*x2, x1*x3, x2*x3
x1*(x2 + x3)	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

  The `step` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the `'Criterion'` name-value pair argument.

  The default value of `'Criterion'` for a linear regression model is `'sse'`. In this case, `stepwiselm` and `step` of `LinearModel` use the *p*-value of an *F*-statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

  Stepwise regression takes these steps when `'Criterion'` is `'sse'`:

  1. Fit the initial model.
  2. Examine a set of available terms not in the model. If any of the terms have *p*-values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest *p*-value and repeat this step; otherwise, go to step 3.

3 If any of the available terms in the model have *p*-values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest *p*-value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term `X1:X2^2` unless both `X1` and `X2^2` are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove `X1` or `X2^2` if `X1:X2^2` remains in the model.

The default value of `'Criterion'` for a generalized linear model is `'Deviance'`. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the `'Criterion'` name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `step` treats a categorical predictor as follows:
  - A model with a categorical predictor that has *L* levels (categories) includes *L* – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `step` treats the group of *L* – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with *L* levels consist of the element-wise product of the *L* – 1 indicator variables with the continuous predictor.
  - Interaction terms between two categorical predictors with *L* and *M* levels consist of the (*L* – 1)*(*M* – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
  - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

  Therefore, if `step` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `step` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `step` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `step` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `step` uses each observation in the fit.

Alternative Functionality

- Use `stepwiseglm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `addTerms` or `removeTerms` to add or remove specific terms.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Plots to Understand Predictor Effects and How to Modify a Model” on page 12-21
“Generalized Linear Models” on page 12-9

Introduced in R2012a

step

Improve linear regression model by adding or removing terms

Syntax

```
NewMdl = step(mdl)
NewMdl = step(mdl,Name,Value)
```

Description

`NewMdl = step(mdl)` returns a linear regression model based on `mdl` using stepwise regression to add or remove one predictor.

`NewMdl = step(mdl,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the criterion to use to add or remove terms and the maximum number of steps to take.

Examples

Modify Linear Regression Model Using `step`

Fit a linear regression model and use `step` to improve the model by adding or removing terms. This example also describes how the `step` function treats a categorical predictor.

Load the `carsmall` data set, and create a table using the `Weight`, `Model_Year`, and `MPG` variables.

```
load carsmall
tbl1 = table(MPG,Weight);
tbl1.Year = categorical(Model_Year);
```

Create a linear regression model of `MPG` as a function of `Weight`.

```
mdl1 = fitlm(tbl1,'MPG ~ Weight')
```

```
mdl1 =
Linear regression model:
    MPG ~ 1 + Weight

Estimated Coefficients:
                    Estimate        SE         tStat       pValue

F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`step` creates two indicator variables, `Year_76` and `Year_82`, because `Year` includes three distinct values. `step` does not consider the square terms of indicator variables because the square of an indicator variable is itself.

Because `'Verbose'` is 2, `step` displays the evaluation process:

- `step` computes the *p*-values for adding `Year` or `Weight^2`. The *p*-value for `Year` is less than both the *p*-value for `Weight^2` and the default threshold value of 0.05; therefore, `step` adds `Year` to the model.
- `step` computes the *p*-values for adding `Weight:Year` or `Weight^2`. Because the *p*-value for `Weight^2` is less than the *p*-value for `Weight:Year`, the `step` function adds `Weight^2` to the model.
- After adding the quadratic term, `step` computes the *p*-value for adding `Weight:Year` again, but the *p*-value is greater than the threshold value. Therefore, `step` does not add the term to the model. `step` does not examine adding `Weight^3` because of the upper bound specified by the `'Upper'` name-value pair argument.
- `step` looks for terms to remove. `step` already examined `Weight^2`, so it computes only the *p*-value for removing `Year`. Because the *p*-value is less than the default threshold value of 0.10, `step` does not remove the term.
- Although the maximum allowed number of steps is 5, `step` terminates the process after two steps because the model does not improve by adding or removing a term.

`step` treats the two indicator variables as one predictor variable and adds `Year` in one step. To treat the two indicator variables as two distinct predictor variables, use `dummyvar` to create separate categorical variables.

```
temp_Year = dummyvar(tbl1.Year);
Year_76 = temp_Year(:,2);
Year_82 = temp_Year(:,3);
```

Create a table containing `MPG`, `Weight`, `Year_76`, and `Year_82`.

```
tbl2 = table(MPG,Weight,Year_76,Year_82);
```

Create a linear regression model of `MPG` as a function of `Weight`, and use `step` to improve the model.

```
mdl2 = fitlm(tbl2,'MPG ~ Weight');
NewMdl2 = step(mdl2,'Upper','quadratic','NSteps',5)
```

```
1. Adding Year_82, FStat = 83.1956, pValue = 1.76163e-14
2. Adding Weight:Year_82, FStat = 8.0641, pValue = 0.0055818
3. Adding Year_76, FStat = 8.1284, pValue = 0.0054157

NewMdl2 =
Linear regression model:
    MPG ~ 1 + Year_76 + Weight*Year_82

```

The model `NewMdl2` includes the interaction term `Weight:Year_82` instead of `Weight^2`, the term included in `NewMdl1`.

Input Arguments

`mdl` — Linear regression model

`LinearModel` object

Linear regression model, specified as a `LinearModel` object created using `fitlm` or `stepwiselm`.

You can use `step` only if you create `mdl` by using `fitlm` with the `'RobustOpts'` name-value pair argument set to the default `'off'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Criterion','aic','Upper','quadratic','Verbose',2` instructs `step` to use the Akaike information criterion, include (at most) the quadratic terms in the model, and display the evaluation process and the decision taken at each step.

`Criterion` — Criterion to add or remove terms

`'sse'` (default) | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'sse'` — *p*-value for an *F*-test of the change in the sum of squared error that results from adding or removing the term
- `'aic'` — Change in the value of Akaike information criterion (AIC)
- `'bic'` — Change in the value of Bayesian information criterion (BIC)
- `'rsquared'` — Increase in the value of R^2
- `'adjrsquared'` — Increase in the value of adjusted R^2

Example: `'Criterion','bic'`

`Lower` — Model specification describing terms that cannot be removed

`'constant'` (default) | character vector or string scalar naming the model | *t*-by-(*p* + 1) terms matrix | character vector or string scalar formula in the form `'Y ~ terms'`

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
`'constant'`	Model contains only a constant (intercept) term.
`'linear'`	Model contains an intercept and linear term for each predictor.
`'interactions'`	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
`'purequadratic'`	Model contains an intercept term and linear and squared terms for each predictor.
`'quadratic'`	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.

Value	Model Type
`'poly`*`ijk`*`'`	Model is a polynomial with all terms up to degree *`i`* in the first predictor, degree *`j`* in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, `'poly13'` has an intercept and x_1, x_2, x_2^2, x_2^3, x_1*x_2, and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A *t*-by-(*p* + 1) matrix, or a "Terms Matrix" on page 33-5997, specifying terms in the model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar "Formula" on page 33-5997 in the form
  `'Y ~ terms'`,
  where the `terms` are in "Wilkinson Notation" on page 33-5998. The variable names in the formula must be valid MATLAB identifiers.

Example: `'Lower','linear'`

Data Types: `single` | `double` | `char` | `string`

`NSteps` — Maximum number of steps to take
1 (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of `'NSteps'` and a positive integer.

Example: `'NSteps',5`

Data Types: `single` | `double`

`PEnter` — Threshold for criterion to add term
scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of `'PEnter'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
`'SSE'`	0.05	If the *p*-value of the *F*-statistic is less than `PEnter` (*p*-value to enter), add the term to the model.
`'AIC'`	0	If the change in the AIC of the model is less than `PEnter`, add the term to the model.
`'BIC'`	0	If the change in the BIC of the model is less than `PEnter`, add the term to the model.

Criterion	Default Value	Decision
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter',0.075

PRemove — Threshold for criterion to remove term
scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.10	If the *p*-value of the *F*-statistic is greater than PRemove (*p*-value to remove), remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the step function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the step function removes the redundant term, regardless of the criterion value.

For more information, see the Criterion name-value pair argument.

Example: 'PRemove',0.05

Upper — Model specification describing largest set of terms in fit
`'interactions'` (default) | character vector or string scalar naming the model | *t*-by-(*p* + 1) terms matrix | character vector or string scalar formula in the form `'Y ~ terms'`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
`'constant'`	Model contains only a constant (intercept) term.
`'linear'`	Model contains an intercept and linear term for each predictor.
`'interactions'`	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
`'purequadratic'`	Model contains an intercept term and linear and squared terms for each predictor.
`'quadratic'`	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
`'poly`*`ijk`*`'`	Model is a polynomial with all terms up to degree *`i`* in the first predictor, degree *`j`* in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, `'poly13'` has an intercept and x_1, x_2, x_2^2, x_2^3, x_1*x_2, and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A *t*-by-(*p* + 1) matrix, or a “Terms Matrix” on page 33-5997, specifying terms in the model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar “Formula” on page 33-5997 in the form
  `'Y ~ terms'`,
  where the `terms` are in “Wilkinson Notation” on page 33-5998. The variable names in the formula must be valid MATLAB identifiers.

Example: `'Upper','quadratic'`

Data Types: `single` | `double` | `char` | `string`

Verbose — Control for display of information
`1` (default) | `0` | `2`

Control for the display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of these values:

- `0` — Suppress all display.

- `1` — Display the action taken at each step.
- `2` — Display the evaluation process and the action taken at each step.

Example: `'Verbose',2`

Output Arguments

`NewMdl` — Linear regression model

`LinearModel` object

Linear regression model, returned as a `LinearModel` object

To overwrite the input argument `mdl`, assign the new model to `mdl`.

```
mdl = step(mdl);
```

More About

Terms Matrix

A terms matrix `T` is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `x1`, `x2`, and `x3` and the response variable `y` in the order `x1`, `x2`, `x3`, and `y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `x2`; equivalently, `x1^0 * x2^1 * x3^0`
- `[1 0 1 0]` — `x1*x3`
- `[2 0 0 0]` — `x1^2`
- `[0 1 2 0]` — `x2*(x3^2)`

The `0` at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include `0` for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form `'`*`y ~ terms`*`'`.

- *`y`* is the response name.
- *`terms`* represents the predictor terms in a model using Wilkinson notation.

To represent predictor and response variables, use the variable names of the table input `tbl` or the variable names specified by using `VarNames`. The default value of `VarNames` is `{'x1','x2',...,'xn','y'}`.

For example:

- `'y ~ x1 + x2 + x3'` specifies a three-variable linear model with intercept.

- `'y ~ x1 + x2 + x3 − 1'` specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include −1 in the formula.

A formula includes a constant term unless you explicitly remove the term using −1.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- − means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
1	Constant (intercept) term
x1^k, where k is a positive integer	x1, $x1^2$, ..., $x1^k$
x1 + x2	x1, x2
x1*x2	x1, x2, x1*x2
x1:x2	x1*x2 only
−x2	Do not include x2
x1*x2 + x3	x1, x2, x3, x1*x2
x1 + x2 + x3 + x1:x2	x1, x2, x3, x1*x2
x1*x2*x3 − x1:x2:x3	x1, x2, x3, x1*x2, x1*x3, x2*x3
x1*(x2 + x3)	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

  The `step` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the `'Criterion'` name-value pair argument.

  The default value of `'Criterion'` for a linear regression model is `'sse'`. In this case, `stepwiselm` and `step` of `LinearModel` use the *p*-value of an *F*-statistic to test models with and

without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when `'Criterion'` is `'sse'`:

1. Fit the initial model.
2. Examine a set of available terms not in the model. If any of the terms have *p*-values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest *p*-value and repeat this step; otherwise, go to step 3.
3. If any of the available terms in the model have *p*-values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest *p*-value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term `X1:X2^2` unless both `X1` and `X2^2` are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove `X1` or `X2^2` if `X1:X2^2` remains in the model.

The default value of `'Criterion'` for a generalized linear model is `'Deviance'`. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the `'Criterion'` name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `step` treats a categorical predictor as follows:
  - A model with a categorical predictor that has *L* levels (categories) includes *L* – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `step` treats the group of *L* – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.

- Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the L – 1 indicator variables with the continuous predictor.
- Interaction terms between two categorical predictors with L and M levels consist of the (L – 1)*(M – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `step` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `step` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

Alternative Functionality

- Use `stepwiselm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `addTerms` or `removeTerms` to add or remove specific terms.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- This function supports model objects fitted with GPU array input arguments.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2012a

stepwise

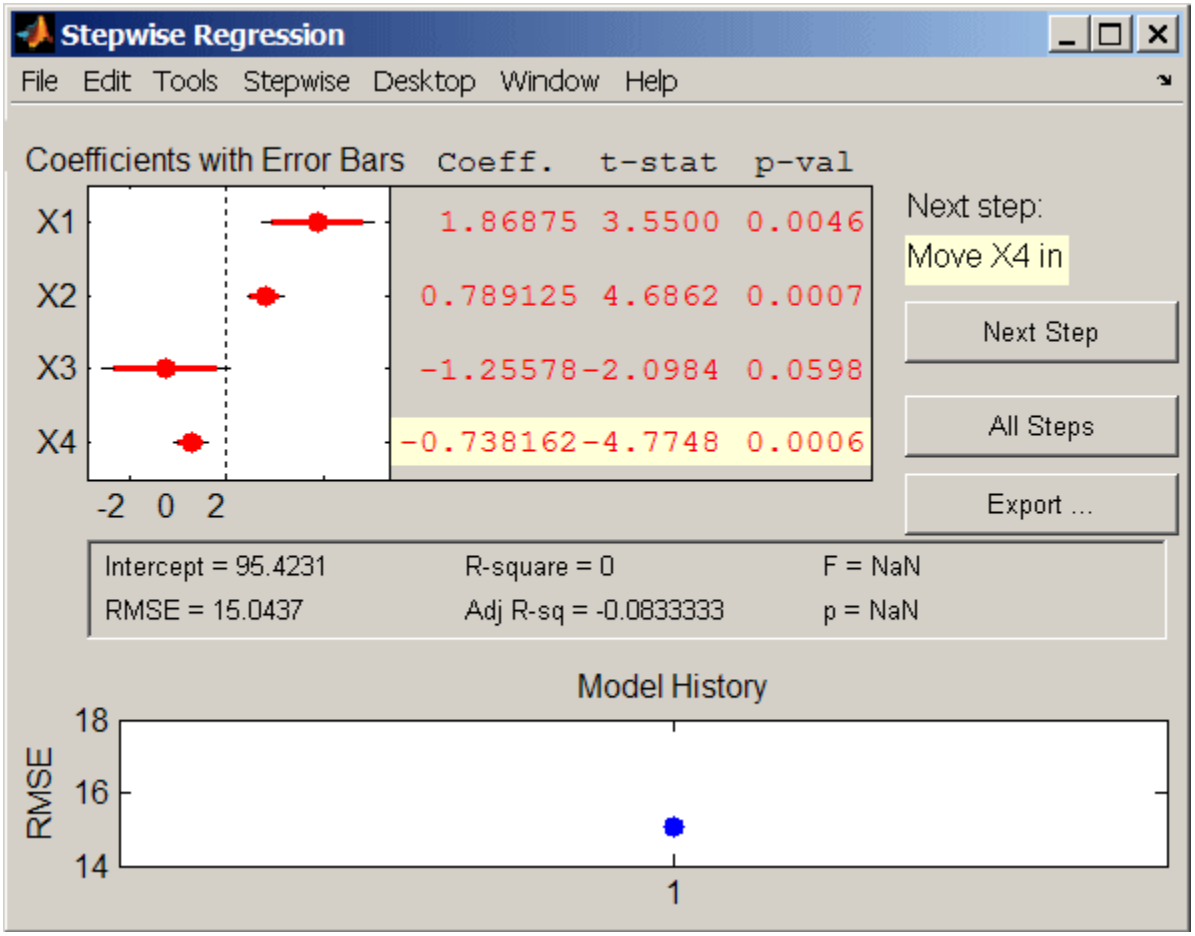
Interactive stepwise regression

Syntax

```
stepwise
stepwise(X,y)
stepwise(X,y,inmodel,penter,premove)
```

Description

`stepwise` uses the sample data in `hald.mat` to display a graphical user interface for performing stepwise regression of the response values in `heat` on the predictive terms in `ingredients`.



The upper left of the interface displays estimates of the coefficients for all potential terms, with horizontal bars indicating 90% (colored) and 95% (grey) confidence intervals. The red color indicates that, initially, the terms are not in the model. Values displayed in the table are those that would result if the terms were added to the model.

The middle portion of the interface displays summary statistics for the entire model. These statistics are updated with each step.

The lower portion of the interface, **Model History**, displays the RMSE for the model. The plot tracks the RMSE from step to step, so you can compare the optimality of different models. Hover over the blue dots in the history to see which terms were in the model at a particular step. Click on a blue dot in the history to open a copy of the interface initialized with the terms in the model at that step.

Initial models, as well as entrance/exit tolerances for the *p*-values of *F*-statistics, are specified using additional input arguments to `stepwise`. Defaults are an initial model with no terms, an entrance tolerance of 0.05, and an exit tolerance of 0.10.

To center and scale the input data (compute *z*-scores) to improve conditioning of the underlying least-squares problem, select `Scale Inputs` from the **Stepwise** menu.

You proceed through a stepwise regression in one of two ways:

1. Click **Next Step** to select the recommended next step. The recommended next step either adds the most significant term or removes the least significant term. When the regression reaches a local minimum of RMSE, the recommended next step is "Move no terms." You can perform all of the recommended steps at once by clicking **All Steps**.
2. Click a line in the plot or in the table to toggle the state of the corresponding term. Clicking a red line, corresponding to a term not currently in the model, adds the term to the model and changes the line to blue. Clicking a blue line, corresponding to a term currently in the model, removes the term from the model and changes the line to red.

To call `addedvarplot` and produce an added variable plot from the `stepwise` interface, select **Added Variable Plot** from the **Stepwise** menu. A list of terms is displayed. Select the term you want to add, and then click **OK**.

Click **Export** to display a dialog box that allows you to select information from the interface to save to the MATLAB workspace. Check the information you want to export and, optionally, change the names of the workspace variables to be created. Click **OK** to export the information.

`stepwise(X,y)` displays the interface using the *p* predictive terms in the *n*-by-*p* matrix `X` and the response values in the *n*-by-1 vector `y`. Distinct predictive terms should appear in different columns of `X`.

Note `stepwise` automatically includes a constant term in all models. Do not enter a column of 1s directly into `X`.

`stepwise` treats `NaN` values in either `X` or `y` as missing values, and ignores them.

`stepwise(X,y,inmodel,penter,premove)` additionally specifies the initial model (`inmodel`) and the entrance (`penter`) and exit (`premove`) tolerances for the *p*-values of *F*-statistics. `inmodel` is either a logical vector with length equal to the number of columns of `X`, or a vector of indices, with values ranging from 1 to the number of columns in `X`. The value of `penter` must be less than or equal to the value of `premove`.

Algorithms

Stepwise regression is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and

then compares the explanatory power of incrementally larger and smaller models. At each step, the *p* value of an *F*-statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

1. Fit the initial model.
2. If any terms not in the model have *p*-values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest *p* value and repeat this step; otherwise, go to step 3.
3. If any terms in the model have *p*-values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest *p* value and go to step 2; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

Introduced before R2006a

stepwiseglm

Create generalized linear regression model by stepwise regression

Syntax

```
mdl = stepwiseglm(tbl)
mdl = stepwiseglm(X,y)
mdl = stepwiseglm(___,modelspec)
mdl = stepwiseglm(___,modelspec,Name,Value)
```

Description

`mdl = stepwiseglm(tbl)` creates a generalized linear model of a table or dataset array `tbl` using stepwise regression to add or remove predictors, starting from a constant model. `stepwiseglm` uses the last variable of `tbl` as the response variable. `stepwiseglm` uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add the model to or remove from the model, based on the value of the `'Criterion'` argument.

`mdl = stepwiseglm(X,y)` creates a generalized linear model of the responses `y` to a data matrix `X`.

`mdl = stepwiseglm(___,modelspec)` specifies the starting model `modelspec` using any of the input argument combinations in previous syntaxes.

`mdl = stepwiseglm(___,modelspec,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion that `stepwiseglm` uses to add or remove terms.

Examples

Generalized Linear Model Using Stepwise Algorithm

Create response data using just three of 20 predictors, and create a generalized linear model using stepwise algorithm to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl =  stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')
```

```
1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

mdl =
Generalized linear regression model:
    log(y) ~ 1 + x5 + x10 + x15
    Distribution = Poisson

Estimated Coefficients:
                   Estimate       SE       tStat       pValue
                   ________    ________    ______    __________

    (Intercept)     1.0115     0.064275    15.737    8.4217e-56
    x5             0.39508     0.066665    5.9263    3.0977e-09
    x10            0.18863      0.05534    3.4085     0.0006532
    x15            0.29295     0.053269    5.4995    3.8089e-08

100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

The starting model is the constant model. `stepwiseglm` by default uses deviance of the model as the criterion. It first adds `x5` into the model, as the *p*-value for the test statistic, deviance (the differences in the deviances of the two models), is less than the default threshold value 0.05. Then, it adds `x15` because given `x5` is in the model, when `x15` is added, the *p*-value for chi-squared test is smaller than 0.05. It then adds `x10` because given `x5` and `x15` are in the model, when `x10` is added, the *p*-value for the chi-square test statistic is again less than 0.05.

Input Arguments

`tbl` — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if `'Distribution'` is `'binomial'`.

- By default, `stepwiseglm` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

X — Predictor variables
matrix

Predictor variables, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

y — Response variable
vector | matrix

Response variable, specified as a vector or matrix.

- If `'Distribution'` is not `'binomial'`, then `y` must be an *n*-by-1 vector, where *n* is the number of observations. Each entry in `y` is the response for the corresponding row of `X`. The data type must be single or double.
- If `'Distribution'` is `'binomial'`, then `y` can be an *n*-by-1 vector or *n*-by-2 matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `logical` | `categorical`

`modelspec` — Starting model
`'constant'` (default) | character vector or string scalar naming the model | *t*-by-(*p* + 1) terms matrix | character vector or string scalar formula in the form `'y ~ terms'`

Starting model for `stepwiseglm`, specified as one of the following:

- A character vector or string scalar naming the model.

Value	Model Type
`'constant'`	Model contains only a constant (intercept) term.
`'linear'`	Model contains an intercept and linear term for each predictor.
`'interactions'`	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
`'purequadratic'`	Model contains an intercept term and linear and squared terms for each predictor.

Value	Model Type
`'quadratic'`	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
`'poly`*`ijk`*`'`	Model is a polynomial with all terms up to degree *`i`* in the first predictor, degree *`j`* in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, `'poly13'` has an intercept and x_1, x_2, x_2^2, x_2^3, x_1*x_2, and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A *t*-by-(*p* + 1) matrix, or a "Terms Matrix" on page 33-6014, specifying terms in the model, where *t* is the number of terms and *p* is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar "Formula" on page 33-6015 in the form
  `'y ~ terms'`,
  where the `terms` are in "Wilkinson Notation" on page 33-6015. The variable names in the formula must be variable names in `tbl` or variable names specified by `Varnames`. Also, the variable names must be valid MATLAB identifiers.

  The software determines the order of terms in a fitted model by using the order of terms in `tbl` or `X`. Therefore, the order of terms in the model can be different from the order of terms in the specified formula.

If you want to specify the smallest or largest set of terms in the model that `stepwiselm` fits, use the `Lower` and `Upper` name-value pair arguments.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Criterion','aic','Distribution','poisson','Upper','interactions'` specifies Akaike Information Criterion as the criterion to add or remove variables to the model, Poisson distribution as the distribution of the response variable, and a model with all possible interactions as the largest model to consider as the fit.

`BinomialSize` — Number of trials for binomial distribution

1 (default) | numeric scalar | numeric vector | character vector | string scalar

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of `'BinomialSize'` and the variable name in `tbl`, a numeric scalar, or a numeric vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column matrix with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double` | `char` | `string`

`CategoricalVars` — Categorical variable list
string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `stepwiseglm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the second and third variables out of six as categorical using either of the following:

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

`Criterion` — Criterion to add or remove terms
`'Deviance'` (default) | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'Deviance'` — *p*-value for an *F*-test or chi-squared test of the change in the deviance that results from adding or removing the term. The *F*-test tests a single model, and the chi-squared test compares two different models.
- `'sse'` — *p*-value for an *F*-test of the change in the sum of squared error that results from adding or removing the term.
- `'aic'` — Change in the value of the Akaike information criterion (AIC).
- `'bic'` — Change in the value of the Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of R^2.
- `'adjrsquared'` — Increase in the value of adjusted R^2.

Example: `'Criterion','bic'`

`DispersionFlag` — Indicator to compute dispersion parameter
`false` for `'binomial'` and `'poisson'` distributions (default) | `true`

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

`true`	Estimate a dispersion parameter when computing standard errors. The estimated dispersion parameter value is the sum of squared Pearson residuals divided by the degrees of freedom for error (DFE).
`false`	Default. Use the theoretical value of 1 when computing standard errors.

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag',true`

`Distribution` — Distribution of the response variable
`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

`'normal'`	Normal distribution
`'binomial'`	Binomial distribution
`'poisson'`	Poisson distribution
`'gamma'`	Gamma distribution
`'inverse gaussian'`	Inverse Gaussian distribution

Example: `'Distribution','gamma'`

`Exclude` — Observations to exclude
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

`Intercept` — Indicator for constant term
`true` (default) | `false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept',false`

`Link` — Link function
canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of `'Link'` and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
`'identity'`	$f(\mu) = \mu$	$\mu = Xb$
`'log'`	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
`'logit'`	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
`'probit'`	$f(\mu) = \Phi^{-1}(\mu)$, where Φ is the cumulative distribution function of the standard normal distribution.	$\mu = \Phi(Xb)$
`'comploglog'`	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
`'reciprocal'`	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
`p` (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
`S` (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: • `S.Link` — The link function • `S.Inverse` — The inverse link function • `S.Derivative` — The derivative of the link function	$f(\mu) =$ `S.Link`(μ)	$\mu =$ `S.Inverse`(Xb)

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see “Canonical Function” on page 33-6016.

Example: `'Link','probit'`

Data Types: `char` | `string` | `single` | `double` | `struct`

`Lower` — Model specification describing terms that cannot be removed from model
`'constant'` (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of the options for `modelspec` naming the model.

Example: `'Lower','linear'`

`NSteps` — Maximum number of steps to take
no limit (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of `'NSteps'` and a positive integer.

Example: `'NSteps',5`

Data Types: `single` | `double`

`Offset` — Offset variable

[ ] (default) | numeric vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of `'Offset'` and the variable name in `tbl` or a numeric vector with the same length as the response.

`stepwiseglm` uses `Offset` as an additional predictor with a coefficient value fixed at 1. In other words, the formula for fitting is

$f(\mu) = \texttt{Offset} + X*b$,

where f is the link function, μ is the mean response, and $X*b$ is the linear combination of predictors X. The `Offset` predictor has coefficient `1`.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char` | `string`

`PEnter` — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of `'PEnter'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
`'Deviance'`	0.05	If the *p*-value of the *F*-statistic or chi-squared statistic is less than `PEnter` (*p*-value to enter), add the term to the model.
`'SSE'`	0.05	If the *p*-value of the *F*-statistic is less than `PEnter`, add the term to the model.
`'AIC'`	0	If the change in the AIC of the model is less than `PEnter`, add the term to the model.
`'BIC'`	0	If the change in the BIC of the model is less than `PEnter`, add the term to the model.
`'Rsquared'`	0.1	If the increase in the R-squared value of the model is greater than `PEnter`, add the term to the model.
`'AdjRsquared'`	0	If the increase in the adjusted R-squared value of the model is greater than `PEnter`, add the term to the model.

For more information, see the `Criterion` name-value pair argument.

Example: `'PEnter',0.075`

`PredictorVars` — Predictor variables
string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

`PRemove` — Threshold for criterion to remove term
scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of `'PRemove'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
`'Deviance'`	0.10	If the *p*-value of the *F*-statistic or chi-squared statistic is greater than `PRemove` (*p*-value to remove), remove the term from the model.
`'SSE'`	0.10	If the *p*-value of the *F*-statistic is greater than `PRemove`, remove the term from the model.
`'AIC'`	0.01	If the change in the AIC of the model is greater than `PRemove`, remove the term from the model.
`'BIC'`	0.01	If the change in the BIC of the model is greater than `PRemove`, remove the term from the model.
`'Rsquared'`	0.05	If the increase in the R-squared value of the model is less than `PRemove`, remove the term from the model.

Criterion	Default Value	Decision
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `stepwiseglm` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When a term is linearly dependent on other terms in the current model, the `stepwiseglm` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove',0.05`

`ResponseVar` — Response variable
last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

`Upper` — Model specification describing largest set of terms in fit
`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the options for `modelspec` naming the model.

Example: `'Upper','quadratic'`

`VarNames` — Names of variables
`{'x1','x2',...,'xn','y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiseglm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

Before specifying `'VarNames',varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string` | `cell`

`Verbose` — Control for display of information
`1` (default) | `0` | `2`

Control for the display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of these values:

- `0` — Suppress all display.
- `1` — Display the action taken at each step.
- `2` — Display the evaluation process and the action taken at each step.

Example: `'Verbose',2`

`Weights` — Observation weights
`ones(n,1)` (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: `single` | `double`

Output Arguments

`mdl` — Generalized linear regression model
`GeneralizedLinearModel` object

Generalized linear regression model, specified as a `GeneralizedLinearModel` object created using `fitglm` or `stepwiseglm`.

More About

Terms Matrix

A terms matrix `T` is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `x1`, `x2`, and `x3` and the response variable `y` in the order `x1`, `x2`, `x3`, and `y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `x2`; equivalently, `x1^0 * x2^1 * x3^0`
- `[1 0 1 0]` — `x1*x3`
- `[2 0 0 0]` — `x1^2`
- `[0 1 2 0]` — `x2*(x3^2)`

The `0` at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include `0` for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form `'y ~ terms'`.

- *y* is the response name.
- *terms* represents the predictor terms in a model using Wilkinson notation.

To represent predictor and response variables, use the variable names of the table input `tbl` or the variable names specified by using `VarNames`. The default value of `VarNames` is `{'x1','x2',...,'xn','y'}`.

For example:

- `'y ~ x1 + x2 + x3'` specifies a three-variable linear model with intercept.
- `'y ~ x1 + x2 + x3 − 1'` specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include `−1` in the formula.

A formula includes a constant term unless you explicitly remove the term using `−1`.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- `+` means include the next variable.
- `−` means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- `*` defines an interaction and all lower-order terms.
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
`1`	Constant (intercept) term
`x1^k`, where `k` is a positive integer	$x1$, $x1^2$, ..., $x1^k$

Wilkinson Notation	Terms in Standard Notation
`x1 + x2`	x1, x2
`x1*x2`	x1, x2, x1*x2
`x1:x2`	x1*x2 only
`-x2`	Do not include x2
`x1*x2 + x3`	x1, x2, x3, x1*x2
`x1 + x2 + x3 + x1:x2`	x1, x2, x3, x1*x2
`x1*x2*x3 - x1:x2:x3`	x1, x2, x3, x1*x2, x1*x3, x2*x3
`x1*(x2 + x3)`	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Canonical Function

The default link function for a generalized linear model is the canonical link function.

Distribution	Canonical Link Function Name	Link Function	Mean (Inverse) Function
`'normal'`	`'identity'`	$f(\mu) = \mu$	$\mu = Xb$
`'binomial'`	`'logit'`	$f(\mu) = \log(\mu/(1 - \mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
`'poisson'`	`'log'`	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
`'gamma'`	`-1`	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
`'inverse gaussian'`	`-2`	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

  The `stepwiseglm` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the `'Criterion'` name-value pair argument.

The default value of `'Criterion'` for a linear regression model is `'sse'`. In this case, `stepwiselm` and `step` of `LinearModel` use the *p*-value of an *F*-statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when `'Criterion'` is `'sse'`:

1. Fit the initial model.
2. Examine a set of available terms not in the model. If any of the terms have *p*-values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest *p*-value and repeat this step; otherwise, go to step 3.
3. If any of the available terms in the model have *p*-values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest *p*-value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term `X1:X2^2` unless both `X1` and `X2^2` are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove `X1` or `X2^2` if `X1:X2^2` remains in the model.

The default value of `'Criterion'` for a generalized linear model is `'Deviance'`. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the `'Criterion'` name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `stepwiseglm` treats a categorical predictor as follows:
  - A model with a categorical predictor that has *L* levels (categories) includes *L* – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `stepwiseglm` treats the group of *L* – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.

- Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the L – 1 indicator variables with the continuous predictor.
- Interaction terms between two categorical predictors with L and M levels consist of the (L – 1)*(M – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `stepwiseglm` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `stepwiseglm` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `stepwiseglm` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `stepwiseglm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `stepwiseglm` uses each observation in the fit.

Alternatives

- Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

Introduced in R2013b

stepwiselm

Perform stepwise regression

Syntax

```
mdl = stepwiselm(tbl)
mdl = stepwiselm(X,y)
mdl = stepwiselm(___,modelspec)
mdl = stepwiselm(___,Name,Value)
```

Description

`mdl = stepwiselm(tbl)` creates a linear model for the variables in the table or dataset array `tbl` using stepwise regression to add or remove predictors, starting from a constant model. `stepwiselm` uses the last variable of `tbl` as the response variable. `stepwiselm` uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add the model to or remove from the model, based on the value of the `'Criterion'` argument.

`mdl = stepwiselm(X,y)` creates a linear model of the responses `y` to the predictor variables in the data matrix `X`.

`mdl = stepwiselm(___,modelspec)` specifies the starting model `modelspec` using any of the input argument combinations in previous syntaxes.

`mdl = stepwiselm(___,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion that `stepwiselm` uses to add or remove terms.

Examples

Fit Linear Model Using Stepwise Regression

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a stepwise linear regression model to the data. Specify 0.06 as the threshold for the criterion to add a term to the model.

```
 mdl = stepwiselm(ingredients,heat,'PEnter',0.06)
```

```
1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054
```

```
mdl =
Linear regression model:
    y ~ 1 + x1 + x2

Estimated Coefficients:
                   Estimate       SE       tStat       pValue
                   ________    ________    ______    __________

    (Intercept)     52.577       2.2862    22.998    5.4566e-10
    x1              1.4683       0.1213    12.105    2.6922e-07
    x2             0.66225     0.045855    14.442     5.029e-08

Number of observations: 13, Error degrees of freedom: 10
Root Mean Squared Error: 2.41
R-squared: 0.979,  Adjusted R-Squared: 0.974
F-statistic vs. constant model: 230, p-value = 4.41e-09
```

By default, the starting model is a constant model. `stepwiselm` performs forward selection and adds the `x4`, `x1`, and `x2` terms (in that order), because the corresponding *p*-values are less than the `PEnter` value of 0.06. `stepwiselm` then uses backward elimination and removes `x4` from the model because, once `x2` is in the model, the *p*-value of `x4` is greater than the default value of `PRemove`, 0.1.

Stepwise Regression Using Specified Model Formula and Variables

Perform stepwise regression using variables stored in a dataset array. Specify the starting model using Wilkinson notation, and identify the response and predictor variables using optional arguments.

Load the sample data.

```
load hospital
```

The hospital dataset array includes the gender, age, weight, and smoking status of patients.

Fit a linear model with a starting model of a constant term and `Smoker` as the predictor variable. Specify the response variable, `Weight`, and categorical predictor variables, `Sex`, `Age`, and `Smoker`.

```
mdl = stepwiselm(hospital,'Weight~1+Smoker',...
'ResponseVar','Weight','PredictorVars',{'Sex','Age','Smoker'},...
'CategoricalVar',{'Sex','Smoker'})
```

```
1. Adding Sex, FStat = 770.0158, pValue = 6.262758e-48
2. Removing Smoker, FStat = 0.21224, pValue = 0.64605

mdl =
Linear regression model:
    Weight ~ 1 + Sex

Estimated Coefficients:
                   Estimate      SE      tStat       pValue
                   ________    ______    ______    ___________

    (Intercept)     130.47     1.1995    108.77    5.2762e-104
    Sex_Male         50.06     1.7496    28.612     2.2464e-49
```

```
Number of observations: 100, Error degrees of freedom: 98
Root Mean Squared Error: 8.73
R-squared: 0.893,  Adjusted R-Squared: 0.892
F-statistic vs. constant model: 819, p-value = 2.25e-49
```

At each step, `stepwiselm` searches for terms to add and remove. At first step, stepwise algorithm adds `Sex` to the model with a *p*-value of 6.26e-48. Then, removes Smoker from the model, since given `Sex` in the model, the variable `Smoker` becomes redundant. `stepwiselm` only includes `Sex` in the final linear model. The weight of the patients do not seem to differ significantly according to age or the status of smoking.

Stepwise Regression Using Terms Matrix

Load a sample data set and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Define the starting model and the upper model using terms matrices.

```
T_starting = [0 0 0] % a constant model
```

```
T_starting = 1×3

     0     0     0
```

```
T_upper = [0 0 0;1 0 0;0 1 0;1 1 0] % a linear model with interactions
```

```
T_upper = 4×3

     0     0     0
     1     0     0
     0     1     0
     1     1     0
```

Create a linear regression model using stepwise regression. Specify the starting model and the upper bound of the model using the terms matrices, and specify `'Verbose'` as 2 to display the evaluation process and the decision taken at each step.

```
mdl = stepwiselm(X,MPG,T_starting,'upper',T_upper,'Verbose',2)
```

```
   pValue for adding x1 is 4.0973e-06
   pValue for adding x2 is 1.6434e-28
1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
   pValue for adding x1 is 0.18493
   No candidate terms to remove

mdl =
Linear regression model:
    y ~ 1 + x2

Estimated Coefficients:
                   Estimate        SE         tStat       pValue
```

```
                    ___________    _________    _______    __________

    (Intercept)         49.238        1.6411     30.002    2.7015e-49
    x2              -0.0086119     0.0005348    -16.103    1.6434e-28

Number of observations: 94, Error degrees of freedom: 92
Root Mean Squared Error: 4.13
R-squared: 0.738,  Adjusted R-Squared: 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

Stepwise Regression with Categorical Predictor

Fit a linear regression model with a categorical predictor using stepwise regression. `stepwiselm` adds or removes a group of indicator variables in one step to add or removes a categorical predictor. This example also shows how to create indicator variables manually and pass them to `stepwiselm` so that `stepwiselm` treats each indicator variable as a separate predictor.

Load the `carsmall` data set, and create a table using the `Weight`, `Model_Year`, and `MPG` variables.

```
load carsmall
Year = categorical(Model_Year);
tbl1 = table(MPG,Weight,Year);
```

Fit a linear regression model of `MPG` using stepwise regression. Specify the starting model as a function of `Weight`. Set the upper bound of the model to `'poly21'`, meaning the model can include (at most) a constant and the terms `Weight`, `Weight^2`, `Year`, and `Weight*Year`. Specify `'Verbose'` as 2 to display the evaluation process and the decision taken at each step.

```
mdl1 = stepwiselm(tbl1,'MPG ~ Weight','Upper','poly21','Verbose',2)
```

```
   pValue for adding Year is 8.2284e-15
   pValue for adding Weight^2 is 0.15454
1. Adding Year, FStat = 47.5136, pValue = 8.22836e-15
   pValue for adding Weight^2 is 0.0022303
   pValue for adding Weight:Year is 0.0071637
2. Adding Weight^2, FStat = 9.9164, pValue = 0.0022303
   pValue for adding Weight:Year is 0.19519
   pValue for removing Year is 2.9042e-16

mdl1 =
Linear regression model:
    MPG ~ 1 + Weight + Year + Weight^2

Estimated Coefficients:
                    Estimate         SE         tStat       pValue
                    ___________    __________    _______    __________

    (Intercept)         54.206        4.7117     11.505    2.6648e-19
    Weight           -0.016404     0.0031249    -5.2493    1.0283e-06
    Year_76             2.0887       0.71491     2.9215     0.0044137
    Year_82             8.1864       0.81531     10.041    2.6364e-16
    Weight^2        1.5573e-06    4.9454e-07      3.149     0.0022303
```

```
Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885,  Adjusted R-Squared: 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`stepwiselm` creates two indicator variables, `Year_76` and `Year_82`, because `Year` includes three distinct values.

Because `'Verbose'` is 2, `stepwiselm` displays the evaluation process:

- `stepwiselm` creates a model as a function of `Weight`.
- `stepwiselm` computes the *p*-values for adding `Year` or `Weight^2`. The *p*-value for `Year` is less than both the *p*-value for `Weight^2` and the default threshold value of 0.05; therefore, `stepwiselm` adds `Year` to the model.
- `stepwiselm` computes the *p*-values for adding `Weight:Year` or `Weight^2`. Because the *p*-value for `Weight^2` is less than the *p*-value for `Weight:Year`, the `stepwiselm` function adds `Weight^2` to the model.
- After adding the quadratic term, `stepwiselm` computes the *p*-value for adding `Weight:Year` again, but the *p*-value is greater than the threshold value. Therefore, `stepwiselm` does not add the term to the model. `stepwiselm` does not examine adding `Weight^3` because of the upper bound specified by the `'Upper'` name-value pair argument.
- `stepwiselm` looks for terms to remove. `stepwiselm` already examined `Weight^2`, so it computes only the *p*-value for removing `Year`. Because the *p*-value is less than the default threshold value of 0.10, `stepwiselm` does not remove the term.
- Although the maximum allowed number of steps is 5, `stepwiselm` terminates the process after two steps because the model does not improve by adding or removing a term.

`stepwiselm` treats the two indicator variables as one predictor variable and adds `Year` in one step. To treat the two indicator variables as two distinct predictor variables, use `dummyvar` to create separate categorical variables.

```
temp_Year = dummyvar(Year);
Year_76 = logical(temp_Year(:,2));
Year_82 = logical(temp_Year(:,3));
```

Create a table containing `MPG`, `Weight`, `Year_76`, and `Year_82`.

```
tbl2 = table(MPG,Weight,Year_76,Year_82);
```

Create a stepwise linear regression model from the same starting model used for `mdl1`.

```
mdl2 = stepwiselm(tbl2,'MPG ~ Weight','Upper','poly211')
```

```
1. Adding Year_82, FStat = 83.1956, pValue = 1.76163e-14
2. Adding Weight:Year_82, FStat = 8.0641, pValue = 0.0055818
3. Adding Year_76, FStat = 8.1284, pValue = 0.0054157

mdl2 =
Linear regression model:
    MPG ~ 1 + Year_76 + Weight*Year_82

Estimated Coefficients:
                        Estimate         SE         tStat       pValue
                       __________    __________    _______    __________
```

```
    (Intercept)             38.844        1.5294     25.397     1.503e-42
    Weight                -0.006272    0.00042673    -14.698    1.5622e-25
    Year_76_1                2.0395       0.71537      2.851     0.0054157
    Year_82_1                19.607        3.8731     5.0623    2.2163e-06
    Weight:Year_82_1    -0.0046268     0.0014979    -3.0888     0.0026806

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.79
R-squared: 0.885,  Adjusted R-Squared: 0.88
F-statistic vs. constant model: 171, p-value = 6.54e-41
```

The model `mdl2` includes the interaction term `Weight:Year_82_1` instead of `Weight^2`, the term included in `mdl1`.

Input Arguments

`tbl` — Input data

table | dataset array

Input data including predictor and response variables, specified as a table or dataset array. The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

- By default, `stepwiselm` takes the last variable as the response variable and the others as the predictor variables.
- To set a different column as the response variable, use the `ResponseVar` name-value pair argument.
- To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.
- To define a model specification, set the `modelspec` argument using a formula or terms matrix. The formula or terms matrix specifies which columns to use as the predictor or response variables.

The variable names in a table do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot specify `modelspec` using a formula.
- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

You can verify the variable names in `tbl` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

`X` — Predictor variables

matrix

Predictor variables, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X.

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an *n*-by-1 vector, where *n* is the number of observations. Each entry in y is the response for the corresponding row of X.

Data Types: `single` | `double` | `logical`

modelspec — Starting model

`'constant'` (default) | character vector or string scalar naming the model | *t*-by-(*p* + 1) terms matrix | character vector or string scalar formula in the form `'y ~ terms'`

Starting model for the stepwise regression, specified as one of the following:

- A character vector or string scalar naming the model.

Value	Model Type
`'constant'`	Model contains only a constant (intercept) term.
`'linear'`	Model contains an intercept and linear term for each predictor.
`'interactions'`	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
`'purequadratic'`	Model contains an intercept term and linear and squared terms for each predictor.
`'quadratic'`	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
`'poly`*`ijk`*`'`	Model is a polynomial with all terms up to degree *`i`* in the first predictor, degree *`j`* in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 though 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, `'poly13'` has an intercept and x_1, x_2, x_2^2, x_2^3, x_1*x_2, and x_1*x_2^2 terms, where x_1 and x_2 are the first and second predictors, respectively.

- A *t*-by-(*p* + 1) matrix, or a “Terms Matrix” on page 33-6031, specifying terms in the model, where *t* is the number of terms and *p* is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar “Formula” on page 33-6031 in the form
  `'y ~ terms'`,
  where the `terms` are in “Wilkinson Notation” on page 33-6031. The variable names in the formula must be variable names in `tbl` or variable names specified by `Varnames`. Also, the variable names must be valid MATLAB identifiers.

The software determines the order of terms in a fitted model by using the order of terms in `tbl` or `X`. Therefore, the order of terms in the model can be different from the order of terms in the specified formula.

If you want to specify the smallest or largest set of terms in the model that `stepwiselm` fits, use the `Lower` and `Upper` name-value pair arguments.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Criterion','aic','Upper','interactions','Verbose',1` instructs `stepwiselm` to use the Akaike information criterion, display the action it takes at each step, and include at most the interaction terms in the model.

`CategoricalVars` — Categorical variable list
string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `stepwiselm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the second and third variables out of six as categorical using either of the following:

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

`Criterion` — Criterion to add or remove terms
`'sse'` (default) | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'sse'` — *p*-value for an *F*-test of the change in the sum of squared error that results from adding or removing the term
- `'aic'` — Change in the value of Akaike information criterion (AIC)
- `'bic'` — Change in the value of Bayesian information criterion (BIC)
- `'rsquared'` — Increase in the value of R^2
- `'adjrsquared'` — Increase in the value of adjusted R^2

Example: `'Criterion','bic'`

`Exclude` — Observations to exclude
logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

`Intercept` — Indicator for constant term
`true` (default) | `false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept',false`

`Lower` — Model specification describing terms that cannot be removed from model
`'constant'` (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of the options for `modelspec` naming the model.

Example: `'Lower','linear'`

`NSteps` — Maximum number of steps to take
no limit (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of `'NSteps'` and a positive integer.

Example: `'NSteps',5`

Data Types: `single` | `double`

`PEnter` — Threshold for criterion to add term
scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of `'PEnter'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
`'SSE'`	0.05	If the *p*-value of the *F*-statistic is less than `PEnter` (*p*-value to enter), add the term to the model.

Criterion	Default Value	Decision
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter',0.075

PredictorVars — Predictor variables
string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in tbl, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]

Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

PRemove — Threshold for criterion to remove term
scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.10	If the *p*-value of the *F*-statistic is greater than PRemove (*p*-value to remove), remove the term from the model.

Criterion	Default Value	Decision
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `stepwiselm` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `stepwiselm` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove',0.05`

`ResponseVar` — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

`Upper` — Model specification describing largest set of terms in fit

`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the options for `modelspec` naming the model.

Example: `'Upper','quadratic'`

`VarNames` — Names of variables
`{'x1','x2',...,'xn','y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

The variable names do not have to be valid MATLAB identifiers. However, if the names are not valid, you cannot use a formula when you fit or adjust a model; for example:

- You cannot use a formula to specify the terms to add or remove when you use the `addTerms` function or the `removeTerms` function, respectively.
- You cannot use a formula to specify the lower and upper bounds of the model when you use the `step` or `stepwiselm` function with the name-value pair arguments `'Lower'` and `'Upper'`, respectively.

Before specifying `'VarNames',varNames`, you can verify the variable names in `varNames` by using the `isvarname` function. If the variable names are not valid, then you can convert them by using the `matlab.lang.makeValidName` function.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string` | `cell`

`Verbose` — Control for display of information
`1` (default) | `0` | `2`

Control for the display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of these values:

- `0` — Suppress all display.
- `1` — Display the action taken at each step.
- `2` — Display the evaluation process and the action taken at each step.

Example: `'Verbose',2`

`Weights` — Observation weights
`ones(n,1)` (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: `single` | `double`

Output Arguments

`mdl` — Linear model
`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

For the properties and methods of the linear model object, `mdl`, see the `LinearModel` class page.

More About

Terms Matrix

A terms matrix `T` is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. The value of `T(i,j)` is the exponent of variable `j` in term `i`.

For example, suppose that an input includes three predictor variables `x1`, `x2`, and `x3` and the response variable `y` in the order `x1`, `x2`, `x3`, and `y`. Each row of `T` represents one term:

- `[0 0 0 0]` — Constant term or intercept
- `[0 1 0 0]` — `x2`; equivalently, `x1^0 * x2^1 * x3^0`
- `[1 0 1 0]` — `x1*x3`
- `[2 0 0 0]` — `x1^2`
- `[0 1 2 0]` — `x2*(x3^2)`

The `0` at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include `0` for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form `'y ~ terms'`.

- *y* is the response name.
- *terms* represents the predictor terms in a model using Wilkinson notation.

To represent predictor and response variables, use the variable names of the table input `tbl` or the variable names specified by using `VarNames`. The default value of `VarNames` is `{'x1','x2',...,'xn','y'}`.

For example:

- `'y ~ x1 + x2 + x3'` specifies a three-variable linear model with intercept.
- `'y ~ x1 + x2 + x3 – 1'` specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include `–1` in the formula.

A formula includes a constant term unless you explicitly remove the term using `–1`.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.

- – means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Terms in Standard Notation
1	Constant (intercept) term
x1^k, where k is a positive integer	x1, $x1^2$, ..., $x1^k$
x1 + x2	x1, x2
x1*x2	x1, x2, x1*x2
x1:x2	x1*x2 only
–x2	Do not include x2
x1*x2 + x3	x1, x2, x3, x1*x2
x1 + x2 + x3 + x1:x2	x1, x2, x3, x1*x2
x1*x2*x3 – x1:x2:x3	x1, x2, x3, x1*x2, x1*x3, x2*x3
x1*(x2 + x3)	x1, x2, x3, x1*x2, x1*x3

For more details, see “Wilkinson Notation” on page 11-91.

Tips

- You cannot use robust regression with stepwise regression. Check your data for outliers before using `stepwiselm`.
- For other methods such as `anova`, or properties of the `LinearModel` object, see `LinearModel`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 32-2.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

  The `stepwiselm` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the `'Criterion'` name-value pair argument.

  The default value of `'Criterion'` for a linear regression model is `'sse'`. In this case, `stepwiselm` and `step` of `LinearModel` use the *p*-value of an *F*-statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to

reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when `'Criterion'` is `'sse'`:

1. Fit the initial model.
2. Examine a set of available terms not in the model. If any of the terms have *p*-values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest *p*-value and repeat this step; otherwise, go to step 3.
3. If any of the available terms in the model have *p*-values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest *p*-value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term `X1:X2^2` unless both `X1` and `X2^2` are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove `X1` or `X2^2` if `X1:X2^2` remains in the model.

The default value of `'Criterion'` for a generalized linear model is `'Deviance'`. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the `'Criterion'` name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `stepwiselm` treats a categorical predictor as follows:
  - A model with a categorical predictor that has *L* levels (categories) includes *L* – 1 indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level. For more details about creating indicator variables, see “Automatic Creation of Dummy Variables” on page 2-49.
  - `stepwiselm` treats the group of *L* – 1 indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor `X`, if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
  - Interaction terms between a continuous predictor and a categorical predictor with *L* levels consist of the element-wise product of the *L* – 1 indicator variables with the continuous predictor.

- Interaction terms between two categorical predictors with L and M levels consist of the (L – 1)*(M – 1) indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `stepwiselm` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `stepwiselm` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `stepwiselm` considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `stepwiselm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `stepwiselm` uses each observation in the fit.

Alternative Functionality

- You can construct a model using `fitlm`, and then manually adjust the model using `step`, `addTerms`, or `removeTerms`.

Introduced in R2013b

stepwisefit

Fit linear regression model using stepwise regression

Syntax

```
b = stepwisefit(X,y)
b = stepwisefit(X,y,Name,Value)
[b,se,pval] = stepwisefit(___)
[b,se,pval,finalmodel,stats] = stepwisefit(___)
[b,se,pval,finalmodel,stats,nextstep,history] = stepwisefit(___)
```

Description

`b = stepwisefit(X,y)` returns a vector `b` of coefficient estimates from stepwise regression of the response vector `y` on the predictor variables in matrix `X`. `stepwisefit` begins with an initial constant model and takes forward or backward steps to add or remove variables, until a stopping criterion is satisfied.

`b = stepwisefit(X,y,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify a nonconstant initial model, or a maximum number of steps that `stepwisefit` can take.

`[b,se,pval] = stepwisefit(___)` returns the coefficient estimates `b`, standard errors `se`, and *p*-values `pval` using any of the input argument combinations in previous syntaxes.

`[b,se,pval,finalmodel,stats] = stepwisefit(___)` also returns a specification of the variables in the final regression model `finalmodel`, and statistics `stats` about the final model.

`[b,se,pval,finalmodel,stats,nextstep,history] = stepwisefit(___)` also returns the recommended next step `nextstep` and information `history` about all the steps taken.

Examples

Stepwise Regression with Default Arguments

Perform a basic stepwise regression and obtain the coefficient estimates.

Load the `hald` data set.

```
load hald
whos % Check variables loaded in workspace
```

```
  Name              Size            Bytes  Class     Attributes

  Description      22x58             2552  char
  hald             13x5               520  double
  heat             13x1               104  double
  ingredients      13x4               416  double
```

This data set contains observations of the heat evolved during cement hardening for various mixtures of four cement ingredients. The response variable is `heat`. The matrix `ingredients` contains four columns of predictors.

Run `stepwisefit` beginning with only a constant term in the model and using the default entry and exit tolerances of 0.05 and 0.10, respectively.

```
b = stepwisefit(ingredients,heat)
```

```
Initial columns included: none
Step 1, added column 4, p=0.000576232
Step 2, added column 1, p=1.10528e-06
Final columns included:  1 4
    {'Coeff'  }    {'Std.Err.'}    {'Status'}    {'P'         }
    {[ 1.4400]}    {[  0.1384]}    {'In'    }    {[1.1053e-06]}
    {[ 0.4161]}    {[  0.1856]}    {'Out'   }    {[    0.0517]}
    {[-0.4100]}    {[  0.1992]}    {'Out'   }    {[    0.0697]}
    {[-0.6140]}    {[  0.0486]}    {'In'    }    {[1.8149e-07]}

b = 4×1

    1.4400
    0.4161
   -0.4100
   -0.6140
```

The `stepwisefit` display shows that columns 1 and 4 are included in the final model. The output `b` includes estimates for all columns, even those that do not appear in the final model. `stepwisefit` computes the estimate for column 2 (or 3) by fitting a model consisting of the final model plus column 2 (or 3).

Tune the Stepwise Procedure

Load the `carsmall` data set, which contains various car measurements.

```
load carsmall
whos
```

```
  Name               Size            Bytes  Class     Attributes

  Acceleration      100x1               800  double
  Cylinders         100x1               800  double
  Displacement      100x1               800  double
  Horsepower        100x1               800  double
  MPG               100x1               800  double
  Mfg               100x13             2600  char
  Model             100x33             6600  char
  Model_Year        100x1               800  double
  Origin            100x7              1400  char
  Weight            100x1               800  double
```

Perform stepwise regression with four continuous variables and the response variable `MPG`.

```
X = [Acceleration Cylinders Displacement Horsepower];
y = MPG;
b4_default = stepwisefit(X,y) % Stepwise regression with default arguments
```

```
Initial columns included: none
Step 1, added column 2, p=1.59001e-25
Step 2, added column 4, p=0.00364266
Step 3, added column 1, p=0.0161414
Final columns included:  1 2 4
    {'Coeff'  }    {'Std.Err.'}    {'Status'}    {'P'         }
    {[-0.4517]}    {[  0.1842]}    {'In'    }    {[    0.0161]}
    {[-2.6407]}    {[  0.4823]}    {'In'    }    {[4.0003e-07]}
    {[ 0.0148]}    {[  0.0157]}    {'Out'   }    {[    0.3472]}
    {[-0.0772]}    {[  0.0204]}    {'In'    }    {[2.6922e-04]}

b4_default = 4×1

   -0.4517
   -2.6407
    0.0148
   -0.0772
```

The term `Displacement` never enters the model. Determine if it is highly correlated with the other three terms by computing the term correlation matrix.

```
corrcoef(X,'Rows','complete') % To exclude rows with missing values from calculation
```

```
ans = 4×4

    1.0000   -0.6438   -0.6968   -0.6968
   -0.6438    1.0000    0.9517    0.8622
   -0.6968    0.9517    1.0000    0.9134
   -0.6968    0.8622    0.9134    1.0000
```

The third row of the correlation matrix corresponds to `Displacement`. This term is highly correlated with the other three terms, especially `Cylinders` (`0.95`) and `Horsepower` (`0.91`).

Redefine the input matrix `X` to include `Weight`. Specify an initial model containing the terms `Displacement` and `Horsepower` by using the `'InModel'` name-value pair argument.

```
X = [Acceleration Cylinders Displacement Horsepower Weight];
inmodel = [false false true true false];
b5_inmodel = stepwisefit(X,y,'InModel',inmodel)
```

```
Initial columns included: 3 4
Step 1, added column 5, p=1.06457e-06
Step 2, added column 2, p=0.00410234
Final columns included:  2 3 4 5
    {'Coeff'  }    {'Std.Err.'}    {'Status'}    {'P'         }
    {[-0.0912]}    {[  0.2032]}    {'Out'   }    {[    0.6548]}

   -0.0449
   -0.0050
```

The final model consists of terms 2–5. However, `Displacement` and `Horsepower` estimates have *p*-values greater than `0.05` in the final model. You can tune the stepwise algorithm to behave more conservatively by using the `'PRemove'` name-value pair argument. For example, setting `'PRemove'` to `0.05` (instead of the default `0.1`) results in a smaller final model with only two terms, each with a *p*-value less than `0.05`.

```
b5_inmodel_premove = stepwisefit(X,y,'InModel',inmodel,'PRemove',0.05)
```

```
Initial columns included: 3 4
Step 1, added column 5, p=1.06457e-06
Step 2, added column 2, p=0.00410234
Step 3, removed column 3, p=0.0862131
Step 4, removed column 4, p=0.239239
Final columns included:  2 5
    {'Coeff'  }    {'Std.Err.'}    {'Status'}    {'P'         }
    {[-0.0115]}    {[  0.1656]}    {'Out'   }    {[    0.9449]}

Usually, you scale to compare estimates of terms that are measured in different scales, such as `Horsepower` and `Weight`. In this case, increasing `Horsepower` by one standard deviation leads to an expected drop of `1` in `MPG`, whereas increasing `Weight` by one standard deviation leads to an expected drop of `4.4` in `MPG`.

Retrieve Detailed Output from Stepwise Regression

Load the `imports-85` data set. This data set contains characteristics of cars imported in 1985. For a list of all column names, see the variable `Description` in the workspace or type `Description` at the command line.

```
load imports-85
whos
```

```
  Name               Size            Bytes  Class     Attributes

  Description        9x79             1422  char
  X                205x26            42640  double
```

Choose a subset of continuous variables to use in stepwise regression, consisting of the predictor variables `engine-size`, `bore`, `stroke`, `compression-ratio`, `horsepower`, `peak-rpm`, `city-mpg`, and `highway-mpg`, and the response variable `price`.

```
varnames = ["engine-size","bore","stroke","compression-ratio","horsepower","peak-rpm","city-mpg"
dataTbl = array2table(X(:,8:16),'VariableNames',varnames); % Create data table with variable name
Xstepw = dataTbl{:,{'engine-size','bore','stroke','compression-ratio','horsepower','peak-rpm','ci
ystepw = dataTbl{:,{'price'}}; % Response vector
```

Run `stepwisefit` of the variable `price` on the other eight variables, first with the default constant initial model and then with an initial model including `highway-mpg`. Omit the display of step information.

```
[betahat_def,se_def,pval_def,finalmodel_def,stats_def] = stepwisefit(Xstepw,ystepw,'Display',"of
inmodel = [false false false false false false false true];
[betahat_in,se_in,pval_in,finalmodel_in,stats_in] = stepwisefit(Xstepw,ystepw,'InModel',inmodel,
```

Inspect the final models returned by `stepwisefit`.

```
finalmodel_def
```

```
finalmodel_def = 1x8 logical array

   1   0   1   1   0   1   1   0
```

```

    0.0024
   -0.2414
    0.0793
```

```
stats_def.intercept % Intercept estimate
```

```
ans = -7.3506e+03
```

Retrieve the history of the default run of `stepwisefit` and the recommended next step. Omit the display of step information.

```
[~,~,~,~,~,nextstep_def,history_def]=stepwisefit(Xstepw,ystepw,'Display',"off");
nextstep_def
```

```
nextstep_def = 0
```

No further steps are recommended (`nextstep_def` is `0`).

```
history_def.('in')
```

```
ans = 7x8 logical array

   1   0   0   0   0   0   0   0
   1   0   0   0   1   0   0   0
   1   0   0   1   1   0   0   0
   1   0   1   1   1   0   0   0
   1   0   1   1   1   1   0   0
   1   0   1   1   1   1   1   0
   1   0   1   1   0   1   1   0
```

The algorithm performs a total of seven steps. The output shows that `engine-size` (term `1`) is added in step `1`, `horsepower` (term `5`) is added in step `2`, and so on.

Input Arguments

`X` — Predictor variables

numeric matrix

Predictor variables, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

`stepwisefit` always includes a constant term in the model. Therefore, do not include a column of 1s in `X`.

Data Types: `single` | `double`

`y` — Response variable

numeric or logical vector

Response variable, specified as an *n*-by-1 numeric or logical vector, where *n* is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double` | `logical`

Note `stepwisefit` treats `NaN` values in either `X` or `y` as missing and ignores all rows containing these values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'PEnter',0.10,'PRemove',0.15,'MaxIter',8` instructs `stepwisefit` to use entry and exit tolerances of `0.10` and `0.15`, respectively, and to take a maximum of 8 steps.

`InModel` — Terms for initial model

logical vector

Terms for the initial model, specified as the comma-separated pair consisting of `'InModel'` and a logical vector specifying terms to include in the initial model. The default is to include no terms.

Example: `'InModel',[true false false true]`

Data Types: `logical`

`PEnter` — Tolerance for adding terms to model

`0.05` (default) | positive scalar

Tolerance for adding terms to the model, specified as the comma-separated pair consisting of `'PEnter'` and a positive scalar specifying the maximum *p*-value for a term to be added. The default is 0.05.

Example: 'PEnter',0.10

Data Types: single | double

PRemove — Tolerance for removing terms from model
maximum of PEnter and 0.10 (default) | positive scalar

Tolerance for removing terms from the model, specified as the comma-separated pair consisting of 'PRemove' and a positive scalar specifying the minimum *p*-value for a term to be removed. The default is the maximum of PEnter and 0.10.

Note PRemove is not allowed to be smaller than PEnter because that would cause stepwisefit to enter an infinite loop, where a variable is repeatedly added to the model and removed from the model.

Example: 'PRemove',0.15

Data Types: single | double

Display — Indicator for displaying step information
'on' (default) | 'off'

Indicator for displaying step information, specified as the comma-separated pair consisting of 'Display' and 'on' or 'off'.

- 'on' displays information about each step in the Command Window (default).
- 'off' omits the display.

Example: 'Display','off'

MaxIter — Maximum number of steps
Inf (default) | positive integer

Maximum number of steps, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer or Inf (default). Inf allows the algorithm to run until no single step improves the model.

Example: 'MaxIter',12

Data Types: double

Keep — Terms to keep in their initial state
logical vector

Terms to keep in their initial state, specified as the comma-separated pair consisting of 'Keep' and a logical vector. The value true for a term specified to be in (or out of) the initial model forces that term to remain in (or out of) the final model. The value false for a term does not force that term to remain in (or out of) the final model. The default is to specify no terms to keep in their initial state.

Example: 'Keep',[true true false false]

Data Types: logical

Scale — Indicator for centering and scaling terms
'off' (default) | 'on'

Indicator for centering and scaling terms, specified as the comma-separated pair consisting of `'Scale'` and `'off'` or `'on'`.

- `'off'` does not center and scale the terms (default).
- `'on'` centers and scales each column of `X` (computes the *z*-scores) before fitting.

Example: `'Scale','on'`

Output Arguments

b — Estimated coefficients

numeric vector

Estimated coefficients, returned as a numeric vector corresponding to the terms in `X`. The `stepwisefit` function calculates the values in `b` as follows:

- If a term is included in the final model, then its corresponding value in `b` is the estimate resulting from fitting the final model.
- If a term is excluded from the final model, then its corresponding value in `b` is the estimate resulting from fitting the final model plus that term.

Note To obtain a full specification of the fitted model, you also need the estimated intercept in addition to `b`. The estimated intercept is provided as a field in the output argument `stats`. For more details see “stepwisefit Fitted Model” on page 33-6045.

se — Standard errors

numeric vector

Standard errors, returned as a numeric vector corresponding to the estimates in `b`.

pval — *p*-values

numeric vector

p-values, returned as a numeric vector that results from testing whether elements of `b` are `0`.

finalmodel — Final model

logical vector

Final model, returned as a logical vector with length equal to the number of columns in `X`, indicating which terms are in the final model.

stats — Additional statistics

structure

Additional statistics, returned as a structure with the following fields. All statistics pertain to the final model except where noted.

Field	Description
`source`	Character vector `'stepwisefit'`
`dfe`	Degrees of freedom for error

Field	Description
df0	Degrees of freedom for the regression
SStotal	Total sum of squares of the response
SSresid	Sum of squares of the residuals
fstat	*F*-statistic for testing the final model vs. no model (mean only)
pval	*p*-value of the *F*-statistic
rmse	Root mean squared error
xr	Residuals for terms not in the final model, computed by subtracting from each term the predicted response of the final model
yr	Residuals for the response using predictors in the final model
B	Coefficients for terms in the final model, with the value for each term not in the model set to the value that would be obtained by adding that term to the model
SE	Standard errors for coefficient estimates
TSTAT	*t* statistics for coefficient estimates
PVAL	*p*-values for coefficient estimates
intercept	Estimated intercept
wasnan	Rows in the data that contain NaN values

nextstep — Recommended next step
nonnegative integer

Recommended next step, returned as a nonnegative integer equal to the index of the next term to add to or remove from the model, or 0 if no further steps are recommended.

history — Information on steps taken
structure

Information on steps taken, returned as a structure with the following fields.

Field	Description
B	Matrix of regression coefficients, where each column is one step and each row is one coefficient vector
rmse	Root mean squared errors for the model at each step
df0	Degrees of freedom for the regression at each step
in	Logical array indicating which predictors are in the model at each step, where each row is one step and each column is one predictor

More About

`stepwisefit` Fitted Model

The final `stepwisefit` fitted model is

$$\hat{y} = \text{stats.intercept} + X(:,\text{finalmodel}) * b(\text{finalmodel}).$$

Here,

- $\hat{y}$ is the predicted mean response.
- `stats.intercept` is the estimated intercept.
- X`(:,finalmodel)` is the input matrix for the terms in the final model.
- `b(finalmodel)` is the vector of coefficient estimates for the terms in the final model.

Algorithms

Stepwise regression is a method for adding terms to and removing terms from a multilinear model based on their statistical significance. This method begins with an initial model and then takes successive steps to modify the model by adding or removing terms. At each step, the *p*-value of an *F*-statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

1. Fit the initial model.
2. If any terms not in the model have *p*-values less than an entry tolerance, add the one with the smallest *p*-value and repeat this step. For example, assume the initial model is the default constant model and the entry tolerance is the default `0.05`. The algorithm first fits all models consisting of the constant plus another term and identifies the term that has the smallest *p*-value, for example term `4`. If the term `4` *p*-value is less than `0.05`, then term `4` is added to the model. Next, the algorithm performs a search among all models consisting of the constant, term `4`, and another term. If a term not in the model has a *p*-value less than `0.05`, the term with the smallest *p*-value is added to the model and the process is repeated. When no further terms exist that can be added to the model, the algorithm proceeds to step 3.
3. If any terms in the model have *p*-values greater than an exit tolerance, remove the one with the largest *p*-value and go to step 2; otherwise, end.

In each step of the algorithm, `stepwisefit` uses the method of least squares to estimate the model coefficients. After adding a term to the model at an earlier stage, the algorithm might subsequently drop that term if it is no longer helpful in combination with other terms added later. The method terminates when no single step improves the model. However, the final model is not guaranteed to be optimal, which means having the best fit to the data. A different initial model or a different sequence of steps might lead to a better fit. In this sense, stepwise models are locally optimal, but are not necessarily globally optimal.

Alternative Functionality

- You can create a model using `fitlm`, and then manually adjust the model using `step`, `addTerms`, and `removeTerms`.
- Use `stepwiselm` if you have data in a table, you have a mix of continuous and categorical predictors, or you want to specify model formulas that can potentially include higher-order and interaction terms.
- Use `stepwiseglm` to create stepwise generalized linear models (for example, if you have a binary response variable and want to fit a classification model).

Introduced before R2006a

subsasgn

Class: `dataset`

(Not Recommended) Subscripted assignment to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

`A = subsasgn(A,S,B)` is called for the syntax `A(i,j)=B`, `A{i,j}=B`, or `A.var=B` when `A` is a dataset array. `S` is a structure array with the fields:

`type`	`'()'`, `'{}'`, or `'.'` specifying the subscript type.
`subs`	Cell array or character vector containing the actual subscripts.

`A(i,j) = B` assigns the contents of the dataset array `B` to a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

The assignment does not use observation names, variable names, or any other properties of `B` to modify properties of `A`; however properties of `A` are extended with default values if the assignment expands the number of observations or variables in `A`. Elements of `B` are assigned into `A` by position, not by matching names.

`A{i,j} = B` assigns the value `B` into an element of the dataset array `A`. `i` and `J` are positive integers, or logical vectors. Cell indexing cannot assign into multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `B` is cast to the type of the target variable if necessary. If the dataset element already exists, `A{i,j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, assignments such as `A{1,'CellVar'} = B` assign into the contents of the target dataset element in the same way that `{}`-indexing of an ordinary cell array does.

For dataset variables that are `n`-D arrays, i.e., each observation is a matrix or array, an assignment such as `A{1,'ArrayVar'} = B` assigns into the second and following dimensions of the target dataset element, i.e., the assignment adds a leading singleton dimension to `B` to account for the observation dimension of the dataset variable.

`A.var = B or A.(varname) = B` assigns `B` to a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. If the dataset variable already exists, the

assignment completely replaces that variable. To assign into an element of the variable, `A.var` or `A.(varname)` may be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames,...) = B` and `A.var{obsnames,...} = B` (when supported by `var`) provide assignment into a dataset variable using observation names.

`A.properties.propertyname = P` assigns to a dataset property. `propertyname` is one of the following:

- `'ObsNames'`
- `'VarNames'`
- `'Description'`
- `'Units'`
- `'DimNames'`
- `'UserData'`
- `'VarDescription'`

To assign into an element of the property, `A.properties.propertyname` may also be followed by further subscripting as supported by the property.

You cannot assign multiple values into dataset variables or properties using assignments such as `[A.CellVar{1:2}] = B`, `[A.StructVar(1:2).field] = B`, or `[A.Properties.ObsNames{1:2}] = B`. Use multiple assignments of the form `A.CellVar{1} = B` instead.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then the contents of that variable for a single observation consists of multiple cells, and you cannot assign to all of them using the syntax `A{1,'CellVar'} = B`. Use multiple assignments of the form `[A.CellVar{1,1}] = B` instead.

See Also

`dataset` | `set` | `subsref`

subsref

Class: `dataset`

(Not Recommended) Subscripted reference for dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = subsref(A,S)
```

Description

`B = subsref(A,S)` is called for the syntax `A(i,j)`, `A{i,j}`, or `A.var` when `A` is a dataset array. `S` is a structure array with the fields:

`type`	Character vector containing `'()'`, `'{}'`, or `'.'` specifying the subscript type.
`subs`	Cell array or character vector containing the actual subscripts.

`B = A(i,j)` returns a dataset array that contains a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

`B` contains the same property values as `A`, subsetted for observations or variables where appropriate.

`B = A{i,j}` returns an element of a dataset variable. `i` and `j` are positive integers, or logical vectors. Cell indexing cannot return multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `A{i,j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, expressions such as `A{1,'CellVar'}` return the contents of the referenced dataset element in the same way that `{}`-indexing on an ordinary cell array does. If the dataset variable is a single column of cells, the contents of a single cell is returned. If the dataset variable has multiple columns or is `n`-D, multiple outputs containing the contents of multiple cells are returned.

For dataset variables that are `n`-D arrays, i.e., each observation is a matrix or an array, expressions such as `A{1,'ArrayVar'}` return `A.ArrayVar(1,:,...)` with the leading singleton dimension squeezed out.

`B = A.var` or `A.(varname)` returns a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. `A.var` or `A.(varname)` may also be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames,...)` and `A.var{obsnames,...}` (when supported by `var`) provide subscripting into a dataset variable using observation names.

`P = A.Properties.propertyname` returns a dataset property. `propertyname` is one of the following:

- `'ObsNames'`
- `'VarNames'`
- `'Description'`
- `'Units'`
- `'DimNames'`
- `'UserData'`
- `'VarDescription'`

`A.properties.propertyname` may also be followed by further subscripting as supported by the property.

Limitations

Subscripting expressions such as `A.CellVar{1:2}`, `A.StructVar(1:2).field`, or `A.Properties.ObsNames{1:2}` are valid, but result in `subsref` returning multiple outputs in the form of a comma-separated list. If you explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1,cellval2] = A.CellVar{1:2}`, those variables will receive the corresponding values. However, if there are no output arguments, only the first output in the comma-separated list is returned.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then subscripting expressions such as `A{1,'CellVar'}` result in `subsref` returning the contents of multiple cells. You should explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1,cellval2] = A{1,'CellVar'}`.

summary

Class: `dataset`

(Not Recommended) Print summary of dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
summary(A)
s = summary(A)
```

Description

`summary(A)` prints a summary of a dataset array and the variables that it contains.

`s = summary(A)` returns a scalar structure `s` that contains a summary of the dataset `A` and the variables that `A` contains. For more information on the fields in `s`, see Outputs.

Summary information depends on the type of the variables in the data set:

- For numerical variables, `summary` computes a five-number summary of the data, giving the minimum, the first quartile, the median, the third quartile, and the maximum.
- For logical variables, `summary` counts the number of `true`s and `false`s in the data.
- For categorical variables, `summary` counts the number of data at each level.

Output Arguments

The following list describes the fields in the structure `s`:

- `Description` — A character array containing the dataset description.
- `Variables` — A structure array with one element for each dataset variable in A. Each element has the following fields:
  - `Name` — A character vector containing the name of the variable.
  - `Description` — A character vector containing the variable's description.
  - `Units` — A character vector containing the variable's units.
  - `Size` — A numeric vector containing the size of the variable.
  - `Class` — A character vector containing the class of the variable.
  - `Data` — A scalar structure containing the following fields.

    For numeric variables:

    - `Probabilities` — A numeric vector containing the probabilities [0.0 .25 .50 .75 1.0] and NaN (if any are present in the corresponding dataset variable).

- `Quantiles` — A numeric vector containing the values that correspond to 'Probabilities' for the corresponding dataset variable, and a count of NaNs (if any are present).

For logical variables:

- `Values` — The logical vector [true false].
- `Counts` — A numeric vector of counts for each logical value.

For categorical variables:

- `Levels` — A cell array containing the labels for each level of the corresponding dataset variable.
- `Counts` — A numeric vector of counts for each level.

`'Data'` is empty if variable is not numeric, categorical, or logical. If a dataset variable has more than one column, then the corresponding `'Quantiles'` or `'Counts'` field is a matrix or an array.

Examples

Summarize Fisher's iris data:

```
load fisheriris
species = nominal(species);
data = dataset(species,meas);
summary(data)
species: [150x1 nominal]
  setosa   versicolor   virginica
      50           50          50
meas: [150x4 double]
  min       4.3000         2         1    0.1000
  1st Q     5.1000    2.8000    1.6000    0.3000
  median    5.8000         3    4.3500    1.3000
  3rd Q     6.4000    3.3000    5.1000    1.8000
  max       7.9000    4.4000    6.9000    2.5000
```

Summarize the data in `hospital.mat`:

```
load hospital
summary(hospital)

Dataset array created from the data file hospital.dat.

The first column of the file ("id") is used for observation
names.  Other columns ("sex" and "smoke") have been
converted from their original coded values into categorical
and logical variables.  Two sets of columns ("sys" and
"dia", "trial1" through "trial4") have been combined into
single variables with multivariate observations.  Column
headers have been replaced with more descriptive variable
names.  Units have been added where appropriate.

LastName: [100x1 cell array of character vectors]
Sex: [100x1 nominal]
     Female      Male
```

```
         53        47

Age: [100x1 double, Units = Yrs]
     min      1st Q      median      3rd Q      max
      25         32          39         44       50

Weight: [100x1 double, Units = Lbs]
     min      1st Q         median        3rd Q        max
     111      130.5000      142.5000      180.5000     202

Smoker: [100x1 logical]
     true      false
       34         66

BloodPressure: [100x2 double, Units = mm Hg]
Systolic/Diastolic
     min              109           68
     1st Q       117.5000      77.5000
     median           122      81.5000
     3rd Q       127.5000           89
     max              138           99

Trials: [100x1 cell, Units = Counts]
From zero to four measurement trials performed
```

struct2dataset

(Not Recommended) Convert structure array to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = struct2dataset(S)
ds = struct2dataset(S,Name,Value)
```

Description

`ds = struct2dataset(S)` converts a structure array to a dataset array.

`ds = struct2dataset(S,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Scalar Structure Array to Dataset Array

Convert a scalar structure array to a dataset array using the default options.

Create a structure array to convert.

```
S.Name = {'CLARK';'BROWN';'MARTIN'};
S.Gender = {'M';'F';'M'};
S.SystolicBP = [124;122;130];
S.DiastolicBP = [93;80;92];
S
```

```
S = struct with fields:
           Name: {3x1 cell}
         Gender: {3x1 cell}
     SystolicBP: [3x1 double]
    DiastolicBP: [3x1 double]
```

The scalar structure array has four fields, each with three rows.

Convert the structure array to a dataset array.

```
ds = struct2dataset(S)
```

```
ds =
    Name              Gender       SystolicBP    DiastolicBP
    {'CLARK' }        {'M'}        124           93
    {'BROWN' }        {'F'}        122           80
```

```
    {'MARTIN'}        {'M'}        130           92
```

The structure field names in `S` become the variable names in the output dataset array. The size of `ds` is 3-by-4.

Convert Nonscalar Structure Array to Dataset Array

Convert a nonscalar structure array to a dataset array, using one of the structure fields for observation names.

Create a nonscalar structure array to convert.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;

S
```

```
S=3×1 struct array with fields:
    Name
    Gender
    SystolicBP
    DiastolicBP
```

This is a 3-by-1 structure array with 4 fields.

Convert the structure array to a dataset array, using the `Name` field for observation names.

```
ds = struct2dataset(S,'ReadObsNames','Name')
```

```
ds =
              Gender       SystolicBP    DiastolicBP
    CLARK     {'M'}        124           93
    BROWN     {'F'}        122           80
    MARTIN    {'M'}        130           92
```

The size of `ds` is 3-by-3 because the structure field `Name` is used for observation names, and not as a dataset array variable.

```
ds.Properties.DimNames
```

```
ans = 1x2 cell
    {'Name'}    {'Variables'}
```

```
ds.Properties.ObsNames
```

```
ans = 3x1 cell
    {'CLARK' }
    {'BROWN' }
    {'MARTIN'}
```

Input Arguments

S — Input structure array

structure array

Input structure array to convert to a dataset array, specified as a scalar structure array with *N* fields, each with *M* rows, or a nonscalar *M*-by-1 structure array with *N* fields.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ReadObsNames','myField'` specifies that the structure field, `myField`, contains observation names.

ReadObsNames — Name of structure field containing observation names for dataset array

`false` (default) | character vector | string scalar

Name of structure field containing observation names for the output dataset array, specified as the comma-separated pair consisting of `'ReadObsNames'` and a character vector or string scalar containing a field name from the input structure array, `S`. When you specify a field name, `struct2dataset` uses that field to create observation names, and sets `ds.Properties.DimNames` equal to `{ReadObsNames,'Variables'}`.

For example, to specify that observation names are in the structure field, `Names`, use

Example: `'ReadObsNames','Names'`

By default, or if `ReadObsNames` is equal to `false`, `struct2dataset` does not create observation names unless you specify names using the name-value pair argument `ObsNames`.

ObsNames — Observation names for dataset array

string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of `'ObsNames'` and a string array or cell array of character vectors containing observation names. The names do not need to be valid MATLAB identifiers, but they must be unique.

AsScalar — Indicator for how to treat scalar structure

`false` | `true`

Indicator for how to treat a scalar input structure array, specified as the comma-separated pair consisting of `'AsScalar'` and either `true` or `false`. The default value is `true` if `S` is a scalar structure array, and `false` otherwise.

By default, `struct2dataset` converts a scalar structure array with *N* fields, each with *M* rows, into an *M*-by-*N* dataset array.

If instead you set `AsScalar` equal to `false` for a scalar input structure array, then `struct2dataset` converts `S` to a dataset array with *N* observations.

Output Arguments

`ds` — Output dataset array

dataset array

Output dataset array, returned by default with *M* observations and *N* variables.

- If `S` is a scalar structure array with *N* fields, each with *M* rows, then `ds` is an *M*-by-*N* dataset array.
- If `S` is a nonscalar *M*-by-1 structure array with *N* fields, then `ds` is an *M*-by-*N* dataset array.
- If `S` is a scalar structure array with *N* fields, each with *M* rows, and `AsScalar` is set equal to `false`, then `ds` is a dataset array with *N* observations.

Introduced in R2012b

surfht

Interactive contour plot

Syntax

```
surfht(z)
surfht(x,y,z)
```

Description

`surfht(z)` creates an interactive contour plot of the data in matrix `z`. `surfht` treats the values in `z` as the height above the plane.

`surfht(x,y,z)` creates an interactive contour plot of the data in matrix `z`, using the *x*-axis values contained in `x` and the *y*-axis values contained in `y`.

Examples

Create an Interactive Contour Plot

This example shows how to use `surfht` to create an interactive contour plot.

Create a grid of the (*x*,*y*) domain from (-2,-2) to (2,2) using `meshgrid`.

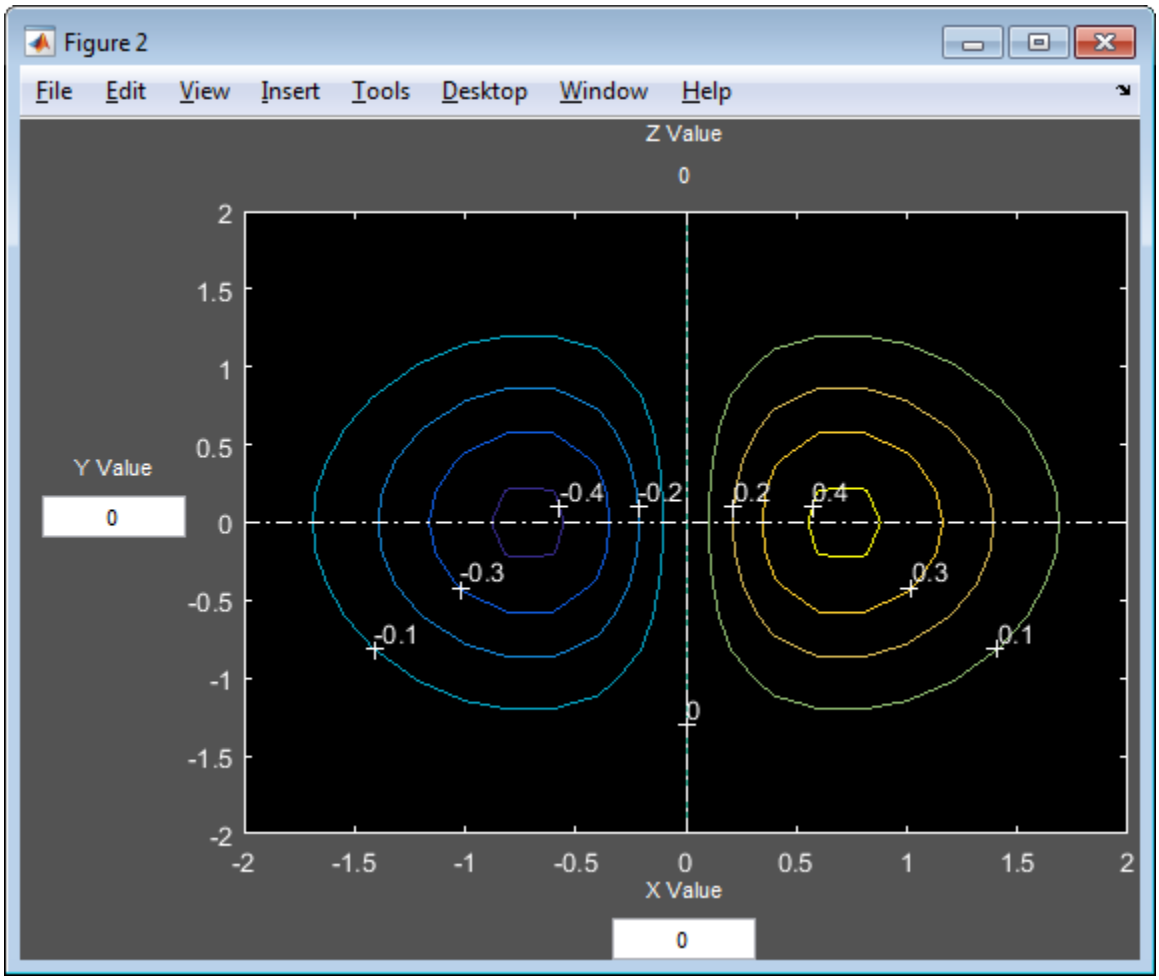
```
[x,y] = meshgrid(-2:0.2:2,-2:0.2:2);
```

Evaluate the function $z(x,y) = x \times \exp(-x^2 - y^2)$ over this domain.

```
z = x.*exp(-x.^2 - y.^2);
```

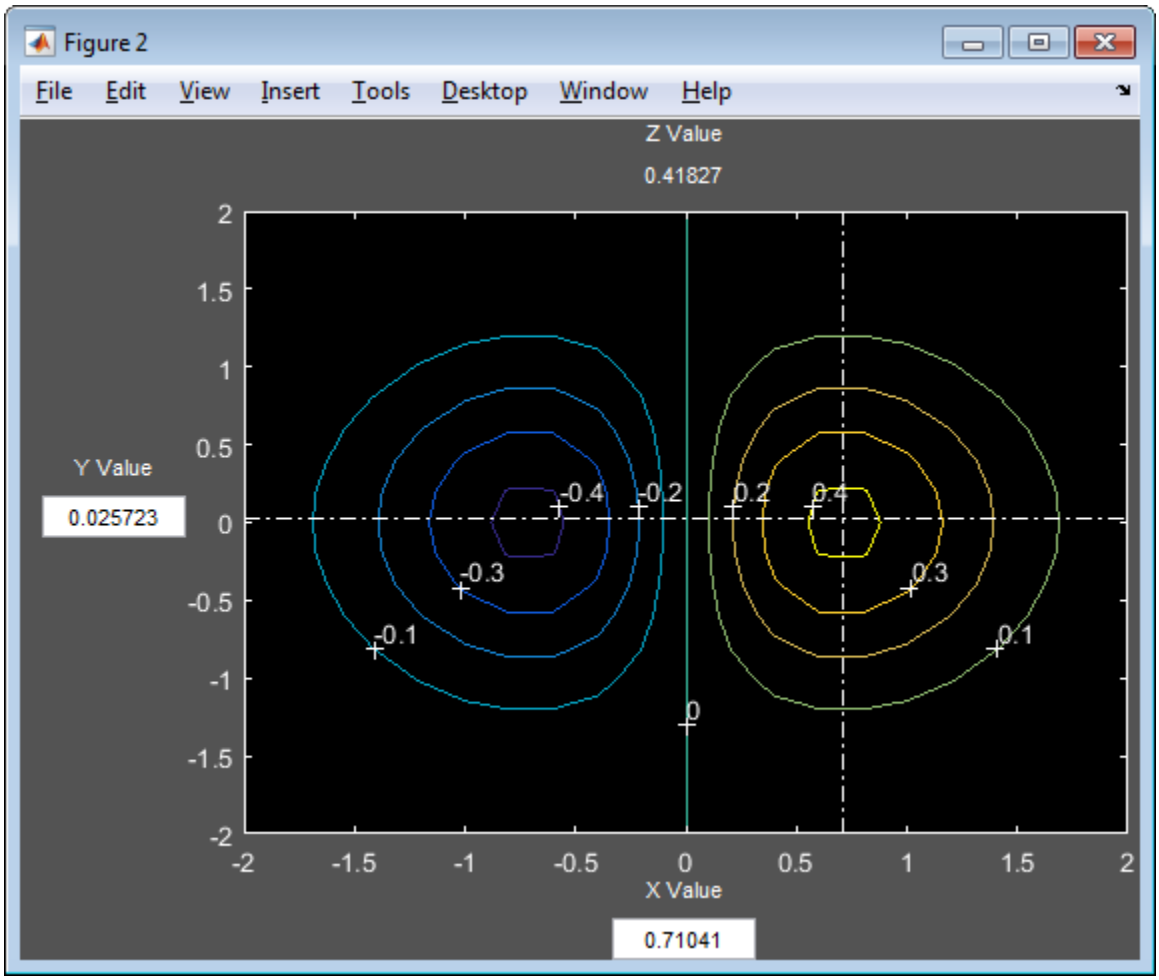
Open an interactive contour plot. Since `meshgrid` creates a grid of the *x* and *y* values, open the plot using the first row of *x* and the first column of *y*.

```
surfht(x(1,:),y(:,1),z)
```



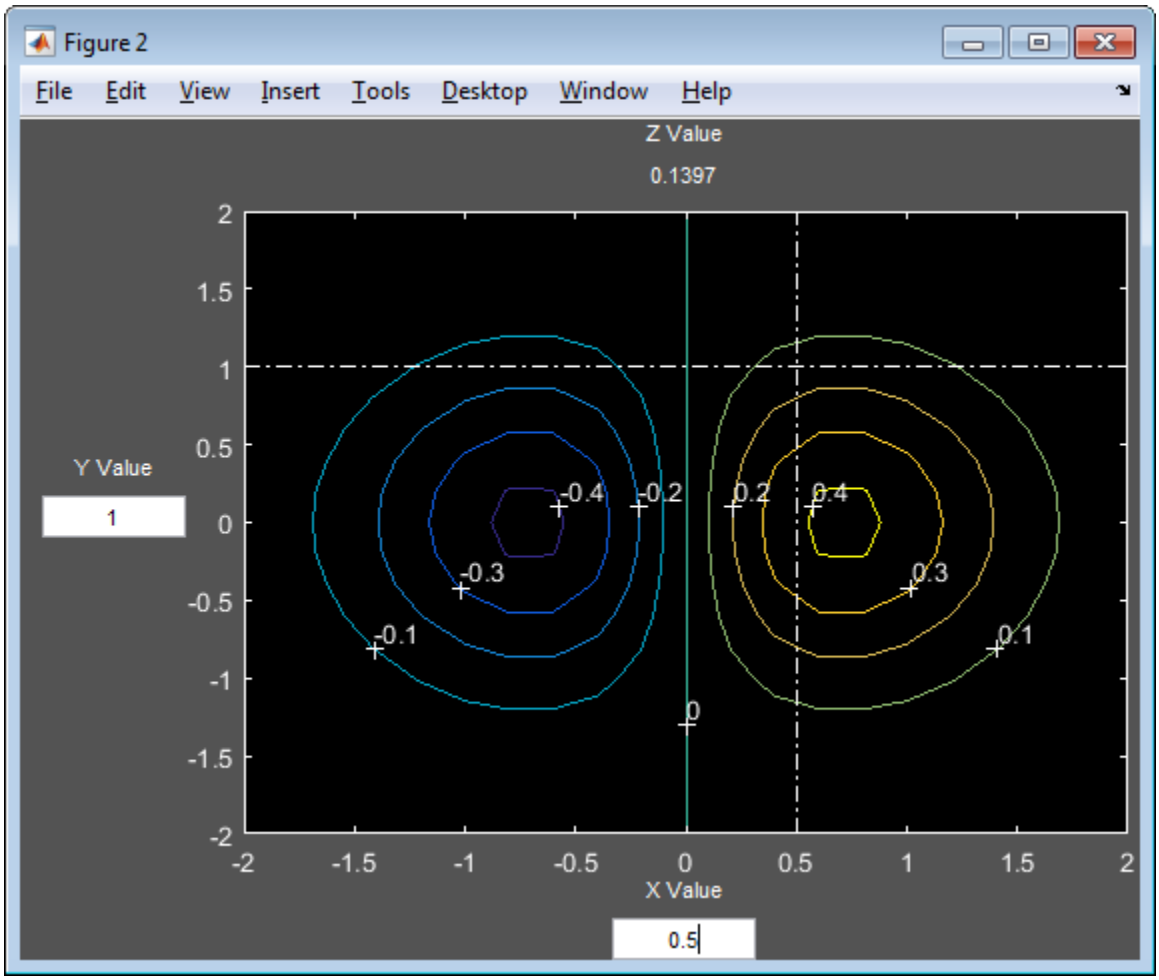
The figure shows a contour plot of the z values along the specified x- and y-axes.

Click the plot to evaluate z at the (x,y) coordinates indicated by the intersecting white lines.



For example, at $x = 0.71041$ and $y = 0.025723$, the value of z is 0.41827.

Alternatively, enter values in the fields labeled `X Value` and `Y Value` to evaluate z at the specified coordinates. For example, evaluate z at $x = 0.5$ and $y = 1$.



The value of *z* is 0.1397.

Input Arguments

z — *z*-axis values for contour plot

numeric matrix

z-axis values for contour plot, specified as a numeric matrix.

`surfht` treats the values in `z` as the height above the plane. By default, the *x*-axis values of the plot are the column indices of `z`, and the *y*-axis values of the plot are the row indices of `z`. To change the *x*- and *y*-axis values, specify `x` and `y`, respectively.

Data Types: `single` | `double`

x — *x*-axis values for contour plot

column indices of `z` (default) | numeric vector

x-axis values for contour plot, specified as a numeric vector. The length of `x` must match the number of columns in `z`.

Data Types: `single` | `double`

y — *y*-axis values for contour plot
row indices of `z` (default) | numeric vector

y-axis values for contour plot, specified as a numeric vector. The length of `y` must match the number of rows in `z`.

Data Types: `single` | `double`

Tips

- The intersection of the vertical and horizontal reference lines on the interactive plot defines the current *x* value and *y* value.
- Drag the dotted white reference lines to watch the interpolated *z* value (at the top of the plot) update simultaneously.
- Alternatively, obtain a specific interpolated *z* value by typing the *x* value and *y* value into editable text fields on the *x*-axis and *y*-axis, respectively.

Introduced before R2006a

survival

Calculate survival of Cox proportional hazards model

Syntax

```
s = survival(coxMdl)
s = survival(coxMdl,X)
s = survival(coxMdl,X,Stratification)
s = survival( ___ ,'Time',T)
[s,Tout] = survival( ___ )
```

Description

`s = survival(coxMdl)` estimates the baseline survival function of a Cox proportional hazards model `coxMdl`. The survival function at time `t` is the estimated probability of survival until time `t`. The term baseline refers to the survival function at the determined baseline of the predictors. This value is stored in `coxMdl.Baseline`, and the default value is the mean of the data set used for training.

`s = survival(coxMdl,X)` estimates the survival function when the predictors have the values in `X`. In this case, `s` is a column for each row of `X`.

`s = survival(coxMdl,X,Stratification)` estimates the survival function for the given value of the stratification variable `Stratification`. You must have one row in `Stratification` for each row in `X`.

Note When you train `coxMdl` using stratification variables and pass predictor variables `X`, `survival` also requires you to pass stratification variables.

`s = survival( ___ ,'Time',T)` computes the survival at times `T` using any of the input argument combinations in the previous syntaxes.

`[s,Tout] = survival( ___ )` also returns the times `Tout` at which each survival estimate is calculated.

Examples

Calculate Survival

Perform a Cox proportional hazards regression on the `lightbulb` data set, which contains simulated lifetimes of light bulbs. The first column of the light bulb data contains the lifetime (in hours) of two different types of bulbs. The second column contains a binary variable indicating whether the bulb is fluorescent or incandescent; 0 indicates the bulb is fluorescent, and 1 indicates it is incandescent. The third column contains the censoring information, where 0 indicates the bulb was observed until failure, and 1 indicates the observation was censored.

Fit a Cox proportional hazards model for the lifetime of the light bulbs, accounting for censoring. The predictor variable is the type of bulb.

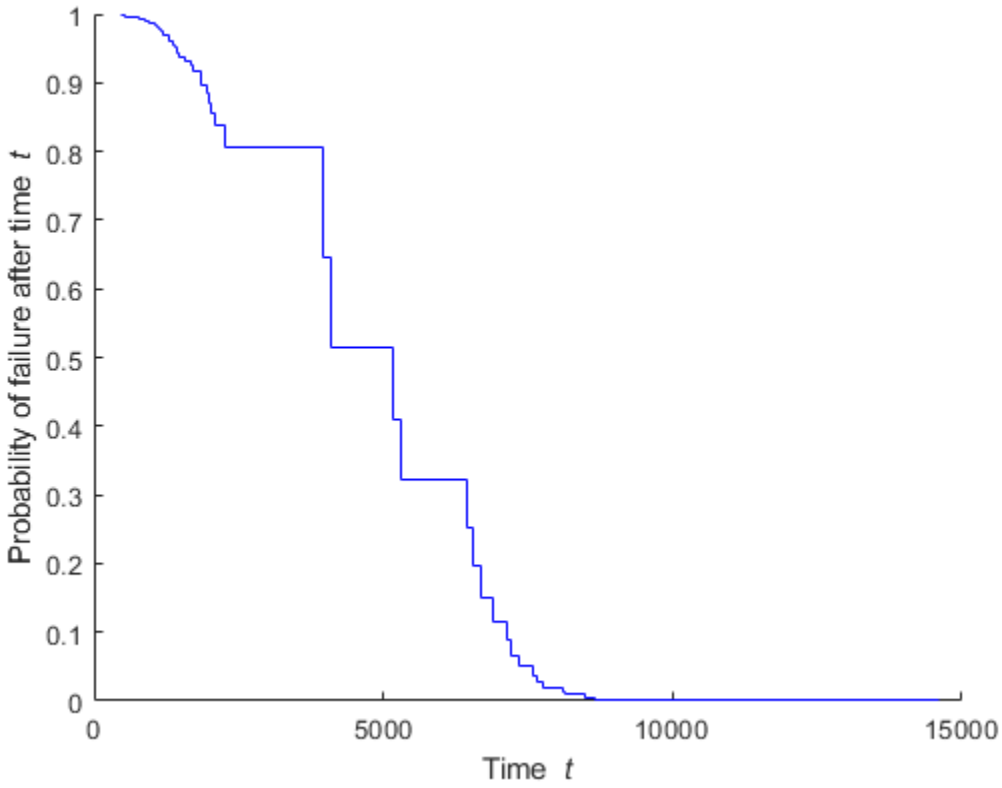
```
load lightbulb
coxMdl = fitcox(lightbulb(:,2),lightbulb(:,1), ...
    'Censoring',lightbulb(:,3));
```

Calculate the baseline survival function as a function of time `t`, meaning the probability that a light bulb fails after time `t`. By default, the baseline is calculated for the mean of the predictor, which in this case is `mean(lightbulb(:,2)) = 0.5`. Return the times `Tout` at which the survival function is calculated.

```
[s,Tout] = survival(coxMdl);
```

Plot the survival as a stairstep graph of time. (The times `Tout` are also in `coxMdl.Hazard(:,1)`.)

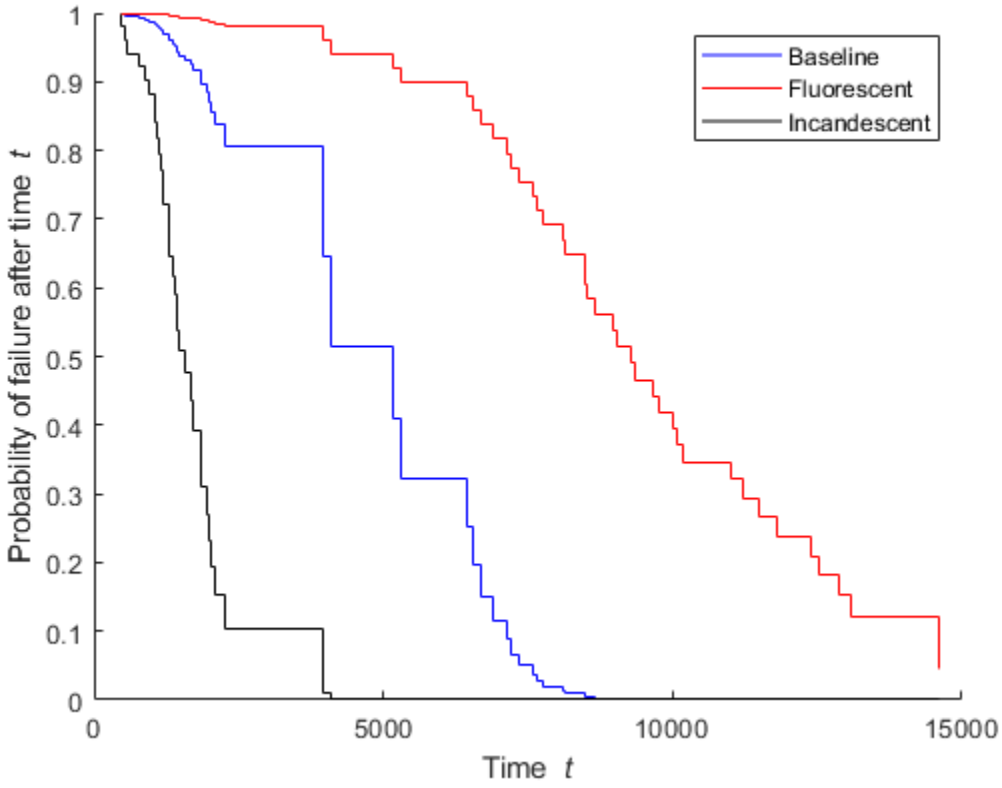
```
hold on;
stairs(Tout,s,'b-')
xlabel 'Time \it t'
ylabel 'Probability of failure after time \it t'
```



Overlay the plot with the survival functions for fluorescent and incandescent bulbs.

```
s_fluorescent = survival(coxMdl,0);
s_incandescent = survival(coxMdl,1);
stairs(Tout,s_fluorescent,'r-')
stairs(Tout,s_incandescent,'k-')
```

```
legend('Baseline','Fluorescent','Incandescent')
hold off
```



To create plots without first creating the survival data, use `plotSurvival`.

Survival for Stratified Model

Load the `coxModel` data. (This simulated data is generated in the example “Cox Proportional Hazards Model Object” on page 14-39.) The model named `coxMdl` has three stratification levels (1, 2, and 3) and a predictor `X` with three categorical values (1, 1/20, and 1/100).

```
load coxModel
```

Calculate the survival function for `X = 1` at the three stratification levels.

```
c1 = categorical(1);
X = [c1;c1;c1];
stratification = [1;2;3];
s = survival(coxMdl,X,stratification);
```

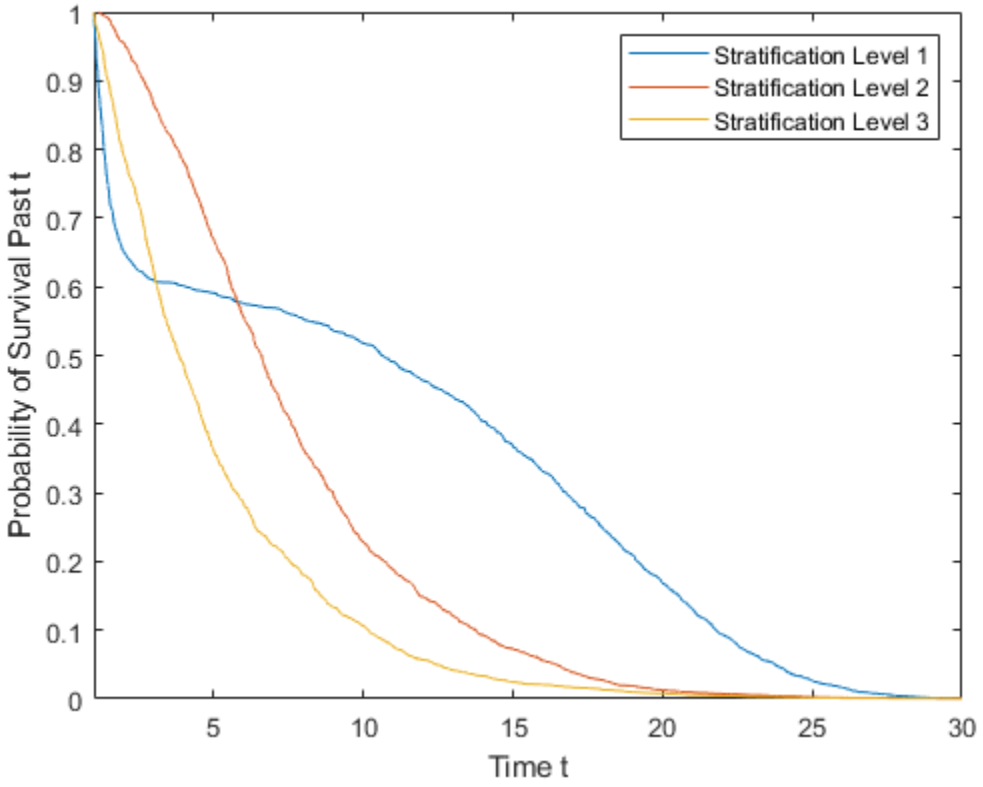
Plot the three survival functions. First, find the times for the three stratification levels.

```
t1 = find(coxMdl.Hazard(:,3) == 1);
t1 = coxMdl.Hazard(t1,1);
t2 = find(coxMdl.Hazard(:,3) == 2);
```

```
t2 = coxMdl.Hazard(t2,1);
t3 = find(coxMdl.Hazard(:,3) == 3);
t3 = coxMdl.Hazard(t3,1);
```

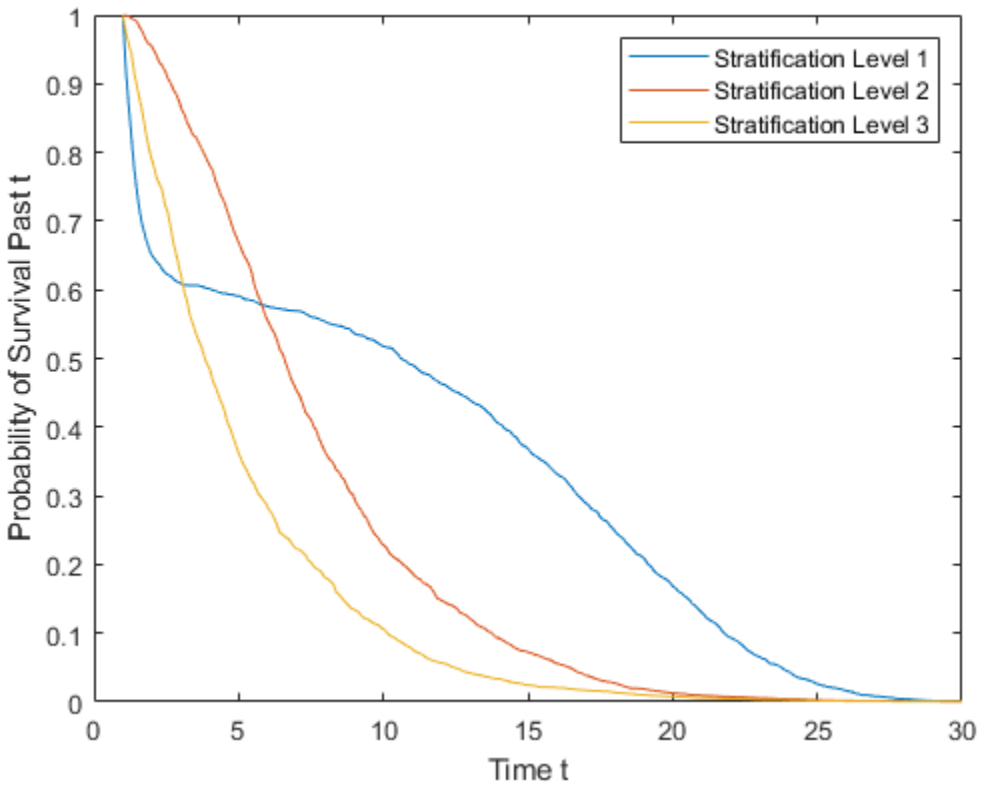
Plot the survival for the three levels. View the plot for times 1 through 30.

```
plot(t1,s{1},t2,s{2},t3,s{3})
xlim([1,30])
legend('Stratification Level 1','Stratification Level 2','Stratification Level 3','Location','no
xlabel('Time t')
ylabel('Probability of Survival Past t')
```



Alternatively, evaluate the survival for times 1 through 30 by specifying the `Time` argument.

```
t = linspace(1,30,300);
st = survival(coxMdl,X,stratification,'Time',t);
figure
plot(t,st{1},t,st{2},t,st{3})
legend('Stratification Level 1','Stratification Level 2','Stratification Level 3','Location','no
xlabel('Time t')
ylabel('Probability of Survival Past t')
```



Input Arguments

`coxMdl` — Fitted Cox proportional hazards model

`CoxModel` object

Fitted Cox proportional hazards model, specified as a `CoxModel` object. Create `coxMdl` using `fitcox`.

`X` — Predictors for model

mean of predictors used for training, but `0` for all categorical predictors (default) | array of predictors of type used for training

Predictors for the model, specified as an array of predictors of the same type used for training `coxMdl`. Each row of `X` represents one set of predictors.

Data Types: `double` | `table` | `categorical`

`Stratification` — Stratification level

variable or variables of type used for training

Stratification level, specified as a variable or variables of the same type used for training `coxMdl`. Specify the same number of rows in `Stratification` as in `X`.

Data Types: `single` | `double` | `logical` | `char` | `string` | `table` | `cell` | `categorical`

T — Times for survival estimates
`coxMdl.Hazard(:,1)` (default) | real vector

Times for survival estimates, specified as a real vector. `survival` sorts the specified times and converts them to a column vector, if necessary. The resulting values are linearly interpolated from times in the training data.

Example: `0:40`

Data Types: `double`

Output Arguments

s — Survival estimates
numeric column vector | cell array of numeric column vectors

Survival estimates, returned as a numeric column vector or a cell array of numeric column vectors.

- For a nonstratified model, `s` is a sorted numeric column vector of estimated probabilities.
- For a stratified model, `s` is a cell array of sorted numeric column vectors of the estimated probabilities for each stratification level.

`survival` returns a column of survival estimates for each row of `X`.

Tout — Times for survival estimates
`mdl.Hazard(:,1)` (default) | numeric column vector | cell array of numeric column vectors

Times for survival estimates, returned as one of the following.

- For a nonstratified model, `Tout` is a sorted numeric column vector of times in the training set.
- For a stratified model, `Tout` is a cell array of sorted numeric column vectors of the training times in the training set for each stratification level.

The `coxMdl.Hazard(:,1)` vector contains the times for both stratified and nonstratified models. For stratified models, the times for different stratification levels are separated by a 0 entry.

Data Types: `double` | `cell`

“Cox Proportional Hazards Model Object” on page 14-39

Introduced in R2021a

table2dataset

(Not Recommended) Convert table to dataset array

Note The `dataset` data type is not recommended. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = table2dataset(t)
```

Description

`ds = table2dataset(t)` converts a table to a dataset array.

Examples

Convert a Table to a Dataset Array

Load the sample data, which contains nutritional information for 77 cereals.

```
load cereal;
```

Create a table containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```
Calories = Calories(1:5);
Protein = Protein(1:5);
Fat = Fat(1:5);
Name = Name(1:5);

cereal = table(Calories,Protein,Fat,'RowNames',Name)
```

```
cereal=5×3 table
                              Calories    Protein    Fat
                              ________    _______    ___

    100% Bran                    70          4        1
    100% Natural Bran           120          3        5
    All-Bran                     70          4        1
    All-Bran with Extra Fiber    50          4        0
    Almond Delight              110          2        2
```

Convert the table to a dataset array.

```
ds = table2dataset(cereal)
```

```
ds =
                              Calories    Protein    Fat
    100% Bran                  70          4         1
```

```
100% Natural Bran            120         3          5
All-Bran                      70         4          1
All-Bran with Extra Fiber     50         4          0
Almond Delight               110         2          2
```

Input Arguments

`t` — Input table

table

Input table to convert to a dataset array, specified as a table. Each variable in `t` becomes a variable in the output dataset array `ds`.

Data Types: `table`

Output Arguments

`ds` — Output dataset array

dataset array

Output dataset array, returned as a dataset array containing the variables from the input table `t`.

“Dataset Arrays” on page 2-112
“Tables”

Introduced in R2013b

tabulate

Frequency table

Syntax

```
tabulate(x)
tbl = tabulate(x)
```

Description

`tabulate(x)` displays a frequency table of the data in the vector `x`. For each unique value in `x`, the `tabulate` function shows the number of instances and percentage of that value in `x`. See `tbl`.

`tbl = tabulate(x)` returns the frequency table `tbl` as a numeric matrix when `x` is numeric and as a cell array otherwise.

Examples

Tabulate Data Vector

Create a frequency table for a vector of data.

Load the `patients` data set. Display the first five entries of the `Gender` variable. Each value indicates the gender of a patient.

```
load patients
Gender(1:5)
```

```
ans = 5x1 cell
    {'Male'  }
    {'Male'  }
    {'Female'}
    {'Female'}
    {'Female'}
```

Generate a frequency table that shows the number and percentage of `Male` and `Female` patients in the data set.

```
tabulate(Gender)
```

```
   Value    Count   Percent
    Male       47     47.00%
  Female       53     53.00%
```

Tabulate Positive Integer Vector

Create a frequency table for a vector of positive integers. By default, if a vector `x` contains only positive integers, then `tabulate` returns 0 counts for the integers between `1` and `max(x)` that do not

appear in `x`. To avoid this behavior, convert the vector `x` to a `categorical` vector before calling `tabulate`.

Load the `patients` data set. Display the first five entries of the `Height` variable. Each value indicates the height, in inches, of a patient.

```
load patients
Height(1:5)
```

```
ans = 5×1

    71
    69
    64
    67
    64
```

Create a frequency table that shows, in its second and third columns, the number and percentage of patients in the data set that have a particular height. Display the first five entries and the last five entries of the matrix that `tabulate` returns. `tbl` contains one row for each height between `1` and `72` inches, where `72` is the maximum height value in `Height`.

```
tbl = tabulate(Height);
first = tbl(1:5,:)
```

```
first = 5×3

     1     0     0
     2     0     0
     3     0     0
     4     0     0
     5     0     0
```

```
last = tbl(end-4:end,:)
```

```
last = 5×3

    68    15    15
    69     8     8
    70    11    11
    71    10    10
    72     4     4
```

Generate a frequency table that shows `Count` and `Percent` values only for heights that appear in the `Height` variable. Convert `Height` to a `categorical` variable, and then call the `tabulate` function.

```
newHeight = categorical(Height);
tabulate(newHeight)
```

```
  Value    Count   Percent
     60        1      1.00%
     62        3      3.00%
     63        7      7.00%
     64       12     12.00%
     65        8      8.00%
```

```
    66       15     15.00%
    67        6      6.00%
    68       15     15.00%
    69        8      8.00%
    70       11     11.00%
    71       10     10.00%
    72        4      4.00%
```

Create Table Array from Tabulated Data

Create a frequency table from a character array by using `tabulate`. Convert the resulting cell array to a `table` array, and visualize the results.

Load the `carsmall` data set. Tabulate the data in the `Origin` variable, which shows the country of origin of each car in the data set. Convert the resulting cell array `tbl` to a `table` array `t`. Change the `Value` column to a `categorical` vector.

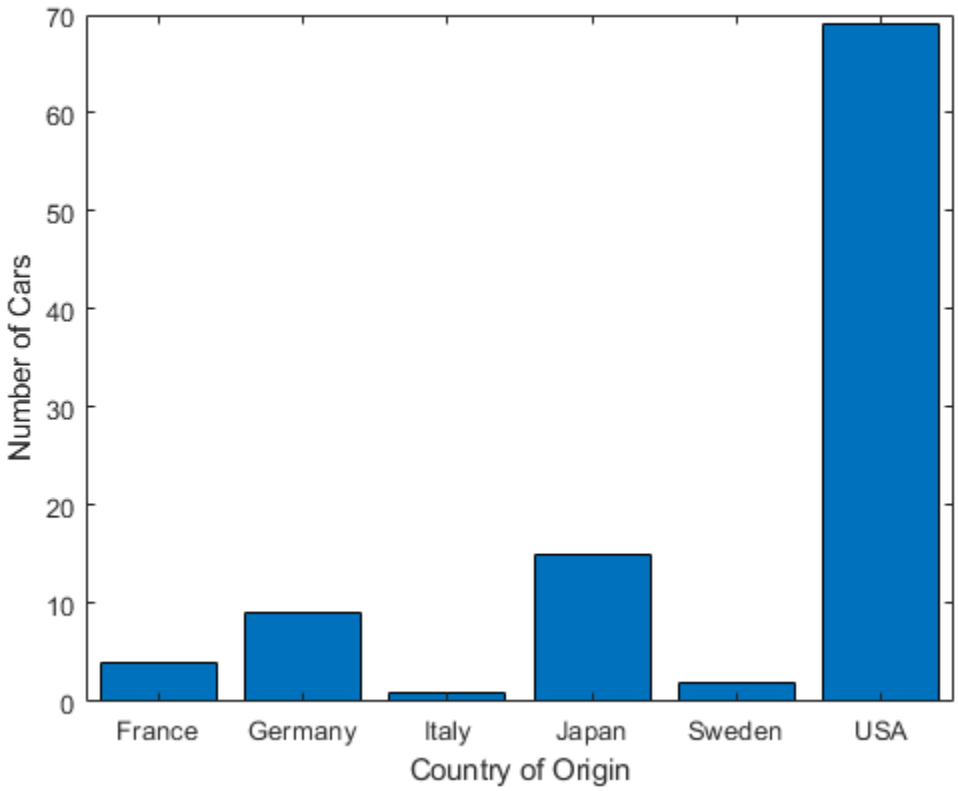
```
load carsmall
tbl = tabulate(Origin);
t = cell2table(tbl,'VariableNames', ...
    {'Value','Count','Percent'});
t.Value = categorical(t.Value)
```

```
t=6×3 table
     Value     Count    Percent
    _______    _____    _______

    USA         69        69
    France       4         4
    Japan       15        15
    Germany      9         9
    Sweden       2         2
    Italy        1         1
```

Create a bar graph from the frequency table.

```
bar(t.Value,t.Count)
xlabel('Country of Origin')
ylabel('Number of Cars')
```



Tabulate Data with Missing Values

Create a frequency table from a numeric vector with `NaN` values.

Load the `carsmall` data set. The `MPG` variable contains the miles per gallon measurement of 100 cars. For six of the cars, the `MPG` value is missing (`NaN`).

```
load carsmall
numcars = length(MPG)
```

```
numcars = 100
```

```
nanindex = isnan(MPG);
numMissingMPG = length(MPG(nanindex))
```

```
numMissingMPG = 6
```

Create a frequency table using `MPG`. Convert the matrix output from `tabulate` to a table, and label the table columns.

```
tbl = tabulate(MPG);
t = array2table(tbl,'VariableNames', ...
    {'Value','Count','Percent'})
```

```
t=37×3 table
    Value    Count    Percent
```

```
_____    _____    _______

   9        1      1.0638
  10        2      2.1277
  11        1      1.0638
  13        4      4.2553
  14        5      5.3191
14.5        1      1.0638
  15        5      5.3191
15.5        1      1.0638
  16        2      2.1277
16.5        2      2.1277
  17        1      1.0638
17.5        2      2.1277
  18        4      4.2553
18.5        1      1.0638
  19        2      2.1277
  20        2      2.1277
   ⋮
```

The frequency table displays data only for the 94 cars with numeric `MPG` values. `tabulate` calculates the percentage of each `MPG` value in this subset of cars, not the entire set of 100 cars.

```
tnumcars = sum(t.Count)
```

```
tnumcars = 94
```

Input Arguments

x — Input data

numeric vector | logical vector | categorical vector | character array | string array | cell array of character vectors

Input data, specified as a numeric vector, logical vector, categorical vector, character array, string array, or cell array of character vectors.

- If `x` is a numeric vector, then `tbl` is a numeric matrix.
- If `x` is a logical vector, categorical vector, character array, string array, or cell array of character vectors, then `tbl` is a cell array.

Note If the elements of `x` are positive integers, then the frequency table includes `0` counts for the integers between `1` and `max(x)` that do not appear in `x`. For an example, see “Tabulate Positive Integer Vector” on page 33-6071.

Data Types: `single` | `double` | `logical` | `categorical` | `char` | `string` | `cell`

Output Arguments

tbl — Frequency table

numeric matrix | cell array

Frequency table, returned as a numeric matrix or cell array. `tbl` includes the following information.

Column	Description
1st column (Value)	Unique values of `x`
2nd column (Count)	Number of instances of each value
3rd column (Percent)	Percentage of each value

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays”.

“Grouping Variables” on page 2-45

Introduced before R2006a

tblread

Read tabular data from file

Syntax

```
[data,varnames,casenames] = tblread
[data,varnames,casenames] = tblread(filename)
[data,varnames,casenames] = tblread(filename,delimiter)
```

Description

`[data,varnames,casenames] = tblread` displays the File Open dialog box for interactive selection of a tabular data file. The file format has variable names in the first row, case names in the first column and data starting in the (2, 2) position. Outputs are:

- `data` — Numeric matrix with a value for each variable-case pair
- `varnames` — Character matrix containing the variable names in the first row of the file
- `casenames` — Character matrix containing the names of each case in the first column of the file

`[data,varnames,casenames] = tblread(filename)` allows command line specification of the name of a file in the current folder, or the complete path name of any file, using the character vector or string scalar *`filename`*.

`[data,varnames,casenames] = tblread(filename,delimiter)` reads from the file using *`delimiter`* as the delimiting character. Accepted values for *`delimiter`* are:

- `' '` or `'space'`
- `'\t'` or `'tab'`
- `','` or `'comma'`
- `';'` or `'semi'`
- `'|'` or `'bar'`

The default value of *`delimiter`* is `'space'`.

Examples

```
[data,varnames,casenames] = tblread('sat.dat')
data =
  470  530
  520  480

varnames =
Male
Female

casenames =
Verbal
Quantitative
```

See Also

`caseread` | `readtable` | `tblwrite` | `tdfread`

Introduced before R2006a

tblwrite

Write tabular data to file

Syntax

```
tblwrite(data,varnames,casenames)
tblwrite(data,varnames,casenames,filename)
tblwrite(data,varnames,casenames,filename,delimiter)
```

Description

`tblwrite(data,varnames,casenames)` displays the **File Open** dialog box for interactive specification of the tabular data output file. The file format has variable names in the first row, case names in the first column and `data` starting in the (2,2) position.

`varnames` is a character matrix or string array containing the variable names. `casenames` is a character matrix or string array containing the names of each case in the first column. `data` is a character matrix or string array with a value for each variable-case pair.

`tblwrite(data,varnames,casenames,filename)` specifies a file in the current folder, or the complete path name of any file in the character vector or string scalar *`filename`*.

`tblwrite(data,varnames,casenames,filename,delimiter)` writes to the file using *`delimiter`* as the delimiting character. The following table lists the accepted values for *`delimiter`* and their equivalent names.

Value	Name
`' '`	`'space'`
`'\t'`	`'tab'`
`','`	`'comma'`
`';'`	`'semi'`
`'|'`	`'bar'`

The default value of *`delimiter`* is `'space'`.

Examples

Continuing the example from `tblread`:

```
tblwrite(data,varnames,casenames,'sattest.dat')
type sattest.dat
                     Male  Female
Verbal               470     530
Quantitative        520     480
```

`casewrite` | `tblread` | `writetable`

Introduced before R2006a

tcdf

Student's *t* cumulative distribution function

Syntax

```
p = tcdf(x,nu)

p = tcdf(x,nu,'upper')
```

Description

`p = tcdf(x,nu)` returns the cumulative distribution function (cdf) of the Student's *t* distribution with `nu` degrees of freedom, evaluated at the values in `x`.

`p = tcdf(x,nu,'upper')` returns the complement of the cdf, evaluated at the values in `x` with `nu` degrees of freedom, using an algorithm that more accurately computes the extreme upper-tail probabilities than subtracting the lower tail value from 1.

Examples

Compute Student's *t* Distribution cdf

Generate a random sample of size `100` from a normally distributed population with mean `1` and standard deviation `2`.

```
rng default   % For reproducibility
mu = 1;
n = 100;
sigma = 2;
x = normrnd(mu,sigma,n,1);
```

Compute the sample mean, sample standard deviation, and *t*-score of the sample.

```
xbar = mean(x);
s = std(x);
t = (xbar-mu)/(s/sqrt(n))
```

```
t = 1.0589
```

Use `tcdf` to compute the probability of a sample of size `100` having a larger *t*-score than the *t*-score of the sample.

```
p = 1-tcdf(t,n-1)
```

```
p = 0.1461
```

This probability is the same as the *p* value returned by a *t* test with null hypothesis that the sample comes from a normal population with mean `1` and alternative hypothesis that the mean is greater than `1`.

```
[h,ptest] = ttest(x,mu,0.05,'right');
ptest
```

```
ptest = 0.1461
```

Compute Complementary cdf (Tail Distribution)

Determine the probability that an observation from the Student's *t* distribution with degrees of freedom `99` falls on the interval `[10 Inf]`.

```
p1 = 1 - tcdf(10,99)
```

```
p1 = 0
```

`tcdf(10,99)` is nearly `1`, so `p1` becomes `0`. Specify `'upper'` so that `tcdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = tcdf(10,99,'upper')
```

```
p2 = 5.4699e-17
```

You can also use `'upper'` to compute a right-tailed *p*-value.

Input Arguments

x — Values at which to evaluate cdf

scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `tcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[-1,0,3,4]`

Data Types: `single` | `double`

nu — Degrees of freedom

positive scalar value | array of positive scalar values

Degrees of freedom for the Student's *t* distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the cdf at multiple values, specify `x` using an array.
- To evaluate the cdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `tcdf` expands each scalar input into a constant array of the same size as the array

inputs. Each element in p is the cdf value of the distribution specified by the corresponding element in nu, evaluated at the corresponding element in x.

Example: `[9,19,49,99]`

Data Types: `single` | `double`

Output Arguments

p — cdf values

scalar value | array of scalar values

cdf values evaluated at the values in x, returned as a scalar value or an array of scalar values. p is the same size as x and nu after any necessary scalar expansion. Each element in p is the cdf value of the distribution specified by the corresponding element in nu, evaluated at the corresponding element in x.

More About

Student's *t* cdf

The Student's *t* distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom. The Student's *t* distribution has zero mean.

The cdf of the Student's *t* distribution is

$$p = F(x|\nu) = \int_{-\infty}^{x} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1+\frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt,$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result *p* is the probability that a single observation from the *t* distribution with ν degrees of freedom falls in the interval $[-\infty, x]$.

For more information, see "Student's t Distribution" on page B-149.

Alternative Functionality

- `tcdf` is a function specific to the Student's *t* distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `tcdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

tdfread

Read tab-delimited file

Syntax

```
tdfread
tdfread(filename)
tdfread(filename,delimiter)

s = tdfread( ___ )
```

Description

`tdfread` opens the Select File to Open dialog box for interactive selection of a data file, and reads the data from the file you select. `tdfread` can read data from tab-delimited text files with `.txt`, `.dat`, or `.csv` file extensions.

Select a file that has variable names in the first row and values separated by tabs in the remaining rows. `tdfread` creates a variable in the workspace for each column of the file, and names each variable according to its first row value.

- If a column contains only numeric data in all rows except the first, then `tdfread` creates a `double` variable.
- Otherwise, `tdfread` creates a `char` variable.

After importing all values, `tdfread` displays information about the imported variables, such as their size, bytes, and class.

`tdfread(filename)` creates variables from the data in `filename`, which is either the name of a file in the current folder or the complete path name of a file.

`tdfread(filename,delimiter)` indicates that the character specified by `delimiter` separates values in the file.

`s = tdfread( ___ )` returns a structure `s` in which each field contains a variable. Specify any of the input argument combinations in the previous syntaxes.

Examples

Create Workspace Variables from Text File

Display the contents of the `sat2.dat` file. Note that the first row of the file contains the variable names.

```
type sat2.dat
```

```
Test,Gender,Score
Verbal,Male,470
Verbal,Female,530
```

```
Quantitative,Male,520
Quantitative,Female,480
```

In the workspace, create the variables `Gender`, `Score`, and `Test` from the columns of the file. Because commas separate the values in the file, specify `','` as the delimiter.

```
tdfread('sat2.dat',',')
```

```
  Name        Size            Bytes  Class     Attributes

  Gender      4x6                48  char
  Score       4x1                32  double
  Test        4x12               96  char
```

Input Arguments

`filename` — Name of file to read

character vector | string scalar

Name of the file to read, specified as a character vector or string scalar.

Depending on the location of the file, `filename` has one of these forms.

Location of File	Form
Current folder or folder on the MATLAB path	Specify the name of the file in `filename`. **Example:** `'myTextFile.txt'`
Folder that is not the current folder or a folder on the MATLAB path	Specify the full or relative path name in `filename`. **Example:** `'C:\myFolder\myTextFile.txt'`

Example: `'sat2.dat'`

Data Types: `char` | `string`

`delimiter` — Delimiter character

`'\t'` or `'tab'` (default) | `'bar'` | `'comma'` | `'semi'` | `'space'` | ...

Delimiter character, specified as one of the values in this table.

Value	Description

`'|'`
 	
`'bar'`
	Vertical bar

`','`
 	
`'comma'`
	Comma

`';'`
 	
`'semi'`
	Semicolon

Value	Description

`' '`
 	
`'space'`
	Space

`'\t'`
 	
`'tab'`
	Tab

Example: `','`

Data Types: `char` | `string`

Alternative Functionality

Consider using the `readtable`, `readmatrix`, or `readcell` MATLAB functions to import data. These functions provide more flexible data importing options than `tdfread`.

See Also

Import Tool | `readcell` | `readmatrix` | `readtable` | `textscan`

Introduced before R2006a

templateDiscriminant

Discriminant analysis classifier template

Syntax

```
t = templateDiscriminant()
t = templateDiscriminant(Name,Value)
```

Description

`t = templateDiscriminant()` returns a discriminant analysis learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcensemble` or `fitcecoc`.

`t = templateDiscriminant(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the discriminant type or the regularization parameter.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Discriminant Analysis Template for Ensemble Learning

Create a nondefault discriminant analysis template for use in `fitcensemble`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for pseudolinear discriminant analysis.

```
t = templateDiscriminant('DiscrimType','pseudoLinear')
```

```
t =
Fit template for classification Discriminant.

    DiscrimType: 'pseudoLinear'
          Gamma: []
          Delta: []
     FillCoeffs: []
     SaveMemory: []
        Version: 1
         Method: 'Discriminant'
```

```
            Type: 'classification'
```

All properties of the template object are empty except for `DiscrimType`, `Method`, and `Type`. When trained on, the software fills in the empty properties with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitcensemble(meas,species,'Method','Subspace','Learners',t);
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0400
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DiscrimType','pseudoLinear','SaveMemory','on'` specifies a template for pseudolinear discriminant analysis that does not store the full covariance matrix.

`Delta` — Linear coefficient threshold
`0` (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `Mdl` has magnitude smaller than `Delta`, `Mdl` sets this coefficient to `0`, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be `0` for quadratic discriminant models.

Data Types: `single` | `double`

`DiscrimType` — Discriminant type
`'linear'` (default) | `'quadratic'` | `'diaglinear'` | `'diagquadratic'` | `'pseudolinear'` | `'pseudoquadratic'`

Discriminant type, specified as the comma-separated pair consisting of `'DiscrimType'` and a character vector or string scalar in this table.

Value	Description	Predictor Covariance Treatment
`'linear'`	Regularized linear discriminant analysis (LDA)	• All classes have the same covariance matrix. • $\widehat{\Sigma}_\gamma = (1-\gamma)\widehat{\Sigma} + \gamma \mathrm{diag}\left(\widehat{\Sigma}\right)$. $\widehat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.
`'diaglinear'`	LDA	All classes have the same, diagonal covariance matrix.
`'pseudolinear'`	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
`'quadratic'`	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
`'diagquadratic'`	QDA	The covariance matrices are diagonal and can vary among classes.
`'pseudoquadratic'`	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note To use regularization, you must specify `'linear'`. To specify the amount of regularization, use the `Gamma` name-value pair argument.

Example: `'DiscrimType','quadratic'`

`FillCoeffs` — `Coeffs` property flag

`'on'` | `'off'`

`Coeffs` property flag, specified as the comma-separated pair consisting of `'FillCoeffs'` and `'on'` or `'off'`. Setting the flag to `'on'` populates the `Coeffs` property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is `'on'`, unless you specify a cross-validation name-value pair, in which case the flag is set to `'off'` by default.

Example: `'FillCoeffs','off'`

`Gamma` — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of `'Gamma'` and a scalar value in the interval [0,1]. `Gamma` provides finer control over the covariance matrix structure than `DiscrimType`.

- If you specify `0`, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.

  - For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
  - For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to `'linear'`.
- If you specify `1`, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: `'Gamma',1`

Data Types: `single` | `double`

`SaveMemory` — Flag to save covariance matrix
`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

Example: `'SaveMemory','on'`

Output Arguments

`t` — Discriminant analysis classification template
template object

Discriminant analysis classification template suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcensemble` or `fitcecoc` to specify how to create the discriminant analysis classifier for the ensemble or ECOC model, respectively.

If you display `t` to the Command Window, then all unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

See Also

`ClassificationDiscriminant` | `fitcecoc` | `fitcensemble` | `predict`

Introduced in R2014a

templateECOC

Error-correcting output codes learner template

Syntax

```
t = templateECOC()
t = templateECOC(Name,Value)
```

Description

`t = templateECOC()` returns an error-correcting output codes (ECOC) classification learner template.

If you specify a default template, then the software uses default values for all input arguments during training.

`t = templateECOC(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments.

For example, you can specify a coding design, whether to fit posterior probabilities, or the types of binary learners.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default ECOC Classification Learner Template

Use `templateECOC` to create a default ECOC template.

```
t = templateECOC()
```

```
t =
Fit template for classification ECOC.

    BinaryLearners: ''
           Coding: ''
      FitPosterior: []
           Options: []
    VerbosityLevel: []
     NumConcurrent: []
           Version: 1
            Method: 'ECOC'
              Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to `testckfold`, the software fills in the empty properties with their respective default values. For

example, the software fills the `BinaryLearners` property with `'SVM'`. For details on other default values, see `fitcecoc`.

`t` is a plan for an ECOC learner. When you create it, no computation occurs. You can pass `t` to `testckfold` to specify a plan for an ECOC classification model to statistically compare with another model.

Statistically Compare Performance of Two ECOC Classification Models

One way to select predictors or features is to train two models where one that uses a subset of the predictors that trained the other. Statistically compare the predictive performances of the models. If there is sufficient evidence that model trained on fewer predictors performs better than the model trained using more of the predictors, then you can proceed with a more efficient model.

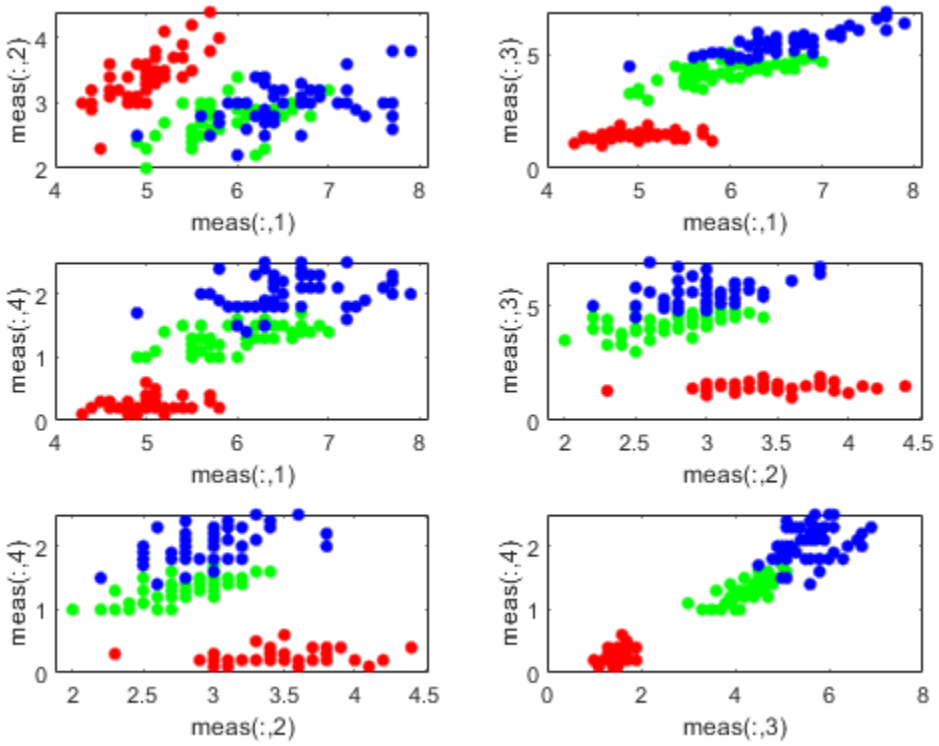
Load Fisher's iris data set. Plot all 2-dimensional combinations of predictors.

```
load fisheriris
d = size(meas,2); % Number of predictors
pairs = nchoosek(1:d,2)
```

```
pairs = 6×2

     1     2
     1     3
     1     4
     2     3
     2     4
     3     4
```

```
for j = 1:size(pairs,1)
    subplot(3,2,j)
    gscatter(meas(:,pairs(j,1)),meas(:,pairs(j,2)),species)
    xlabel(sprintf('meas(:,%d)',pairs(j,1)))
    ylabel(sprintf('meas(:,%d)',pairs(j,2)))
    legend off
end
```



Based on the scatterplot, `meas(:,3)` and `meas(:,4)` seem like they separate the groups well.

Create an ECOC template. Specify to use a one-versus-all coding design.

```
t = templateECOC('Coding','onevsall');
```

By default, the ECOC model uses linear SVM binary learners. You can choose other, supported algorithms by specifying them using the `'Learners'` name-value pair argument.

Test whether an ECOC model that is just trained using predictors 3 and 4 performs at most as well as an ECOC model that is trained using all predictors. Rejecting this null hypothesis means that the ECOC model trained using predictors 3 and 4 performs better than the ECOC model trained using all predictors. Suppose C_1 represents the classification error of the ECOC model trained using predictors 3 and 4 and C_2 represents the classification error of the ECOC model trained using all predictors, then the test is:

$$H_0: C_1 \geq C_2$$
$$H_1: C_1 < C_2$$

By default, `testckfold` conducts a 5-by-2 k-fold F test, which is not appropriate as a one-tailed test. Specify to conduct a 5-by-2 k-fold t test.

```
rng(1); % For reproducibility
[h,pValue] = testckfold(t,t,meas(:,pairs(6,:)),meas,species,...
    'Alternative','greater','Test','5x2t')
```

```
h = logical
   0

pValue = 0.8940
```

The `h = 0` indicates that there is not enough evidence to suggest that the model trained using predictors 3 and 4 is more accurate than the model trained using all predictors.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Coding','ternarycomplete','FitPosterior',true,'Learners','tree'` specifies a ternary complete coding design, to transform scores to posterior probabilities, and to grow classification trees for all binary learners.

`Coding` — Coding design
`'onevsone'` (default) | `'allpairs'` | `'binarycomplete'` | `'denserandom'` | `'onevsall'` | `'ordinal'` | `'sparserandom'` | `'ternarycomplete'` | numeric matrix

Coding design name, specified as the comma-separated pair consisting of `'Coding'` and a numeric matrix or a value in this table.

Value	Number of Binary Learners	Description
`'allpairs'` and `'onevsone'`	$K(K – 1)/2$	For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.
`'binarycomplete'`	$2^{(K – 1)} – 1$	This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are `-1` and `1` with at least one positive and negative class in the assignment.
`'denserandom'`	Random, but approximately $10 \log_2 K$	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 33-1646.

Value	Number of Binary Learners	Description
`'onevsall'`	K	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.
`'ordinal'`	K – 1	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.
`'sparserandom'`	Random, but approximately 15 $\log_2 K$	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 33-1646.
`'ternarycomplete'`	$\left(3^K - 2^{(K+1)} + 1\right)/2$	This design partitions the classes into all ternary combinations. All class assignments are `0`, `-1`, and `1` with at least one positive and one negative class in the assignment.

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a K-by-L matrix. Each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in `ClassNames`. Compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be `-1`, `0`, or `1`, and the value must correspond to a dichotomous class assignment. This table describes the meaning of `Coding(i,j)`, that is, the class that learner `j` assigns to observations in class `i`.

Value	Dichotomous Class Assignment
–1	Learner `j` assigns observations in class `i` to a negative class.
`0`	Before training, learner `j` removes observations in class `i` from the data set.
`1`	Learner `j` assigns observations in class `i` to a positive class.

- Every column must contain at least one `-1` or `1`.
- For all column indices `i`,`j` such that `i` ≠ `j`, `Coding(:,i)` cannot equal `Coding(:,j)` and `Coding(:,i)` cannot equal `-Coding(:,j)`.

- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 33-1644.

Example: `'Coding','ternarycomplete'`

Data Types: `char` | `string` | `double` | `single` | `int16` | `int32` | `int64` | `int8`

`FitPosterior` — Flag indicating whether to transform scores to posterior probabilities
`false` or `0` (default) | `true` or `1`

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of `'FitPosterior'` and a `true` (`1`) or `false` (`0`).

If `FitPosterior` is `true`, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using `kfoldPredict`, `predict`, or `resubPredict`.

`fitcecoc` does not support fitting posterior probabilities if:

- The ensemble method is `AdaBoostM2`, `LPBoost`, `RUSBoost`, `RobustBoost`, or `TotalBoost`.
- The binary learners (`Learners`) are linear or kernel classification models that implement SVM. To obtain posterior probabilities for linear or kernel classification models, implement logistic regression instead.

Example: `'FitPosterior',true`

Data Types: `logical`

`Learners` — Binary learner templates
`'svm'` (default) | `'discriminant'` | `'kernel'` | `'knn'` | `'linear'` | `'naivebayes'` | `'tree'` | template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of `'Learners'` and a character vector, string scalar, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM, and the ensembles that use `GentleBoost`, `LogitBoost`, and `RobustBoost`, to solve multiclass problems. However, `fitcecoc` also supports multiclass models as binary classifiers.

- If `Learners` is a character vector or string scalar, then the software trains each binary learner using the default values of the specified algorithm. This table summarizes the available algorithms.

Value	Description
`'discriminant'`	Discriminant analysis. For default options, see `templateDiscriminant`.
`'kernel'`	Kernel classification model. For default options, see `templateKernel`.
`'knn'`	*k*-nearest neighbors. For default options, see `templateKNN`.
`'linear'`	Linear classification model. For default options, see `templateLinear`.

Value	Description
'naivebayes'	Naive Bayes. For default options, see templateNaiveBayes.
'svm'	SVM. For default options, see templateSVM.
'tree'	Classification trees. For default options, see templateTree.

- If Learners is a template object, then each binary learner trains according to the stored options. You can create a template object using:
  - templateDiscriminant, for discriminant analysis.
  - templateEnsemble, for ensemble learning. You must at least specify the learning method (Method), the number of learners (NLearn), and the type of learner (Learners). You cannot use the AdaBoostM2 ensemble method for binary learning.
  - templateKernel, for kernel classification.
  - templateKNN, for *k*-nearest neighbors.
  - templateLinear, for linear classification.
  - templateNaiveBayes, for naive Bayes.
  - templateSVM, for SVM.
  - templateTree, for classification trees.
- If Learners is a cell vector of template objects, then:
  - Cell *j* corresponds to binary learner *j* (in other words, column *j* of the coding design matrix), and the cell vector must have length *L*. *L* is the number of columns in the coding design matrix. For details, see Coding.
  - To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners. The former returns a score in the range (-∞,∞), and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as predict and loss.
  - You cannot specify linear classification model learner templates with any other template.
  - Similarly, you cannot specify kernel classification model learner templates with any other template.

By default, the software trains learners using default SVM templates.

Example: 'Learners','tree'

Output Arguments

t — ECOC classification template

template object

ECOC classification template, returned as a template object. Pass t to testckfold to specify how to create an ECOC classifier whose predictive performance you want to compare with another classifier.

If you display t to the Command Window, then all, unspecified options appear empty ([]). However, the software replaces empty options with their corresponding default values during training.

`ClassificationECOC` | `designecoc` | `fitcecoc` | `predict` | `templateDiscriminant` | `templateEnsemble` | `templateKNN` | `templateSVM` | `templateTree` | `testckfold`

Introduced in R2015a

templateEnsemble

Ensemble learning template

Syntax

```
t = templateEnsemble(Method,NLearn,Learners)
t = templateEnsemble(Method,NLearn,Learners,Name,Value)
```

Description

`t = templateEnsemble(Method,NLearn,Learners)` returns an ensemble learning template that specifies to use the ensemble aggregation method `Method`, `NLearn` learning cycles, and weak learners `Learners`.

All other options of the template (`t`) specific to ensemble learning appear empty, but the software uses their corresponding default values during training.

`t = templateEnsemble(Method,NLearn,Learners,Name,Value)` returns an ensemble template with additional options specified by one or more name-value pair arguments.

For example, you can specify the number of predictors in each random subspace learner, learning rate for shrinkage, or the target classification error for `RobustBoost`.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those options that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create an Ensemble Learning Template

Use `templateEnsemble` to specify an ensemble learning template. You must specify the ensemble method, the number of learning cycles, and the type of weak learners. For this example, specify the AdaBoostM1 method, 100 learners, and classification tree weak learners.

```
t = templateEnsemble('AdaBoostM1',100,'tree')
```

```
t =
Fit template for classification AdaBoostM1.

                Type: 'classification'
              Method: 'AdaBoostM1'
    LearnerTemplates: 'Tree'
              NLearn: 100
           LearnRate: []
```

All properties of the template object are empty except for `Method`, `Type`, `LearnerTemplates`, and `NLearn`. When trained on, the software fills in the empty properties with their respective default values. For example, the software fills the `LearnRate` property with `1`.

`t` is a plan for an ensemble learner, and no computation takes place when you specify it. You can pass `t` to `fitcecoc` to specify ensemble binary learners for ECOC multiclass learning.

Create an Ensemble Template for ECOC Multiclass Learning

Create an ensemble template for use in `fitcecoc`.

Load the arrhythmia data set.

```
load arrhythmia
tabulate(categorical(Y));
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
     15        5      1.11%
     16       22      4.87%
```

```
rng(1); % For reproducibility
```

Some classes have small relative frequencies in the data.

Create a template for a AdaBoostM1 ensemble of classification trees, and specify to use 100 learners and a shrinkage of 0.1. By default, boosting grows stumps (i.e., one node having a set of leaves). Since there are classes with small frequencies, the trees must be leafy enough to be sensitive to the minority classes. Specify the minimum number of leaf node observations to 3.

```
tTree = templateTree('MinLeafSize',20);
t = templateEnsemble('AdaBoostM1',100,tTree,'LearnRate',0.1);
```

All properties of the template objects are empty except for `Method` and `Type`, and the corresponding properties of the name-value pair argument values in the function calls. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

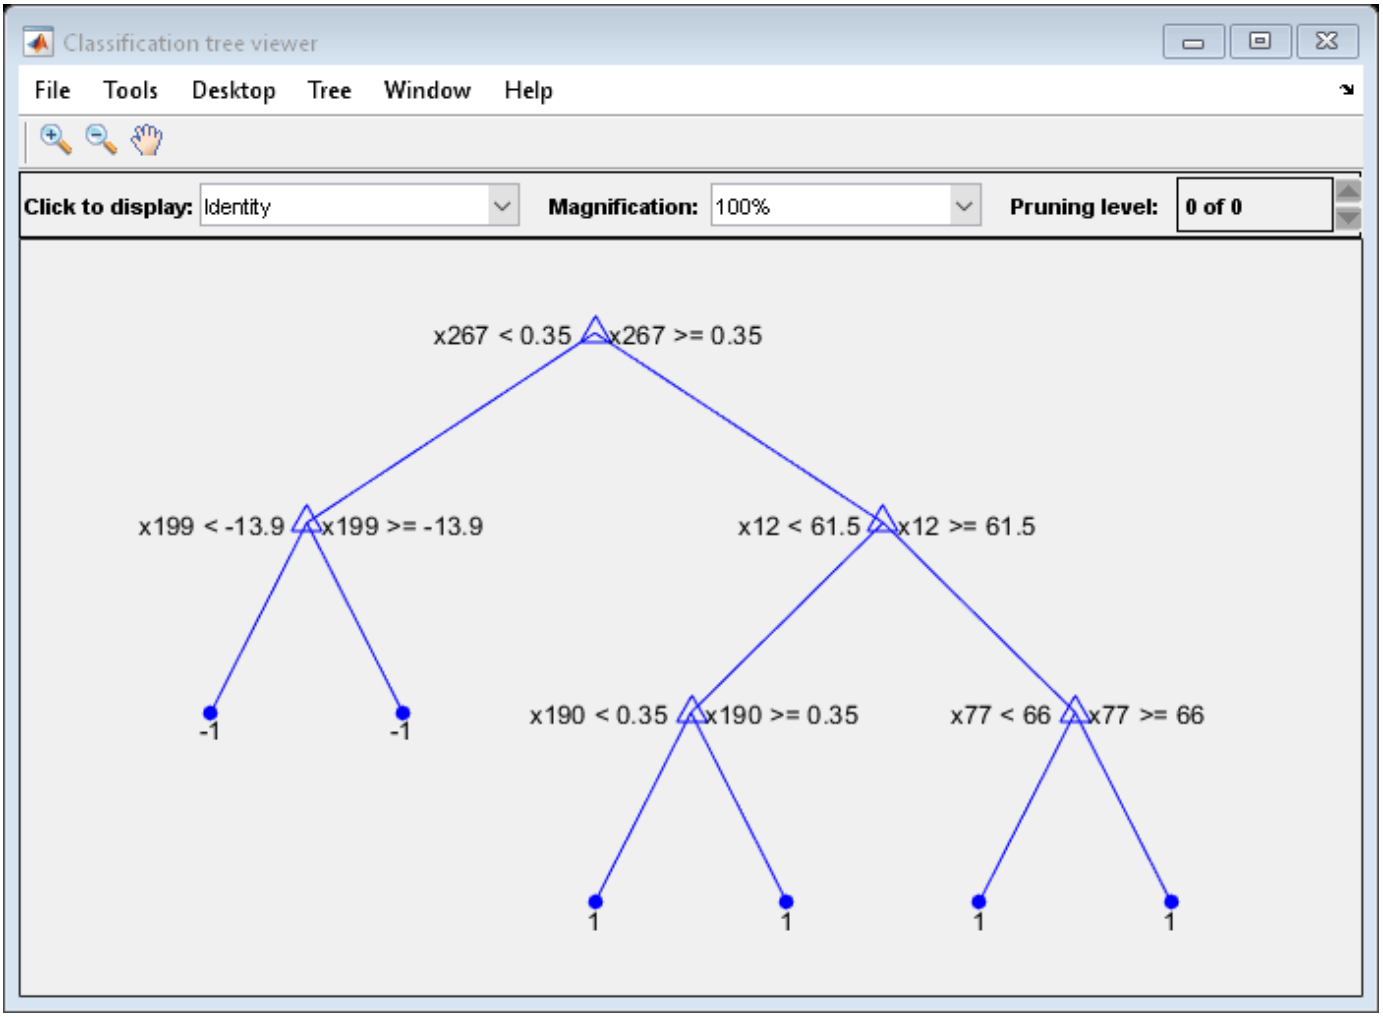
Specify `t` as a binary learner for an ECOC multiclass model. Train using the default one-versus-one coding design.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

- `Mdl` is a `ClassificationECOC` multiclass model.
- `Mdl.BinaryLearners` is a 78-by-1 cell array of `CompactClassificationEnsemble` models.
- `Mdl.BinaryLearners{j}.Trained` is a 100-by-1 cell array of `CompactClassificationTree` models, for `j` = 1,...,78.

You can verify that one of the binary learners contains a weak learner that isn't a stump by using `view`.

```
view(Mdl.BinaryLearners{1}.Trained{1},'Mode','graph')
```



Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0819
```

Speed Up Training ECOC Classifiers Using Binning and Parallel Computing

Train a one-versus-all ECOC classifier using a `GentleBoost` ensemble of decision trees with surrogate splits. To speed up training, bin numeric predictors and use parallel computing. Binning is valid only when `fitcecoc` uses a tree learner. After training, estimate the classification error using 10-fold cross-validation. Note that parallel computing requires Parallel Computing Toolbox™.

Load Sample Data

Load and inspect the `arrhythmia` data set.

```
load arrhythmia
[n,p] = size(X)
```

```
n = 452
```

```
p = 279
```

```
isLabels = unique(Y);
nLabels = numel(isLabels)
```

```
nLabels = 13
```

```
tabulate(categorical(Y))
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
     15        5      1.11%
     16       22      4.87%
```

The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (`Y`). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

Train One-Versus-All ECOC Classifier

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify `'GentleBoost'` for the method, `100` for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```
tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

`tEnsemble` is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. To speed up training, use binning and parallel computing.

- Binning (`'NumBins',50`) — When you have a large training data set, you can speed up training (a potential decrease in accuracy) by using the `'NumBins'` name-value pair argument. This argument is valid only when `fitcecoc` uses a tree learner. If you specify the `'NumBins'` value, then the software bins every numeric predictor into a specified number of equiprobable bins, and

then grows trees on the bin indices instead of the original data. You can try `'NumBins',50` first, and then change the `'NumBins'` value depending on the accuracy and training speed.

- Parallel computing (`'Options',statset('UseParallel',true)`) — With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. The number of workers depends on your system configuration. When you use decision trees for binary learners, `fitcecoc` parallelizes training using Intel® Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the `'UseParallel'` option is not helpful on a single computer. Use this option on a cluster.

Additionally, specify that the prior probabilities are $1/K$, where $K = 13$ is the number of distinct classes.

```
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
                'Prior','uniform','NumBins',50,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

`Mdl` is a `ClassificationECOC` model.

Cross-Validation

Cross-validate the ECOC classifier using 10-fold cross-validation.

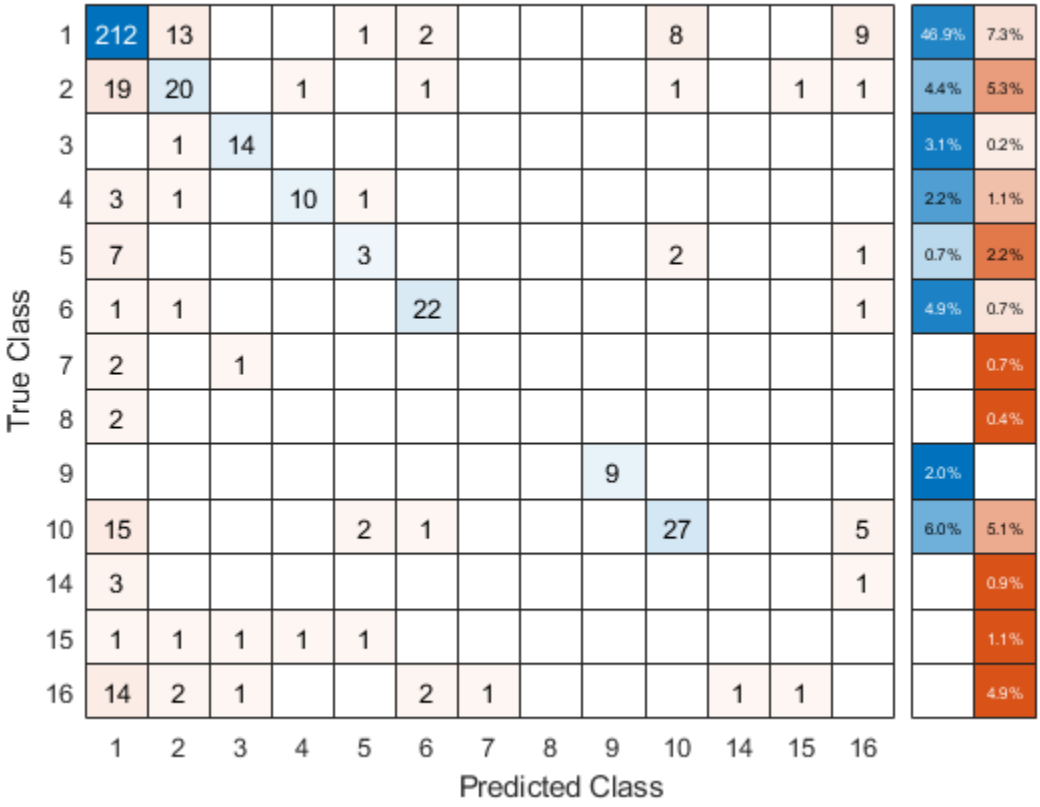
```
CVMdl = crossval(Mdl,'Options',options);
```

```
Warning: One or more folds do not contain points from all the groups.
```

`CVMdl` is a `ClassificationPartitionedECOC` model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering `CVMdl.Trained{1}`.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using `confusionchart`. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

```
oofLabel = kfoldPredict(CVMdl,'Options',options);
ConfMat = confusionchart(Y,oofLabel,'RowSummary','total-normalized');
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
```



Reproduce Binned Data

Reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

```
X = Mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are `0` for categorical predictors. If `X` contains `NaN`s, then the corresponding `Xbinned` values are `NaN`s.

Input Arguments

`Method` — Ensemble aggregation method

`'AdaBoostM1'` | `'LogitBoost'` | `'GentleBoost'` | `'RUSBoost'` | `'Subspace'` | `'Bag'` | `'AdaBoostM2'` | `'LSBoost'` | ...

Ensemble aggregation method, specified as one of the method names in this list.

- For classification with two classes:
  - `'AdaBoostM1'`
  - `'LogitBoost'`
  - `'GentleBoost'`
  - `'RobustBoost'` (requires Optimization Toolbox)
  - `'LPBoost'` (requires Optimization Toolbox)
  - `'TotalBoost'` (requires Optimization Toolbox)
  - `'RUSBoost'`
  - `'Subspace'`
  - `'Bag'`
- For classification with three or more classes:
  - `'AdaBoostM2'`
  - `'LPBoost'` (requires Optimization Toolbox)
  - `'TotalBoost'` (requires Optimization Toolbox)
  - `'RUSBoost'`
  - `'Subspace'`
  - `'Bag'`
- For regression:
  - `'LSBoost'`
  - `'Bag'`

If you specify `'Method','Bag'`, then specify the problem type using the `Type` name-value pair argument, because you can specify `'Bag'` for classification and regression problems.

For details about ensemble aggregation algorithms and examples, see “Ensemble Algorithms” on page 18-39 and “Choose an Applicable Ensemble Aggregation Method” on page 18-32.

`NLearn` — Number of ensemble learning cycles

positive integer | `'AllPredictorCombinations'`

Number of ensemble learning cycles, specified as a positive integer or `'AllPredictorCombinations'`.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NLearn*numel(Learners)` learners.
- If you specify `'AllPredictorCombinations'`, then set `Method` to `'Subspace'` and specify one learner only in `Learners`. With these settings, the software trains learners for all possible combinations of predictors taken `NPredToSample` at a time. Consequently, the software trains `nchoosek(size(X,2),NPredToSample)` learners.

For more details, see “Tips” on page 33-6111.

Data Types: `single` | `double` | `char` | `string`

`Learners` — Weak learners to use in ensemble

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Settings
Discriminant analysis	`'Discriminant'`	`templateDiscriminant`	Recommended for `'Subspace'`
k nearest neighbors	`'KNN'`	`templateKNN`	For `'Subspace'` only
Decision tree	`'Tree'`	`templateTree`	All methods except `'Subspace'`

For more details, see `NLearn` and “Tips” on page 33-6111.

Example: For an ensemble composed of two types of classification trees, supply `{t1 t2}`, where `t1` and `t2` are classification tree templates.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'LearningRate',0.05,'NPrint',5` specifies to use `0.05` as the learning rate and to display a message to the command line every time it trains `5` learners.

General Ensemble Options

`NPrint` — Printout frequency

`'off'` (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of `'NPrint'` and a positive integer or `'off'`.

To track the number of *weak learners* or *folds* that the software trained so far, specify a positive integer. That is, if you specify the positive integer *m* and:

- Do not specify any cross-validation option of the fitting function (for example, `CrossVal`), then the software displays a message to the command line every time it completes training *m* weak learners.

- A cross-validation option, then the software displays a message to the command line every time it finishes training *m* folds.

If you specify `'off'`, then the software does not display a message when it completes training weak learners.

Tip When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: `'NPrint',5`

Data Types: `single` | `double` | `char` | `string`

Type — Supervised learning type

`'classification'` | `'regression'`

Supervised learning type, specified as the comma-separated pair consisting of `'Type'` and `'classification'` or `'regression'`.

- If `Method` is `'bag'`, then the supervised learning type is ambiguous. Therefore, specify `Type` when bagging.
- Otherwise, the value of `Method` determines the supervised learning type.

Example: `'Type','classification'`

Sampling Options for Boosting Methods and Bagging

FResample — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in (0,1].

To use `'FResample'`, specify `'bag'` for `Method` or set `Resample` to `'on'`.

Example: `'FResample',0.75`

Data Types: `single` | `double`

Replace — Flag indicating to sample with replacement

`'on'` (default) | `'off'`

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of `'Replace'` and `'off'` or `'on'`.

- For `'on'`, the software samples the training observations with replacement.
- For `'off'`, the software samples the training observations without replacement. If you set `Resample` to `'on'`, then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to `'bag'` or set `Resample` to `'on'`, `Replace` has no effect.

Example: `'Replace','off'`

`Resample` — Flag indicating to resample

`'off'` | `'on'`

Flag indicating to resample, specified as the comma-separated pair consisting of `'Resample'` and `'off'` or `'on'`.

- If `Method` is a boosting method, then:
  - `'Resample','on'` specifies to sample training observations using updated weights as the multinomial sampling probabilities.
  - `'Resample','off'`(default) specifies to reweight observations at every learning iteration.
- If `Method` is `'bag'`, then `'Resample'` must be `'on'`. The software resamples a fraction of the training observations (see `FResample`) with or without replacement (see `Replace`).

If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, and LSBoost Method Options

`LearnRate` — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of `'LearnRate'` and a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than `1`, for example, `0.1` is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate',0.1`

Data Types: `single` | `double`

RUSBoost Method Options

`LearnRate` — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of `'LearnRate'` and a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than `1`, for example, `0.1` is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate',0.1`

Data Types: `single` | `double`

`RatioToSmallest` — Sampling proportion with respect to lowest-represented class

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of `'RatioToSmallest'` and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are *K* classes in the training data and the lowest-represented class has *m* observations in the training data.

- If you specify the positive numeric scalar *s*, then the software samples *s***m* observations from each class, that is, it uses the same sampling proportion for each class. For more details, see "Algorithms" on page 33-6112.
- If you specify the numeric vector `[s1,s2,...,sK]`, then the software samples *si***m* observations from class *i*, *i* = 1,...,*K*. The elements of `RatioToSmallest` correspond to the order of the class names specified using the `ClassNames` name-value pair argument of the fitting function (see "Tips" on page 33-6111).

The default value is `ones(K,1)`, which specifies to sample *m* observations from each class.

Example: `'RatioToSmallest',[2,1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options

`MarginPrecision` — Margin precision to control convergence speed

`0.1` (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of `'MarginPrecision'` and a numeric scalar in the interval [0,1]. `MarginPrecision` affects the number of boosting iterations required for convergence.

Tip To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision',0.5`

Data Types: `single` | `double`

RobustBoost Method Options

`RobustErrorGoal` — Target classification error

`0.1` (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of `'RobustErrorGoal'` and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed `1`.

Tip For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal',0.05`

Data Types: `single` | `double`

`RobustMarginSigma` — Classification margin distribution spread

`0.1` (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of `'RobustMarginSigma'` and a positive numeric scalar. Before specifying `RobustMarginSigma`, consult the literature on `RobustBoost`, for example, [19].

Example: `'RobustMarginSigma',0.5`

Data Types: `single` | `double`

`RobustMaxMargin` — Maximal classification margin
`0` (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of `'RobustMaxMargin'` and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below `RobustMaxMargin`.

Example: `'RobustMaxMargin',1`

Data Types: `single` | `double`

Random Subspace Method Options

`NPredToSample` — Number of predictors to sample
`1` (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of `'NPredToSample'` and a positive integer in the interval 1,...,*p*, where *p* is the number of predictor variables (`size(X,2)` or `size(Tbl,2)`).

Data Types: `single` | `double`

Output Arguments

`t` — Classification template for ensemble learning
classification template object

Classification template for ensemble learning, returned as a template object. You can pass `t` to, for example, `fitcecoc` to specify how to create the ensemble learning classifier for the ECOC model.

If you display `t` in the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Tips

- `NLearn` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems, or `resume` for regression problems.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of `1` for `FResample`.

- In classification problems (that is, `Type` is `'classification'`):
  - If the ensemble aggregation method (`Method`) is `'bag'` and:
    - The misclassification cost is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
    - The class prior probabilities are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

    For smaller sample sizes, these combinations can result in a very low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it might be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using the `Cost` name-value pair argument of the fitting function, or a less skewed prior probability vector using `Prior` name-value pair argument of the fitting function.
  - Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the `ClassNames` name-value pair argument of the fitting function.
    - To quickly determine the class order, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for `ClassNames`. For example, suppose the response variable (`Y`) is a cell array of labels. This code specifies the class order in the variable `classNames`.

      ```
      Ycat = categorical(Y);
      classNames = categories(Ycat)
      ```

      `categorical` assigns `<undefined>` to unclassified observations and `categories` excludes `<undefined>` from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.
    - To specify that order should be from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to `ClassNames`. Following from the previous example, this code specifies the class order from lowest- to most-represented in `classNamesLH`.

      ```
      Ycat = categorical(Y);
      classNames = categories(Ycat);
      freq = countcats(Ycat);
      [~,idx] = sort(freq);
      classNamesLH = classNames(idx);
      ```

Algorithms

- For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-39.
- If you specify `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows stumps by default. A decision stump is one root node connected to two terminal, leaf nodes. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.

- The software generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For the RUSBoost ensemble aggregation method (`Method`), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are 2 classes in the training data, *A* and *B*. *A* have 100 observations and *B* have 10 observations. Also, suppose that the lowest-represented class has *m* observations in the training data.
  - If you set `'RatioToSmallest',2`, then *s***m* = `2*10 = 20`. Consequently, the software trains every learner using 20 observations from class *A* and 20 observations from class *B*. If you set `'RatioToSmallest',[2 2]`, then you will obtain the same result.
  - If you set `'RatioToSmallest',[2,1]`, then *s1***m* = `2*10 = 20` and *s2***m* = `1*10 = 10`. Consequently, the software trains every learner using 20 observations from class *A* and 10 observations from class *B*.
- For ensembles of decision trees, and for dual-core systems and above, `fitcensemble` and `fitrensemble` parallelize training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.

Introduced in R2014b

templateKernel

Kernel model template

Syntax

```
t = templateKernel()
t = templateKernel(Name,Value)
```

Description

`templateKernel` creates a template suitable for fitting a Gaussian kernel classification model for nonlinear classification.

The template specifies the binary learner model, number of dimensions of expanded space, kernel scale, box constraint, and regularization strength, among other parameters. After creating the template, train the model by passing the template and data to `fitcecoc`.

`t = templateKernel()` returns a kernel model template.

If you create a default template, then the software uses default values for all input arguments during training.

`t = templateKernel(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. For example, you can implement logistic regression or specify the number of dimensions of the expanded space.

If you display `t` in the Command Window, then some properties of `t` appear empty (`[]`). During training, the software uses default values for the empty properties.

Examples

Create Default Kernel Model Template

Create a default kernel model template and use it to train an error-correcting output codes (ECOC) multiclass model.

Load Fisher's iris data set.

```
load fisheriris
```

Create a default kernel model template.

```
t = templateKernel()
```

```
t =
Fit template for classification Kernel.

             BetaTolerance: []
                 BlockSize: []
             BoxConstraint: []
```

```
                Epsilon: []
    NumExpansionDimensions: []
         GradientTolerance: []
        HessianHistorySize: []
            IterationLimit: []
               KernelScale: []
                    Lambda: []
                   Learner: 'svm'
              LossFunction: []
                    Stream: []
             VerbosityLevel: []
                   Version: 1
                    Method: 'Kernel'
                      Type: 'classification'
```

During training, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t)
```

```
Mdl =
  CompactClassificationECOC
      ResponseName: 'Y'
        ClassNames: {'setosa'  'versicolor'  'virginica'}
    ScoreTransform: 'none'
    BinaryLearners: {3x1 cell}
      CodingMatrix: [3x3 double]

  Properties, Methods
```

`Mdl` is a `CompactClassificationECOC` multiclass classifier.

Specify Kernel Model Template Options

Create a kernel model template with additional options to implement logistic regression with a kernel scale parameter selected by a heuristic procedure.

```
t = templateKernel('Learner','logistic','KernelScale','auto')
```

```
t =
Fit template for classification Kernel.

             BetaTolerance: []
                 BlockSize: []
             BoxConstraint: []
                   Epsilon: []
    NumExpansionDimensions: []
         GradientTolerance: []
        HessianHistorySize: []
            IterationLimit: []
               KernelScale: 'auto'
                    Lambda: []
```

```
          Learner: 'logistic'
     LossFunction: []
           Stream: []
    VerbosityLevel: []
          Version: 1
           Method: 'Kernel'
             Type: 'classification'
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:
`'Learner','logistic','NumExpansionDimensions',2^15,'KernelScale','auto'`
specifies to implement logistic regression after mapping the predictor data to the 2^15 dimensional space using feature expansion with a kernel scale parameter selected by a heuristic procedure.

Kernel Classification Options

`Learner` — Linear classification model type

`'svm'` (default) | `'logistic'`

Linear classification model type, specified as the comma-separated pair consisting of `'Learner'` and `'svm'` or `'logistic'`.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in $\mathbb{R}^p$ to a high-dimensional space ($\mathbb{R}^m$).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
`'svm'`	Support vector machine	$y \in \{-1,1\}$; 1 for the positive class and –1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
`'logistic'`	Logistic regression	Same as `'svm'`	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: `'Learner','logistic'`

`NumExpansionDimensions` — Number of dimensions of expanded space

`'auto'` (default) | positive integer

Number of dimensions of the expanded space, specified as the comma-separated pair consisting of `'NumExpansionDimensions'` and `'auto'` or a positive integer. For `'auto'`, the `templateKernel`

function selects the number of dimensions using `2.^ceil(min(log2(p)+5,15))`, where `p` is the number of predictors.

For details, see “Random Feature Expansion” on page 33-6120.

Example: `'NumExpansionDimensions',2^15`

Data Types: `char` | `string` | `single` | `double`

`KernelScale` — Kernel scale parameter
1 (default) | `'auto'` | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar. The software obtains a random basis for random feature expansion by using the kernel scale parameter. For details, see “Random Feature Expansion” on page 33-6120.

If you specify `'auto'`, then the software selects an appropriate kernel scale parameter using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed by using `rng` before training.

Example: `'KernelScale','auto'`

Data Types: `char` | `string` | `single` | `double`

`BoxConstraint` — Box constraint
1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

This argument is valid only when `'Learner'` is `'svm'`(default) and you do not specify a value for the regularization term strength `'Lambda'`. You can specify either `'BoxConstraint'` or `'Lambda'` because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Example: `'BoxConstraint',100`

Data Types: `single` | `double`

`Lambda` — Regularization term strength
`'auto'` (default) | nonnegative scalar

Regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and `'auto'` or a nonnegative scalar.

For `'auto'`, the value of `'Lambda'` is $1/n$, where n is the number of observations.

You can specify either `'BoxConstraint'` or `'Lambda'` because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$.

Example: `'Lambda',0.01`

Data Types: `char` | `string` | `single` | `double`

Convergence Controls

`BetaTolerance` — Relative tolerance on linear coefficients and bias term
`1e–5` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`GradientTolerance` — Absolute gradient tolerance
`1e-6` (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let $\nabla \mathscr{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t. If $\|\nabla \mathscr{L}_t\|_\infty = \max|\nabla \mathscr{L}_t| <$ GradientTolerance, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

Example: `'GradientTolerance',1e-5`

Data Types: `single` | `double`

`IterationLimit` — Maximum number of optimization iterations
positive integer

Maximum number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The default value is 1000 if the transformed data fits in memory, as specified by the `BlockSize` name-value pair argument. Otherwise, the default value is 100.

Example: `'IterationLimit',500`

Data Types: `single` | `double`

Other Kernel Classification Options

`BlockSize` — Maximum amount of allocated memory
`4e^3` (4GB) (default) | positive scalar

Maximum amount of allocated memory (in megabytes), specified as the comma-separated pair consisting of `'BlockSize'` and a positive scalar.

If `templateKernel` requires more memory than the value of `'BlockSize'` to hold the transformed predictor data, then the software uses a block-wise strategy. For details about the block-wise strategy, see “Algorithms” on page 33-6723.

Example: `'BlockSize',1e4`

Data Types: `single` | `double`

`RandomStream` — Random number stream
global stream (default) | random stream object

Random number stream for reproducibility of data transformation, specified as the comma-separated pair consisting of `'RandomStream'` and a random stream object. For details, see “Random Feature Expansion” on page 33-6120.

Use `'RandomStream'` to reproduce the random basis functions that `templateKernel` uses to transform the predictor data to a high-dimensional space. For details, see “Managing the Global Stream Using RandStream” and “Creating and Controlling a Random Number Stream”.

Example: `'RandomStream',RandStream('mlfg6331_64')`

`HessianHistorySize` — Size of history buffer for Hessian approximation
`15` (default) | positive integer

Size of the history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. At each iteration, `templateKernel` composes the Hessian approximation by using statistics from the latest `HessianHistorySize` iterations.

Example: `'HessianHistorySize',10`

Data Types: `single` | `double`

`Verbose` — Verbosity level
`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either `0` or `1`. `Verbose` controls the display of diagnostic information at the command line.

Value	Description
`0`	`templateKernel` does not display diagnostic information.
`1`	`templateKernel` displays the value of the objective function, gradient magnitude, and other diagnostic information.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

`t` — Kernel model template
template object

Kernel model template, returned as a template object. To train a kernel classification model for multiclass problems, pass `t` to `fitcecoc`.

If you display `t` in the Command Window, then some properties appear empty (`[]`). The software replaces the empty properties with their corresponding default values during training.

More About

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel classification algorithm to use for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

The kernel classification algorithm searches for an optimal hyperplane that separates the data into two classes after mapping features into a high-dimensional space. Nonlinear features that are not linearly separable in a low-dimensional space can be separable in the expanded high-dimensional space. All the calculations for hyperplane classification use only dot products. You can obtain a nonlinear classification model by replacing the dot product x_1x_2' with the nonlinear kernel function $G(x_1, x_2) = \langle\varphi(x_1), \varphi(x_2)\rangle$, where x_i is the ith observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the "kernel trick"). However, evaluating $G(x_1,x_2)$ (Gram matrix) for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle\varphi(x_1), \varphi(x_2)\rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in $\mathbb{R}^p$ to a high-dimensional space ($\mathbb{R}^m$). The Random Kitchen Sink scheme uses the random transformation

$$T(x) = m^{-1/2}\exp(iZx')',$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N\left(0, \sigma^{-2}\right)$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces the computation cost to $O(m\log p)$ and reduces storage to $O(m)$.

The `templateKernel` function uses the Fastfood scheme for random feature expansion and uses linear classification to train a Gaussian kernel classification model. Unlike solvers in the `templateSVM` function, which require computation of the n-by-n Gram matrix, the solver in `templateKernel` only needs to form a matrix of size n-by-m, with m typically much less than n for big data.

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, and aids in preventing overfitting (regularization). Increasing the box constraint can lead to longer training times.

The box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Algorithms

`templateKernel` minimizes the regularized objective function using a Limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) solver with ridge (L_2) regularization. To find the type of LBFGS solver used for training, type `FitInfo.Solver` in the Command Window.

- `'LBFGS-fast'` — LBFGS solver.
- `'LBFGS-blockwise'` — LBFGS solver with a block-wise strategy. If `templateKernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then it uses a block-wise strategy.
- `'LBFGS-tall'` — LBFGS solver with a block-wise strategy for tall arrays.

When `templateKernel` uses a block-wise strategy, `templateKernel` implements LBFGS by distributing the calculation of the loss and gradient among different parts of the data at each iteration. Also, `templateKernel` refines the initial estimates of the linear coefficients and the bias term by fitting the model locally to parts of the data and combining the coefficients by averaging. If you specify `'Verbose',1`, then `templateKernel` displays diagnostic information for each data pass and stores the information in the `History` field of `FitInfo`.

When `templateKernel` does not use a block-wise strategy, the initial estimates are zeros. If you specify `'Verbose',1`, then `templateKernel` displays diagnostic information for each iteration and stores the information in the `History` field of `FitInfo`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations when you train a model by passing a kernel model template and tall arrays to `fitcecoc`:

- The default values for these name-value pair arguments are different when you work with tall arrays.
  - `'Verbose'` — Default value is `1`.
  - `'BetaTolerance'` — Default value is relaxed to `1e–3`.
  - `'GradientTolerance'` — Default value is relaxed to `1e–5`.
  - `'IterationLimit'` — Default value is relaxed to `20`.

- If `'KernelScale'` is `'auto'`, then `templateKernel` uses the random stream controlled by `tallrng` for subsampling. For reproducibility, you must set a random number seed for both the global stream and the random stream controlled by `tallrng`.
- If `'Lambda'` is `'auto'`, then `templateKernel` might take an extra pass through the data to calculate the number of observations.
- `templateKernel` uses a block-wise strategy. For details, see “Algorithms” on page 33-6121.

For more information, see “Tall Arrays”.

`fitcecoc` | `fitckernel`

Introduced in R2018b

templateKNN

k-nearest neighbor classifier template

Syntax

```
t = templateKNN()
t = templateKNN(Name,Value)
```

Description

`t = templateKNN()` returns a *k*-nearest neighbor (KNN) learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcensemble` or `fitcecoc`.

`t = templateKNN(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the nearest neighbor search method, the number of nearest neighbors to find, or the distance metric.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a *k*-Nearest Neighbor Template for Ensemble

Create a nondefault *k*-nearest neighbor template for use in `fitcensemble`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for a 5-nearest neighbor search, and specify to standardize the predictors.

```
t = templateKNN('NumNeighbors',5,'Standardize',1)
```

```
t =
Fit template for classification KNN.

       NumNeighbors: 5
           NSMethod: ''
           Distance: ''
         BucketSize: ''
        IncludeTies: []
```

```
     DistanceWeight: []
         BreakTies: []
          Exponent: []
               Cov: []
             Scale: []
    StandardizeData: 1
            Version: 1
             Method: 'KNN'
               Type: 'classification'
```

All properties of the template object are empty except for `NumNeighbors`, `Method`, `StandardizeData`, and `Type`. When you specify `t` as a learner, the software fills in the empty properties with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitcensemble(meas,species,'Method','Subspace','Learners',t);
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0600
```

Create a *k*-Nearest Neighbor Template for ECOC Multiclass Learning

Create a nondefault *k*-nearest neighbor template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for a 5-nearest neighbor search, and specify to standardize the predictors.

```
t = templateKNN('NumNeighbors',5,'Standardize',1)
```

```
t =
Fit template for classification KNN.

       NumNeighbors: 5
           NSMethod: ''
           Distance: ''
         BucketSize: ''
        IncludeTies: []
     DistanceWeight: []
         BreakTies: []
          Exponent: []
               Cov: []
             Scale: []
    StandardizeData: 1
            Version: 1
             Method: 'KNN'
               Type: 'classification'
```

All properties of the template object are empty except for `NumNeighbors`, `Method`, `StandardizeData`, and `Type`. When you specify `t` as a learner, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0467
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NumNeighbors',4,'Distance','minkowski'` specifies a 4-nearest neighbor classifier template using the Minkowski distance measure.

`BreakTies` — Tie-breaking algorithm

`'smallest'` (default) | `'nearest'` | `'random'`

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies','nearest'`

`BucketSize` — Maximum data points in node

`50` (default) | positive integer value

Maximum number of data points in the leaf node of the *k*d-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize',40`

Data Types: `single` | `double`

`Cov` — Covariance matrix

`cov(X,'omitrows')` (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when `'Distance'` is `'mahalanobis'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

`Distance` — Distance metric
`'cityblock'` | `'chebychev'` | `'correlation'` | `'cosine'` | `'euclidean'` | `'hamming'` | function handle | ...

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see `NSMethod`).

NSMethod	Distance Metric Names
`exhaustive`	Any distance metric of `ExhaustiveSearcher`
`kdtree`	`'cityblock'`, `'chebychev'`, `'euclidean'`, or `'minkowski'`

This table includes valid distance metrics of `ExhaustiveSearcher`.

Distance Metric Names	Description
`'cityblock'`	City block distance.
`'chebychev'`	Chebychev distance (maximum coordinate difference).
`'correlation'`	One minus the sample linear correlation between observations (treated as sequences of values).
`'cosine'`	One minus the cosine of the included angle between observations (treated as vectors).
`'euclidean'`	Euclidean distance.
`'hamming'`	Hamming distance, percentage of coordinates that differ.
`'jaccard'`	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
`'mahalanobis'`	Mahalanobis distance, computed using a positive definite covariance matrix `C`. The default value of `C` is the sample covariance matrix of `X`, as computed by `cov(X,'omitrows')`. To specify a different value for `C`, use the `'Cov'` name-value pair argument.
`'minkowski'`	Minkowski distance. The default exponent is `2`. To specify a different exponent, use the `'Exponent'` name-value pair argument.
`'seuclidean'`	Standardized Euclidean distance. Each coordinate difference between `X` and a query point is scaled, meaning divided by a scale value `S`. The default value of `S` is the standard deviation computed from `X`, `S = std(X,'omitnan')`. To specify another value for `S`, use the `Scale` name-value pair argument.
`'spearman'`	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

Distance Metric Names	Description

`@distfun`	Distance function handle. *`distfun`* has the form
	`function D2 = distfun(ZI,ZJ)`
	`% calculation of  distance`
	`...`
	where
	• `ZI` is a `1`-by-`N` vector containing one row of `X` or `Y`.
	• `ZJ` is an `M2`-by-`N` matrix containing multiple rows of `X` or `Y`.
	• `D2` is an `M2`-by-`1` vector of distances, and `D2(k)` is the distance between observations `ZI` and `ZJ(k,:)`.

If you specify `CategoricalPredictors` as `'all'`, then the default distance metric is `'hamming'`. Otherwise, the default distance metric is `'euclidean'`.

For definitions, see “Distance Metrics” on page 18-12.

Example: `'Distance','minkowski'`

Data Types: `char` | `string` | `function_handle`

`DistanceWeight` — Distance weighting function
`'equal'` (default) | `'inverse'` | `'squaredinverse'` | function handle

Distance weighting function, specified as the comma-separated pair consisting of `'DistanceWeight'` and either a function handle or one of the values in this table.

Value	Description
`'equal'`	No weighting
`'inverse'`	Weight is 1/distance
`'squaredinverse'`	Weight is $1/\text{distance}^2$
`@fcn`	*`fcn`* is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, `'squaredinverse'` is equivalent to `@(d)d.^(-2)`.

Example: `'DistanceWeight','inverse'`

Data Types: `char` | `string` | `function_handle`

`Exponent` — Minkowski distance exponent
2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of `'Exponent'` and a positive scalar value. This argument is only valid when `'Distance'` is `'minkowski'`.

Example: `'Exponent',3`

Data Types: `single` | `double`

`IncludeTies` — Tie inclusion flag
`false` (default) | `true`

Tie inclusion flag, specified as the comma-separated pair consisting of `'IncludeTies'` and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the `K`th smallest distance. If `IncludeTies` is `true`, `predict` includes all these neighbors. Otherwise, `predict` uses exactly `K` neighbors.

Example: `'IncludeTies',true`

Data Types: `logical`

`NSMethod` — Nearest neighbor search method
`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — Creates and uses a *k*d-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
  - `'euclidean'`
  - `'cityblock'`
  - `'minkowski'`
  - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm. When predicting the class of a new point `xnew`, the software computes the distance values from all points in `X` to `xnew` to find nearest neighbors.

The default is `'kdtree'` when `X` has `10` or fewer columns, `X` is not sparse or a `gpuArray`, and the distance metric is a `'kdtree'` type; otherwise, `'exhaustive'`.

Example: `'NSMethod','exhaustive'`

`NumNeighbors` — Number of nearest neighbors to find
`1` (default) | positive integer value

Number of nearest neighbors in `X` to find for classifying each point when predicting, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer value.

Example: `'NumNeighbors',3`

Data Types: `single` | `double`

`Scale` — Distance scale
`std(X,'omitnan')` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of `'Scale'` and a vector containing nonnegative scalar values with length equal to the number of columns in `X`. Each coordinate difference between `X` and a query point is scaled by the corresponding element of `Scale`. This argument is only valid when `'Distance'` is `'seuclidean'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

`Standardize` — Flag to standardize predictors
`false` (default) | `true`

Flag to standardize the predictors, specified as the comma-separated pair consisting of `'Standardize'` and `true` (`1`) or `false` (`0`).

If you set `'Standardize',true`, then the software centers and scales each column of the predictor data (`X`) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify `'Standardize',1` and either of `'Scale'` or `'Cov'`.

It is good practice to standardize the predictor data.

Example: `'Standardize',true`

Data Types: `logical`

Output Arguments

`t` — *k*NN classification template

template object

*k*NN classification template suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcensemble` or `fitcecoc` to specify how to create the KNN classifier for the ensemble or ECOC model, respectively.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

`ClassificationKNN` | `ExhaustiveSearcher` | `fitcecoc` | `fitcensemble`

Topics

“Random Subspace Classification” on page 18-104

Introduced in R2014a

templateLinear

Linear classification learner template

Syntax

```
t = templateLinear()
t = templateLinear(Name,Value)
```

Description

`templateLinear` creates a template suitable for fitting a linear classification model to high-dimensional data for multiclass problems.

The template specifies the binary learner model, regularization type and strength, and solver, among other things. After creating the template, train the model by passing the template and data to `fitcecoc`.

`t = templateLinear()` returns a linear classification learner template.

If you specify a default template, then the software uses default values for all input arguments during training.

`t = templateLinear(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. For example, you can specify to implement logistic regression, specify the regularization type or strength, or specify the solver to use for objective-function minimization.

If you display `t` in the Command Window, then all options appear empty (`[]`) except options that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Train Multiclass Linear Classification Model

Train an ECOC model composed of multiple binary, linear classification models.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

Create a default linear-classification-model template.

```
t = templateLinear();
```

To adjust the default values, see the “Name-Value Pair Arguments” on page 33-6131 on `templateLinear` page.

Train an ECOC model composed of multiple binary, linear classification models that can identify the product given the frequency distribution of words on a documentation web page. For faster training time, transpose the predictor data, and specify that observations correspond to columns.

```
X = X';
rng(1); % For reproducibility
Mdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns')
```

```
Mdl =
  CompactClassificationECOC
      ResponseName: 'Y'
        ClassNames: [1x13 categorical]
    ScoreTransform: 'none'
    BinaryLearners: {78x1 cell}
      CodingMatrix: [13x78 double]

  Properties, Methods
```

Alternatively, you can train an ECOC model composed of default linear classification models using `'Learners','Linear'`.

To conserve memory, `fitcecoc` returns trained ECOC models composed of linear classification learners in `CompactClassificationECOC` model objects.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Learner','logistic','Regularization','lasso','CrossVal','on'` specifies to implement logistic regression with a lasso penalty, and to implement 10-fold cross-validation.

Linear Classification Options

Lambda — Regularization term strength

`'auto'` (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and `'auto'`, a nonnegative scalar, or a vector of nonnegative values.

- For `'auto'`, `Lambda` = 1/*n*.
  - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then *n* is the number of in-fold observations.
  - Otherwise, *n* is the training sample size.
- For a vector of nonnegative values, `templateLinear` sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.

- If `Solver` is `'sgd'` or `'asgd'` and `Regularization` is `'lasso'`, `templateLinear` does not use the previous coefficient estimates as a warm start on page 33-1767 for the next optimization iteration. Otherwise, `templateLinear` uses warm starts.
- If `Regularization` is `'lasso'`, then any coefficient estimate of 0 retains its value when `templateLinear` optimizes using subsequent values in `Lambda`.
- `templateLinear` returns coefficient estimates for each specified regularization strength.

Example: `'Lambda',10.^(-(10:-2:2))`

Data Types: `char` | `string` | `double` | `single`

`Learner` — Linear classification model type
`'svm'` (default) | `'logistic'`

Linear classification model type, specified as the comma-separated pair consisting of `'Learner'` and `'svm'` or `'logistic'`.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
`'svm'`	Support vector machine	$y \in \{-1,1\}$; 1 for the positive class and –1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
`'logistic'`	Logistic regression	Same as `'svm'`	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: `'Learner','logistic'`

`Regularization` — Complexity penalty type
`'lasso'` | `'ridge'`

Complexity penalty type, specified as the comma-separated pair consisting of `'Regularization'` and `'lasso'` or `'ridge'`.

The software composes the objective function for minimization from the sum of the average loss function (see `Learner`) and the regularization term in this table.

Value	Description
`'lasso'`	Lasso (L1) penalty: $\lambda \sum_{j=1}^{p} \left|\beta_j\right|$
`'ridge'`	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^{p} \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use `Lambda`.

The software excludes the bias term (β_0) from the regularization penalty.

If `Solver` is `'sparsa'`, then the default value of `Regularization` is `'lasso'`. Otherwise, the default is `'ridge'`.

Tip

- For predictor variable selection, specify `'lasso'`. For more on variable selection, see “Introduction to Feature Selection” on page 15-49.
- For optimization accuracy, specify `'ridge'`.

Example: `'Regularization','lasso'`

`Solver` — Objective function minimization technique

`'sgd'` | `'asgd'` | `'dual'` | `'bfgs'` | `'lbfgs'` | `'sparsa'` | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description	Restrictions
`'sgd'`	Stochastic gradient descent (SGD) [4][2]	
`'asgd'`	Average stochastic gradient descent (ASGD) [7]	
`'dual'`	Dual SGD for SVM [1][6]	`Regularization` must be `'ridge'` and `Learner` must be `'svm'`.
`'bfgs'`	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [3]	Inefficient if `X` is very high-dimensional.
`'lbfgs'`	Limited-memory BFGS (LBFGS) [3]	`Regularization` must be `'ridge'`.
`'sparsa'`	Sparse Reconstruction by Separable Approximation (SpaRSA) [5]	`Regularization` must be `'lasso'`.

If you specify:

- A ridge penalty (see `Regularization`) and the predictor data set contains 100 or fewer predictor variables, then the default solver is `'bfgs'`.
- An SVM model (see `Learner`), a ridge penalty, and the predictor data set contains more than 100 predictor variables, then the default solver is `'dual'`.
- A lasso penalty and the predictor data set contains 100 or fewer predictor variables, then the default solver is `'sparsa'`.

Otherwise, the default solver is `'sgd'`.

For more details on which solver to choose, see “Tips” on page 33-6141.

Example: `'Solver',{'sgd','lbfgs'}`

`Beta` — Initial linear coefficient estimates

`zeros(p,1)` (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of `'Beta'` and a p-dimensional numeric vector or a p-by-L numeric matrix. p is the number of predictor variables in `X` and L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a p-dimensional vector, then the software optimizes the objective function L times using this process.

  1. The software optimizes using `Beta` as the initial value and the minimum value of `Lambda` as the regularization strength.
  2. The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 33-1767, and the next smallest value in `Lambda` as the regularization strength.
  3. The software implements step 2 until it exhausts all values in `Lambda`.

- If you specify a p-by-L matrix, then the software optimizes the objective function L times. At iteration j, the software uses `Beta(:,j)` as the initial value and, after it sorts `Lambda` in ascending order, uses `Lambda(j)` as the regularization strength.

If you set `'Solver','dual'`, then the software ignores `Beta`.

Data Types: `single` | `double`

`Bias` — Initial intercept estimate

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of `'Bias'` and a numeric scalar or an L-dimensional numeric vector. L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a scalar, then the software optimizes the objective function L times using this process.

  1. The software optimizes using `Bias` as the initial value and the minimum value of `Lambda` as the regularization strength.
  2. The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in `Lambda` as the regularization strength.
  3. The software implements step 2 until it exhausts all values in `Lambda`.

- If you specify an L-dimensional vector, then the software optimizes the objective function L times. At iteration j, the software uses `Bias(j)` as the initial value and, after it sorts `Lambda` in ascending order, uses `Lambda(j)` as the regularization strength.
- By default:

  - If `Learner` is `'logistic'`, then let g_j be 1 if `Y(j)` is the positive class, and -1 otherwise. `Bias` is the weighted average of the g for training or, for cross-validation, in-fold observations.
  - If `Learner` is `'svm'`, then `Bias` is 0.

Data Types: `single` | `double`

`FitBias` — Linear model intercept inclusion flag

`true` (default) | `false`

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of `'FitBias'` and `true` or `false`.

Value	Description
`true`	The software includes the bias term b in the linear model, and then estimates it.
`false`	The software sets $b = 0$ during estimation.

Example: `'FitBias',false`

Data Types: `logical`

`PostFitBias` — Flag to fit linear model intercept after optimization

`false` (default) | `true`

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of `'PostFitBias'` and `true` or `false`.

Value	Description
`false`	The software estimates the bias term b and the coefficients β during optimization.
`true`	To estimate b, the software: **1** Estimates β and b using the model **2** Estimates classification scores **3** Refits b by placing the threshold on the classification scores that attains maximum accuracy

If you specify `true`, then `FitBias` must be true.

Example: `'PostFitBias',true`

Data Types: `logical`

`Verbose` — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either `0` or `1`. `Verbose` controls the display of diagnostic information at the command line.

Value	Description
`0`	`templateLinear` does not display diagnostic information.
`1`	`templateLinear` periodically displays the value of the objective function, gradient magnitude, and other diagnostic information.

Example: `'Verbose',1`

Data Types: `single` | `double`

SGD and ASGD Solver Options

`BatchSize` — Mini-batch size
positive integer

Mini-batch size, specified as the comma-separated pair consisting of `'BatchSize'` and a positive integer. At each iteration, the software estimates the gradient using `BatchSize` observations from the training data.

- If the predictor data is a numeric matrix, then the default value is `10`.
- If the predictor data is a sparse matrix, then the default value is `max([10,ceil(sqrt(ff))])`, where `ff = numel(X)/nnz(X)`, that is, the fullness factor of `X`.

Example: `'BatchSize',100`

Data Types: `single` | `double`

`LearnRate` — Learning rate
positive scalar

Learning rate, specified as the comma-separated pair consisting of `'LearnRate'` and a positive scalar. `LearnRate` controls the optimization step size by scaling the subgradient.

- If `Regularization` is `'ridge'`, then `LearnRate` specifies the initial learning rate γ_0. `templateLinear` determines the learning rate for iteration t, γ_t, using

  $$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

  - λ is the value of `Lambda`.
  - If `Solver` is `'sgd'`, then $c = 1$.
  - If `Solver` is `'asgd'`, then c is 0.75 [7].
- If `Regularization` is `'lasso'`, then, for all iterations, `LearnRate` is constant.

By default, `LearnRate` is `1/sqrt(1+max((sum(X.^2,obsDim))))`, where `obsDim` is `1` if the observations compose the columns of the predictor data `X`, and `2` otherwise.

Example: `'LearnRate',0.01`

Data Types: `single` | `double`

`OptimizeLearnRate` — Flag to decrease learning rate
`true` (default) | `false`

Flag to decrease the learning rate when the software detects divergence (that is, over-stepping the minimum), specified as the comma-separated pair consisting of `'OptimizeLearnRate'` and `true` or `false`.

If `OptimizeLearnRate` is `'true'`, then:

1. For the few optimization iterations, the software starts optimization using `LearnRate` as the learning rate.
2. If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.

3 The software iterates step 2 until the objective function decreases.

Example: `'OptimizeLearnRate',true`

Data Types: `logical`

`TruncationPeriod` — Number of mini-batches between lasso truncation runs

`10` (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of `'TruncationPeriod'` and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing k = `TruncationPeriod` mini-batches, the software truncates the estimated coefficient j using

$$\widehat{\beta}_j^* = \begin{cases} \widehat{\beta}_j - u_t & \text{if } \widehat{\beta}_j > u_t, \\ 0 & \text{if } \left|\widehat{\beta}_j\right| \le u_t, \\ \widehat{\beta}_j + u_t & \text{if } \widehat{\beta}_j < -u_t. \end{cases}$$

- For SGD, $\widehat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t. λ is the value of `Lambda`.
- For ASGD, $\widehat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If `Regularization` is `'ridge'`, then the software ignores `TruncationPeriod`.

Example: `'TruncationPeriod',100`

Data Types: `single` | `double`

SGD and ASGD Convergence Controls

`BatchLimit` — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of `'BatchLimit'` and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
  - The software passes through the data `PassLimit` times.
  - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is `ceil(1e6/BatchSize)`. `BatchSize` is the value of the `'BatchSize'` name-value pair argument.
- If you specify `'BatchLimit'` and `'PassLimit'`, then the software chooses the argument that results in processing the fewest observations.
- If you specify `'BatchLimit'` but not `'PassLimit'`, then the software processes enough batches to complete up to one entire pass through the data.

Example: `'BatchLimit',100`

Data Types: `single` | `double`

`BetaTolerance` — Relative tolerance on linear coefficients and bias term
`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`NumCheckConvergence` — Number of batches to process before next convergence check
positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: `'NumCheckConvergence',100`

Data Types: `single` | `double`

`PassLimit` — Maximal number of passes
`1` (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

The software processes all observations when it completes one pass through the data.

When the software passes through the data `PassLimit` times, it terminates optimization.

If you specify `'BatchLimit'` and `PassLimit`, then the software chooses the argument that results in processing the fewest observations.

Example: `'PassLimit',5`

Data Types: `single` | `double`

Dual SGD Convergence Controls

`BetaTolerance` — Relative tolerance on linear coefficients and bias term
`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`DeltaGradientTolerance` — Gradient-difference tolerance
`1` (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 33-1862 violators, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then the software terminates optimization.
- If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'DeltaGapTolerance',1e-2`

Data Types: `double` | `single`

`NumCheckConvergence` — Number of passes through entire data set to process before next convergence check
`5` (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

Example: `'NumCheckConvergence',100`

Data Types: `single` | `double`

`PassLimit` — Maximal number of passes
`10` (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PassLimit` times, it terminates optimization.

Example: `'PassLimit',5`

Data Types: `single` | `double`

BFGS, LBFGS, and SpaRSA Convergence Controls

`BetaTolerance` — Relative tolerance on linear coefficients and bias term
`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t. If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 <$ BetaTolerance, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance',1e-6`

Data Types: `single` | `double`

`GradientTolerance` — Absolute gradient tolerance
`1e-6` (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let $\nabla \mathscr{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t. If $\|\nabla \mathscr{L}_t\|_\infty = \max|\nabla \mathscr{L}_t| <$ GradientTolerance, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'GradientTolerance',1e-5`

Data Types: `single` | `double`

`HessianHistorySize` — Size of history buffer for Hessian approximation
`15` (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest `HessianHistorySize` iterations.

The software does not support `'HessianHistorySize'` for SpaRSA.

Example: `'HessianHistorySize',10`

Data Types: `single` | `double`

`IterationLimit` — Maximal number of optimization iterations
`1000` (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer. `IterationLimit` applies to these values of `Solver`: `'bfgs'`, `'lbfgs'`, and `'sparsa'`.

Example: `'IterationLimit',500`

Data Types: `single` | `double`

Output Arguments

`t` — Linear classification model learner template

template object

Linear classification model learner template, returned as a template object. To train a linear classification model using high-dimensional data for multiclass problems, pass `t` to `fitcecoc`.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

More About

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn','columns'`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if the predictor data is high-dimensional and `Regularization` is `'ridge'`, set any of these combinations for `Solver`:
  - `'sgd'`
  - `'asgd'`
  - `'dual'` if `Learner` is `'svm'`
  - `{'sgd','lbfgs'}`
  - `{'asgd','lbfgs'}`
  - `{'dual','lbfgs'}` if `Learner` is `'svm'`

  Other combinations can result in poor optimization accuracy.
- For better optimization accuracy if the predictor data is moderate- through low-dimensional and `Regularization` is `'ridge'`, set `Solver` to `'bfgs'`.
- If `Regularization` is `'lasso'`, set any of these combinations for `Solver`:
  - `'sgd'`
  - `'asgd'`
  - `'sparsa'`
  - `{'sgd','sparsa'}`
  - `{'asgd','sparsa'}`
- When choosing between SGD and ASGD, consider that:
  - SGD takes less time per iteration, but requires more iterations to converge.
  - ASGD requires fewer iterations to converge, but takes more time per iteration.

- If the predictor data has few observations, but many predictor variables, then:
  - Specify `'PostFitBias',true`.
  - For SGD or ASGD solvers, set `PassLimit` to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, `BatchSize` affects the rate of convergence.
  - If `BatchSize` is too small, then the software achieves the minimum in many iterations, but computes the gradient per iteration quickly.
  - If `BatchSize` is too large, then the software achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rate (see `LearnRate`) speed-up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- If `Regularization` is `'lasso'`, then experiment with various values of `TruncationPeriod`. For example, set `TruncationPeriod` to `1`, `10`, and then `100`.
- For efficiency, the software does not standardize predictor data. To standardize the predictor data (`X`), enter

  ```
  X = bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2));
  ```

  The code requires that you orient the predictors and observations as the rows and columns of `X`, respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations when you train a model by passing a linear model template and tall arrays to `fitcecoc`:

- The default values for these name-value pair arguments are different when you work with tall arrays.
  - `'Lambda'` — Can be `'auto'` (default) or a scalar
  - `'Regularization'` — Supports only `'ridge'`
  - `'Solver'` — Supports only `'lbfgs'`
  - `'FitBias'` — Supports only `true`
  - `'Verbose'` — Default value is `1`
  - `'BetaTolerance'` — Default value is relaxed to `1e–3`
  - `'GradientTolerance'` — Default value is relaxed to `1e–3`
  - `'IterationLimit'` — Default value is relaxed to `20`
- When `fitcecoc` uses a `templateLinear` object with tall arrays, the only available solver is LBFGS. The software implements LBFGS by distributing the calculation of the loss and gradient among different parts of the tall array at each iteration. If you do not specify initial values for `Beta` and `Bias`, the software refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays”.

Introduced in R2016a

templateNaiveBayes

Naive Bayes classifier template

Syntax

```
t = templateNaiveBayes()
t = templateNaiveBayes(Name,Value)
```

Description

`t = templateNaiveBayes()` returns a naive Bayes on page 33-6148 template suitable for training error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcecoc`.

`t = templateNaiveBayes(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. All properties of `t` are empty, except those you specify using `Name,Value` pair arguments.

For example, you can specify distributions for the predictors.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default Naive Bayes Template

Use `templateNaiveBayes` to specify a default naive Bayes template.

```
t = templateNaiveBayes()
```

```
t =
Fit template for classification NaiveBayes.

    DistributionNames: [1x0 double]
               Kernel: []
              Support: []
                Width: []
              Version: 1
               Method: 'NaiveBayes'
                 Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values. For

example, the software fills the `DistributionNames` property with a 1-by- `D` cell array of character vectors with `'normal'` in each cell, where `D` is the number of predictors. For details on other default values, see `fitcnb`.

`t` is a plan for a naive Bayes learner, and no computation occurs when you specify it. You can pass `t` to `fitcecoc` to specify naive Bayes binary learners for ECOC multiclass learning.

Create a Naive Bayes Template for ECOC Multiclass Learning

Create a nondefault naive Bayes template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for naive Bayes binary classifiers, and specify kernel distributions for all predictors.

```
t = templateNaiveBayes('DistributionNames','kernel')
```

```
t =
Fit template for classification NaiveBayes.

    DistributionNames: 'kernel'
               Kernel: []
              Support: []
                Width: []
              Version: 1
               Method: 'NaiveBayes'
                 Type: 'classification'
```

All properties of the template object are empty except for `DistributionNames`, `Method`, and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0333
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DistributionNames','mn'` specifies to treat all predictors as token counts for a multinomial model.

`DistributionNames` — Data distributions
`'kernel'` | `'mn'` | `'mvmn'` | `'normal'` | string array | cell array of character vectors

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of `'DistributionNames'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description
`'kernel'`	Kernel smoothing density estimate.
`'mn'`	Multinomial distribution. If you specify `mn`, then all features are components of a multinomial distribution. Therefore, you cannot include `'mn'` as an element of a string array or a cell array of character vectors. For details, see “Algorithms” on page 33-1799.
`'mvmn'`	Multivariate multinomial distribution. For details, see “Algorithms” on page 33-1799.
`'normal'`	Normal (Gaussian) distribution.

If you specify a character vector or string scalar, then the software models all the features using that distribution. If you specify a 1-by-*P* string array or cell array of character vectors, then the software models feature *j* using the distribution in element *j* of the array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to `'mvmn'`. Otherwise, the default distribution is `'normal'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'DistributionNames','mn'`

Example: `'DistributionNames',{'kernel','normal','kernel'}`

`Kernel` — Kernel smoother type
`'normal'` (default) | `'box'` | `'epanechnikov'` | `'triangle'` | string array | cell array of character vectors

Kernel smoother type, specified as the comma-separated pair consisting of `'Kernel'` and a character vector or string scalar, a string array, or a cell array of character vectors.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
`'box'`	Box (uniform)	$f(x) = 0.5I\{\|x\| \le 1\}$
`'epanechnikov'`	Epanechnikov	$f(x) = 0.75\left(1 - x^2\right)I\{\|x\| \le 1\}$
`'normal'`	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}}\exp\left(-0.5x^2\right)$
`'triangle'`	Triangular	$f(x) = (1 - \|x\|)I\{\|x\| \le 1\}$

If you specify a 1-by-*P* string array or cell array, with each element of the array containing any value in the table, then the software trains the classifier using the kernel smoother type in element *j* for feature *j* in `X`. The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is `'kernel'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Kernel',{'epanechnikov','normal'}`

`Support` — Kernel smoothing density support
`'unbounded'` (default) | `'positive'` | string array | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of `'Support'` and `'positive'`, `'unbounded'`, a string array, a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, `[L,U]`, where `L` and `U` are the finite lower and upper bounds, respectively, for the density support.
`'positive'`	The density support is all positive real values.
`'unbounded'`	The density support is all real values.

If you specify a 1-by-*P* string array or cell array, with each element in the string array containing any text value in the table and each element in the cell array containing any value in the table, then the software trains the classifier using the kernel support in element *j* for feature *j* in `X`. The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is `'kernel'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'KSSupport',{[-10,20],'unbounded'}`

Data Types: `char` | `string` | `cell` | `double`

`Width` — Kernel smoothing window width
matrix of numeric values | numeric column vector | numeric row vector | scalar

Kernel smoothing window width, specified as the comma-separated pair consisting of `'Width'` and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are *K* class levels and *P* predictors. This table summarizes the available options for setting the kernel smoothing window width.

Value	Description
K-by-*P* matrix of numeric values	Element (*k*,*j*) specifies the width for predictor *j* in class *k*.
K-by-1 numeric column vector	Element *k* specifies the width for all predictors in class *k*.
1-by-*P* numeric row vector	Element *j* specifies the width in all class levels for predictor *j*.
scalar	Specifies the bandwidth for all features in all classes.

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify `Width` and it contains `NaN`s, then the software selects widths for the elements containing `NaN`s.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Width',[NaN NaN]`

Data Types: `double` | `struct`

Output Arguments

`t` — Naive Bayes classification template

template object

Naive Bayes classification template suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcecoc` to specify how to create the naive Bayes classifier for the ECOC model.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

More About

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Although the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm takes these steps:

1. Estimate the densities of the predictors within each class.
2. Model posterior probabilities according to Bayes rule. That is, for all $k = 1,...,K$,

$$\widehat{P}(Y = k \mid X_1, .., X_P) = \frac{\pi(Y = k) \prod_{j=1}^{P} P\left(X_j \middle| Y = k\right)}{\sum_{k=1}^{K} \pi(Y = k) \prod_{j=1}^{P} P\left(X_j \middle| Y = k\right)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
- $X_1,...,X_P$ are the random predictors of an observation.
- $\pi(Y = k)$ is the prior probability that a class index is k.

3 Classify an observation by estimating the posterior probability for each class, and then assign the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability $\widehat{P}(Y = k|X_1, .., X_P) \propto \pi(Y = k)P_{mn}(X_1, ..., X_P|Y = k)$, where $P_{mn}(X_1, ..., X_P|Y = k)$ is the probability mass function of a multinomial distribution.

Algorithms

- If you specify `'DistributionNames','mn'` when training `Mdl` using `fitcnb`, then the software fits a multinomial distribution using the bag-of-tokens model on page 33-1798. The software stores the probability that token j appears in class k in the property `DistributionParameters{k,j}`. Using additive smoothing [2], the estimated probability is

  $$P(\text{token } j \,|\, \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

  where:

  - $c_{j|k} = n_k \frac{\sum_{i:\, y_i \in \text{class } k} x_{ij} w_i}{\sum_{i:\, y_i \in \text{class } k} w_i}$, which is the weighted number of occurrences of token j in class k.
  - n_k is the number of observations in class k.
  - w_i is the weight for observation i. The software normalizes weights within a class such that they sum to the prior probability for that class.
  - $c_k = \sum_{j=1}^{P} c_{j|k}$, which is the total weighted number of occurrences of all tokens in class k.
- If you specify `'DistributionNames','mvmn'` when training `Mdl` using `fitcnb`, then:

  1 For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.

  2 For predictor j in class k, the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.

  3 The software stores the probability that predictor j, in class k, has level L in the property `DistributionParameters{k,j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

  $$P(\text{predictor } j = L \,|\, \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

  where:

- $m_{j|k}(L) = n_k \frac{\sum_{i:y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i:y_i \in \text{class } k} w_i}$, which is the weighted number of observations for which predictor j equals L in class k.
- n_k is the number of observations in class k.
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
- w_i is the weight for observation i. The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j.
- m_k is the weighted number of observations in class k.

Introduced in R2014b

templateSVM

Support vector machine template

Syntax

```
t = templateSVM()
t = templateSVM(Name,Value)
```

Description

`t = templateSVM()` returns a support vector machine (SVM) learner template suitable for training error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a binary learner, or one in a set of binary learners, in `fitcecoc` to train an ECOC multiclass classifier.

`t = templateSVM(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the box constraint, the kernel function, or whether to standardize the predictors.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default Support Vector Machine Template

Use `templateSVM` to specify a default SVM template.

```
t = templateSVM()
```

```
t =
Fit template for classification SVM.

         StandardizeData: []
      SaveSupportVectors: []
          VerbosityLevel: []
                 Version: 2
                  Method: 'SVM'
                    Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values. For example, the software fills the `KernelFunction` property with `'linear'`. For details on other default values, see `fitcsvm`.

`t` is a plan for an SVM learner, and no computation occurs when you specify it. You can pass `t` to `fitcecoc` to specify SVM binary learners for ECOC multiclass learning. However, by default, `fitcecoc` uses default SVM binary learners.

Create an SVM Template for ECOC Multiclass Learning

Create a nondefault SVM template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for SVM binary classifiers, and specify to use a Gaussian kernel function.

```
t = templateSVM('KernelFunction','gaussian')
```

```
t =
Fit template for classification SVM.

                    Alpha: [0x1 double]
             BoxConstraint: []
                 CacheSize: []

             KKTTolerance: []
            IterationLimit: []
            KernelFunction: 'gaussian'
               KernelScale: []
              KernelOffset: []
```

```
    KernelPolynomialOrder: []
                  NumPrint: []
                       Nu: []
            OutlierFraction: []
          RemoveDuplicates: []
           ShrinkagePeriod: []
                    Solver: ''
           StandardizeData: []
       SaveSupportVectors: []
           VerbosityLevel: []
                  Version: 2
                   Method: 'SVM'
                     Type: 'classification'
```

All properties of the template object are empty except for `DistributionNames`, `Method`, and `Type`. When trained on, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

`Mdl` is a `ClassificationECOC` multiclass classifier. By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0200
```

Retain and Discard Support Vectors of SVM Binary Learners

When you train an ECOC model with linear SVM binary learners, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties of the binary learners by default. You can choose instead to retain the support vectors and related values, and then discard them from the model later.

Load Fisher's iris data set.

```
load fisheriris
rng(1); % For reproducibility
```

Train an ECOC model using the entire data set. Specify retaining the support vectors by passing in the appropriate SVM template.

```
t = templateSVM('SaveSupportVectors',true);
MdlSV = fitcecoc(meas,species,'Learners',t);
```

`MdlSV` is a trained `ClassificationECOC` model with linear SVM binary learners. By default, `fitcecoc` implements a one-versus-one coding design, which requires three binary learners for three-class learning.

Access the estimated α (alpha) values using dot notation.

```
alpha = cell(3,1);
alpha{1} = MdlSV.BinaryLearners{1}.Alpha;
alpha{2} = MdlSV.BinaryLearners{2}.Alpha;
alpha{3} = MdlSV.BinaryLearners{3}.Alpha;
alpha
```

```
alpha=3×1 cell array
    { 3x1 double}
    { 3x1 double}
    {23x1 double}
```

`alpha` is a 3-by-1 cell array that stores the estimated values of α.

Discard the support vectors and related values from the ECOC model.

```
Mdl = discardSupportVectors(MdlSV);
```

`Mdl` is similar to `MdlSV`, except that the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties of all the linear SVM binary learners are empty (`[]`).

```
areAllEmpty = @(x)isempty([x.Alpha x.SupportVectors x.SupportVectorLabels]);
cellfun(areAllEmpty,Mdl.BinaryLearners)
```

```
ans = 3x1 logical array

   1
   1
   1
```

Compare the sizes of the two ECOC models.

```
vars = whos('Mdl','MdlSV');
100*(1 - vars(1).bytes/vars(2).bytes)
```

```
ans = 4.7075
```

`Mdl` is about 5% smaller than `MdlSV`.

Reduce your memory usage by compacting `Mdl` and then clearing `Mdl` and `MdlSV` from the workspace.

```
CompactMdl = compact(Mdl);
clear Mdl MdlSV;
```

Predict the label for a random row of the training data using the more efficient SVM model.

```
idx = randsample(size(meas,1),1)
```

```
idx = 63
```

```
predictedLabel = predict(CompactMdl,meas(idx,:))
```

```
predictedLabel = 1x1 cell array
    {'versicolor'}
```

```
trueLabel = species(idx)
```

```
trueLabel = 1x1 cell array
    {'versicolor'}
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'BoxConstraint',0.1,'KernelFunction','gaussian','Standardize',1` specifies a box constraint of `0.1`, to use the Gaussian (RBF) kernel, and to standardize the predictors.

`BoxConstraint` — Box constraint
1 (default) | positive scalar

Box constraint on page 33-1862, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

For one-class learning, the software always sets the box constraint to `1`.

For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see "Algorithms" on page 33-1865.

Example: `'BoxConstraint',100`

Data Types: `double` | `single`

`CacheSize` — Cache size
`1000` (default) | `'maximal'` | positive scalar

Cache size, specified as the comma-separated pair consisting of `'CacheSize'` and `'maximal'` or a positive scalar.

If `CacheSize` is `'maximal'`, then the software reserves enough memory to hold the entire *n*-by-*n* Gram matrix on page 33-1862.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of memory for training the model.

Example: `'CacheSize','maximal'`

Data Types: `double` | `single` | `char` | `string`

`ClipAlphas` — Flag to clip alpha coefficients
`true` (default) | `false`

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of `'ClipAlphas'` and either `true` or `false`.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is C_j, $j = 1,...,n$, where n is the training sample size.

Value	Description
`true`	At each iteration, if α_j is near 0 or near C_j, then MATLAB sets α_j to 0 or to C_j, respectively.
`false`	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the `Alpha` property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: `'ClipAlphas',false`

Data Types: `logical`

`DeltaGradientTolerance` — Tolerance for gradient difference
nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

If `DeltaGradientTolerance` is `0`, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The default values are:

- `1e-3` if the solver is SMO (for example, you set `'Solver','SMO'`)
- `0` if the solver is ISDA (for example, you set `'Solver','ISDA'`)

Example: `'DeltaGradientTolerance',1e-2`

Data Types: `double` | `single`

`GapTolerance` — Feasibility gap tolerance
`0` (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of `'GapTolerance'` and a nonnegative scalar.

If `GapTolerance` is `0`, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: `'GapTolerance',1e-2`

Data Types: `double` | `single`

`IterationLimit` — Maximal number of numerical optimization iterations
`1e6` (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: `'IterationLimit',1e8`

Data Types: `double` | `single`

`KernelFunction` — Kernel function

`'linear'` | `'gaussian'` | `'rbf'` | `'polynomial'` | function name

Kernel function used to compute the elements of the Gram matrix on page 33-1862, specified as the comma-separated pair consisting of `'KernelFunction'` and a kernel function name. Suppose $G(x_j,x_k)$ is element (j,k) of the Gram matrix, where x_j and x_k are p-dimensional vectors representing observations j and k in `X`. This table describes supported kernel function names and their functional forms.

Kernel Function Name	Description	Formula
`'gaussian'` or `'rbf'`	Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning	$G(x_j, x_k) = \exp\left(-\|x_j - x_k\|^2\right)$
`'linear'`	Linear kernel, default for two-class learning	$G(x_j, x_k) = x_j' x_k$
`'polynomial'`	Polynomial kernel. Use `'PolynomialOrder',q` to specify a polynomial kernel of order q.	$G(x_j, x_k) = (1 + x_j' x_k)^q$

You can set your own kernel function, for example, `kernel`, by setting `'KernelFunction','kernel'`. The value `kernel` must have this form.

```
function G = kernel(U,V)
```

where:

- `U` is an m-by-p matrix. Columns correspond to predictor variables, and rows correspond to observations.
- `V` is an n-by-p matrix. Columns correspond to predictor variables, and rows correspond to observations.
- `G` is an m-by-n Gram matrix on page 33-1862 of the rows of `U` and `V`.

`kernel.m` must be on the MATLAB path.

It is a good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function `'mysigmoid'` rather than `'sigmoid'`.

Example: `'KernelFunction','gaussian'`

Data Types: `char` | `string`

`KernelOffset` — Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of `'KernelOffset'` and a nonnegative scalar.

The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- `0` if the solver is SMO (that is, you set `'Solver','SMO'`)

- `0.1` if the solver is ISDA (that is, you set `'Solver','ISDA'`)

Example: `'KernelOffset',0`

Data Types: `double` | `single`

`KernelScale` — Kernel scale parameter
`1` (default) | `'auto'` | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of `'KernelScale'` and `'auto'` or a positive scalar. The software divides all elements of the predictor matrix `X` by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify `'auto'`, then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using `rng` before training.
- If you specify `KernelScale` and your own kernel function, for example, `'KernelFunction','kernel'`, then the software throws an error. You must apply scaling within `kernel`.

Example: `'KernelScale','auto'`

Data Types: `double` | `single` | `char` | `string`

`KKTTolerance` — Karush-Kuhn-Tucker complementarity conditions violation tolerance
nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions on page 33-1862 violation tolerance, specified as the comma-separated pair consisting of `'KKTTolerance'` and a nonnegative scalar.

If `KKTTolerance` is `0`, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The default values are:

- `0` if the solver is SMO (for example, you set `'Solver','SMO'`)
- `1e-3` if the solver is ISDA (for example, you set `'Solver','ISDA'`)

Example: `'KKTTolerance',1e-2`

Data Types: `double` | `single`

`NumPrint` — Number of iterations between optimization diagnostic message output
`1000` (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you specify `'Verbose',1` and `'NumPrint',numprint`, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: `'NumPrint',500`

Data Types: `double` | `single`

`OutlierFraction` — Expected proportion of outliers in training data
`0` (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of `'OutlierFraction'` and a numeric scalar in the interval [0,1).

Suppose that you set `'OutlierFraction',outlierfraction`, where `outlierfraction` is a value greater than 0.

- For two-class learning, the software implements robust learning. In other words, the software attempts to remove 100*`outlierfraction`% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that `outlierfraction` of the observations in the training set have negative scores.

Example: `'OutlierFraction',0.01`

Data Types: `double` | `single`

`PolynomialOrder` — Polynomial kernel function order
3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer.

If you set `'PolynomialOrder'` and `KernelFunction` is not `'polynomial'`, then the software throws an error.

Example: `'PolynomialOrder',2`

Data Types: `double` | `single`

`SaveSupportVectors` — Store support vectors, their labels, and the estimated *α* coefficients
`true` | `false`

Store support vectors, their labels, and the estimated *α* coefficients as properties of the resulting model, specified as the comma-separated pair consisting of `'SaveSupportVectors'` and `true` or `false`.

If `SaveSupportVectors` is `true`, the resulting model stores the support vectors in the `SupportVectors` property, their labels in the `SupportVectorLabels` property, and the estimated *α* coefficients in the `Alpha` property of the compact, SVM learners.

If `SaveSupportVectors` is `false` and `KernelFunction` is `'linear'`, the resulting model does not store the support vectors and the related estimates.

To reduce memory consumption by compact SVM models, specify `SaveSupportVectors`.

For linear, SVM binary learners in an ECOC model, the default value is `false`. Otherwise, the default value is `true`.

Example: `'SaveSupportVectors',true`

Data Types: `logical`

ShrinkagePeriod — Number of iterations between reductions of active set
0 (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod',0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod',1000

Data Types: double | single

Solver — Optimization routine
'ISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

Value	Description
'ISDA'	Iterative Single Data Algorithm (see [30])
'L1QP'	Uses quadprog to implement $L1$ soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see "Quadratic Programming Definition" (Optimization Toolbox).
'SMO'	Sequential Minimal Optimization (see [17])

The default value is 'ISDA' if you set 'OutlierFraction' to a positive value for two-class learning, and 'SMO' otherwise.

Example: 'Solver','ISDA'

Standardize — Flag to standardize predictor data
false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize',true:

- The software centers and scales each column of the predictor data (X) by the weighted column mean and standard deviation, respectively (for details on weighted standardizing, see "Algorithms" on page 33-1865). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the classifier using the standardized predictor matrix, but stores the unstandardized data in the classifier property X.

Example: 'Standardize',true

Data Types: logical

Verbose — Verbosity level
0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0`, `1`, or `2`. The value of `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software does not display or save convergence information.
`1`	The software displays diagnostic messages and saves convergence criteria every `numprint` iterations, where `numprint` is the value of the name-value pair argument `'NumPrint'`.
`2`	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: `'Verbose',1`

Data Types: `double` | `single`

Output Arguments

`t` — SVM classification template

template object

SVM classification template suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcecoc` to specify how to create the SVM classifier for the ECOC model.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Tip

By default and for efficiency, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties for all linear SVM binary learners. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors',true)
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

`ClassificationECOC` | `ClassificationSVM` | `fitcecoc` | `fitcsvm`

Introduced in R2014b

templateTree

Create decision tree template

Syntax

```
t = templateTree
t = templateTree(Name,Value)
```

Description

`t = templateTree` returns a default decision tree learner template suitable for training an ensemble (boosted and bagged decision trees) or error-correcting output code (ECOC) multiclass model. Specify `t` as a learner using:

- `fitcensemble` for classification ensembles
- `fitrensemble` for regression ensembles
- `fitcecoc` for ECOC model classification

If you specify a default decision tree template, then the software uses default values for all input arguments during training. It is good practice to specify the type of decision tree, e.g., for a classification tree template, specify `'Type','classification'`. If you specify the type of decision tree and display `t` in the Command Window, then all options except `Type` appear empty (`[]`).

`t = templateTree(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the algorithm used to find the best split on a categorical predictor, the split criterion, or the number of predictors selected for each split.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Classification Template with Surrogate Splits

Create a decision tree template with surrogate splits, and use the template to train an ensemble using sample data.

Load Fisher's iris data set.

```
load fisheriris
```

Create a decision tree template of tree stumps with surrogate splits.

```
t = templateTree('Surrogate','on','MaxNumSplits',1)
```

```
t =
Fit template for Tree.
```

```
       Surrogate: 'on'
    MaxNumSplits: 1
```

Options for the template object are empty except for `Surrogate` and `MaxNumSplits`. When you pass `t` to the training function, the software fills in the empty options with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t)
```

```
Mdl =
  ClassificationEnsemble
              ResponseName: 'Y'
    CategoricalPredictors: []
               ClassNames: {'setosa'  'versicolor'  'virginica'}
           ScoreTransform: 'none'
          NumObservations: 150
               NumTrained: 100
                   Method: 'AdaBoostM2'
             LearnerNames: {'Tree'}
     ReasonForTermination: 'Terminated normally after completing the requested number of training
                  FitInfo: [100x1 double]
       FitInfoDescription: {2x1 cell}

  Properties, Methods
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0333
```

Optimize Regression Ensemble Using Cross-Validation

One way to create an ensemble of boosted regression trees that has satisfactory predictive performance is to tune the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles as well.

This example manually finds optimal parameters by using the cross-validation option (the `'KFold'` name-value pair argument) and the `kfoldLoss` function. Alternatively, you can use the `'OptimizeHyperparameters'` name-value pair argument to optimize hyperparameters automatically. See “Optimize Regression Ensemble” on page 33-2314.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

The default values of the tree depth controllers for boosting regression trees are:

- `10` for `MaxNumSplits`.

- `5` for `MinLeafSize`
- `10` for `MinParentSize`

To search for the optimal tree-complexity level:

1. Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most n - 1 splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.
2. Estimate the cross-validated mean-squared error (MSE) for each ensemble.
3. For tree-complexity level j, $j = 1 \ldots J$, compare the cumulative, cross-validated MSE of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
4. Choose the curve that achieves the minimal MSE, and note the corresponding learning cycle and learning rate.

Cross-validate a deep regression tree and a stump. Because the data contain missing values, use surrogate splits. These regression trees serve as benchmarks.

```
rng(1) % For reproducibility
MdlDeep = fitrtree(Tbl,'MPG','CrossVal','on','MergeLeaves','off', ...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(Tbl,'MPG','MaxNumSplits',1,'CrossVal','on', ...
    'Surrogate','on');
```

Cross-validate an ensemble of 150 boosted regression trees using 5-fold cross-validation. Using a tree template:

- Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \ldots, 2^m\}$. m is such that 2^m is no greater than n - 1.
- Turn on surrogate splits.

For each variant, adjust the learning rate using each value in the set {0.1, 0.25, 0.5, 1}.

```
n = size(Tbl,1);
m = floor(log2(n - 1));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 2.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);

for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitrensemble(Tbl,'MPG','NumLearningCycles',numTrees, ...
            'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end
end
```

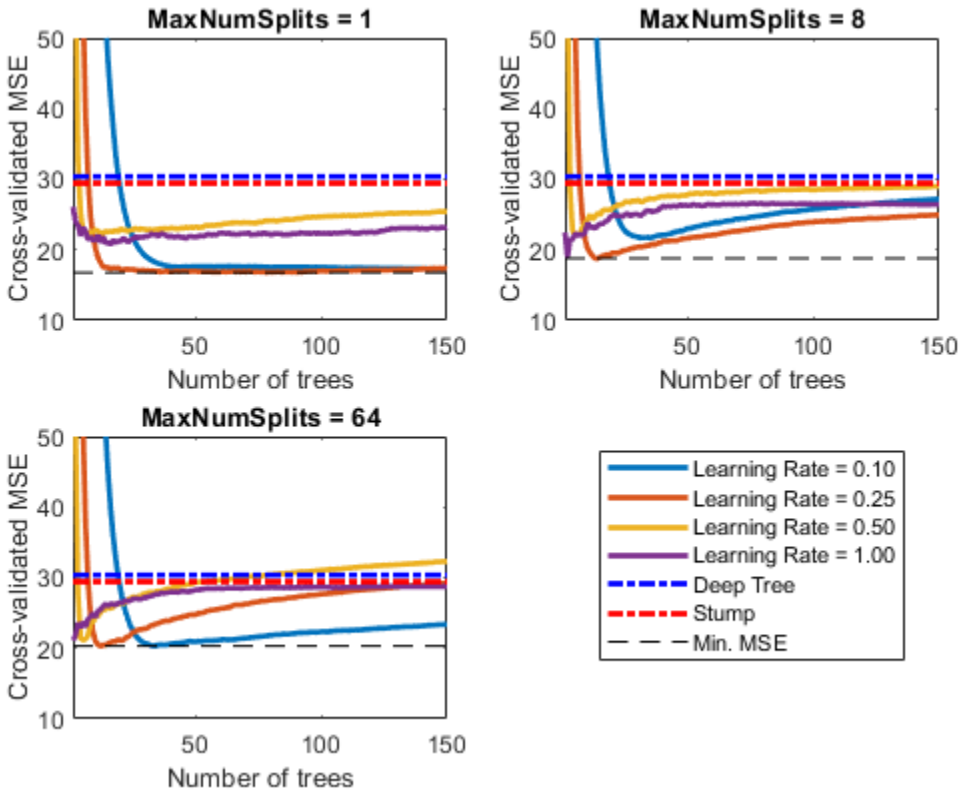
Estimate the cumulative, cross-validated MSE of each ensemble.

```
kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
```

```
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);
```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```
mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3
    subplot(2,2,k)
    plot(squeeze(error(:,mnsPlot(k),:)),'LineWidth',2)
    axis tight
    hold on
    h = gca;
    plot(h.XLim,[errorDeep errorDeep],'-.b','LineWidth',2)
    plot(h.XLim,[errorStump errorStump],'-.r','LineWidth',2)
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1],'--k')
    h.YLim = [10 50];
    xlabel('Number of trees')
    ylabel('Cross-validated MSE')
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
    hold off
end
hL = legend([cellstr(num2str(learnRate','Learning Rate = %0.2f')); ...
        'Deep Tree';'Stump';'Min. MSE']);
hL.Position(1) = 0.6;
```



Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);
fprintf('\nMin. MSE = %0.5f',minErr)
```

```
Min. MSE = 16.77593
```

```
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
```

```
Optimal Parameter Values:
Num. Trees = 78
```

```
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...
    maxNumSplits(idxMNS),learnRate(idxLR))
```

```
MaxNumSplits = 1
Learning Rate = 0.25
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```
tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS),'Surrogate','on');
MdlFinal = fitrensemble(Tbl,'MPG','NumLearningCycles',idxNumTrees, ...
    'Learners',tFinal,'LearnRate',learnRate(idxLR))
```

```
MdlFinal =
  RegressionEnsemble

           Regularization: []

  Properties, Methods
```

`MdlFinal` is a `RegressionEnsemble`. To predict the fuel economy of a car given its number of cylinders, volume displaced by the cylinders, horsepower, and weight, you can pass the predictor data and `MdlFinal` to `predict`.

Instead of searching optimal values manually by using the cross-validation option (`'KFold'`) and the `kfoldLoss` function, you can use the `'OptimizeHyperparameters'` name-value pair argument. When you specify `'OptimizeHyperparameters'`, the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using `'OptimizeHyperparameters'` can be different from those obtained using manual search.

```
t = templateTree('Surrogate','on');
mdl = fitrensemble(Tbl,'MPG','Learners',t, ...
    'OptimizeHyperparameters',{'NumLearningCycles','LearnRate','MaxNumSplits'})
```

```

  Properties, Methods
```

Unbiased Estimates of Predictor Importance Using Parallel Computing

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```
numMfg = 28
```

```
numModelYear = numel(categories(Model_Year))
```

```
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 500 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. To reproduce random predictor selections, set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

```
rng('default'); % For reproducibility
t = templateTree('PredictorSelection','curvature','Surrogate','on', ...
    'Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitrensemble(X,'MPG','Method','bag','NumLearningCycles',500, ...
    'Learners',t);
```

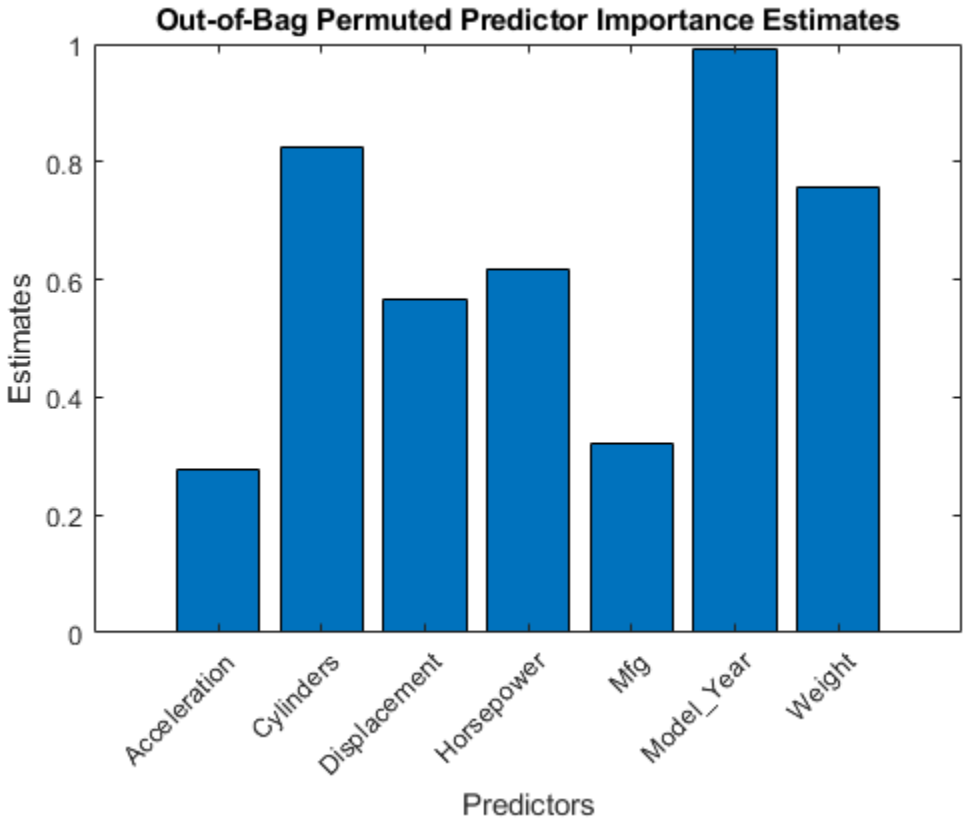
Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel.

```
options = statset('UseParallel',true);
imp = oobPermutedPredictorImportance(Mdl,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Compare the estimates using a bar graph.

```
figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```



In this case, `Model_Year` is the most important predictor, followed by `Cylinders`. Compare these results to the results in “Estimate Importance of Predictors” on page 33-4355.

Create an Ensemble Template for ECOC Multiclass Learning

Create an ensemble template for use in `fitcecoc`.

Load the arrhythmia data set.

```
load arrhythmia
tabulate(categorical(Y));
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
```

```
     15        5      1.11%
     16       22      4.87%
```

```
rng(1); % For reproducibility
```

Some classes have small relative frequencies in the data.

Create a template for a AdaBoostM1 ensemble of classification trees, and specify to use 100 learners and a shrinkage of 0.1. By default, boosting grows stumps (i.e., one node having a set of leaves). Since there are classes with small frequencies, the trees must be leafy enough to be sensitive to the minority classes. Specify the minimum number of leaf node observations to 3.

```
tTree = templateTree('MinLeafSize',20);
t = templateEnsemble('AdaBoostM1',100,tTree,'LearnRate',0.1);
```

All properties of the template objects are empty except for `Method` and `Type`, and the corresponding properties of the name-value pair argument values in the function calls. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

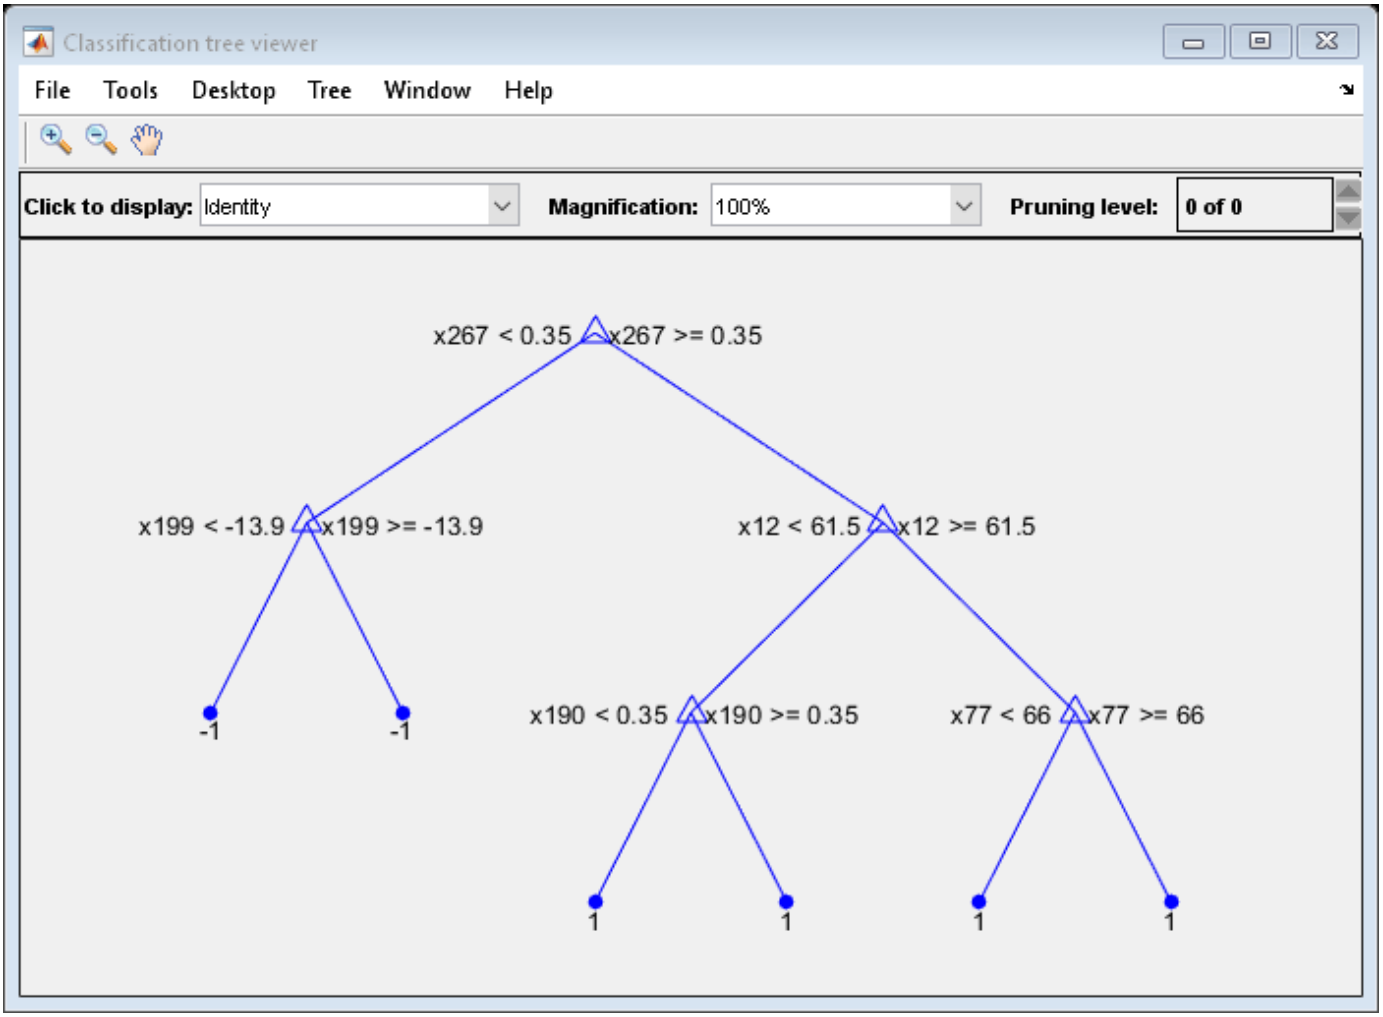
Specify `t` as a binary learner for an ECOC multiclass model. Train using the default one-versus-one coding design.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

- `Mdl` is a `ClassificationECOC` multiclass model.
- `Mdl.BinaryLearners` is a 78-by-1 cell array of `CompactClassificationEnsemble` models.
- `Mdl.BinaryLearners{j}.Trained` is a 100-by-1 cell array of `CompactClassificationTree` models, for `j` = 1,...,78.

You can verify that one of the binary learners contains a weak learner that isn't a stump by using `view`.

```
view(Mdl.BinaryLearners{1}.Trained{1},'Mode','graph')
```



Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0819
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Surrogate','on','NumVariablesToSample','all'` specifies a template with surrogate splits, and uses all available predictors at each split.

For Classification Trees and Regression Trees

`MaxNumSplits` — Maximal number of decision splits
positive integer

Maximal number of decision splits (or branch nodes) per tree, specified as the comma-separated pair consisting of `'MaxNumSplits'` and a positive integer. `templateTree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see “Algorithms” on page 33-6181.

For bagged decision trees and decision tree binary learners in ECOC models, the default is *n* – *1*, where *n* is the number of observations in the training sample. For boosted decision trees, the default is `10`.

Example: `'MaxNumSplits',5`

Data Types: `single` | `double`

`MergeLeaves` — Leaf merge flag
`'off'` | `'on'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and either `'on'` or `'off'`.

When `'on'`, the decision tree merges leaves that originate from the same parent node, and that provide a sum of risk values greater or equal to the risk associated with the parent node. When `'off'`, the decision tree does not merge leaves.

For boosted and bagged decision trees, the defaults are `'off'`. For decision tree binary learners in ECOC models, the default is `'on'`.

Example: `'MergeLeaves','on'`

`MinLeafSize` — Minimum observations per leaf
positive integer value

Minimum observations per leaf, specified as the comma-separated pair consisting of `'MinLeafSize'` and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, the decision tree uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

For boosted and bagged decision trees, the defaults are `1` for classification and `5` for regression. For decision tree binary learners in ECOC models, the default is `1`.

Example: `'MinLeafSize',2`

`MinParentSize` — Minimum observations per branch node
positive integer value

Minimum observations per branch node, specified as the comma-separated pair consisting of `'MinParentSize'` and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, the decision tree uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

- If you specify `MinLeafSize`, then the default value for `'MinParentSize'` is `10`.
- If you do not specify `MinLeafSize`, then the default value changes depending on the training model. For boosted and bagged decision trees, the default value is `2` for classification and `10` for regression. For decision tree binary learners in ECOC models, the default value is `10`.

Example: `'MinParentSize',4`

`NumVariablesToSample` — Number of predictors to select at random for each split
positive integer value | `'all'`

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. Alternatively, you can specify `'all'` to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify `'NumVariablesToSample'` as `'all'`. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

For boosted decision trees and decision tree binary learners in ECOC models, the default is `'all'`. The default for bagged decision trees is the square root of the number of predictors for classification, or one third of the number of predictors for regression.

Example: `'NumVariablesToSample',3`

Data Types: `single` | `double` | `char` | `string`

`PredictorSelection` — Algorithm used to select the best split predictor
`'allsplits'` (default) | `'curvature'` | `'interaction-curvature'`

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of `'PredictorSelection'` and a value in this table.

Value	Description
`'allsplits'`	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].
`'curvature'`	Curvature test — Selects the split predictor that minimizes the *p*-value of chi-square tests of independence between each predictor and the response [3][4]. Training speed is similar to standard CART.
`'interaction-curvature'`	Interaction test — Chooses the split predictor that minimizes the *p*-value of chi-square tests of independence between each predictor and the response, and that minimizes the *p*-value of a chi-square test of independence between each pair of predictors and response [3]. Training speed can be slower than standard CART.

For `'curvature'` and `'interaction-curvature'`, if all tests yield *p*-values greater than 0.05, then MATLAB stops splitting nodes.

Tip

- The curvature and interaction tests are not recommended for boosting decision trees. To train an ensemble of boosted trees that has greater accuracy, use standard CART instead.
- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.

- If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
- If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `oobPermutedPredictorImportance` for classification problems, `oobPermutedPredictorImportance` for regression problems, and "Introduction to Feature Selection" on page 15-49.

- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [3].
- Prediction speed is unaffected by the value of `'PredictorSelection'`.

For details on how `templateTree` selects split predictors, see "Node Splitting Rules" on page 33-1928 (classification), "Node Splitting Rules" on page 33-2413 (regression), and "Choose Split Predictor Selection Technique" on page 19-14.

Example: `'PredictorSelection','curvature'`

`Prune` — Flag to estimate optimal sequence of pruned subtrees
`'off'` | `'on'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then the software trains the classification tree learners without pruning them, but estimates the optimal sequence of pruned subtrees for each learner in the ensemble or decision tree binary learner in ECOC models. Otherwise, the software trains the classification tree learners without estimating the optimal sequence of pruned subtrees.

For boosted and bagged decision trees, the default is `'off'`.

For decision tree binary learners in ECOC models, the default is `'on'`.

Example: `'Prune','on'`

`PruneCriterion` — Pruning criterion
`'error'` | `'impurity'` | `'mse'`

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and a pruning criterion valid for the tree type.

- For classification trees, you can specify `'error'` (default) or `'impurity'`. If you specify `'impurity'`, then `templateTree` uses the impurity measure specified by the `'SplitCriterion'` name-value pair argument.
- For regression trees, you can specify only `'mse'`(default).

Example: `'PruneCriterion','impurity'`

`Reproducible` — Flag to enforce reproducibility
`false` (logical `0`) (default) | `true` (logical `1`)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of `'Reproducible'` and either `false` or `true`.

If `'NumVariablesToSample'` is not `'all'`, then the software selects predictors at random for each split. To reproduce the random selections, you must specify `'Reproducible',true` and set the seed of the random number generator by using `rng`. Note that setting `'Reproducible'` to `true` can slow down training.

Example: `'Reproducible',true`

Data Types: `logical`

`SplitCriterion` — Split criterion
`'gdi'` | `'twoing'` | `'deviance'` | `'mse'`

Split criterion, specified as the comma-separated pair consisting of `'SplitCriterion'` and a split criterion valid for the tree type.

- For classification trees:
  - `'gdi'` for Gini's diversity index (default)
  - `'twoing'` for the twoing rule
  - `'deviance'` for maximum deviance reduction (also known as cross entropy)
- For regression trees:
  - `'mse'` for mean squared error (default)

Example: `'SplitCriterion','deviance'`

`Surrogate` — Surrogate decision splits
`'off'` (default) | `'on'` | `'all'` | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of `'Surrogate'` and one of `'off'`, `'on'`, `'all'`, or a positive integer value.

- When `'off'`, the decision tree does not find surrogate splits at the branch nodes.
- When `'on'`, the decision tree finds at most 10 surrogate splits at each branch node.
- When set to `'all'`, the decision tree finds all surrogate splits at each branch node. The `'all'` setting can consume considerable time and memory.
- When set to a positive integer value, the decision tree finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. This setting also lets you compute measures of predictive association between predictors.

Example: `'Surrogate','on'`

Data Types: `single` | `double` | `char` | `string`

`Type` — Decision tree type
`'classification'` | `'regression'`

Decision tree type, specified as a value in the table

Value	Description
`'classification'`	Grow classification tree learners. The fitting functions `fitcensemble` and `fitcecoc` set this value when you pass `t` to them.
`'regression'`	Grow regression tree learners. The fitting function `fitrensemble` sets this value when you pass `t` to it.

Tip Although `t` infers `Type` from the fitting function to which it is supplied, the following occur when you set `Type`:

- The display of `t` shows all options. Each unspecified option is an empty array `[]`.
- `templateTree` checks specifications for errors.

Example: `'Type','classification'`

Data Types: `char` | `string`

For Classification Trees Only

`AlgorithmForCategorical` — Algorithm for best categorical predictor split
`'Exact'` | `'PullLeft'` | `'PCA'` | `'OVAbyClass'`

Algorithm to find the best split on a categorical predictor for data with C categories for data and $K \geq 3$ classes, specified as the comma-separated pair consisting of `'AlgorithmForCategorical'` and one of the following.

Value	Description
`'Exact'`	Consider all $2^{C-1} - 1$ combinations.
`'PullLeft'`	Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.
`'PCA'`	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.

Value	Description
`'OVAbyClass'`	Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

The software selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, it always performs the exact search. Use the `'AlgorithmForCategorical'` name-value pair argument to specify a particular algorithm.

For more details, see “Splitting Categorical Predictors in Classification Trees” on page 19-25.

Example: `'AlgorithmForCategorical','PCA'`

`MaxNumCategories` — Maximum category levels in split node
`10` (default) | nonnegative scalar value

Maximum category levels in the split node, specified as the comma-separated pair consisting of `'MaxNumCategories'` and a nonnegative scalar value. A classification tree splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxNumCategories` levels in the split node. Otherwise, it finds the best categorical split using one of the inexact algorithms. Note that passing a small value can increase computation time and memory overload.

Example: `'MaxNumCategories',8`

For Regression Trees Only

`QuadraticErrorTolerance` — Quadratic error tolerance
`1e-6` (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of `'QuadraticErrorTolerance'` and a positive scalar value. A regression tree stops splitting nodes when the weighted mean squared error per node drops below `QuadraticErrorTolerance`$*\varepsilon$, where ε is the weighted mean squared error of all n responses computed before growing the decision tree.

$$\varepsilon = \sum_{i=1}^{n} w_i (y_i - \bar{y})^2 .$$

w_i is the weight of observation i, given that the weights of all the observations sum to one ($\sum_{i=1}^{n} w_i = 1$), and

$$\bar{y} = \sum_{i=1}^{n} w_i y_i$$

is the weighted average of all the responses.

Example: `'QuadraticErrorTolerance',1e-4`

Output Arguments

`t` — Decision tree template for classification or regression

template object

Decision tree template for classification or regression suitable for training an ensemble (boosted and bagged decision trees) or error-correcting output code (ECOC) multiclass model, returned as a template object. Pass `t` to `fitcensemble`, or `fitrensemble`, or `fitcecoc` to specify how to create the decision tree for the classification ensemble, regression ensemble, or ECOC model, respectively.

If you display `t` in the Command Window, then all unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Algorithms

- To accommodate `MaxNumSplits`, the software splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, then the software follows this procedure.

  1. Determine how many branch nodes in the current layer need to be unsplit so that there would be at most `MaxNumSplits` branch nodes.
  2. Sort the branch nodes by their impurity gains.
  3. Unsplit the desired number of least successful branches.
  4. Return the decision tree grown so far.

  This procedure aims at producing maximally balanced trees.
- The software splits branch nodes layer by layer until at least one of these events occurs.

  - There are `MaxNumSplits` + 1 branch nodes.
  - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
  - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.
  - The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case of this event is when all nodes are pure (i.e., all observations in the node have the same class).
  - For values `'curvature'` or `'interaction-curvature'` of `PredictorSelection`, all tests yield *p*-values greater than 0.05.

  `MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set `'MaxNumSplits'`, then splitting might stop due to the value of `MinParentSize` before `MaxNumSplits` splits occur.
- For details on selecting split predictors and node-splitting algorithms when growing decision trees, see “Algorithms” on page 33-1928 for classification trees and “Algorithms” on page 33-2413 for regression trees.

Introduced in R2014a

test

Test indices for cross-validation

Syntax

```
idx = test(c)
idx = test(c,i)
```

Description

`idx = test(c)` returns the test indices `idx` for a `cvpartition` object `c` of type `'holdout'` or `'resubstitution'`.

- If `c.Type` is `'holdout'`, then `idx` specifies the observations in the test set.
- If `c.Type` is `'resubstitution'`, then `idx` specifies all observations.

`idx = test(c,i)` returns the test indices for repetition `i` of a `cvpartition` object `c` of type `'kfold'` or `'leaveout'`.

- If `c.Type` is `'kfold'`, then `idx` specifies the observations in the `i`th test set or fold.
- If `c.Type` is `'leaveout'`, then `idx` specifies the observation reserved for testing at repetition `i`.

Examples

Identify Test Indices in Holdout Partition

Identify the observations that are in the test (holdout) set of a `cvpartition` object.

Partition 10 observations for holdout validation. Select approximately 30% of the observations to be in the test set.

```
rng('default') % For reproducibility
c = cvpartition(10,'Holdout',0.30)
```

```
c =
Hold-out cross validation partition
   NumObservations: 10
       NumTestSets: 1
         TrainSize: 7
          TestSize: 3
```

Identify the test set observations. Observations that correspond to 1s are in the test set.

```
holdout = test(c)
```

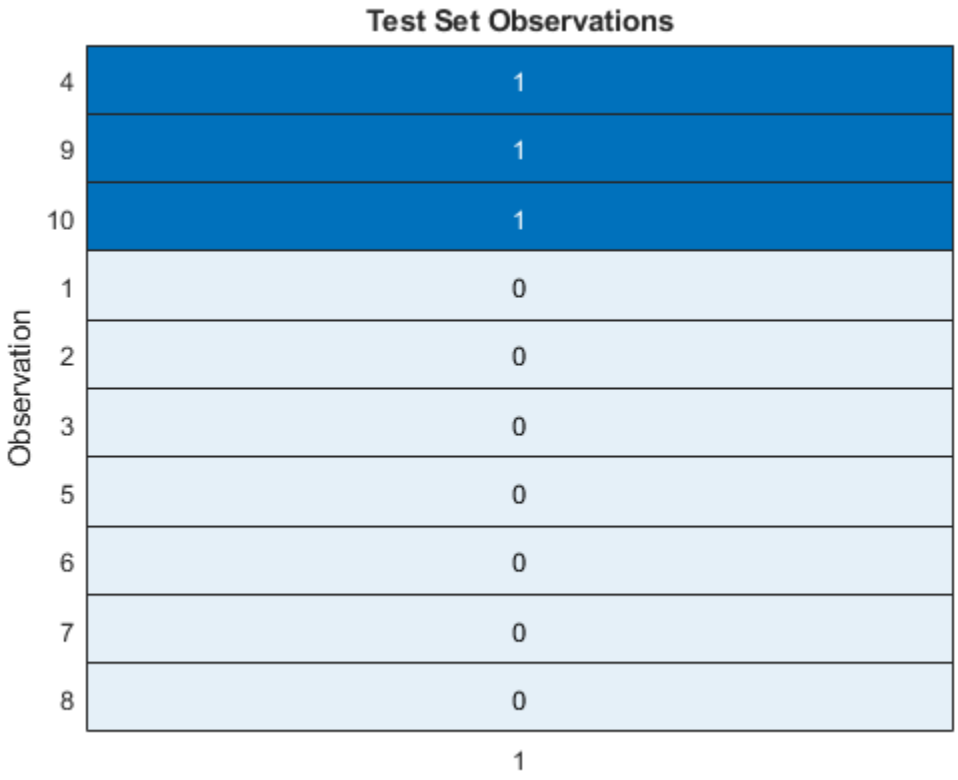
```
holdout = 10x1 logical array

   0
   0
   0
```

```
     1
     0
     0
     0
     0
     1
     1
```

Visualize the results. The fourth, ninth, and tenth observations are in the test set.

```
h = heatmap(double(holdout),'ColorbarVisible','off');
sorty(h,'1','descend')
ylabel('Observation')
title('Test Set Observations')
```



Identify Test Indices in k-Fold Partition

Identify the observations that are in the test sets, or folds, of a `cvpartition` object for 3-fold cross-validation.

Partition 10 observations for 3-fold cross-validation. Notice that `c` contains three repetitions of training and test data.

```
rng('default') % For reproducibility
c = cvpartition(10,'KFold',3)

c =
K-fold cross validation partition
   NumObservations: 10
       NumTestSets: 3
         TrainSize: 7  6  7
          TestSize: 3  4  3
```

Identify the test set observations for each repetition of training and test data. Observations that correspond to 1s are in the corresponding test set (fold).

```
fold1 = test(c,1)

fold1 = 10x1 logical array

   1
   1
   0
   0
   0
   0
   0
   0
   1
   0

fold2 = test(c,2);
fold3 = test(c,3);
```

Visualize the results. The first, second, and ninth observations are in the first test set. The third, sixth, eighth, and tenth observations are in the second test set. The fourth, fifth, and seventh observations are in the third test set.

```
data = [fold1,fold2,fold3];
h = heatmap(double(data),'ColorbarVisible','off');
sorty(h,{'1','2','3'},'descend')
xlabel('Repetition')
ylabel('Observation')
title('Test Set Observations')
```

Input Arguments

`c` — Validation partition

`cvpartition` object

Validation partition, specified as a `cvpartition` object. The validation partition type of `c`, `c.Type`, is `'kfold'`, `'holdout'`, `'leaveout'`, or `'resubstitution'`.

`i` — Repetition index

positive integer scalar

Repetition index, specified as a positive integer scalar. Specifying `i` indicates to find the observations in the `i`th test set (fold).

Data Types: `single` | `double`

Output Arguments

`idx` — Indices for test set observations

logical vector

Indices for test set observations, returned as a logical vector. A value of 1 indicates that the corresponding observation is in the test set. A value of 0 indicates that the corresponding observation is in the training set.

Introduced in R2008a

testcholdout

Compare predictive accuracies of two classification models

Syntax

```
h = testcholdout(YHat1,YHat2,Y)
h = testcholdout(YHat1,YHat2,Y,Name,Value)
[h,p,e1,e2] = testcholdout( ___ )
```

Description

`testcholdout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `testcholdout` can conduct several McNemar test on page 33-6198 variations, including the asymptotic test, the exact-conditional test, and the mid-*p*-value test. For cost-sensitive assessment on page 33-6196, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

`h = testcholdout(YHat1,YHat2,Y)` returns the test decision, by conducting the mid-*p*-value McNemar test on page 33-6198, from testing the null hypothesis that the predicted class labels `YHat1` and `YHat2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

`h = 1` indicates to reject the null hypothesis at the 5% significance level. `h = 0` indicates to not reject the null hypothesis at 5% level.

`h = testcholdout(YHat1,YHat2,Y,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the type of alternative hypothesis, specify the type of test, or supply a cost matrix.

`[h,p,e1,e2] = testcholdout( ___ )` returns the *p*-value for the hypothesis test (`p`) and the respective classification loss on page 33-6200 of each set of predicted class labels (`e1` and `e2`) using any of the input arguments in the previous syntaxes.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the `ionosphere` data set.

```
load ionosphere
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1);                              % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP);            % Training-set indices
idxTest = test(CVP);                 % Test-set indices
```

`CVP` is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
MdlSVM = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
t = templateTree('Reproducible',true);  % For reproducibility of random predictor selections
MdlBag = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag','Learners',t);
```

`MdlSVM` is a trained `ClassificationSVM` model. `MdlBag` is a trained `ClassificationBaggedEnsemble` model.

Label the test-set observations using the trained models.

```
YhatSVM = predict(MdlSVM,X(idxTest,:));
YhatBag = predict(MdlBag,X(idxTest,:));
```

`YhatSVM` and `YhatBag` are vectors continuing the predicted class labels of the respective models.

Test whether the two models have equal predictive accuracies.

```
h = testcholdout(YhatSVM,YhatBag,Y(idxTest))
```

```
h = logical
   0
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the `ionosphere` data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1);                              % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP);            % Training-set indices
idxTest = test(CVP);                 % Test-set indices
```

`CVP` is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
MdlLinear = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
MdlRBF = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

`MdlLinear` and `MdlRBF` are trained `ClassificationSVM` models.

Label the test-set observations using the trained models.

```
YhatLinear = predict(MdlLinear,X(idxTest,:));
YhatRBF = predict(MdlRBF,X(idxTest,:));
```

`YhatLinear` and `YhatRBF` are vectors continuing the predicted class labels of the respective models.

Test the null hypothesis that the simpler model (`MdlLinear`) is at most as accurate as the more complex model (`MdlRBF`). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- *p*-value test (the cost-insensitive testing default). Request to return *p*-values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);

[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = testcholdout(YhatLinear,YhatRBF,Y(idxTest),...
    'Alternative','greater','Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = testcholdout(YhatLinear,YhatRBF,Y(idxTest),...
    'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})
```

```
ans=4×2 table
            Asymp          MidP
          __________    __________

    h              1             1
    p     7.2801e-09    2.7649e-10
    e1       0.13714       0.13714
    e2       0.33143       0.33143
```

The *p*-value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `testcholdout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or if the false-positive and false-negative costs are imbalanced, you can statistically compare the predictive performance of two classification models by including a cost matrix in the analysis.

Load the `arrhythmia` data set. Determine the class representations in the data.

```
load arrhythmia;
Y = categorical(Y);
tabulate(Y);
```

```
  Value    Count   Percent
      1      245     54.20%
      2       44      9.73%
      3       15      3.32%
      4       15      3.32%
      5       13      2.88%
      6       25      5.53%
      7        3      0.66%
      8        2      0.44%
      9        9      1.99%
     10       50     11.06%
     14        4      0.88%
     15        5      1.11%
     16       22      4.87%
```

There are 16 classes, however some are not represented in the data set (for example, class 13). Most observations are classified as not having arrhythmia (class 1). The data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status (class 16) from the data set.

```
idx = (Y ~= '16');
Y = Y(idx);
X = X(idx,:);
Y(Y ~= '1') = 'WithArrhythmia';
Y(Y == '1') = 'NoArrhythmia';
Y = removecats(Y);
```

Create a partition that evenly splits the data into training and test sets.

```
rng(1);                              % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP);            % Training-set indices
idxTest = test(CVP);                 % Test-set indices
```

`CVP` is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the "no arrhythmia" class is five times worse than misclassifying a patient without arrhythmia into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate predicted class. When you conduct a cost-sensitive analysis, a good practice is to specify the order of the classes.

```
Cost = [0 1;5 0];
ClassNames = {'NoArrhythmia','WithArrhythmia'};
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and another that uses LogitBoost. Because there are missing values in the data set, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate','on');
numTrees = 50;
MdlAda = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','AdaBoostM1',...
    'NumLearningCycles',numTrees,'Learners',t,...
    'Cost',Cost,'ClassNames',ClassNames);
MdlLogit = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','LogitBoost',...
```

```
    'NumLearningCycles',numTrees,'Learners',t,...
    'Cost',Cost,'ClassNames',ClassNames);
```

`MdlAda` and `MdlLogit` are trained `ClassificationEnsemble` models.

Label the test-set observations using the trained models.

```
YhatAda = predict(MdlAda,X(idxTest,:));
YhatLogit = predict(MdlLogit,X(idxTest,:));
```

`YhatLinear` and `YhatRBF` are vectors containing the predicted class labels of the respective models.

Test whether the AdaBoostM1 ensemble (`MdlAda`) and the LogitBoost ensemble (`MdlLogit`) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return *p*-values and misclassification costs.

```
[h,p,e1,e2] = testcholdout(YhatAda,YhatLogit,Y(idxTest),'Cost',Cost)
```

```
h = logical
   0

p = 0.3334

e1 = 0.5581

e2 = 0.4698
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Input Arguments

YHat1 — Predicted class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Predicted class labels of the first classification model, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If `YHat1` is a character array, then each element must correspond to one row of the array.

`YHat1`, `YHat2`, and `Y` must have equal lengths.

It is a best practice for `YHat1`, `YHat2`, and `Y` to share the same data type.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

YHat2 — Predicted class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Predicted class labels of the second classification model, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If `YHat2` is a character array, then each element must correspond to one row of the array.

`YHat1`, `YHat2`, and `Y` must have equal lengths.

It is a best practice for `YHat1`, `YHat2`, and `Y` to share the same data type.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Y — True class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

True class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If `Y` is a character array, then each element must correspond to one row of the array.

`YHat1`, `YHat2`, and `Y` must have equal lengths.

It is a best practice for `YHat1`, `YHat2`, and `Y` to share the same data type.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alternative','greater','Test','asymptotic','Cost',[0 2;1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

`Alpha` — Hypothesis test significance level
`0.05` (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: `'Alpha',0.1`

Data Types: `single` | `double`

`Alternative` — Alternative hypothesis to assess
`'unequal'` (default) | `'greater'` | `'less'`

Alternative hypothesis to assess, specified as the comma-separated pair consisting of `'Alternative'` and one of the values listed in the table.

Value	Alternative hypothesis
`'unequal'` (default)	For predicting `Y`, `YHat1` and `YHat2` have unequal accuracies.
`'greater'`	For predicting `Y`, `YHat1` is more accurate than `YHat2`.
`'less'`	For predicting `Y`, `YHat1` is less accurate than `YHat2`.

Example: `'Alternative','greater'`

`ClassNames` — Class names
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. You must set `ClassNames` using the data type of `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost`.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train and test models using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

`Cost` — Misclassification cost
square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure array.

- If you specify the square matrix `Cost`, then `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
  - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`.

If you specify `Cost`, then `testcholdout` cannot conduct one-sided, exact, or mid-*p* tests. You must also specify `'Alternative','unequal','Test','asymptotic'`. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

A best practice is to supply the same cost matrix used to train the classification models.

The default is `Cost(i,j) = 1` if `i ~= j`, and `Cost(i,j) = 0` if `i = j`.

Example: `'Cost',[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `single` | `double` | `struct`

`CostTest` — Cost-sensitive test type
`'likelihood'` (default) | `'chisquare'`

Cost-sensitive test type, specified as the comma-separated pair consisting of `'CostTest'` and `'chisquare'` or `'likelihood'`. Unless you specify a cost matrix using the `Cost` name-value pair argument, `testcholdout` ignores `CostTest`.

This table summarizes the available options for cost-sensitive testing.

Value	Asymptotic test type	Requirements
`'chisquare'`	Chi-square test	Optimization Toolbox license to implement `quadprog`
`'likelihood'`	Likelihood ratio test	None

For more details, see “Cost-Sensitive Testing” on page 33-6196.

Example: `'CostTest','chisquare'`

`Test` — Test to conduct
`'asymptotic'` | `'exact'` | `'midp'`

Test to conduct, specified as the comma-separated pair consisting of `'Test'` and `'asymptotic'`, `'exact'`, and `'midp'`. This table summarizes the available options for cost-insensitive testing.

Value	Description
`'asymptotic'`	Asymptotic McNemar test
`'exact'`	Exact-conditional McNemar test
`'midp'` (default)	Mid-*p*-value McNemar test

For more details, see “McNemar Tests” on page 33-6198.

For cost-sensitive testing, `Test` must be `'asymptotic'`. When you specify the `Cost` name-value pair argument, and choose a cost-sensitive test using the `CostTest` name-value pair argument, `'asymptotic'` is the default.

Example: `'Test','asymptotic'`

Note `NaN`s, `<undefined>` values, empty character vectors (`''`), empty strings (`""`), and `<missing>` values indicate missing data values. `testcholdout`:

- Treats missing values in `YHat1` and `YHat2` as misclassified observations.
- Removes missing values in `Y` and the corresponding values of `YHat1` and `YHat2`

Output Arguments

`h` — Hypothesis test result
`1` | `0`

Hypothesis test result, returned as a logical value.

`h = 1` indicates the rejection of the null hypothesis at the `Alpha` significance level.

`h = 0` indicates failure to reject the null hypothesis at the `Alpha` significance level.

Data Types: `logical`

p — *p*-value
scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. `p` is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`testcholdout` estimates `p` using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see "McNemar Tests" on page 33-6198. For details on test statistics derived from cost-sensitive tests, see "Cost-Sensitive Testing" on page 33-6196.

e1 — Classification loss
scalar

Classification loss on page 33-6200 that summarizes the accuracy of the first set of class labels (`YHat1`) predicting the true class labels (`Y`), returned as a scalar.

For cost-insensitive testing, `e1` is the misclassification rate. That is, `e1` is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, `e1` is the misclassification cost. That is, `e1` is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 — Classification loss
scalar

Classification loss on page 33-6200 that summarizes the accuracy of the second set of class labels (`YHat2`) predicting the true class labels (`Y`), returned as a scalar.

For cost-insensitive testing, `e2` is the misclassification rate. That is, `e2` is the proportion of misclassified observations, which is a scalar in the interval [0,1].

For cost-sensitive testing, `e2` is the misclassification cost. That is, `e2` is the weighted average of the costs of misclassification, in which the weights are the respective estimated proportions of misclassified observations.

More About

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. By conducting a cost-sensitive analysis, you can account for the cost imbalance when you train the classification models and when you statistically compare them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss. Use misclassification cost instead to compare classification models.

Misclassification costs are often imbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick typically causes some inconvenience, but does not pose significant danger. In this situation, you

assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\widehat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with the following characteristics. k is the true class, i is the label assigned by the first classification model, and j is the label assigned by the second classification model. The unknown true value of $\widehat{\pi}_{ijk}$ is π_{ijk}. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. Additionally, $\sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \widehat{\pi}_{ijk} = 1$.
- c_{ij} is the relative cost of assigning label j to an observation with true class i. $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i,j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K, which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

  $$\delta = \sum_{i=1}^{K} \sum_{j=1}^{K} \sum_{k=1}^{K} \left(c_{ki} - c_{kj}\right)\pi_{ijk}.$$

- The hypothesis test is

  $$H_0: \delta = 0$$
  $$H_1: \delta \neq 0.$$

  The available cost-sensitive tests are appropriate for two-tailed testing.

Available asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

  $$t^*_{\chi^2} = \sum_{i \neq j} \sum_{k} \frac{\left(n_{ijk} + 1 - \left(n_{test} + K^3\right)\widehat{\pi}^{(1)}_{ijk}\right)^2}{n_{ijk} + 1}.$$

  If $1 - F_{\chi^2}\left(t^*_{\chi^2}; 1\right) < \alpha$, then reject H_0.

  - $\widehat{\pi}^{(1)}_{ijk}$ are estimated by minimizing $t^*_{\chi^2}$ under the constraint that $\delta = 0$.
  - $F_{\chi^2}(x; 1)$ is the χ^2 cdf with one degree of freedom evaluated at x.
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk}, which are binomial random variables with sample size n_{test} and success probability π_{ijk}. The random variables represent the random number of observations with: true class k, label i assigned by the first classification model, and label j assigned by the second classification model. Jointly, the distribution of the random variables is multinomial.

  The test statistic is

  $$t^*_{LRT} = 2\log\left[\frac{P\left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \widehat{\pi}_{ijk} = \widehat{\pi}^{(2)}_{ijk}\right)}{P\left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \widehat{\pi}_{ijk} = \widehat{\pi}^{(3)}_{ijk}\right)}\right].$$

If $1 - F_{\chi^2}\left(t^*_{LRT}; 1\right) < \alpha$, then reject H_0.

- $\hat{\pi}^{(2)}_{ijk} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk}.
- $\hat{\pi}^{(3)}_{ijk} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to $\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 cdf with one degree of freedom evaluated at x.

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

1. Partition the data into training and test sets.
2. Train both classification models using the training set.
3. Predict class labels using the test set.
4. Summarize the results in a two-by-two table similar to this figure.

		Model 2		
		Correct	Incorrect	
Model 1	Correct	n_{11}	n_{12}	$n_{1\bullet}$
	Incorrect	n_{21}	n_{22}	$n_{2\bullet}$
		$n_{\bullet 1}$	$n_{\bullet 2}$	n_{test}

n_{ii} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij}, $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are $\hat{\pi}_{2\bullet} = n_{2\bullet}/n$ and $\hat{\pi}_{\bullet 2} = n_{\bullet 2}/n$, respectively. A two-sided test for comparing the accuracy of the two models is

$H_0: \pi_{\bullet 2} = \pi_{2\bullet}$

$H_1: \pi_{\bullet 2} \neq \pi_{2\bullet}$.

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0: \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for the available McNemar test variants: the asymptotic, exact-conditional, and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance level α) are:
  - For one-sided tests, the test statistic is

    $$t_{a1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

    If $1 - \Phi\left(\left|t_1^*\right|\right) < \alpha$, where Φ is the standard Gaussian cdf, then reject H_0.
  - For two-sided tests, the test statistic is

    $$t_{a2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

    If $1 - F_{\chi^2}\left(t_2^*; m\right) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 cdf evaluated at x, then reject H_0.

  The asymptotic test requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution.
  - The total number of discordant pairs, $n_d = n_{12} + n_{21}$, must be greater than 10 ([1], Ch. 10.1.4).
  - In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α, as suggested in simulation studies in [18]. However, the asymptotic McNemar test performs well in terms of statistical power.
- Exact-Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance level α) are ([36], [38]):
  - For one-sided tests, the test statistic is

    $$t_1^* = n_{12}.$$

    If $F_{\text{Bin}}\left(t_1^*; n_d, 0.5\right) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial cdf with sample size n and success probability p evaluated at x, then reject H_0.
  - For two-sided tests, the test statistic is

    $$t_2^* = \min(n_{12}, n_{21}).$$

    If $F_{\text{Bin}}\left(t_2^*; n_d, 0.5\right) < \alpha/2$, then reject H_0.

  The exact-conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid-p-value test ([1], Ch. 3.6.3).
- Mid-p-value test — The mid-p-value McNemar test statistics and rejection regions (for significance level α) are ([32]):

- For one-sided tests, the test statistic is

  $t_1^* = n_{12}$.

  If $F_{\text{Bin}}\left(t_1^* - 1; n_{12} + n_{21}, 0.5\right) + 0.5 f_{\text{Bin}}\left(t_1^*; n_{12} + n_{21}, 0.5\right) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial cdf and pdf, respectively, with sample size n and success probability p evaluated at x, then reject H_0.
- For two-sided tests, the test statistic is

  $t_2^* = \min(n_{12}, n_{21})$.

  If $F_{\text{Bin}}\left(t_2^* - 1; n_{12} + n_{21} - 1, 0.5\right) + 0.5 f_{\text{Bin}}\left(t_2^*; n_{12} + n_{21}, 0.5\right) < \alpha/2$, then reject H_0.

The mid-*p*-value test addresses the over-conservative behavior of the exact-conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are the misclassification rate and cost.

`testcholdout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (that is, the unrestricted classification losses). n_{ijk} is the number of test-sample observations with: true class k, label i assigned by the first classification model, and label j assigned by the second classification model. The corresponding estimated proportion is $\widehat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K, the number of classes.

- The misclassification rate, or classification error, is a scalar in the interval [0,1] representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

  $$e_1 = \sum_{j=1}^{K} \sum_{k=1}^{K} \sum_{i \neq k} \widehat{\pi}_{ijk}.$$

  For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

  Classification accuracy decreases as the misclassification rate increases to 1.
- The misclassification cost is a nonnegative scalar that is a measure of classification quality relative to the values of the specified cost matrix. Its interpretation depends on the specified costs of misclassification. The misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective estimated proportions of misclassified observations. The misclassification cost for the first classification model is

  $$e_1 = \sum_{j=1}^{K} \sum_{k=1}^{K} \sum_{i \neq k} \widehat{\pi}_{ijk} c_{ki},$$

where c_{kj} is the cost of classifying an observation into class j if its true class is k. For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as the misclassification cost increases.

Tips

- It is a good practice to obtain predicted class labels by passing any trained classification model and new predictor data to the `predict` method. For example, for predicted labels from an SVM model, see `predict`.
- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 33-6196.

`testckfold`

Topics

“Hypothesis Tests”

Introduced in R2015a

testckfold

Compare accuracies of two classification models by repeated cross-validation

Syntax

```
h = testckfold(C1,C2,X1,X2)
h = testckfold(C1,C2,X1,X2,Y)
h = testckfold(___,Name,Value)
[h,p,e1,e2] = testckfold(___)
```

Description

`testckfold` statistically assesses the accuracies of two classification models by repeatedly cross-validating the two models, determining the differences in the classification loss, and then formulating the test statistic by combining the classification loss differences. This type of test is particularly appropriate when sample size is limited.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. Available tests include a 5-by-2 paired *t* test, a 5-by-2 paired *F* test, and a 10-by-10 repeated cross-validation *t* test. For more details, see "Repeated Cross-Validation Tests" on page 33-6218. To speed up computations, `testckfold` supports parallel computing (requires a Parallel Computing Toolbox license).

`h = testckfold(C1,C2,X1,X2)` returns the test decision that results from conducting a 5-by-2 paired *F* cross-validation test. The null hypothesis is the classification models `C1` and `C2` have equal accuracy in predicting the true class labels using the predictor and response data in the tables `X1` and `X2`. `h = 1` indicates to reject the null hypothesis at the 5% significance level.

`testckfold` conducts the cross-validation test by applying `C1` and `C2` to all predictor variables in `X1` and `X2`, respectively. The true class labels in `X1` and `X2` must be the same. The response variable names in `X1`, `X2`, `C1.ResponseName`, and `C2.ResponseName` must be the same.

For examples of ways to compare models, see "Tips" on page 33-6221.

`h = testckfold(C1,C2,X1,X2,Y)` applies the full classification model or classification templates `C1` and `C2` to all predictor variables in the tables or matrices of data `X1` and `X2`, respectively. `Y` is the table variable name corresponding to the true class labels, or an array of true class labels.

`h = testckfold(___,Name,Value)` uses any of the input arguments in the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the type of alternative hypothesis, the type of test, or the use of parallel computing.

`[h,p,e1,e2] = testckfold(___)` also returns the *p*-value for the hypothesis test (`p`) and the respective classification losses on page 33-6220 for each cross-validation run and fold (`e1` and `e2`).

Examples

Compare Classification Tree Predictor-Selection Algorithms

At each node, `fitctree` chooses the best predictor to split using an exhaustive search by default. Alternatively, you can choose to split the predictor that shows the most evidence of dependence with the response by conducting curvature tests. This example statistically compares classification trees grown via exhaustive search for the best splits and grown by conducting curvature tests with interaction.

Load the `census1994` data set.

```
load census1994.mat
rng(1) % For reproducibility
```

Grow a default classification tree using the training set, `adultdata`, which is a table. The response-variable name is `'salary'`.

```
C1 = fitctree(adultdata,'salary')
```

```
C1 =
  ClassificationTree
             PredictorNames: {1x14 cell}
               ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
                ClassNames: [<=50K    >50K]
             ScoreTransform: 'none'
            NumObservations: 32561

  Properties, Methods
```

`C1` is a full `ClassificationTree` model. Its `ResponseName` property is `'salary'`. `C1` uses an exhaustive search to find the best predictor to split on based on maximal splitting gain.

Grow another classification tree using the same data set, but specify to find the best predictor to split using the curvature test with interaction.

```
C2 = fitctree(adultdata,'salary','PredictorSelection','interaction-curvature')
```

```
C2 =
  ClassificationTree
             PredictorNames: {1x14 cell}
               ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
                ClassNames: [<=50K    >50K]
             ScoreTransform: 'none'
            NumObservations: 32561

  Properties, Methods
```

`C2` also is a full `ClassificationTree` model with `ResponseName` equal to `'salary'`.

Conduct a 5-by-2 paired *F* test to compare the accuracies of the two models using the training set. Because the response-variable names in the data sets and the `ResponseName` properties are all equal, and the response data in both sets are equal, you can omit supplying the response data.

```
h = testckfold(C1,C2,adultdata,adultdata)
```

```
h = logical
   0
```

`h = 0` indicates to not reject the null hypothesis that `C1` and `C2` have the same accuracies at 5% level.

Compare Accuracies of Two Different Classification Models

Conduct a statistical test comparing the misclassification rates of the two models using a 5-by-2 paired *F* test.

Load Fisher's iris data set.

```
load fisheriris;
```

Create a naive Bayes template and a classification tree template using default options.

```
C1 = templateNaiveBayes;
C2 = templateTree;
```

`C1` and `C2` are template objects corresponding to the naive Bayes and classification tree algorithms, respectively.

Test whether the two models have equal predictive accuracies. Use the same predictor data for each model. `testckfold` conducts a 5-by-2, two-sided, paired *F* test by default.

```
rng(1); % For reproducibility
h = testckfold(C1,C2,meas,meas,species)
```

```
h = logical
   0
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Compare Classification Accuracies of Simple and Complex Models

Conduct a statistical test to assess whether a simpler model has better accuracy than a more complex model using a 10-by-10 repeated cross-validation *t* test.

Load Fisher's iris data set. Create a cost matrix that penalizes misclassifying a setosa iris twice as much as misclassifying a virginica iris as a versicolor.

```
load fisheriris;
tabulate(species)
```

```
       Value    Count   Percent
      setosa       50     33.33%
```

```
  versicolor       50     33.33%
   virginica       50     33.33%
```

```
Cost = [0 2 2;2 0 1;2 1 0];
ClassNames  = {'setosa' 'versicolor' 'virginica'};...
    % Specifies the order of the rows and columns in Cost
```

The empirical distribution of the classes is uniform, and the classification cost is slightly imbalanced.

Create two ECOC templates: one that uses linear SVM binary learners and one that uses SVM binary learners equipped with the RBF kernel.

```
tSVMLinear = templateSVM('Standardize',true); % Linear SVM by default
tSVMRBF = templateSVM('KernelFunction','RBF','Standardize',true);
C1 = templateECOC('Learners',tSVMLinear);
C2 = templateECOC('Learners',tSVMRBF);
```

`C1` and `C2` are ECOC template objects. `C1` is prepared for linear SVM. `C2` is prepared for SVM with an RBF kernel training.

Test the null hypothesis that the simpler model (`C1`) is at most as accurate as the more complex model (`C2`) in terms of classification costs. Conduct the 10-by-10 repeated cross-validation test. Request to return *p*-values and misclassification costs.

```
rng(1); % For reproducibility
[h,p,e1,e2] = testckfold(C1,C2,meas,meas,species,...
    'Alternative','greater','Test','10x10t','Cost',Cost,...
    'ClassNames',ClassNames)
```

```
h = logical
   0

p = 0.1077

e1 = 10×10

         0         0         0    0.0667         0    0.0667    0.1333         0    0.1333
    0.0667    0.0667         0         0         0         0    0.0667         0    0.0667    0.0
         0         0         0         0         0    0.0667    0.0667    0.0667    0.0667    0.0
    0.0667    0.0667         0    0.0667         0    0.0667         0         0    0.0667
    0.0667    0.0667    0.0667         0    0.0667    0.0667         0         0         0
         0         0    0.1333         0         0    0.0667         0         0    0.0667    0.0
    0.0667    0.0667         0         0    0.0667         0         0    0.0667         0    0.0
    0.0667         0    0.0667    0.0667         0    0.1333         0    0.0667         0
         0    0.0667    0.1333    0.0667    0.0667         0         0         0         0
         0    0.0667    0.0667    0.0667    0.0667         0         0    0.0667         0

e2 = 10×10

         0         0         0    0.1333         0    0.0667    0.1333         0    0.2667
    0.0667    0.0667         0    0.1333         0         0         0    0.1333    0.1333    0.0
    0.1333    0.1333         0         0         0    0.0667         0    0.0667    0.0667    0.0
         0    0.1333         0    0.0667    0.1333    0.1333         0         0    0.0667
    0.0667    0.0667    0.0667         0    0.0667    0.1333    0.1333         0         0    0.0
    0.0667         0    0.0667    0.0667         0    0.0667    0.1333         0    0.0667    0.0
    0.2000    0.0667         0         0    0.0667         0         0    0.1333         0    0.0
    0.2000         0         0    0.1333         0    0.1333         0    0.0667         0
```

```
         0    0.0667    0.0667    0.0667    0.1333         0    0.2000         0         0
    0.0667    0.0667         0    0.0667    0.1333         0         0    0.0667    0.1333    0.0
```

The *p*-value is slightly greater than 0.10, which indicates to retain the null hypothesis that the simpler model is at most as accurate as the more complex model. This result is consistent for any significance level (`Alpha`) that is at most 0.10.

`e1` and `e2` are 10-by-10 matrices containing misclassification costs. Row *r* corresponds to run *r* of the repeated cross validation. Column *k* corresponds to test-set fold *k* within a particular cross-validation run. For example, element (2,4) of `e2` is 0.1333. This value means that in cross-validation run 2, when the test set is fold 4, the estimated test-set misclassification cost is 0.1333.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the accuracy between the two models.

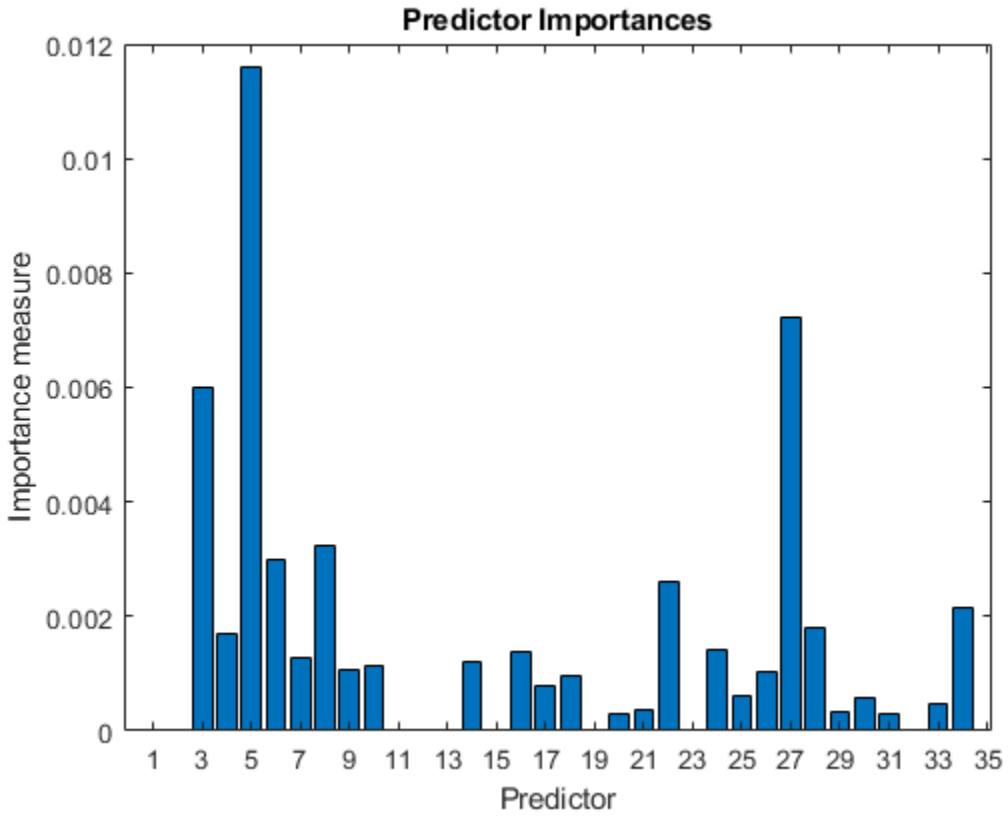
Load the `ionosphere` data set.

```
load ionosphere
```

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```
t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
predImp = predictorImportance(C);

bar(predImp)
h = gca;
h.XTick = 1:2:h.XLim(2);
title('Predictor Importances')
xlabel('Predictor')
ylabel('Importance measure')
```



Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp,'descend');
idx5 = idxSort(1:5);
```

Test whether the two models have equal predictive accuracies. Specify the reduced data set and then the full predictor data. Use parallel computing to speed up computations.

```
s = RandStream('mlfg6331_64');
Options = statset('UseParallel',true,'Streams',s,'UseSubstreams',true);

[h,p,e1,e2] = testckfold(C,C,X(:,idx5),X,Y,'Options',Options)
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

h = logical
   0

p = 0.4161

e1 = 5×2

    0.0686    0.0795
    0.0800    0.0625
    0.0914    0.0568
    0.0400    0.0739
```

```
    0.0914    0.0966

e2 = 5×2

    0.0914    0.0625
    0.1257    0.0682
    0.0971    0.0625
    0.0800    0.0909
    0.0914    0.1193
```

`testckfold` treats trained classification models as templates, and so it ignores all fitted parameters in `C`. That is, `testckfold` cross validates `C` using only the specified options and the predictor data to estimate the out-of-fold classification losses.

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble.

Input Arguments

`C1` — Classification model template or trained classification model

classification model template object | trained classification model object

Classification model template or trained classification model, specified as any classification model template object or trained classification model object described in these tables.

Template Type	Returned By
Classification tree	`templateTree`
Discriminant analysis	`templateDiscriminant`
Ensemble (boosting, bagging, and random subspace)	`templateEnsemble`
Error-correcting output codes (ECOC), multiclass classification model	`templateECOC`
*k*NN	`templateKNN`
Naive Bayes	`templateNaiveBayes`
Support Vector Machine (SVM)	`templateSVM`

Trained Model Type	Model Object	Returned By
Classification tree	`ClassificationTree`	`fitctree`
Discriminant analysis	`ClassificationDiscriminant`	`fitcdiscr`
Ensemble of bagged classification models	`ClassificationBaggedEnsemble`	`fitcensemble`
Ensemble of classification models	`ClassificationEnsemble`	`fitcensemble`
ECOC model	`ClassificationECOC`	`fitcecoc`

Trained Model Type	Model Object	Returned By
Generalized additive model (GAM)	`ClassificationGAM`	`fitcgam`
*k*NN	`ClassificationKNN`	`fitcknn`
Naive Bayes	`ClassificationNaiveBayes`	`fitcnb`
Neural network	`ClassificationNeuralNetwork` (with observations in rows)	`fitcnet`
SVM	`ClassificationSVM`	`fitcsvm`

For efficiency, supply a classification model template object instead of a trained classification model object.

C2 — Classification model template or trained model

classification model template object | trained classification model object

Classification model template or trained classification model, specified as any classification model template object or trained classification model object described in these tables.

Template Type	Returned By
Classification tree	`templateTree`
Discriminant analysis	`templateDiscriminant`
Ensemble (boosting, bagging, and random subspace)	`templateEnsemble`
Error-correcting output codes (ECOC), multiclass classification model	`templateECOC`
*k*NN	`templateKNN`
Naive Bayes	`templateNaiveBayes`
Support Vector Machine (SVM)	`templateSVM`

Trained Model Type	Model Object	Returned By
Classification tree	`ClassificationTree`	`fitctree`
Discriminant analysis	`ClassificationDiscriminant`	`fitcdiscr`
Ensemble of bagged classification models	`ClassificationBaggedEnsemble`	`fitcensemble`
Ensemble of classification models	`ClassificationEnsemble`	`fitcensemble`
ECOC model	`ClassificationECOC`	`fitcecoc`
Generalized additive model (GAM)	`ClassificationGAM`	`fitcgam`
*k*NN	`ClassificationKNN`	`fitcknn`
Naive Bayes	`ClassificationNaiveBayes`	`fitcnb`
Neural network	`ClassificationNeuralNetwork` (with observations in rows)	`fitcnet`

Trained Model Type	Model Object	Returned By
SVM	`ClassificationSVM`	`fitcsvm`

For efficiency, supply a classification model template object instead of a trained classification model object.

X1 — Data used to apply to first full classification model or template
numeric matrix | table

Data used to apply to the first full classification model or template, `C1`, specified as a numeric matrix or table.

Each row of `X1` corresponds to one observation, and each column corresponds to one variable. `testckfold` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.

`X1` and `X2` must be of the same data type, and `X1`, `X2`, `Y` must have the same number of observations.

If you specify `Y` as an array, then `testckfold` treats all columns of `X1` as separate predictor variables.

Data Types: `double` | `single` | `table`

X2 — Data used to apply to second full classification model or template
numeric matrix | table

Data used to apply to the second full classification model or template, `C2`, specified as a numeric matrix or table.

Each row of `X2` corresponds to one observation, and each column corresponds to one variable. `testckfold` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.

`X1` and `X2` must be of the same data type, and `X1`, `X2`, `Y` must have the same number of observations.

If you specify `Y` as an array, then `testckfold` treats all columns of `X2` as separate predictor variables.

Data Types: `double` | `single` | `table`

Y — True class labels
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors | character vector | string scalar

True class labels, specified as a categorical, character, or string array, a logical or numeric vector, a cell array of character vectors, or a character vector or string scalar.

- For a character vector or string scalar, `X1` and `X2` must be tables, their response variables must have the same name and values, and `Y` must be the common variable name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then `Y` is `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.
- For all other supported data types, `Y` is an array of true class labels.
  - If `Y` is a character array, then each element must correspond to one row of the array.

- `X1`, `X2`, `Y` must have the same number of observations (rows).

- If both of these statements are true, then you can omit supplying `Y`.

  - `X1` and `X2` are tables containing the same response variable (values and name).
  - `C1` and `C2` are full classification models containing `ResponseName` properties specifying the response variable names in `X1` and `X2`.

  Consequently, `testckfold` uses the common response variable in the tables. For example, if the response variables in the tables are `X1.Labels` and `X2.Labels`, and the values of `C1.ResponseName` and `C2.ResponseName` are `'Labels'`, then you do not have to supply `Y`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alternative','greater','Test','10x10t','Options',statsset('UseParallel',true)` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the 10-by-10 t test, and to use parallel computing for cross-validation.

`Alpha` — Hypothesis test significance level

`0.05` (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: `'Alpha',0.1`

Data Types: `single` | `double`

`Alternative` — Alternative hypothesis to assess

`'unequal'` (default) | `'greater'` | `'less'`

Alternative hypothesis to assess, specified as the comma-separated pair consisting of `'Alternative'` and one of the values listed in the table.

Value	Alternative Hypothesis Description	Supported Tests
`'unequal'` (default)	For predicting `Y`, the set of predictions resulting from `C1` applied to `X1` and `C2` applied to `X2` have unequal accuracies.	`'5x2F'`, `'5x2t'`, and `'10x10t'`
`'greater'`	For predicting `Y`, the set of predictions resulting from `C1` applied to `X1` is more accurate than `C2` applied to `X2`.	`'5x2t'` and `'10x10t'`
`'less'`	For predicting `Y`, the set of predictions resulting from `C1` applied to `X1` is less accurate than `C2` applied to `X2`.	`'5x2t'` and `'10x10t'`

For details on supported tests, see `Test`.

Example: `'Alternative','greater'`

`X1CategoricalPredictors` — Flag identifying categorical predictors
`[]` (default) | logical vector | numeric vector | `'all'`

Flag identifying categorical predictors in the first test-set predictor data (`X1`), specified as the comma-separated pair consisting of `'X1CategoricalPredictors'` and one of the following:

- A numeric vector with indices from `1` through `p`, where `p` is the number of columns of `X1`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X1` is a categorical variable.
- `'all'`, meaning all predictors are categorical.

Specification of `X1CategoricalPredictors` is appropriate if:

- At least one predictor is categorical and `C1` is a classification tree, an ensemble of classification trees, an ECOC model, or a naive Bayes classification model.
- All predictors are categorical and `C1` is a *k*NN classification model.

If you specify `X1CategoricalPredictors` for any other case, then `testckfold` throws an error. For example, the function cannot train SVM learners using categorical predictors.

The default is `[]`, which indicates that there are no categorical predictors.

Example: `'X1CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string`

`X2CategoricalPredictors` — Flag identifying categorical predictors
`[]` (default) | logical vector | numeric vector | `'all'`

Flag identifying categorical predictors in the second test-set predictor data (`X2`), specified as the comma-separated pair consisting of `'X2CategoricalPredictors'` and one of the following:

- A numeric vector with indices from `1` through `p`, where `p` is the number of columns of `X2`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X2` is a categorical variable.
- `'all'`, meaning all predictors are categorical.

Specification of `X2CategoricalPredictors` is appropriate if:

- At least one predictor is categorical and `C2` is a classification tree, an ensemble of classification trees, an ECOC model, or a naive Bayes classification model.
- All predictors are categorical and `C2` is a *k*NN classification model.

If you specify `X2CategoricalPredictors` for any other case, then `testckfold` throws an error. For example, the function cannot train SVM learners using categorical predictors.

The default is `[]`, which indicates that there are no categorical predictors.

Example: `'X2CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string`

`ClassNames` — Class names
categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. You must set `ClassNames` using the data type of `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost`.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train and test models using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default is the set of all distinct class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

`Cost` — Classification cost
square matrix | structure array

Classification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure array.

- If you specify the square matrix `Cost`, then `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
  - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
  - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

For cost-sensitive testing use, `testcholdout`.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is `Cost(i,j) = 1` if `i ~= j`, and `Cost(i,j) = 0` if `i = j`.

Example: `'Cost',[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

`LossFun` — Loss function
`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'classiferror'`, `'binodeviance'`, `'exponential'`, `'hinge'`, or a function handle.

- The following table lists the available loss functions.

Value	Loss Function
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential loss
'hinge'	Hinge loss

- Specify your own function using function handle notation.

  Suppose that `n = size(X,1)` is the sample size and there are `K` unique classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

  - The output argument `lossvalue` is a scalar.
  - *`lossfun`* is the name of your function.
  - `C` is an `n`-by-`K` logical matrix with rows indicating which class the corresponding observation belongs to. The column order corresponds to the class order in the `ClassNames` name-value pair argument.

    Construct `C` by setting `C(p,q) = 1` if observation `p` is in class `q`, for each row. Set all other elements of row `p` to `0`.
  - `S` is an `n`-by-`K` numeric matrix of classification scores. The column order corresponds to the class order in the `ClassNames` name-value pair argument. `S` is a matrix of classification scores.
  - `W` is an `n`-by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to `1`.
  - `Cost` is a `K`-by-`K` numeric matrix of classification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of `0` for correct classification and a cost of `1` for misclassification.

  Specify your function using `'LossFun',@lossfun`.

`Options` — Parallel computing options
`[]` (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `testckfold` uses `'Streams'`, `'UseParallel'`, and `'UseSubtreams'` fields.

This table summarizes the available options.

Option	Description
`'Streams'`	A `RandStream` object or cell array of such objects. If you do not specify `Streams`, the software uses the default stream or streams. If you specify `Streams`, use a single object except when the following are true: • You have an open parallel pool. • `UseParallel` is `true`. • `UseSubstreams` is `false`. In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and `Streams` must supply a single random number stream.
`'UseParallel'`	If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting `'UseParallel',true`.
`'UseSubstreams'`	Set to `true` to compute in parallel using the stream specified by `'Streams'`. Default is `false`. For example, set `Streams` to a type allowing substreams, such as `'mlfg6331_64'` or `'mrg32k3a'`.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

`Prior` — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and `'empirical'`, `'uniform'`, a numeric vector, or a structure.

This table summarizes the available options for setting prior probabilities.

Value	Description
`'empirical'`	The class prior probabilities are the class relative frequencies in `Y`.
`'uniform'`	All class prior probabilities are equal to 1/*K*, where *K* is the number of classes.
numeric vector	Each element is a class prior probability. Specify the order using the `ClassNames` name-value pair argument. The software normalizes the elements such that they sum to `1`.

Value	Description
structure	A structure `S` with two fields: • `S.ClassNames` contains the class names as a variable of the same type as `Y`. • `S.ClassProbs` contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to `1`.

Example: `'Prior',struct('ClassNames',{{'setosa','versicolor'}},'ClassProbs',[1,2])`

Data Types: `char` | `string` | `single` | `double` | `struct`

`Test` — Test to conduct
`'5x2F'` (default) | `'5x2t'` | `'10x10t'`

Test to conduct, specified as the comma-separated pair consisting of `'Test'` and one of he following: `'5x2F'`, `'5x2t'`, `'10x10t'`.

Value	Description	Supported Alternative Hypothesis
`'5x2F'` (default)	5-by-2 paired *F* test. Appropriate for two-sided testing only.	`'unequal'`
`'5x2t'`	5-by-2 paired *t* test	`'unequal'`, `'less'`, `'greater'`
`'10x10t'`	10-by-10 repeated cross-validation *t* test	`'unequal'`, `'less'`, `'greater'`

For details on the available tests, see “Repeated Cross-Validation Tests” on page 33-6218. For details on supported alternative hypotheses, see `Alternative`.

Example: `'Test','10x10t'`

`Verbose` — Verbosity level
`0` (default) | `1` | `2`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0`, `1`, or `2`. `Verbose` controls the amount of diagnostic information that the software displays in the Command Window during training of each cross-validation fold.

This table summarizes the available verbosity level options.

Value	Description
`0`	The software does not display diagnostic information.
`1`	The software displays diagnostic messages every time it implements a new cross-validation run.

Value	Description
2	The software displays diagnostic messages every time it implements a new cross-validation run, and every time it trains on a particular fold.

Example: `'Verbose',1`

Data Types: `double` | `single`

`Weights` — Observation weights
`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector.

The size of `Weights` must equal the number of rows of `X1`. The software weighs the observations in each row of `X` with the corresponding weight in `Weights`.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: `double` | `single`

Notes:

- `testckfold` treats trained classification models as templates. Therefore, it ignores all fitted parameters in the model. That is, `testckfold` cross-validates using only the options specified in the model and the predictor data.
- The repeated cross-validation tests depend on the assumption that the test statistics are asymptotically normal under the null hypothesis. Highly imbalanced cost matrices (for example, `Cost = [0 100;1 0]`) and highly discrete response distributions (that is, most of the observations are in a small number of classes) might violate the asymptotic normality assumption. For cost-sensitive testing, use `testcholdout`.
- `NaN`s, `<undefined>` values, empty character vectors (`''`), empty strings (`""`), and `<missing>` values indicate missing data values.
  - For the treatment of missing values in `X1` and `X2`, see the appropriate classification model training function reference page: `fitctree`, `fitcdiscr`, `fitcensemble`, `fitcecoc`, `fitcgam`, `fitcknn`, `fitcnb`, or `fitcsvm`.
  - `testckfold` removes missing values in `Y` and the corresponding rows of `X1` and `X2`.

Output Arguments

`h` — Hypothesis test result
`1` | `0`

Hypothesis test result, returned as a logical value.

`h = 1` indicates the rejection of the null hypothesis at the `Alpha` significance level.

`h = 0` indicates failure to reject the null hypothesis at the `Alpha` significance level.

Data Types: `logical`

p — *p*-value
scalar in the interval [0,1]

p-value of the test, returned as a scalar in the interval [0,1]. `p` is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`testckfold` estimates `p` using the distribution of the test statistic, which varies with the type of test. For details on test statistics, see “Repeated Cross-Validation Tests” on page 33-6218.

e1 — Classification losses
numeric matrix

Classification losses on page 33-6220, returned as a numeric matrix. The rows of `e1` correspond to the cross-validation run and the columns correspond to the test fold.

`testckfold` applies the first test-set predictor data (`X1`) to the first classification model (`C1`) to estimate the first set of class labels.

`e1` summarizes the accuracy of the first set of class labels predicting the true class labels (`Y`) for each cross-validation run and fold. The meaning of the elements of `e1` depends on the type of classification loss.

e2 — Classification losses
numeric matrix

Classification losses on page 33-6220, returned as a numeric matrix. The rows of `e2` correspond to the cross-validation run and the columns correspond to the test fold.

`testckfold` applies the second test-set predictor data (`X2`) to the second classification model (`C2`) to estimate the second set of class labels.

`e2` summarizes the accuracy of the second set of class labels predicting the true class labels (`Y`) for each cross-validation run and fold. The meaning of the elements of `e2` depends on the type of classification loss.

More About

Repeated Cross-Validation Tests

Repeated cross-validation tests form the test statistic for comparing the accuracies of two classification models by combining the classification loss differences resulting from repeatedly cross-validating the data. Repeated cross-validation tests are useful when sample size is limited.

To conduct an *R*-by-*K* test:

1. Randomly divide (stratified by class) the predictor data sets and true class labels into *K* sets, *R* times. Each division is called a run and each set within a run is called a fold. Each run contains the complete, but divided, data sets.
2. For runs $r = 1$ through *R*, repeat these steps for $k = 1$ through *K*:
    a. Reserve fold *k* as a test set, and train the two classification models using their respective predictor data sets on the remaining $K - 1$ folds.

b Predict class labels using the trained models and their respective fold k predictor data sets.

c Estimate the classification loss by comparing the two sets of estimated labels to the true labels. Denote e_{crk} as the classification loss when the test set is fold k in run r of classification model c.

d Compute the difference between the classification losses of the two models:

$$\widehat{\delta}_{rk} = e_{1rk} - e_{2rk}.$$

At the end of a run, there are K classification losses per classification model.

3 Combine the results of step 2. For each $r = 1$ through R:

- Estimate the within-fold averages of the differences and their average: $\bar{\delta}_r = \frac{1}{K}\sum_{k=1}^{K}\widehat{\delta}_{kr}$.
- Estimate the overall average of the differences: $\bar{\delta} = \frac{1}{KR}\sum_{r=1}^{R}\sum_{k=1}^{K}\widehat{\delta}_{rk}$.
- Estimate the within-fold variances of the differences: $s_r^2 = \frac{1}{K}\sum_{k=1}^{K}\left(\widehat{\delta}_{rk} - \bar{\delta}_r\right)^2$.
- Estimate the average of the within-fold differences: $\bar{s}^2 = \frac{1}{R}\sum_{r=1}^{R}s_r^2$.
- Estimate the overall sample variance of the differences: $S^2 = \frac{1}{KR-1}\sum_{r=1}^{R}\sum_{k=1}^{K}\left(\widehat{\delta}_{rk} - \bar{\delta}\right)^2$.

Compute the test statistic. All supported tests described here assume that, under H_0, the estimated differences are independent and approximately normally distributed, with mean 0 and a finite, common standard deviation. However, these tests violate the independence assumption, and so the test-statistic distributions are approximate.

- For $R = 2$, the test is a paired test. The two supported tests are a paired t and F test.
  - The test statistic for the paired t test is

$$t^*_{paired} = \frac{\widehat{\delta}_{11}}{\sqrt{\bar{s}^2}}.$$

    t^*_{paired} has a t-distribution with R degrees of freedom under the null hypothesis.

    To reduce the effects of correlation between the estimated differences, the quantity $\widehat{\delta}_{11}$ occupies the numerator rather than $\bar{\delta}$.

    5-by-2 paired t tests can be slightly conservative [4].
  - The test statistic for the paired F test is

$$F^*_{paired} = \frac{\frac{1}{RK}\sum_{r=1}^{R}\sum_{k=1}^{K}\left(\widehat{\delta}_{rk}\right)^2}{\bar{s}^2}.$$

F^*_{paired} has an F distribution with RK and R degrees of freedom.

A 5-by-2 paired F test has comparable power to the 5-by-2 t test, but is more conservative [1].

- For $R > 2$, the test is a repeated cross-validation test. The test statistic is

$$t^*_{CV} = \frac{\bar{\delta}}{S/\sqrt{\nu + 1}}.$$

t^*_{CV} has a t distribution with ν degrees of freedom. If the differences were truly independent, then $\nu = RK - 1$. In this case, the degrees of freedom parameter must be optimized.

For a 10-by-10 repeated cross-validation t test, the optimal degrees of freedom between 8 and 11 ([2] and [3]). `testckfold` uses $\nu = 10$.

The advantage of repeated cross-validation tests over paired tests is that the results are more repeatable [3]. The disadvantage is that they require high computational resources.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. In general, for a fixed cost matrix, classification accuracy decreases as classification loss increases.

`testckfold` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (that is, the unrestricted classification losses). In the definitions that follow:

- The classification losses focus on the first classification model. The classification losses for the second model are similar.
- n_{test} is the test-set sample size.
- $I(x)$ is the indicator function. If x is a true statement, then $I(x) = 1$. Otherwise, $I(x) = 0$.
- $\widehat{p}_{1j}$ is the predicted class assignment of classification model 1 for observation j.
- y_j is the true class label of observation j.
- Binomial deviance has the form

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j \log\left(1 + \exp\left(-2y'_j f(X_j)\right)\right)}{\sum_{j=1}^{n_{test}} w_j}$$

where:

- $y_j = 1$ for the positive class and -1 for the negative class.
- $f(X_j)$ is the classification score.

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see [5].

- Exponential loss is similar to binomial deviance and has the form

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j \exp\left(-y_j f(X_j)\right)}{\sum_{j=1}^{n_{test}} w_j}.$$

y_j and $f(X_j)$ take the same forms here as in the binomial deviance formula.

- Hinge loss has the form

$$e_1 = \frac{\sum_{j=1}^{n} w_j \max\left\{0, 1 - y_j' f\left(X_j\right)\right\}}{\sum_{j=1}^{n} w_j},$$

y_j and $f(X_j)$ take the same forms here as in the binomial deviance formula.

Hinge loss linearly penalizes for misclassified observations and is related to the SVM objective function used for optimization. For more details on hinge loss, see [5].

- Misclassification rate, or classification error, is a scalar in the interval [0,1] representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j I(\widehat{p}_{1j} \neq y_j)}{\sum_{j=1}^{n_{test}} w_j}.$$

Tips

- Examples of ways to compare models include:
  - Compare the accuracies of a simple classification model and a more complex model by passing the same set of predictor data.
  - Compare the accuracies of two different models using two different sets of predictors.
  - Perform various types of Feature Selection on page 15-49. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).
- If both of these statements are true, then you can omit supplying `Y`.
  - `X1` and `X2` are tables containing the response variable and use the same response variable name.
  - `C1` and `C2` are full classification models containing equal `ResponseName` properties (e.g. `strcmp(C1.ResponseName,C2.ResponseName) = 1`).

  Consequently, `testckfold` uses the common response variable in the tables.
- One way to perform cost-insensitive feature selection is:

1. Create a classification model template that characterizes the first classification model (`C1`).
2. Create a classification model template that characterizes the second classification model (`C2`).
3. Specify two predictor data sets. For example, specify `X1` as the full predictor set and `X2` as a reduced set.
4. Enter `testckfold(C1,C2,X1,X2,Y,'Alternative','less')`. If `testckfold` returns `1`, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the `'Alternative','less'` specification in step 4.`testckfold` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- The tests are appropriate for the misclassification rate classification loss on page 33-6220, but you can specify other loss functions (see `LossFun`). The key assumptions are that the estimated classification losses are independent and normally distributed with mean 0 and finite common variance under the two-sided null hypothesis. Classification losses other than the misclassification rate can violate this assumption.
- Highly discrete data, imbalanced classes, and highly imbalanced cost matrices can violate the normality assumption of classification loss differences.

Algorithms

If you specify to conduct the 10-by-10 repeated cross-validation *t* test using `'Test','10x10t'`, then `testckfold` uses 10 degrees of freedom for the *t* distribution to find the critical region and estimate the *p*-value. For more details, see [2] and [3].

Alternatives

Use `testcholdout`:

- For test sets with larger sample sizes
- To implement variants of the McNemar test to compare two classification model accuracies
- For cost-sensitive testing using a chi-square or likelihood ratio test. The chi-square test uses `quadprog`, which requires an Optimization Toolbox license.

tiedrank

Rank adjusted for ties

Syntax

```
[R,TIEADJ] = tiedrank(X)
[R,TIEADJ] = tiedrank(X,1)
[R,TIEADJ] = tiedrank(X,0,1)
```

Description

`[R,TIEADJ] = tiedrank(X)` computes the ranks of the values in the vector `X`. If any `X` values are tied, `tiedrank` computes their average rank. The return value `TIEADJ` is an adjustment for ties required by the nonparametric tests `signrank` and `ranksum`, and for the computation of Spearman's rank correlation.

`[R,TIEADJ] = tiedrank(X,1)` computes the ranks of the values in the vector `X`. `TIEADJ` is a vector of three adjustments for ties required in the computation of Kendall's tau. `tiedrank(X,0)` is the same as `tiedrank(X)`.

`[R,TIEADJ] = tiedrank(X,0,1)` computes the ranks from each end, so that the smallest and largest values get rank 1, the next smallest and largest get rank 2, etc. These ranks are used in the Ansari-Bradley test.

Examples

Counting from smallest to largest, the two 20 values are 2nd and 3rd, so they both get rank 2.5 (average of 2 and 3):

```
tiedrank([10 20 30 40 20])
ans =
    1.0000    2.5000    4.0000    5.0000    2.5000
```

Algorithms

`tiedrank` treats `NaN`s in `X` as missing values and ignores them. The rank of `NaN`s in the output argument `R` is `NaN`.

tinv

Student's *t* inverse cumulative distribution function

Syntax

```
x = tinv(p,nu)
```

Description

`x = tinv(p,nu)` returns the inverse cumulative distribution function (icdf) of the Student's *t* distribution evaluated at the probability values in `p` using the corresponding degrees of freedom in `nu`.

Examples

Compute Student's *t* icdf

Find the 95th percentile of the Student's *t* distribution with `50` degrees of freedom.

```
p = .95;
nu = 50;
x = tinv(p,nu)
```

```
x = 1.6759
```

Compute Student's *t* icdf for Multiple Distributions

Compute the 99th percentile of the Student's *t* distribution for `1` to `6` degrees of freedom.

```
percentile = tinv(0.99,1:6)
```

```
percentile = 1×6

   31.8205    6.9646    4.5407    3.7469    3.3649    3.1427
```

Compute Confidence Interval Using Student's *t* icdf

Find a 95% confidence interval estimating the mean of a population by using `tinv`.

Generate a random sample of size `100` drawn from a normal population with mean `10` and standard deviation `2`.

```
mu = 10;
sigma = 2;
n = 100;
```

```
rng default   % For reproducibility
x = normrnd(mu,sigma,n,1);
```

Compute the sample mean, standard error, and degrees of freedom.

```
xbar = mean(x);
se = std(x)/sqrt(n);
nu = n - 1;
```

Find the upper and lower confidence bounds for the 95% confidence interval.

```
conf = 0.95;
alpha = 1 - conf;
pLo = alpha/2;
pUp = 1 - alpha/2;
```

Compute the critical values for the confidence bounds.

```
crit = tinv([pLo pUp], nu);
```

Determine the confidence interval for the population mean.

```
ci = xbar + crit*se
```

```
ci = 1×2

    9.7849   10.7075
```

This confidence interval is the same as the `ci` value returned by a `t` test of a null hypothesis that the sample comes from a normal population with mean `mu`.

```
[h,p,ci2] = ttest(x,mu,'Alpha',alpha);
ci2
```

```
ci2 = 2×1

    9.7849
   10.7075
```

Input Arguments

p — Probability values at which to evaluate icdf

scalar value in `[0,1]` | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value or an array of scalar values, where each element is in the range `[0,1]`.

- To evaluate the icdf at multiple values, specify `p` using an array.
- To evaluate the icdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `p` and `nu` are arrays, then the array sizes must be the same. In this case, `tinv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding probability in `p`.

Example: `[0.1 0.5 0.9]`

Data Types: `single` | `double`

nu — Degrees of freedom
positive scalar value | array of positive scalar values

Degrees of freedom for the Student's *t* distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the icdf at multiple values, specify p using an array.
- To evaluate the icdfs of multiple distributions, specify nu using an array.

If either or both of the input arguments p and nu are arrays, then the array sizes must be the same. In this case, `tinv` expands each scalar input into a constant array of the same size as the array inputs. Each element in x is the icdf value of the distribution specified by the corresponding element in nu, evaluated at the corresponding probability in p.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

Output Arguments

x — icdf values
scalar value | array of scalar values

icdf values evaluated at the probabilities in p, returned as a scalar value or an array of scalar values. x is the same size as p and nu after any necessary scalar expansion. Each element in x is the icdf value of the distribution specified by the corresponding element in nu, evaluated at the corresponding probability in p.

More About

Student's *t* icdf

The Student's *t* distribution is a one-parameter family of curves. The parameter ν is the degrees of freedom. The Student's *t* distribution has zero mean.

The *t* inverse function is defined in terms of the Student's *t* cdf as

$$x = F^{-1}(p|\nu) = \left\{x : F(x|\nu) = p\right\},$$

where

$$p = F(x|\nu) = \int_{-\infty}^{x} \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1+\frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt,$$

ν is the degrees of freedom, and $\Gamma(\cdot)$ is the Gamma function. The result *x* is the solution of the integral equation where you supply the probability *p*.

For more information, see “Student's t Distribution” on page B-149.

Alternative Functionality

- `tinv` is a function specific to the Student's *t* distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `tinv` is faster than the generic function `icdf`.

tpdf

Student's *t* probability density function

Syntax

```
y = tpdf(x,nu)
```

Description

`y = tpdf(x,nu)` returns the probability density function (pdf) of the Student's *t* distribution with `nu` degrees of freedom, evaluated at the values in `x`.

Examples

Compute Student's *t* Distribution pdf

The value of the pdf at the mode is an increasing function of the degrees of freedom.

The mode of the Student's *t* distribution is at $x = 0$. Compute the pdf at the mode for degrees of freedom `1` to `6`.

```
tpdf(0,1:6)
```

```
ans = 1×6

    0.3183    0.3536    0.3676    0.3750    0.3796    0.3827
```

The *t* distribution converges to the standard normal distribution as the degrees of freedom approach infinity.

Compute the difference between the pdfs of the standard normal distribution and the Student's *t* distribution pdf with `30` degrees of freedom.

```
difference = tpdf(-2.5:2.5,30)-normpdf(-2.5:2.5)
```

```
difference = 1×6

    0.0035   -0.0006   -0.0042   -0.0042   -0.0006    0.0035
```

Input Arguments

x — Values at which to evaluate pdf

scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value or an array of scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.

- To evaluate the pdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `tpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[-1 0 3 4]`

Data Types: `single` | `double`

`nu` — degrees of freedom
positive scalar value | array of positive scalar values

Degrees of freedom for the Student's *t* distribution, specified as a positive scalar value or an array of positive scalar values.

- To evaluate the pdf at multiple values, specify `x` using an array.
- To evaluate the pdfs of multiple distributions, specify `nu` using an array.

If either or both of the input arguments `x` and `nu` are arrays, then the array sizes must be the same. In this case, `tpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

Output Arguments

`y` — pdf values
scalar value | array of scalar values

pdf values evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x` and `nu` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding element in `nu`, evaluated at the corresponding element in `x`.

More About

Student's *t* pdf

The Student's *t* distribution is a one-parameter family of curves. The parameterν is the degrees of freedom. The Student's *t* distribution has zero mean.

The pdf of the Student's *t* distribution is

$$y = f(x \mid \nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1+\frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}},$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result y is the probability of observing a particular value of x from the Student's t distribution with ν degrees of freedom.

For more information, see "Student's t Distribution" on page B-149.

Alternative Functionality

- `tpdf` is a function specific to the Student's t distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, specify the probability distribution name and its parameters. Note that the distribution-specific function `tpdf` is faster than the generic function `pdf`.

"Student's t Distribution" on page B-149

Introduced before R2006a

training

Training indices for cross-validation

Syntax

```
idx = training(c)
idx = training(c,i)
```

Description

`idx = training(c)` returns the training indices `idx` for a `cvpartition` object `c` of type `'holdout'` or `'resubstitution'`.

- If `c.Type` is `'holdout'`, then `idx` specifies the observations in the training set.
- If `c.Type` is `'resubstitution'`, then `idx` specifies all observations.

`idx = training(c,i)` returns the training indices for repetition `i` of a `cvpartition` object `c` of type `'kfold'` or `'leaveout'`.

- If `c.Type` is `'kfold'`, then `idx` specifies the observations in the `i`th training set.
- If `c.Type` is `'leaveout'`, then `idx` specifies the observations reserved for training at repetition `i`.

Examples

Identify Training Indices in Holdout Partition

Identify the observations that are in the training set of a `cvpartition` object for holdout validation.

Partition 10 observations for holdout validation. Select approximately 30% of the observations to be in the test (holdout) set.

```
rng('default') % For reproducibility
c = cvpartition(10,'Holdout',0.30)
```

```
c =
Hold-out cross validation partition
   NumObservations: 10
       NumTestSets: 1
         TrainSize: 7
          TestSize: 3
```

Identify the training set observations. Observations that correspond to 1s are in the training set.

```
set = training(c)
```

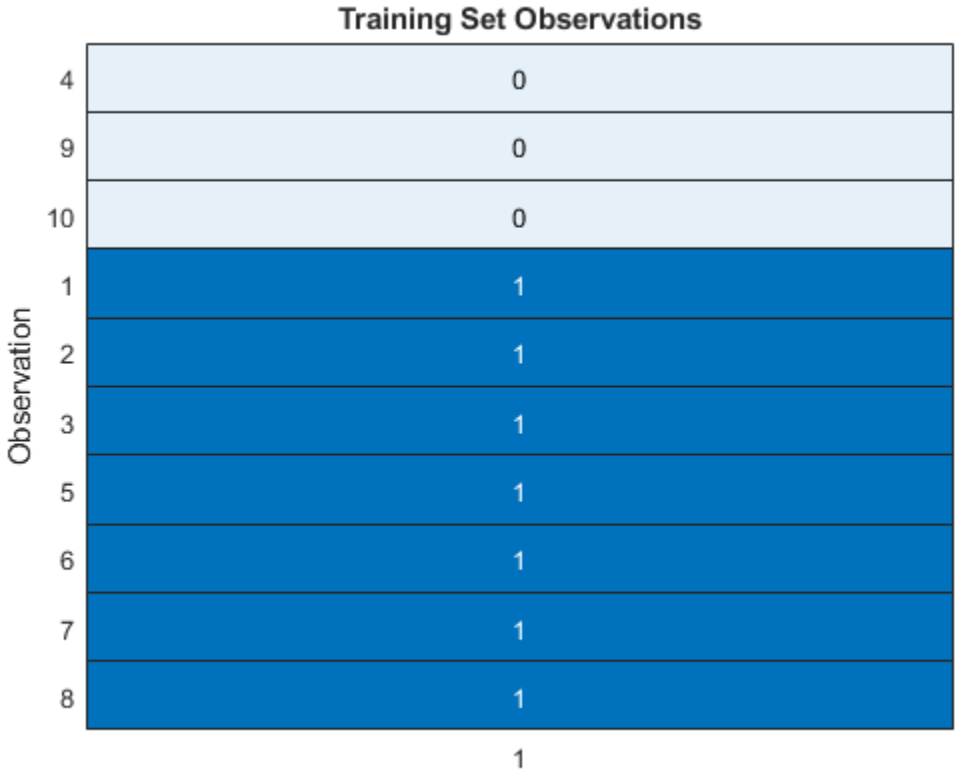
```
set = 10x1 logical array

   1
   1
```

```
1
0
1
1
1
1
0
0
```

Visualize the results. All observations except the fourth, ninth, and tenth are in the training set.

```
h = heatmap(double(set),'ColorbarVisible','off');
sorty(h,'1','ascend')
ylabel('Observation')
title('Training Set Observations')
```



Identify Training Indices in k-Fold Partition

Identify the observations that are in the training sets of a `cvpartition` object for 3-fold cross-validation.

Partition 10 observations for 3-fold cross-validation. Notice that `c` contains three repetitions of training and test data.

```
rng('default') % For reproducibility
c = cvpartition(10,'KFold',3)

c =
K-fold cross validation partition
   NumObservations: 10
       NumTestSets: 3
         TrainSize: 7  6  7
          TestSize: 3  4  3
```

Identify the training set observations for each repetition of training and test data. Observations that correspond to 1s are in the corresponding training set.

```
set1 = training(c,1)

set1 = 10x1 logical array

   0
   0
   1
   1
   1
   1
   1
   1
   0
   1

set2 = training(c,2);
set3 = training(c,3);
```

Visualize the results. All observations except the first, second, and ninth are in the first training set. All observations except the third, sixth, eighth, and tenth are in the second training set. All observations except the fourth, fifth, and seventh are in the third training set.

```
data = [set1,set2,set3];
h = heatmap(double(data),'ColorbarVisible','off');
sorty(h,{'1','2','3'},'ascend')
xlabel('Repetition')
ylabel('Observation')
title('Training Set Observations')
```

Input Arguments

`c` — Validation partition

`cvpartition` object

Validation partition, specified as a `cvpartition` object. The validation partition type of `c`, `c.Type`, is `'kfold'`, `'holdout'`, `'leaveout'`, or `'resubstitution'`.

`i` — Repetition index

positive integer scalar

Repetition index, specified as a positive integer scalar. Specifying `i` indicates to find the observations in the `i`th training set.

Data Types: `single` | `double`

Output Arguments

`idx` — Indices for training set observations

logical vector

Indices for training set observations, returned as a logical vector. A value of 1 indicates that the corresponding observation is in the training set. A value of 0 indicates that the corresponding observation is in the test set.

See Also

`cvpartition` | `test`

Introduced in R2008a

transform

Transform predictors into extracted features

Syntax

```
z = transform(Mdl,x)
```

Description

`z = transform(Mdl,x)` transforms the data `x` into the features `z` via the model `Mdl`.

Examples

Transform Data to Learned Features

Create a feature transformation model with 100 features from the `SampleImagePatches` data.

```
rng('default') % For reproducibility
data = load('SampleImagePatches');
q = 100;
X = data.X;
Mdl = sparsefilt(X,q)
```

```
Warning: Solver LBFGS was not able to converge to a solution.
```

```
Mdl =
  SparseFiltering
           ModelParameters: [1x1 struct]
             NumPredictors: 363
        NumLearnedFeatures: 100
                        Mu: []
                     Sigma: []
                   FitInfo: [1x1 struct]
          TransformWeights: [363x100 double]
    InitialTransformWeights: []

  Properties, Methods
```

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Transform the first five rows of the input data `X` to the new feature space.

```
y = transform(Mdl,X(1:5,:));
size(y)
```

```
ans = 1×2
```

```
     5   100
```

Input Arguments

`Mdl` — Feature extraction model

`SparseFiltering` object | `ReconstructionICA` object

Feature extraction model, specified as a `SparseFiltering` object or as a `ReconstructionICA` object. Create `Mdl` by using the `sparsefilt` function or the `rica` function.

`x` — Predictor data

matrix with `p` columns | table of numeric values with `p` columns

Predictor data, specified as a matrix with `p` columns or as a table of numeric values with `p` columns. Here, `p` is the number of predictors in the model, which is `Mdl.NumPredictors`. Each row of the input matrix or table represents one data point to transform.

Data Types: `single` | `double` | `table`

Output Arguments

`z` — Transformed data

`n`-by-`q` matrix

Transformed data, returned as an `n`-by-`q` matrix. Here, `n` is the number of rows in the input data `x`, and `q` is the number of features, which is `Mdl.NumLearnedFeatures`.

Algorithms

`transform` converts data to predicted features by using the learned weight matrix `W` to map input predictors to output features.

- For `rica`, input data `X` maps linearly to output features `XW`. See “Reconstruction ICA Algorithm” on page 15-132.
- For `sparsefilt`, input data maps nonlinearly to output features $\widehat{F}$(`X`,`W`). See “Sparse Filtering Algorithm” on page 15-130.

Caution The result of `transform` for sparse filtering depends on the number of data points. In particular, the result of applying `transform` to each row of a matrix separately differs from the result of applying `transform` to the entire matrix at once.

“Feature Extraction” on page 15-130

Introduced in R2017a

transform

Transform new data using generated features

Syntax

```
NewTbl = transform(Transformer,Tbl)
NewTbl = transform(Transformer,Tbl,Index)
```

Description

`NewTbl = transform(Transformer,Tbl)` returns a table with transformed features generated by the `FeatureTransformer` object `Transformer`. The input `Tbl` must contain the required variables, whose data types must match those of the variables originally passed to `gencfeatures` when `Transformer` was created.

`NewTbl = transform(Transformer,Tbl,Index)` returns a subset of the transformed features, where `Index` indicates the features to return.

Examples

Compute Cross-Validation Loss Using Generated Features

Generate features to train a linear classifier. Compute the cross-validation classification error of the model by using the `crossval` function.

Load the `ionosphere` data set, and create a table containing the predictor data.

```
load ionosphere
Tbl = array2table(X);
```

Create a random partition for stratified 5-fold cross-validation.

```
rng("default") % For reproducibility of the partition
cvp = cvpartition(Y,"KFold",5);
```

Compute the cross-validation classification loss for a linear model trained on the original features in `Tbl`.

```
CVMdl = fitclinear(Tbl,Y,"CVPartition",cvp);
cvloss = kfoldLoss(CVMdl)
```

```
cvloss = 0.1339
```

Create the custom function `myloss` (shown at the end of this example). This function generates 20 features from the training data, and then applies the same training set transformations to the test data. The function then fits a linear classifier to the training data and computes the test set loss.

Note: If you use the live script file for this example, the `myloss` function is already included at the end of the file. Otherwise, you need to create this function at the end of your .m file or add it as a file on the MATLAB® path.

Compute the cross-validation classification loss for a linear model trained on features generated from the predictors in `Tbl`.

```
newcvloss = mean(crossval(@myloss,Tbl,Y,"Partition",cvp))
```

```
newcvloss = 0.0770
```

```
function testloss = myloss(TrainTbl,trainY,TestTbl,testY)
[Transformer,NewTrainTbl] = gencfeatures(TrainTbl,trainY,20);
NewTestTbl = transform(Transformer,TestTbl);
Mdl = fitclinear(NewTrainTbl,trainY);
testloss = loss(Mdl,NewTestTbl,testY, ...
    "LossFun","classiferror");
end
```

Train Model Using Subset of Generated Features

Train a linear classifier using only the numeric generated features returned by `gencfeatures`.

Load the `patients` data set. Create a table from a subset of the variables.

```
load patients
Tbl = table(Age,Diastolic,Height,SelfAssessedHealthStatus, ...
    Smoker,Systolic,Weight,Gender);
```

Partition the data into training and test sets. Use approximately 70% of the observations as training data, and 30% of the observations as test data. Partition the data using `cvpartition`.

```
rng("default")
c = cvpartition(Tbl.Gender,"Holdout",0.30);
TrainTbl = Tbl(training(c),:);
TestTbl = Tbl(test(c),:);
```

Use the training data to generate 25 new features. Specify the minimum redundancy maximum relevance (MRMR) feature selection method for selecting new features.

```
Transformer = gencfeatures(TrainTbl,"Gender",25, ...
    "FeatureSelectionMethod","mrmr")
```

```
Transformer =
  FeatureTransformer with properties:

                    Type: 'classification'
           TargetLearner: 'linear'
    NumEngineeredFeatures: 24
      NumOriginalFeatures: 1
         TotalNumFeatures: 25
```

Inspect the generated features.

```
Info = describe(Transformer)
```

```
Info=25×4 table
                                        Type        IsOriginal         InputVariables
```

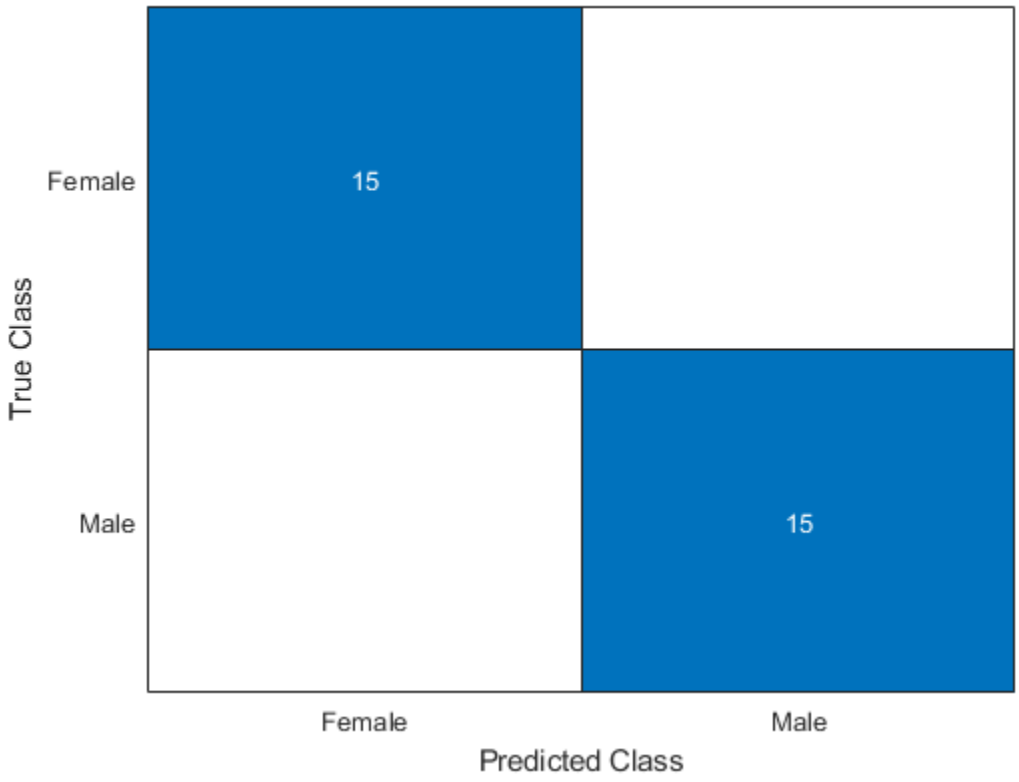
zsc(Height./Weight)            Numeric          false       Height, Weight              "Heig
zsc(Height.*Weight)            Numeric          false       Height, Weight              "Heig
zsc(Diastolic+Weight)          Numeric          false       Diastolic, Weight           "Dias
zsc(Age.*Weight)               Numeric          false       Age, Weight                 "Age
  ⋮
```

Transform the training and test sets, but retain only the numeric predictors.

```
numericIdx = (Info.Type == "Numeric");
NewTrainTbl = transform(Transformer,TrainTbl,numericIdx);
NewTestTbl = transform(Transformer,TestTbl,numericIdx);
```

Train a linear model using the transformed training data. Visualize the accuracy of the model's test set predictions by using a confusion matrix.

```
Mdl = fitclinear(NewTrainTbl,TrainTbl.Gender);
testLabels = predict(Mdl,NewTestTbl);
confusionchart(TestTbl.Gender,testLabels)
```



Input Arguments

`Transformer` — Feature transformer
`FeatureTransformer` object

Feature transformer, specified as a `FeatureTransformer` object.

`Tbl` — Features to transform
table

Features to transform, specified as a table. The rows must correspond to observations, and the columns must correspond to the predictors used to generate the transformed features stored in `Transformer`. You can enter `describe(Transformer).InputVariables` to see the list of features that `Tbl` must contain.

Data Types: `table`

`Index` — Features to return
numeric vector | logical vector | string array | cell array of character vectors

Features to return, specified as a numeric or logical vector indicating the position of the features, or a string array or cell array of character vectors indicating the names of the features.

Example: `1:12`

Data Types: `single` | `double` | `logical` | `string` | `cell`

Output Arguments

`NewTbl` — Transformed features

table

Transformed features, returned as a table. Each row corresponds to an observation, and each column corresponds to a generated feature.

TreeBagger class

Bag of decision trees

Description

`TreeBagger` bags an ensemble of decision trees for either classification or regression. Bagging stands for bootstrap aggregation. Every tree in the ensemble is grown on an independently drawn bootstrap replica of input data. Observations not included in this replica are "out of bag" for this tree.

`TreeBagger` relies on the `ClassificationTree` and `RegressionTree` functionality for growing individual trees. In particular, `ClassificationTree` and `RegressionTree` accepts the number of features selected at random for each decision split as an optional input argument. That is, `TreeBagger` implements the random forest algorithm [1].

For regression problems, `TreeBagger` supports mean and quantile regression (that is, quantile regression forest [2]).

- To predict mean responses or estimate the mean-squared error given data, pass a `TreeBagger` model and the data to `predict` or `error`, respectively. To perform similar operations for out-of-bag observations, use `oobPredict` or `oobError`.
- To estimate quantiles of the response distribution or the quantile error given data, pass a `TreeBagger` model and the data to `quantilePredict` or `quantileError`, respectively. To perform similar operations for out-of-bag observations, use `oobQuantilePredict` or `oobQuantileError`.

Construction

TreeBagger	Create bag of decision trees

Object Functions

append	Append new trees to ensemble
compact	Compact ensemble of decision trees
error	Error (misclassification probability or MSE)
fillprox	Proximity matrix for training data
growTrees	Train additional trees and add to ensemble
margin	Classification margin
mdsprox	Multidimensional scaling of proximity matrix
meanMargin	Mean classification margin
oobError	Out-of-bag error
oobMargin	Out-of-bag margins
oobMeanMargin	Out-of-bag mean margins
oobPredict	Ensemble predictions for out-of-bag observations
oobQuantileError	Out-of-bag quantile loss of bag of regression trees
oobQuantilePredict	Quantile predictions for out-of-bag observations from bag of regression trees
partialDependence	Compute partial dependence

plotPartialDependence	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
predict	Predict responses using ensemble of bagged decision trees
quantileError	Quantile loss using bag of regression trees
quantilePredict	Predict response quantile using bag of regression trees

Properties

`ClassNames`

A cell array containing the class names for the response variable `Y`. This property is empty for regression trees.

`ComputeOOBPrediction`

A logical flag specifying whether out-of-bag predictions for training observations should be computed. The default is `false`.

If this flag is `true`, the following properties are available:

- `OOBIndices`
- `OOBInstanceWeight`

If this flag is `true`, the following methods can be called:

- `oobError`
- `oobMargin`
- `oobMeanMargin`

`ComputeOOBPredictorImportance`

A logical flag specifying whether out-of-bag estimates of variable importance should be computed. The default is `false`. If this flag is `true`, then `ComputeOOBPrediction` is true as well.

If this flag is `true`, the following properties are available:

- `OOBPermutedPredictorDeltaError`
- `OOBPermutedPredictorDeltaMeanMargin`
- `OOBPermutedPredictorCountRaiseMargin`

`Cost`

Square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

This property is:

- read-only
- empty (`[]`) for ensembles of regression trees

DefaultYfit

Default value returned by `predict` and `oobPredict`. The `DefaultYfit` property controls what predicted value is returned when no prediction is possible. For example, when `oobPredict` needs to predict for an observation that is in-bag for all trees in the ensemble.

- For classification, you can set this property to either `''` or `'MostPopular'`. If you choose `'MostPopular'` (the default), the property value becomes the name of the most probably class in the training data. If you choose `''`, the in-bag observations are excluded from computation of the out-of-bag error and margin.
- For regression, you can set this property to any numeric scalar. The default value is the mean of the response for the training data. If you set this property to `NaN`, the in-bag observations are excluded from computation of the out-of-bag error and margin.

DeltaCriterionDecisionSplit

A numeric array of size 1-by-*Nvars* of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

InBagFraction

Fraction of observations that are randomly selected with replacement for each bootstrap replica. The size of each replica is *Nobs*×`InBagFraction`, where *Nobs* is the number of observations in the training set. The default value is 1.

MergeLeaves

A logical flag specifying whether decision tree leaves with the same parent are merged for splits that do not decrease the total risk. The default value is `false`.

Method

Method used by trees. The possible values are `'classification'` for classification ensembles, and `'regression'` for regression ensembles.

MinLeafSize

Minimum number of observations per tree leaf. By default, `MinLeafSize` is 1 for classification and 5 for regression. For decision tree training, the `MinParent` value is set equal to `2*MinLeafSize`.

NumTrees

Scalar value equal to the number of decision trees in the ensemble.

NumPredictorSplit

A numeric array of size 1-by-*Nvars*, where every element gives a number of splits on this predictor summed over all trees.

NumPredictorsToSample

Number of predictor or feature variables to select at random for each decision split. By default, `NumPredictorsToSample` is equal to the square root of the total number of variables for classification, and one third of the total number of variables for regression.

OOBIndices

Logical array of size *Nobs*-by-*NumTrees*, where *Nobs* is the number of observations in the training data and *NumTrees* is the number of trees in the ensemble. A `true` value for the (*i*,*j*) element indicates that observation *i* is out-of-bag for tree *j*. In other words, observation *i* was not selected for the training data used to grow tree *j*.

OOBInstanceWeight

Numeric array of size *Nobs*-by-1 containing the number of trees used for computing the out-of-bag response for each observation. *Nobs* is the number of observations in the training data used to create the ensemble.

OOBPermutedPredictorCountRaiseMargin

A numeric array of size 1-by-*Nvars* containing a measure of variable importance for each predictor variable (feature). For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

OOBPermutedPredictorDeltaError

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

OOBPermutedPredictorDeltaMeanMargin

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

OutlierMeasure

A numeric array of size *Nobs*-by-1, where *Nobs* is the number of observations in the training data, containing outlier measures for each observation.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

This property is:

- read-only
- empty (`[]`) for ensembles of regression trees

Proximity

A numeric matrix of size *Nobs*-by-*Nobs*, where *Nobs* is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1s on the diagonal and off-diagonal elements ranging from 0 to 1.

Prune

The `Prune` property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

SampleWithReplacement

A logical flag specifying if data are sampled for each decision tree with replacement. This property is `true` if `TreeBagger` samples data with replacement and `false` otherwise. Default value is `true`.

TreeArguments

Cell array of arguments for `fitctree` or `fitrtree`. These arguments are used by `TreeBagger` when growing new trees for the ensemble.

Trees

A cell array of size *NumTrees*-by-1 containing the trees in the ensemble.

SurrogateAssociation

A matrix of size *Nvars*-by-*Nvars* with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting `'surrogate'` to `'on'`, this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting `'surrogate'` to `'off'` (default), `SurrogateAssociation` is diagonal.

PredictorNames

A cell array containing the names of the predictor variables (features). `TreeBagger` takes these names from the optional `'names'` parameter. The default names are `'x1'`, `'x2'`, etc.

W

Numeric vector of weights of length *Nobs*, where *Nobs* is the number of observations (rows) in the training data. `TreeBagger` uses these weights for growing every decision tree in the ensemble. The default `W` is `ones(Nobs,1)`.

X

A table or numeric matrix of size *Nobs*-by-*Nvars*, where *Nobs* is the number of observations (rows) and *Nvars* is the number of variables (columns) in the training data. If you train the ensemble using a table of predictor values, then `X` is a table. If you train the ensemble using a matrix of predictor values, then `X` is a matrix. This property contains the predictor (or feature) values.

Y

A size *Nobs* array of response data. Elements of `Y` correspond to the rows of `X`. For classification, `Y` is the set of true class labels. Labels can be any grouping variable on page 2-45, that is, a numeric or

logical vector, character matrix, string array, cell array of character vectors, or categorical vector. `TreeBagger` converts labels to a cell array of character vectors for classification. For regression, `Y` is a numeric vector.

Examples

Train Ensemble of Bagged Classification Trees

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees using the entire data set. Specify `50` weak learners. Store which observations are out of bag for each tree.

```
rng(1); % For reproducibility
Mdl = TreeBagger(50,meas,species,'OOBPrediction','On',...
    'Method','classification')
```

```
Mdl =
  TreeBagger
Ensemble with 50 bagged decision trees:
                    Training X:              [150x4]
                    Training Y:              [150x1]
                        Method:       classification
                NumPredictors:                    4
       NumPredictorsToSample:                    2
                   MinLeafSize:                   1
                InBagFraction:                    1
       SampleWithReplacement:                     1
        ComputeOOBPrediction:                     1
 ComputeOOBPredictorImportance:                   0
                     Proximity:                  []
                    ClassNames:        'setosa'    'versicolor'     'virginica'

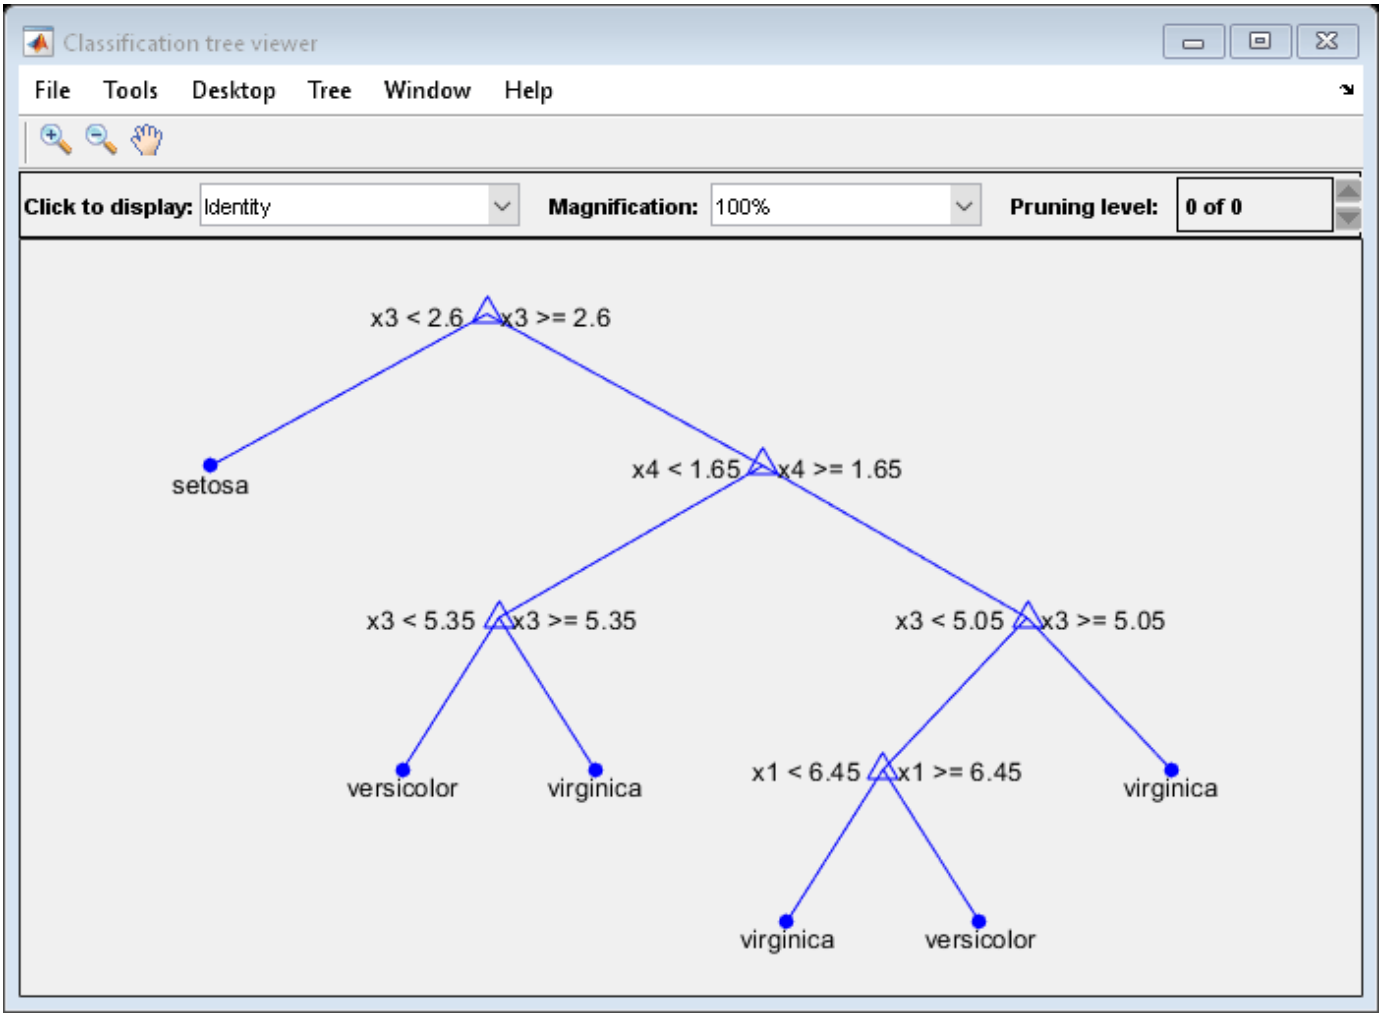
  Properties, Methods
```

`Mdl` is a `TreeBagger` ensemble.

`Mdl.Trees` stores a 50-by-1 cell vector of the trained classification trees (`CompactClassificationTree` model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trees{1},'Mode','graph')
```

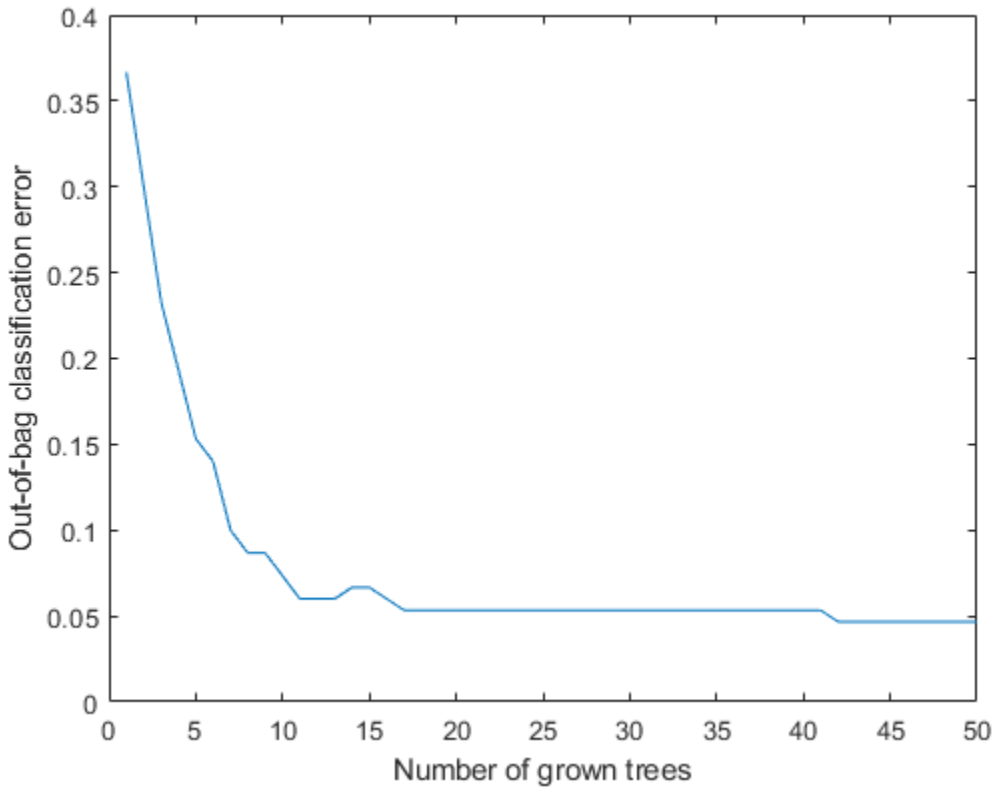


By default, `TreeBagger` grows deep trees.

`Mdl.OOBIndices` stores the out-of-bag indices as a matrix of logical values.

Plot the out-of-bag error over the number of grown classification trees.

```
figure;
oobErrorBaggedEnsemble = oobError(Mdl);
plot(oobErrorBaggedEnsemble)
xlabel 'Number of grown trees';
ylabel 'Out-of-bag classification error';
```



The out-of-bag error decreases with the number of grown trees.

To label out-of-bag observations, pass `Mdl` to `oobPredict`.

Train Ensemble of Bagged Regression Trees

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

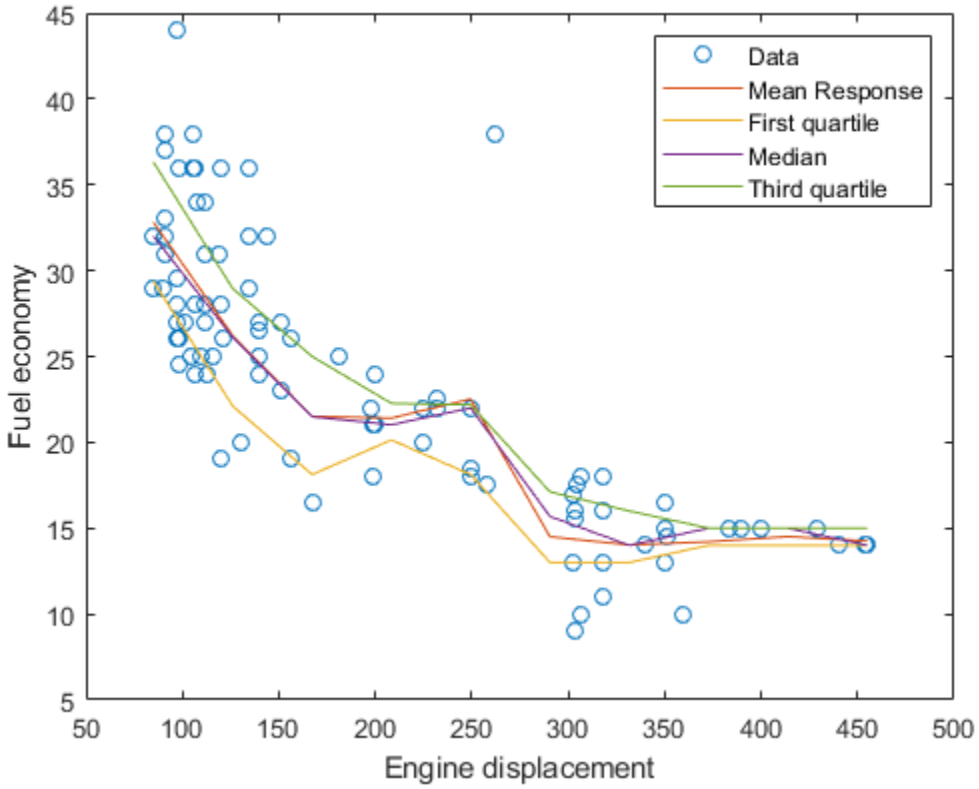
Using a trained bag of regression trees, you can estimate conditional mean responses or perform quantile regression to predict conditional quantiles.

For ten equally-spaced engine displacements between the minimum and maximum in-sample displacement, predict conditional mean responses and conditional quartiles.

```
predX = linspace(min(Displacement),max(Displacement),10)';
mpgMean = predict(Mdl,predX);
mpgQuartiles = quantilePredict(Mdl,predX,'Quantile',[0.25,0.5,0.75]);
```

Plot the observations, and estimated mean responses and quartiles in the same figure.

```
figure;
plot(Displacement,MPG,'o');
hold on
plot(predX,mpgMean);
plot(predX,mpgQuartiles);
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Mean Response','First quartile','Median','Third quartile');
```



Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
```

```
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
rng('default'); % For reproducibility
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```
numMfg = 28
```

```
numModelYear = numel(categories(Model_Year))
```

```
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 200 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. Store the out-of-bag information for predictor importance estimation.

```
Mdl = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
    'PredictorSelection','curvature','OOBPredictorImportance','on');
```

`TreeBagger` stores predictor importance estimates in the property `OOBPermutedPredictorDeltaError`. Compare the estimates using a bar graph.

```
imp = Mdl.OOBPermutedPredictorDeltaError;

figure;
bar(imp);
title('Curvature Test');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `Model_Year` is the most important predictor, followed by `Weight`.

Compare the `imp` to predictor importance estimates computed from a random forest that grows trees using standard CART.

```
MdlCART = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
    'OOBPredictorImportance','on');

impCART = MdlCART.OOBPermutedPredictorDeltaError;

figure;
bar(impCART);
title('Standard CART');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `Weight`, a continuous predictor, is the most important. The next two most importance predictor are `Model_Year` followed closely by `Horsepower`, which is a continuous predictor.

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

Tip

For a `TreeBagger` model object `B`, the `Trees` property stores a cell vector of `B.NumTrees` `CompactClassificationTree` or `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(B.Trees{t})
```

Alternative Functionality

Statistics and Machine Learning Toolbox offers three objects for bagging and random forest:

- `ClassificationBaggedEnsemble` created by `fitcensemble` for classification
- `RegressionBaggedEnsemble` created by `fitrensemble` for regression

- `TreeBagger` created by `TreeBagger` for classification and regression

For details about the differences between `TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`), see “Comparison of TreeBagger and Bagged Ensembles” on page 18-44.

TreeBagger

Class: `TreeBagger`

Create bag of decision trees

Individual decision trees tend to overfit. Bootstrap-aggregated (bagged) decision trees combine the results of many decision trees, which reduces the effects of overfitting and improves generalization. `TreeBagger` grows the decision trees in the ensemble using bootstrap samples of the data. Also, `TreeBagger` selects a random subset of predictors to use at each decision split as in the random forest algorithm [1].

By default, `TreeBagger` bags classification trees. To bag regression trees instead, specify `'Method','regression'`.

For regression problems, `TreeBagger` supports mean and quantile regression (that is, quantile regression forest [5]).

Syntax

```
Mdl = TreeBagger(NumTrees,Tbl,ResponseVarName)
Mdl = TreeBagger(NumTrees,Tbl,formula)
Mdl = TreeBagger(NumTrees,Tbl,Y)
B = TreeBagger(NumTrees,X,Y)
B = TreeBagger(NumTrees,X,Y,Name,Value)
```

Description

`Mdl = TreeBagger(NumTrees,Tbl,ResponseVarName)` returns an ensemble of `NumTrees` bagged classification trees trained using the sample data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`.

`Mdl = TreeBagger(NumTrees,Tbl,formula)` returns an ensemble of bagged classification trees trained using the sample data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. Specify `Formula` using Wilkinson notation. For more information, see “Wilkinson Notation” on page 11-91.

`Mdl = TreeBagger(NumTrees,Tbl,Y)` returns an ensemble of classification trees using the predictor variables in table `Tbl` and class labels in vector `Y`.

`Y` is an array of response data. Elements of `Y` correspond to the rows of `Tbl`. For classification, `Y` is the set of true class labels. Labels can be any grouping variable on page 2-45, that is, a numeric or logical vector, character matrix, string array, cell array of character vectors, or categorical vector. `TreeBagger` converts labels to a cell array of character vectors. For regression, `Y` is a numeric vector. To grow regression trees, you must specify the name-value pair `'Method','regression'`.

`B = TreeBagger(NumTrees,X,Y)` creates an ensemble `B` of `NumTrees` decision trees for predicting response `Y` as a function of predictors in the numeric matrix of training data, `X`. Each row in `X` represents an observation and each column represents a predictor or feature.

`B = TreeBagger(NumTrees,X,Y,Name,Value)` specifies optional parameter name-value pairs:

`'InBagFraction'`	Fraction of input data to sample with replacement from the input data for growing each new tree. Default value is 1.
`'Cost'`	Square matrix `C`, where `C(i,j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in the `ClassNames` property of the trained `TreeBagger` model `B`. Alternatively, `cost` can be a structure `S` having two fields: • `S.ClassNames` containing the group names as a categorical variable, character array, string array, or cell array of character vectors • `S.ClassificationCosts` containing the cost matrix `C` The default value is `C(i,j) = 1` if `i ~= j`, and `C(i,j) = 0` if `i = j`. If `Cost` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large penalty. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.
`'SampleWithReplacement'`	`'on'` to sample with replacement or `'off'` to sample without replacement. If you sample without replacement, you need to set `'InBagFraction'` to a value less than one. Default is `'on'`.
`'OOBPrediction'`	`'on'` to store info on what observations are out of bag for each tree. This info can be used by `oobPrediction` to compute the predicted class probabilities for each tree in the ensemble. Default is `'off'`.
`'OOBPredictorImportance'`	`'on'` to store out-of-bag estimates of feature importance in the ensemble. Default is `'off'`. Specifying `'on'` also sets the `'OOBPrediction'` value to `'on'`. If an analysis of predictor importance is your goal, then also specify `'PredictorSelection','curvature'` or `'PredictorSelection','interaction-curvature'`. For more details, see `fitctree` or `fitrtree`.
`'Method'`	Either `'classification'` or `'regression'`. Regression requires a numeric `Y`.
`'NumPredictorsToSample'`	Number of variables to select at random for each decision split. Default is the square root of the number of variables for classification and one third of the number of variables for regression. Valid values are `'all'` or a positive integer. Setting this argument to any valid value but `'all'` invokes Breiman's random forest algorithm [1].
`'NumPrint'`	Number of training cycles (grown trees) after which `TreeBagger` displays a diagnostic message showing training progress. Default is no diagnostic messages.
`'MinLeafSize'`	Minimum number of observations per tree leaf. Default is 1 for classification and 5 for regression.

`'Options'`	A structure that specifies options that govern the computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:
	• `'UseParallel'` — If `true` and Parallel Computing Toolbox is installed, then the software uses an existing parallel pool for parallel trees, or, depending on parallel preferences, the software opens and uses a new pool if none is currently open. Otherwise, the software computes in serial. Default is `false`, meaning serial computation.
	For dual-core systems and above, `TreeBagger` parallelizes training using Intel Threading Building Blocks (TBB). Therefore, using the `'UseParallel'` option on a single computer may not speed up computation much and may consume more memory than in serial. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.
	• `'UseSubstreams'` — If `true` select each bootstrap replicate using a separate Substream of the random number generator (aka Stream). This option is available only with `RandStream` types that support Substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Default is `false`, do not use a different Substream to compute each bootstrap replicate.
	• `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `TreeBagger` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
	  • `UseParallel` is `true`
	  • `UseSubstreams` is `false`
	In that case, use a cell array the same size as the Parallel pool.

`'Prior'`	Prior probabilities for each class. Specify as one of:
	• A character vector or string scalar:
	  • `'Empirical'` determines class probabilities from class frequencies in `Y`. If you pass observation weights, they are used to compute the class probabilities. This is the default.
	  • `'Uniform'` sets all class probabilities equal.
	• A vector (one scalar value for each class). The order of the elements `Prior` corresponds to the order of the classes in the `ClassNames` property of the trained `TreeBagger` model `B`.
	• A structure `S` with two fields:
	  • `S.ClassNames` containing the class names as a categorical variable, character array, string array, or cell array of character vectors
	  • `S.ClassProbs` containing a vector of corresponding probabilities
	If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.
	If `Prior` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large prior probability. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large prior probability. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

`'PredictorNames'`	Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.
	• If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
	  • The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
	  • By default, `PredictorNames` is `{'x1','x2',...}`.
	• If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `TreeBagger` uses the predictor variables in `PredictorNames` and the response only in training.
	  • `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
	  • By default, `PredictorNames` contains the names of all predictor variables.
	  • It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

`'CategoricalPredictors'`	Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following. • A numeric vector with indices from `1` to `p`, where `p` is the number of columns of `X`. • A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable. • A string array or cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values. • A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length. • `'all'`, meaning all predictors are categorical.
`'ChunkSize'`	Chunk size, specified as the comma-separated pair consisting of `'ChunkSize'` and a positive integer. The chunk size specifies the number of observations in each chunk of data. The default value is `50000`. **Note** This option only applies when using `TreeBagger` on tall arrays. See “Extended Capabilities” on page 33-0 for more information.

In addition to the optional arguments above, `TreeBagger` accepts these optional `fitctree` and `fitrtree` arguments.

Supported `fitctree` arguments	Supported `fitrtree` arguments
`AlgorithmForCategorical`	`MaxNumSplits`
`MaxNumCategories`	`MergeLeaves`
`MaxNumSplits`	`PredictorSelection`
`MergeLeaves`	`Prune`
`PredictorSelection`	`PruneCriterion`
`Prune`	`QuadraticErrorTolerance`
`PruneCriterion`	`SplitCriterion`
`SplitCriterion`	`Surrogate`
`Surrogate`	`Weights`
`'Weights'`	

Examples

Train Ensemble of Bagged Classification Trees

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees using the entire data set. Specify `50` weak learners. Store which observations are out of bag for each tree.

```
rng(1); % For reproducibility
Mdl = TreeBagger(50,meas,species,'OOBPrediction','On',...
    'Method','classification')
```

```
Mdl =
  TreeBagger
Ensemble with 50 bagged decision trees:
                    Training X:              [150x4]
                    Training Y:              [150x1]
                        Method:       classification
                NumPredictors:                    4
         NumPredictorsToSample:                    2
                     MinLeafSize:                 1
                InBagFraction:                    1
         SampleWithReplacement:                   1
          ComputeOOBPrediction:                   1
 ComputeOOBPredictorImportance:                   0
                      Proximity:                  []
                    ClassNames:        'setosa'    'versicolor'     'virginica'

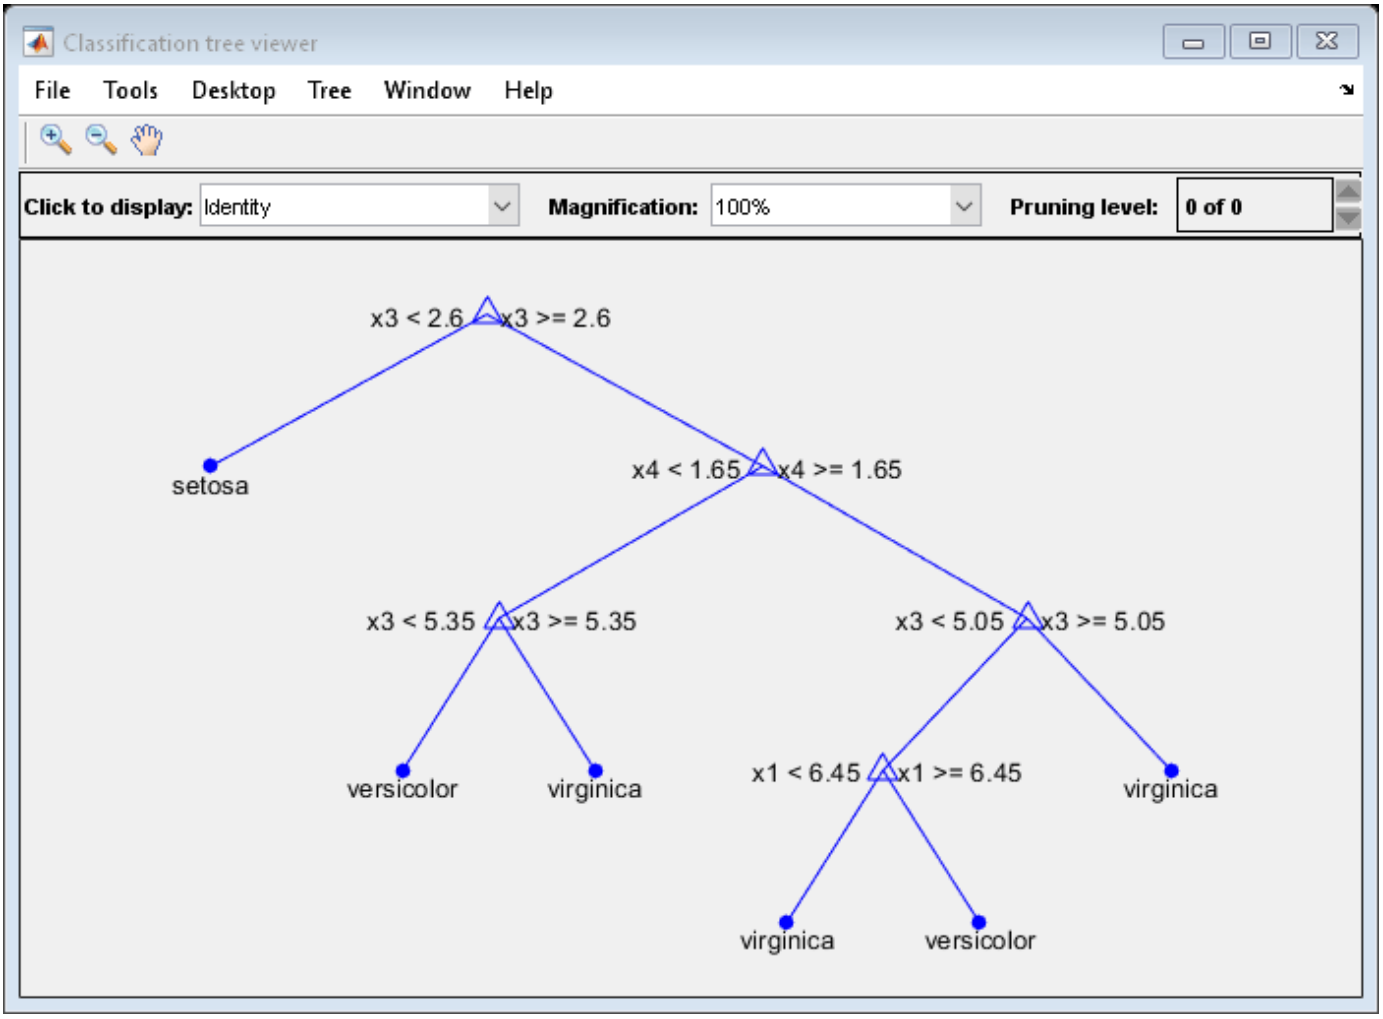
  Properties, Methods
```

`Mdl` is a `TreeBagger` ensemble.

`Mdl.Trees` stores a 50-by-1 cell vector of the trained classification trees (`CompactClassificationTree` model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trees{1},'Mode','graph')
```

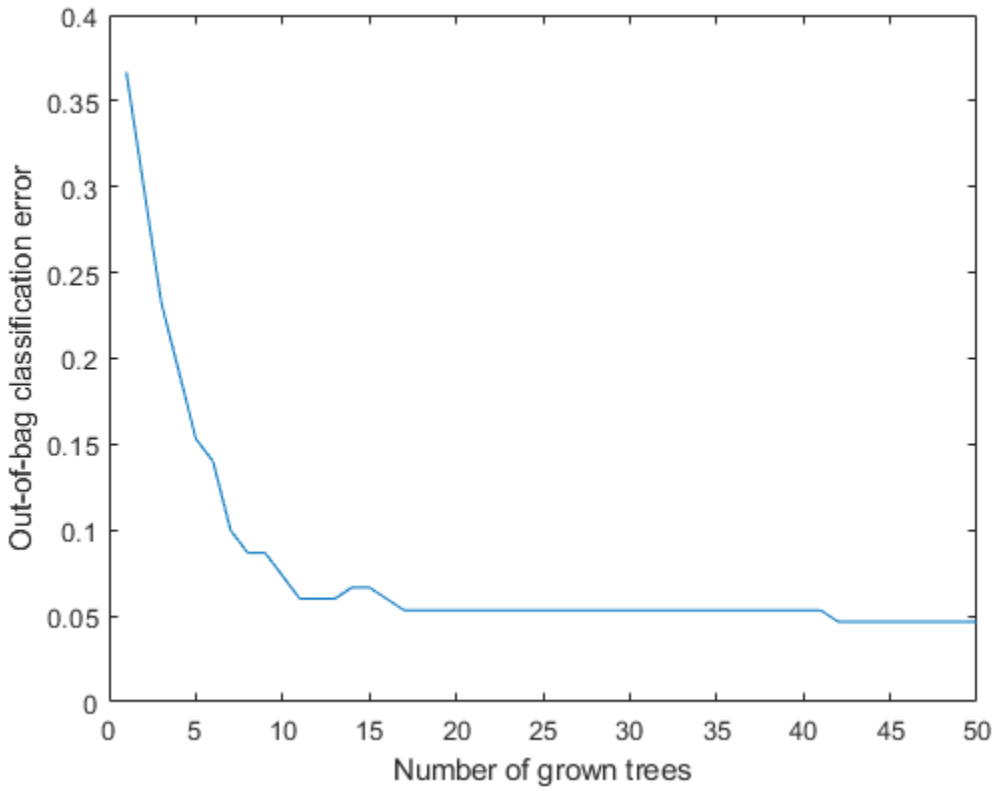


By default, `TreeBagger` grows deep trees.

`Mdl.OOBIndices` stores the out-of-bag indices as a matrix of logical values.

Plot the out-of-bag error over the number of grown classification trees.

```
figure;
oobErrorBaggedEnsemble = oobError(Mdl);
plot(oobErrorBaggedEnsemble)
xlabel 'Number of grown trees';
ylabel 'Out-of-bag classification error';
```



The out-of-bag error decreases with the number of grown trees.

To label out-of-bag observations, pass `Mdl` to `oobPredict`.

Train Ensemble of Bagged Regression Trees

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

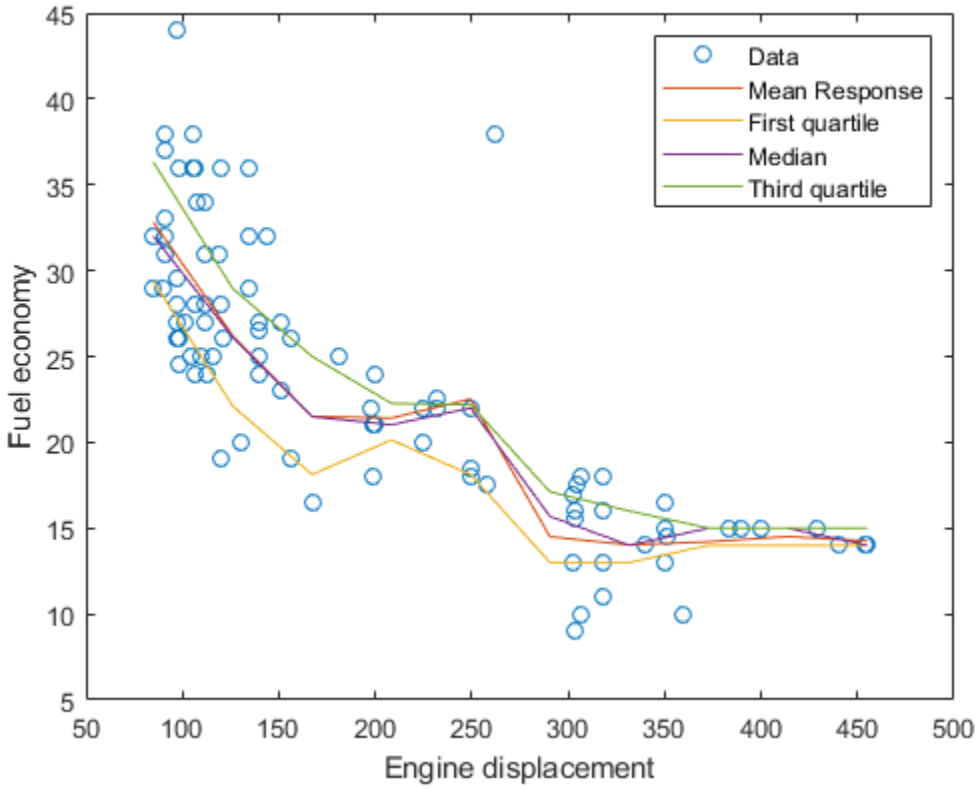
Using a trained bag of regression trees, you can estimate conditional mean responses or perform quantile regression to predict conditional quantiles.

For ten equally-spaced engine displacements between the minimum and maximum in-sample displacement, predict conditional mean responses and conditional quartiles.

```
predX = linspace(min(Displacement),max(Displacement),10)';
mpgMean = predict(Mdl,predX);
mpgQuartiles = quantilePredict(Mdl,predX,'Quantile',[0.25,0.5,0.75]);
```

Plot the observations, and estimated mean responses and quartiles in the same figure.

```
figure;
plot(Displacement,MPG,'o');
hold on
plot(predX,mpgMean);
plot(predX,mpgQuartiles);
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Mean Response','First quartile','Median','Third quartile');
```



Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
```

```
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
    Model_Year,Weight,MPG);
rng('default'); % For reproducibility
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```
numMfg = 28
```

```
numModelYear = numel(categories(Model_Year))
```

```
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 200 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. Store the out-of-bag information for predictor importance estimation.

```
Mdl = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
    'PredictorSelection','curvature','OOBPredictorImportance','on');
```

`TreeBagger` stores predictor importance estimates in the property `OOBPermutedPredictorDeltaError`. Compare the estimates using a bar graph.

```
imp = Mdl.OOBPermutedPredictorDeltaError;

figure;
bar(imp);
title('Curvature Test');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `Model_Year` is the most important predictor, followed by `Weight`.

Compare the `imp` to predictor importance estimates computed from a random forest that grows trees using standard CART.

```
MdlCART = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
    'OOBPredictorImportance','on');

impCART = MdlCART.OOBPermutedPredictorDeltaError;

figure;
bar(impCART);
title('Standard CART');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `Weight`, a continuous predictor, is the most important. The next two most importance predictor are `Model_Year` followed closely by `Horsepower`, which is a continuous predictor.

Train Ensemble of Bagged Classification Trees on Tall Array

Train an ensemble of bagged classification trees for observations in a tall array, and find the misclassification probability of each tree in the model for weighted observations. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data.

When you perform calculations on tall arrays, MATLAB® uses either a parallel pool (default if you have Parallel Computing Toolbox™) or the local MATLAB session. To run the example using the local MATLAB session when you have Parallel Computing Toolbox, change the global execution environment by using the `mapreducer` function.

```
mapreducer(0)
```

Create a datastore that references the location of the folder containing the data set. Select a subset of the variables to work with, and treat `'NA'` values as missing data so that `datastore` replaces them with `NaN` values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month','DayofMonth','DayOfWeek',...
                            'DepTime','ArrDelay','Distance','DepDelay'};
```

```
ds.TreatAsMissing = 'NA';
tt  = tall(ds) % Tall table
```

```
tt =

  Mx7 tall table

    Month    DayofMonth    DayOfWeek    DepTime    ArrDelay    Distance    DepDelay
    _____    __________    _________    _______    ________    ________    ________

     10          21            3          642          8          308          12
     10          26            1         1021          8          296           1
     10          23            5         2055         21          480          20
     10          23            5         1332         13          296          12
     10          22            4          629          4          373          -1
     10          28            3         1446         59          308          63
     10           8            4          928          3          447          -2
     10          10            6          859         11          954          -1

         10          21           3         642           8         308
         10          26           1        1021           8         296
         10          23           5        2055          21         480
         10          23           5        1332          13         296
         10          22           4         629           4         373
         10          28           3        1446          59         308
         10           8           4         928           3         447
         10          10           6         859          11         954
```

```
          :           :           :           :           :           :
          :           :           :           :           :           :
```

Create a tall array for the observation weights by arbitrarily assigning double weights to the observations in class 1.

```
W = Y+1; % Weights
```

Remove rows in `X`, `Y`, and `W` that contain missing data.

```
R = rmmissing([X Y W]); % Data with missing entries removed
X = R(:,1:end-2);
Y = R(:,end-1);
W = R(:,end);
```

Train an ensemble of 20 bagged decision trees using the entire data set. Specify a weight vector and uniform prior probabilities. For reproducibility, set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs”.

```
rng('default')
tallrng('default')
tMdl = TreeBagger(20,X,Y,'Weights',W,'Prior','Uniform')
```

```
Evaluating tall expression using the Local MATLAB Session:

tMdl =
  CompactTreeBagger
Ensemble with 20 bagged decision trees:
              Method:       classification
       NumPredictors:                    6
          ClassNames: '0' '1'

  Properties, Methods
```

`tMdl` is a `CompactTreeBagger` ensemble with 20 bagged decision trees.

Calculate the misclassification probability of each tree in the model. Attribute a weight contained in the vector `W` to each observation by using the `'Weights'` name-value pair argument.

```
terr = error(tMdl,X,Y,'Weights',W)
```

```
Evaluating tall expression using the Local MATLAB Session:

```

Find the average misclassification probability for the ensemble of decision trees.

```
avg_terr = mean(terr)
```

```
avg_terr = 0.1022
```

Tips

- Avoid large estimated out-of-bag error variances by setting a more balanced misclassification cost matrix or a less skewed prior probability vector.
- The `Trees` property of `B` stores a cell array of `B.NumTrees` `CompactClassificationTree` or `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell array, enter

  ```
  view(B.Trees{t})
  ```
- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. Consider specifying the curvature or interaction test if any of the following are true:

  - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
  - If an analysis of predictor importance is your goal. `TreeBagger` stores predictor importance estimates in the `OOBPermutedPredictorDeltaError` property of `Mdl`.

  For more information on predictor selection, see `PredictorSelection` for classification trees or `PredictorSelection` for regression trees.

Algorithms

- `TreeBagger` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For details on selecting split predictors and node-splitting algorithms when growing decision trees, see “Algorithms” on page 33-1928 for classification trees and “Algorithms” on page 33-2413 for regression trees.

Alternative Functionality

Statistics and Machine Learning Toolbox offers three objects for bagging and random forest:

- `ClassificationBaggedEnsemble` created by `fitcensemble` for classification
- `RegressionBaggedEnsemble` created by `fitrensemble` for regression
- `TreeBagger` created by `TreeBagger` for classification and regression

For details about the differences between `TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`), see “Comparison of TreeBagger and Bagged Ensembles” on page 18-44.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitations:

- Supported syntaxes for tall `X`, `Y`, `Tbl` are:
  - `B = TreeBagger(NumTrees,Tbl,Y)`
  - `B = TreeBagger(NumTrees,X,Y)`
  - `B = TreeBagger(___,Name,Value)`
- For tall arrays, `TreeBagger` supports classification but does not support regression.
- Supported name-value pairs are:
  - `'NumPredictorsToSample'` — Default value is the square root of the number of variables for classification.
  - `'MinLeafSize'` — Default value is `1` if the number of observations is less than 50,000. If the number of observations is 50,000 or greater, then the default value is `max(1,min(5,floor(0.01*NobsChunk)))`, where `NobsChunk` is the number of observations in a chunk.
  - `'ChunkSize'` (only for tall arrays) — Default value is `50000`.

In addition, `TreeBagger` supports these optional arguments of `fitctree`:

- `'AlgorithmForCategorical'`
- `'CategoricalPredictors'`
- `'Cost'` — The columns of the cost matrix `C` cannot contain `Inf` or `NaN` values.
- `'MaxNumCategories'`
- `'MaxNumSplits'`
- `'MergeLeaves'`
- `'PredictorNames'`
- `'PredictorSelection'`
- `'Prior'`
- `'Prune'`
- `'PruneCriterion'`
- `'SplitCriterion'`
- `'Surrogate'`
- `'Weights'`

- For tall data, `TreeBagger` returns a `CompactTreeBagger` object that contains most of the same properties as a full `TreeBagger` object. The main difference is that the compact object is more memory efficient. The compact object does not include properties that include the data, or that include an array of the same size as the data.
- The number of trees contained in the returned `CompactTreeBagger` object can differ from the number of trees specified as input to the `TreeBagger` function. `TreeBagger` determines the number of trees to return based on factors that include the size of the input data set and the number of data chunks available to grow trees.
- Supported `CompactTreeBagger` methods are:

  - `combine`
  - `error`
  - `margin`
  - `meanMargin`
  - `predict`
  - `setDefaultYfit`

  The `error`, `margin`, `meanMargin`, and `predict` methods do not support the name-value pair arguments `'Trees'`, `'TreeWeights'`, or `'UseInstanceForTree'`. The `meanMargin` method additionally does not support `'Weights'`.
- `TreeBagger` creates a random forest by generating trees on disjoint chunks of the data. When more data is available than is required to create the random forest, the data is subsampled. For a similar example, see Random Forests for Big Data (Genuer, Poggi, Tuleau-Malot, Villa-Vialaneix 2015).

  Depending on how the data is stored, it is possible that some chunks of data contain observations from only a few classes out of all the classes. In this case, `TreeBagger` might produce inferior results compared to the case where each chunk of data contains observations from most of the classes.

- During training of the `TreeBagger` algorithm, the speed, accuracy, and memory usage depend on a number of factors. These factors include values for `NumTrees`, `'ChunkSize'`, `'MinLeafSize'`, and `'MaxNumSplits'`.

  For an *n*-by-*p* tall array `X`, `TreeBagger` implements sampling during training. This sampling depends on these variables:

  - Number of trees `NumTrees`
  - Chunk size `'ChunkSize'`
  - Number of observations *n*
  - Number of chunks *r* (approximately equal to *n*/`'ChunkSize'`)

  Because the value of *n* is fixed for a given `X`, your settings for `NumTrees` and `'ChunkSize'` determine how `TreeBagger` samples `X`.

  1. If *r* > `NumTrees`, then `TreeBagger` samples `'ChunkSize' * NumTrees` observations from `X`, and trains one tree per chunk (with each chunk containing `'ChunkSize'` number of observations). This scenario is the most common when you work with tall arrays.
  2. If *r* ≤ `NumTrees`, then `TreeBagger` trains approximately `NumTrees`/*r* trees in each chunk, using bootstrapping within the chunk.
  3. If *n* ≤ `'ChunkSize'`, then `TreeBagger` uses bootstrapping to generate samples (each of size *n*) on which to train individual trees.

- When specifying a value for `NumTrees`, consider the following:

  - If you run your code on Apache Spark, and your data set is distributed with Hadoop® Distributed File System (HDFS™), start by specifying a value for `NumTrees` that is at least twice the number of partitions in HDFS for your data set. This setting prevents excessive data communication among Apache Spark executors and can improve performance of the `TreeBagger` algorithm.
  - `TreeBagger` copies fitted trees into the client memory in the resulting `CompactTreeBagger` model. Therefore, the amount of memory available to the client creates an upper bound on the value you can set for `NumTrees`. You can tune the values of `'MinLeafSize'` and `'MaxNumSplits'` for more efficient speed and memory usage at the expense of some predictive accuracy. After tuning, if the value of `NumTrees` is less than twice the number of partitions in HDFS for your data set, then consider repartitioning your data in HDFS to have larger partitions.

  After specifying a value for `NumTrees`, set `'ChunkSize'` to ensure that `TreeBagger` uses most of the data to grow trees. Ideally, `'ChunkSize' * NumTrees` should approximate *n*, the number of rows in your data. Note that the memory available in the workers for training individual trees can also determine an upper bound for `'ChunkSize'`.

  You can adjust the Apache Spark memory properties to avoid out-of-memory errors and support your workflow. See `parallel.cluster.Hadoop` (Parallel Computing Toolbox) for more information.

For more information, see “Tall Arrays for Out-of-Memory Data”.

Automatic Parallel Support
Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, specify the `'Options'` name-value argument in the call to this function and set the `'UseParallel'` field of the options structure to `true` using `statset`.

For example: `'Options',statset('UseParallel',true)`

For more information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2009a

trimmean

Mean, excluding outliers

Syntax

```
m = trimmean(X,percent)
m = trimmean(X,percent,flag)
m = trimmean( ___ ,'all')
m = trimmean( ___ ,dim)
m = trimmean( ___ ,vecdim)
```

Description

`m = trimmean(X,percent)` returns the mean of values of `X`, computed after removing the outliers of `X`. For example, if `X` is a vector that has `n` values, `m` is the mean of `X` excluding the highest and lowest `k` data values, where `k = n*(percent/100)/2`.

- If `X` is a vector, then `trimmean(X,percent)` is the mean of all the values of `X`, computed after removing the outliers.
- If `X` is a matrix, then `trimmean(X,percent)` is a row vector of column means, computed after removing the outliers.
- If `X` is a multidimensional array, then `trimmean` operates along the first nonsingleton dimension of `X`.

`m = trimmean(X,percent,flag)` specifies how to trim when `k` (half the number of outliers) is not an integer.

`m = trimmean( ___ ,'all')` returns the trimmed mean of all the values in `X` using any of the input argument combinations in the previous syntaxes.

`m = trimmean( ___ ,dim)` returns the trimmed mean along the operating dimension `dim` of `X`.

`m = trimmean( ___ ,vecdim)` returns the trimmed mean over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `trimmean(X,10,[1 2])` returns a 1-by-1-by-4 array. Each value of the output array is the mean of the middle 90% of the values on the corresponding page of `X`.

Examples

Efficiency of Trimmed Mean

Find the relative efficiency of the 10% trimmed mean to the sample mean for a given data set.

Generate a 100-by-100 matrix of random numbers from the standard normal distribution. This matrix represents 100 samples, each containing 100 data points.

```
rng default;  % For reproducibility
X = normrnd(0,1,100,100);
```

Compute the sample mean and the 10% trimmed mean for each column of the data matrix.

```
m = mean(X); % Sample mean
trim = trimmean(X,10); % Trimmed mean
```

Compute the relative efficiency of the trimmed mean to the sample mean. The relative efficiency is the variance of the sample mean divided by the variance of the trimmed mean.

```
vm = var(m) % Variance of the sample mean
```

```
vm = 0.0094
```

```
vtrim = var(trim) % Variance of the trimmed mean
```

```
vtrim = 0.0097
```

```
efficiency = vm/vtrim % Relative efficiency of the trimmed mean to the sample mean
```

```
efficiency = 0.9663
```

The sample mean has a smaller variance than the trimmed mean (`efficiency < 1`). Therefore, the trimmed mean is less efficient than the sample mean.

Control Trimming for Distribution with Outliers

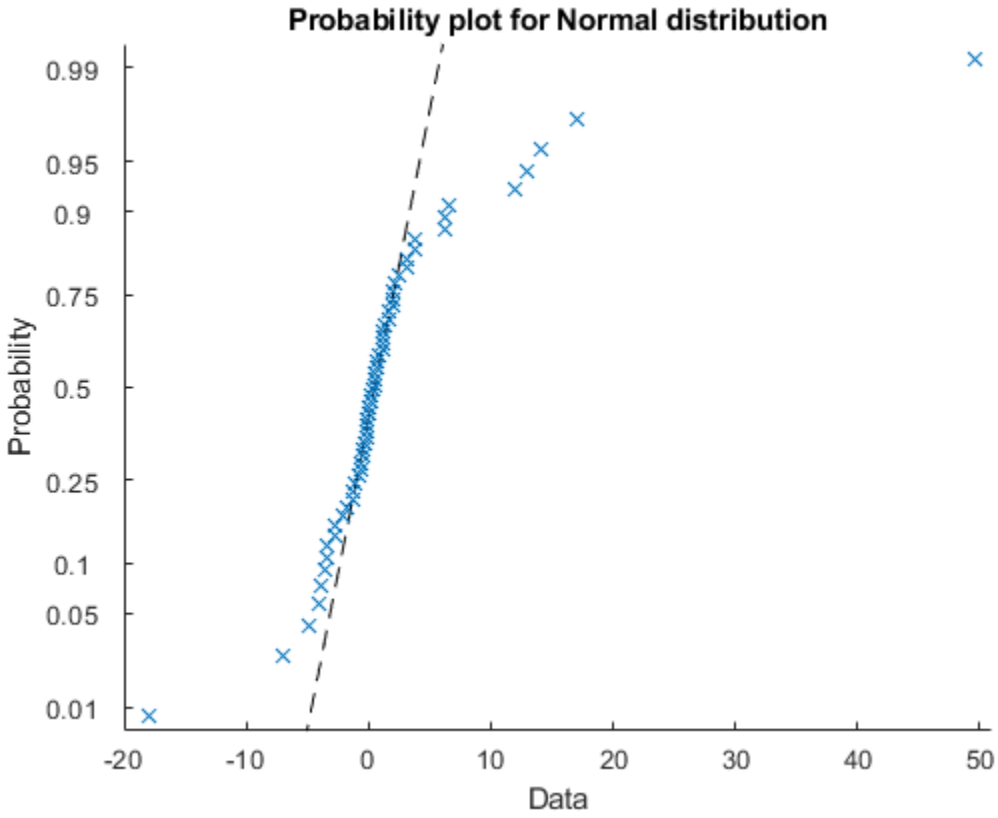
Control the trimming for a distribution with outliers when `k` (half the number of outliers to be trimmed) is not an integer.

Generate a vector of random numbers from the Student's *t* distribution with degrees of freedom equal to 1. The Student's *t* distribution tends to have outliers.

```
rng default;  % For reproducibility
nu = 1; % Degrees of freedom
n = 60; % Number of rows
m = 1;  % Number of columns
x = trnd(nu,n,m); % Vector
```

Visualize the distribution using a normal probability plot.

```
probplot(x)
```



Although the distribution is symmetric around zero, several outliers affect the mean.

Find the mean of the data.

```
mn = mean(x)
```

```
mn = 1.6452
```

Find the 33% trimmed mean of the data.

```
trim = trimmean(x,33)
```

```
trim = 0.4940
```

The 33% trimmed mean is closer to zero, which is more representative of the data. For the 33% trimmed mean, `k` is not an integer (`k = 60*(33/100)/2` gives a value of `9.9`). Therefore, `trimmean` rounds `k` to the nearest integer (`10`) by default.

Control trimming by rounding `k` down to the next smaller integer (`9`). Specify the control for trimming to `'floor'`.

```
trim = trimmean(x,33,'floor')
```

```
trim = 0.4933
```

Find Trimmed Mean Along Given Dimension

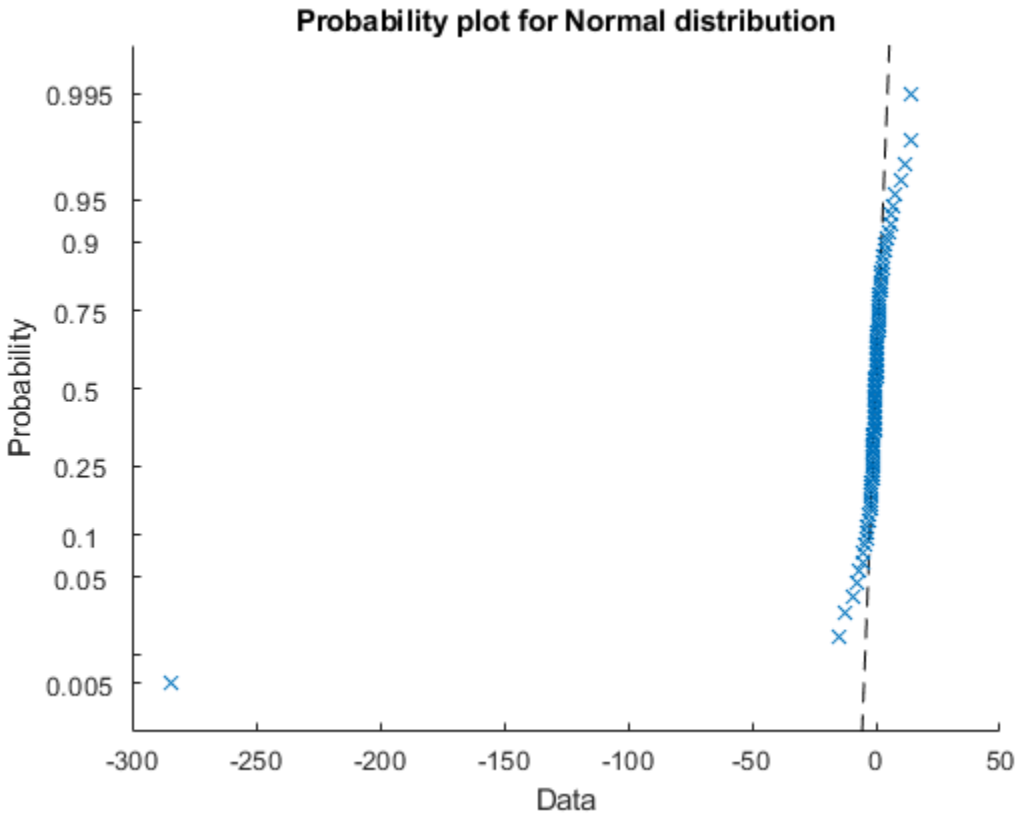
Find the trimmed mean along different dimensions for a matrix.

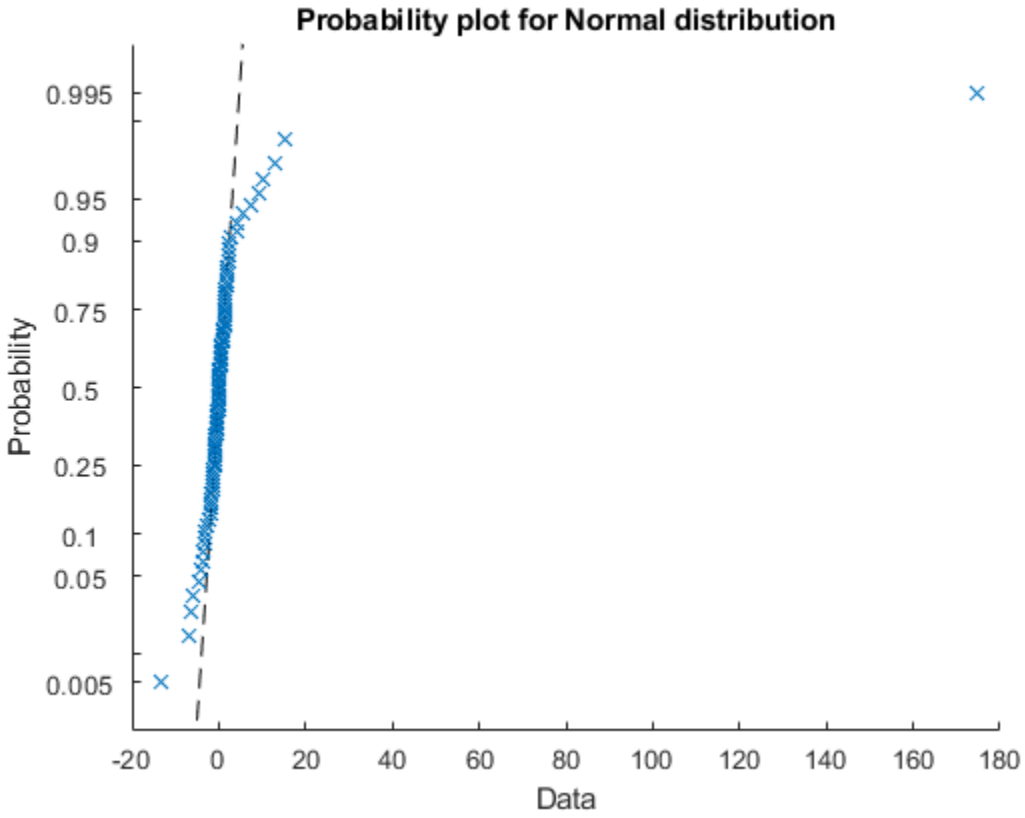
Generate a matrix of random numbers from the Student's *t* distribution. The Student's *t* distribution tends to have outliers.

```
rng('default')
nu = 1; % Degrees of freedom
n = 2; % Number of rows
m = 100;  % Number of columns
X = trnd(nu,n,m);
```

Visualize the distribution for each row of X using a normal probability plot.

```
for i = 1:n
    figure()
    probplot(X(i,:))
end
```





Find the mean for each row of X.

```
mn = mean(X,2)
```

```
mn = 2×1

   -2.7379
    2.0087
```

Find the 30% trimmed mean for each row of X. Specify `dim = 2` as the operating dimension.

```
trim = trimmean(X,30,2)
```

```
trim = 2×1

   -0.0868
    0.1115
```

The 30% trimmed mean of each row is closer to zero, which is more representative of the data.

Trimmed Mean Along Vector of Dimensions

Calculate the trimmed mean over multiple dimensions by using the `'all'` and `vecdim` input arguments.

Create a 5-by-4-by-2 array with some outlier values.

```
X = reshape(1:40,[5 4 2]);
X([3 37]) = -100
```

```
X =
X(:,:,1) =

     1     6    11    16
     2     7    12    17
  -100     8    13    18
     4     9    14    19
     5    10    15    20

X(:,:,2) =

    21    26    31    36
    22    27    32  -100
    23    28    33    38
    24    29    34    39
    25    30    35    40
```

Find the 10% trimmed mean of `X`.

```
mall = trimmean(X,10,'all')
```

```
mall = 19.4722
```

`mall` is the mean of the middle 90% of the values in `X`.

Find the 10% trimmed mean for each page of `X`.

```
mpage = trimmean(X,10,[1 2])
```

```
mpage =
mpage(:,:,1) =

   10.3889

mpage(:,:,2) =

   29.6111
```

For example, `mpage(1,1,2)` is the mean of the middle 90% of the values in `X(:,:,2)`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If X is a vector, then `trimmean(X,percent)` is the mean of all the values of X, computed after removing the outliers.
- If X is a matrix, then `trimmean(X,percent)` is a row vector of column means, computed after removing the outliers.
- If X is a multidimensional array, then `trimmean` operates along the first nonsingleton dimension of X.

To specify the operating dimension when X is a matrix or an array, use the `dim` input argument.

`trimmean` treats `NaN` values in X as missing values and removes them.

Data Types: `single` | `double`

`percent` — Percentage
scalar

Percentage of input data to be trimmed, specified as a scalar between `0` and `100`.

`trimmean` uses the value of `percent` to determine the number of outliers (highest and lowest `k` values in X) to remove from X before computing the mean. For X with `n` values, `k = n*(percent/100)/2`.

Data Types: `single` | `double`

`flag` — Control for trimming
`'round'` (default) | `'floor'` | `'weighted'`

Control for trimming when `k` (half the number of outliers) is not an integer, specified as one of the values in this table.

Value	Description
`'round'`	Round `k` to the nearest integer (round to a smaller integer if `k` is a half integer). This value is the default.
`'floor'`	Round `k` down to the next smaller integer.
`'weighted'`	If `k = i + f`, where `i` is an integer and `f` is a fraction, compute a weighted mean with weight `(1 − f)` for the `(i + 1)th` and `(n − i)th` values, and full weight for the values between them.

Data Types: `char` | `string`

`dim` — Dimension
positive integer scalar

Dimension along which to operate, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension of X whose size does not equal 1.

Consider a two-dimensional array X:

- If `dim` is equal to 1, then `trimmean(X,percent,1)` returns a row vector containing the trimmed mean for each column in X.
- If `dim` is equal to 2, then `trimmean(X,percent,2)` returns a column vector containing the trimmed mean for each row in X.

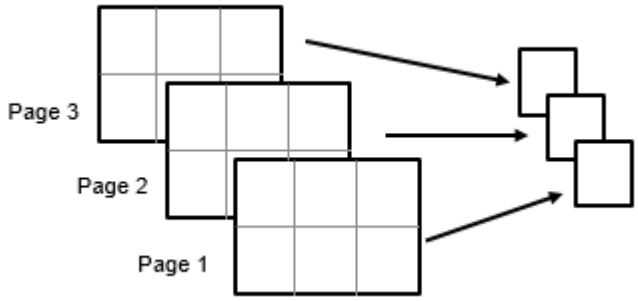
If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `trimmean` returns X.

Data Types: `single` | `double`

`vecdim` — Vector of dimensions
positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `m` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `m`.

For example, if `X` is a 2-by-3-by-3 array, then `trimmean(X,10,[1 2])` returns a 1-by-1-by-3 array. Each element of the output is the mean of the middle 90% of the values on the corresponding page of `X`.



Data Types: `single` | `double`

Output Arguments

`m` — Trimmed mean
scalar | vector | matrix | multidimensional array

Trimmed mean values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- The trimmed mean is a robust estimate of the location of a data sample. If the data contains outliers, then the trimmed mean represents the center of the data better than the sample mean. However, if all the data is from the same probability distribution, then the trimmed mean is less efficient than the sample mean as an estimator of the data location.

Extended Capabilities

GPU Arrays
Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

trnd

Student's *t* random numbers

Syntax

```
r = trnd(nu)
r = trnd(nu,sz1,...,szN)
r = trnd(nu,sz)
```

Description

`r = trnd(nu)` generates a random number from the Student's *t* distribution with `nu` degrees of freedom.

`r = trnd(nu,sz1,...,szN)` generates an array of random numbers from the Student's *t* distribution, where `sz1,...,szN` indicates the size of each dimension.

`r = trnd(nu,sz)` generates an array of random numbers from the Student's *t* distribution, where size vector `sz` specifies `size(r)`.

Examples

Generate Student's *t* Distribution Random Number

Generate a single random number from the Student's *t* distribution with `10` degrees of freedom.

```
nu = 10;
r = trnd(nu)
```

```
r = 1.0585
```

Generate Student's *t* Distribution Random Numbers

Generate a 1-by-6 array of Student's *t* random numbers with `1` degree of freedom.

```
nu1 = ones(1,6); % 1-by-6 array of ones
r1 = trnd(nu1)
```

```
r1 = 1×6

    0.2108    7.8450  -11.0511    0.4134    4.3293   -0.8323
```

If you specify `nu` as a scalar, it expands into a constant array with dimensions specified by `sz1,...,szn`.

Generate a 2-by-6 array of Student's *t* random numbers with `3` degrees of freedom

```
nu2 = 3;
sz1 = 2;
sz2 = 6;
r2 = trnd(nu2,sz1,sz2)
```

```
r2 = 2×6

    0.9257    0.3379    0.6477   -2.2792   -2.8371    0.3632
   -0.2996   -0.6845   -1.2554   -0.5134    1.0458   -0.5521
```

If you specify both `nu` and `sz` as arrays, then the dimensions specified by `sz` must match the dimension of `nu`.

Generate a 1-by-6 array of Student's *t* random numbers with `1` to `6` degrees of freedom.

```
nu3 = 1:6;
sz = [1 6];
r3 = trnd(nu3,sz)
```

```
r3 = 1×6

    1.3609    0.1845   -4.0246   -0.8724   -0.7507    2.3493
```

Input Arguments

`nu` — Degrees of freedom

scalar value | array of scalar values

Degrees of freedom for the Student's *t* distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple distributions, specify `nu` using an array. Each element in `r` is the random number generated from the distribution specified by the corresponding degrees of freedom in `nu`.

Example: `[9 19 49 99]`

Data Types: `single` | `double`

`sz1,...,szN` — Size of each dimension (as separate arguments)

integers

Size of each dimension, specified as separate arguments of integers.

If `nu` is an array, then the specified dimensions `sz1,...,szN` must match the dimensions of `nu`. The default values of `sz1,...,szN` are the dimensions of `nu`.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `trnd` ignores trailing dimensions with a size of `1`. For example, `trnd(5,3,1,1,1)` produces a 3-by-1 vector of random numbers from the distribution with `5` degrees of freedom.

Example: `3,5`

Data Types: `single` | `double`

`sz` — Size of each dimension (as a row vector)
row vector of integers

Size of each dimension, specified as a row vector of integers.

If `nu` is an array, then the specified dimensions `sz` must match the dimensions of `nu`. The default values of `sz` are the dimensions of `nu`.

- If you specify a single value [`sz1`], then `r` is a square matrix of size `sz1`-by-`sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `trnd` ignores trailing dimensions with a size of `1`. For example, `trnd(5,[3 1 1 1])` produces a 3-by-1 vector of random numbers from the distribution with `5` degrees of freedom.

Example: `[3 5]`

Data Types: `single` | `double`

Output Arguments

`r` — Student's *t* random numbers
scalar value | array of scalar values

Student's *t* random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1,...,szN` or `sz`. Each element in `r` is the random number generated from the distribution specified by the corresponding degrees of freedom in `nu`.

Alternative Functionality

- `trnd` is a function specific to the Student's *t* distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Note that the distribution-specific function `trnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a user interface for random number generation.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers from the sequence of numbers returned by MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

truncate

Package: `prob`

Truncate probability distribution object

Syntax

```
t = truncate(pd,lower,upper)
```

Description

`t = truncate(pd,lower,upper)` returns a probability distribution `t`, which is the probability distribution `pd` truncated to the specified interval with lower limit, `lower`, and upper limit, `upper`.

Examples

Truncate a Probability Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Truncate the distribution to have a lower limit of -2 and an upper limit of 2.

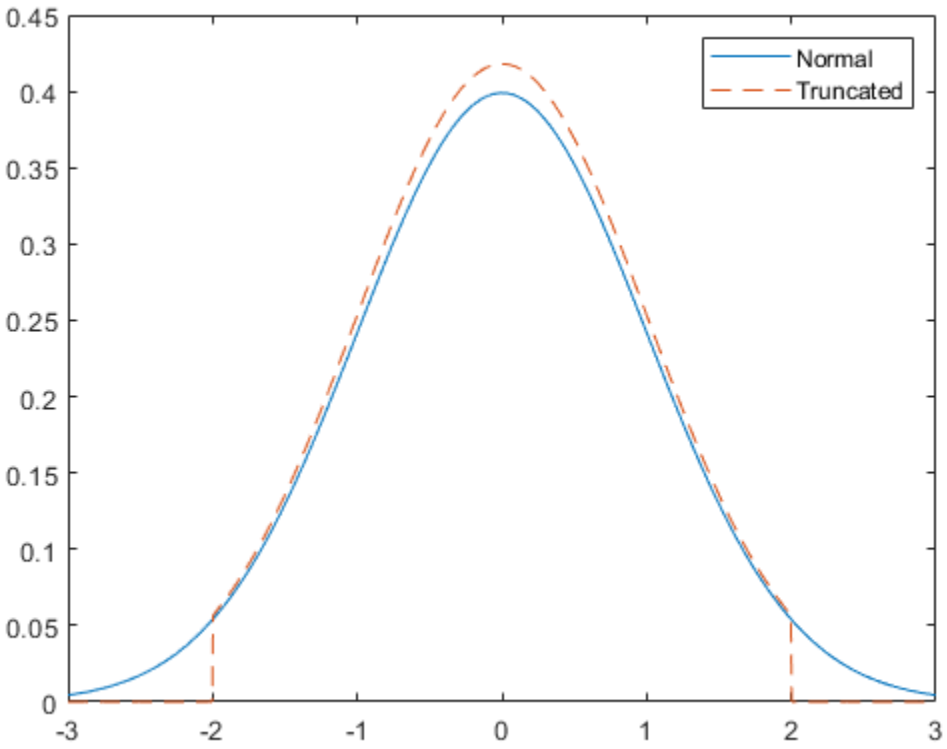
```
t = truncate(pd,-2,2)
```

```
t =
  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
  Truncated to the interval [-2, 2]
```

Plot the pdf of the original and truncated distributions for a visual comparison.

```
x = linspace(-3,3,1000);
figure
plot(x,pdf(pd,x))
hold on
plot(x,pdf(t,x),'LineStyle','--')
legend('Normal','Truncated')
hold off
```



Generate Random Numbers from a Truncated Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

Truncate the distribution by restricting it to positive values. Set the lower limit to 0 and the upper limit to infinity.

```
t = truncate(pd,0,inf)
```

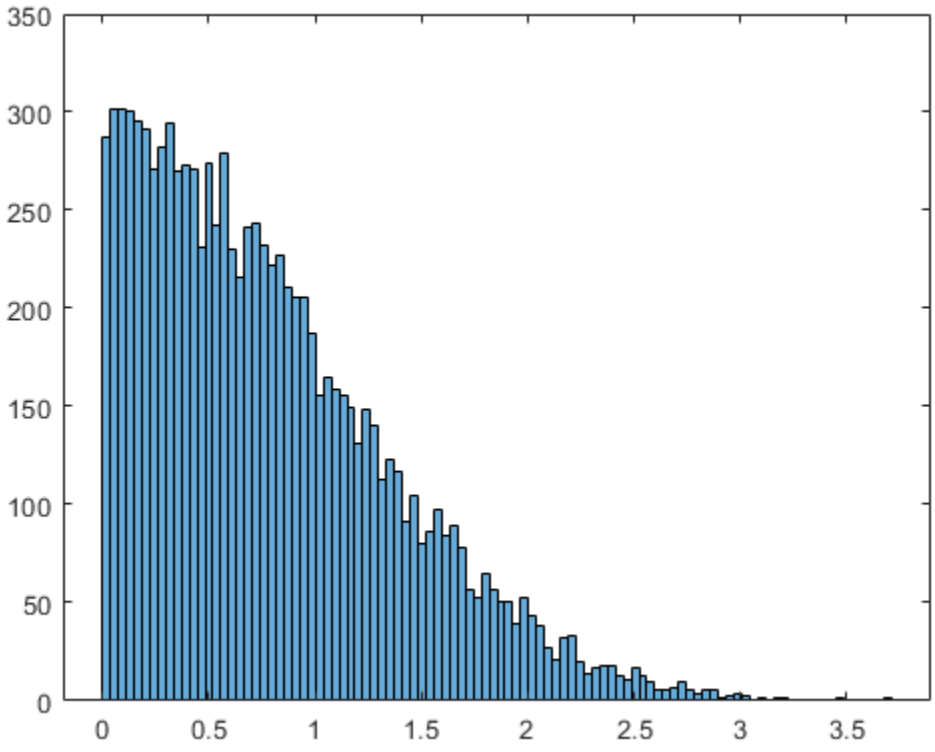
```
t =
  NormalDistribution

  Normal distribution
       mu = 0
    sigma = 1
```

```
  Truncated to the interval [0, Inf]
```

Generate random numbers from the truncated distribution and visualize with a histogram.

```
r = random(t,10000,1);
histogram(r,100)
```



Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
`makedist`	Create a probability distribution object using specified parameter values.
`fitdist`	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

lower — Lower truncation limit

scalar value

Lower truncation limit, specified as a scalar value.

Data Types: `single` | `double`

`upper` — Upper truncation limit
scalar value

Upper truncation limit, specified as a scalar value.

Data Types: `single` | `double`

Output Arguments

`t` — Truncated distribution
probability distribution object

Truncated distribution, returned as a probability distribution object. The probability distribution function (pdf) of `t` is 0 outside the truncation interval. Inside the truncation interval, the pdf of `t` is equal to the pdf of `pd`, but divided by the probability assigned to that interval by `pd`.

The object properties of `t` are the same as those of `pd` with these exceptions:

- The `Truncation` property of `t` stores the truncation interval.
- The `IsTruncated` property of `t` is 1.
- The `InputData` property of `t` is empty. For a fitted distribution object, the `InputData` property stores the data used for distribution fitting. The truncated distribution object does not store the input data.

Extended Capabilities

C/C++ Code Generation
Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `pd` can be a fitted probability distribution object for beta, exponential, extreme value, lognormal, normal, and Weibull distributions. Create `pd` by fitting a probability distribution to sample data from the `fitdist` function. For an example, see “Code Generation for Probability Distribution Objects” on page 32-82.
- A truncated probability distribution object cannot be an input argument of an entry-point function. To evaluate a truncated distribution using object functions such as `cdf`, `pdf`, `mean`, and so on, call `truncate` and one or more of these object functions within a single entry-point function.

For more information on code generation, see “Introduction to Code Generation” on page 32-2 and “General Code Generation Workflow” on page 32-5.

Introduced in R2013a

tsne

t-Distributed Stochastic Neighbor Embedding

Syntax

```
Y = tsne(X)
Y = tsne(X,Name,Value)
[Y,loss] = tsne( ___ )
```

Description

`Y = tsne(X)` returns a matrix of two-dimensional embeddings of the high-dimensional rows of `X`.

`Y = tsne(X,Name,Value)` modifies the embeddings using options specified by one or more name-value pair arguments.

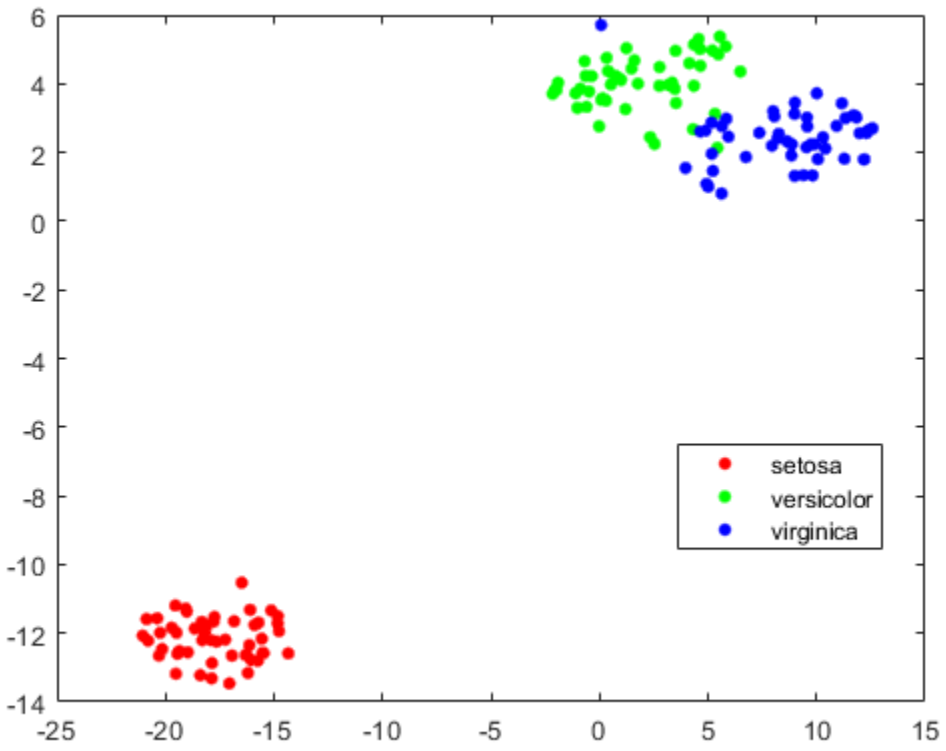
`[Y,loss] = tsne( ___ )`, for any input arguments, also returns the Kullback-Leibler divergence between the joint distributions that model the data `X` and the embedding `Y`.

Examples

Visualize Fisher Iris Data

The Fisher iris data set has four-dimensional measurements of irises, and corresponding classification into species. Visualize this data by reducing the dimension using `tsne`.

```
load fisheriris
rng default % for reproducibility
Y = tsne(meas);
gscatter(Y(:,1),Y(:,2),species)
```



Compare Distance Metrics

Use various distance metrics to try to obtain a better separation between species in the Fisher iris data.

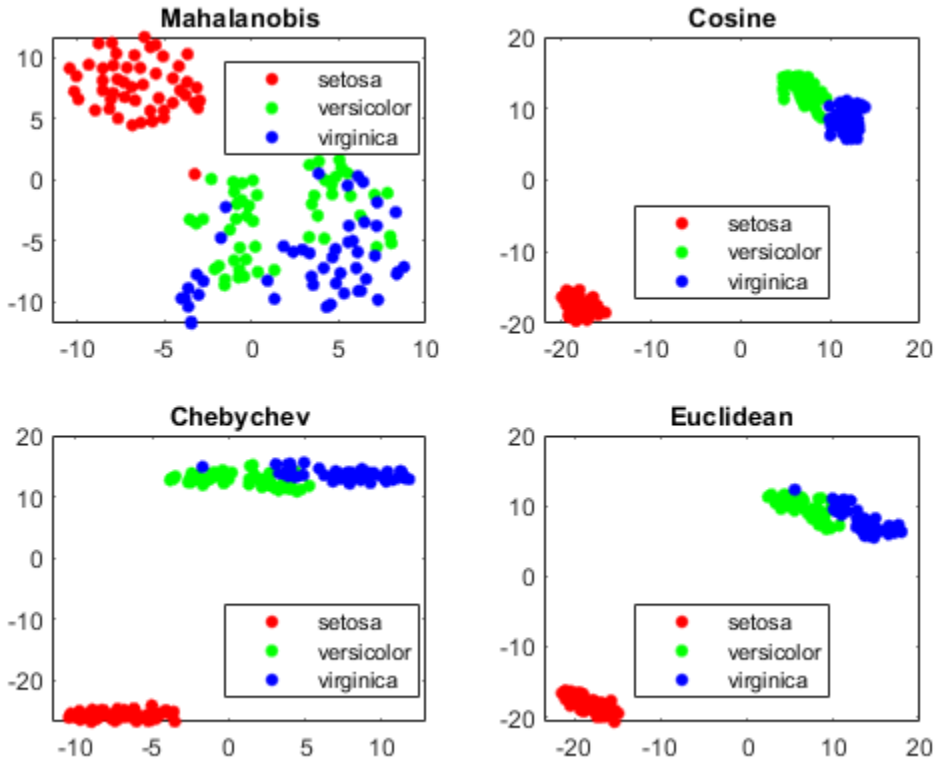
```
load fisheriris

rng('default') % for reproducibility
Y = tsne(meas,'Algorithm','exact','Distance','mahalanobis');
subplot(2,2,1)
gscatter(Y(:,1),Y(:,2),species)
title('Mahalanobis')

rng('default') % for fair comparison
Y = tsne(meas,'Algorithm','exact','Distance','cosine');
subplot(2,2,2)
gscatter(Y(:,1),Y(:,2),species)
title('Cosine')

rng('default') % for fair comparison
Y = tsne(meas,'Algorithm','exact','Distance','chebychev');
subplot(2,2,3)
gscatter(Y(:,1),Y(:,2),species)
title('Chebychev')
```

```
rng('default') % for fair comparison
Y = tsne(meas,'Algorithm','exact','Distance','euclidean');
subplot(2,2,4)
gscatter(Y(:,1),Y(:,2),species)
title('Euclidean')
```



In this case, the cosine, Chebychev, and Euclidean distance metrics give reasonably good separation of clusters. But the Mahalanobis distance metric does not give a good separation.

Plot Results with NaN Input Data

`tsne` removes input data rows that contain any `NaN` entries. Therefore, you must remove any such rows from your classification data before plotting.

For example, change a few random entries in the Fisher iris data to `NaN`.

```
load fisheriris
rng default % for reproducibility
meas(rand(size(meas)) < 0.05) = NaN;
```

Embed the four-dimensional data into two dimensions using `tsne`.

```
Y = tsne(meas,'Algorithm','exact');
```

```
Warning: Rows with NaN missing values in X or 'InitialY' values are removed.
```

Determine how many rows were eliminated from the embedding.

```
length(species)-length(Y)
```

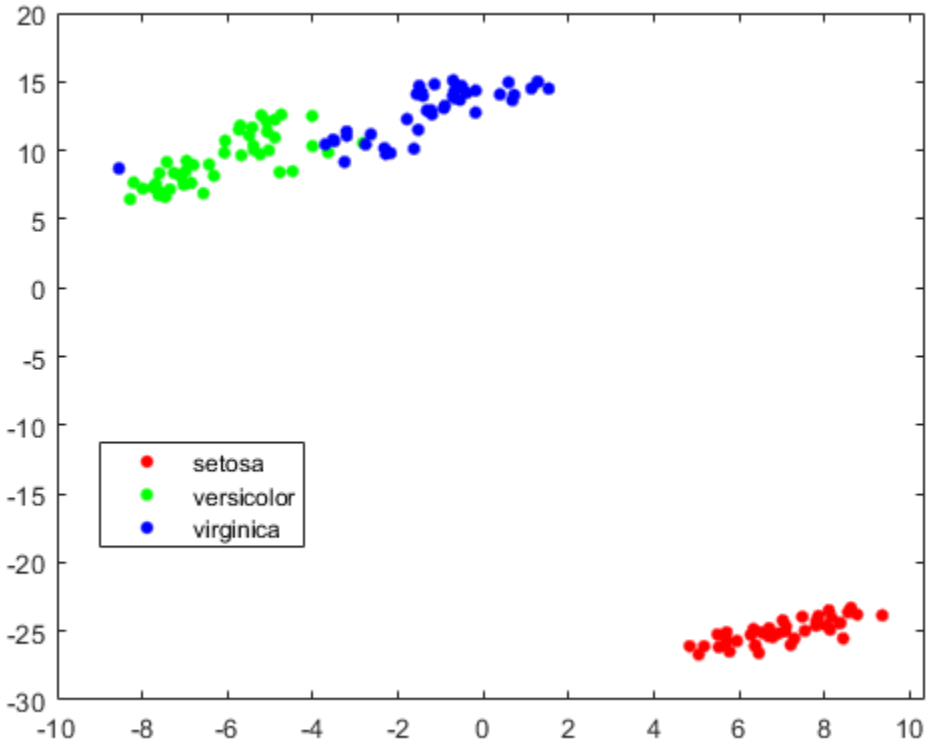
```
ans = 22
```

Prepare to plot the result by locating the rows of `meas` that have no `NaN` values.

```
goodrows = not(any(isnan(meas),2));
```

Plot the results using only the rows of `species` that correspond to rows of `meas` with no `NaN` values.

```
gscatter(Y(:,1),Y(:,2),species(goodrows))
```



Compare t-SNE Loss

Find both 2-D and 3-D embeddings of the Fisher iris data, and compare the loss for each embedding. It is likely that the loss is lower for a 3-D embedding, because this embedding has more freedom to match the original data.

```
load fisheriris
rng default % for reproducibility
[Y,loss] = tsne(meas,'Algorithm','exact');
rng default % for fair comparison
[Y2,loss2] = tsne(meas,'Algorithm','exact','NumDimensions',3);
fprintf('2-D embedding has loss %g, and 3-D embedding has loss %g.\n',loss,loss2)
```

```
2-D embedding has loss 0.1255, and 3-D embedding has loss 0.0956204.
```

As expected, the 3-D embedding has lower loss.

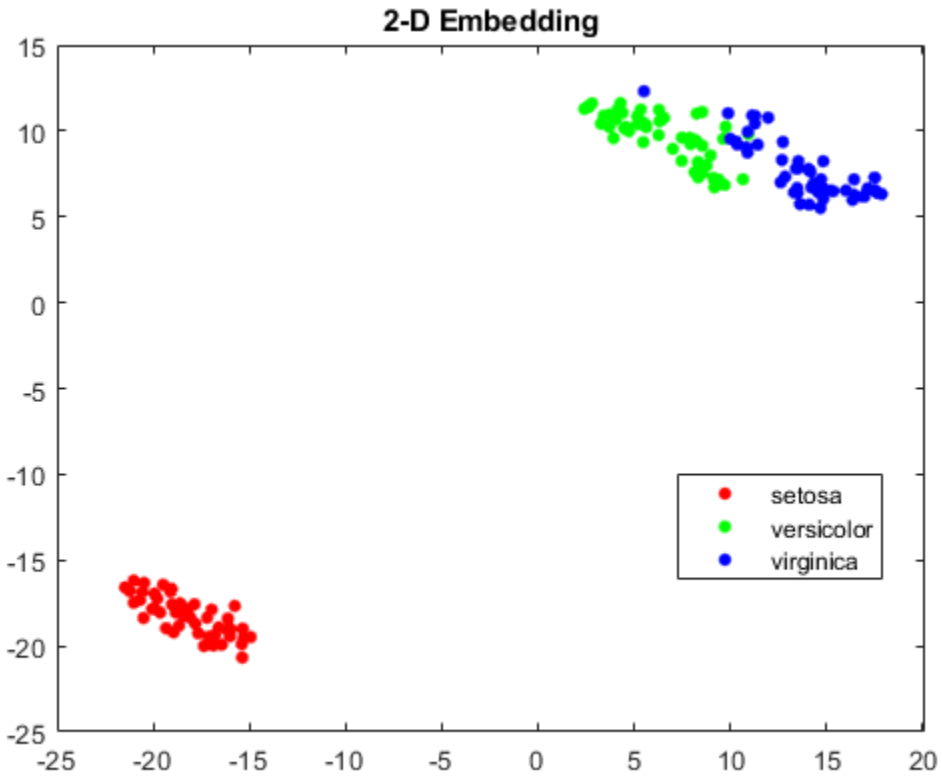
View the embeddings. Use RGB colors `[1 0 0]`, `[0 1 0]`, and `[0 0 1]`.

For the 3-D plot, convert the species to numeric values using the `categorical` command, then convert the numeric values to RGB colors using the `sparse` function as follows. If `v` is a vector of positive integers 1, 2, or 3, corresponding to the species data, then the command

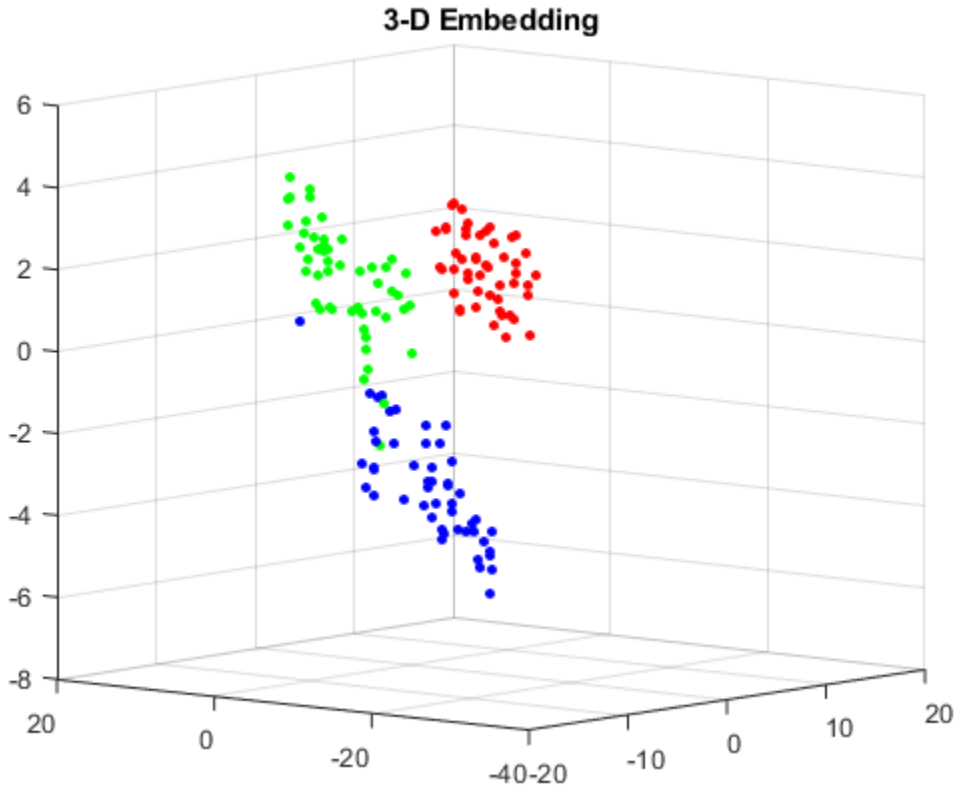
```
sparse(1:numel(v),v,ones(size(v)))
```

is a sparse matrix whose rows are the RGB colors of the species.

```
gscatter(Y(:,1),Y(:,2),species,eye(3))
title('2-D Embedding')
```



```
figure
v = double(categorical(species));
c = full(sparse(1:numel(v),v,ones(size(v)),numel(v),3));
scatter3(Y2(:,1),Y2(:,2),Y2(:,3),15,c,'filled')
title('3-D Embedding')
view(-50,8)
```



Input Arguments

X — Data points

n-by-m matrix

Data points, specified as an n-by-m matrix, where each row is one m-dimensional point.

`tsne` removes rows of X that contain any `NaN` values before creating an embedding. See “Plot Results with NaN Input Data” on page 33-6298.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `Y = tsne(X,'Algorithm','Exact','NumPCAComponents',50)`

Algorithm Control

`Algorithm` — `tsne` algorithm

`'barneshut'` (default) | `'exact'`

`tsne` algorithm, specified as `'barneshut'` or `'exact'`. The `'exact'` algorithm optimizes the Kullback-Leibler divergence of distributions between the original space and the embedded space. The

'barneshut' algorithm performs an approximate optimization that is faster and uses less memory when the number of data rows is large.

Note For the 'barneshut' algorithm, tsne uses knnsearch to find the nearest neighbors.

Example: 'exact'

Distance — Distance metric
'euclidean' (default) | 'seuclidean' | 'cityblock' | 'chebychev' | 'minkowski' | 'mahalanobis' | 'cosine' | 'correlation' | 'spearman' | 'hamming' | 'jaccard' | function handle

Distance metric, specified by one of the following. For definitions of the distance metrics, see pdist.

- 'euclidean' — Euclidean distance.
- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between rows in X and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from S = std(X,'omitnan').
- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance, which is the maximum coordinate difference.
- 'minkowski' — Minkowski distance with exponent 2. This is the same as Euclidean distance.
- 'mahalanobis' — Mahalanobis distance, computed using the positive definite covariance matrix cov(X,'omitrows').
- 'cosine' — 1 minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' — One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman' — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming' — Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using @ (for example, @distfun). For details, see “More About” on page 33-6305.

In all cases, tsne uses squared pairwise distances to calculate the Gaussian kernel in the joint distribution of X.

Example: 'mahalanobis'

Exaggeration — Size of natural clusters in data
4 (default) | scalar value 1 or greater

Size of natural clusters in data, specified as a scalar value 1 or greater.

A large exaggeration makes tsne learn larger joint probabilities of Y and creates relatively more space between clusters in Y. tsne uses exaggeration in the first 99 optimization iterations.

If the value of Kullback-Leibler divergence increases in the early stage of the optimization, try reducing the exaggeration. See “tsne Settings” on page 15-117.

Example: `10`

Data Types: `single` | `double`

`NumDimensions` — Dimension of the output `Y`
`2` (default) | positive integer

Dimension of the output `Y`, specified as a positive integer. Generally, set `NumDimensions` to `2` or `3`.

Example: `3`

Data Types: `single` | `double`

`NumPCAComponents` — PCA dimension reduction
`0` (default) | nonnegative integer

PCA dimension reduction, specified as a nonnegative integer. Before `tsne` embeds the high-dimensional data, it first reduces the dimensionality of the data to `NumPCAComponents` using the `pca` function. When `NumPCAComponents` is `0`, `tsne` does not use PCA.

Example: `50`

Data Types: `single` | `double`

`Perplexity` — Effective number of local neighbors of each point
`30` (default) | positive scalar

Effective number of local neighbors of each point, specified as a positive scalar. See “t-SNE Algorithm” on page 15-104.
